Object Request Broker (ORB) software task CPU utilization thresholds generate critical-level alerts or alarms based on the percentage of SMC CPU resources it is consuming at the time of polling.

Critical-level alerts or alarms are triggered for CPU usage by the ORBs software task based on the following rules:

- **Enter condition:** Actual CPU usage percentage > High Threshold
- **Clear condition:** Actual CPU usage percentage ≤ Low Threshold

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

■ `threshold cpu-orbs-crit`

Example

The following command configures a critical-level alarm threshold of 35 percent of CPU utilization by the ORBS task and a clear threshold of 35 percent:

```
threshold cpu-orbs-crit 35 clear 35
```

threshold cpu-orbs-warn

Configures threshold for generating warning-level alerts or alarms based on the percentage of CPU utilization by the ORBS software task

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
threshold cpu-orbs-warn high_thresh [ clear low_thresh ]
[ default ] threshold cpu-orbs-warn
```

default

Restores this parameter to its default setting.

high_thresh

Default: 50

The high threshold percent of CPU utilization by the ORB software task that must be exceeded as measured at the time of polling to generate a warning-level alert or alarm.

high_thresh is measured in percentage of total CPU utilization and can be configured to any integer value 0 through 100. A value of 0 disables the threshold.

clear low_thresh

Default: 50

The low threshold percent of CPU utilization by the ORB software task that maintains a previously generated alarm condition. If the percentage is measured as less than or equal to the low threshold at the time of polling, a clear alarm will be generated.

low_thresh is measured in percentage of total CPU utilization and can be configured to any integer value 0 through 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

Object Request Broker (ORB) software task CPU utilization thresholds generate warning-level alerts or alarms based on the percentage of SMC CPU resources it is consuming at the time of polling.

Warning-level alerts or alarms are triggered for CPU usage by the ORBs software task based on the following rules:

- **Enter condition:** Actual CPU usage percentage > High Threshold
- **Clear condition:** Actual CPU usage percentage ≤ Low Threshold

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

■ threshold cpu-orbs-warn

Example

The following command configures a warning-level alarm threshold of 25 percent of CPU utilization by the ORBS task and a clear threshold of 25 percent:

```
threshold cpu-orbs-warn 25 clear 25
```

threshold cpu-session-throughput

Configures thresholds for CPU session throughput for the system.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
threshold cpu-session-throughput high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold session throughput that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is measured in Kilobytes per second (Kbps) and can be configured to any integer value between 0 and 1000000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold session thereabout that maintains a previously generated alarm condition. If the throughput falls below the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is measured in Kilobytes per second (Kbps) and can be configured to any integer value between 0 and 1000000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

CPU session throughput thresholds generate alerts or alarms based on total throughput for all Session Manager tasks running on each PSC/PSC2 CPU during the polling interval. Although, a single threshold is configured for all CPUs, separate alerts or alarms can be generated for each CPU.

Alerts or alarms are triggered for CPU session throughput based on the following rules:

- **Enter condition:** Actual CPU session throughput \geq High Threshold
- **Clear condition:** Actual CPU session throughput $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Important: This command is not supported on all platforms.

■ `threshold cpu-session-throughput`

Example

The following command configures a high threshold count of 900 Kbps session throughput and a low threshold of 500 Kbps for a system using the Alarm thresholding model:

```
threshold cpu-session-throughput 900 clear 500
```

threshold cdr-file-space

Configures the threshold for monitoring the percentage of total file space allocated for CDRs used during the polling interval.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
threshold cdr-file-space high_thresh [ clear low_thresh ]
```

```
default threshold cdr-file-space
```

default

Configures the default setting.

high_thresh

Default: 90

The high threshold for percentage of total allocated CDR file space used that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

high_thresh is measured in percentage of total allocated CDR file space used and can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold for percentage of total allocated CDR file space used that maintains a previously generated alarm condition. If the space usage falls below the low threshold within the polling interval, a clear alarm is generated.

low_thresh is measured in percentage of total allocated CDR file space used and can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

CDR file space usage generate alerts or alarms based on the percentage of total allocated CDR file space used during the polling interval.

Alerts or alarms are triggered for CDR file space usage session based on the following rules:

- **Enter condition:** Actual percentage of allocated CDR file space usage ³ specified percentage of total CDR file space.
- **Clear condition:** Actual CDR file space used < specified clear percentage of total allocated CDR file space usage.

■ `threshold cdr-file-space`

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **`threshold poll`** command to configure the polling interval and the **`threshold monitoring`** command to enable thresholding for this value.

Example

The following command configures a threshold of 65 percent of total allocated CDR file space usage and a clear threshold of 35 percent:

```
threshold cdr-file-space 65 clear 35
```

threshold confilt-block

Configures the threshold for Content Filtering rating operations blocked during a polling interval at which the threshold are raised or cleared.

Product

CF

Privilege

Security Administrator, Administrator

Syntax

```
threshold confilt-block high_thresh_value [ clear low_thresh_value ]
```

```
default threshold confilt-block
```

high_thresh

Default: 90

The high threshold for number of rating operations blocked for content filtering service that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

high_thresh is measured in numbers of total rating operations blocked and can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold for the total number of rating operations blocked for a content filtering service that maintains a previously generated alarm condition. If the threshold falls below the low threshold within the polling interval, a clear alarm is generated.

low_thresh is measured in number of total rating operations blocked and can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

Usage

Use this command to configure the threshold for a content filtering service to generate alerts or alarms based on the number of rating operations blocked for a content filtering service during the polling interval.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll confilt-block** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a threshold of 65 percent of total rating operations blocked and a clear threshold of 35 percent:

```
threshold confilt-block 65 clear 35
```

threshold confilt-rating

Configures the threshold for Content Filtering rating operations performed during a polling interval at which the threshold are raised or cleared.

Product

CF

Privilege

Security Administrator, Administrator

Syntax

```
threshold confilt-rating high_thresh_value [ clear low_thresh_value ]
```

```
default threshold confilt-rating
```

high_thresh

Default: 90

The high threshold for number of rating operations performed for content filtering service that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

high_thresh is measured in numbers of total rating operations performed and can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold for the total number of rating operations performed for a content filtering service that maintains a previously generated alarm condition. If the threshold falls below the low threshold within the polling interval, a clear alarm is generated.

low_thresh is measured in umber of total rating operations performed and can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

Usage

Use this command to configure the threshold for a content filtering service to generates alerts or alarms based on the number of rating operations performed for a content filtering service during the polling interval.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll confilt-rating** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a threshold of 65 percent of total rating operations performed and a clear threshold of 35 percent:

```
threshold confilt-rating 65 clear 35
```

threshold cpu-utilization

Configures thresholds for CPU utilization for the system.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
threshold cpu-utilization high_thresh [ clear low_thresh ]
```

high_thresh

Default: 85

The high threshold CPU utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 100.

clear *low_thresh*

Default: 85

The low threshold CPU utilization percentage that maintains a previously generated alarm condition. If the utilization percentage falls below the low threshold within the polling interval, a clear alarm will be generated.

low_thresh can be configured to any integer value between 0 and 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

CPU utilization thresholds generate alerts or alarms based on the utilization percentage of each PSC/PSC2 CPU during the specified polling interval. Although, a single threshold is configured for all CPUs, separate alerts or alarms can be generated for each CPU.

Alerts or alarms are triggered for CPU utilization based on the following rules:

- **Enter condition:** Average measured CPU utilization for last 5 minutes ³ High Threshold
- **Clear condition:** Average measured CPU utilization for last 5 minutes < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Important: This command is not supported on all platforms.

Example

■ threshold cpu-utilization

The following command configures a high threshold CPU utilization percentage of 90 for an system using the Alert thresholding model:

```
threshold cpu-utilization 90
```

threshold dcca-bad-answer

Configures the threshold for invalid or bad responses to the system from Diameter server.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] threshold dcca-bad-answer high_thresh [ clear low_thresh ]
```

default

Disables the threshold for configured alarm and set the *high_thresh* and *low_thresh* values to 0.

high_thresh

Default: 0

The high threshold number of invalid messages or responses that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value between 0 and 1044000.

clear *low_thresh*

Default: 0

The low threshold number of invalid messages/responses that maintains a previously generated alarm condition. If the number of failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1044000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

In the event that the system receives invalid message or response from Diameter server **dcca-bad-answer** is generated.

DCCA bad answer messages size threshold generates alerts or alarms based on the number of invalid response or messages received during the specified polling interval.

Alerts or alarms are triggered for DCCA bad answers based on the following rules:

- **Enter condition:** Actual number of DCCA bad answer messages ³ High Threshold
- **Clear condition:** Actual number of DCCA bad answer messages < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Example

■ `threshold dcca-bad-answer`

The following command configures a high threshold count of *250* DCCA bad answer messages and low threshold of *100* for an system using the Alarm thresholding model:

```
threshold dcca-bad-answer 250 clear 100
```

threshold dcca-protocol-error

Configures the threshold for Diameter Credit Control Application (DCCA) protocol error from Diameter server.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] threshold dcca-protocol-error high_thresh [ clear low_thresh ]
```

default

Disables the threshold for configured alarm and sets the *high_thresh* and *low_thresh* values to 0.

high_thresh

Default: 0

The high threshold number of protocol error received from Diameter server that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value between 0 and 1044000.

clear *low_thresh*

Default: 0

The low threshold number of protocol error received from Diameter server that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1044000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

In the event that the system receives the protocol errors from Diameter server, **dcca-protocol-error** is generated.

DCCA protocol error threshold generates alerts or alarms based on the number of protocol error messages received from Diameter server during the specified polling interval.

Alerts or alarms are triggered for DCCA protocol error based on the following rules:

- **Enter condition:** Actual number of DCCA protocol error ³ High Threshold
- **Clear condition:** Actual number of DCCA protocol errors < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Example

■ `threshold dcca-protocol-error`

The following command configures a high threshold count of *250* protocol errors and low threshold of *100* for an system using the Alarm thresholding model:

```
threshold dcca-protocol-error 250 clear 100
```

threshold dcca-rating-failed

Configures Diameter Credit Control Application (DCCA) Rating Group (content-id) request reject thresholds.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] threshold dcca-rating-failed high_thresh [ clear low_thresh ]
```

default

Disables the threshold for configured alarm and sets the *high_thresh* and *low_thresh* values to 0.

high_thresh

Default: 0

The high threshold number of requests for a block of credits due to invalid Rating Group (content-id), rejected from the Diameter server that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value between 0 and 1044000.

clear *low_thresh*

Default: 0

The low threshold number of requests for a block of credits due to invalid Rating Group (content-id), rejected from the Diameter server that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1044000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

In the event that the Diameter server rejects the system request for a block of credits due to invalid Rating Group, defined as content-id, **dcca-rating-failed** message is generated.

Rating Group failed threshold generates alerts or alarms based on the number of requests rejected from Diameter server during the specified polling interval.

Alerts or alarms are triggered for Rating Group failed based on the following rules:

- **Enter condition:** Actual number of DCCA Rating Group failed ³ High Threshold
- **Clear condition:** Actual number of DCCA Rating Group failed < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

■ threshold dcca-rating-failed

Example

The following command configures a high threshold count of *250* requests rejected and low threshold of *100* for an system using the Alarm thresholding model:

```
threshold dcca-rating-failed 250 clear 100
```

threshold dcca-unknown-rating-group

Configures the unknown Diameter Credit Control Application (DCCA) Rating Group (content-id) returned by Diameter to system thresholds.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] threshold dcca-unknown-rating-group high_thresh [ clear low_thresh ]
```

default

Disables the threshold for configured alarm and sets the *high_thresh* and *low_thresh* values to 0.

high_thresh

Default: 0

The high threshold number of unknown Rating Group (content-id) sent by Diameter server and received by system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value between 0 and 1044000.

clear *low_thresh*

Default: 0

The low threshold number of unknown Rating Group (content-id) sent by Diameter server and received by system that maintains a previously generated alarm condition. If the number of errors falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1044000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

In the event that the Diameter server sends invalid Rating Groups, **content-ids** to the system, **dcca-unknown-rating-group** message is generated.

Unknown Rating Group threshold generates alerts or alarms based on the number of unknown Rating Groups received by the system from Diameter server during the specified polling interval.

Alerts or alarms are triggered for unknown rating groups based on the following rules:

- **Enter condition:** Actual number of unknown rating groups ³ High Threshold
- **Clear condition:** Actual number of unknown rating groups < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

■ `threshold dcca-unknown-rating-group`

Example

The following command configures a high threshold count of *250* unknown rating groups and low threshold of *100* for an system using the Alarm thresholding model:

```
threshold dcca-unknown-rating-group 250 clear 100
```

threshold diameter diameter-retry-rate

This command configures Diameter Retry Rate threshold for generating alerts or alarms based on the percentage of Diameter requests that were retried during the polling interval.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
threshold diameter diameter-retry-rate high_thresh [ clear low_thresh ]
```

```
default threshold diameter diameter-retry-rate
```

default

Configures the default setting.

Default: Disables the thresholds; the threshold values are reset to 0.

high_thresh

Default: 0

Specifies the high threshold. If, within the polling interval, the percentage of Diameter requests retried equals or exceeds *high_thresh* an alert or alarm is generated.*high_thresh* must be an integer from 0 through 100.

clear *low_thresh*

Default: 0

Specifies the low threshold. If, within the polling interval, the percentage of Diameter requests retried falls below *low_thresh*, a clear alarm is generated.*low_thresh* must be an integer from 0 through 100.

Important: This value is applicable for the Alarm mode, and ignored for the Alert mode. In addition, if this value is not configured for the Alarm mode, the system assumes it is identical to the high threshold.

Usage

Diameter Retry Rate threshold generates alerts or alarms based on the percentage of Diameter requests that were retried during the specified polling interval.

Alerts or alarms are triggered based on the following rules:

- **Enter condition:** Percentage of Diameter requests retried \geq High Threshold
- **Clear condition:** Percentage of Diameter requests retried $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

■ threshold diameter diameter-retry-rate

Example

The following command configures a high threshold of 75 percent, and a low threshold of 50 percent for a system using the Alarm thresholding model:

```
threshold diameter diameter-retry-rate 75 clear 50
```

threshold edr-file-space

Configures the threshold for monitoring the percentage of total file space allocated for EDRs used during the polling interval.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] threshold edr-file-space high_thresh [ clear low_thresh ]
```

high_thresh

Default: 90

The high threshold for percentage of total allocated EDR file space used that must be met or exceeded at the end of the polling interval to generate an alert or alarm.

high_thresh is measured in percentage of total allocated EDR file space used and can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold for percentage of total allocated EDR file space used that maintains a previously generated alarm condition. If the space usage falls below the low threshold within the polling interval, a clear alarm is generated.

low_thresh is measured in percentage of total allocated EDR file space used and can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

EDR file space usage generate alerts or alarms based on the percentage of total allocated EDR file space used during the polling interval.

Alerts or alarms are triggered for EDR file space usage session based on the following rules:

- **Enter condition:** Actual percentage of allocated EDR file space usage ³ specified percentage of total EDR file space.
- **Clear condition:** Actual EDR file space used < specified clear percentage of total allocated EDR file space usage.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

■ threshold edr-file-space

Example

The following command configures a threshold of 65 percent of total allocated EDR file space usage and a clear threshold of 35 percent:

```
threshold edr-file-space 65 clear 35
```

threshold edr-udr-dropped flow control

This command configures thresholds to monitor the total number of EDRs and UDRs discarded due to flow control.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
threshold edr-udr-dropped-flow-control high_thresh [ clear low_thresh ]
```

```
default threshold edr-udr-dropped-flow-control
```

default

Configures the default setting.

Default: High threshold: 90; Low threshold: 10

high_thresh

Default: 90

The high threshold for total number of EDRs + UDRs dropped due to flow control, which must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh must be an integer from 0 through 100000.

A value of 0 indicates the threshold.

clear *low_thresh*

Default: 10

The low threshold for total number of EDRs + UDRs dropped that maintains a previously generated alarm condition. If the total number of EDRs + UDRs dropped falls below the low threshold within the polling interval, a clear alarm is generated.

low_thresh must be an integer from 0 through 100000, and must be lower than *high_thresh*.

A value of 0 disables the threshold.

Usage

Use this command to configure thresholds to monitor the total number of EDRs + UDRs discarded due to flow control. Alerts or alarms are generated based on the total number of EDRs + UDRs dropped during polling interval.

Alerts or alarms are triggered for EDR file space usage session based on the following rules:

- **Enter condition:** Actual number of EDRs + UDRs dropped \geq specified number of EDRs + UDRs dropped.
- **Clear condition:** Actual number of EDR + UDRs dropped $<$ specified clear number of EDRs + UDRs dropped.

If a trigger condition exists at the end of the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

■ threshold edr-udr-dropped flow control

Example

The following command configures a high threshold of *90* and a clear threshold of *45* to monitor EDRs + UDRs dropped due to flow control:

```
threshold edr-udr-dropped-flow-control 90 clear 45
```

threshold fw-deny-rule

This command configures thresholds for Stateful Firewall Deny Rule.

Product

FW

Privilege

Security Administrator, Administrator

Syntax

```
threshold fw-deny-rule high_thresh [ clear low_thresh ]
```

```
default threshold fw-deny-rule
```

default

Disables the threshold and sets *high_thresh* and *low_thresh* to the default values.

high_thresh

Specifies the Stateful Firewall Deny-Rule threshold value, which if met or exceeded generates an alert or alarm.

high_thresh must be an integer from 0 through 1000000.

Default: 0

clear *low_thresh*

Specifies the Stateful Firewall Deny-Rule alarm clear threshold value. If, in the same polling interval, the threshold falls below *low_thresh* a clear alarm is generated.

low_thresh must be an integer from 0 through 1000000.

Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

When the number of Deny-Rule exceeds a given value, a threshold is raised and it is cleared when the number of Deny-Rule fall below a value within the polling interval.

Refer to the **threshold poll** command to configure the polling interval, and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a Stateful Firewall Deny Rule high threshold of *1000* and a low threshold of *100* for a system using the Alarm Thresholding model:

```
threshold fw-deny-rule 1000 clear 100
```

threshold fw-dos-attack

This command configures thresholds for Stateful Firewall Denial-of-Service (DoS) attacks.

Product

FW

Privilege

Security Administrator, Administrator

Syntax

```
threshold fw-dos-attack high_thresh [ clear low_thresh ]
```

```
default threshold fw-dos-attack
```

default

Disables the threshold and sets *high_thresh* and *low_thresh* to the default values.

high_thresh

Specifies the Stateful Firewall DoS attacks threshold value, which if met or exceeded generates an alert or alarm.

high_thresh must be an integer from 0 through 1000000.

Default: 0

clear *low_thresh*

Specifies the Stateful Firewall DoS attacks clear threshold value. If, in the same polling interval, the threshold falls below *low_thresh* a clear alarm is generated.

low_thresh must be an integer from 0 through 1000000.

Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

When the number of DoS attacks exceed a given value, a threshold is raised and it is cleared when the number of DoS attacks fall below a value within the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a Stateful Firewall DoS attacks high threshold of *1000* and a low threshold of *100* for a system using the Alarm Thresholding model:

```
threshold fw-dos-attack 1000 clear 100
```

threshold fw-drop-packet

This command configures thresholds for Stateful Firewall drop packets.

Product

FW

Privilege

Security Administrator, Administrator

Syntax

```
threshold fw-drop-packet high_thresh [ clear low_thresh ]
```

```
default threshold fw-drop-packet
```

default

Disables the threshold and sets *high_thresh* and *low_thresh* to the default values.

high_thresh

Specifies the Stateful Firewall drop packets threshold value, which if met or exceeded generates an alert or alarm.

high_thresh must be an integer from 0 through 1000000.

Default: 0

clear *low_thresh*

Specifies the Stateful Firewall drop packets clear threshold value. If, in the same polling interval, the threshold falls below *low_thresh* a clear alarm is generated.

low_thresh must be an integer from 0 through 1000000.

Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

When the number of drop packets exceed a given value, a threshold is raised and it is cleared when the number of drop packets fall below a value within the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a Stateful Firewall drop packets high threshold of *1000* and a low threshold of *100* for a system using the Alarm thresholding model:

```
threshold fw-drop-packet 1000 clear 100
```

threshold fw-no-rule

This command configures thresholds for Stateful Firewall no rules.

Product

FW

Privilege

Security Administrator, Administrator

Syntax

```
threshold fw-no-rule high_thresh [ clear low_thresh ]
```

```
default threshold fw-no-rule
```

default

Disables the threshold and sets *high_thresh* and *low_thresh* to the default values.

high_thresh

Specifies the Stateful Firewall no rules threshold value, which if met or exceeded generates an alert or alarm.

high_thresh must be an integer from 0 through 1000000.

Default: 0

clear *low_thresh*

Specifies the Stateful Firewall no rules clear threshold value. If, in the same polling interval, the threshold falls below *low_thresh* a clear alarm is generated.

low_thresh must be an integer from 0 through 1000000.

Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

When the number of no rules exceed a given value, a threshold is raised and it is cleared when the number of no rules fall below a value within the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a Stateful Firewall no rules high threshold of *1000* and a low threshold of *100* for a system using the Alarm Thresholding model:

```
threshold fw-no-rule 1000 clear 100
```

threshold license

Configures thresholds for session license utilization for the system.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] threshold license remaining-sessions low_thresh clear high_thresh
```

remaining-sessions *low_thresh*

Default: 10

The low threshold session license utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.

low_thresh can be configured to any integer value between 0 and 100.

clear *high_thresh*

Default: 10

The high threshold session license utilization percentage that maintains a previously generated alarm condition. If the utilization percentage rises above the high threshold within the polling interval, a clear alarm will be generated.

high_thresh can be configured to any integer value between 0 and 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

Session license utilization thresholds generate alerts or alarms based on the utilization percentage of all session capacity licenses during the specified polling interval.

As described in Chapter 7 of the Administration and Configuration Guide, the system uses session capacity license to dictate the maximum number of simultaneous sessions that can be supported. There are multiple session types that require licenses (i.e. Simple IP, Mobile IP, L2TP, etc.). Although, a single threshold is configured for all session types, alerts or alarms can be generated for each type.

Alerts or alarms are triggered for session license utilization based on the following rules:

- **Enter condition:** Actual session license utilization percentage per session type \leq Low Threshold
- **Clear condition:** Actual session license utilization percentage per session type $>$ High Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

■ threshold license

The following command configures a session license low threshold percentage of 10 and a high threshold of 35 for an system using the Alarm thresholding model:

```
threshold license remaining-sessions 10 clear 35
```

threshold mgmt-cpu-memory-usage

Configures the thresholds for CPU memory usage.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
threshold mgmt-cpu-memory-usage high_thresh [ clear low_thresh
```

high_thresh

Default: 0

The high threshold percent of CPU memory usage that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh is measured in percentage of total memory used and can be configured to any integer value 0 through 100. A value of 0 disables the threshold.

clear *low_thresh*

The low threshold percent of CPU memory usage that maintains a previously generated alarm condition. If the percentage falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh is measured in percentage of total memory used and can be configured to any integer value 0 through 100. A value of 0 disables the threshold.

 **Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

CPU memory usage thresholds generate alerts or alarms based on memory usage for the SMC CPU during the polling interval. A single threshold enables CPU monitoring for both the active and standby SMCs allowing for alerts or alarms to be generated for each CPU.

Alerts or alarms are triggered for SMC CPU memory usage based on the following rules:

- **Enter condition:** Actual CPU memory usage \geq High Threshold
- **Clear condition:** Actual CPU memory usage $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

 **Important:** This command is not supported on all platforms.

Example

■ threshold mgmt-cpu-memory-usage

The following command configures a threshold of 65 percent of total SMC CPU memory usage and a clear threshold of 35 percent:

```
threshold mgmt-cpu-memory-usage 65 clear 35
```

threshold mgmt-cpu-utilization

Configures the thresholds for CPU utilization.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
threshold mgmt-cpu-utilization high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold CPU utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 100.

clear *low_thresh*

The low threshold CPU utilization percentage that maintains a previously generated alarm condition. If the utilization percentage falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh can be configured to any integer value between 0 and 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

CPU utilization thresholds generate alerts or alarms based on the utilization percentage of each SMC CPU during the specified polling interval. Although, a single threshold is configured for both SMC CPUs, separate alerts or alarms can be generated for each CPU.

Alerts or alarms are triggered for SMC CPU utilization based on the following rules:

- **Enter condition:** Average measured CPU utilization for last 5 minutes ³ High Threshold
- **Clear condition:** Average measured CPU utilization for last 5 minutes < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Important: This command is not supported on all platforms.

Example

■ threshold mgmt-cpu-utilization

The following command configures a high threshold SMC CPU utilization percentage of *90* for an system using the Alert thresholding model:

```
threshold mgmt-cpu-utilization 90
```

threshold mme-attach-failure

Use this command to configure thresholds for the total number of MME Attach Failure messages to count across all the MME services in the system as threshold limit to generate alert or alarm.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-mme-attach-failure high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0 (Disabled)

The high threshold number of total MME Attach Failure messages across all MME services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 100000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0 (Disabled)

The low threshold number of total MME Attach Failure messages across all services on a system that maintains a previously generated alarm condition. If the number of MME Attach Failure messages, across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 100000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of MME Attach Failure message across all the MME services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of MME Attach Failure message based on the following rules:

- **Enter condition:** Actual total number of MME Attach Failure messages \geq High Threshold
- **Clear condition:** Actual total number of MME Attach Failure messages $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll mme-attach-failure** command to configure the polling interval and the **threshold monitoring mme-service** command to enable thresholding for this value.

■ threshold mme-attach-failure

Example

The following command configures the limit of MME Attach Failure high threshold count of *10000* for an system using the Alert thresholding model:

```
threshold mme-attach-failure 10000
```

threshold mme-auth-failure

Use this command to configure thresholds for the total number of MME Auth Failure messages to count across all the MME services in the system as threshold limit to generate alert or alarm.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-mme-auth-failure high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0 (Disabled)

The high threshold number of total MME Auth Failure messages across all MME services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 100000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0 (Disabled)

The low threshold number of total MME Auth Failure messages across all services on a system that maintains a previously generated alarm condition. If the number of MME Attach Failure messages, across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 100000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of MME Auth Failure message across all the MME services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of MME Auth Failure message based on the following rules:

- **Enter condition:** Actual total number of MME Auth Failure messages \geq High Threshold
- **Clear condition:** Actual total number of MME Auth Failure messages $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll mme-auth-failure** command to configure the polling interval and the **threshold monitoring mme-service** command to enable thresholding for this value.

■ `threshold mme-auth-failure`

Example

The following command configures a total MME Auth Failure high threshold count of *10000* for an system using the Alert thresholding model:

```
threshold mme-auth-failure 10000
```

threshold model

Configures the thresholding model for the system to use.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
threshold model { alarm | alert }
```

alarm

Selects the alarm thresholding model as described in the Usage section for this command.

alert

Selects the alert thresholding model as described in the Usage section for this command.

Usage

The system supports the following thresholding models:

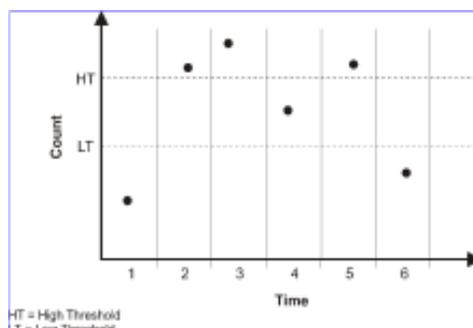

- **Alert:** A value is monitored and an alert condition occurs when the value reaches or exceeds the configured high threshold within the specified polling interval. The alert is generated then generated and/or sent at the end of the polling interval.

In the example shown in the figure below, this model generates alerts during period 2, 3, and 5 at the point where the count exceeded HT.

- **Alarm:** Both high and low threshold are defined for a value. An alarm condition occurs when the value reaches or exceeds the configured high threshold within the specified polling interval. The alert is generated then generated and/or sent at the end of the polling interval.

The alarm is cleared at the end of the first interval where the measured value is below the low threshold. In the example shown in the figure below, this model generates an alarm during period 2 when the count exceeds HT. A second alarm is generated in period 6 when the count falls beneath LT. The second alarm indicates a “clear” condition.

Figure 5. Thresholding Model Example

Important: Note that for certain values, the alert or alarm serves to warn of low quantities (i.e., memory, session licenses, etc.). In these cases, the low threshold is the condition that must be met or exceeded within the polling interval to generate the alert or alarm. Once the high threshold is exceeded during an interval, the low quantity condition is cleared.

Refer to the **threshold monitoring** command for additional information on thresholding.

Example

The following command configures the system to support the Alarm thresholding model:

```
threshold model alarm
```

threshold monitoring

Enables thresholding for the selected value.

Product

All

Privilege

Administrator

Syntax

```
[ no | default ] threshold monitoring { aaa-acct-archive-size | aaa-acct-failure
| aaa-auth-failure | aaa-retry-rate | aaamgr-request-queue | asngw | call-setup
| content-filtering | cpu-resource | cpu-session-throughput | cscf-service |
diameter | ecs | fa-service | firewall | ha-service | hnbgw-service | hsgw-
service | ipsec | license | lma-service | mme-service | packets-filtered-dropped
| packets-forwarded-to-cpu | pdsn-service | pdg-service | pdif-service | pgw-
service | route-service | sgw-service | subscriber | system | tpo }
```

no

Disables threshold monitoring for the specified value.

default

Sets / restores default value assigned for the specified parameter.

aaa-acct-archive-size

Enables threshold monitoring for the size of the AAA accounting record archive.

aaa-acct-failure

Enables threshold monitoring for AAA accounting failures and AAA accounting failure rate values. Refer to the **threshold aaa-acct-failure** and **threshold aaa-acct-failure-rate** commands for additional information on these values.

aaa-auth-failure

Enables threshold monitoring for AAA authentication failures and AAA authentication failure rate values. Refer to the **threshold aaa-auth-failure** and **threshold aaa-auth-failure-rate** commands for additional information on these values.

aaa-retry-rate

Enables threshold monitoring for the AAA retry rate value. Refer to the **threshold aaa-retry-rate** command for additional information on this value.

aaamgr-request-queue

Enables threshold monitoring for AAA Manager Requests for each AAA manager process. Refer to the **threshold aaamgr-request-queue** command for additional information on these values.

asngw

Enables the threshold monitoring for ASN-GW services.

call-setup

Enables threshold monitoring for the call setup, call setup failures, and no-resource rejected call values. Refer to the **threshold call-setup**, **threshold call-setup-failure**, **threshold ppp-setup-fail-rate**, **threshold rp-setup-fail-rate**, and **threshold call-reject-no-resource** commands for additional information on these values.

cpu-resource

Enables threshold monitoring for CPU thresholds. Refer to the **threshold 10sec-cpu-utilization**, **threshold cpu-available-memory**, **threshold cpu-load**, **threshold cpu-memory-usage**, **threshold cpu-orbs-crit**, **threshold cpu-orbs-warn**, **threshold cpu-session-throughput**, **threshold cpu-utilization**, **threshold mgmt-cpu-memory-usage**, and **threshold mgmt-cpu-utilization** commands for additional information on these values.

cpu-session-throughput

Enables threshold monitoring for the CPU session throughput value. Refer to the **threshold cpu-session-throughput** command for additional information on this value.

content-filtering

Enables threshold monitoring for the Content Filtering in-line service.

cscf-service

Enables threshold monitoring for the CSCF service.

diameter

Enables threshold monitoring for Diameter.

ecs

Enables threshold monitoring for the Active Charging Service (ACS)/Enhanced Charging Service (ECS).

fa-service

Enables threshold monitoring for Registration Reply errors for each FA service. Refer to the **threshold reg-reply-error** FA Service Configuration Mode command for additional information on this value.

firewall

Enables threshold monitoring for the Stateful Firewall in-line service.

Default: Disabled

Refer to the **threshold fw-deny-rule**, **threshold fw-dos-attack**, **threshold fw-drop-packet**, and **threshold fw-no-rule** commands for additional information on this value.

Important: Stateful Firewall thresholds can only be enabled if the Stateful Firewall license is present.

ha-service

Enables threshold monitoring for Registration Reply errors, re-registration reply errors, deregistration reply errors, and average calls setup per second for each HA service and average calls setup per second at the context level.

Refer to the **threshold init-rrq-rcvd-rate**, **threshold reg-reply-error**, **threshold rereg-reply-error**, and **threshold dereg-reply-error** HA Service Configuration Mode commands and the **threshold ha-service init-rrq-rcvd-rate** Context Configuration mode command for additional information on this value.

hnbgw-service

Enables threshold monitoring for HNB-GW sessions including Iu-CS and Iu-PS sessions for HNB-GW services on a system at the system level.

Important: This keyword is required to activate the threshold alarm/alert for HNB-GW service to use **threshold total-hnbgw-hnb-sessions**, **threshold total-hnbgw-iu-sessions**, and **threshold total-hnbgw-ue-sessions** command for threshold values.

hsgw-service

Enables threshold monitoring for HSGW services.

Refer to the **threshold total-hsgw-sessions** for more information on HSGW thresholds.

ipsec

Enables monitoring of IPSec thresholds.

refer to the HA-Service Configuration Mode chapter of the Command Line Interface Reference for information on the IPSec thresholds.

license

Enables threshold monitoring for the session license value.

Refer to the **threshold license** command for additional information on this value.

lma-service

Enables threshold monitoring for LMA services.

Refer to the **threshold total-lma-sessions** for more information on LMA thresholds.

mme-service

Default: Disabled.

Enables threshold monitoring for the MME services.

Refer to the **threshold total-mme-sessions** commands for additional information on this value.

packets-filtered-dropped

Enables threshold monitoring for the filtered/dropped packet value.

Refer to the **threshold packets-filtered-dropped** command for additional information on this value.

packets-forwarded-to-cpu

Enables threshold monitoring for the forwarded packet value.
Refer to the **threshold packets-forwarded-to-cpu** command for additional information on this value.

pdg-service

Enables threshold monitoring for PDG service.
Threshold monitoring for PDG service is disabled by default.

pdif-service

Enables threshold monitoring for PDIF service.

pdsn-service

Enables threshold monitoring for average calls setup per second for contexts and for PDSN services, A11 Request.
Refer to the **threshold packets-forwarded-to-cpu** command for additional information on this value.

pgw-service

Enables threshold monitoring for P-GW services.
Refer to the **threshold total-pgw-sessions** for more information on P-GW thresholds.

route-service

Enables threshold monitoring for BGP/VRF route services.
Refer to the **ip maximum-routes** command in Context configuration mode and **threshold route-service bgp-routes** in this mode for more information on route thresholds.

sgw-service

Enables threshold monitoring for S-GW services.
Refer to the **threshold total-sgw-sessions** for more information on S-GW thresholds.

subscriber

Enables threshold monitoring for the subscriber and session values.
Refer to the **threshold subscriber active**, **threshold subscriber total**, **threshold total-ggsn-sessions**, **threshold total-gprs-sessions**, **threshold total-gprs-pdp-sessions**, **threshold total-ha-sessions**, **threshold total-lns-sessions**, **threshold total-pdsn-sessions**, **threshold total-sgsn-sessions**, **threshold total-sgsn-pdp-sessions**, **threshold per-service-ggsn-sessions**, **threshold per-service-ha-sessions**, **threshold per-service-lns-sessions**, and **threshold per-service-pdsn-sessions** commands for additional information on these values.

system

Enables system (chassis) thresholds monitoring.

tpo

Enables thresholds monitoring for Traffic Performance Optimizer (TPO) in-line service.

Usage

Thresholding on the system is used to monitor the system for conditions that could potentially cause errors or outage. Typically, these conditions are temporary (i.e high CPU utilization, or packet collisions on a network) and are quickly resolved. However, continuous or large numbers of these error conditions within a specific time interval may be indicative of larger, more severe issues. The purpose of thresholding is to help identify potentially severe conditions so that immediate action can be taken to minimize and/or avoid system downtime.

Thresholding reports conditions using one of the following mechanisms:

- **SNMP traps:** SNMP traps have been created that indicate the condition (high threshold crossing and/or clear) of each of the monitored values. Complete descriptions and other information pertaining to these traps is located in the `starentMIB(8164).starentTraps(2)` section of the SNMP MIB Reference.

The generation of specific traps can be enabled or disabled on the system allowing you to view only those traps that are most important to you.

- **Logs:** The system provides a facility called `threshold` for which active and event logs can be generated. As with other system facilities, logs are generated Log messages pertaining to the condition of a monitored value are generated with a severity level of `WARNING`.

- **Alarm System:** High threshold alarms generated within the specified polling interval are considered “outstanding” until a the condition no longer exists and/or a condition clear alarm is generated.

“Outstanding” alarms are reported to through the system’s alarm subsystem and are viewable through the system’s CLI.

The following table indicates the reporting mechanisms supported by each of the above models.

Table 22. Thresholding Reporting Mechanisms by Model

Model	SNMP Traps	Logs	Alarm System
Alert	X	X	
Alarm	X	X	X

In addition to the values that can be enabled by this command, the system supports the enabling of threshold monitoring for IP pool address availability (refer to the `ip pool` and `threshold` commands in this reference) and port utilization (refer to the `threshold` commands in this chapter).

Example

The following command enables thresholding for subscriber totals:

```
threshold monitoring subscriber
```

threshold nat-port-chunks-usage

This command configures the NAT port chunk utilization threshold settings.

Important: This command is only available in Release 8.3 and later releases.

Product

NAT

Privilege

Security Administrator, Administrator

Syntax

```
threshold nat-port-chunks-usage high_thresh [ clear low_thresh ]
```

```
default threshold nat-port-chunks-usage
```

default

Configures the default settings.

high_thresh

Default: 0

Specifies the high nat-port-chunks-usage threshold that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh must be an integer from 0 through 100. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

Specifies the low nat-port-chunks-usage threshold that must be met within the polling interval for a clear alarm to be generated.

low_thresh must be an integer from 0 through 100. A value of 0 disables the threshold. If not set, the *high_thresh* will be high and low threshold setting.

Usage

Use this command to configure the NAT port chunk utilization threshold settings.

Example

The following command sets the NAT port chunk utilization threshold settings to a high of 75 and a low of 15:

```
threshold nat-port-chunks-usage 75 clear 15
```

threshold packets-filtered-dropped

Configures filtered/dropped packet thresholds for the system.

Product

PDSN, GGSN, HA, SGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold packets-filtered-dropped high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of filtered/dropped packets experienced by the system resulting from ACL rules that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value between 0 and 1000000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of filtered/dropped packets experienced by the system resulting from ACL rules that maintains a previously generated alarm condition. If the number of packets falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1000000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Filtered/dropped packet thresholds generate alerts or alarms based on the total number of packets that were filtered or dropped by the system as a result of access control list (ACL) rules during the specified polling interval.

Alerts or alarms are triggered for filtered/dropped packets based on the following rules:

- **Enter condition:** Actual number of filtered/dropped packets \geq High Threshold
- **Clear condition:** Actual number of filtered/dropped packets $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value. In addition, refer to information on ACLs in this reference.

Example

■ threshold packets-filtered-dropped

The following command configures a filtered/dropped packet high threshold count of 150000 for an system using the Alert thresholding model:

```
threshold packets-filtered-dropped 150000
```

threshold packets-forwarded-to-cpu

Configures forwarded packet thresholds for the system.

Product

PDSN, GGSN, HA, SGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold packets-forwarded-to-cpu high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of forwarded packets experienced by the system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value between 0 and 1000000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of forwarded packets experienced by the system that maintains a previously generated alarm condition. If the number of packets falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1000000000. A value of 0 disables the threshold.

 **Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Forwarded packet thresholds generate alerts or alarms based on the total number of packets that were forwarded to active system CPU(s) during the specified polling interval. Packets are forwarded to active system CPUs when the NPUs do not have adequate information to properly route them.

 **Important:** Ping and/or traceroute packets are intentionally forwarded to system CPUs for processing. These packet types are included in the packet count for this threshold.

Alerts or alarms are triggered for forwarded packets based on the following rules:

- **Enter condition:** Actual number of forwarded packets \geq High Threshold
- **Clear condition:** Actual number of forwarded packets $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

■ `threshold packets-forwarded-to-cpu`

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a forwarded packet high threshold count of 10000 for an system using the Alert thresholding model:

```
threshold packets-forwarded-to-cpu 10000
```

threshold pdg-current-active-sessions

Configures the threshold for monitoring the total number of all current PDG sessions only.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
threshold pdg-current-active-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Configures the total number of active PDG sessions to be monitored on a chassis. *high_thresh* is any integer from 0 to 300000.

There is no default, but 0 means that there is no threshold monitoring.

clear *low_thresh*

Clears any percentage of the number of sessions being monitored using the *high_thresh* variable defined above.

low_thresh is any integer from 0 to 300000.

Usage

Thresholds are provided for monitoring the overall PDG usage on a chassis. This command is used to monitor the total number of active PDG sessions for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 active PDG sessions on a chassis:

```
threshold pdg-current-active-sessions 300000
```

which turns out to be too many, so the following command clears 100000:

```
threshold pdg-current-active-sessions 300000 clear 100000
```

threshold pdg-current-sessions

Configures the threshold for monitoring the total number of all current PDG sessions, including inactive sessions.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
threshold pdg-current-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Configures the total number of PDG sessions on a chassis, both active and inactive. *high_thresh* is any integer from 0 to 300000.

There is no default, but 0 means that there is no threshold monitoring.

clear *low_thresh*

Clears any percentage of the number of sessions being monitored using the *high_thresh* variable defined above.

low_thresh is any integer from 0 to 300000.

Usage

Thresholds are provided for monitoring the overall PDG usage on a chassis. This command is used to monitor the total number of PDG sessions, both active and inactive, for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 active and inactive PDG sessions on a chassis:

```
threshold pdg-current-sessions 300000
```

which turns out to be too many, so the following command clears 100000:

```
threshold pdg-current-sessions 300000 clear 100000
```

threshold pdif-current-sessions

Configures the threshold for monitoring the total number of all current pdif sessions, including inactive sessions.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
threshold pdif-current-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Configures the total number of PDIF sessions on a chassis, both active and inactive. *high_thresh* is any integer from 0 to 300000.

There is no default, but 0 means that there is no threshold monitoring.

clear *low_thresh*

Clears any percentage of the number of sessions being monitored using the *high_thresh* variable defined above. *low_thresh* is any integer from 0 to 300000.

Usage

Thresholds are provided for monitoring the overall PDIF usage on a chassis. This command is used to monitor the total number of PDIF sessions, both active and inactive, for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 active and inactive PDIF sessions on a chassis:

```
threshold pdif-current-sessions 300000
```

which turns out to be too many, so the following command clears 100000:

```
threshold pdif-current-sessions 300000 clear 100000
```

threshold pdif-current-active-sessions

Configures the threshold for monitoring the total number of current pdif sessions only.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
threshold pdif-current-active sessions high_thresh [ clear low_thresh ]
```

high_thresh

Configures the total number of active PDIF sessions to be monitored on a chassis. *high_thresh* is any integer from 0 to 300000.

There is no default, but 0 means that there is no threshold monitoring.

clear *low_thresh*

Clears any percentage of the number of sessions being monitored using the *high_thresh* variable defined above. *low_thresh* is any integer from 0 to 300000.

Usage

Thresholds are provided for monitoring the overall PDIF usage on a chassis. This command is used to monitor the total number of active PDIF sessions for an entire chassis.

Example

The following command configures a monitoring threshold of 300000 active PDIF sessions on a chassis:

```
threshold pdif-current-active-sessions 300000
```

which turns out to be too many, so the following command clears 100000:

```
threshold pdif-current-active-sessions 300000 clear 100000
```

threshold per-service-ggsn-sessions

Configures thresholds for the number of PDP contexts per GGSN service in the system.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold per-service-ggsn-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of PDP contexts for any one GGSN service that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 4000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of PDP contexts for any one GGSN service that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of PDP contexts for any GGSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of PDP contexts for any GGSN service \geq High Threshold
- **Clear condition:** Actual number of PDP contexts $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a high threshold count of 10000 subscriber attaches per GGSN service for the Alert thresholding model:

■ threshold per-service-ggsn-sessions

```
threshold per-service-ggsn-sessions 10000
```

threshold per-service-gprs-pdp-sessions

Configures thresholds for the number of 2G-activated PDP contexts per GPRS service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold per-service-gprs-pdp-sessions high_thresh [ clear low_thresh
```

high_thresh

Default: 0

The high threshold number of 2G-activated PDP contexts for any one GPRS service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 4000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of 2G-activated PDP contexts for any one GPRS service. This number or higher maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, then a clear alarm will be generated.

The number can be configured to any integer value between 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of 2G-activated PDP contexts for any GPRS service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of PDP contexts for any GPRS service \geq High Threshold
- **Clear condition:** Actual number of PDP contexts $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a high threshold count of 10000 2G-activated PDP contexts per GPRS service for the Alert thresholding model:

■ threshold per-service-gprs-pdp-sessions

```
threshold per-service-gprs-sessions 10000
```

threshold per-service-gprs-sessions

Configures the thresholds for the number of 2G-attached subscribers per GPRS service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold per-service-gprs-sessions high_thresh [ clear low_thresh
```

high_thresh

Default: 0

The high threshold number of 2G-attached subscribers for any one GPRS service. This threshold number must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 2000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of 2G-attached subscribers for any one GPRS service. The number of subscribers must remain above this threshold in order to maintain a previously generated alarm condition. If the number of 2G subscribers falls beneath the low threshold within the polling interval, then a clear alarm will be generated.

The number can be configured to any integer value between 0 and 2000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of 2G-attached subscribers for any GPRS service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of 2G-attached subscribers for any GPRS service \geq High Threshold
- **Clear condition:** Actual number of 2G-attached subscribers $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

■ threshold per-service-gprs-sessions

The following command configures a high threshold count of *10000* 2G-attaches per GPRS service for the Alert thresholding model:

```
threshold per-service-gprs-sessions 10000
```

threshold per-service-ha-sessions

Configures thresholds for the number of HA sessions per HA service in the system.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold per-service-ha-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of HA sessions for any one HA service that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 500000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of HA sessions for any one HA service that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 500000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of HA sessions for any HA service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for HA sessions based on the following rules:

- **Enter condition:** Actual number of HA sessions for any HA service ³ High Threshold
- **Clear condition:** Actual number of HA sessions < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a HA session per service high threshold count of 10000 for an system using the Alert thresholding model:

■ threshold per-service-ha-sessions

```
threshold per-service-ha-sessions 10000
```

threshold per-service-lns-sessions

Configures thresholds for the number of LNS sessions per LNS service in the system.

Product

PDSN, GGSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold per-service-lns-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of LNS sessions for any one LNS service that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 500000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of LNS sessions for any one LNS service that maintains a previously generated alarm condition. If the number of LNS sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 500000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of LNS sessions for any LNS service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for LNS sessions based on the following rules:

- **Enter condition:** Actual number of LNS sessions for any LNS service \geq High Threshold
- **Clear condition:** Actual number of LNS sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a LNS session per service high threshold count of *10000* for an system using the Alert thresholding model:

■ threshold per-service-lns-sessions

```
threshold per-service-lns-sessions 10000
```

threshold per-service-pdsn-sessions

Configures thresholds for the number of PDSN sessions per PDSN service in the system.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold per-service-pdsn-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of PDSN sessions for any one PDSN service that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 500000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of PDSN sessions for any one PDSN service that maintains a previously generated alarm condition. If the number of PDSN sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 500000. A value of 0 disables the threshold.

 **Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of PDSN sessions for any PDSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDSN sessions based on the following rules:

- **Enter condition:** Actual number of PDSN sessions for any PDSN service \geq High Threshold
- **Clear condition:** Actual number of PDSN sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a HA session per service high threshold count of 10000 for an system using the Alert thresholding model:

■ threshold per-service-pdsn-sessions

```
threshold per-service-pdsn-sessions 10000
```

threshold per-service-sgsn-pdp-sessions

Configures the thresholds for the number of 3G-activated PDP contexts per SGSN service on the system.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold per-service-sgsn-pdp-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of 3G-activated PDP contexts for any one SGSN service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 4000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of 3G-activated PDP contexts for any one SGSN service. This number or higher maintains a previously generated alarm condition. If the number of 3G-activated PDP contexts falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 2400000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of 3G-activated PDP contexts for any SGSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of 3G-activated PDP contexts for any SGSN service \geq High Threshold
- **Clear condition:** Actual number of 3G-activated PDP contexts $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a high threshold count of 10000 3G-activated PDP contexts per SGSN service for the system's Alert thresholding model:

■ threshold per-service-sgsn-pdp-sessions

```
threshold per-service-sgsn-sessions 10000
```

threshold per-service-sgsn-sessions

Configures the thresholds for the number of 3G-attached subscribers per SGSN service in the system.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold per-service-sgsn-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of 3G-attached subscribers for any one SGSN service. This number must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 2000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of 3G-attached subscribers for any one SGSN service. This number must be met or exceeded to maintain a previously generated alarm condition. If the number of subscribers falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 2000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the number of 3G-attached subscribers for any one SGSN service in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for PDP contexts based on the following rules:

- **Enter condition:** Actual number of 3G-attached subscribers for any single SGSN service \geq High Threshold
- **Clear condition:** Actual number of 3G-attached subscribers for any single SGSN service $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

■ threshold per-service-sgsn-sessions

The following command configures a high threshold count of *10000* 3G-attached subscribers per SGSN service for a system using the Alert thresholding model:

```
threshold per-service-sgsn-sessions 10000
```

threshold tpo-dns-failure

This command configures thresholds for monitoring TPO DNS resolution failures.

Important: This is a restricted command. For more information contact your local sales representative.

Product

TPO

Privilege

Security Administrator, Administrator

Syntax

```
threshold tpo-dns-failure high_thresh [ clear low_thresh ]
```

high_thresh

Specifies that if in a polling interval the number of TPO DNS failures experienced by the system meets or exceeds *high_thresh* an alert or alarm should be generated.

high_thresh must be an integer from 0 through 300000.

clear *low_thresh*

Specifies that if, within the polling interval, the number of TPO DNS failures experienced by the system falls below *low_thresh* a clear alarm should be generated.

low_thresh must be an integer from 0 through 300000.

Usage

Use this command to configure thresholds for monitoring TPO DNS resolution failures.

threshold tpo-low-compression-gain

This command configures thresholds for monitoring TPO low-compression-gain comparison results.

Important: This is a restricted command. For more information contact your local sales representative.

Product

TPO

Privilege

Security Administrator, Administrator

Syntax

```
threshold tpo-low-compression-gain high_thresh [ clear low_thresh ]
```

high_thresh

Specifies that if in a polling interval the number of TPO low-compression-gain comparison results experienced by the system meets or exceeds *high_thresh* an alert or alarm should be generated. *high_thresh* must be an integer from 0 through 300000.

clear *low_thresh*

Specifies that if, within the polling interval, the number of TPO low-compression-gain comparison results experienced by the system falls below *low_thresh* a clear alarm should be generated. *low_thresh* must be an integer from 0 through 300000.

Usage

Use this command to configure thresholds for monitoring TPO DNS resolution failures.

threshold tpo-rto-timeout

This command configures thresholds for monitoring TPO retransmission timeout (RTO).

Important: This is a restricted command. For more information contact your local sales representative.

Product

TPO

Privilege

Security Administrator, Administrator

Syntax

```
threshold tpo-rto-timeout high_thresh [ clear low_thresh ]
```

high_thresh

Specifies that if in a polling interval the number of TPO RTOs experienced by the system meets or exceeds *high_thresh* an alert or alarm should be generated.

high_thresh must be an integer from 0 through 300000.

clear *low_thresh*

Specifies that if, within the polling interval, the number of TPO RTOs experienced by the system falls below *low_thresh* a clear alarm should be generated.

low_thresh must be an integer from 0 through 300000.

Usage

Use this command to configure thresholds for monitoring TPO DNS resolution failures.

threshold poll

This command configures the polling interval over which to count or measure the thresholding value.

Product

```

default

Restores the specified parameter to its default value.

10sec-cpu-utilization percent

Default: 300 seconds (5 minutes)

Configures the polling interval for measuring a 10 second average of CPU utilization.

Important: When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

all-rrp-failure

Default: 0

Configures the polling interval over which to count A11 Registration Response failures. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

all-rrq-msg-discard

Default: 0

Configures the polling interval over which to count how many A11 Registration Request messages are discarded. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

all-rac-msg-discard

Default: 0

Configures the polling interval over which to count how many A11 Registration Acknowledgement messages are discarded. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

aaa-acct-archive-size

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count archived AAA accounting messages.

aaa-acct-failure

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count failed AAA accounting requests.

aaa-acct-failure-rate

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percentage of AAA accounting failures.

aaa-auth-failure

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count failed authentication requests.

aaa-auth-failure-rate

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percentage of AAA authentication failures.

aaa-retry-rate

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percent of AAA request message retries.

aaamgr-request-queue

Default: 0

Configures the polling interval over which to count the number AA Manager Requests for each AAA manager process. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

active-subscriber

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of active subscriber sessions.

all-ppp-send-discard

Default: 0

Configures the polling interval over which to count the number of discarded PPP send packets. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

available-ip-pool-group

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure IP pool utilization.

Important: When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

call-reject-no-resource

Default: 900 seconds (15 minutes)

Configures the polling interval over which to count the number of calls rejected due to insufficient resources.

call-setup

Default: 900 seconds (15 minutes)

Configures the polling interval over which to count the number of calls setup.

call-setup-failure

Default: 900 seconds (15 minutes)

Configures the polling interval over which to count the number of calls setup failures.

call-setup-failures

Default: 300 seconds (5 minutes)

Configures the polling interval in seconds over which to count CSCF call setup failures.

time must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

call-total-active

Default: 300 seconds (5 minutes)

Configures the polling interval in seconds over which to count CSCF total active calls.

time must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

cpu-available-memory

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure PSC/PSC2 CPU memory availability.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

 **Important:** This command is not supported on all platforms

cpu-load

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure PSC/PSC2 CPU load using a 5 minute average measurement.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

 **Important:** This command is not supported on all platforms

cpu-memory-usage

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percentage of total PSC/PSC2 CPU memory used.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

 **Important:** This command is not supported on all platforms

cpu-orbs-crit

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percentage of CPU utilization by the ORBS software task for critical-level alerts.

cpu-orbs-warn

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percentage of CPU utilization by the ORBS software task for warning-level alerts.

cpu-session-throughput

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure PSC/PSC2 CPU session throughput.

**Important:** This command is not supported on all platforms

cpu-utilization

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure PSC/PSC2 CPU utilization.

**Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)**Important:** This command is not supported on all platforms

cscf-invite-rcvd

Default: 300 seconds (5 minutes)

Configures the polling interval in seconds over which to count the CSCF calls.

time must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

cscf-reg-rcvd

Default: 300 seconds (5 minutes)

Configures the polling interval in seconds over which to count the CSCF registrations.

time must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

cscf-service-route-failures

Default: 300 seconds (5 minutes)

Configures the polling interval in seconds over which to count the CSCF service route failures.

time must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

dcca-bad-answers

Configures the polling interval in seconds over which to count Diameter bad answers.

dcca-protocol-error

Configures the polling interval in seconds over which to count Diameter protocol errors.

dcca-rating-failed

Configures the polling interval in seconds over which to count Diameter rating failures.

dcca-unknown-rating-group

Configures the polling interval in seconds over which to count Diameter unknown rating group errors.

dereg-reply-error

Default: 0

Configures the polling interval over which to measure the number of de-registration reply errors for HA services. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

edr-file-space

Configures the polling interval in seconds over which to count EDR file space.

edr-udr-dropped-flow-control

Configures the polling interval in seconds over which to count EDR-UDRs Dropped due to Flow Control at ACSMGR.

error-no-resource

Default: 300 seconds (5 minutes)

Configures the polling interval in seconds over which to count CSCF No Resource Errors. *time* must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

error-presence

Default: 300 seconds (5 minutes)

Configures the polling interval in seconds over which to count CSCF Presence Errors. *time* must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

error-reg-auth

Default: 300 seconds (5 minutes)

Configures the polling interval in seconds over which to count CSCF Reg-Auth Errors. *time* must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

error-tcp

Default: 300 seconds (5 minutes)

Configures the polling interval in seconds over which to count CSCF TCP Errors. *time* must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

fa-reg-reply-error

Default: 0

Configures the polling interval over which to measure the number of registration reply errors for FA services. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

fng-current-active-sessions

Configures the polling interval in seconds over which to count FNG current active sessions.

fng-current-sessions

Configures the polling interval in seconds over which to count FNG current sessions.

fw-deny-rule

Default: 900 seconds (15 minutes)

Configures the Stateful Firewall Deny-Rule threshold polling interval. For this threshold the interval time range is from 60 through 900 seconds.

fw-dos-attack

Default: 900 seconds (15 minutes)

Configures the Stateful Firewall DoS-Attacks threshold polling interval. For this threshold the interval time range is from 60 through 900 seconds.

fw-drop-packet

Default: 900 seconds (15 minutes)

Configures the Stateful Firewall Drop-Packet threshold polling interval. For this threshold the interval time range is from 60 through 900 seconds.

fw-no-rule

Default: 900 seconds (15 minutes)

Configures the Stateful Firewall No-Rule threshold polling interval. For this threshold the interval time range is from 60 through 900 seconds.

ha-init-rrq-rcvd-rate

Default: 0

Configures the polling interval over which to measure the average number of calls setup per minute for the context. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

ha-svc-init-rrq-rcvd-rate

Default: 0

Configures the polling interval over which to measure the average number of calls setup per minute for HA services. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

ip-pool-free

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percentage of the IP pool addresses that are in the free state.

Important: When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

ip-pool-hold

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percentage of the IP pool address that are in the hold state.

Important: When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

ip-pool-release

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percentage of IP pool address that are in the release state.

Important: When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

ip-pool-used

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure the percentage of the IP pool addresses that are used.

Important: When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

ipsec-ipsec-call-req-rej

Default: 900

Configures the polling interval over which to count the IPsec call requests that are rejected.

ipsec-ike-failrate

Default: 900

Configures the polling interval over which to count the IPsec IKE failure rate.

ipsec-ike-failures

Default: 900

Configures the polling interval over which to count the IPsec IKE failures.

ipsec-ike-requests

Default: 900

Configures the polling interval over which to count the IPsec IKE request.

ipsec-tunnels-established

Default: 900

Configures the polling interval over which to count the IPsec tunnels established.

ipsec-tunnels-setup

Default: 900

Configures the polling interval over which to count the IPsec tunnels setup.

license-remaining-session

Default: 900 seconds (15 minutes)

Configures the polling interval over which to measure session license utilization.

mgmt-cpu-memory-usage interval

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure SMC CPU memory usage.

Important: When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

Important: This command is not supported on all platforms

mgmt-cpu-utilization

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure SMC CPU usage.

Important: When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

Important: This command is not supported on all platforms.

nat-port-chunks-usage

Important: This keyword is only available in Release 8.3 and later.

Default: 900 seconds (15 minutes)

Configures the polling interval over which to measure NAT port chunks usage.

packets-filtered-dropped

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the filtered/dropped packets.

packets-forwarded-to-cpu

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the forwarded packets.

pdg-current-active-sessions

Configures how frequently the system polls the pdg-current-active-sessions threshold.

pdg-current-sessions

Configures how frequently the system polls the pdg-current-sessions threshold.

threshold poll pdif-current-sessions interval *period*

Configures the polling interval for all current PDIF sessions in seconds rounded to the nearest multiple of 30 seconds. *period* is any integer from 30 to 60000.

threshold poll pdif-current-active-sessions interval *period*

Configures the polling interval for active sessions only in seconds rounded to the nearest multiple of 30 seconds. *period* is any integer from 30 to 60000.

pdsn-init-rrq-rcvd-rate

Default: 0

Configures the polling interval over which to measure the average number of calls setup per second for a PDSN-service. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

pdsn-svc-init-rrq-rcvd-rate

Configures the polling interval in seconds over which to count PDSN per-service call received rate.

per-service-asngw-sessions

Configures the polling interval in seconds over which to count per service ASNGW sessions.

per-service-ggsn-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the number of PDP contexts per GGSN service.

Important: When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

per-service-gprs-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval during which the SGSN counts the number of 2G-attached subscriber per GPRS service.

Important: When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

per-service-gprs-pdp-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval during which the SGSN counts the number of 2G-activated PDP contexts per GPRS service.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

per-service-ha-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the number of HA sessions per HA service.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

per-service-lns-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the number of LNS sessions per LNS service.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

per-service-pdsn-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the number of PDSN sessions per PDSN service.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

per-service-sgsn-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval during which the SGSN counts the number of 3G-attached subscribers per SGSN service.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

per-service-sgsn-pdp-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval during which the SGSN counts the number of 3G-activated PDP contexts per SGSN service.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

port-high-activity

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure for high port activity.

 **Important:** This command is not supported on all platforms

port-rx-utilization

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure receive port utilization.

 **Important:** This command is not supported on all platforms

port-tx-utilization

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure transmit port utilization.

 **Important:** This command is not supported on all platforms

ppp-setup-fail-rate

Default: 900 seconds (15 minutes)

Configure the polling interval over which to measure the PPP setup failure rate.

reg-reply-error

Default: 0

Configures the polling interval over which to measure number of registration reply errors for HA services. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

reg-total-active

Default: 300 seconds (5 minutes)

Configures the polling interval over which to measure CSCF Total Active Registrations. *time* must be an integer value from 60 to 60000 and expressed in multiples of 30. The system will round up all other configured values to a multiple of 30.

rereg-reply-error

Default: 0

Configures the polling interval over which to measure number of re-registration reply errors for HA services. When specifying **interval time** for this threshold, the range is from 60 through 900 seconds.

rp-setup-fail-rate

Default: 900 seconds (15 minutes)

Configure the polling interval over which to measure the RP setup failure rate.

spc-cpu-memory-usage interval

 **Important:** This command has been renamed to **threshold mgmt-cpu-memory-usage**. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.

 **Important:** This command is not supported on all platforms

spc-cpu-utilization

 **Important:** This command has been renamed to **threshold mgmt-cpu-utilization**. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.

 **Important:** This command is not supported on all platforms

storage-utilization

Default: 900 seconds (15 minutes)

Configures the polling interval over which to record the CompactFlash utilization percentage threshold interval in seconds.

total-asngw-sessions

Configures the polling interval over which to measure total ASNGW sessions on the system.

total-ggsn-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of GGSN sessions on the system.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-gprs-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of 2G-attached subscribers on the system.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-gprs-pdp-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of 2G-activated PDP contexts per GPRS sessions on the system.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-ha-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of HA sessions on the system.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-hsgw-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of HSGW sessions on the system.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-lma-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of LMA sessions on the system.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-lns-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of LNS sessions on the system.

 **Important:** When specifying **interval time** for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-pdsn-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of PDSN sessions on the system.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-pgw-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of P-GW sessions on the system.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-sgsn-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of SGSN sessions on the system.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-sgsn-pdp-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of SGSN sessions on the system.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-sgw-sessions

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of S-GW sessions on the system.

 **Important:** When specifying *interval time* for this threshold, the range is from 30 through 60000 seconds. If the value entered is not a multiple of 30, the value is automatically rounded up to the next highest multiple of 30. (If you enter 35, the value is rounded to 60.)

total-subscriber

Default: 300 seconds (5 minutes)

Configures the polling interval over which to count the total number of subscriber sessions.

interval time

Specifies the amount of time that comprises the polling interval.

time is measured in seconds and can be configured to any integer value from 60 to 60000 unless otherwise noted in keyword descriptions.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system's support for thresholding.

Example

The following command configures the polling interval for the total subscribers threshold value to 600 seconds (10 minutes):

```
threshold poll total-subscriber interval 600
```

threshold poll asngw-auth-failure

Configures the polling interval over which to count or measure the thresholding value for ASN Gateway authentication failure.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll asngw-auth-failure interval dur
```

```
default threshold poll asngw-auth-failure interval
```

default

Restores the specified parameter to its default value 300 seconds.

interval *dur*

Default: 300 seconds.

Specifies the amount of time that comprises the polling interval.

dur is measured in seconds and can be configured to any integer value from 30 to 60000 in multiple of 30.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for the ASN Gateway authentication failure threshold:

```
threshold poll asngw-auth-failure interval 600
```

threshold poll asngw-handoff-denial

Configures the polling interval over which to count or measure the thresholding value for ASN Gateway hand-off denial.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll asngw-handoff-denial interval dur
```

```
default threshold poll asngw-handoff-denial interval
```

default

Restores the specified parameter to its default value 300 seconds.

interval *dur*

Default: 300 seconds.

Specifies the polling interval time.

dur is measured in seconds and can be configured to any integer value from 30 to 60000 in multiple of 30.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for hand-off denial threshold:

```
threshold poll asngw-handoff-denial interval 600
```

threshold poll asngw-max-eap-retry

Configures the polling interval over which to count or measure the thresholding value for maximum EAP authentication retries.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll asngw-max-eap-retry interval dur
```

```
default threshold poll asngw-max-eap-retry interval
```

default

Restores the specified parameter to its default value 300 seconds.

interval *dur*

Default: 300 seconds.

Specifies the amount of time that comprises the polling interval.

dur is measured in seconds and can be configured to any integer value from 30 to 60000 in multiple of 30.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for maximum EAP authentication retry threshold:

```
threshold poll asngw-max-eap-retry interval 600
```

threshold poll asngw-network-entry-denial

Configures the polling interval over which to count or measure the thresholding value for network entry denial to an MS.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll asngw-network-entry-denial interval dur
```

```
default threshold poll asngw-network-entry-denial interval
```

default

Restores the specified parameter to its default value 300 seconds.

interval *dur*

Default: 300 seconds.

Specifies the amount of time that comprises the polling interval.

dur is measured in seconds and can be configured to any integer value from 30 to 60000 in multiple of 30.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for network entry denial threshold:

```
threshold poll asngw-network-entry-denial interval 600
```

threshold poll asngw-r6-invalid-nai

Configures the polling interval over which to count or measure the thresholding value for invalid NAIs in R6 messages.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll asngw-r6-invalid-nai interval dur
```

```
default threshold poll asngw-r6-invalid-nai interval
```

default

Restores the specified parameter to its default value 300 seconds.

interval *dur*

Default: 300 seconds.

Specifies the amount of time that comprises the polling interval.

dur is measured in seconds and can be configured to any integer value from 30 to 60000 in multiple of 30.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for invalid NAIs in R6 messages threshold:

```
threshold poll asngw-r6-invalid-nai interval 600
```

threshold poll asngw-session-setup-timeout

Configures the polling interval over which to count or measure the thresholding value for session setup timeout.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll asngw-session-setup-timeout interval dur
```

```
default threshold poll asngw-session-setup-timeout interval
```

default

Restores the specified parameter to its default value 300 seconds.

interval *dur*

Default: 300 seconds.

Specifies the amount of time that comprises the polling interval.

dur is measured in seconds and can be configured to any integer value from 30 to 60000 in multiple of 30.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for session setup timeout threshold:

```
threshold poll asngw-session-setup-timeout interval 600
```

threshold poll asngw-session-timeout

Configures the polling interval over which to count or measure the thresholding value for session timeout.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll asngw-session-timeout interval dur
```

```
default threshold poll asngw-session-timeout interval
```

default

Restores the specified parameter to its default value 300 seconds.

interval *dur*

Default: 300 seconds.

Specifies the amount of time that comprises the polling interval.

dur is measured in seconds and can be configured to any integer value from 30 to 60000 in multiple of 30.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for session timeout threshold:

```
threshold poll asngw-session-timeout interval 600
```

threshold poll cdr-file-space

This command configures the polling interval for CDR File Space Usage threshold.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll cdr-file-space interval duration
```

```
default threshold poll cdr-file-space interval
```

default

Configures the default setting.
Default: 300 seconds.

interval *duration*

Specifies the polling interval for CDR File Space Usage threshold, in seconds.
duration must be an integer value from 60 through 60000.

Usage

This command configures the polling interval for CDR File Space Usage threshold.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for the CDR file space usage threshold:

```
threshold poll cdr-file-space interval 600
```

threshold poll confilt-block

This command configures the polling interval Content Filtering Block threshold.

Product

CF

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll confilt-block interval duration
```

```
default threshold poll confilt-block
```

default

Configures the default setting.
Default: 300 seconds.

interval *duration*

Specifies the polling interval for Content Filtering Block threshold, in seconds.
duration must be an integer value from 60 through 60000.

Usage

This command configures the polling interval Content Filtering Block threshold.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for the content filtering blocking threshold:

```
threshold poll confilt-block interval 600
```

threshold poll confilt-rating

This command configures the polling interval for the Content Filtering Rating threshold.

Product

CF

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll confilt-rating interval duration
```

```
default threshold poll confilt-rating
```

default

Configures the default setting.
Default: 300 seconds.

interval *dur*

Specifies the polling interval for the Content Filtering Rating threshold, in seconds.
duration must be an integer value from 60 through 60000.

Usage

This command configures the polling interval for the Content Filtering Rating threshold.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for the content filtering rating processing threshold:

```
threshold poll confilt-rating interval 600
```

threshold poll dcca-protocol-error

This command configures the polling interval for DCCA Protocol Error threshold.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll dcca-protocol-error interval duration
```

```
default threshold poll dcca-protocol-error interval
```

default

Configures the default setting.
Default: 900 seconds

interval *duration*

Specifies the polling interval for DCCA Protocol Error threshold, in seconds.
duration must be an integer value from 60 through 60000.

Usage

Use this the polling interval for DCCA Protocol Error threshold.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholding in this chapter.

Example

The following command configures the polling interval to 600 seconds for the DCCA protocol error threshold:

```
threshold poll dcca-protocol-error interval 600
```

threshold poll dcca-rating-failed

This command configures the polling interval for DCCA Rating Failed threshold.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll dcca-rating-failed interval duration
```

```
default threshold poll dcca-rating-failed interval
```

default

Configures the default setting.
Default: 900 seconds

interval *duration*

Specifies the polling interval for DCCA Rating Failed threshold.
duration must be an integer value from 60 through 60000.

Usage

This command configures the polling interval for DCCA Rating Failed threshold.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholding in this chapter.

Example

The following command configures the polling interval to 600 seconds for the Diameter Credit Control Application (DCCA) Rating Group (content-id) request reject thresholds:

```
threshold poll dcca-rating-failed interval 600
```

threshold poll dcca-bad-answers

This command configures the polling interval for DCCA Bad Answers threshold—invalid or bad response to the system from the Diameter server.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll dcca-bad-answers interval duration
```

```
default threshold poll dcca-bad-answers interval
```

default

Configures the default setting.

Default: 900 seconds

interval *duration*

Specifies the polling interval for DCCA Bad Answers threshold, in seconds.

duration must be an integer value from 60 through 60000.

Usage

This command configures the polling interval for DCCA Bad Answers threshold.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholding in this chapter.

Example

The following command configures the polling interval to 600 seconds for invalid or bad response threshold to the system from Diameter server:

```
threshold poll dcca-rating-failed interval 600
```

threshold poll dcca-unknown-rating-group

This command configures the polling interval for DCCA Unknown Rating Group threshold.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll dcca-unknown-rating-group interval duration
```

```
default threshold poll dcca-unknown-rating-group interval
```

default

Configures the default setting.
Default: 900 seconds

interval *duration*

Specifies the polling interval for DCCA Unknown Rating Group threshold, in seconds.
duration must be an integer value from 60 through 60000.

Usage

This command configures the polling interval for DCCA Unknown Rating Group threshold.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands for additional information on the system's support for thresholding in this chapter.

Example

The following command configures the polling interval to 600 seconds to threshold for the unknown DCCA Rating Group (content-id) returned by Diameter to system:

```
threshold poll dcca-unknown-rating-group interval 600
```

threshold poll diameter-retry-rate

This command configures the polling interval for Diameter Retry Rate threshold.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll diameter-retry-rate interval duration
```

```
default threshold poll diameter-retry-rate interval
```

default

Configures the default setting.
Default: 300 seconds

interval *duration*

Specifies the polling interval for Diameter Retry Rate threshold, in seconds.
duration must be an integer from 60 through 60000. The input will be rounded up to the closest multiple of 30.

Usage

This command specifies the polling interval for Diameter Retry Rate threshold.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring** and other threshold commands in this chapter for additional information on the system's support for thresholding.

Example

The following command configures the Diameter Retry Rate threshold polling interval to 600 seconds:

```
threshold poll diameter-retry-rate interval 600
```

threshold poll edr-file-space

This command configures the polling interval for EDR File Space Usage threshold.

Product

ECS

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll edr-file-space interval duration
```

interval *duration*

Default: 300 seconds.

Specifies the polling interval for EDR File Space Usage threshold, in seconds.

duration must be an integer value from 60 through 60000.

Usage

This command configures the polling interval for EDR File Space Usage threshold

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring ecs** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval to 600 seconds for the EDR file space usage threshold:

```
threshold poll edr-file-space interval 600
```

threshold poll mme-attach-failure

This command configures the polling interval to count the MME Attach Failure messages across all MME services in the system.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll mme-attach-failure interval dur
```

```
default threshold poll mme-attach-failure interval
```

default

Restores the poll interval value to its default value of 900 seconds.

interval *dur*

Default: 900 seconds.

Specifies the amount of time that comprises the polling interval for threshold to count the MME Attach Failure messages across all MME services in the system.

dur is measured in seconds and can be configured to any integer value from 30 to 60000 in multiple of 30.

Usage

Use this command to configure the polling interval to count the MME Attach Failure messages across all MME services in the system to generate threshold value.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring mme-service** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval of 600 seconds to count the MME Attach Failure messages for threshold limit:

```
threshold poll mme-attach-failure interval 600
```

threshold poll mme-auth-failure

This command configures the polling interval to count the MME Authentication Failure messages across all MME services in the system.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll mme-auth-failure interval dur
```

```
default threshold poll mme-auth-failure interval
```

default

Restores the specified poll interval value to its default value of 900 seconds.

interval *dur*

Default: 900 seconds.

Specifies the amount of time that comprises the polling interval for threshold to count the MME Authentication Failure messages across all MME services in the system.

dur is measured in seconds and can be configured to any integer value from 30 to 60000 in multiple of 30.

Usage

Use this command to configure the polling interval to count the MME Auth Failure messages across all MME services in the system to generate threshold value.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold monitoring mme-service** and other threshold commands for additional information on the system's support for thresholds in this chapter.

Example

The following command configures the polling interval of 600 seconds to count the MME Auth Failure messages for threshold limit:

```
threshold poll mme-auth-failure interval 600
```

threshold poll total-hnbgw-hnb-sessions

This command configures the polling interval over which to count or measure the thresholding value for the total number of IuH sessions between HNB and HNB-GW to count across all the HNB-GW services on a system to trigger alert or alarm.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] threshold poll total-hnbgw-hnb-sessions interval time
```

default

Restores the threshold poll interval value to its default value of 300 seconds.

interval *time*

Default: 900 seconds

Specifies the amount of time that comprises the polling interval over which to count the total number of IuH sessions between HNB and HNB-GW to count across all the HNB-GW services on a system.

time is measured in seconds and can be configured to any integer value from 30 to 60000.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

 **Important:** All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system's support for thresholding.

 **Important:** To enable SNMP trap for threshold monitoring of this threshold use **snmp trap enable ThreshTotalHNBGWHnbSess** command in this mode.

Example

The following command configures the polling interval for the total number IuH session, between HNB and HNB-GW to count across all the HNB-GW services on a system, threshold polling duration value to 600 seconds (10 minutes):

```
threshold poll total-hnbgw-hnb-sessions interval 600
```

threshold poll total-hnbgw-iu-sessions

This command configures the polling interval over which to count or measure the thresholding value for the total number of subscriber sessions on HNB-GW service (over Iu-CS/Iu-PS interface) to count across all the HNB-GW services on a system to trigger alert or alarm.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] threshold poll total-hnbgw-iu-sessions interval time
```

default

Restores the threshold poll interval value to its default value of 300 seconds.

interval *time*

Default: 900 seconds

Specifies the amount of time that comprises the polling interval over which to count the total number of subscriber sessions on HNB-GW service to count across all the HNB-GW services on a system.

time is measured in seconds and can be configured to any integer value from 30 to 60000.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system's support for thresholding.

Important: To enable SNMP trap for threshold monitoring to this threshold use **snmp trap enable ThreshTotalHNBGWiuSess** command in this mode.

Example

The following command configures the polling interval for the total subscriber sessions, on HNB-GW service to count across all the HNB-GW services on a system, threshold polling duration value to 600 seconds (10 minutes):

```
threshold poll total-hnbgw-iu-sessions interval 600
```

threshold poll total-hnbgw-ue-sessions

This command configures the polling interval over which to count or measure the thresholding value for the total number of UEs connected to HNB-GW service to count across all the HNB-GW services on a system to trigger alert or alarm.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] threshold poll total-hnbgw-ue-sessions interval time
```

default

Restores the threshold poll interval value to its default value of 300 seconds.

interval *time*

Default: 900 seconds

Specifies the amount of time that comprises the polling interval over which to count the total number UEs connected to HNB-GW service to count across all the HNB-GW services on a system.

time is measured in seconds and can be configured to any integer value from 30 to 60000.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system's support for thresholding.

Important: To enable SNMP trap for threshold monitoring to this threshold use **snmp trap enable ThreshTotalHNBGWUeSess** command in this mode.

Example

The following command configures the polling interval for the total number of UEs connected to HNB-GW service, to count across all the HNB-GW services on a system, threshold polling duration value to 600 seconds (10 minutes):

```
threshold poll total-hnbgw-ue-sessions interval 600
```

threshold poll total-mme-sessions

This command configures the polling interval over which to count or measure the thresholding value for MME sessions on the system.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] threshold poll total-mme-sessions interval time
```

default

Restores the threshold poll interval value to its default value of 300 seconds.

interval *time*

Default: 900 seconds

Specifies the amount of time that comprises the polling interval over which to count the total number of MME sessions on the system.

time is measured in seconds and can be configured to any integer value from 30 to 60000.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system's support for thresholding.

Example

The following command configures the polling interval for the total MME session threshold polling duration value to 600 seconds (10 minutes):

```
threshold poll total-mme-sessions interval 600
```

threshold poll port-rx-utilization

Enables the generation of alerts or alarms based on the port utilization percentage for data received during the polling interval.

Product

All

Privilege

Administrator Security Administrator

Syntax

```
threshold poll port-rx-utilization interval seconds
```

interval *seconds*

Configures the threshold polling interval in multiples of 30 seconds from 30 to 60000

Usage

Receive port utilization thresholds generate alerts or alarms based on the utilization percentage of each configured port in relation to data received during the specified polling interval. This threshold is configured on a per-port basis configured using the port *port-type slot#/port#* command syntax.

Important: This command is not available on all platforms

Important: Ports configured for half-duplex do not differentiate between data received and data transmitted. (The transmitted and received percentages are combined.) Therefore, to avoid redundant alarms, it is recommended that only the receive **or** transmit utilization threshold be configured.

Example

Use the following example to configure a threshold poll interval of 300 seconds (5 minutes)

```
threshold poll port-rx-utilization interval 300
```

threshold poll port-tx-utilization

Enables the generation of alerts or alarms based on the port utilization percentage for data transmitted during the polling interval.

Product

All

Privilege

Administrator Security Administrator

Syntax

```
threshold poll port-tx-utilization interval seconds
```

interval *seconds*

Configures the threshold polling interval in multiples of 30 seconds from 30 to 60000

Usage

Transmit port utilization thresholds generate alerts or alarms based on the utilization percentage of each configured port in relation to data transmitted during the specified polling interval. This threshold is configured on a per-port basis configured using the port *port-type slot#/port#* command syntax.

Important: This command is not available on all platforms

Important: Ports configured for half-duplex do not differentiate between data received and data transmitted. (The transmitted and received percentages are combined.) Therefore, to avoid redundant alarms, it is recommended that only the receive **or** transmit utilization threshold be configured.

Example

Use the following example to configure a threshold poll interval of 300 seconds (5 minutes)

```
threshold poll port-tx-utilization interval 300
```

threshold poll port-high-activity

Enables the generation of alerts or alarms based on the overall port utilization percentage during the polling interval.

Product

All

Privilege

Administrator Security Administrator

Syntax

```
threshold poll port-high-activity interval seconds
```

interval *seconds*

Configures the threshold polling interval in multiples of 30 seconds from 30 to 60000

Usage

High port activity thresholds generate alerts or alarms based on the peak utilization percentage of each configured port during the specified polling interval. This threshold is configured on a per-port basis. Alerts or alarms are triggered for high port activity based on the following rules:

Enter condition: Actual percent peak utilization of a port ³High Threshold

Clear condition: Actual percent peak utilization of a port < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval. This threshold is configured on a per-port basis configured using the port *port-type slot#/port#* command syntax.

Important: This command is not available on all platforms

Example

Use the following example to configure the polling interval over which to measure for high port activity to 300 seconds:

```
threshold poll port-high-activity interval 300
```

threshold poll route-service

This command configures the polling interval over which to count or measure the thresholding value for route services on the system.

Product

All

Privilege

Administrator Security Administrator

Syntax

```
[ default ] threshold poll route-service interval dur
```

default

Restores the threshold poll interval value to its default value of 900 seconds.

interval *time*

Default: 900 seconds

Specifies the amount of time that comprises the polling interval over which to count the total number of BGP route on the system.

dur is measured in seconds and can be configured to any integer value from 30 to 60000.

Usage

This command dictates the time period over which to monitor the specified value for threshold crossing.

Important: All configured polling intervals are rounded up to the closest multiple of 30. For example, if a polling interval is configured for 130 seconds, the system uses a polling interval of 150 seconds.

Refer to the **threshold model** and **threshold monitoring** commands for additional information on the system's support for thresholding.

Example

The following command configures the polling interval for the total BGP routes threshold polling duration value to 600 seconds (10 minutes):

```
hreshold poll route-service interval 600
```

threshold poll tpo-dns-failure

This command configures the threshold polling interval for monitoring TPO DNS resolution failures.

Important: This is a restricted command. For more information contact your local sales representative.

Product

TPO

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll tpo-dns-failure interval interval
```

```
default threshold poll tpo-dns-failure interval
```

default

Configures the default setting.

Default: 900 seconds

interval

Specifies the polling interval in seconds.

Important: The system rounds up the value to the closest multiple of 30.

interval must be an integer from 30 through 60000.

Usage

Use this command to configure the threshold polling interval for monitoring TPO DNS resolution failures.

Example

The following command configures the polling interval for TPO DNS resolution failures threshold to 600 seconds:

```
threshold poll tpo-dns-failure interval 600
```

threshold poll tpo-low-compression-gain

This command configures the threshold polling interval for monitoring TPO low-compression-gain results.

 **Important:** This is a restricted command. For more information contact your local sales representative.

Product

TPO

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll tpo-low-compression-gain interval interval
```

```
default threshold poll tpo-low-compression-gain interval
```

default

Configures the default setting.

Default: 900 seconds

interval

Specifies the polling interval in seconds.

 **Important:** The system rounds up the value to the closest multiple of 30.

interval must be an integer from 30 through 60000.

Usage

Use this command to configure the threshold polling interval for monitoring TPO low-compression-gain results.

Example

The following command configures the polling interval for TPO low-compression-gain results threshold to 600 seconds:

```
threshold poll tpo-low-compression-gain interval 600
```

threshold poll tpo-rto-timeout

This command configures the threshold polling interval for monitoring TPO retransmission timeouts.

Important: This is a restricted command. For more information contact your local sales representative.

Product

TPO

Privilege

Security Administrator, Administrator

Syntax

```
threshold poll tpo-rto-timeout interval interval
```

```
default threshold poll tpo-rto-timeout interval
```

default

Configures the default setting.

Default: 900 seconds

interval

Specifies the polling interval in seconds.

Important: The system rounds up the value to the closest multiple of 30.

interval must be an integer from 30 through 60000.

Usage

Use this command to configure the threshold polling interval for monitoring TPO retransmission timeouts.

Example

The following command configures the polling interval for TPO retransmission timeouts threshold to 600 seconds:

```
threshold poll tpo-rto-timeout interval 600
```

threshold ppp-setup-fail-rate

Configures PPP setup failure rate thresholds.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold ppp-setup-fail-rate high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold rate for PPP setup failures experienced by the system that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold rate for PPP setup failures experienced by the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

PPP setup failure rate thresholds generate alerts or alarms based on the rate of call setup failures experienced by the system during the specified polling interval. The failure rate is the percentage of failures as determined by number of PPP setup failures divided by the total number of PPP sessions initiated.

Alerts or alarms are triggered for PPP setup failure rates based on the following rules:

- **Enter condition:** Actual number of call setup failures \geq High Threshold
- **Clear condition:** Actual number of call setup failures $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a PPP setup failure rate high threshold of 50 and a clear threshold of 45:

■ threshold ppp-setup-fail-rate

```
threshold ppp-setup-fail-rate 50 clear 45
```

threshold route-service bgp-routes

This command configures the threshold limits for route services to BGP routes.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold route-service bgp-routes high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold rate for BGP routes on the system that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold rate for BGP routes on the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to configure a threshold in percentage of maximum BGP routes allowed. If the percentage of the number of BGP routes in a context (including all VRFs) reaches *high_thresh*, a notification is generated. Optionally, if the threshold subsystem is configured in 'alarm' mode, a **Threshold_Clear** notification is generated when the percentage of the number of BGP routes in a context (including all VRFs) goes below *low_thresh*. The maximum number of BGP routes is also sent by BGP task when getting the stats

Alerts or alarms are triggered for BGP routes based on the following rules:

- **Enter condition:** Actual number of call setup failures > High Threshold
- **Clear condition:** Actual number of call setup failures < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

■ threshold route-service bgp-routes

Example

The following command configures system for high threshold of 50 and a clear threshold of 45:

```
threshold route-service bgp-routes 50 clear 45
```

threshold rp-setup-fail-rate

Configures RP setup failure rate thresholds.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold rp-setup-fail-rate high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold rate for RP setup failures experienced by the system that must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold rate for RP setup failures experienced by the system that maintains a previously generated alarm condition. If the number of setup failures falls beneath the low threshold within the polling interval, a clear alarm will be generated.

low_thresh can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

RP setup failure rate thresholds generate alerts or alarms based on the rate of call setup failures experienced by the system during the specified polling interval. The failure rate is the percentage of failures as determined by number of Registration Request Messages rejected divided by the total number of Registration Request Messages received.

Alerts or alarms are triggered for RP setup failure rates based on the following rules:

- **Enter condition:** Actual number of call setup failures \geq High Threshold
- **Clear condition:** Actual number of call setup failures $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a RP setup failure rate high threshold of 50 and a clear threshold of 45:

■ threshold rp-setup-fail-rate

```
threshold rp-setup-fail-rate 50 clear 45
```

threshold spc-cpu-memory-usage

This command has been renamed to **threshold mgmt-cpu-memory-usage**. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.

Important: This command is not supported on all platforms.

■ `threshold spc-cpu-utilization`

threshold spc-cpu-utilization

This command has been renamed to **threshold mgmt-cpu-utilization**. Please refer to that command for details. Note that for backwards compatibility, the system accepts this command as valid.

threshold storage-utilization

Configures SMC CompactFlash memory utilization thresholds.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
threshold storage-utilization high_thresh [ clear low_thresh ]
```

high_thresh

Default: 90

The high threshold memory utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

clear *low_thresh*

Default: 90

The low threshold memory utilization percentage that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 100. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

CompactFlash memory utilization thresholds generate alerts or alarms based on the utilization percentage of the CompactFlash on each installed SMC during the specified polling interval. Although, a single threshold is configured for both SMCs, separate alerts or alarms can be generated for each.

Alerts or alarms are triggered for CompactFlash memory utilization based on the following rules:

- **Enter condition:** Actual percentage memory utilization \geq High Threshold
- **Clear condition:** Actual percentage memory utilization $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a high threshold CompactFlash utilization percentage of 85 for an system using the Alert thresholding model:

■ threshold storage-utilization

`threshold storage-utilization 85`

threshold subscriber active

Configures active subscriber thresholds for the system.

Product

PDSN, GGSN, SGSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold subscriber active high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of active subscriber sessions facilitated by the system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value between 0 and 100000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of active subscriber sessions facilitated by the system that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 100000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Active subscriber thresholds generate alerts or alarms based on the total number of active subscriber sessions facilitated by the system during the specified polling interval.

Alerts or alarms are triggered for active subscriber totals based on the following rules:

- **Enter condition:** Actual total number of active subscriber sessions \geq High Threshold
- **Clear condition:** Actual total number of active subscriber sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures an active subscriber high threshold count of *150000* and a low threshold of *1500* for an system using the Alarm thresholding model:

■ threshold subscriber active

```
threshold subscriber active 150000 clear 1500
```

threshold subscriber total

Configures total subscriber thresholds for the system.

Product

PDSN, GGSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold subscriber total high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of subscriber sessions (active and dormant) facilitated by the system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value between 0 and 100000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of subscriber sessions (active and dormant) facilitated by the system that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 100000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Total subscriber thresholds generate alerts or alarms based on the total number of subscriber sessions (active and dormant) facilitated by the system during the specified polling interval.

Alerts or alarms are triggered for subscriber totals based on the following rules:

- **Enter condition:** Actual total number of subscriber sessions \geq High Threshold
- **Clear condition:** Actual total number of subscriber sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures an active subscriber high threshold count of 450000 and a low threshold of 250000 for an system using the Alarm thresholding model:

■ threshold subscriber total

```
threshold subscriber total 450000 clear 250000
```

threshold total-ggsn-sessions

Configures thresholds for the total number of GGSN sessions across all the services in the system.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-ggsn-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0 (Disabled)

The high threshold number of total GGSN sessions across all the sessions in the system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 4000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0 (Disabled)

The low threshold number of total GGSN sessions that maintains a previously generated alarm condition. If the number of GGSN sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 4000000. A value of 0 disables the threshold.

 **Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of GGSN sessions across all the services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of GGSN sessions based on the following rules:

- **Enter condition:** Actual total number of GGSN sessions \geq High Threshold
- **Clear condition:** Actual total number of GGSN sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total GGSN session high threshold count of *10000* for an system using the Alert thresholding model:

■ threshold total-ggsn-sessions

```
threshold total-ggsn-sessions 10000
```

threshold total-gprs-sessions

Configures thresholds for the total number of GPRS sessions in the system.

Product

SGSN

Privilege

Administrator

Syntax

```
threshold total-gprs-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of total GPRS sessions for all GPRS services that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 1 through 2000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of total GPRS sessions for all GPRS services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 2000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of GPRS sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for GPRS sessions based on the following rules:

- **Enter condition:** Actual total number of GPRS sessions \geq High Threshold
- **Clear condition:** Actual total number of GPRS sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total number of GPRS sessions high threshold count of *10000* for a system using the Alert thresholding model:

■ threshold total-gprs-sessions

```
threshold total-gprs-sessions 10000
```

threshold total-gprs-pdp-sessions

Configures thresholds for the total number of PDP contexts per GPRS sessions in the system.

Product

SGSN

Privilege

Administrator

Syntax

```
threshold total-gprs-pdp-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of total PDP contexts per GPRS session for all GPRS services that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 1 through 2000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of total PDP contexts per GPRS session for all GPRS services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 2000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of GPRS sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for GPRS sessions based on the following rules:

- **Enter condition:** Actual total number of PDP Contexts \geq High Threshold
- **Clear condition:** Actual total number of PDP contexts $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total number of PDP contexts per GPRS session high threshold count of *10000* for a system using the Alert thresholding model:

■ threshold total-gprs-pdp-sessions

```
threshold total-gprs-pdp-sessions 10000
```

threshold total-ha-sessions

Configures thresholds for the total number of HA sessions across all services in the system.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-ha-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of HA sessions for all HA services that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 4000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of HA sessions for all HA services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of HA sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for HA sessions based on the following rules:

- **Enter condition:** Actual total number of HA sessions \geq High Threshold
- **Clear condition:** Actual total number of HA sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total number of HA sessions high threshold count of *10000* for an system using the Alert thresholding model:

■ threshold total-ha-sessions

```
threshold total-ha-sessions 10000
```

threshold total-hnbgw-hnb-sessions

Use this command to configure thresholds for the total number of IuH sessions between HNB and HNB-GW to count across all the HNB-GW services in the system as threshold limit to generate alert or alarm.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-hnbgw-hnb-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0 (Disabled)

The high threshold number of total HNB-HNB-GW sessions on IuH interface across all HNB-GW services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 1000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0 (Disabled)

The low threshold number of total HNB-HNB-GW sessions on IuH interface across all services on a system that maintains a previously generated alarm condition. If the number of HNB-HNB-GW sessions on IuH interface, across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of HNB-HNB-GW sessions on IuH interface across all HNB-GW services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of HNB-HNB-GW sessions on IuH interface based on the following rules:

- **Enter condition:** Actual total number of HNB-HNB-GW sessions on IuH interface > High Threshold
- **Clear condition:** Actual total number of HNB-HNB-GW sessions on IuH interface < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll total-hnbgw-hnb-sessions** command to configure the polling interval and the **threshold monitoring hnbgw-service** command to enable thresholding for this value.

■ `threshold total-hnbgw-hnb-sessions`

Important: To enable SNMP trap for threshold monitoring to this threshold use `snmp trap enable ThreshTotalHNBGWHnbSess` command in this mode.

Example

The following command configures the total number of HNB-GW-HNB sessions on IuH interface to high threshold count of `10000` for an system using the Alert thresholding model:

```
threshold total-hnbgw-hnb-sessions 10000
```

threshold total-hnbgw-iu-sessions

Use this command to configure thresholds for the total number of subscriber session, towards Core Networks (CN) across all the HNB-GW services over Iu interface (Iu-CS/Iu-PS interface) on a system, as threshold limit to generate alert or alarm.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-hnbgw-iu-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0 (Disabled)

The high threshold number of total subscriber sessions towards CN across all HNB-GW services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 3000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0 (Disabled)

The low threshold number of total number of subscriber sessions towards CN across all services on a system that maintains a previously generated alarm condition. If the number of subscriber sessions on across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 3000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of subscriber sessions towards CN across all HNB-GW services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of subscriber sessions towards CN across all HNB-GW service on a system based on the following rules:

- **Enter condition:** Actual total number of subscriber sessions across all HNB-GW service on a system > High Threshold
- **Clear condition:** Actual total number of subscriber sessions across all HNB-GW service on a system < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

■ `threshold total-hnbgw-iu-sessions`

Refer to the `threshold poll total-hnbgw-iu-sessions` command to configure the polling interval and the `threshold monitoring hnbgw-service` command to enable thresholding for this value.

Important: To enable SNMP trap for threshold monitoring to this threshold use `snmp trap enable ThreshTotalHNBGWiuSess` command in this mode.

Example

The following command configures the total number of subscriber sessions towards CN across all HNB-GW service on a system to high threshold count of `30000` for a system using the Alert thresholding model:

```
threshold total-hnbgw-iu-sessions 30000
```

threshold total-hnbgw-ue-sessions

Use this command to configure thresholds for the total number of UEs connected to HNB-GW service to count across all the HNB-GW services in the system as threshold limit to generate alert or alarm.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-hnbgw-ue-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0 (Disabled)

The high threshold number of total number of UEs connected across all HNB-GW services on a system that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 4000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0 (Disabled)

The low threshold number of total number of UEs connected to HNB-GW service across all HNB-GW services on a system that maintains a previously generated alarm condition. If the number of UE sessions across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 4000000. A value of 0 disables the threshold.

 **Important:** This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of UEs connected to HNB-GW service across all HNB-GW services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of UEs connected across all HNB-GW service on a system based on the following rules:

- **Enter condition:** Actual total number of UEs connected to HNB-GW service across all HNB-GW services on a system > High Threshold
- **Clear condition:** Actual total number of UEs connected to HNB-GW service across all HNB-GW services on a system < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

■ `threshold total-hnbgw-ue-sessions`

Refer to the `threshold poll total-hnbgw-ue-sessions` command to configure the polling interval and the `threshold monitoring hnbgw-service` command to enable thresholding for this value.

Important: To enable SNMP trap for threshold monitoring to this threshold use `snmp trap enable ThreshTotalHNBGWUeSess` command in this mode.

Example

The following command configures the total number of UEs connected to HNB-GW service across all HNB-GW services on a system to high threshold count of `40000` for an system using the Alert thresholding model:

```
threshold total-hnbgw-ue-sessions 40000
```

threshold total-hsgw-sessions

Configures thresholds for the total number of HSGW sessions across all services in the system.

Product

HSGW

Privilege

Administrator

Syntax

```
threshold total-hsgw-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of HSGW sessions for all HSGW services that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 1 through 1500000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of HSGW sessions for all HSGW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1500000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of HSGW sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for HSGW sessions based on the following rules:

- **Enter condition:** Actual total number of HSGW sessions \geq High Threshold
- **Clear condition:** Actual total number of HSGW sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total number of HSGW sessions high threshold count of 500000 for an system using the Alert thresholding model:

■ threshold total-hsgw-sessions

```
threshold total-hsgw-sessions 500000
```

threshold total-lma-sessions

Configures thresholds for the total number of LMA sessions across all services in the system.

Product

P-GW

Privilege

Administrator

Syntax

```
threshold total-lma-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of LMA sessions for all LMA services that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 1 through 1500000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of LMA sessions for all LMA services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1500000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of LMA sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for LMA sessions based on the following rules:

- **Enter condition:** Actual total number of LMA sessions \geq High Threshold
- **Clear condition:** Actual total number of LMA sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total number of LMA sessions high threshold count of *500000* for an system using the Alert thresholding model:

■ threshold total-lma-sessions

```
threshold total-lma-sessions 500000
```

threshold total-lns-sessions

Configures thresholds for the total number of LNS sessions in the system.

Product

PDSN, GGSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-lns-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of total LNS sessions that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 4000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of total LNS sessions that maintains a previously generated alarm condition. If the number of LNS sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of LNS sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of LNS sessions based on the following rules:

- **Enter condition:** Actual total number of LNS sessions \geq High Threshold
- **Clear condition:** Actual total number of LNS sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total LNS session high threshold count of 10000 for an system using the Alert thresholding model:

■ threshold total-lns-sessions

```
threshold total-lns-sessions 10000
```

threshold total-mme-sessions

Use this command to configure thresholds for the total number of MME sessions across all the MME services in the system.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-mme-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0 (Disabled)

The high threshold number of total MME sessions that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 4000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0 (Disabled)

The low threshold number of total MME sessions that maintains a previously generated alarm condition. If the number of MME sessions, across all the services in a system, falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to monitor and set alarms or alerts when the total number of MME sessions across all the MME services in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of MME sessions based on the following rules:

- **Enter condition:** Actual total number of MME sessions \geq High Threshold
- **Clear condition:** Actual total number of MME sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll total-mme-sessions** command to configure the polling interval and the **threshold monitoring mme-service** command to enable thresholding for this value.

Example

■ `threshold total-mme-sessions`

The following command configures a total MME session high threshold count of *10000* for a system using the Alert thresholding model:

```
threshold total-mme-sessions 10000
```

threshold total-pdsn-sessions

Configures thresholds for the total number of PDSN sessions in the system.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold total-pdsn-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of total PDSN sessions that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 0 through 4000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of total PDSN sessions that maintains a previously generated alarm condition. If the number of PDSN sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 4000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of PDSN sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for the total number of PDSN sessions based on the following rules:

- **Enter condition:** Actual total number of PDSN sessions \geq High Threshold
- **Clear condition:** Actual total number of PDSN sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total PDSN session high threshold count of 10000 for an system using the Alert thresholding model:

■ threshold total-pdsn-sessions

```
threshold total-pdsn-sessions 10000
```

threshold total-pgw-sessions

Configures thresholds for the total number of P-GW sessions across all services in the system.

Product

P-GW

Privilege

Administrator

Syntax

```
threshold total-pgw-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of P-GW sessions for all P-GW services that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 1 through 1500000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of P-GW sessions for all P-GW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1500000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of P-GW sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for P-GW sessions based on the following rules:

- **Enter condition:** Actual total number of P-GW sessions \geq High Threshold
- **Clear condition:** Actual total number of P-GW sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total number of P-GW sessions high threshold count of 500000 for an system using the Alert thresholding model:

■ threshold total-pgw-sessions

```
threshold total-pgw-sessions 500000
```

threshold total-sgw-sessions

Configures thresholds for the total number of S-GW sessions across all services in the system.

Product

S-GW

Privilege

Administrator

Syntax

```
threshold total-sgw-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of S-GW sessions for all S-GW services that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 1 through 1500000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of S-GW sessions for all S-GW services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 1500000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of S-GW sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for S-GW sessions based on the following rules:

- **Enter condition:** Actual total number of S-GW sessions \geq High Threshold
- **Clear condition:** Actual total number of S-GW sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total number of S-GW sessions high threshold count of 500000 for an system using the Alert thresholding model:

■ threshold total-sgw-sessions

```
threshold total-sgw-sessions 500000
```

threshold total-sgsn-sessions

Configures thresholds for the total number of SGSN sessions in the system.

Product

SGSN

Privilege

Administrator

Syntax

```
threshold total-sgsn-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of total SGSN sessions for all SGSN services that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 1 through 2000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of total SGSN sessions for all SGSN services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 2000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of SGSN sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for SGSN sessions based on the following rules:

- **Enter condition:** Actual total number of SGSN sessions \geq High Threshold
- **Clear condition:** Actual total number of SGSN sessions $<$ Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total number of SGSN sessions high threshold count of *10000* for a system using the Alert thresholding model:

■ threshold total-sgsn-sessions

```
threshold total-sgsn-sessions 10000
```

threshold total-sgsn-pdp-sessions

Configures thresholds for the total number of PDP contexts per SGSN sessions in the system.

Product

SGSN

Privilege

Administrator

Syntax

```
threshold total-sgsn-pdp-sessions high_thresh [ clear low_thresh ]
```

high_thresh

Default: 0

The high threshold number of total PDP contexts per SGSN session for all SGSN services that must be met or exceeded within the polling interval to generate an alert or alarm.

The number can be configured to any integer value from 1 through 2000000. A value of 0 disables the threshold.

clear *low_thresh*

Default: 0

The low threshold number of total PDP contexts per SGSN session for all SGSN services that maintains a previously generated alarm condition. If the number of sessions falls beneath the low threshold within the polling interval, a clear alarm will be generated.

The number can be configured to any integer value between 0 and 2000000. A value of 0 disables the threshold.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Monitor and set alarms or alerts when the total number of SGSN sessions in the system is equal to or greater than the set limit.

Alerts or alarms are triggered for SGSN sessions based on the following rules:

- **Enter condition:** Actual total number of PDP contexts³ High Threshold
- **Clear condition:** Actual total number of PDP contexts < Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command to configure the polling interval and the **threshold monitoring** command to enable thresholding for this value.

Example

The following command configures a total number of PDP contexts per SGSN session high threshold count of *10000* for a system using the Alert thresholding model:

■ threshold total-sgsn-pdp-sessions

```
threshold total-sgsn-pdp-sessions 10000
```

timestamps

Enables/disables the generation of a timestamp in response to each commands entered. The timestamp does not appear in any logs as it is a CLI output only. This command affects all future CLI sessions. Use the **timestamps** command in the Exec Mode to change the behavior for the current CLI session only.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
timestamps
```

```
no timestamps
```

no

Disables generation of timestamp output for each command entered. When omitted, the output of a timestamp for each entered command is enabled.

Usage

Enable the timestamps when logging a CLI session on a remote terminal such that each command will have a line of text indicating the time when the command was entered.

Example

```
timestamps
```

```
no timestamps
```

upgrade limit

Configures upgrade session limits, which are used to trigger the system as to when it may execute the software upgrade.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
upgrade limit [ time session_life ] [ usage session_num ]
```

upgrade limit

This command issued with no keywords sets all parameters to their defaults.

time *session_life*

Default: 120

Defines the maximum number of minutes that a session may exist on the system, undergoing a software upgrade, before it is terminated by the system. As individual user sessions reach this lifetime limit, the system terminates the individual session(s). *session_life* must be an integer ranging from 1 through 1440.

usage *session_num*

Default: 100

This keyword defines a low threshold limit of sessions running either on a PSC/PSC2 or system-wide. When a software upgrade is invoked, this parameter applies to the entire system.

When the threshold is crossed (when the number of sessions on the PSC/PSC2 or system is less than this value), the remaining sessions on the card or system are terminated allowing the upgrade to begin. The remaining sessions on the PSC/PSC2 or system are terminated regardless of their session life.

session_num must be an integer from 0 to 6000.

Usage

Use this command to configure upgrade session limits, which are used to trigger the system as to when it may execute the software upgrade.

Important: This command is not supported on all platforms.

Important: Software Patch Upgrades are not supported in this release.

Example

The following command sets the number of minutes a session can exist to *200* and the minimum number of sessions that may exist before terminating them to *50*:

```
upgrade limit time 200 usage 50
```

url-blacklisting database

This command configures URL Blacklisting database directory parameters.

Product

CF

Privilege

Security Administrator, Administrator

Syntax

```
url-blacklisting database { directory path path | max-versions max_versions |
override file file_name }
```

```
default url-blacklisting database { directory path | max-versions | override
file }
```

default

Configures the default values.

directory path *path*

Specifies the path to the directory to be used for storing URL Blacklisting databases.

path must be a string of 1 through 255 characters in length.

Default: /flash/bl

max-versions *max_versions*

Specifies the maximum number of URL Blacklisting database versions to be maintained in the URL Blacklisting database directory path with the base file name specified by the URL Blacklisting database override file.

max_versions must be an integer from 0 through 3.

Default: 0

override file *file_name*

Specifies the URL Blacklisting database override file name.

file_name must be in *name.extension* format. For example, *abc.bin*. And, must be a string of 1 through 10 characters in length.

Default: optblk.bin

Usage

Use this command to configure URL Blacklisting database directory parameters.

Example

The following command configures the maximum number of URL Blacklisting database versions to be maintained to 3:

```
url-blacklisting database max-versions 3
```

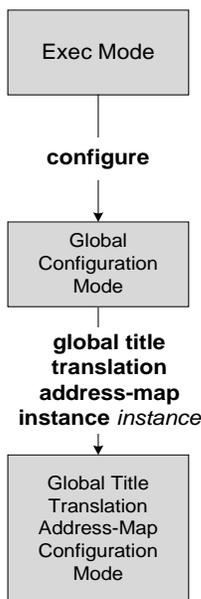

Chapter 118

Global Title Translation Address-Map Configuration Mode Commands

The Global Title Translation (GTT) Address-Map configuration mode provides the commands to create, configure, and manage a specific GTT address map database.

Upon accessing this mode, your prompt should look similar to the following:

```
[local] <hostname> (config-gtt-assoc-<instance#>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

associate

This command associates (links) the global title translation (GTT) address-map with a specific GTT association, which includes the translation action rules.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
associate gtt-association assoc_num action id id
```

```
no association
```

no

Removes the association definition from the GTT address-map configuration.

```
gtt-association assoc_num
```

Identifies a specific GTT association to link (associate) with the GTT address-map.
assoc_num: Must be an integer from 1 to 16.

```
action id id
```

Identifies a specific action defined in the GTT association database configuration.
id: Must be an integer from 1 to 8.

Usage

Create an association between a specific translation action rule in a specific GTT association and this GTT address-map.

Example

```
associate gtt-association 1 action id 1
```

description

This command defines a descriptive string to facilitate identification of this particular global title translation (GTT) address-map. This is used for operator reference only.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
description string
```

```
no description
```

no

Removes the description string from the current global title translation address-map configuration.

string

Specifies the alphanumeric string that is stored. must be from 1 through 127 alphanumeric characters. Strings with spaces must be enclosed in double-quotes. See the example below.

Usage

Use this command to set a description for reference by operators.

Example

```
description "GTT for Finnish national carrier."
```

■ end

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the configuration mode and returns to the Global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Global configuration mode.

gt-address

Configures the SCCP global title address.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gt-address gt_address
```

```
no gt-address
```

no

Removes the GT address from the GTT address-map configuration.

gt_address

Up to 15 digits.

Usage

Define the SCCP short address.

Example

```
gt-address 01040552873424
```

mode

Configures the mode of operation of the SCCP entities.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mode [ dominant | loadshare ]
```

dominant

This instructs the system to maintain the associated entity as the primary traffic pipe.

loadshare

This instructs the system to distribute the traffic load.

Usage

This command configure load balance for the system.

Example

```
mode loadshare
```

out-address

Identifies the out-going address of the SCCP entity. After this command is completed, the system enters the Out-Address configuration mode. Refer to the Out-Address Configuration Mode chapter for information about commands to define the out-address.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

out-address *name*

no out-address

no

Removes the **out-address** definition from the GSS address-map configuration.

name

Defines a unique string to identify the out-going address using 1 to 63 alphanumeric characters.

Usage

Use this command to identify the address of the SCCP in the GTT configuration. This command also provides access to the Out-Address configuration mode so that the parameters for the out-going SCCP can be configured and maintained.

Example

out-address *SCCP_London*

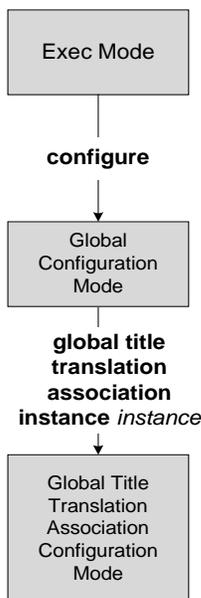

Chapter 119

Global Title Translation Association Configuration Mode Commands

The Global Title Translation (GTT) Association configuration mode provides the commands to create the rules for translating the global titles (destination point codes and subsystem address in the messages) used for routing at the SCCP layer.

Upon accessing this mode, your prompt should look similar to the following:

```
[local] <hostname> (config-gtt-addrmap-<instance#>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

action

This command configures the actions that determine the operation of rules of the global title translation (GTT).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
action id id type action_type start-digit value end-digit value
no action id id
```

id

id uniquely identifies an action. The *id* must be an integer from 1 to 8.

type *action_type*

The following defines the action rules that will determine how global titles (GT) are translated to locally understood addresses - in most cases point codes (PC). The command can be re-issued multiple times to define multiple action rules.

- **constant**: Defines the starting digit in the range of digits in the incoming global titles that are translated to fixed addresses.
- **fixed**: Defines the starting digit in a fixed range of digits used for performing GTT.
- **gt-to-pc**: Use these digits as first of range of global title digits in incoming message to convert to point code for routing.
- **insert-pc**: Defines the rule for inserting destination point code before the incoming GTAI and change TT, ES and NAI. Use digits of incoming message global title digits as pc for routing.
- **selins**: Selective insertion type to perform GTT.
- **strip-pc**: Strip first 6 digits from GTAI if first 6 dgts in stripped point code are in INT format.
- **var-asc**: Use a variable number of digits, in ascending order, to perform GTT.
- **var-des**: Use a variable number of digits, in descending order, to perform GTT.

start-digit *value*

value must be an integer from 0 to 255.

end-digit *value*

value must be an integer from 0 to 255.

Usage

Use this command to create GTT association rules. Rules can be based on ranges of digits or modified ranges depending upon the action types included in the commands.

Example

Use the following command to create a global title translation rule that bases the translation on a fixed range of digits starting at 23 and ending at 122:

```
action id 1 type fixed start-digit 23 end-digit 122
```

description

This command defines a descriptive string to facilitate identification of this particular global title translation (GTT) association. This is used for operator reference only.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
description string
```

```
no description
```

string

Specifies the alphanumeric string that is stored. must be from 1 through 127 alphanumeric characters. Strings with spaces must be enclosed in double-quotes. See the example below.

no

Removes the description string from the current global title translation association configuration.

Usage

Use this command to set a description for reference by operators.

Example

The following command sets the description to identify a routing domain for messages transmitted within a national boundary.

```
description "GTT database 2"
```

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the configuration mode and returns to the Global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Global configuration mode.

gt-format

This command creates an instance of a global title formatting that is applied to the database in the process of address translation. Once the command is completed, the system enters global title (GT) format database configuration mode. The commands for configuration can be found in the GT Format Configuration Mode chapter in this reference guide.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gt-format format_num
```

format_num

- 1: Selects GT-format 1 options which include **nature-of-address** and **odd/even**. Once selected, the system enters GT-Format1 configuration mode.
- 2: Selects GT-format2 options which include **translation-type**. Once selected, the system enters GT-Format2 configuration mode.
- 3: Selects GT-format3 options which include **encoding-scheme**, **numbering-plan**, and **translation-type**. Once selected, the system enters GT-Format3 configuration mode.
- 4: Selects GT-format4 options which include **encoding-scheme**, **nature-of-address**, **numbering-plan**, and **translation-type**. Once selected, the system enters GT-Format4 configuration mode.

Usage

Selects GT format #2 for the database GTT process.

Example

Use this command to associate the GT format for GTT:

```
gt-format 2
```

variant

This command configures the choice of national standard protocols to associate with the GTT process databases.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

variant *type*

default

Sets the **variant** configuration to **itu**.

type

The following network variant national standards-based protocols are possible:

- **ansi**
- **china**
- **itu**
- **japan**

Usage

Use this command to select the national standard protocols to associate with the GTT process database.

Example

The following command sets the variant to *ansi*:

```
variant ansi
```

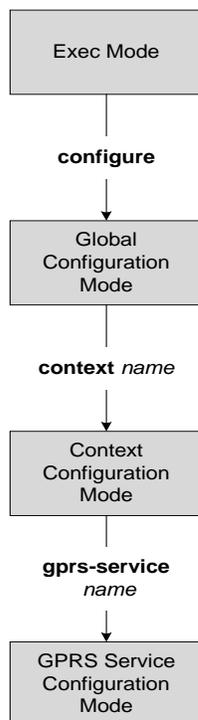

Chapter 120

GPRS Service Configuration Mode Commands

The GPRS Service Configuration Mode is used within the context configuration mode to define the criteria the SGSN needs to operate within a GPRS network. The GPRS Service works with other services, such as SGSN GPRS Tunneling Protocol (see SGTP Service Configuration Mode Commands) and Mobile Application Part (see MAP Service Configuration Mode Commands), to handle communication parameters required to work with other network entities such as the base station subsystem (BSS).

The prompt for this mode appears as:

```
[context_name]hostname(config-gprs-service)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

accounting

Defines the accounting context name and enables/disables specific types of CDR generation for the accounting in the GPRS service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
accounting { cdr-types { mcdr | scdr | sms { mo-cdr | mt-cdr } + | context
cntx_name }
```

```
default accounting cdr-types
```

```
no accounting ( cdr-types | context }
```

default

Returns the system to default CDR generation which includes M-CDR, S-CDR, and SMS CDRs.

no

Disables all CDR types.

```
cdr-types { mcdr | scdr | sms { mo-cdr | mt-cdr }
```

Default: all types enabled.

Defines the types of CDRs to be generated within the specified GPRS service for accounting:

- **mcdr**: Enables generation of M-CDRs.
- **scdr**: Enables generation of S-CDRs.
- **sms**: Enables generation of SMS-type CDRs based on one of the following:
 - **mo-cdr**: SMS CDRs originates from the mobile.
 - **mt-cdr**: SMS CDRs terminates at the mobile.

+

This symbol indicates that more than one keyword can be used and repeated. This enables you to include more than one type of CDR selection in a single command.

```
context cntx_name
```

Specifies an accounting context to be associated with the GPRS service.

cntx_name: Define a string of 1 to 79 alphanumeric characters.

Usage

Use this command to define the type of CDRs to generate for GPRS service. By default all types of CDRs are generated. Note that change of this configuration will be applied to new calls and/or to new PDP contexts only.

By default, generation of the S-CDR, M-CDR, SMS-MT-CDR, and SMS MO-CDR types is enabled.

Example

The following command configures the system to generate only M-CDRs for accounting in the current GPRS service:

```
accounting cdr-types mcdx
```

admin-disconnect-behavior

This command defines some of the actions the SGSN will take during an Admin-Disconnect procedure.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
admin-disconnect-behavior { clear-subscription | detach-type { reattach-not-
required | reattach-required } }
```

```
default admin-disconnect-behavior { clear-subscription | detach-type }
```

clear-subscription

Including this keyword in the configuration instructs the SGSN to clear subscriber contexts and the subscription data database whenever the **clear subscribers all** command is issued (from the Exec mode) for attached subscribers. As well, the SGSN will issue an appropriate Map-Purge-MS-Req to the HLR if needed.

Default: disabled

detach-type

Including this keyword defines which type of detach instruction to include in the Detach-Request message during an Admin-Disconnect procedure. One of the following options must be included when this command is entered:

- **reattach-not-required**
- **reattach-required**

Default: reattach-required

default

Including the **default** keyword in the command, instructs the SGSN to use the default value for the specified parameter.

no

Returns the SGSN to the default where this clear function is disabled

Usage

Using the **clear subscribers all** command (in the Exec Mode) will clear subscriber contexts and the subscription data database, and if needed, issue an appropriate Map-Purge-MS-Req to the HLR.

Include the **clear-subscription** keyword with this command configuration to ensure that more than attached MM-context and active PDP-contexts are cleared when the **clear subscribers all** command is issued for attached subscribers.

To clear subscription data for detached subscribers, refer to the **sgsn clear-detached-subscriptions** command described in the *Exec* mode chapter.

Including the **detach-type** keyword with this command instructs the SGSN to include either a 'reattach-required' or a 'reattach-no-required' instruction in the Detach-Request message.

Example

Enable the clearing function so that subscription data is cleared from the HLR database:

```
admin-disconnect-behavior clear-subscription
```

associate-service

Identifies services to be associated with the GPRS Service.

Important: This command can be used before the associated service instance is created and configured but care should be used to match the service names.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] associate-service { gs name | map name | sgtp name } [ context
ctxt_name ]
```

no

Removes the service association definition from the configuration.

gs name

Specifies the Gs service configuration to associate with this GPRS service.
name must be a string of 1 to 63 alphanumeric characters with no spaces.

map name

Specifies the MAP service configuration to associate with this GPRS service.
name must be a string of 1 to 63 alphanumeric characters with no spaces.

sgtp name

Specifies the SGTP service configuration to associate with this GPRS service.
name must be a string of 1 to 63 alpha numeric characters with no spaces.

context ctxt_name

Defines the context in which the service was created.
ctxt_name must be a string of 1 to 63 alphanumeric characters with no spaces.

Usage

Use this command to associate other services, that have been or will be configured, to this GPRS service.

Example

The following command associates Gs service *gs1* with this GPRS service.

```
associate-service gs gs1 context sgsn2
```

cc profile

Configures the charging characteristic (CC) profile index properties.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] cc profile index { buckets number | interval time | tariff time1 mins
hours [ time2 mins hours [ time3 mins hours [ time4 mins hours ] ] ] | volume {
downlink octets uplink octets | total octets } }
```

default cc profile index

no

Removes the a specific charging characteristics configuration definition.

default

Resets the charging characteristics to system defaults.

index

Configures a profile index for the parameter to be specified. index can be configured to any integer value from 0 to 15.

Important: 3GPP standards suggest that profile index values of 1, 2, 4, and 8 be used for hot billing, flat rate billing, prepaid billing and normal billing, respectively. A single charging characteristics profile can contain multiple behavior settings.

buckets number

Default: 4

Specifies the number of statistics container changes due to QoS changes or tariff time that can occur before an accounting record should be closed.

number can be configured to any integer value from 1 through 4.

interval time

time is measured in seconds and can be configured to any integer value from 60 to 40,000,000.

tariff time1 mins hours time2 mins hours time3 mins hours time4 mins hours

Specifies time-of-day time values to close the current statistics container (but not necessarily the accounting record). Six different tariff times may be specified. If less than six times are required, the same time can be specified multiple times.

Important: The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

For each of the different tariff times, the following parameters must be configured:

- *mins*: The minutes of the hour, an integer value from 0 to 59.
- *hours*: The hour of the day, an integer value from 0 to 23.

```
volume { downlink vol_down_octets uplink vol_up_octets | total
total_octets }
```

Specifies the downlink, uplink, and total volumes that must be met before closing a CDR.

vol_down_octets : Measured in octets; can be configured to any integer value from 100,000 to 4,000,000,000.

vol_up_octets : Measured in octets; can be configured to any integer value from 100,000 to 4,000,000,000.

total_octets : The total traffic volume (up and downlink) measured in octets; can be configured to any integer value from 100,000 to 4,000,000,000.

Usage

Charging characteristics consist of a profile index and behavior settings. This command configures profile indexes for the SGSN's charging characteristics. The SGSN supports up to 16 profile indexes.

This command works in conjunction with the `cc-sgsn` command located in the APN configuration mode that dictates which CCs should be used for subscriber PDP contexts.

Example

The following command configures a profile index of 10 for tariff times of 7:00 AM and 7:30 PM:

```
cc profile 10 tariff time1 0 7 time2 30 19
```

check-imei-timeout-action

This command configures the action to be taken on the Gf interface if a Check-IMEI fails due to a timeout.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
check-imei-timeout-action [ continue | reject ]
```

```
default check-imei-timeout-action
```

default

Rejects the Attach or ISRAU procedure if a Check-IMEI timeout occurs.

continue

Instructs the SGSN to continue the Attach or ISRAU procedure if a Check-IMEI timeout occurs because the EIR is not reachable. This functionality matches standard call flow.

reject

Instructs the SGSN to reject the Attach or ISRAU procedure if a Check-IMEI timeout occurs.

Usage

Use this command to control the SGSN reaction if a Check-IMEI fails due to a timeout.

The **continue** option allows the SGSN to go forward with the MS Attach if the first Check-IMEI fails to reach the EIR due to a timeout. Any subsequent activity (such as a RAU or Service Request) would force another Check-IMEI towards the EIR. If this subsequent MAP Check-IMEI should fail, then the same policy of continuing the procedure would apply.

Example

Use the following command to reject Attach Requests if the Check-IMEI timer runs out:

```
check-imei-timeout-action reject
```

cipherring-algorithm

This command configures the priority, ordering, for the use of the GPRS encryption cipherring algorithms.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
cipherring-algorithm priority priority algorithm
```

```
default cipherring-algorithm priority priority algorithm
```

default

Returns the system cipherring-algorithm priority to the default of GEA0 - which means that no cipherring will be done.

priority

Defines the priority or order of use for the cipherring algorithm.
priority must be an integer from 1 to 8.

algorithm

Identifies the algorithm to be matched to the priority. Options include:

- *gea0* - No cipherring
- *gea1* - GPRS Encryption Algorithm - GEA1
- *gea2* - GPRS Encryption Algorithm - GEA2
- *gea3* - GPRS Encryption Algorithm - GEA3
- *gea4* - GPRS Encryption Algorithm - GEA4 (not yet supported)
- *gea5* - GPRS Encryption Algorithm - GEA5 (not yet supported)
- *gea6* - GPRS Encryption Algorithm - GEA6 (not yet supported)
- *gea7* - GPRS Encryption Algorithm - GEA7 (not yet supported)

Usage

Use this command to specify the order (priority) of usage for the GPRS encryption algorithms. All of the GPRS encapsulation algorithms use a 64-bit key derived from a common mechanism: the mobile receives a random challenge, then the SIM calculates an authentication signature and an encryption key.

Example

The following command sets no cipherring to be used after two encryption algorithms have been used:

```
cipherring-algorithm priority 3 gea0
```

■ ciphering-algorithm

dns israu-mcc-mnc-encoding

Configures either decimal or hexadecimal format for the MCC and MNC values in the DNS query.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
dns israu-mcc-mnc-encoding { decimal | hexadecimal }  
default dns israu-mcc-mnc-encoding
```

default

Resets the SGSN to send the MCC and MNC values in decimal format for DNS queries.

decimal

Default.

Instructs the SGSN to send the MCC and MNC in decimal format in the DNS query.

hexadecimal

Instructs the SGSN to send the MCC and MNC in hexadecimal format in the DNS query.

Usage

Use this command to determine the type of encoding for the MCC and MNC to be included in the DNS query. For example:

In decimal, the MNC/MCC in a DNS query would appear like:

```
rac0017.1ac42e3.mnc310.mcc722.gprs
```

In hexadecimal, the MNC/MCC in a DNS query would appear like:

```
rac0017.1ac42e3.mnc0136.mcc02d2.gprs
```

Example

Use hexadecimal values for the MCC/MNC in the DNS query.

```
dns israu-mcc-mnc-encoding hexadecimal
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the previous configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

gmm

This command defines the GPRS mobility management parameters for the SGSN service.

 **Important:** The `gmm` command can be repeated to set each timer as needed.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gmm { accept-procedure [ new-tlli | old-tlli ] | ciph-gmm-msg-from-unknown-ms {
detach | ignore } | mobile-reachable-timeout mins | negotiate-t3314-timeout secs
| purge-timeout mins | T3302-timeout mins | T3312-timeout mins | T3313-timeout
secs | T3350-timeout secs | T3360-timeout secs | T3370-timeout secs | trau-
timeoutsecs }
```

```
default gmm { ciph-gmm-msg-from-unknown-ms | mobile-reachable-timeout |
negotiate-t3314-timeout | purge-timeout | T3302-timeout | T3312-timeout | T3313-
timeout | T3350-timeout | T3360-timeout | T3370-timeout | trau-timeout }
```

```
no gmm negotiate-t3314-timeout
```

default

Resets the specified timer timeout to the system default.

no

Removes the specified GMM definition from the configuration.

accept-procedure [new-tlli | old-tlli]

Default: new-tlli

This keyword enables the use of either a new TLLI (temporary logical link identifier) or an old TLLI for attach-accept or RAU-accept messages sent by the SGSN to the MS during related procedures.

ciph-gmm-msg-from-unknown-ms { detach | ignore }

Configures how the SGSN will behave when it receives a ciphered GMM message from an unknown MS.

detach - Instructs the SGSN to send a Detach message to the MS.

ignore - Instructs the SGSN to send an Ignore (drop) message to the MS.

Default: **ignore**

mobile-reachable-timeout mins

Default: 58 minutes

Timer value for the mobile reachability timer.

mins must be an integer from 4 to 1440.

negotiate-T3314-timeout *secs*

Set the number of seconds for the T3314-timeout ready timer value. Value sent out from SGSN so MS can negotiate ready timer.

secs must be an integer from 0 to 11160. Default is 44 seconds.

- If the MS does not send the ready timer in the Attach/RAU request, then the SGSN sends this T3314-timeout (ready timer) value.
- If the MS sends the requested value of the ready timer in the Attach/RAU Request, and if the requested value is less than or equal to the value of the negotiate-T3314-timeout timer, then the SGSN sends Att/RAU Accept with the requested T3314 value.
- If the MS sends the requested value of the ready timer in the Attach/RAU Request, and if the requested value is greater than the value of the negotiate-T3314-timeout timer, then the SGSN sends Att/RAU Accept with the negotiate-T3314-timeout value.

Important: This is the only GMM timer that can be disabled by entering **no** at the beginning of the command syntax. **no gmm negotiate-t3314-timeout** By disabling negotiation of the T3314-timeout value, if the MS sends the requested value of the ready timer in the Att/RAU Request, then the SGSN sends the T3314-timeout value in the Att/RAU Accept.

purge-timeout *mins*

Default: 10080 minutes

Value defines the mm-context lifetime in minutes.

mins must be an integer from 1 to 20160.

T3302-timeout *mins*

Default: 12 minutes

Defines the number of minutes for timer to send to MS.

mins is an integer from 1 to 186.

T3312-timeout *min*

Default: 54 minutes

Periodic RAU update timer to send to MS.

mins is an integer from 0 to 186.

T3313-timeout *secs*

Default: 5 seconds

Initial page timeout timer for retransmission for Paging Requests.

secs is an integer from 1 to 60.

T3314-timeout *secs*

Default: 44 seconds

Ready Timer for controlling Cell Update Procedure.

secs must be an integer from 0 to 11519.

T3350-timeout *secs*

Default :6 seconds

Retransmission timer for Attach Accept/RAU Accept/P-TMSI Realloc Command.

secs must be an integer from 1 to 20.

T3360-timeout*secs*

Default :6 seconds

Retransmission timer for Authentication Request.

secs must be an integer from 1 to 20.

T3370-timeout *secs*

Default :6 seconds

Retransmission timer for Identity Request.

secs must be an integer from 1 to 20.

trau-timeout *secs*

This timer is available in releases 9.0 and higher.

Default: 30

Specifies the number of seconds the “old” 3G SGSN waits to purge the MS’s data. This timer is started by the “old” SGSN after completion of the inter-SGSN RAU.

secs : Must be an integer from 5 to 60.

Usage

Use this command to set GMM timers.

Example

Set the t3370 timer expiration for 15 seconds:

```
gmm t3370-timeout 15
```

llc

Configures the timers that control the data flow for the logical link control (LLC) sub-layer.

Important: This command may be repeated as often as necessary to define the needed timers.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
llc { iov-ui-in-xid-reset | n201u-max { sapi11 pkt-size | sapi3 pkt-size | sapi5
pkt-size | sapi9 pkt-size } | pdu-lifetime secs | t200 sapi1 time | t200 sapi11
time | t200 sapi3 time | t200 sapi5 time | t200 sapi7 time | t200 sapi9 time |
uplink-pdu-len-validation }
```

```
default { iov-ui-in-xid-reset | n201u-max { sapi11 | sapi3 | sapi5 | sapi9 } |
pdu-lifetime | T200 sapi1 | T200 sapi11 | T200 sapi3 | T200 sapi5 | T200 sapi7 |
T200 sapi9 | uplink-pdu-len-validation }
```

```
no llc uplink-pdu-len-validation
```

default

Resets the configuration to the default values.

no

Disables the **uplink-pdu-len-validation**.

iov-ui-in-xid-reset

This keyword makes it possible for the operator to configure whether or not to send IOV-UI in an XID-RESET. This is useful when the MS is not setup to accept IOV-UI (for example, MS sends Attach/RAU Requests with cksn=7) and including IOV-UI in the XID-Reset would result in Attach/RAU failure.

Default: Enabled

n201u-max sapi n pkt_size

This keyword sets the maximum number of octets, per service access point identifier (SAPI), for the downlink data packets. This is the upper limit that the SGSN will negotiate with the subscriber for packets sent from the SGSN to the BSC.

sapi n : Command must identify one of the following SAPI: sapi11, sapi3, sapi5, or sapi9.

pkt_size : Must be an integer from 140 to 1520. Default size is 1520 octets.

pdu-lifetime secs

Defines LLC layer PDU lifetime at the BSC. .

secs must be an integer from 0 to 90.
Default: 6

T200 sapi1 time

Sets the retransmission timer (in seconds) for sapi1.
time must be an integer of 1 to 10.
Default: 5

T200 sapi11 time

Sets the retransmission timer (in seconds) for sapi11.
time must be an integer of 1 to 50.
Default: 40

T200 sapi3 time

Sets the retransmission timer (in seconds) for sapi3.
time must be an integer of 1 to 10.
Default: 5

T200 sapi5 time

Sets the retransmission timer (in seconds) for sapi5.
time must be an integer of 1 to 20.
Default: 10

T200 sapi7 time

Sets the retransmission timer (in seconds) for sapi7.
time must be an integer of 1 to 40.
Default: 20

T200 sapi9 time

Sets the retransmission timer (in seconds) for sapi9.
time must be an integer of 1 to 40.
Default: 20

uplink-pdu-len-validation

Available in releases 8.1 and higher.

This feature enables validation of the size of the uplink LLC packets. With validation enabled, the SGSN will drop any uplinked packets that are larger than the negotiated limit.

If the **no** form of the command is used, then this feature is disabled. The SGSN will be more flexible with uplink packet sizes. So if the SGSN and MS have a mismatch and the MS sends packets that are larger than expected, then the SGSN will not drop the packets.

Default: Enabled.

Usage

Use the command repeatedly to configure additional timers and features for the LLC sub-layer.

Example

Set the T200 retransmission timer to timeout at 12 seconds for SAPI5:

```
llc t200 sapi5 12
```

Use the following command to instruct the SGSN to ignore the N201_U packet size limits for uplink packets from an MS:

```
no uplink-pdu-len-validation
```

nri

This command configures the network resource identifier (NRI) to identify a specific SGSN. The NRI is stored in the P-TMSI. The SGSN uses a portion of this NRI to set the parameters for Gb flex (SGSN pooling) functionality.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
nri length nri_length { nri-value nri_value | null-nri-value null_nri_value
non-broadcast-lac lac_id rac rac_id [ nri-value value ]
```

```
no nri
```

no

Removes the configured NRI value and location in P-TMSI for retrieval by this SGSN operator policy.

nri length *nri_length*

Specifies the number of bits to be used in the P-TMSI, bits 23 to 18, to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length will be of zero length.

nri_length : Must be an integer from 1 to 6 to identify the number of bits.

null-nri-value *null_nri_value*

Configures the null NRI value which must be unique across the pool areas. This keyword is used for the offloading procedure for SGSN pooling (enabled with the **sgsn offloading** command, see the *Exec Mode* chapter).

null_nri_value : 0 (zero) indicates the keyword is not to be used and 1 to 63 are used to identify the SGSN to be used for the offloading procedure for SGSN pooling. There is no default value for this parameter.

non-broadcast lac *lac_id* **rac** *rac_id*

Defines the non-broadcast LAC/RAC to be used in combination with the null-NRI for the offloading procedure.

lac_id defines a location area code associated with a BSS. Must be an integer between 1 and 65535.

rac_id defines the remote area code to be associated with a BSS. Must be an integer between 1 and 255.

nri-value *nri_value*

Specifies the MS-assigned value of the NRI to retrieve from the P-TMSI. This value must not exceed the maximum possible value specified by the NRI length. The NRI value must be unique across the pool or across all overlapping pools.

nri_value must be an integer from 1 to 63 to identify a specific SGSN in a pool. Use of 0 (zero) value is not recommended.

Multiple NRI values can be identified by providing multiple nri-values separated by a blank space for example: **nri length 6 nri-value 29 43 61**

Usage

Use this command to add or remove the Gb flex pool configuration for this GPRS service. The command can be repeated to specify different values for any of the keyword parameters. If more than one NRI is configured, the GPRS service will round-robin between the available NRIs when new subscribers (re)connect.

Use this command to retrieve the NRI (identity of an SGSN) stored in bits 23 to 18 of the packet-temporary mobile subscriber identity (P-TMSI). If more than one NRI value is configured, the GPRS service will round-robin between the available NRIs when new subscribers (re)connect.

Example

The following command specifies the NRI length as 5 bits, identifies SGSN 23 with LAC 222 and RAC 12 for offloading procedure with NRIs 6 and 41:

```
nri length 5 null-nri-value 34 non-broadcast lac 222 rac 12 nri-value 6  
41
```

paging-policy

Configures the paging parameters for the GPRS service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
paging-policy { last-known-area { all | bsc | cell | location-area | routing-
area } + | max-retransmissions retran_num }
```

```
no paging-policy last-known-area { bsc | cell | location-area | routing-area }
```

```
default paging-policy { last-known-area | max-retransmissions }
```

no

Disables the paging-policy definition for this GPRS service configuration.

default

Resets the defaults for parameters managed by this paging policy.

last-known-area

Select one or more paging areas and enter them in preferred paging order:

- **all** : Pages in the last known BSC.
- **bsc** : Pages in last known BSC.
- **cell** : Pages in last known cell.
- **location area** : Pages in last known location area.
- **routing area** : Pages in last known routing area.

By default, paging occurs in the following order:
cell, BSC, routing area, location area.

max-retransmission *retran_num*

Configures the maximum number of retries for a page request per paging area.

retran_num: Enter an integer from 0 to 5.

- **2** : default.
- **0** : disables retransmission for paging request so that the SGSN only sends a single 2G PS-paging request to the BSC with no retransmissions.

+

Keywords can be repeated or combined as needed to complete the paging policy configuration.

Usage

Use this command to configure the order of preference for retransmitting into specified paging-areas.

Example

Use the following command to instruct the SGSN to page the cell and BSC as the last-known areas :

```
paging-policy last-known-area cell bsc
```

peer-nsei

This command associates a peer (remote) network service entity (NSEI) for a BSS with this GPRS service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
peer-nsei nse_id { lac lac_id rac rac_id | pooled }
```

```
[ no ] peer-nsei nse_id { lac lac_id rac rac_id | pooled }
```

no

Removes the NSEI LAC/RAC or pooling configuration from this BSS peer configuration.

nse_id

Defines the NSEI for this GPRS service.

nse_id must be an integer from 0 to 65535.

lac *lac_id*

Defines a location area code associated with the NSE BSS.

lac_id must be an integer between 1 and 65535.

rac *rac_id*

Defines the remote area code to be associated with the NSE BSS

rac_id must be an integer between 1 and 255.

pooled

Enables pooling with non-pooled BSCs within the pool area.

Usage

Use this command repeatedly to associate one or more LAC/RAC combinations and/or pooling with this peer-GPRS service configuration.

The Network Service Entity (NSE) at the BSS and the SGSN provides the network management functionality required for the operation of the Gb interface. Each NSE is identified by means of NSE identifier (NSEI).

Example

The following command configures the NSE with identifier as *4114* having location area code *234* and routing area code as *22*:

```
peer-nsei 4114 lac 234 rac 22
```

The following command enables Gb flex (pooling) functionality for this GPRS service:

```
peer-nsei 4114 pooled
```

plmn

This command identifies the Public Land Mobile Network (PLMN) for the GPRS service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
plmn id mcc mcc_num mnc mnc_num
```

```
no plmn id
```

no

Removes the PLMN information from the configuration for the current SGSN service.

mcc *mcc_num*

Define the mobile country code (MCC) portion of the PLMN Id.

mnc_num must be a 3 digit integer from 100 to 999.

mnc *mnc_num*

Define the mobile network code (MNC) portion of the PLMN Id.

mnc_num must be a 2 or 3 digit integer from 00 to 999.

Usage

Use this command to set PLMN parameters for the current SGSN service.

Example

The following command identifies the PLMN MCC as 200 and the MNC as 10:

```
plmn id mcc 200 mnc 10
```

setup-timout

This command configures the maximum number of seconds allowed for session setup.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
setup-timout seconds
```

```
default setup-timout
```

default

Returns the configuration to the default, 60 seconds.

seconds

An integer from 1 to 1000000.

Usage

Use this command to set the time allowed for session setup.

Example

The following command sets the maximum session setup time to 300 seconds:

```
setup-timout 300
```

sgsn-context-request

This command specifies whether or not the PTMSI signature check should be skipped if the PTMSI signature is not included in the SGSN context request.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] sgsn-context-request ptmsi-signature-absence allowed
```

default

Returns the configuration to the default action to perform the PTMSI signature check.

no

Removes this definition from the system configuration.

Usage

Use this command to skip the PTMSI signature check.

Example

The following command instructs the system to perform the PTMSI signature check.

```
default sgsn-context-request ptmsi-signature-absence
```

sgsn-number

Define the SGSN E.164 number to be used when interacting via MAP protocol for this GPRS service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sgsn-number sgsn_number
```

```
no sgsn-number
```

no

Disables the use of this definition in the system configuration.

sgsn_number

Enter a string of 1 to 16 digits to identify the SGSN's E.164 identification.

Usage

Use this command to identify the ISDN number for the SGSN associated with this GPRS service.

The SGSN supports multiple SGSN numbers – different numbers in the 2G GPRS service configuration and the the 3G SGSN service configuration. If an HLR-initiated dialog is received, the SGSN will perform a lookup based on the IMSI and find the correct SGSN number with which the MS is associated. Subsequent messaging will use this address.

Example

Disable the E.164 number for this GPRS service.

```
no sgsn-number
```

sm

This command configures the session management (SM) parameters associated with this particular GPRS service context.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sm { activate-max-retransmissions num_retries | deactivate-max-retransmissions
num_retries | ignore-pco-decode-error | modify-max-retransmissions num_retries |
partial-apn-match | requested-apn-from-first-subrec | t3385-timeout secs |
t3386-timeout secs | t3395-timeout secs | trim-trailing-spaces-in-apn }

default sm { activate-max-retransmissions | deactivate-max-retransmissions |
ignore-pco-decode-error | modify-max-retransmissions | t3385-timeout | t3386-
timeout | t3395-timeout | trim-trailing-spaces-in-apn }
```

default

Resets the SM parameters to the defaults.

activate-max-retransmissions *num_retries*

Defines the maximum number of retries to transmit 'activate PDP context request'.

num_retries: Must be an integer from 1 to 10.

Default: 4

deactivate-max-retransmissions *num_retries*

Defines the maximum number of retries to transmit 'deactivate PDP context request'.

num_retries: Must be an integer from 1 to 10.

Default: 4

ignore-pco-decode-error

Enables the SGSN to ignore received decode errors that are due to incorrectly encoded PCO IE length in SM Requests.

Default: disabled

modify-max-retransmissions *num_retries*

Defines the maximum number of retries to transmit 'modify PDP context request'.

num_retries: integer from 1 to 10.

Default: 4

partial-apn-match

Enables partial matching of requested APN during APN selection.

Partial APN or APN with trailing spaces may be present in an Activate Request because incorrect information was keyed in by the user. Though it is valid to reject such Activation Requests, it increases the signaling between the MS and the SGSN. This has an impact on the radio resources.

requested-apn-from-first-subrec

Enables use of a 'requested APN' from the first subscription record. When this feature is enabled, the PDP Activation is not rejected during APN Selection; instead, the APN from the first subscription record is used as the requested APN and the SGSN continues with the rest of the APN Selection process.

A requested APN is an optional IE in an Activate PDP Request. To get the requested PDP type, if multiple PDP subscription records exist for the subscriber, then the MS has to include the APN information to choose the PDP subscription record during APN selection. Otherwise, such activations will be rejected during APN selection (per TS 23.060 Appendix A). Though it is valid to reject such activation requests, it increases the signaling between the MS and the SGSN, which impacts the radio resources.

t3385-timeout *secs*

Defines the maximum amount of time for retransmission of 'activate request' messages.

secs : Must be an integer from 1 to 60.

Default: 8

t3386-timeout *secs*

Defines the maximum amount of time for retransmission of 'modify request' messages.

secs : Must be an integer from 1 to 60.

Default: 8 seconds.

t3395-timeout *secs*

Defines the maximum amount of time for retransmission of 'deactivate request' messages.

secs : Must be an integer from 1 to 60.

Default: 8

trim-trailing-spaces-in-apn

Enables SGSN to strip off any trailing space(s) in requested APN.

If a requested APN in an Activate PDP Context Request has any trailing spaces, then those trailing spaces will be removed and the length field will be updated.

Usage

Repeat this command with different keywords (parameters) to configure the SM (session management) as needed for this GPRS service. Keywords can be used to optimize signaling between the MS and the SGSN to reduce the impact on the radio resources.

Example

Reset the number of retransmission messages for deactivate PDP context request to 5.

```
sm deactivate-max-retransmissions 5
```

sndcp

Define the SNDTCP reassembly-timeout interval associated with this GPRS service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sndcp reassembly-timeout time
```

```
default sndcp reassembly-timeout
```

default

Resets the timer configuration to the default value.

time

Defines the interval.

time: Must be an integer from 1 to 5. The default is 5 seconds.

Usage

Use this command to modify the SNDTCP reassembly timer.

Example

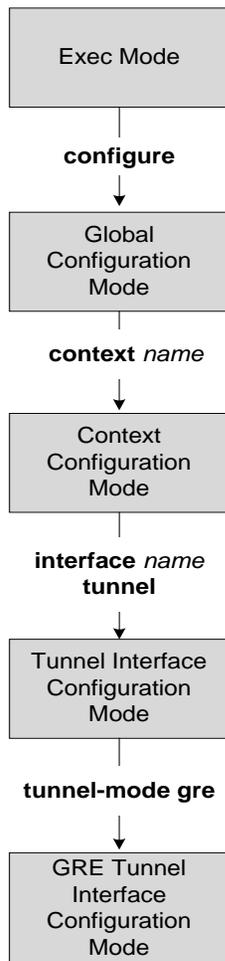

Reset the default for the timer.

```
default sndcp reassembly-timeout
```

Chapter 121

GRE Tunnel Interface Configuration Mode Commands

The Generic Routing Encapsulation (GRE) Tunnel Interface Configuration Mode is used to create and manage the GRE tunneling interfaces for addresses, address resolution options, etc.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

destination

This command configures the destination IPv4 address of the tunnel by specifying the IPv4 destination end address. This is a mandatory configuration for GRE tunnel interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[no] destination address ip_address
```

no

Removes/disassociates the configured destination IP address from specific GRE tunnel interface configuration.

address *ip_address*

Configures the IP address for the interface specifying the IPv4 IP address. *ip_address* must be specified using the standard IPv4 dotted decimal notation.

Usage

Use this command to configure the destination IPv4 address of the tunnel by specifying the IP address of destination tunnel end for GRE tunnel interface.

Important: State of source address will affect the operational state of the tunnel.

Example

The following command sets the 1.2.3.4 as destination IP address of the GRE tunnel interface:

```
destination address1.2.3.4
```

end

Exits the interface configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the Interface Configuration Mode and returns to the Context Configuration Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

keepalive

This command configures various parameters for sending Keepalives to the remote end-point in GRE tunnel interface configuration. By default sending keepalives is disabled.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
keepalive [interval time_interval num-retry retry]
```

```
[default | no] keepalive
```

default

Sets the sending of Keepalives with default parameters.

interval: 10 seconds

num-retry: 3 retries

no

Disables the keepalive and turns off the sending of Keepalives messages.

interval *time_interval*

Default: 10

Specifies the time interval (in seconds) between two Keepalives sent to remote ends of GRE tunnel interface configuration.

time_interval must be an integer from 5 through 3600.

num-retry *retry*

Default: 3

Specifies number of retransmission of keepalives to remote node without getting any response before the remote node is marked as dead/down.

retry must be an integer between 0 through 10.

Usage

Use this command to configure the parameters for sending Keepalives to the remote end-point of GRE tunnel. It also configures the interval at which GRE Keepalives are sent on the interface and number of retries without getting a response from the remote end-point before the tunnel is shutdown. By default, Keepalives will not be sent.

Example

The following command enables the keepalive and sets the other parameters to defaults:

```
default keepalive
```

■ keepalive

source

This command configures the source IPv4 address of the tunnel either by specifying the IP address (host address) or by specifying another configured non-tunnel IPv4 interface. This is a mandatory configuration for GRE tunnel interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[no] source {address ip_address | interface interface_name}
```

no

Removes/disassociates the configured source IP address or host interface from specific GRE tunnel interface configuration.

address *ip_address*

Configures the IP address for the interface specifying the IPv4 IP address.

ip_address must be specified using the standard IPv4 dotted decimal notation.

interface *interface_name*

Specifies the name of the preconfigured non-tunnel IPv4 interface, whose address is used as the source address of the GRE tunnel.

Usage

Use this command to configure the source IPv4 address of the tunnel either by specifying the IP address (host address) or by specifying another configured non-tunnel IPv4 interface for GRE tunnel interface.

Important: State of source address will affect the operational state of the tunnel.

Example

The following command sets the 1.2.3.4 as source IP address of the GRE tunnel interface:

```
source address 1.2.3.4
```

tos

This command configures the parameters/action for the TOS parameter in the IPv4 tunnel transport protocol header.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip tos {value [ af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 |
af41 | af42 | af43 | be | ef | lower-bits tos_value] | copy}
```

```
no ip tos
```

default

Sets the IP TOS to lower bits value of 0.

value [tos_value]

Default: **af11**

Specifies the IP QoS DSCP per-hop behavior to be marked on the outer header of signalling packets originating from the Access Gateway. This is a standards-based feature (RFC 2597). The following forwarding types are supported:

af11: Designates the use of Assured Forwarding 11 per-hop behavior

af12: Designates the use of Assured Forwarding 12 per-hop behavior

af13: Designates the use of Assured Forwarding 13 per-hop behavior

af21: Designates the use of Assured Forwarding 21 per-hop behavior

af22: Designates the use of Assured Forwarding 22 per-hop behavior

af23: Designates the use of Assured Forwarding 23 per-hop behavior

af31: Designates the use of Assured Forwarding 31 per-hop behavior

af32: Designates the use of Assured Forwarding 32 per-hop behavior

af33: Designates the use of Assured Forwarding 33 per-hop behavior

af41: Designates the use of Assured Forwarding 41 per-hop behavior

af42: Designates the use of Assured Forwarding 42 per-hop behavior

af43: Designates the use of Assured Forwarding 43 per-hop behavior

be: Designates the use of Best Effort forwarding per-hop behavior

ef: Designates the use of Expedited Forwarding per-hop behavior typically dedicated to low-loss, low-latency traffic.

The assured forwarding behavior groups are listed in the table below.

	Class 1	Class 2	Class 3	Class 4
Low Drop	AF11	AF21	AF31	AF41
Medium Drop	AF12	AF22	AF32	AF42
High Drop	AF13	AF23	AF33	AF43

Traffic marked with a higher class is given priority during congestion periods. If congestion occurs to traffic with the same class, the packets with the higher AF value are dropped first.

lower-bits *tos_value*

Default: 0

Sets the least-significant 6 bits in the TOS byte with the specified numeric value.

tos_value must be an integer from 0 through 255.

copy

This keyword instructs the system to copy the TOS value from the passenger IPv4 packet or Traffic class value from the passenger IPv6 packet to the TOS value of the IPv4 tunnel transport protocol header

Usage

Use this command either to set the TOS parameter in the IPv4 tunnel transport protocol header to the specified value or instructs to copy the TOS value from the passenger IPv4 packet or Traffic class value from the passenger IPv6 packet to the TOS value of the IPv4 tunnel transport protocol header. If one of the enumerated values is set, the DSCP bits which are the six most-significant bits in the TOS byte are marked. If the integer value is set, it will be written into the six least-significant bits of the TOS byte.

Example

The following command instructs the system to copy the TOS value from the passenger IPv4 packet or Traffic class value from the passenger IPv6 packet to the TOS value of the IPv4 tunnel transport protocol header:

```
tos copy
```

ttl

This command configures the Time to live (TTL) parameter to be used in the tunnel transport protocol header for the current GRE tunnel interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ttl ttl_value
```

```
default ttl
```

default

Sets the TTL value to system default value; i.e. 15.

ttl_value

Default: 15

Specifies the maximum time to live to be used in the tunnel transport protocol header

The time to live (TTL) is not a measure of time but the number of hops through the network.

ttl_value must be an integer between 1 through 255.

Usage

Use this command to set the TTL parameter to be used in tunnel transport protocol header for GRE tunnel configuration.

Example

The following configures the IP address to associate with the interface:

```
ttl 10
```

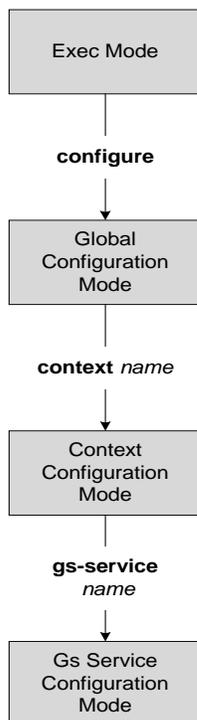

Chapter 122

Gs Service Configuration Mode Commands

The Gs Service configuration mode configures the parameters used to setup and maintain a Gs interface for a connection between the SGSN and an MSC/VLR.

Upon accessing this mode, your prompt should look similar to the following:

```
[<context_name>]<hostname>(config-gs-service)#
```

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

associate-sccp-network

This command associates a previously defined Signaling Connection Control Part (SCCP) network instance with the Gs service. This association is required to access Visitor Location Register(s) (VLRs).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
associate-sccp-network sccp_net_id
```

```
no associate-sccp-network
```

no

Removes the associated SCCP network configuration instance from this Gs service configuration.

sccp_net_id

Identifies the SCCP network configuration instance to associate with this Gs interface to enable connection with VLR(s).

sccp_network_num: Must be an integer from 1 through 12.

Usage

Use this command to associate the SCCP network configuration instance with the Gs interface in this service.

Important: A single SCCP network configuration instance can not be shared with multiple Gs services.

Important: To enable a Gs service, the user needs to configure **ssn** with the **bssap+** command.

Example

Following command associates SCCP network 2 with this Gs service.

```
associate-sccp-network 2
```

bssap+

This command defines the Base Station System Application Part Plus configuration parameters for the Gs service to enable the SGSN to access a Visitor Location Register(s) (VLRs).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] bssap+ ssn ss_num
```

no

Removes the configured BSSAP+ subsystem number from this Gs service.

ssn *ss_num*

Specifies the subsystem number to configure in this Gs interface to use BSSAP+. *ss_num* must be an integer from 1 through 255.

Usage

Use this command to configure the BSSAP+ subsystem with Gs interface in this service to communicate with VLR(s).

Important: A single SCCP network configuration instance can not be shared with multiple Gs services.

Important: To start a Gs service, the user needs to configure the `command` parameter.

Example

Following command configures subsystem 101 with BSSAP+ in this Gs service.

```
bssap+ ssn 101
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the previous configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous configuration mode.

max-retransmission

This command configures the retransmission values for different procedure counters in Gs service as described in TS 29.018.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-retransmissions { n8 | n9 | n10 | n12 } retrans_num
```

```
default max-retransmissions { n8 | n9 | n10 | n12 }
```

no

Removes the configured Gs procedures from this Gs service.

```
{ n8 | n9 | n10 | n12 }
```

Specifies the various Gs service procedures that are available to be used to communicate with VLR(s).

- **n8**: Defines the maximum number of retries for explicit IMSI detach from a non-GPRS service. Default is 2.
- **n9**: Defines the maximum number of retries for explicit IMSI detach from a non-GPRS service. Default is 2.
- **n10**: Defines the maximum number of retries for implicit IMSI detach from the GPRS service. Default is 2.
- **n12**: Defines the maximum number of retries for BSSAP+ to send Reset Indication messages. Default is 2.

```
retrans_num
```

Default: 2

Specifies the number of re-transmission of message for specified procedures.

retrans_num: Must be an integer from 0 through 10.

Usage

Use this command to configure the retransmission values for specific procedure counters in Gs service. counters are based on TS 29.018.

This command can be entered for each procedure counter separately.

Example

Following command configure retransmission value as 3 for counter for procedure to send BSSAP+ Reset Indication messages in this Gs service.

```
max-retransmissions n12 3
```

non-pool-area

This command creates a non-pool area for a set of subscriber location area code (LAC) values that can be used with a specific VLR for the Gs service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
non-pool-area non_pool_name { use-vlr vlr_name lac lac_num } +
```

```
no non-pool-area non_pool_name
```

no

Removes the configured non-pool area from this Gs service.

non_pool_name

Specifies the name of the non-pool area to configure with this command.

non_pool_name must be an alpha and/or numeric string of 1 to 63 characters.

use-vlr *vlr_name*

Specifies the name of the VLR to be associated with this non-pool area.

vlr_name is the name of VLR and must be an alpha and/or numeric string of 1 to 63 characters.

lac *lac_num*

Specifies the subscribers' location area code to be attached with this non-pool area and specific VLR. This LAC of subscriber is obtained from the radio area indicator (RAI).

lac_num is the LAC value and must be an integer value from 1 through 65535.

+

More than one of the above keywords can be entered within a single command.

Usage

Use this command to specify the non-pool area containing VLR name to use for a set of LAC.

This command can be used multiple times, subject to a limit of 32 LAC values (the total for **non-pool-area** and **pool-area** configurations) per Gs service.

Example

Following command configure a non-pool area *starpool1* to use VLR named *starvlr1* for LAC *101* in a Gs service.

```
non-pool-area starpool1 use-vlr starvlr1 lac 101
```

pool-area

This command creates a pool area configuration instance. This command also enters the Pool Area configuration mode to define the set of VLRs to use for a pool area for a set of subscriber location area code (LAC) values in the Gs service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
pool-area pool_name [ -noconfirm ]
```

```
no pool-area non_pool_name
```

no

Removes the configured pool area from this Gs service.

pool_name

Specifies the name of the pool area to configure with this command for VLR pooling and association of a LAC.

pool_name: Must be an alpha and/or numeric string of 1 to 63 characters.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Use this command to create/enter the pool area configuration mode. This mode is used to configure the set of VLRs to be used for a set of subscriber LAC.

This command can be used multiple times, subject to a limit of 32 LAC values (the total number of **non-pool-area** and **pool-area** configurations) per Gs service.

Example

The following command configures a pool area named *starpool1* in a Gs service without any confirmation prompt.

```
pool-area starpool1 -noconfirm
```

sgsn-number

Define the SGSN's E164 number to associate an SGSN with this Gs Service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sgsn-number E.164_number
```

E.164_number

Defines the SGSN's 'telephone' number, the ISDN number for per ITU-T E.164 numbering plan. The number must be a numerical string of 1 to 15 digits.

Usage

For releases 8.1 or higher, use this command to define the SGSN's E.164 ISDN number. This value should match the **sgsn-number** defined for SGSN Service or GPRS Service.

Important: Note: the Gs Service will not start unless the SGSN's E.164 number is configured.

Example

```
sgsn-number 12345678901234
```

timeout

This command configures various timers defining the wait before retransmitting a specific message for Gs service procedures.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
timeout { t6-1-timer t6_1_dur | t8-timer t8_dur | t9-timer t9_dur | t10-timer
t10_dur | t12-1-timer minute t12_1_dur | t12-2-timer t12_2_dur}

[ default ] timeout { t6-1-timer | t8-timer | t9-timer | t10-timer | t12-1-timer
| t12-2-timer }
```

default

Sets the timer value to wait in seconds/minutes to default values. Default values for timers are:

- **t6-1-timer**: 10 seconds
- **t8-timer**: 4 seconds
- **t9-timer**: 4 seconds
- **t10-timer**: 4
- **t12-1-timer**: 54 mins (+ 8 seconds)
- **t12-2-timer**: 4 seconds

t6-1-timer t6_1_dur

Default: 10

Specifies the retransmission timer value to guard the location update.

t6_1_dur is the waiting duration in seconds before retransmitting the specific message and must be an integer from 10 through 90.

t8-timer t8_dur

Default: 4

Specifies the retransmission timer value to guard the explicit IMSI detach from the GPRS service procedure.

t8_dur is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.

t9-timer t9_dur

Default: 4

Specifies the retransmission timer value to guard the explicit IMSI detach from the non-GPRS service procedure.

t9_dur is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.

t10-timer *t10_dur*

Default: 4

Specifies the retransmission timer value to guard the implicit IMSI detach from the GPRS service procedure. *t10_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.

t12-1-timer minute *t12_1_dur*

Default: 54 minutes (plus 8 seconds for transmission delay)

Specifies the retransmission timer value to control the resetting of SGSN-Reset variable procedure. *t12_1_dur* is the waiting duration in minutes before retransmitting reset message for the SGSN Reset variable and must be an integer from 0 through 380.

t12-2-timer *t12_2_dur*

Default: 4

Specifies the retransmission timer value to guard the SGSN reset procedure. *t12_2_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 30.

Usage

Use this command to configure the time, for different procedure timers, to wait before retransmitting a procedure message.

This command can be repeated for each timer to configure multiple timers.

Example

Following command sets the timeout duration of 4 seconds for t8 timer to wait before retransmitting the procedure message to explicitly do the IMSI detach from GPRS service:

```
default timeout t8-timer
```

vlr

This command defines a VLR configuration for use with this Gs service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
vlr vlr_name isdn-number E164_num [ bssap+ ssn ssn ] [ point-code pt_code ]
no vlr vlr_name
```

no

Removes the configured VLR from the Gs service.

vlr_name

Specifies the name of the VLR to configure in this Gs mode with ISDN number.

vlr_name must be an alpha and/or numeric string of 1 to 63 characters.

isdn-number *E164_num*

Specifies the VLR number to configure with this command.

E164_num: The ISDN number for the target VLR. Value must be defined according to the E.164 numbering plan and must be a numeric string of 1 to 15 digits.

bssap+ ssn *ssn*

Specifies the subsystem number to configure with this VLR to use BSSAP+.

ssn: Must be an integer from 1 through 255. Default value is 252.

point-code *pt_code*

Specifies SS7 address of VLR in point code value to this configured VLR name.

pt_code: Must be in SS7 point code dotted-decimal ###.###.### format or decimal ##### format.

Usage

Use this command to define VLR configuration instances to be associated with the Gs service.

A maximum of 32 VLRs can be configured per Gs service.

Example

Following command configures the VLR named *starvlr1* with an ISDN number *12344567*, a subsystem number of *252*, and a point code value of *123.345.567*:

```
vlr starvlr1 isdn-number 12344567 point-code 123.345.567
```

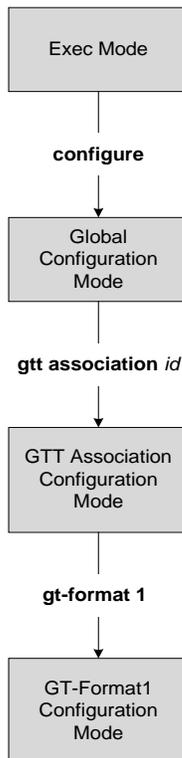

Chapter 123

GT-Format1 Configuration Mode Commands

The GT-Format1 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Upon accessing this mode, your prompt should look similar to the following:

```
[local]<hostname>(config-gtt-1-format1)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the configuration mode and returns to the Global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Global configuration mode.

nature-of-address

Configures the indicator to identify the nature of the address.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
nature-of-address { international | national | subscriber }
```

international

Identifies the numbers as international.

national

Identifies the numbers as matching the national configuration.

subscriber

Identifies the numbers as subscriber numbers.

Usage

Configure the identify of the GT format as national.

Example

```
nature-or-address national
```

odd-even-indicator

Configures the bits for matching the global title translation.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

odd-even-indicator *type*

type

- **odd**: Sets the odd bit for matching the GTT.
- **even**: Sets the even bit for matching the GTT.

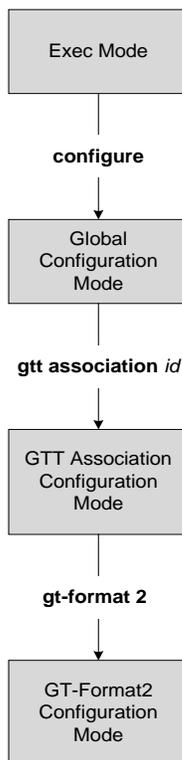

Chapter 124

GT-Format2 Configuration Mode Commands

The GT-Format2 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Upon accessing this mode, your prompt should look similar to the following:

```
[local]<hostname>(config-gtt-format<#>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the configuration mode and returns to the Global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Global configuration mode.

translation-type

Configures the translation type to be applied during the translation process.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
translation-type number
```

number

Must be an integer between 0 and 255.

Default is 0

Usage

Use this command to configure the GTT translation type to be applied during global title translation process.

Example

```
translation-type 232
```

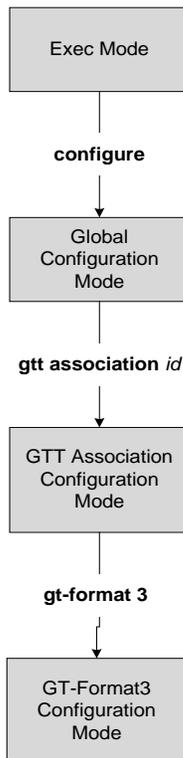

Chapter 125

GT-Format3 Configuration Mode Commands

The GT-Format3 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Upon accessing this mode, your prompt should look similar to the following:

```
[local]<hostname>(config-gtt-1-format<#>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

encoding-scheme

Configures the encoding-scheme to use during global title translation (GTT).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
encoding scheme scheme_type
```

scheme_type

Select one of the following encoding scheme types to determine the encoding type to be used during GTT:

- **bcd-even**: BCD even encoding scheme
- **bcd-odd**: BCD odd encoding scheme
- **nw-specific**: Network specific encoding scheme
- **unknown**: Unknown encoding scheme

Usage

Select BCD even encoding for GTT

Example

```
encoding scheme bcd-even
```

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the configuration mode and returns to the Global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Global configuration mode.

numbering-plan

Configures the GTT process to apply one of the numbering-plans during the GT translation process.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
numbering-plan plan_type
```

plan_type

Select one of the following numbering plans be employed during GTT:

- **data**: Data numbering plan
- **generic**: Generic number plan
- **isdn** : ISDN tel numbering plan
- **isdn-mobile**: ISDN mobile numbering plan
- **land-mobile**: Land mobile numbering plan
- **maritime-mobile**: Maritime mobile numbering plan
- **nw-specific** : Private network / network-specific numbering plan
- **telex**: Telex numbering plan
- **unknown**: Unknown numbering plan

Usage

Select ISN telephone number plan for GTT process.

Example

The following command sets the numbering plan to use during GTT processing to isdn

```
numbering-plan isdn
```

translation-type

Configures the global title translation (GTT) process to apply a specific number for translation during the GTT process.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
translation-type number
```

number

Must be an integer between 0 and 255.

Default is 0

Usage

Use this command to define the translation-type to be used during the global title translation process.

Example

```
translation-type 233
```

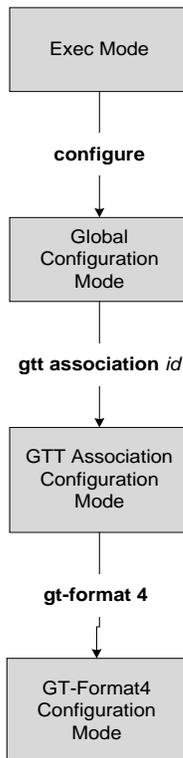

Chapter 126

GT-Format4 Configuration Mode Commands

The GT-Format4 configuration mode is a sub-mode for either the Global Title Translation Association configuration mode or the Global Title Translation Address-Map configuration mode. This sub-mode configures a set of rules used in the global title translation (GTT) process.

Upon accessing this mode, your prompt should look similar to the following:

```
[local]<hostname>(config-gtt-1-format<#>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

encoding-scheme

Configures the encoding-scheme to use during GTT.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
encoding scheme scheme_type
```

scheme_type

Select one of the following encoding scheme types to determine the encoding type to be used during GTT:

- **bcd-even**: BCD even encoding scheme
- **bcd-odd**: BCD odd encoding scheme
- **nw-specific**: Network-specific encoding scheme
- **unknown**: Unknown encoding scheme

Usage

Select BCD even encoding for GTT

Example

```
encoding scheme bcd-even
```

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the configuration mode and returns to the Global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Global configuration mode.

nature-of-address

Configures the indicator to identify the nature of the address.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
nature-of-address { international | national | subscriber )
```

international

Identifies the numbers as international.

national

Identifies the numbers as matching the national configuration.

subscriber

Identifies the numbers as subscriber numbers.

Usage

Configure the identify of the GT format as national.

Example

```
nature-or-address national
```

numbering-plan

Configures the GTT process to apply one of the numbering-plans during the GT translation process.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
numbering-plan plan_type
```

plan_type

Select one of the following numbering plans be employed during GTT:

- data**: Data numbering plan
- generic**: Generic number plan
- isdn** : ISDN tel numbering plan
- isdn-mobile**: ISDN mobile numbering plan
- land-mobile**: Land mobile numbering plan
- maritime-mobile**: Maritime mobile numbering plan
- nw-specific** : Private network/ network-specific numbering plan
- telex**: Telex numbering plan
- unknown**: Unknown numbering plan

Usage

Select ISN telephone number plan for GTT process.

Example

```
numbering-plan isdn
```

translation-type

Configures the GTT process to apply a specific number for translation during the GTT process.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
translation-type number
```

number

Must be an integer between 0 and 255.

Default is 0.

Usage

Use this command to configure the translation-type to be implemented during the global title translation process.

Example

```
translation-type 231
```

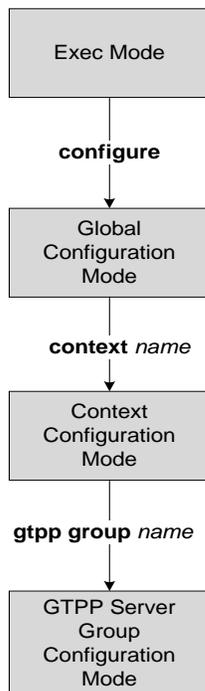

Chapter 127

GTPP Server Group Configuration Mode Commands

The GTPP Server Group Configuration Mode is used to create and manage the GTPP server groups within the context or system.

GTPP server group commands facilitate the setup of the SMC hard disk for CDR storage. As well, for accounting and charging functionality within a context, these commands can be used to configure the management of a group (list) of charging gateway function (CGF) servers on a per subscriber or per GGSN APN level.

In this mode, your prompt will be similar to `[context_name]hostname(config-gtpp-group)#`

gtp attribute

Enables the specification of some of the optional fields in the CDRs that the GSN (GGSN or SGSN) generates and/or how the information is to be presented.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp attribute { camel-info | cell-plmn-id | diagnostics | duration-ms | imei |
local-record-sequence-number | msisdn | node-id-suffix STRING | plmn-id | rat |
record-extensions rat | sms { destination-number | recording-entity | service-
centre } } +
```

```
default gtp attribute { cell-plmn-id | diagnostics | duration-ms | imei |
local-record-sequence-number | msisdn | plmn-id | rat | record-extensions rat |
sms { destination-number | recording-entity | service-centre } }
```

```
no gtp attribute { cell-plmn-id | diagnostics | duration-ms | imei | local-
record-sequence-number | msisdn | node-id-suffix | plmn-id | rat | record-
extensions rat | sms { destination-number | recording-entity | service-centre }
}
```

default

Resets the default attribute values for this GTPP group configuration.

no

Disables the specified optional field so that the information will not be present in generated CDRs.

camel-info

SGSN only

Default: Disabled

Enter this keyword to include CAMEL-specific fields in SGSN CDRs.

cell-plmn-id

SGSN only

Default: Disabled

Enter this keyword to enable the system to include the Cell PLMN ID field in the M-CDR.

diagnostics

Default: Disabled

Enter this keyword to enable the system to include the Diagnostic field in the CDR that is created when PDP contexts are released. The field will include one of the following values:

- 26 - For GGSN: if the GGSN sends “delete PDP context request” for any other reason (e.g., the operator types “clear subscribers” on the GGSN). For SGSN: The SGSN includes this cause code in

the S-CDR to indicate that a secondary PDP context activation request or a PDP context modification request has been rejected due to insufficient resources.

- 36** - For GGSN: this cause code is sent in the G-CDR to indicate the PDP context has been deactivated in the GGSN due to the SGSN having sent a “delete PDP context request” to the GGSN. For SGSN, this cause code is used to indicate a regular MS or network-initiated PDP context deactivation.
- 37** - when the network initiates a QoS modification, the SGSN sends in the S-CDR to indicate that the MS initiation deactivate request message has been rejected with QoS not accepted as the cause.
- 38** - if the GGSN sends “delete PDP context request” due to GTP-C/GTP-U echo timeout with SGSN. If the SGSN sends this cause code, it indicates PDP context has been deactivated due to path failure, specifically GTP-C/GTP-U echo timeout.
- 39** - SGSN only - this code indicates the network (GGSN) has requested a PDP context reactivation after a GGSN restart.
- 40** - if the GGSN sends “delete PDP context request” due to receiving a RADIUS Disconnect-Request message.

duration-ms

Default: Disabled

Specifies that the information contained in the mandatory Duration field be reported in milliseconds instead of seconds (as the standards require).

imei

Default: Disabled

For SGSN: includes the IMEI value in the S-CDR.

For GGSN: includes the IMEISV value in the G-CDR.

local-record-sequence-number

Default: Disabled

This keyword provides both the local record sequence number and the Node ID. In the x-CDRs, this field indicates the number of CDRs generated by the node and is unique within the session manager.

The Node ID field is included in the x-CDR for any of several reasons, such as when PDP contexts are released or if partial-CDR is generated based on configuration. The field will consist of a AAA Manager identifier automatically appended to the name of the SGSN or GGSN service.

The name of the SGSN or GGSN service may be truncated, because the maximum length of the Node ID field is 20 bytes. Since each AAA Manager generates CDRs independently, this allows the Local Record Sequence Number and Node ID fields to uniquely identify a CDR.

Important: If this keyword is enabled and the **gtp centralized-lrsn-creation** option is enabled with the **gtp single-source centralized-lrsn** command, then the Node ID format changes as follows. <1-byte-AAaproxy-restart-counter> <3-byte AAAproxy instance number> <node-id-suffix> If “centralized-lrsn-creation” is not enabled, then node-id format for CDRs generated by Sessmgr is as follows. <1-byte Sessmgr restart-value> <3-byte Sessmgr instance number> <node-id-suffix> If “centralized-lrsn-creation” is not enabled, then node-id format for CDRs generated by ACSMGR is as follows. <1-byte ACSmgr restart-value> <3-byte ACSmgr instance number> <Active charging service-name>

msisdn

Default: Enabled

For SGSN: includes the MSISDN value in the S-CDR.

For GGSN: includes the MSISDN value in the G-CDR.

node-id-suffix *STRING*

Default: Disabled

Specifies the string suffix to use in the NodeID field of GTPP CDRs. Each Session Manager task generates a unique NodeID string per GTPP context.

STRING: This is the configured Node-ID-Suffix having any string between 1 to 16 characters.

Important: The NodeID field is a printable string of the *ndddSTRING* format: *n*: The first digit is the Sessmgr restart counter having a value between 0 and 7. *ddd*: The number of sessmgr instances. Uses the specified NodeID-suffix in all CDRs. The "Node-ID" field consists of sessMgr Recovery counter (1 digit) *n* + AAA Manager identifier (3 digits) *ddd* + the configured Node-Id-suffix (1 to 16 characters) *STRING*. If the centralized LRSN feature is enabled, the "Node-ID" field will consist of only the specified NodeID-suffix (NodeID-prefix is not included). If this option is not configured, then GTPP group name will be used instead (For default GTPP groups, context-name will be used).

Important: If this **node-id-suffix** is not configured, the GGSN uses the GTPP context name as the Node-id-suffix (truncated to 16 characters) and the SGSN uses the GTPP group named as the node-id-suffix.

plmn-id [**unknown-use**]

Default: Enabled

For SGSN, reports the SGSN PLMN Identifier value (the RAI) in the S-CDR provided if the dictionary supports it.

For GGSN, reports the SGSN PLMN Identifier value (the RAI) in the G-CDR if it was originally provided by the SGSN in the GTP create PDP context request. It is omitted if the SGSN does not supply one.

Normally when SGSN PLMN-id information is not available, the attribute `sgsnPLMNIdentifier` is not included in the CDR. This keyword enables the inclusion of the `sgsnPLMNIdentifier` with a specific value when the SGSN PLMN-id is not available.

unknown-use *hex_num*: must be a hexadecimal number from 0x0 through 0xFFFFFFFF to identify a foreign SGSN that has not provided a PLMN-id. For GGSN only.

rat

Default: Enabled

For SGSN: includes the RAT (identifies the radio access technology type) value in the S-CDR.

For GGSN: includes the RAT (identifies the radio access technology type) value in the G-CDR.

record-extensions **rat**

Default: Disabled

Enables network operators and/or manufacturers to add their own recommended extensions to the CDRs according to the standard record definitions from 3GPP TS 32.298 Release 7 or higher.

sms { **destination-number** | **recording-entity** | **service-centre** }

This keyword is specific to the SGSN.

Entering this keyword causes the inclusion of an SMS-related field in the SMS-MO-CDR or SMS-MT-CDR.

destination-number - Entering this option includes the "destinationNumber" field in the SMS-MO-CDR or SMS-MT-CDR.

recording-entity - Entering this option includes the "recordingEntity" field in the SMS-MO-CDR or SMS-MT-CDR.

service-centre - Entering this option includes the "serviceCentre" field in the SMS-MO-CDR or SMS-MT-CDR.

+

Indicates that this command can be entered multiple times to configure multiple attributes.

Usage

This command dictates some of the optional information fields that should be reported in CDRs generated by the GGSN. In addition, it controls how the information for some of the mandatory fields are reported. Fields described as optional by the standards but not listed above will always be present in the CDRs, except for Record Extensions (which will never be present).

Example

The following command dictates that the time provided in the Duration field of the CDR is reported in milliseconds:

```
gtp attribute duration-ms
```

gtp charging-agent

Configures the IP address and port of the system interface within the current context used to communicate with the CGF or the GSS.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp charging-agent address ip_address [ port port ]
```

```
no gtp charging-agent
```

no

Removes a previously configured charging agent address.

address *ip_address*

Specifies the IP address of the interface configured within the current context that is used to transmit G-CDR records to the CGF or the GSS.

ip_address must be configured using dotted decimal notation.

port *port*

It is an optional parameter. It specifies the Charging Agent UDP port. If **port** is not defined, the IP will take the default port number 49999.

Default: 49999

port must be followed by an integer, ranging from 1 to 65535.

Important: Configuring GTPP charging-agent on port 3386 may interfere with ggsn-service configured with the same ip address.

Usage

This command can be used to establish a UDP interface to connect to the GSS or this command can establish a Ga interface to connect to the CFG. These interfaces must exist in the same context in which GTPP functionality is configured (refer to the **gtp** commands in this chapter).

This command instructs the system as to what interface to use. The IP address supplied is also the address by which the GGSN/SGSN is known to the CGF or the GSS. Therefore, the IP address used for the Ga or UDP interface could be identical to one bound to a GGSN/SGSN service (a Gn interface).

If no GGSN/SGSN services are configured in the same context as the Ga/UDP interface, the address configured by this command is used to receive unsolicited GTPP packets.

Example

The following command configures the system to use the interface with an IP address of 192.168.13.10 as the accounting interface with port 20000 to the CGF:

```
gtp charging-agent address 192.168.13.10
```

```
gtp charging-agent address 192.168.13.10 port 20000
```

gtp data-request sequence-numbers

Configures the range of sequence numbers to be used in the GTPP data record transfer record (DRT). Use this command to set the start value for the sequence number.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp data-request sequence-numbers start { 0 | 1 }
```

```
default gtp data-request sequence-numbers start
```

default

Default is 0 (zero).

start { 0 | 1 }

Specifies the value of the start sequence number for the GTPP Data Record Transfer Request. Default: 0

- 0**: Designates the start sequence number as 0.
- 1**: Designates the start sequence number as 1.

Usage

When the GGSN/SGSN is configured to send GTPP echo request packets, the SGSN always uses 0 as the sequence number in those packets. Re-using 0 as a sequence number in the DRT packets is allowed by the 3GPP standards; however, this CLI command ensures the possibility of inter-operating with CGFs that can not properly handle the re-use of sequence number 0 in the echo request packets.

Example

The following command sets the sequence to start at 1.

```
gtp data-request sequence-numbers start 1
```

gtp deadtime

Configures the amount of time the GGSN/SGSN waits before attempting to communicate with a CGF that was previously marked as unreachable (non-responsive).

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp deadtime time
```

```
default deadtime
```

default

Resets the deadtime to the default of 120 seconds.

time

Default: 120

Specifies the amount of time that must elapse before the system attempts to communicate with a CGF that was previously unreachable.

time is measured in seconds and can be configured to any integer value from 1 to 65535.

Usage

If the system is unable to communicate with a configured CGF, after a pre-configured number of failures the system marks the CGF as being down.

This command specifies the amount of time that the system waits prior to attempting to communicate with the downed CGF.

Refer to the **gtp detect-dead-server** and **gtp max-retries** commands for additional information on the process the system uses to mark a CGF as down.

Example

The following command configures the system to wait 60 seconds before attempting to re-communicate with a CGF that was marked as down:

```
gtp deadtime 60
```

gtp dead-server suppress-cdrs

This command configures the action the GGSN or the SGSN will take on CDRs generated during a communication failure between the GGSN or the SGSN and the GTPP servers.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] gtp dead-server suppress-cdrs
```

no

Removes the suppression instruction from the configuration and sets the CDR suppression mode as disabled.

default

Resets the GGSN or the SGSN to the default mode: disable suppression of CDRs when GTPP server detected as “dead” or unreachable.

Usage

For the GGSN: This command works in conjunction with the **gtp detect-dead-server** to set an action when a communication failure is detected between the GGSN and a configured GTPP server. It disables the archiving of CDRs on the system when the GTPP server is unreachable or dead.

For the GGSN and the SGSN: Typically, during a communication or server failure, the GGSN or SGSN retains the GTPP requests until the system buffer runs out of resources. This command enables suppression of the CDRs, so with this command the GGSN or the SGSN will start purging all CDRs associated with this GTPP group as soon as the GGSN/SGSN detects that the GTPP server is down or that a communication failure has occurred. The CDRs generated, for the period while the server is down/unreachable, will also be purged.

Example

The following command configures the system to start purging CDRs when a communication failure with a server is detected:

```
gtp dead-server suppress-cdrs
```

gtp detect-dead-server

Configures the number of consecutive communication failures that could occur before the system marks a CGF as 'dead' (unreachable).

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp detect-dead-server consecutive-failures max_number
```

```
default gtp detect-dead-server consecutive-failures
```

default

Resets the system to the default number of consecutive failures.

consecutive-failures *max_number*

Default: 5

Specifies the number of failures that could occur before marking a CGF as down. If 0 (zero) is the value entered, then the system will mark the CGF as dead after a single instance of **max-retries** has been attempted with no success, regardless of configured **deadtime**.

max_number could be configured to any integer value from 0 to 1000.

Usage

This command works in conjunction with the **gtp max-retries** parameter to set a limit to the number of communication failures that can occur with a configured CGF.

The **gtp max-retries** parameter limits the number of attempts to communicate with a CGF. Once that limit is reached, the system treats it as a single failure. The **gtp detect-dead-server** parameter limits the number of consecutive failures that can occur before the system marks the CGF as down and communicate with the CGF of next highest priority.

If all of the configured CGFs are down, the system ignores the detect-dead-server configuration and attempt to communicate with highest priority CGF again.

If the system receives a GTPP Node Alive Request, Echo Request, or Echo Response message from a CGF that was previously marked as down, the system immediately treats it as being active.

Refer to the **gtp max-retries** command for additional information.

Example

The following command configures the system to allow 8 consecutive communication failures with a CGF before it marks it as down:

```
gtp detect-dead-server consecutive-failures 8
```

gtp dictionary

This command designates specific dictionary used by GTPP for specific context.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp dictionary { custom1 | custom10 | custom11 | custom12 | custom13 | custom14
| custom15 | custom16 | custom17 | custom18 | custom19 | custom20 | custom21 |
custom22 | custom23 | custom24 | custom25 | custom26 | custom27 | custom28 |
custom29 | custom3 | custom30 | custom31 | custom32 | custom33 | custom34 |
custom35 | custom36 | custom37 | custom38 | custom39 | custom4 | custom40 |
custom5 | custom6 | custom7 | custom8 | custom9 | standard }
```

default gtp dictionary

default

Configures the default dictionary.

custom1

Custom-defined dictionary. It conforms to TS 32.015 v 3.6.0 for R99. It supports the encoding of IP addresses in text format for G-CDRs.

custom2

Custom-defined dictionary.

custom3

Custom-defined dictionary. It conforms to TS 32.015 v 3.6.0 for R99 but it does support the encoding of IP addresses in binary format for CDRs.

custom4

Custom-defined dictionary. It conforms to TS 32.015 v 3.6.0 for R99 except that:

- the Data Record Format Version information element contains 0x1307 instead of 0x1308
- “QoSRequested” is not present in the LoTV containers
- “QoSnegotiated” is added only for the first container and the container after a QoS change

custom5 ... custom20

Custom-defined dictionaries.

custom21 ... custom25

Custom-defined dictionaries for GGSN only.

custom26

Custom-defined dictionary for customization of G-CDR records for GGSN only. This is compliant to 3GPP TS 32.298 (R6 v 6.5.0) for proprietary fields and encoding.

custom27

Custom-defined dictionary for customization of S-CDR records for SGSN only. This is compliant to 3GPP TS 32.298 (R6 v 6.6.0) for propriert fields and encoding.

custom28 ... custom30

Custom-defined dictionaries for GGSN only.

custom31 ... custom40

Custom-defined dictionaries for SGSN only.

- **custom31**: Custom-defined dictionary for S-CDR encoding. This dictionary is based on 3GPP 32.298 v6.4.1 with a field appended for PLMN-ID.

standard

Default: Enabled

A dictionary conforming to TS 32.215 v 4.6.0 for R4 (and also R5 - extended QoS format).

Usage

Use this command to designate specific dictionary used by GTPP for specific context.

Example

The following command configures the system to use custom3 dictionary to encode IP address in Binary format in G-CDRs:

```
gtp dictionary custom3
```

gtp duplicate-hold-time

This command configures the number of minutes to hold onto CDRs that are possibly duplicates while waiting for the primary CGF to come back up.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp duplicate-hold-time minutes minutes
```

```
default gtp duplicate-hold-time
```

default

Resets the configuration to the default value of 60 minutes for the duplicate hold time.

minutes

When the primary CGF is down, the number of minutes to hold onto CDRs that may be duplicates. *minutes* must be an integer from 1 to 10080. Default is 60.

Usage

Use this command to configure how long to hold onto CDRs, that are possibly duplicates, while waiting for the primary CGF to come back up. If the GGSN determines that the primary CGF is down, CDRs that were sent to the primary CGF, but not acknowledged, are sent by the GGSN to the secondary CGF as “possibly duplicates”. When the primary CGF comes back up, the GGSN uses GTPP to determine whether the possibly duplicate CDRs were received by the primary CGF. Then the secondary CGF is told whether to release or cancel those CDRs. This command configures how long the system should wait for the primary CGF to come back up. As soon as the configured time expires, the secondary CGF is told to release all of the possibly duplicate CDRs.

Example

Use the following command to set the amount of time to hold onto CDRs to 2 hours (120 minutes):

```
gtp duplicate-hold-time minutes 120
```

gtp echo-interval

Configures the frequency at which the system sends GTPP echo packets to configured CGFs.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp echo-interval time
```

```
{ default | no } gtp echo-interval
```

default

Resets the configuration to the default echo-interval of 60 seconds.

no

Disables the use of the echo protocol except for the scenarios described in the Usage section for this command.

time

Specifies the number of seconds for sending GTPP echo packets.

time must be an integer from 60 to 3600. Default: 60

Usage

The GTPP echo protocol is used by the system to ensure that it can communicate with configured CGFs. The system initiates this protocol for each of the following scenarios:

- Upon system boot
- Upon the configuration of a new CGF server on the system using the **gtp server** command as described in this chapter
- Upon the execution of the **gtp test accounting** command as described in the Exec Mode Commands chapter of this reference
- Upon the execution of the **gtp sequence-numbers private-extensions** command as described in this chapter

The echo-interval command is used in conjunction with the **gtp max-retries** and **gtp timeout** commands as described in this chapter.

In addition to receiving an echo response for this echo protocol, if we receive a GTPP Node Alive Request message or a GTPP Echo Request message from a presumed dead CGF server, we will immediately assume the server is active again.

The alive/dead status of the CGFs is used by the AAA Managers to affect the sending of CDRs to the CGFs. If all CGFs are dead, the AAA Managers will still send CDRs, (refer to the **gtp deadtime** command), albeit at a slower rate than if a CGF were alive. Also, AAA Managers independently determine if CGFs are alive/dead.

gtp echo-interval

Example

The following command configures an echo interval of 120 seconds:

```
gtp echo-interval 120
```

gtppegcdr

Configures the eG-CDR parameters and triggers.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtppegcdr { final-record [ [ include-content-ids { all | only-with-traffic } ]
[ closing-cause { same-in-all-partials | unique } ] ] | losdv-max-containers
max_losdv_containers | lotdv-max-containers max_lotdv_containers | service-data-
flow threshold { interval interval | volume { downlink bytes [ uplink bytes ] |
total bytes | uplink bytes [ downlink bytes ] } } | service-idle-timeout { 0 |
service_idle_timeout } }
```

```
default gtppegcdr { final-record include-content-ids only-with-traffic closing-
cause same-in-all-partials | losdv-max-containers | lotdv-max-containers |
service-idle-timeout 0 }
```

```
no gtppegcdr service-data-flow threshold { interval | volume { downlink [
uplink ] | total | uplink [ downlink ] } }
```

```
final-record [ [ include-content-ids { all | only-with-traffic } ] [
closing-cause { same-in-all-partials | unique } ] ]
```

Enables configuration of the final eG-CDR.

- **include-content-ids:** Controls which content-ids are being included in the final eG-CDR.
 - **all:** Specifies that all content-ids be included in the final eG-CDR.
 - **only-with-traffic:** Specifies that only content-ids with traffic be included in the final eG-CDRs.
- **closing-cause:** Configures closing cause for the final eG-CDR.
 - **same-in-all-partials:** Specifies that the same closing cause is to be included for multiple final eG-CDRs.
 - **unique:** Specifies that the closing cause for final eG-CDRs is to be unique.

```
losdv-max-containers max_losdv_containers
```

The maximum number of List of Service Data Volume (LoSDV) containers in one eG-CDR.

max_losdv_containers must be an integer from 1 through 255.

Default: 10

```
lotdv-max-containers max_lotdv_containers
```

The maximum number of List of Traffic Data Volume (LoTDV) containers in one eG-CDR.

max_lotdv_containers must be an integer from 1 through 8.

Default: 8

```
service-data-flow threshold { interval interval | volume { downlink bytes
[ uplink bytes ] | total bytes | uplink bytes [ downlink bytes ] } }
```

Configures the thresholds for closing a service data flow container within an eG-CDR.

- **interval** *interval*: Specifies the time interval, in seconds, to close the eG-CDR if the minimum time duration thresholds for service data flow containers satisfied in flow-based charging.

interval must be an integer from 60 through 40000000.

Default: Disabled

- **volume** { **downlink** *bytes* [**uplink** *bytes*] | **total** *bytes* | **uplink** *bytes* [**downlink** *bytes*] }: Specifies the volume octet counts for the generation of the interim eG-CDRs to service data flow container in FBC.

- **downlink** *bytes*: Specifies the limit for the number of downlink octets after which the eG-CDR is closed.

- **total** *bytes*: Specifies the limit for the total number of octets (uplink+downlink) after which the eG-CDR is closed.

- **uplink** *bytes*: Specifies the limit for the number of uplink octets after which the eG-CDR is closed.

- *bytes* must be an integer from 10000 through 400000000.

A service data flow container has statistics for an individual content ID. When the threshold is reached, the service data flow container is closed.

```
service-idle-timeout { 0 | service_idle_timeout }
```

Specifies a time period where if no data is reported for a service flow, then the service container is closed and added to eG-CDR (as part of LOSDV container list) with service condition change as ServiceIdleOut.

0: Specifies there is no service-idle-timeout trigger.

service_idle_timeout must be an integer from 10 through 86,400.

Default: 0

Usage

Use this command to configure individual triggers for eG-CDR generation.

Example

Use the following command to set the maximum number of LoSDV containers to 7:

```
gtpg egcdr losdv-max-containers 7
```

gtp error-response

This command configures the response when the system receives an error response after transmitting a DRT (data record transfer) request.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp error-response { discard-cdr | retry-request }
```

```
default gtp error-response
```

default

Resets the system's configuration to the default value for error-response. Default is retry-request.

discard-cdr

Instructs the system to purge the request upon receipt of an error response and not to retry.

retry-request

Instructs the system to retry sending a DRT after receiving an error response. This is the default behavior.

Usage

This command configures the system's response to receiving an error message after sending a DRT request.

Example

```
gtp error-response discard-cdr
```

gtp max-cdrs

Configures the maximum number of charging data records (CDRs) to be included in a packet.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp max-cdrs max_cdrs [ wait-time wait_time ]
```

```
default gtp max-cdrs
```

default

Sets the default configuration.

max_cdrs

Default: 1

Specifies the maximum number of CDRs to insert in a single packet.

max_cdrs must be an integer from 1 through 255.

wait-time *wait_time*

Default: Disabled

Configures the number of seconds the GSN waits to send the packet while accumulating CDRs as defined by **max-cdr**. If the **wait-time** interval expires before **max-cdrs** is reached, then this keyword over-rides and the packet is sent.

wait_time must be an integer from 1 through 300.

 **Important:** **wait-time** interval can only be enabled if the value for **max-cdrs** *max_cdrs* is greater than 1.

Usage

The system places CDRs into a packet until either **max-cdrs** is met, **wait-time** times out, or the maximum PDU size, configured by the **gtp max-pdu-size** command, is met.

The **gtp max-pdu-size** and the **wait-time** parameters take priority over **max-cdrs**.

 **Important:** This command's configuration is ignored if CDRs are stored on an SMC hard disk.

Example

The following command configures the system to place a maximum of 10 CDRs in a single GTPP packet with a wait-time of 30 seconds:

```
gtp max-cdrs 10 wait-time 30
```

gtp max-pdu-size

Configures the maximum payload size of a single GTPP packet that could be sent by the system.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp max-pdu-size pdu_size
```

```
default gtp max-pdu-size
```

default

Resets the default **max-pdu-size** of 4096.

pdu_size

Default: 4096

Specifies the maximum payload size of the GTPP packet. The payload includes the CDR and the GTPP header.

pdu_size is measured in octets and can be configured to any integer value from 1024 to 65400.

Usage

The GTPP packet contains headers (layer 2, IP, UDP, and GTPP) followed by the CDR. Each CDR contains one or more volume containers. If a packet containing one CDR exceeds the configured maximum payload size, the system creates and send the packet containing the one CDR regardless.

The larger the packet data unit (PDU) size allowed, the more volume containers that can be fit into the CDR. The system performs standard IP fragmentation for packets that exceed the system's maximum transmission unit (MTU).

Important: The maximum size of an IPv4 PDU (including the IPv4 and subsequent headers) is 65,535. However, a slightly smaller limit is imposed by this command because the system's max-pdu-size doesn't include the IPv4 and UDP headers, and because the system may need to encapsulate GTPP packets in a different/larger IP packet (for sending to a backup device).

Example

The following command configures a maximum PDU size of 2048 octets:

```
gtp max-pdu-size 2048
```

gtp max-retries

Configures the maximum number of times the system attempts to communicate with an unresponsive CGF.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp max-retries max_attempts
```

```
default gtp max-retries
```

default

Resets the systems **max-retries** to the default of 4.

max_attempts

Default: 4

Specifies the number of times the system attempts to communicate with a CGF that is not responding. *max_attempts* can be configured to any integer value from 1 to 15.

Usage

This command works in conjunction with the **gtp detect-dead-server** and **gtp timeout** parameters to set a limit to the number of communication failures that can occur with a configured CGF. When the value specified by this parameter is met, a failure is logged. The **gtp detect-dead-server** parameter specifies the number of consecutive failures that could occur before the server is marked as down. In addition, the **gtp timeout** command controls the amount of time between re-tries. If the value for the max-retries is met, the system begins storing CDRs in Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context). Archived CDRs are re-transmitted to the CGF until they are acknowledged or the system's memory buffer is exceeded. Refer to the **gtp detect-dead-server** and **gtp timeout** commands for additional information.

Example

The following command configures the maximum number of re-tries to be 8.

```
gtp max-retries 8
```

gtp mbms bucket

This command configures the traffic data volume (bucket) limit of charging buckets due to QoS changes of tariff time that can occur before a G-MBMS-CDR should be closed.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp mbms buckets number
```

```
[ no ] gtp mbms buckets
```

no

Disables the configured traffic data volume bucket limits trigger for G-MBMS-CDR generation for MBMS user service data.

buckets *number*

Default: 4

Specifies the number of statistics container changes due to QoS changes or tariff time that can occur before a G-MBMS-CDR should be closed.

number can be configured to any integer value from 1 through 4.

Usage

Use this command to configure the traffic data volume (bucket) based G-MBMS-CDR generation triggers for MBMS user data service.

Example

The following command configures the bucket-based trigger to generate G-MBMS-CDRs after changes in 2 container:

```
gtp mbms buckets 2
```

gtp mbms interval

This command configures the interval duration for interval-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp mbms interval duration_sec
```

```
no gtp mbms interval
```

no

Disables the interval-based trigger for G-MBMS-CDR generation for MBMs user service data.

interval *duration_sec*

Default: Disabled

Specifies the normal time duration that must elapse before closing an accounting record provided that any or all of the following conditions occur:

- Downlink traffic volume is reached within the time interval
- Tariff time based trigger occurred within the time interval
- Data volume (up and downlink) bucket trigger occurred within the time interval

duration_sec is measured in seconds and can be configured to any integer value from 60 through 40,000,000.

Usage

Use this command to configure the G-MBMS-CDR generation triggers for MBMS user data service.

Example

The following command configures the interval-based trigger to generate G-MBMS-CDRs in every 60 seconds:

```
gtp mbms interval 60
```

gtp mbms tariff

This command configures the tariff slots for tariff-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp mbms tariff time1 mins hours [ time2 mins hours [ time3mins hours [ time4mins hours ] ] ]
```

```
[ no ] gtp mbms tariff
```

no

Disables the tariff-based triggers for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

```
tariff time1 mins hours [ time2mins hours [ time3mins hours [ time4mins hours ] ] ]
```

Default: Disabled

Specifies time-of-day time values to close the current statistics container (but not necessarily the accounting record).

Important: The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

For each of the different tariff times, the following parameters must be configured:

- *mins*: The minutes of the hour, an integer value from 0 through 59.
- *hours*: The hour of the day, an integer value from 0 through 23.

Usage

Use this command to configure the tariff-time-based triggers for G-MBMS-CDR generation in MBMS user data service.

Example

The following command configures the tariff-time-based trigger to generate G-MBMS-CDRs every day at 11 hours and 30 min:

```
gtp mbms tariff time1 30 11
```

gtp mbms volume

This command configures the download traffic data volume based trigger for GTPP MBMS Charging Data Record (G-MBMS-CDR) generation.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp mbms volume download_bytes
```

```
[ no ] gtp mbms volume
```

no

Disables the configured download traffic data volume based trigger for G-MBMS-CDR generation for MBMs user service data.

volume *download_bytes*

Default: Disabled

Specifies the threshold of downlink data volumes that must be met before a G-MBMS-CDR should be closed. *download_bytes* is the total download traffic volume measured in octets and can be configured to any integer value from 100,000 through 4,000,000,000.

Usage

Use this command to configure the traffic data volume (download) based G-MBMS-CDR generation triggers for MBMS user data service.

Example

The following command configures the traffic data volume (download) limit to trigger to generate G-MBMS-CDRs after reaching 150,000 octets:

```
gtp mbms volume download_bytes
```

gtp redirection-allowed

Configures the system to allow/disallow the redirection of CDRs when the primary CGF is unavailable.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] gtp redirection-allowed
```

default

Resets the system to allow redirection of CDRs.

no

Removes the redirection definition from the configuration.

Usage

This command allows operators to better handle erratic network links, without having to remove the configuration of the backup server(s) via the **no gtp server** command.

This functionality is enabled by default.

If the **no gtp redirection-allowed** command is executed, the system only sends CDRs to the primary CGF. If that CGF goes down, the system will buffer the CDRs in memory until the CGF comes back or until the system runs out of buffer memory. In addition, if the primary CGF announces its intent to go down (with a GTPP Redirection Request message), the system responds to that request with an error response.

Example

The following command configures the system to allow the redirection of CDRs when the primary CGF is unavailable:

```
default gtp redirection-allowed
```

gtp redirection-disallowed

This command has been obsoleted and is replaced by the **gtp redirection-allowed** command.

gtpserver

Configures the charging gateway function (CGF) accounting server(s) with in GTPP server group that the system is to communicate with.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpserver ip_address [ max msgs ] [ priority priority ] [ udp-port port ] [ node-alive { enable | disable } ] [ -noconfirm ]
```

```
no gtpserver ip_address [ udp-port port ]
```

no

Deletes a previously configured CGF.

ip_address

Specifies the IP address of the CGF in dotted decimal notation for IPv4 or colon notation for IPv6.

max *msgs*

Default: 256

Specifies the maximum number of outstanding or unacknowledged GTPP packets (from any one AAA Manager task) allowed for this CGF before the system begins buffering the packets.

msgs can be configured to any integer value from 1 to 256.

priority*priority*

Default: 1000

Specifies the relative priority of this CGF. When multiple CGFs are configured, the priority is used to determine which CGF server to send accounting data to.

priority can be configured to any integer value from 1 to 1000. When configuring two or more servers with the same priority you will be asked to confirm that you want to do this. If you use the **-noconfirm** option, you are not asked for confirmation and multiple servers could be assigned the same priority.

udp-port*port*

Default: 3386

Specifies the UDP port over which the GGSN communicates with the CGF. *port* can be configured to any integer value between 1 and 65535.

node-alive { **enable** | **disable** }

Default: Disable.

This optional keyword allows operator to enable/disable GGSN to send Node Alive Request to GTPP Server (i.e. CGF). This configuration can be done per GTPP Server basis.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Use this command to configure the CGF(s) that the system sends CDR accounting data to.

Multiple CGFs can be configured using multiple instances of this command subject to the following limits:

- Up to 4 CGFs can be configured in one GTPP server group
- Total 32 CGFs can be configured per context.

Each configured CGF can be assigned a priority. The priority is used to determine which server to use for any given subscriber based on the routing algorithm that has been implemented. A CGF with a priority of “1” has the highest priority.

Important: The configuration of multiple CGFs with the same IP address but different port numbers is not supported.

Each CGF can also be configured with the maximum allowable number of unacknowledged GTPP packets. Since multiple AAA Manager tasks could be communicating with the same CGF, the maximum is based on any one AAA Manager instance. If the maximum is reached, the system buffers the packets Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context).

Example

The following command configures a CGF with an IP address of 192.168.2.2 and a priority of 5.

```
gtp server 192.168.2.2 priority 5
```

The following command deletes a previously configured CGF with an IP address of 100.10.35.7:

```
no gtp server 100.10.35.7
```

gtp source-port-validation

This command configures whether the system validates the UDP source port in received GTPP messages.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[no | default] gtp source-port-validation
```

no

Validates the IP source address but not the UDP source port.

default

Restores this parameter to its default setting of enabled.

Usage

This command configures whether the system validates the UDP source port in received GTPP messages.

Example

The following command disables UDP port validation:

```
no gtp source-port-validation
```

gtp storage-server

Configures information for the GTPP back-up storage server.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp storage-server ip_address port port_num
```

```
no gtp storage-server ip_address port port_num
```

no

Removes a previously configured back-up storage server.

ip_address

The IP address of the back-up storage server expressed in dotted decimal notation.

port *port_num*

Default: 3386

Specifies the UDP port number over which the GGSN communicates with the back-up storage server.

Usage

This command identifies the connection to the GSS. One backup storage server can be configured per GTPP group.

Example

The following command configures a GSS with an IP address of 192.168.1.2:

```
gtp storage-server 192.168.1.2
```

gtp storage-server local file

Configures the parameters for GTPP files stored locally on the GTPP storage server.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp storage-server local file { compression { gzip | none } | format { custom1
| custom2 | custom3 | custom4 | custom5 | custom6 | custom7 | custom8 } | name {
format string [ max-file-seq-numseq_number ] | prefix prefix } | purge-
processed-files [ purge-interval purge_dur ] | rotation { cdr-count count |
time-interval time [ force-file-rotation ] | volume mb size } }
```

```
default gtp storage-server local file { compression | format | name { format |
prefix } | purge-processed-files | rotation { cdr-count | time-interval | volume
} }
```

```
no gtp storage-server local file { purge-processed-files | rotation { cdr-count
| time-interval } }
```

no

Removes a previously configured parameters for local storage of CDR files on HDD on SMC card.

compression { gzip | none }

Configures the type of compression to be used on the files stored locally.

gzip – Enables Gzip file compression.

none – Disables Gzip file compression -this is the default value.

format custom1 .. 8

Configures the file format to be used to format files to be stored locally.

custom1 – File format custom1 - this is the default file format.

custom2 to custom5 Customer specific CDR file formats.

custom6 – File format custom6 with a block size of 8K for CDR files.

custom7 – File format custom7 is a customer specific CDR file format.

custom8 – File format custom8 is a customer specific CDR file format. It uses *node-id-suffix_date_time_fixed-length-seq-num.u* format for file naming where:

- *date* is date in MMDDYYYY (01312010) for mat
- *time* is time in HHMMSS (023508) format
- *fixed-length-seq-num* is the fixed length of srquence number for specific file having 6 digit counter starting from 000001 and end to 999999. Once file sequence reached to 999999 the sequence will be reset to 000001.

name format *string*

This keyword allows the format of the CDR filenames to be configured independently from the file format so that the name format contains the file name with conversion specifications.

string – Enter a string of 1 to 127 alphanumeric characters. The string **must begin** with the % (percent sign).

- **%y:** = year as a decimal number without century (range 00 to 99).
- **%Y:** = year as a decimal number with century.
- **%m:** = month as a decimal number (range 01 to 12).
- **%d:** = day of the month as a decimal number (range 01 to 31).
- **%H:** = hour as a decimal number 24-hour format (range 00 to 23).
- **%h:** = hour as a decimal number 12-hour format (range 01 to 12).
- **%M:** = minute as a decimal number (range 00 to 59).
- **%S:** = second as a decimal number (range 00 to 60). (The range is up to 60 to allow occasional leap seconds.)
- **%Q:** = File sequence number. Field width may be specified between the % and the Q. If the natural size of the field is smaller than this width, then the result string is padded (on the left) to the specified width with 0s
- **%N:** = No of CDRs in the file. Field width may be specified between the % and the N. If the natural size of the field is smaller than this width, then the result string is padded (on the left) to the specified width with 0s
- **%%:** = This field is used to add % to the CDR file name.
- **max-file-seq-no:** This can be configured optionally. It indicates the maximum value of sequence number in file name (starts from 1). Once the configured max-file-seq-no limit is reached, the sequence number will restart from 1. If no max-file-seq-no is specified then file sequence number ranges from 1- 4294967295.

By default the above keyword is not configured (default gtp storage-server local file name format). In which case the CDR filenames are generated based on the file format as before (maintains backward compatibility).

name prefix *prefix*

Defines the prefix to be used for the file name. By default the file name prefix would be 'GTPP-group-name + VPN-ID'. It is possible to have a NULL value prefix where the system would enter a default, which would be *group+vpn*,

prefix – Enter a string of 1 to 64 alphanumeric characters or do not enter a value (NULL).

purge-processed-files [**purge-interval** *purge_dur*]

Default: Disabled

Enables the GSN to periodically delete locally processed (*.p) CDR files from the HDD on the SMC card.

Important: This option is available only when GTPP server storage mode is configured for local storage of CDRs with the **gtp storage-server mode local** command.

purge-interval *purge_dur* provides an option for user to control the purge interval duration in minutes by setting *purge_dur*.

purge_dur must be an integer from 1 through 259200.

Default: 60 minutes

```
rotation {cdr-count count | time-interval time [ force-rotation ] |
volume size }
```

Specifies rotation related configuration for GTPP files stored locally.

cdr-count *count* - Configure the CDR count for the file rotation. Enter a value from 1000 to 65000. Default value 10000.

time-interval *time* - Configure the time interval for file rotation. Enter a value in seconds ranging from 30 to 86400. Default value is 3600 seconds (1 hour).

force-file-rotation - Force CDR file-rotation at specified interval, configured with **time-interval** *time* keyword, even if there are no CDRs generated. By default this keyword is "Disbaled".

volume *size* - Configure the file volume, in MB, for file rotation. Enter a value ranging from 2 to 40. This trigger can not be disabled. Default value is 10MB.

Usage

This command configures the parameters for storage of GTPP packets as files on the local server - meaning the hard disk.

Example

The following command configures rotation for every 1.5 hours for locally stored files.

```
gtp storage-server local file rotation time-interval 5400
```

Configuring file name format along with max-file-seq-no:

```
gtp storage-server local file name format processed_2g_%Y%m%d_%5Q_%N.cdr
max-file-seq-no 2345
```

Configuring file name prefix with a NULL value:

```
gtp storage-server local file name prefix NULL
```

gtp storage-server max-retries

Configures the maximum number of times the system attempts to communicate with an unresponsive GTPP back-up storage server.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp storage-server max-retries max_attempts
```

```
default gtp storage-server max-retries
```

default

Restores the system to the default value of 2 retry attempts.

max_attempts

Default: 2

Specifies the number of times the system attempts to communicate with a GTPP back-up storage server that is not responding.

max_attempts can be configured to any integer value from 1 to 15.

Usage

This command works in conjunction with the **gtp storage-server timeout** parameters to set a limit to the number of communication failures that can occur with a configured GTPP back-up storage server. The **gtp storage-server timeout** command controls the amount of time between re-tries. Refer to the **gtp storage-server timeout** command for additional information.

Example

The following command configures the maximum number of re-tries to be 8.

```
gtp storage-server max-retries 8
```

gtp storage-server mode

This command configures storage mode, local or remote, for CDRs. Local storage mode is available with ASR 5000 platforms only.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp storage-server mode { local | remote | streaming }
```

```
default gtp storage-server mode
```

default

Returns the GTPP group configuration to the default 'remote' value for the GTPP storage server mode.

local

Default: Disabled

Specifies the use of the hard disk on the SMC for storing CDRs.

Important: This option is available with ASR 5000 platforms only.

remote

Specifies the use of an external server for storing CDRs. This is the default value.

Important: When the external server is down, the Session Managers will start buffering up to a maximum of 26400 CDRs or a total of 120 MB worth of CDRs, whichever limit reaches first.

streaming

Default: Disabled

This keyword allows the operator to configure "streaming" mode of operation for GTPP group. When this keyword is supplied the CDRs will be stored in following fashion:

- When GTPP link is active with CGF, CDRs are sent to a CGF via GTPP and local hard disk is NOT used as long as every record is acknowledged in time.
- If the GTPP connection is considered to be down, all streaming CDRs will be saved temporarily on the local hard disk and once the connection is restored, unacknowledged records will be retrieved from the hard disk and sent to the CGF.

Important: This option is available with ASR 5000 platforms only.

Usage

This command configures whether the CDRs should be stored on the hard disk of the SMC or remotely, on an external server.

Example

The following command configures use of a hard disk for storing CDRs.

```
gtp storage-server mode local
```

gtp storage-server timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the GTPP back-up storage server.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp storage-server timeout duration
```

```
default gtp storage-server timeout
```

default

Restores the timeout duration to the 30-second default.

duration

Default: 30

Specifies the maximum amount of time the system waits for a response from the GTPP back-up storage server before assuming the packet is lost.

duration is measured in seconds and can be configured to any integer value from 30 to 120.

Usage

This command works in conjunction with the **gtp storage-server max-retries** command to establish a limit on the number of times that communication with a GTPP back-up storage server is attempted before a failure is logged.

This parameter specifies the time between retries.

Example

The following command configures a retry timeout of 60 seconds:

```
gtp storage-server timeout 60
```

gtp suppress-cdrs zero-volume-and-duration

This command suppresses the CDRs created by session having zero duration and/or zero volume. By default this mode is 'disabled'.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp suppress-cdrs zero-volume-and-duration { gdrs [ egdrs ] | egdrs [ gdrs ] }
```

```
default gtp suppress-cdrs zero-volume-and-duration
```

default

Disables the CDR suppression mode.

gdrs [egdrs]

Specifies that this command will handle G-CDRs before eG-CDRs.

gdrs [egdrs]

Specifies that this command will handle eG-CDRs before G-CDRs.

Usage

Use this command to suppress the CDRs (G-CDRs and eG-CDRs) which were created due with zero-duration session and zero-volume session due to any reason. By default this command is disabled and system will not suppress any CDR.

Example

The following command configures the system to suppression the eG-CDRs created for a zero duration session or zero volume session:

```
gtp suppress-cdrs zero-volume-and-duration egdrs gdrs
```

gtp timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the CGF.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp timeout time
```

```
default gtp timeout
```

default

Resets the systems GTPP timeout value to 20 seconds.

time

Default: 20

Specifies the maximum amount of time the system waits for a response from the CGF before assuming the packet is lost.

time is measured in seconds and can be configured to any integer value from 1 to 60.

Usage

This command works in conjunction with the **gtp max-retries** command to establish a limit on the number of times that communication with a CGF is attempted before a failure is logged.

This parameter specifies the time between retries.

Example

The following command configures a retry timeout of 30 seconds:

```
gtp timeout 30
```

gtp trigger

This commands disables GTPP trigger conditions that cause either partial CDR record closure or opening of a new CDR record container. GTPP Triggers are specified in 3GPP TS 32.251 v6.6.0. All GTPP trigger changes take affect immediately, except **volume-limit**.

Product

ECS, GGSN, PGW, SGW, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] gtp trigger { cell-update | direct-tunnel | egcdr max-losdv | inter-
plmn-sgsn-change | ms-timezone-change | plmn-id-change | qos-change | rat-change
| routing-area-update | sgsn-change-limit | serving-node-change-limit | tariff-
time-change | time-limit | volume-limit }
```

default gtp trigger

default

Sets the specified trigger condition back to the default setting. All trigger conditions are enabled by default.

no

Re-enables the specified trigger condition.

cell-update

Enables the cell update trigger for S-CDRs, if the dictionary specified in the **gtp dictionary** configuration includes support for cell update. This trigger is available only for 2G. Currently, custom18 dictionary supports the cell update trigger.

direct-tunnel

Enables the direct tunnel trigger for CDRs.

egcdr max-losdv

Default: Disabled

Enables the trigger for an eG-CDR if the List of Service Data Volume (LoSDV) containers crosses the configured limit for LOSDV containers.

inter-plmn-sgsn-change

This keyword is for GGSN only.

Default: Enabled

Disabling this trigger ignores an Inter-PLMN SGSN change and doesn't release a G-CDR.

ms-timezone-change

This keyword is specific to GGSN.

Default: Enabled

No partial record closure for a time zone change occurs when this trigger is disabled. MS Time zone change should be applicable only for 3GPP R6 based GTPP dictionaries.

plmn-id-change

This trigger keyword is specific to the 2G SGSN and is proprietary (non-standard).

Default: Disabled

Enables the PLMNID change trigger for S-CDRs if the dictionary specified in the **gtp dictionary** configuration supports the PLMNID change. If enabled, the SGSN generates a partial S-CDR when the MS changes the PLMN while under the same SGSN (intra-system intra-SGSN PLMN-ID handover). Currently, custom18 dictionary supports this trigger.

qos-change

Default: Enabled

Enables the QoS-change trigger for CDRs. Disabling this trigger ignores a QoS-change and does not open a new CDR for it.

rat-change

Default: Enabled

This keyword enable/disable the partial record closure for a RAT change. If disabled no partial record closure for a RAT change occurs. RAT change should be applicable only for 3GPP R6 based GTPP dictionaries. In SGSN, RAT change trigger (2G<->3G) means inter-service handoff (SGSN service <-> GPRS service). If this trigger is enabled, after the RAT change interim CDR is generated. After this RAT change CDR, CDR thresholds such as volume/time etc. and GTPP Group are applicable from new service. If RAT change trigger is disabled, the CDR thresholds and GTPP group etc. will not change and will continue to use from old service.

After the RAT change the **System Type** field in CDR changes to indicate the new system type. If this trigger is disabled then the next CDR generated will indicate **System Type** but the data count in the CDR does not necessarily belong to the system type indicated in CDR instead it may belong to both 2G and 3G as CDR is not closing when handover takes place.

Important: However **System Type** field in CDR related change is not applicable to customized CDR formats which does not use **System Type** field

routing-area-update

Enables the routing-area-update trigger for CDRs.

sgsn-change-limit [also-intra-sgsn-multiple-address-group-change]

This keyword is obsolete and is available to maintain the backward compatibility for existing customers. The new keyword for **sgsn-change-limit** is **serving-node-change-limit**.

Default: Enabled

Disabling this trigger ignores an SGSN change and does not add the SGSN IP address into the SGSN address list of the CDR. This helps to reduce the release of CDRs due to SGSN changes crossing the configured limit. **also-intra-sgsn-multiple-address-group-change** : This keyword includes Intra-SGSN group changes as an SGSN change.

```
serving-node-change-limit [ also-intra-sgsn-multiple-address-group-change ]
```

This keyword is enabled for PGW, SGW, and GGSN. However, the **also-intra-sgsn-multiple-address-group-change** is enabled only for GGSN.

Default: Enabled

Disabling this trigger ignores an SGSN change and does not add the SGSN IP address into the SGSN address list of the CDR. This helps to reduce the release of CDRs due to SGSN changes crossing the configured limit.
also-intra-sgsn-multiple-address-group-change : This keyword includes Intra-SGSN group changes as an SGSN change.

```
tariff-time-change
```

Default: Enabled

When this trigger is disabled container closure does not happen for a tariff-time change.

This trigger is applicable for G-MB-CDRs for MBMS session too.

```
time-limit
```

Default: Enabled

When this trigger is disabled no partial record closure occurs when the configured time limit is reached.

This trigger is applicable for G-MB-CDRs for MBMS session too.

```
volume-limit
```

Default: Enabled

When this trigger is disabled no partial record closure occurs when volume limit is reached.

This trigger is applicable for G-MB-CDRs for MBMS session too.

Usage

Use this command to disable or re-enable GTPP triggers that can cause partial CDR record closure or cause a new CDR to be created.

Example

The following command disables partial record closure when a configured time limit is reached:

```
gtp trigger time-limit
```

The following command re-enables partial record closure when a configured time limit is reached:

```
no gtp trigger time-limit
```

gtp transport-layer

This command selects the transport layer protocol for Ga interface for communication between AGW (GSNs) and GTPP servers.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtp transport-layer { tcp | udp }
```

```
default gtp transport-layer
```

default

Resets the transport layer protocol to GTPP servers to the default UDP.

tcp

Default: Disabled

Enables the system to implement TCP as transport layer protocol for communication with GTPP server.

udp

Default: Enabled

Enables the system to implement UDP as transport layer protocol for communication with GTPP server.

Usage

Use this command to select the TCP or UDP as the transport layer protocol for Ga interface communication between GTPP servers and AGWs (GSNs).

Example

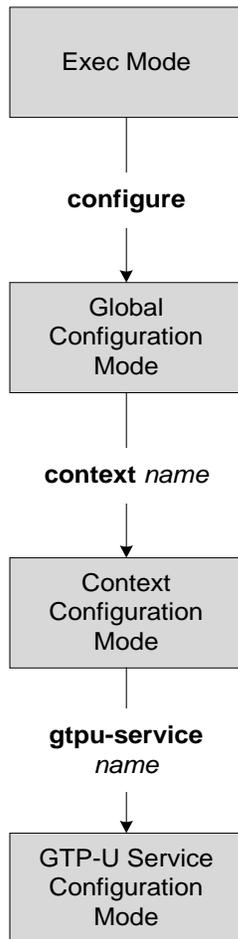

The following command enables TCP as the transport layer protocol for the GSN's Ga interface.

```
gtp transport-layer tcp
```

Chapter 128

GTP-U Service Configuration Mode Commands

The GTP-U Service Configuration Mode is used to manage parameters applied to incoming GTP-U packets.

bind

Configures the IP address to use for GTP-U data packets.

Product

GGSN, P-GW, S-GW

Privilege

Administrator

Syntax

```
[ no ] bind { ipv4-address ipv4_address [ crypto-template crypto_template ] [
ike-bind-address { ipv4_address } ] [ ipv6-address ipv6_address ] | ipv6-address
ipv6_address [ crypto-template crypto_template ] [ ike-bind-address {
ipv6_address } ] [ ipv4-address ipv4_address ] }
```

no

removes a configured IP address from this service.

ipv4-address *ipv4_address*

Binds this service to the IPv4 address of a configured interface.

ipv4_address must be entered as a standard IPv4 address in dotted decimal notation.

ipv6-address *ipv6_address*

Binds this service to the IPv6 address of a configured interface.

ipv6_address must be entered as a standard IPv6 address in colon-separated notation.

crypto-template *crypto_template*

Configures crypto template for IPsec, which enables IPsec tunneling for this GTP-U address. Must be followed by the name of an existing crypto template.

crypto_template must be from 1 to 127 alpha and/or numeric characters

ike-bind-address *ip_address*

Configures an IKE bind address. Must be followed by IPV4 or IPv6 address; IP address type must be the same as the GTP-U address type.

ipv4_address must be entered as a standard IPv4 address in dotted decimal notation.

ipv6_address must be entered as a standard IPv6 address in colon-separated notation.

Important: This keyword is only applicable if a crypto template is bound to the GTP-U address.

Usage

Use this command to bind the service to an interface for sending/receiving GTP-U packets.

Important: A GTP-U service can support a maximum of 12 GTP-U endpoints/interfaces.

Example

The following command configures the IPv4 address for this GTP-U service as *1 . 2 . 3 . 4*:

```
bind ipv4-address 1 . 2 . 3 . 4
```

echo-interval

Configures the rate at which GPRS Tunneling Protocol (GTP) v1-U echo packets are sent.

Product

GGSN, P-GW, S-GW

Privilege

Administrator

Syntax

```
echo-interval seconds
```

```
[ default | no ] echo-interval
```

seconds

Specifies the number of seconds between the sending of a GTP-Uv1 echo packet. *seconds* must be an integer value from 60 to 3600.

default

Returns the command to its default setting of disabled.

no

Removes the configured echo-interval setting.

Usage

Use this command to configure the rate at which GTP-Uv1 echo packets are sent.

Example

The following command sets the rate between the sending of echo packets at 120 seconds:

```
echo-interval 120
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

extension-header

Configures the addition of an extension header in the GTP-U packet header, allowing for error indication messages.

Product

GGSN, P-GW, S-GW

Privilege

Administrator

Syntax

```
[ default | no ] extension-header source-udp-port
```

default

Returns the command to its default setting of disabled.

no

Disables the feature.

source-udp-port

Configures extension header type UDP Port support in GTP-U header for GTP-U Error Indication messages.

Usage

Example

The following command enables the inclusion of an extension header to allow for error indication messages:

```
extension-header source-udp-port
```

ipsec-allow-error-ind-in-clear

Configures whether error-indication is dropped or sent without IPsec tunnel.

Product

P-GW

Privilege

Administrator

Syntax

```
[ default | no ] ipsec-allow-error-ind-in-clear
```

default

Error-indication is dropped if no IPSEC tunnel is present for that peer.

no

Disables the feature.

Usage

Use this command to determine whether error-indication is dropped or sent without IPsec tunnel.

On receiving data packets for a session that doesn't exist, error-indication needs to be sent back to the peer. If there is no IPsec tunnel present with that peer, error-indication may be either dropped or sent without any IPsec tunnel.

Example

The following command allows error-indication to be sent without any IPsec tunnel:

```
ipsec-allow-error-ind-in-clear
```

ipsec-tunnel-idle-timeout

Configures the IPsec tunnel idle timeout after which IPsec tunnel deletion is triggered.

Product

P-GW

Privilege

Administrator

Syntax

```
ipsec-tunnel-idle-timeout seconds
```

```
default ipsec-tunnel-idle-timeout
```

seconds

Default: 60

Specifies the number of seconds an IPsec tunnel is idle before tunnel deletion is triggered. *seconds* must be an integer value between 10 and 600.

default

Returns the command to its default setting of 60.

Usage

When there are no bearers on a particular IPsec tunnel, GTPUMGR initiates the delete for that tunnel. This timer helps to avoid unnecessary IPsec tunnel deletions for an idle tunnel.

Example

The following command sets the IPsec tunnel idle timeout to 100 seconds

```
ipsec-tunnel-idle-timeout 100
```

max-retransmissions

Configures the maximum retry limit for GTP-U echo retransmissions.

Product

GGSN, P-GW, S-GW

Privilege

Administrator

Syntax

```
max-retransmissions num
```

```
no max-retransmissions
```

num

Default: 4

Specifies the number of GTP-U echo message retransmissions allowed before triggering a path failure error condition. *num* must be an integer value from 0 to 15.

no

Disables the feature.

Usage

Use this command to set the maximum number of GTP-U echo message retransmissions in order to define a limit that triggers a path failure error.

Example

The following command sets the maximum GTP-U echo message retransmissions for this service to *10*:

```
max-retransmissions 10
```

path-failure detection-policy

Configures a path failure detection policy on GTP-U echo messages that have been retransmitted the maximum number of retry times.

Product

GGSN, P-GW, S-GW

Privilege

Administrator

Syntax

```
path-failure detection-policy gtp echo  
[ default | no ] path-failure detection-policy
```

gtp echo

Sets the detection policy to detect a failure upon reaching the maximum number of GTP-U echo message retransmissions.

default

Resets the command to its default setting of enabled.

no

Disables the feature.

Usage

Use this command to set the detection policy for path failures.

Example

The following command sets the path failure detection policy to detect failures upon reaching the maximum number of GTP-U echo message retries:

```
path-failure detection-policy gtp echo
```

retransmission-timeout

Configures retransmission timeout for GTP-U echo message retransmissions for this service.

Product

GGSN, P-GW, S-GW

Privilege

Administrator

Syntax

```
retransmission-timeout seconds
```

```
default retransmission-timeout
```

seconds

Default: 5

Specifies the number of seconds between the re-sending of GTP-U echo messages. *seconds* must be an integer value between 1 and 20.

default

Returns the command to its default setting of 5.

Usage

Use this command to set the number of seconds between the retransmission of GTP-U echo messages.

Example

The following command sets the number of seconds between the sending of GTP-U echo messages to 7:

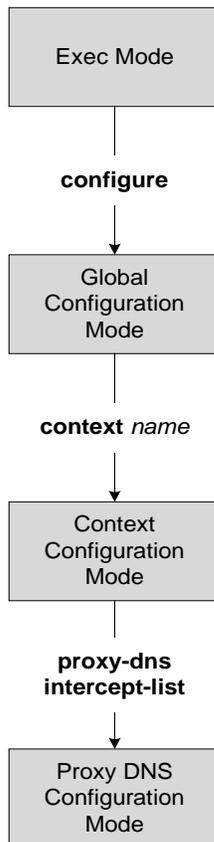

```
retransmission-timeout 7
```

Chapter 129

HA Proxy DNS Configuration Mode Commands

The HA Proxy DNS Configuration Mode is used to create rules for HA proxy DNS intercept lists that redirect packets with unknown foreign DNS addresses to a home network DNS server.

 **Important:** HA Proxy DNS Intercept is a license-enabled feature.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the HA Proxy DNS Configuration Mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the HA Proxy DNS Configuration Mode and returns to the Context Configuration Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the Context Configuration Mode.

pass-thru

Sets IP addresses that should be allowed through the proxy DNS intercept feature.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] pass-thru ip_address [ /ip_mask ]
```

no

Removes the DNS IP address from the pass-thru rule.

```
pass-thru ip_address [ /ip_mask ]
```

Specifies an DNS IP address that is allowed through the intercept feature.

ip_address [/*ip_mask*]: Specifies the IP address and network mask bits. *ip_address* [/*ip_mask*] is specified using the standard IPv4 or IPv6 dotted decimal notation and the mask bits are a numeric value which is the number of bits in the subnet mask (x.x.x.x/x).

Usage

Use this command to identify DNS IP addresses that should be allowed through the intercept feature. For a more detailed explanation of the proxy DNS intercept feature, see the **proxy-dns intercept-list** command in the *Context Configuration Mode Commands* chapter. A maximum of 16 intercept rules (either **redirect** or **pass-thru**) are allowed for each intercept list.

Important: To allow packets through that do not match either the **pass-thru** or **redirect** rules, set a **pass-thru** rule address as: 0.0.0.0/0. If a packet does not match either the **pass-thru** or **redirect** rule, the packet is dropped.

Example

The following command allows a foreign network's DNS with an IP address of 12.3.456.789 to avoid being redirected:

```
pass-thru 12.3.456.789
```

redirect

DNS IP addresses from foreign networks matching an IP address in this command are redirected to a home network DNS.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] redirect any [ primary-dns ip_address [ secondary-dns ip_address ] ]
```

no

Removes the DNS IP address from the redirect rule.

primary-dns ip_address

Specifies the IP address of the primary home network DNS.

ip_address is specified using the standard IPv4 or IPv6 dotted decimal notation.

secondary-dns ip_address

Specifies the IP address of the secondary home network DNS.

ip_address is specified using the standard IPv4 or IPv6 dotted decimal notation.

Usage

Use this command to identify DNS IP addresses from foreign networks that are to be redirected to the home DNS. For a more detailed explanation of the Proxy DNS feature, see the `proxy-dns intercept-list` command in the Context Configuration Mode Commands chapter. A maximum of 16 intercept rules (either **redirect** or **pass-thru**) are allowed for each intercept list.

Since this command is configured in the source context, the destination context containing the path to the home network DNS is identified using the Context Configuration Mode command `ip dns-proxy source-address`.

Important: If a packet does not match the **pass-thru** or **redirect** rule, the packet is dropped. If **primary-dns** or **secondary-dns** is not configured, DNS messages are redirected to the primary-dns-server (or the secondary-dns-server) configured for the subscriber OR inside the context.

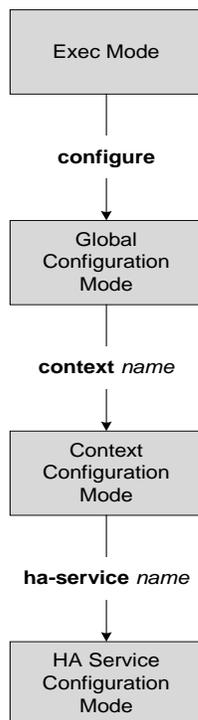

The following command identifies a foreign network DNS with an IP address of 1.23.456.789 and redirects it to a primary home network DNS with an IP address of 1.98.765.432:

```
redirect 1.23.456.789 primary-dns 1.98.765.432.
```

Chapter 130

HA Service Configuration Mode Commands

The Home Agent Service Configuration Mode is used to create and manage the Home Agent (HA) services associated with the current context.

aaa

Configures the sending of subscriber session AAA accounting by the HA service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
aaa { accounting | group string }
```

```
no { accounting | group }
```

no

Disables AAA accounting for the HA service.

accounting

accounting Enables the sending of AAA accounting information for subscriber sessions by the Home Agent (HA), by default is enabled.

group

group configures aaa group for ha-service, **group** has lower priority than subscriber/apn config.

Usage

Enabling the HA service will send all accounting data (start, stop, and interim) to the configured AAA servers.

The chassis is shipped from the factory with the AAA accounting enabled.

Important: In order for this command to function properly, AAA accounting must be enabled for the context in which the HA service is configured using the `aaa accounting subscriber radius` command.

Example

The following command disables aaa accounting for the HA service:

```
no aaa accounting
```

authentication

Configures authentication parameters for a specific HA service of a specific context.

Product

HA, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
authentication {aaa-distributed-mip-keys [ disabled | optional | required ]|dmu-
refresh-key | imsi-auth|mn-aaa {allow-noauth | always| dereg-noauth | noauth |
renew-reg-noauth | renew-and-dereg-noauth } | mn-ha { allow-noauth | always } |
pmip-auth | stale-key-disconnect }
```

```
no authentication {imsi-auth | pmip-auth }
```

```
default authentication { aaa-distributed-mip-keys | dmu-refresh-key | imsi-
auth | mn-aaa | mn-ha | pmip-auth | stale-key-disconnect }
```

no

Disable the parameter.

default

Reset the specified option to its default setting.

aaa-distributed-mip-keys [disabled | optional | required]

Configures use of AAA distributed MIP keys for authenticating RRQ for WiMAX HA calls. Default is disabled.

disabled: Disables using AAA distributed WiMAX MIP keys for authenticating MIP RRQ.

optional: Use AAA distributed WiMAX MIP keys for authenticating RRQ with fallback option to use static/3GPP2 based MIP keys.

required: AAA distributed WiMAX MIP keys for authenticating MIP RRQ are mandatory

dmu-refresh-key

Typically, when a DMU resets then the next MIP re-registration causes MN-HA authorization failure and the HA rejects the MIP RRQ. This parameter enables the HA to retrieve the MN-HA key again from the AAA during the call and to use the freshly retrieved key value to recheck authentication.

Default is disabled.

imsi-auth

Enable uses the IMSI to determine if MN-AAA or MN-FAC extensions are not present in the RRQ.

Default is disabled.

```
mn-aaa { allow-noauth | always | dereg-noauth | noauth | renew-reg-noauth
| renew-and-dereg-noauth }
```

Specifies how mobile node-to-AAA authentication extension in registration requests from the mobile node should be handled by the HA service.

Default is always.

allow-noauth: Specifies that the HA service does not require authentication for every mobile node registration request. However, if the mn-aaa extension is received, the HA service will authenticate it.

always: Specifies that the HA service will perform authentication each time a mobile node registers.

dereg-noauth: Disables authentication request upon de-registration.

noauth: Specifies that the HA service will not look for mn-aaa extension and will not authenticate it.

renew-reg-noauth: Specifies that the HA service will not perform authentication for mobile node re-registrations. Initial registration and de-registration will be handled normally.

renew-and-dereg-noauth: Disables authentication request upon re-registration and de-registration.

```
mn-ha { allow-noauth | always }
```

Specifies whether the HA service looks for an MN-HA authentication extension in the RRQ.

Default is always.

allow-noauth: Allows a request that does not contain the auth extension.

always: A request should always contain the auth extension to be accepted.

```
pmip-auth
```

Specifies whether the HA service looks for an MN-HA authentication extension in the RRQ.

Default is always.

allow-noauth: Allows a request that does not contain the auth extension.

always: A request should always contain the auth extension to be accepted.

```
stale-key-disconnect
```

If MN-HA auth fails for MIP renew and dereg, disconnects the call immediately.

Disabled by default.

Usage

The **authentication** command, combined with a keyword, can be used to specify how the system will perform authentication of registration request messages.

Example

The following command configures the HA service to always perform mobile node authentication for every registration request.

```
authentication mn-aaa always
```

The following command configures the HA service to always look for an MN-HA authentication extension in the RRQ.

```
authentication mn-ha always
```

bind

Binds the HA service to a logical IP interface serving as the Pi interface and specifies the maximum number of subscribers that can access this service over the interface.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
bind address address [ max-subscribers count ]
```

```
no bind address
```

address

Specifies the IP address (*address*) of the interface configured as the Pi interface. *address* is specified in dotted decimal notation.

max-subscribers *count*

Default: 500000

Specifies the maximum number of subscribers that can access this service on this interface. *count* can be configured to any integer value between 0 and 4,000,000.

Important: The maximum number of subscribers supported is dependant on the license key installed and the number of active PACs/PSCs installed in the system. A fully loaded system with 13 active PACs/PSCs can support 1,000,000 total subscribers. Refer to the license key command for additional information.

Usage

Associate the HA service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an Pi interface. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the **max-subscribers** option, be sure to consider the following:

- The total number of interfaces that you will configuring for use as Pi interfaces
- The maximum number of subscriber sessions that all of these interfaces may handle during peak busy hours
- The average bandwidth for each of the sessions
- The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Use the **no bind address** command to delete a previously configured binding.

Example

The following command would bind the logical IP interface with the address of 192.168.3.1 to the HA service and specifies that a maximum of 600 simultaneous subscriber sessions can be facilitated by the interface/service at any given time.

```
bind address 192.168.3.1 max-subscribers 600
```

The following command disables a binding that was previously configured:

```
no bind address
```

default subscriber

Specifies the name of a subscriber profile configured within the same context as the HA service from which to base the handling of all other subscriber sessions handled by the HA service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
default subscriber profile_name
```

```
no default subscriber profile_name
```

profile_name

Specifies the name of the configured subscriber profile. *profile_name* can be between 1 and 127 alpha and/or number characters and is case sensitive.

Usage

Each subscriber profile specifies “rules” such as permissions, PPP settings, and timeout values.

By default, the HA service will use the information configured for the subscriber named default within the same context. This command allows for multiple HA services within the same context to apply different “rules” to sessions they process. Each set of rules can be configured under a different subscriber name which is pointed to by this command.

Use the **no default subscriber** *profile_name* command to delete the configured default subscriber.

Example

To configure the HA service to apply the rules configured for a subscriber named *user1* to every other subscriber session it processes, enter the following command:

```
default subscriber user1
```

encapsulation allow gre

Enables or disables the use of Generic Routing Encapsulation (GRE) when establishing a MIP (Mobile IP) session with an FA. When enabled, if requested by the FA, GRE encapsulation is used when establishing a Mobile IP (MIP) session. If disabled, when an FA requests GRE encapsulation, the HA denies the request.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
encapsulation allow { gre | keyless-gre }
```

```
no encapsulation allow { gre | keyless-gre }
```

gre

Default: Enabled.

Configures the use of GRE in Mobile IP session with an FA.

keyless-gre

Default: Disabled.

Configures the GRE without key encapsulation in Mobile IP session with an FA.

Usage

Use to disable or re-enable the use of GRE encapsulation or Key-less encapsulation for MIP sessions.

In case of chassis HA operating with other vendor equipment, which does not support the 3GPP2 to exchange key, this command with **keyless-gre** keyword will make the chassis HA to accept MIP data with legacy GRE.

Example

To disable GRE encapsulation for MIP sessions, enter the following command:

```
no encapsulation allow gre
```

To re-enable GRE encapsulation for MIP sessions, enter the following command:

```
encapsulation allow gre
```

To enable Key-less GRE encapsulation for MIP sessions, enter the following command:

```
encapsulation allow keyless-gre
```

end

Exits the HA service configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the HA service configuration mode and returns to the context configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

fa-ha-spi

Configures the security parameter index (SPI) between the HA service and the FA.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
fa-ha-spi remote-address fa_ip_address spi-number number { encrypted secret
enc_secret | secret secret } [ description string ] [ hash-algorithm { hmac-md5
| md5 | rfc2002-md5 } ] [ replay-protection { timestamp [ timestamp-tolerance
tolerance ] | nonce } ] [ ] Sprint Only +
```

```
no fa-ha-spi remote-address ha_ip_address spi-number number
```

remote-address *fa_ip_address*

Specifies the IP address of the FA. *fa_ip_address* is an IP address or an IP address and mask expressed in dotted decimal notation.

Important: The system supports unlimited peer FA addresses per HA but only maintains statistics for a maximum of 8192 peer FAs. If more than 8192 FAs are attached, older statistics are identified and overwritten.

spi-number *number*

Specifies the SPI (number) which indicates a security context between the FA and the HA in accordance with RFC 2002.

number can be configured to any integer value between 256 and 4294967295.

encrypted secret *enc_secret* | **secret** *secret*

Configures the shared-secret between the HA service and the FA. The secret can be either encrypted or non-encrypted.

encrypted secret *enc_secret*: Specifies the encrypted shared key (*enc_secret*) between the HA service and the FA. *enc_secret* must be between 1 and 254 alpha and/or numeric characters and is case sensitive.

secret *secret*: Specifies the shared key (*secret*) between the HA service and the FA. *secret* must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **secret** keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

description *string*

This is a description for the SPI. *string* must be an alpha and or numeric string of from 1 through 31 characters.

```
hash-algorithm { hmac-md5 | md5 | rfc2002-md5 }
```

Default: hmac-md5

Specifies the hash-algorithm used between the HA service and the FA.

hmac-md5: Configures the hash-algorithm to implement HMAC-MD5 per RFC 2002bis.

md5: Configures the hash-algorithm to implement MD5 per RFC 1321.

rfc2002-md5: Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.

```
replay-protection { timestamp [timestamp-tolerance tolerance ]| nonce }
```

Specifies the replay-protection scheme that should be implemented by the FA service for this SPI.

nonce: Configures replay protection to be implemented using NONCE per RFC 2002.

timestamp: Configures replay protection to be implemented using timestamps per RFC 2002.

timestamp-tolerance: Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. *tolerance* is measured in seconds and can be configured to any integer value between 1 and 65535. The default is 60.

```
traffic-group grp_num
```

The traffic-group attribute is meant to tag the remote FA so that traffic policy can be enforced according to the traffic-group value. This attribute can be used by ECS to handle subscriber traffic coming from FAs with a specified traffic group differently.

Note: the functionality controlled by this keyword is only available if a License for Content Access Control has been purchased and enabled.

grp_num must be an integer from 1 through 255.

+

More than one of the above keywords can be entered within a single command.

Usage

An SPI is a security mechanism configured and shared by the HA service and the FA. Please refer to RFC 2002 for additional information.

Though it is possible for FAs and HAs to communicate without SPIs being configured, the use of them is recommended for security purposes. It is also recommended that a “default” SPI with a remote address of 0.0.0.0/0 be configured on both the HA and FA to prevent hackers from spoofing addresses.

Important: The SPI configuration on the HA must match the SPI configuration for the FA service on the system in order for the two devices to communicate properly.

A maximum of 2048 SPIs can be configured per HA service.

Use the **no** version of this command to delete a previously configured SPI.

Example

The following command configures the FA service to use an SPI of 512 when communicating with an HA with the IP address 192.168.0.2. The key that would be shared between the HA and the FA service is q397F65. When communicating with this HA, the FA service will also be configured to use the rfc2002-md5 hash-algorithm.

```
fa-ha-spi remote-address 192.168.0.2 spi-number 512 secret q397F65 hash-algorithm rfc2002-md5
```

The following command deletes the configured SPI of 400 for an HA with an IP address of 172.100.3.200:

```
no fa-ha-spi remote-address 172.100.3.200 spi-number 400
```

gre

Configures Generic Routing Encapsulation (GRE) parameters.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
gre { checksum | checksum-verify | reorder-timeout timeout | sequence-mode {
none | reorder } | sequence-numbers }
```

```
no gre { checksum | checksum-verify | sequence-numbers }
```

no

Disables the specified functionality.

checksum

Default: disabled

Enables the introduction of the checksum field in outgoing GRE packets.

checksum-verify

Default: disabled

Enables verification of the GRE checksum (if present) in incoming GRE packets.

reorder-timeout *timeout*

Default: 100

Configures maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets. *timeout* must be an integer from 0 through 5000.

sequence-mode { **none** | **reorder** }

Default: none

Configures how incoming out-of-sequence GRE packets should be handled.

none: Disables reordering of incoming out-of-sequence GRE packets.

reorder: Enables reordering of incoming out-of-sequence GRE packets.

sequence-numbers

Default: Disabled

Enables the insertion of sequence numbers into the GRE packets.

Usage

Use this command to configure how the HA service handles GRE packets.

Example

To set maximum number of milliseconds to wait before processing reordered out-of-sequence GRE packets to *500* milliseconds, enter the following command:

```
gre reorder-timeout 500
```

To enable the reordering of incoming out of sequence GRE packets, enter the following command:

```
gre sequence-mode reorder
```

To enable the insertion or removal of GRE sequence numbers in GRE packets, enter the following command:

```
gre sequence-numbers
```

idle-timeout-mode

Configures the method the HA service uses to determine when to reset a session idle timer.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
idle-timeout-mode { aggressive | handoff | normal } [ upstream-only ]
```

```
default idle-timeout-mode
```

default

Reset the idle timeout mode to the default settings.
Defaults: aggressive, upstream -only is disabled.

aggressive

The session idle timer is reset only when MIP user data is detected. This is the default behavior.

handoff

The session idle timer is reset MIP user data is detected and when an inter-Access Gateway/FA handoff occurs.

normal

The session idle timer is reset when MIP user data is detected and when any MIP control signaling occurs.

upstream-only

Only upstream user data (data from the mobile node) resets the idle timer for the session. This is disabled by default.

Usage

Use this command to set how the current HA service resets the idle timer for a session.

Example

To reset the idle timer whenever user data is detected or whenever an inter-Access Gateway/FA occurs, use the following command:

```
idle-timeout-mode handoff
```

ip context-name

Specifies name of the destination context to be applied to the subscribers; this would take precedence over the same in subscriber configuration and RADIUS return attributes.

This new configuration overrides the local subscriber configuration as well as the return attributes sent by RADIUS. All calls coming to this HA service are assigned this particular destination context and IP address is allocated from the specified IP pool or group that is configured in the context specified in the service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
ip context-name name
```

name

Specifies the name of the context to assign the subscriber to once authenticated. name must be from 1 to 79 alpha and/or numeric characters.

no

Usage

Removes the current assigned context from the subscriber's data. Set the name of the destination context to be applied to the subscribers.

Example

```
ip context-name sampleName  
no ip context-name sampleName
```

ip local-port

Configures the local User Datagram Protocol (UDP) port for the Pi interfaces' IP socket on which to listen for MOBILE IP Registration messages.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
ip local-port number
```

number

Specifies the UDP port number.

number can be any integer value between 1 and 65535.

Usage

Specify the UDP port that should be used for communications between the FA service and the HA.
The chassis is shipped from the factory with the local port set to 434.

Example

The following command specifies a UDP port of 3950 for the HA service to use to communicate with the HA on the Pi interface:

```
ip local-port 3950
```

ip pool

Specifies name of the IP address pool or group to use for subscriber IP address allocation; this takes precedence over the same in subscriber configuration and RADIUS return attributes.

This new configuration overrides the local subscriber configuration as well as the return attributes sent by RADIUS. All calls coming to this HA service are assigned this particular destination context and IP address is allocated from the specified IP pool or group that is configured in the context specified in the service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
ip pool name
```

name

Specifies the logical name of the IP address pool. *name* must be from 1 to 31 alpha and/or numeric characters.

no

Indicates the IP address pool specified is to be removed from the current context's configuration or disable the specified option for an IP pool.

Usage

Define a pool of IP addresses for the context to use in assigning IPs for this service.

Example

The specifies name of the IP address pool or group to use for subscriber IP address allocation:**ip pool pool1**

The following command removes the specified IP address pool:**no ip pool pool1**

isakmp

Configures the crypto map for a peer HA and configures the default crypto map for the FA service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
isakmp { peer-fa fa_address | ] } | skew-lifetime time | aaa-context context_name
}
```

```
no isakmp { peer-fa fa_address | default | skew-lifetime | aaa-context } default
crypto map command is for Combo Phone license
```

no

Deletes the reference to the crypto map for the specified HA, deletes the reference for the default crypto map, resets the skew-lifetime to the default, or resets the aaa-context to the default.

```
peer-fa fa_address { crypto map map_name [| encrypted ] secret secret ]}
```

Configures a crypto map for a peer FA.

- *fa_address*: IP address of the peer FA to which this IPSEC SA will be established.
- **crypto map** *map_name*: The name of a crypto map configured in the same context that defines the IPSec tunnel properties. *map_name* is the name of the crypto map and can be from 1 to 63 alpha and/or numeric characters.
- **encrypted**: This keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **secret** keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.
- **secret** *secret*: The pre-shared secret that will be used to during the IKE negotiation. *secret* is the secret string and can be from 1 to 127 alpha and/or numeric characters.

```
skew-lifetime time
```

Default: 10 seconds

Configures the IKE pre-shared key's time skew.

time is the amount of time the IKE S key fetched from AAA is considered valid after the key has expired. It is measured in seconds and can be configured to any integer value from 1 to 65534.

```
aaa-context context_name
```

Default: The context in which the service is configured

Configures the name of the context on the system in which AAA functionality is performed.

context_name is the name of the context through which the HA service accesses the HAAA server to fetch the IKE S Key and S Lifetime parameters. The name must be from 1 to 63 alpha and/or numeric characters and is case sensitive.

Usage

Use this command to configure the FA-service's per-HA IPSec parameters. These dictate how the HA service is to establish an IPSec SA with the specified FA.

Important: For maximum security, it is recommended that the above command be executed for every possible FA that the HA service communicates with.

Note that once an IPSec tunnel is established between the FA and HA for a particular subscriber, all new Mobile IP sessions using the same FA and HA are passed over the tunnel regardless of whether or not IPSec is supported for the new subscriber sessions. Data for existing Mobile IP sessions is unaffected.

Example

The following command creates a reference for an HA with the IP address 1.2.3.4 to a crypto map named `map1`:

```
isakmp peer-fa 1.2.3.4 crypto-map map1
```

The following command deletes the crypto map reference for the HA with the IP address 1.2.3.4.

```
no isakmp peer-fa 1.2.3.4
```

The following command sets the time an S key can be used after the S lifetime expires to `120` seconds.

```
isakmp skew-lifetime 120
```

The following command creates the default reference for an HA to a crypto map named `map1`, where peer address is unknown:

```
isakmp default crypto-map map1
```

mn-ha-spi

Configures the security parameter index (SPI) between the HA service and the mobile node.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
mn-ha-spi spi-number number [ description string ] [ encrypted secret enc_secret
| secret secret ] [ hash-algorithm { hmac-md5 | md5 | rfc2002-md5 } ] [ permit-
any-hash-algorithm ] [ replay-protection { nonce | timestamp } ] [ timestamp-
tolerance tolerance ]
```

```
no mn-ha-spi spi-number number
```

spi-number *number*

Specifies the SPI (number) which indicates a security context between the mobile node and the HA service in accordance with RFC 2002. *number* can be configured to any integer value between 256 and 4294967295.

description *string*

This is a description for the SPI. *string* must be an alpha and or numeric string of from 1 through 31 characters.

encrypted secret *enc_secret* | **secret** *secret*

Configures the shared-secret between the HA service and the mobile node. The secret can be either encrypted or non-encrypted.

encrypted secret *enc_secret*: Specifies the encrypted shared key (*enc_secret*) between the HA service and the mobile node. *enc_secret* must be between 1 and 254 alpha and/or numeric characters and is case sensitive.

secret *secret*: Specifies the shared key (*secret*) between the HA service and the mobile node. *secret* must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **secret** keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

hash-algorithm { **hmac-md5** | **md5** | **rfc2002-md5** }

Default: hmac-md5

Specifies the hash-algorithm used between the HA service and the mobile node.

hmac-md5: Configures the hash-algorithm to implement HMAC-MD5 per RFC 2002bis.

md5: Configures the hash-algorithm to implement MD5 per RFC 1321.

rfc2002-md5: Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.

permit-any-hash-algorithm

Default: disabled

Allows verification of the MN-HA authenticator using all other hash-algorithms after failure with configured hash-algorithm. Successful algorithm is logged to aid in troubleshooting and is used to create the MN-HA authenticator in the Registration Reply message.

replay-protection { **nonce** | **timestamp** }

Default: timestamp

Specifies the replay-protection scheme that should be implemented by the HA service for this SPI.

nonce: configures replay protection to be implemented using NONCE per RFC 2002.

timestamp: configures replay protection to be implemented using timestamps per RFC 2002.

timestamp-tolerance *tolerance*

Default: 60

Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. If this is set to 0, then time stamp tolerance checking is disabled at the receiving end.

tolerance is measured in seconds and can be configured to any integer value between 0 and 65535.

Usage

An SPI is a security mechanism configured and shared by the HA service and the mobile node. Please refer to RFC 2002 for additional information.

Use the no version of this command to delete a previously configured SPI.

Example

The following command configures the HA service to use an SPI of 640 when communicating with a mobile node. The key that would be shared between the mobile node and the HA service is q397F65.

```
mn-ha-spi spi-number 640 secret q397F65
```

The following command deletes the configured SPI of 400:

```
no mn-ha-spi spi-number 400
```

nat-traversal

This command enables NAT traversal and also configures the forcing of UDP tunnels for NAT traversal.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
nat-traversal [force-accept]
```

```
no nat-traversal [force-accept]
```

```
default nat-traversal [force-accept]
```

no

Disables NAT traversal or disables forcing the acceptance of UDP tunnels for NAT traversal.

default

Reset the defaults for this command.

Default: NAT traversal disabled, force-accept disabled.

force-accept

This keyword configures the HA to accept requests when NAT is not detected but the Force (F) bit is set in the RRQ with the UDP Tunnel Request. By default this type of request is rejected if NAT is not detected.

Usage

Use this command to enable NAT traversal and enable the forcing of UDP tunnels for NAT traversal.

Example

The following command enables NAT traversal for the current HA service and forces the HA to accept UDP tunnels for NAT traversal:

```
nat-traversal force-accept
```

optimize tunnel-reassembly

Configures HA to FA optimization for tunnel reassembly.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
optimize tunnel-reassembly
```

```
[no] optimize tunnel-reassembly
```

Usage

Enabling this functionality fragments large packets prior to encapsulation for easier processing. Tunnel reassembly optimization is disabled by default.

Important: Cisco Systems strongly recommends that you do not use this command without first consulting Cisco Systems Technical Support. This command applies to very specific scenarios where packet reassembly is not supported at the far end of the tunnel. There are cases where the destination network may either discard the data, or be unable to reassemble the packets.

Important: This functionality works best when the HA service is communicating with an FA service running in a system. However, an HA service running in the system communicating with an FA from a different manufacturer will operate correctly even if this parameter is enabled.

Use the **no** version of this command to disable tunnel optimization if enabled.

Example

The following command enables tunnel reassembly optimization:

```
optimize tunnel-reassembly
```

policy bc-query-result

Configures the response code to send in a binding cache (BC) query result in response to a network failure or error.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
policy bc-query-result network-failure code
```

```
[ default ] policy bc-query-result network-failure
```

```
network-failure code
```

Default: *0xFFFF*

Specify the response code for BC responses sent on network failures.

code must be either *0xFFFF* or *0xFFFE*.

Usage

Use this command to specify the type of response code to send in a P-MIP BC query result.

Example

The following command sets the P-MIP BC query result response code to *0xFFFE*:

```
policy bc-query-result network-failure 0xFFFE
```

policy nw-reachability-fail

Specifies the action to take upon detection of an up-stream network -reachability failure.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
policy nw-reachability-fail { reject [ use-reject-code { admin-prohibited |
insufficient-resources } ] | redirect ip_addr1 [ weight value ] [ ip_addr2 [
weight value ] ... ip_addr16 [ weight value ] ] }
```

```
no policy nw-reachability-fail [ redirect ip_addr1 ... ip_addr16
```

]

```
no policy nw-reachability-fail [ redirect ip_addr1 ... ip_addr16 ]
```

Deletes the network reachability policy completely or deletes the specified redirect addresses from the policy.

```
reject [ use-reject-code { admin-prohibited | insufficient-resources } ]
```

Upon network reachability failure reject all new calls for this context.

use-reject-code { **admin-prohibited** | **insufficient-resources** }: When rejecting calls send the specified reject code. If this keyword is not specified the admin-prohibited reject code is sent by default.

```
reject [ use-reject-code { admin-prohibited | insufficient-resources } ]
```

Upon network reachability failure reject all new calls for this context. If no reject code is specified, the HA sends a registration reply code of 81H (admin-prohibited).

use-reject-code { **admin-prohibited** | **insufficient-resources** }: Use the specified reject code when rejecting traffic.

admin-prohibited: When this keyword is specified and traffic is rejected, the error code 81H (admin-prohibited) is returned.

insufficient-resources: When this keyword is specified and traffic is rejected, the error code 82H (insufficient resources) is returned.

```
redirect ip_addr1 [ weight value ] [ ip_addr2 [ weight value ] ...
ip_addr16 [ weight value ] ]
```

Upon network reachability failure redirect all calls to the specified IP address.

ip_addr1: This must be an IPv4 address specified in dotted decimal notation. Up to 16 IP addresses and optional weight values can be entered on one command line.

weight value: When multiple addresses are specified, they are selected in a weighted round-robin scheme. If a weight is not specified the entry is automatically assigned a weight of 1. *value* must be an integer from 1 through 10.

Usage

Use this command to set the action for the HA service to take upon a network reachability failure.

Important: Refer to the context configuration mode command **nw-reachability server** to configure network reachability servers.

Important: Refer to the subscriber configuration mode command **nw-reachability-server** to bind the network reachability to a specific subscriber.

Important: Refer to the **nw-reachability server server_name** keyword of the context configuration mode **ip pool** command bind the network reachability server to an IP pool.

Example

To set the HA service to reject all new calls on a network reachability failure, enter the following command:

```
policy nw-reachability-fail reject
```

Use the following command to set the HA service to redirect all calls to the HA at IP address *192.168.100.10* and *192.168.200.10* on a network reachability failure:

```
policy nw-reachability-fail redirect 192.168.100.10 192.168.200.10
```

policy overload

Configures the overload policy within the HA service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
policy overload { redirectaddress [ weightweight_num ] [ address2 [
weightweight_num ] ... address16[ weightweight_num ] ] | reject[ use-reject-code
{ admin-prohibited | insufficient-resources } ] }
```

```
no policy overload [ redirectaddress [ address2...address16 ]
```

```
no policy overload [ redirect address [ address2...address16 ] ]
```

Deletes a previously set policy or removes a redirect IP address.

overload: This keyword without any options deletes the complete overload policy from the PDSN service.

overload redirect address [address2 ... address16]: deletes up to 16 IP addresses from the overload redirect policy. The IP addresses must be expressed in IP v4 dotted decimal notation

```
redirect address [ weight weight_num ] [ address2 [ weight weight_num ]
... address16 [ weight weight_num ]
```

This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the HA service rejects new sessions with a Registration Reply Code of 136H (unknown home agent address) and provides the IP address of an alternate HA. This command can be issued multiple times.

address: The IP address of an alternate HA expressed in IP v4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

weight weight_num: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. *weight_num* must be an integer from 1 through 10.

```
reject [ use-reject-code { admin-prohibited | insufficient-resources } ] ]
```

This option causes any overload traffic to be rejected. If no reject code is specified, the HA sends a registration reply code of 81H (admin-prohibited).

use-reject-code { admin-prohibited | insufficient-resources }: Use the specified reject code when rejecting traffic.

admin-prohibited: When this keyword is specified and traffic is rejected, the error code 81H (admin-prohibited) is returned.

insufficient-resources: When this keyword is specified and traffic is rejected, the error code 82H (insufficient resources) is returned.

Usage

■ policy overload

The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system.

The system automatically invokes the overload policy when an on-line software upgrade is started.

Use the **no** version of this command to restore the default policy.

The setting for overload policy is reject.

Example

The following command enables an overload redirect policy for the HA service that will send overload calls to either of two destinations with weights of *1* and *10* respectively:

```
policy overload redirect 192.168.100.10 weight 1 192.168.100.20 weight 10
```

policy null-username

Configures the current HA service to accept or reject an RRQ without an NAI extension.

Important: This command is customer specific and is license enabled.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
policy null-username { accept-static | reject }
```

```
no policy null-username
```

no

Set the HA back to the default behavior of rejecting an RRQ without an NAI extension.

accept-static

This enable the HA to accept an RRQ with a static (i.e, non-zero) home address request but without NAI extension, when MN-AAA authentication is disabled at the HA. MN-NAI is required for MN-AAA authentication.

reject

Default. This is the default behavior of rejecting an RRQ without an NAI extension.

Usage

Use this command to enable or disable the HA from accepting an RRQ without an NAI.

Example

The following command enables the current HA service to accept RRQs that do not have an NAI extension:

```
policy null-username accept-static
```

private-address allow-no-reverse-tunnel

This command allows the HA service to accept private addresses without using reverse tunneling.

Important: This command is customer specific and is license enabled.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
private-address allow-no-reverse-tunnel
```

```
no private-address allow-no-reverse-tunnel
```

no

Reject MIP calls that use private addresses and do not use reverse tunneling.

Usage

Use this command to enable or disable the HA from accepting calls that use private addresses without reverse tunneling.

Example

The following command enables the current HA service to accept MIP calls that use private addresses but do not use reverse tunneling:

```
private-address allow-no-reverse-tunnel
```

reg-lifetime

Specifies the longest registration lifetime that the HA service will allow in any Registration Request message from the mobile node.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
reg-lifetime time
```

```
no reg-lifetime
```

no

Sets the registration lifetime to infinite.

time

Specifies the registration lifetime.

time is measured in seconds and can be configured to any integer value between 1 and 65534.

Usage

Use to limit a mobile nodes lifetime. If the mobile node requests a shorter lifetime than what is specified, it is granted. However, Per RFC 2002, should a mobile node request a lifetime that is longer than the maximum allowed by this parameter, the HA service will respond with the value configured by this command as part of the Registration Reply.

The chassis is shipped from the factory with the registration lifetime set to 600 seconds.

Example

The following command configures the registration lifetime for the HA service to be 2400 seconds:

```
reg-lifetime 2400
```

The following command configures an infinite registration lifetime for MIP calls:

```
no reg-lifetime
```

reverse-tunnel

Enables the use of reverse tunneling for a Mobile IP sessions when requested by the mobile node.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
reverse-tunnel
```

```
no reverse-tunnel
```

no

Indicates the reverse tunnel option is to be disabled. When omitted, the reverse tunnel option is enabled.

Usage

Reverse tunneling involves tunneling datagrams originated by the mobile node to the HA service via the FA. When an MN arrives at a foreign network, it listens for agent advertisements and selects an FA that supports reverse tunnels. The MN requests this service when it registers through the selected FA. At this time, the MN may also specify a delivery technique such as Direct or the Encapsulating Delivery Style.

Among the advantages of using reverse-tunneling are that:

- All datagrams from the mobile node seem to originate from its home network
- The FA can keep track of the HA that the mobile node is registered to and tunnel all datagrams from the mobile node to its HA

Use the **no** version of this command to disable reverse tunneling. If reverse tunneling is disabled, and the mobile node does not request it, triangular routing will be performed. routing will be used.

The chassis is shipped from the factory with the reverse tunnel enabled.

Important: If reverse tunneling is disabled on the system and a mobile node requests it, the call will be rejected with a reply code of 74H (reverse-tunneling unavailable).

Example

The following command disables reverse-tunneling support for the HA service:

```
no reverse-tunnel
```

revocation

Enables the MIP revocation feature and configures revocation parameters.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
revocation { enable | max-retransmission number | negotiate-i-bit |
retransmission-timeout secs | send-nai-ext | trigger { handoff | idle-timeout }
}
```

```
no revocation { enable | negotiate-i-bit | send-nai-ext | trigger { handoff |
idle-timeout } }
```

no

Completely disables registration revocation on the HA, disables trigger handoff, or disables revocation on idle timer expiration.

enable

Enables the MIP registration revocation feature on the HA. When enabled, if revocation is negotiated with an FA and a MIP binding is terminated, the HA can send a Revocation message to the FA. This feature is disabled by default.

max-retransmission *number*

Default: 3

The maximum number of retransmissions of a Revocation message before the revocation fails. *number* must be an integer from 0 through 10.

negotiate-i-bit

Default: disabled

Enables the HA to negotiate the i-bit via PRQ/RRP messages and processes the i-bit revocation messages.

retransmission-timeout *secs*

Default: 3

The number of seconds to wait for a Revocation Acknowledgement from the FA before retransmitting the Revocation message. *secs* must be an integer from 1 through 10.

send-nai-ext

Default: off

Enables sending the NAI extension in the revocation message.

trigger { handoff | idle-timeout }

handoff: Default: Enabled

Triggers the HA to send a Revocation message to the FA when an inter-Access Gateway/FA handoff of the MIP session occurs. If this is disabled, the HA is never triggered to send a Revocation message.

idle-timeout: Default: Enabled

Triggers the HA to send a Revocation message to the FA when a session idle timer expires.

Usage

Use this command to enable or disable the MIP revocation feature on the HA or to change settings for this feature. Both the HA and the FA must have Registration Revocation enabled and FA/HA authorization must be in use for Registration Revocation to be negotiated successfully.

Example

The following command enables Registration Revocation on the HA:

```
revocation enable
```

The following command sets the maximum number of retries for a Revocation message to 10:

```
revocation max-retransmission 10
```

The following command sets the timeout between retransmissions to 3:

```
revocation retransmission-timeout 3
```

The behavior of send MIP revocation to FA is as follows:

1st retry: Retransmit in 3 seconds after previous MIP revocation send.

2nd retry : Retransmit in 6 seconds after previous MIP revocation send (9 seconds after sending initial MIP revocation).

3rd retry : Retransmit in 12 seconds after previous MIP revocation send (21 seconds after sending initial MIP revocation).

4th retry : Retransmit in 24 seconds after previous MIP revocation send (45 seconds after sending initial MIP revocation).

5th retry : Retransmit in 48 seconds after previous MIP revocation send (93 seconds after sending initial MIP revocation).

Important: The value of retransmission-timeout doubles. HA disconnects the session forcibly in 120 seconds after sending initial MIP revocation.

setup-timeout

The maximum amount of time allowed for session setup.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
setup-timeout seconds
```

seconds

Default: 60 seconds

The maximum amount of time, in seconds, to allow for setup of a session. must be an integer from 1 through 1000000

Usage

Use this command to set the maximum amount of time allowed for setting up a session.

Example

To set the maximum time allowed for setting up a session to 5 minutes (300 seconds), enter the following command:

```
setup-timeout 300
```

simul-bindings

Specifies the maximum number of “care-of” addresses that can simultaneously be bound for the same user as identified by NAI and Home address.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
simul-bindings number
```

number

Configures the maximum number of simultaneous “care-of” bindings that the HA service will maintain for any given subscriber.

number can be configured to any integer value between 1 and 3.

Usage

Per RFC 2002, the HA service creates a mobile binding record (MBR) for each subscriber session it is facilitating. Each MBR is associated with a care-of address. As the mobile node roams, it is possible that the session will be associated with a new care of address.

Typically, the HA service will delete an old binding and create a new one when the information in the Registration Request changes. However, the mobile could request that the HA maintains previously stored MBRs. This command allows you to configure the maximum number of MBRs that can be stored per subscriber if the requested.

The chassis is shipped from the factory with the simultaneous sessions set to 3.

Example

The following command configures the HA service to support up to 4 MBRs per subscriber:

```
simul-bindings 4
```

threshold init-rrq-rcvd-rate

Set an alarm or alert based on the average number of calls setup per second for the context.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold init-rrq-rcvd-rate high_thresh [ clear low_thresh ]
```

```
no threshold init-rrq-rcvd-rate
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold average number of calls setup per second must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear *low_thresh*

Default:0

The low threshold average number of calls setup per second that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the average number of calls setup per second is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of calls setup per second based on the following rules:

- **Enter condition:** Actual number of calls setup per second > High Threshold
- **Clear condition:** Actual number of calls setup per second < Low Threshold

Example

The following command configures a number of calls setup per second threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold init-rrq-rcvd-rate 1000 clear 500
```

threshold ipsec-call-req-rej

Configures a threshold for the total IPSec calls request rejected.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold ipsec-call-req-rej high_thresh [ clear low_thresh ]
```

```
no threshold ipsec-call-req-rej
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of IPSec call requests rejected per second must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 1000000.

clear *low_thresh*

Default: 0

The low threshold number of IPSec call requests rejected per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thresh can be configured to any integer value between 0 and 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of IPSec call requests rejected is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPSec IKE requests on the following rules:

- **Enter condition:** Actual number of IPSec IKE requests > High Threshold
- **Clear condition:** Actual number of IPSec IKE requests < Low Threshold

Example

The following command configures a number of IPSec call requests rejected threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-call-req-rej 1000 clear 800
```

threshold ipsec-ike-failrate

Configures a threshold for the percentage of IPsec IKE failures.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold ipsec-ike-failrate high_thresh [ clear low_thresh ]  
no threshold ipsec-ike-failrate
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold percentage of IPsec IKE failures per second must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 100.

clear *low_thresh*

Default: 0

The low threshold percentage of IPsec IKE failures per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thresh can be configured to any integer value between 0 and 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the percentage of IPsec IKE failures is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the percentage of IPsec IKE failures on the following rules:

- **Enter condition:** Percentage of IPsec IKE failures > High Threshold
- **Clear condition:** Percentage of IPsec IKE failures < Low Threshold

Example

The following command configures a percentage of IPsec IKE failures threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-ike-failrate 90 clear 80
```

threshold ipsec-ike-requests

Configures a threshold for the total IPsec IKE failures.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold ipsec-ike-failures high_thresh [ clear low_thresh ]
```

```
no threshold ipsec-ike-failures
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of IPsec IKE failures per second must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 1000000.

clear *low_thresh*

Default: 0

The low threshold number of call IPsec IKE failures per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thresh can be configured to any integer value between 0 and 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of IPsec IKE failures is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPsec IKE failures on the following rules:

- **Enter condition:** Actual number of IPsec IKE failures > High Threshold
- **Clear condition:** Actual number of IPsec IKE failures < Low Threshold

Example

The following command configures a number of IPsec IKE failures threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-ike-failures 1000 clear 800
```

threshold ipsec-ike-failures

Configures a threshold for the total IPsec IKE failures.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold ipsec-ike-failures high_thresh [clear low_thresh ]
```

```
no threshold ipsec-ike-failures
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of IPsec IKE failures per second must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 1000000.

clear *low_thresh*

Default:0

The low threshold number of call IPsec IKE failures per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thresh can be configured to any integer value between 0 and 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of IPsec IKE failures is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPsec IKE failures on the following rules:

- **Enter condition:** Actual number of IPsec IKE failures > High Threshold
- **Clear condition:** Actual number of IPsec IKE failures < Low Threshold

Example

The following command configures a number of IPsec IKE failures threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-ike-failures 1000 clear 800
```

threshold ipsec-tunnels-established

Configures a threshold for the total IPsec tunnels established.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold ipsec-tunnels-established high_thresh [ clear low_thresh ]
```

```
no threshold ipsec-tunnels-established
```

```
no
```

Deletes the alert or alarm.

```
high_thresh
```

Default: 0

The high threshold number of IPsec tunnels established per second must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 1000000.

```
clear low_thresh
```

Default:0

The low threshold number of call IPsec tunnels established per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thresh can be configured to any integer value between 0 and 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of IPsec tunnels established is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPsec tunnels established on the following rules:

- **Enter condition:** Actual number of IPsec tunnels established > High Threshold
- **Clear condition:** Actual number of IPsec tunnels established £ Low Threshold

Example

The following command configures a number of IPsec tunnels established threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-tunnels-established 1000 clear 800
```

threshold ipsec-tunnels-setup

Configures a threshold for the total IPsec tunnels setup.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold ipsec-tunnels-setup high_thresh [ clear low_thresh ]
```

```
no threshold ipsec-tunnels-setup
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of IPsec tunnels setup per second must be met or exceeded within the polling interval to generate an alert or alarm.

high_thresh can be configured to any integer value between 0 and 1000000.

```
clear low_thresh
```

Default:0

The low threshold number of call IPsec tunnels setup per second that must be met or exceeded within the polling interval to clear an alert or alarm.

low_thresh can be configured to any integer value between 0 and 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of IPsec tunnels setup is equal to or greater than a specified number per second.

Alerts or alarms are triggered for the number of IPsec tunnels setup on the following rules:

- **Enter condition:** Actual number of IPsec tunnels setup > High Threshold
- **Clear condition:** Actual number of IPsec tunnels setup < Low Threshold

Example

The following command configures a number of IPsec tunnels setup threshold of 1000 and a low threshold of 800 for a system using the Alarm thresholding model:

```
threshold ipsec-tunnels-setup 1000 clear 800800
```

threshold reg-reply-error

Set an alarm or alert based on the number of registration reply errors per HA service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold reg-reply-error high_thresh [ clear low_thresh ]
```

```
no threshold reg-reply-error
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear *low_thresh*

Default:0

The low threshold number of registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of registration reply errors is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of registration reply errors on the following rules:

- **Enter condition:** Actual number of registration reply errors > High Threshold
- **Clear condition:** Actual number of registration reply errors < Low Threshold

Example

The following command configures a registration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold reg-reply-error 1000 clear 500
```

threshold rereg-reply-error

Set an alarm or alert based on the number of re-registration reply errors per HA service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold rereg-reply-error high_thresh [ clear low_thresh ]
```

```
no threshold rereg-reply-error
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of re-registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear *low_thresh*

Default:0

The low threshold number of re-registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of re-registration reply errors is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of re-registration reply errors on the following rules:

- **Enter condition:** Actual number of re-registration reply errors > High Threshold
- **Clear condition:** Actual number of re-registration reply errors < Low Threshold

Example

The following command configures a reregistration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold dereg-reply-error 1000 clear 500
```

threshold dereg-reply-error

Set an alarm or alert based on the number of de-registration reply errors per HA service.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
threshold dereg-reply-error high_thresh [ clear low_thresh ]
```

```
no threshold dereg-reply-error
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of de-registration reply errors that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear *low_thresh*

Default:0

The low threshold number of de-registration reply errors that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of de-registration reply errors is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of de-registration reply errors on the following rules:

- **Enter condition:** Actual number of de-registration reply errors > High Threshold
- **Clear condition:** Actual number of de-registration reply errors < Low Threshold

Example

The following command configures a de-registration reply error threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold reg-reply-error 1000 clear 500
```

wimax-3gpp2 interworking

Configures the interworking between WiMAX and 3GPP2 network at HA. This support provides handoff capabilities from 4G to 3G (PDSN) network access and vice-versa.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] wimax-3gpp2 interworking
```

no

Disables the pre-configured interworking between WiMAX and 3GPP2 networks at HA level.

default

Configures the **WiMAX-3GPP2 interworking** to default setting; i.e. disabled.

Usage

Use this command to enable/disable the interworking between WiMAX and 3GPP2 network for seamless session continuity.

This functionality provides HA support for both 4G and 3G technology HA (WiMAX HA and PDSN/HA) for handoff from 4G and 3G network access (ASN GW/FA and PDSN/FA) and vice-versa.

Important: Use this command in conjunction with **authentication aaa-distributed-mip-keys required** command.

Example

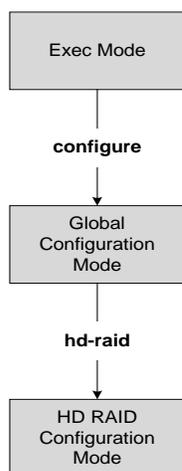

The following command enables the interworking for a subscriber between WiMAX and 3GPP2 network.

```
wimax-3gpp2 interworking
```

Chapter 131

HD RAID Configuration Mode Commands

This mode develops default policies designed to minimize administrative intervention when setting up a RAID on ASR 5000 SMC hard disks.

default

Sets or restores the default condition for the selected parameter

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
default ( overwrite { invalid | unknown | valid } disk | select )
```

```
overwrite { invalid | unknown | valid } disk
```

Configures the system to overwrite any of the disk types

```
select
```

Selects the newer of the valid RAID disks when two valid RAID disks are available.

Usage

Selects default parameters

Example

Use the following example to select the newest disk in an SMC pair:

```
default select
```

end

Exits the HD RAID configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the HD RAID configuration mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

overwrite

Sets the RAID overwrite properties.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] overwrite { invalid | unknown | valid } disk [ -noconfirm ]
```

no

Prevents a disk from being overwritten.

default

Configures the default overwrite action:

invalid

This option allows the system to automatically overwrite invalid disks including empty disks, wrongly partitioned disks, and partially constructed disks.
This is the default overwrite action.

unknown

This option allows the system to automatically overwrite unknown disks that has a valid RAID superblock but is not configured in the standard way; most likely because it has data from a different version.

valid

This option allows the system to automatically overwrite a disk that is a clean RAID component but not part of the current or selected RAID.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Sets a policy for automatically overwriting different disk types. If there is a disk that satisfies the changed overwrite policy then the disk would overwrite immediately.

Example

The following command configures a policy for overwriting invalid RAID disks:

```
overwrite invalid disk -noconfirm
```

select

Configures the disk preference when both hard disks on the ASR 5000 have valid RAID information.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] select { newer | none } disk [ -noconfirm ]
```

default

Configures the command to its default condition.

newer

Selects the newer disk by timestamp and event counter in superblocks. If all are the same, then the same array will start with both SMC disks, but a different array will need admin intervention).

none

Does not select any disk but defers to administrator intervention.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Determines the selected disc when two valid disks from either the same or different RAIDs are running on the ASR 5000.

Example

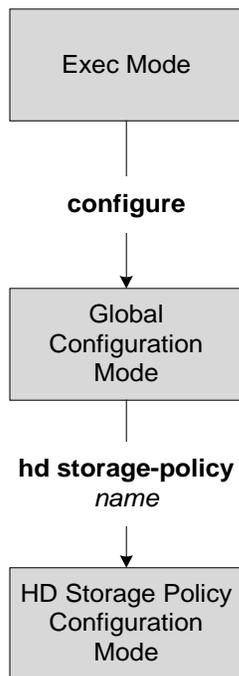

This command forces the RAID to be configured on the newer SMC hard disk:

```
select newer disk -noconfirm
```

Chapter 132

HD Storage Policy Configuration Mode Commands

The HD Storage Policy Configuration Mode is used to configure directory name and file parameters for Diameter record files being stored on the HD storage device.

directory

Configures the name of the directory on the HD storage drive where Diameter records are stored.

Product

HSGW, P-GW, S-GW

Privilege

Administrator

Syntax

```
directory name dir_name
```

```
default directory name
```

default

Returns the command to its default setting of using the policy name as the directory name.

name *dir_name*

Specifies the name to be applied to the directory. *dir_name* must be an alpha and or numeric string from 1 to 63 characters.

When configured, the actual directory path is:

```
/hd-raid/records/<record-type>/<dir_name>/
```

So if the directory name variable is entered as “*sgwpgw*”, the path is:

```
/hd-raid/records/acr/sgwpgw
```

Usage

Use this command to name a directory on the HD storage drive where Diameter records are to be stored.

Example

The following command configures a directory named *cdr1*:

```
directory name cdr1
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax**end**

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

file

Configures file parameters for Diameter records being stored on the HD storage device.

Product

HSGW, P-GW, S-GW

Privilege

Administrator

Syntax

```
file { format acr { custom1...custom10 } | name { extension string | prefix
string } | rotation { record-count num | time-interval sec | volume mb mbytes }
}
```

```
default file { format acr | name prefix | rotation { record-count | time-
interval | volume } }
```

```
no file ( extension | rotation { record-count | time-interval } }
```

default

Returns the command to the default settings for the specified keywords.

no

Removes the configuration for the specified parameters.

```
format acr { custom1...custom10 }
```

Default: **custom1**

Specifies the file format used when storing records on the HD storage device. **custom1** is a vendor-specific file format.

```
name { extension string | prefix string }
```

Specifies a string to be pre-pended or appended to the filenames. By default, the policy name is used for the prefix.

extension string: Specifies a file extension to append to the filename. *string* must be an alpha and/or numeric string from 1 to 10 characters.

prefix string: Specifies a file prefix to append to the filename. *string* must be an alpha and/or numeric string from 1 to 63 characters. This parameter replaces the policy name used by default.

```
rotation { record-count num | time-interval sec | volume mb mbytes }
```

Specifies the triggers that prompt file rotation on the HD storage drive. All options can be configured and upon reaching any of the thresholds, file rotation is initiated.

record-count num: Specifies that file rotation is to occur when the number of records reaches the number configured in this keyword. *num* must be an integer value from 1000 to 65000. Default = 10000

time-interval sec: Specifies that file rotation is to occur a time intervals configure in this keyword. *sec* must be an integer value from 30 to 86400. Default = 3600 (1 hour)

volume mb mbytes: Specifies that file rotation is to occur when the record volume exceeds the value configured in the keyword. *mbytes* must be an integer value from 2 to 40. Default = 4 (mb)

Usage

Use this command to configure file parameters for Diameter records being stored on the HD storage device.

Example

The following command set the file rotation thresholds for files being stored on the HD storage device:

```
file rotation volume mb 4
file rotation record-count 15000
file rotation time-interval 7200
```

The following command replaces the policy name as the prefix of all files being stored through this policy with the prefix *sgw*:

```
file name prefix sgw
```

Chapter 133

HLR Configuration Mode Commands

The HLR Configuration Mode provides the commands and parameters to configure the home location register (HLR) node that is the database containing the subscriber profile and connection information for a specific GPRS/UMTS core network.

In this mode, your prompt will look similar to:

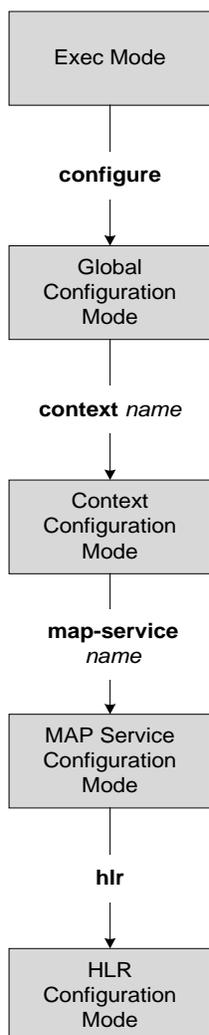

```
[<context_name>]hostname(config-map-service-<svr_name>-hlr)#
```

The HLR Configuration Mode is a sub-mode derived from the MAP Configuration Mode which controls the MAP service configuration. It is the MAP service that provides the application-layer protocol support used to connect the HLR to other nodes in the network such as the SGSN.

When the mode is accessed, the command line will appear similar to

```
[<ctx_name>]asr5000(config-map-service-<service_name>-hlr)#
```

■ file

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

acn-version-retention

This command configures the ACN version retention method.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
acn-version-retention { per-imsi-prefix | per-subscriber }  
default acn-version-retention
```

default

Returns the configuration to the default value: retains the version information per IMSI prefix.

per-imsi-prefix

Retain ACN version information, for communication with the HLR, on a per IMSI prefix basis.

per-subscriber

Retain ACN version information, for communication with the HLR, on a per buscriber basis.

Usage

By default, the SGSN sends ACN version 3 SAI (service area identity) to the HLR. If the SGSN receives an error message indicating that the HLR does not support that version, then the SGSN tries again with an ACN version 2 SAI. Next time the SGSN communicates with that HLR, it retains that version information and version persists based on the IMSI prefix.

Use this command to enable the SGSN to retain version according to subscriber.

Example

Configure the SGSN to retain version information according to the IMSI prefix:

```
default acn-version-retention
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the MAP Service configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the MAP Service configuration mode.

imsi

This command sets up IMSI (International Mobile Subscriber Identity) -based configuration. (IMSI) prefix which includes the Mobile Country Code (MCC), the Mobile Network Code (MNC).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] imsi { any | starts-with prefix_number } { imsi [ sgsn-source-address-format point-code-ssn [ source-ssn ssn ] | isdn isdn_number | mobile-global-title mgt_number [ max-gt-address-len max_gt_address ] | point-code pt-code } }
```

no

Removes the imsi-prefix definition from the configuration.

any

Configures acceptance of any IMSI prefix.

start-with *prefix_number*

Selects IMSI prefix-based routing.
prefix_number is a string of up to 15 integers.

imsi

Enables configurable default behavior for routing.
Entering **imsi** with the **any** keyword preserves the default behavior and the E.212 address is used as a destination address and the MAP request will be sent towards the HLR.
If this keyword is not used with the **any** keyword, then the MAP request will be rejected.

isdn *isdn_number*

Defines the E.164 number of the HLR.
isdn_number is a string of integers, up to 15.

mobile-global-title *mgt_number* [max-gt-address-len *max_gt_address*]

Defines the mobile global title address that the MCC/MNC portion of the IMSI will be converted to. If the maximum GT address length is specified (optional) and if the length of the MGT string is greater than defined, then the least significant digits will be omitted.
mgt_number is a string of integers, up to 18.
max_gt_address is an integer from 1 to 32.

point-code *pt-code* source-ssn *ssn*

Defines the point code for the HLR.
pt-code is a string of digits, up to 11; SS7 format preferred.

sgsn-source-address-format point-code-ssn

Selects HLR call process according to SCCP calling party address of the SGSN. This will be filled at MAP level, including the ITU point code address.

source-ssn *ssn*

Defines the SSN of the source that will be used for the call filtering.

ssn: Must be an integer from 1 to 255.

Usage

Routing will be done according to IMSI parameters configured with this command or according to the mobile global title address (replacing the MCC/MNC portion of the IMSI) is so specified.

Example

```
imsi starts-with 3 isdn 123456789 sgsn-source-address-form at point-code-ssn
```

policy routing

This command configures the policy for the routing of MAP messages. If this command is not configured or disabled (with the **default** keyword), then routing is done according to the configuration of the IMSI parameters.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] policy routing { hlr-isdn | ms-isdn }
```

default

Resets the policy routing to the system default, disabled.

no

Removes the policy routing configuration from the system.

hlr-isdn

Selects HLR-ISDN based routing.

ms-isdn

Selects mobile station (MS)-ISDN based routing.

Usage

Use this command to set the policy for routing MAP messages.

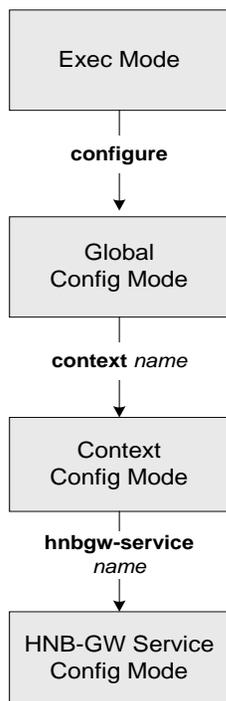

Example

```
policy routing hlr-isdn
```

Chapter 134

HNB-GW Service Configuration Mode Commands

The 3G UMTS Home-NodeB Gateway Service Configuration Mode is used to create, provide, and manage the Femto UMTS HNB access with UMTS core network in a 3G UMTS network.

access-control-db

This command configures the access control database parameters in HNB-GW service instance to provide HNB and UE access control functionality on HNB-GW node.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
access-control-db imsi-purge-timeout {immediiate | dur }
```

```
default access-control-db imsi-purge-timeout
```

default

Sets the default value to HNB-UE access control database on HNB-GW service instance. Default timeout duration for purging of IMSI White List from HNB-GW Access Control database is 24 hours. By this command the HNB-GW service waits for 24 hours after all referenced HNBs de-registered and purge the records after that.

immediiate

Sets the HNB-GW service to purge the HNB-UE access control database on HNB-GW service instance immediately after all referenced HNBs de-registered.

imsi-purge-timeout *dur*

Sets the timeout duration for access control database on HNB-GW service instance to wait for *dur* minutes before purging the IMSI values received as White List from HMS/BAC. After all HNBs de-registered, the Access Control database on HNB-GW maintain the IMSI White List received from HMS/BAC during HNB registration procedure in HNB-GW service for the configured *dur* in minutes before purging the list. The *dur* is timeout value in minutes and must be an integer from 1 through 1440.

Usage

Use this command to configure the HNB-UE access control database parameters on HNB-GW service. This command sets the timeout duration to maintain the IMSI White List received from HMS/BAC during HNB registration procedure in HNB-GW service for the configured *dur* in minutes after de-registration of all referenced HNBs from HNB-GW node and then purge the database.

Example

Following command sets the HNB-GW service instance to purge all IMSI records from HNB-UE access control database immediately after all referenced HNBs de-registered from HNB-GW service instance.

```
access-control-db imsi-purge-timeout immediiate
```

associate gtpu-service

This command associates a previously configured GTP-U service to bind the HNB-GW service with an HNB towards the HNB side. A GTP-U service must be configured in Context Configuration mode before using this configuration.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
associate gtpu-service svc_name
```

```
no associate gtpu-service
```

no

Removes the associated GTP-U service from this HNB-GW service configuration.

svc_name

Identifies the name of the GTP-U service pre-configured in Context configuration mode to associate with an HNB-GW service towards the Home-NodeB side.

The *svc_name* must be an alphanumeric string from 1 through 63 characters.

Usage

Use this command to configure GTP-U data plan between HNB-GW service and Home-NodeB. The service defined for GTP-U can be configured in Context configuration mode.

Important: Another GTP-U service can be used to bind the HNB-GW service towards the Core Network and can be configured in HNB-PS Configuration mode. For more information on GTP-U service configuration, refer *GTP-U Service Configuration Mode Commands*.

Example

Following command associates GTP-U service named *gtpu-hnb1* with specific HNB-GW service towards Home-NodeB side.

```
associate gtpu-service gtpu-hnb1
```

associate rtp pool

This command associates a previously defined RTP pool (IP pool) with the HNB-GW service. This pool is used by HNB-GW to send an IP address to HNB where HNB uses it to map the RTP streams over Iuh interface. This command is used for RTP stream management on HNB-GW.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
associate rtp pool pool_name
```

```
no associate rtp pool
```

no

Removes the associated RTP pool (IP pool) from this HNB-GW service configuration.

pool_name

Identifies the name of the RTP IP pool pre-configured in Context configuration mode to associate with an HNB-GW service to be used for assignment of IP address to HNB-GW node and send it to HNB to map the RTP streams with it over Iuh interface.

The *pool_name* must be an alphanumeric string from 1 through 31 characters.

Important: For IP pool (RTP pool) configuration, refer **ip pool** command in *Context Configuration Mode Commands* chapter.

Usage

Use this command to associate an RTP pool (IP Pool) with an HNB-GW service for allotment of RTP IP address to HNB-GW node and send the same to HNB for RTP stream management support. The HNB maps the RTP streams with received IP address(es) while communicating with HNB-GW over Iuh interface where HNB-GW communicates with MSC/VLR through IuCS-over-IP tunnel.

This command is used for RTP stream management on HNB-GW.

Important: This command must be used to provide IP address for mapping of RTP streams on Iuh interface between HNB and HNB-GW.

Example

Following command associates RTP pool named *rtp_1* with HNB-GW service for RTP stream end point from Home-NodeB:

```
associate rtp pool rtp_1
```

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

handin

This command configures the HNB-GW service instance to allow/disallow the incoming hand-over of an MS in HNB-GW via SRNS Relocation procedure for the particular PS/CS core network (CN) domain.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[no | default] handin cn-domain [cs | ps]
```

no

Disallows the incoming MS hand-over for the particular CN domain via SRNS Relocation procedure in an HNB-GW service instance.

default

Sets the HNB-GW service instance to allow the incoming MS hand-over for the particular CN domain via SRNS Relocation procedure in an HNB-GW service instance.

cs

Sets the HNB-GW service instance to allow the incoming MS hand-over for the CS core network domain via SRNS Relocation procedure in an HNB-GW service instance.

ps

Sets the HNB-GW service instance to allow the incoming MS hand-over for the PS core network domain via SRNS Relocation procedure in an HNB-GW service instance.

Usage

Use this command to set HNB-GW service instance for allowing/disallowing incoming hand-over of an MS in HNB-GW via SRNS Relocation procedure for PS or CS core network domain.

Example

The following command configures the HNB-GW service instance to allow hand-over of an MS in HNB-W via SRNS Relocation procedure for PS core network domain:

```
handin ps
```

ip iu-qos-dscp

This command enables/disables DSCP marking parameter for control and data packets carried by the IP protocols and their payloads on IuCS/IuPS interface towards MSC/SGSN.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
ip iu-qos-dscp protocol { sctp payload all | udp payload { gtpu | rtcp| rtp} }
dscp_code
```

```
[default | no] ip iu-qos-dscp protocol { sctp payload all | udp payload { gtpu
| rtcp| rtp} }
```

no

Use of this keyword to make the configuration **pass-through mode** or not marking DSCP at all in the packets. Use of this keyword is allowed even when there is no previous DSCP configuration done.

default

Restores the QoS parameters to its default setting.

sctp payload all dscp_code

Specifies the QoS traffic pattern towards MSC/SGSN in SCTP protocol association over IuCS/IuPS interface.

By this keyword the Traffic classes specified by a user based on SCTP protocol and all type of payload identified based on the transport level port numbers.

By default DSCP codes **cs5** is supported for **all** payloads in SCTP protocol.

udp payload { gtpu | rtcp| rtp} dscp_code

Specifies the QoS traffic pattern towards MSC/SGSN in SCTP protocol association over IuCS/IuPS interface.

By this keyword the Traffic classes specified by a user based on UDP protocol and GTPU, RTCP, and RTP type of payload identified based on the transport level port numbers.

Default DSCP code in UDP traffic are:

- GTP-U**: cs1
- RTCP**: ef
- RTP**: af41

dscp_code

Specifies the QoS DSCP codes supported for SCTP and UDP traffic and its payloads towards MSC/SGSN over IuCS/IuPS interface.

following type of DSCP codes *dscp_code* are supported over IuH interface:

- af11**: Marks traffic as Assured Forwarding 11 PHB (high throughput data)
- af12**: Marks traffic as Assured Forwarding 12 PHB (high throughput data)
- af13**: Marks traffic as Assured Forwarding 13 PHB (high throughput data)
- af21**: Marks traffic as Assured Forwarding 21 PHB (low latency data)
- af22**: Marks traffic as Assured Forwarding 22 PHB (low latency data)
- af23**: Marks traffic as Assured Forwarding 23 PHB (low latency data)
- af31**: Marks traffic as Assured Forwarding 31 PHB (multimedia streaming)
- af32**: Marks traffic as Assured Forwarding 32 PHB (multimedia streaming)
- af33**: Marks traffic as Assured Forwarding 33 PHB (multimedia streaming)
- af41**: Marks traffic as Assured Forwarding 41 PHB (multimedia conferencing). This is the default DSCP code for RTP payloads in UDP protocol.
- af42**: Marks traffic as Assured Forwarding 42 PHB (multimedia conferencing)
- af43**: Marks traffic as Assured Forwarding 43 PHB (multimedia conferencing)
- cs1**: Marks traffic with Class Selector 1 (low priority data). This is the default DSCP code for GTP-U payloads in UDP protocol.
- cs2**: Marks traffic with Class Selector 2 (OAM)
- cs3**: Marks traffic with Class Selector 3 (broadcast video)
- cs4**: Marks traffic with Class Selector 4 (real-time interactive)
- cs5**: Marks traffic with Class Selector 5 (signaling). This is the default DSCP code for all SCTP payloads.
- cs6**: Marks traffic with Class Selector 6 (network control)
- df** : Marks traffic as Default Forwarding (best effort: DSCP = 0)
- ef**: Marks traffic as Expedited Forwarding PHB (telephony). This is the default DSCP code for RTCP payloads in UDP protocol.

Usage

Use this command to enable/disable the DSCP marking for control and data packets carried by the IP protocols and their payloads on IuCS/PS. This command assigns the DSCP levels to specific traffic patterns in order to ensure that the packets are delivered according to the precedence with which they are tagged. The Diffserv markings are applied to the IP header of every subscriber data packet transmitted over IuCS/IuPs interface(s) towards MSC/SGSN.

This command adds DSCP marking on egress traffic going towards CN (CS/PS). To make the configuration **pass-through mode** or not marking DSCP at all in the packets, **no** variant of command is used. Use of **no** is allowed even when there is no previous DSCP configuration done.

Important: In this configuration **no** keyword is not meant to disable/remove a previous configuration, like with other commands on ASR5000.

When DSCP configuration is not specified, DSCP value in the ingress (from CN) and egress (to HNB) packets remain unchanged (pass-through mode). Multiple traffic classes can share the same code point value.

Following type shown in following tables respectively:

Table 23. Supported DSCP Codes and Service Class

Service Class	DSCP Code	Service Class	DSCP Code
high throughput data	af11 af12 af13	low priority data	cs1
low latency data	af21 af22 af23	OAM	cs2
multimedia streaming	af31 af32 af33	broadcast video	cs3
multimedia conferencing	af41 af42 af43	real-time interactive	cs4
best effort/ default forwarding, value zero	df	Signaling	cs5
telephony	ef	network control	cs6

The DSCP level can be configured for multiple traffic patterns within a single instance of this command.

Example

The following command configures the DSCP code for the SCTP IuCS/IuPS streaming traffic pattern for all payloads to be **ef**:

```
ip iu-qos-dscp protocol sctp payload all ef
```

ip iuh-qos-dscp

This command enables/disables DSCP marking parameter for control and data packets carried by the IP protocols and their payloads on IuH towards HNB.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
ip iuh-qos-dscp protocol { sctp payload all | udp payload { gtpu | rtcp | rtp } }
dscp_code
```

```
[default | no] ip iuh-qos-dscp protocol { sctp payload all | udp payload { gtpu
| rtcp | rtp } }
```

no

Use of this keyword to make the configuration **pass-through mode** or not marking DSCP at all in the packets. Use of this keyword is allowed even when there is no previous DSCP configuration done.

default

Restores the QoS parameters to its default setting.

sctp payload all dscp_code

Specifies the QoS traffic pattern towards HNB in SCTP protocol association over IuH interface.

By this keyword the Traffic classes specified by a user based on SCTP protocol and all type of payload identified based on the transport level port numbers.

By default DSCP codes **cs5** is supported for **all** payloads in SCTP protocol.

udp payload { gtpu | rtcp | rtp } dscp_code

Specifies the QoS traffic pattern towards HNB in SCTP protocol association over IuH interface.

By this keyword the Traffic classes specified by a user based on UDP protocol and GTPU, RTCP, and RTP type of payload identified based on the transport level port numbers.

Default DSCP code in UDP traffic are:

- **GTP-U**: cs1
- **RTCP**: ef
- **RTP**: af41

dscp_code

Specifies the QoS DSCP codes supported for SCTP and UDP traffic and its payloads towards HNB over IuH interface.

following type of DSCP codes *dscp_code* are supported over IuH interface:

- **af11**: Marks traffic as Assured Forwarding 11 PHB (high throughput data)

- **af12**: Marks traffic as Assured Forwarding 12 PHB (high throughput data)
- **af13**: Marks traffic as Assured Forwarding 13 PHB (high throughput data)
- **af21**: Marks traffic as Assured Forwarding 21 PHB (low latency data)
- **af22**: Marks traffic as Assured Forwarding 22 PHB (low latency data)
- **af23**: Marks traffic as Assured Forwarding 23 PHB (low latency data)
- **af31**: Marks traffic as Assured Forwarding 31 PHB (multimedia streaming)
- **af32**: Marks traffic as Assured Forwarding 32 PHB (multimedia streaming)
- **af33**: Marks traffic as Assured Forwarding 33 PHB (multimedia streaming)
- **af41**: Marks traffic as Assured Forwarding 41 PHB (multimedia conferencing). This is the default DSCP code for RTP payloads in UDP protocol.
- **af42**: Marks traffic as Assured Forwarding 42 PHB (multimedia conferencing)
- **af43**: Marks traffic as Assured Forwarding 43 PHB (multimedia conferencing)
- **cs1**: Marks traffic with Class Selector 1 (low priority data). This is the default DSCP code for GTP-U payloads in UDP protocol.
- **cs2**: Marks traffic with Class Selector 2 (OAM)
- **cs3**: Marks traffic with Class Selector 3 (broadcast video)
- **cs4**: Marks traffic with Class Selector 4 (real-time interactive)
- **cs5**: Marks traffic with Class Selector 5 (signaling). This is the default DSCP code for all SCTP payloads.
- **cs6**: Marks traffic with Class Selector 6 (network control)
- **df** : Marks traffic as Default Forwarding (best effort: DSCP = 0)
- **ef**: Marks traffic as Expedited Forwarding PHB (telephony). This is the default DSCP code for RTCP payloads in UDP protocol.

Usage

Use this command to enable/disable the DSCP marking for control and data packets carried by the IP protocols and their payloads on IuH. This command assigns the DSCP levels to specific traffic patterns in order to ensure that the packets are delivered according to the precedence with which they are tagged. The Diffserv markings are applied to the IP header of every subscriber data packet transmitted over IuH interface(s) towards HNB.

This command adds DSCP marking on egress traffic going towards HNB. To make the configuration **pass-through mode** or not marking DSCP at all in the packets, **no** variant of command is used. Use of **no** is allowed even when there is no previous DSCP configuration done.

Important: In this configuration **no** keyword is not meant to disable/remove a previous configuration, like with other commands on ASR5000.

When DSCP configuration is not specified, DSCP value in the ingress (from CN) and egress (to HNB) packets remain unchanged (pass-through mode). Multiple traffic classes can share the same code point value. Following type shown in following tables respectively:

Table 24. Supported DSCP Codes and Service Class

Service Class	DSCP Code	Service Class	DSCP Code
high throughput data	af11 af12 af13	low priority data	cs1
low latency data	af21 af22 af23	OAM	cs2
multimedia streaming	af31 af32 af33	broadcast video	cs3
multimedia conferencing	af41 af42 af43	real-time interactive	cs4
best effort/ default forwarding, value zero	df	Signaling	cs5
telephony	ef	network control	cs6

The DSCP level can be configured for multiple traffic patterns within a single instance of this command.

Example

The following command configures the DSCP code for the SCTP IuH streaming traffic pattern for all payloads to be **ef**:

```
ip iuh-qos-dscp protocol sctp payload all ef
```

radio-network-plmn

This command creates/removes and enters the HNB-RN-PLMN Configuration mode and associates/disassociates it with HNB-GW service. This mode provides configuration mode to configure various parameters for radio network public mobile land networks (PLMNs). A maximum of 16 radio PLMN IDs can be configured in an HNB-GW service.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
radio-network-plmn mcc mcc_num mnc mnc_num [ -noconfirm ]
```

```
no radio-network-plmn mcc mcc_num mnc mnc_num
```

no

Removes the configured radio network PLMN identifier for an HNB-GW service.

Caution: Removing the PLMN identifier is a disruptive operation; the HNB-GW service shall be re-started.

mcc *mcc_num*

Specifies the mobile country code (MCC) part of radio network PLMN identifier. *mcc_num* must be an integer value from 101 through 998.

mnc *mnc_num*

Specifies the mobile network code (MNC) part of radio network PLMN identifier. *mnc_num* must be an integer value from 01 through 99 or 100 through 998.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

Usage

Use this command to configure the radio network PLMN identifier for an HNB-GW service. This command also creates a configuration mode to configure various parameters for defined radio network PLMN identifier in HNB-GW service.

Caution: Changing or removing the PLMN identifier is a disruptive operation; the MME service shall be re-started.

Entering this command results in the following prompt:

```
[context_name]hostname(config-radio-network-plmn)#
```

A maximum of 16 radio network PLMN identifiers are supported for an HNB-GW service.

■ radio-network-plmn

Example

The following command configures the radio network PLMN identifier with MCC value as *102* and MNC value as *20* for an HNB-GW service:

```
radio-network-plmn mnc 102 mnc 20
```

ranap reset

This command configures various RAN Application Part reset procedure parameters in HNB access network through HNB-GW service instance.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
ranap reset {ack-timeout timer_value | guard-timeout g_timer | hnbgw-initiated | max-retransmissions retries}
```

```
default ranap reset {ack-timeout | guard-timeout | hnbgw-initiated | max-retransmissions}
```

```
no ranap hnbgw-initiated
```

default

Resets the RANAP RESET parameters on HNB-GW service instance.

no

Disables the RANAP RESET procedure related parameters in an HNB-GW service instance.

ack-timeout *timer_value*

Set the timer value in seconds to wait for Reset Acknowledge from SGSN/MSC. This is used during HNB-GW initiated RANAP RESET procedure in HNB-GW service instance.

timer_value must be an integer value from 5 through 10.

Default: 10

guard-timeout *g_timer_value*

Sets the timer value to send Reset Acknowledge to SGSN/MSC. After this duration the HNBGW sends RESET-ACK to SGSN/MSC. This is used during SGSN/MSC initiated RANAP RESET procedure in HNB-GW service instance.

g_timer_value must be an integer value from 5 through 10.

Default: 10

hnbgw-initiated

Enables the HNB-GW Initiated RANAP RESET procedures.

Default: Disabled

max-retransmission *retries*

Sets the maximum number of retries allowed for transmission of RESET-ACK message to SGSN/MSC. This is used during RANAP RESET procedure in HNB-GW service instance.

retries must be an integer value from 0 through 2. When 0 is used retransmission is disabled.

ranap reset

Default: 1

Usage

Use this command to configure the RANAP RESET procedure related parameters in HNB-GW service.

Example

The following command configures the HNB-GW initiated RANAP RESET Procedure for an HNB-GW service:

```
ranap reset hnbgw-initiated
```

rtcp report

This command enables/disables the generation of RTP Control Protocol (RTCP) packet/report types on a per HNBGW service instance basis. It also sets the time interval in seconds between two consecutive RTCP reports.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
rtcp report interval dur
```

```
[no | default] rtcp report interval
```

no

Disables the RTCP report generation on HNB-GW service. When RTP configuration is not explicitly mentioned, this is the default behavior.

default

Restores the report interval value to its default value of 5 seconds.

interval *dur*

Default: 5 seconds.

Sets the time interval in seconds between two consecutive RTCP reports.

dur is measured in seconds and can be configured to any integer value from 5 to 30.

Usage

Use this command to configure the enabling or disabling of the generation of RTCP packet/ report types on a per HNBGW service instance basis and sets the specified time interval in seconds between two consecutive RTCP reports.

RTCP enables the receiver to detect if there is any packet loss and needs to compensate for any delay jitter. RTP and RTCP protocols work independently of the underlying Transport layer and Network layer protocols. Whenever this command is disabled, RTCP report generation stops from the next expiry of the previously configured interval and after enabling, reports are generated only for the calls that established as new calls in the future. For existing calls reports generated as per configuration in place.

RTCP reports are generated for each RAB for RTP received from and sent to IuH interface.

Important: The same interval is applicable for all kinds of RTCP packets/ reports across all sessions on an HNB-GW service.

Example

The following command configures the RTCP report generation interval to 15 seconds on an HNB-GW service for RTP stream:

■ rtcp report

```
rtcp report interval 15
```

rtp mux

This command configures the HNB-GW service to allow an Home-NodeB to multiplex multiple RTP streams in one IP packet. This configuration support is provided for RTP stream management feature on HNB-GW.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[no | default] rtp mux
```

default

Sets the multiplexing option to default state of “disabled”.

no

Removes the configured option to multiplex multiple RTP stream in one packet by Home-NodeB in HNB-GW configuration.

Usage

Use this command to allow an Home-NodeB to multiplex multiple RTP streams in one IP packet. This configuration support is provided for RTP stream management feature on HNB-GW and it is disabled by default.

Example

The following command sets the HNB-GW to allow HNB to multiplex multiple RTP stream in one packet:

```
rtp mux
```

sctp

This command configures the SCTP related parameters like timeout duration for various timers and cookie life over IuH interface an HNB-GW service.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```

sctp alpha-rto alpha_rto_dur

sctp beta-rto beta_rto_dur

sctp checksum-type [ adler32 | crc32 ]

sctp cookie-life cookie_life

sctp max-retx [ init | path | assoc ] max_retry

sctp mtu-size [ start | min | max ] mtu_byte

sctp rto { initial ini_rto_dur | min min_rto_dur | max max_rto_dur }

sctp sack-frequency sack_frq

sctp sack-period sack_dur

sctp max-in-strms in_strms

sctp max-out-strms out_strms

default sctp { alpha-rto | beta-rto | checksum-type | cookie-life | max-retx [
init | path | assoc] | mtu-size [start | min | max] | rto { initial | min |
max} | sack-frequency | sack-period | max-in-strms | max-out-strms }

```

default

Restores the SCTP parameters to default value in HNB-GW service instance. Default values for all parameters are as follows:

- **alpha-rto**: 5 seconds
- **beta-rto**: 10 seconds
- **checksum-type**: CRC32
- **cookie-life**: 600 ms
- **max-retx init**: 5 retries
- **max-retx path**: 5 retries
- **max-retx assoc**: 10 retries

- mtu-size min**: 508 Bytes
- mtu-size max**: 1500 Bytes
- mtu-size start**: 508 Bytes
- rto initial**: 30 seconds
- rto min**: 10 seconds
- rto max**: 600 seconds
- sack-frequency**: 2
- sack-period**: 2 ms
- max-in-strms**: 4
- max-out-strms**: 4

alpha-rto *alpha_rto_dur*

Default: 5

Sets the alpha retransmission timeout duration in seconds for SCTP association between HNB and HNB-GW. *dur* is measured in seconds and can be configured to any integer value from 0 to 65535. A 'zero' value disables the timer in this configuration.

beta-rto *beta_rto_dur*

Default: 10

Sets the beta retransmission timeout duration in seconds for SCTP association between HNB and HNB-GW. *dur* is measured in seconds and can be configured to any integer value from 0 to 65535. A 'zero' value disables the timer in this configuration.

checksum-type [**adler32** | **crc32**]

Default: CRC32

Sets the checksum algorithm type to be used in SCTP association between HNB and HNB-GW for packet validation.

adler32: specifies the SCTP association to use Adler32 checksum algorithm for packet validation. By default this is disabled.

crc32: specifies the SCTP association to use 32-bit cyclic redundancy check (CRC) algorithm for packet validation. By default this is enabled.

cookie-life *cookie_life*

Default: 600

Sets the COOKIE life in ms for SCTP association between HNB and HNB-GW.

cookie_life is measured in milliseconds and can be configured to any integer value from 500 to 120000.

max-retx [**init** | **path** | **assoc**] *max_retry* }

Sets the maximum number of retries allowed in SCTP states for SCTP association between HNB and HNB-GW.

init: This option sets the maximum attempts allowed after T1-init timer expires. If the T1-init timer expires then the HNB-GW retransmits INIT chunk and re-start the T1-init timer without changing state. This is repeated up to the configured times with this configuration. After that, the HNB-GW aborts the initialization process. Default number of attempts *max_retry* for this state is 5.

path: This option sets the maximum attempts allowed after T3-rtx timer expires. Each time the T3-rtx timer expires on any address, or when a HEARTBEAT sent to an idle address is not acknowledged within a RTO, the error counter of that destination address incremented. When the value in the error counter exceeds this protocol parameter of that HNB address, the HNB-GW marks the destination transport address as inactive. Default number of attempts *max_retry* for this state is 5.

assoc: This option sets the maximum number of consecutive retransmissions to its peer is allowed. If the value of this counter exceeds the limit configured with this keyword the HNB-GW considers the peer HNB unreachable and stop transmitting any more data to it. The SCTP association is automatically closed when the peer endpoint becomes unreachable. Default number of attempts *max_retry* for this state is 10. *max_retry* can be configured to any integer value from 1 to 255.

mtu-size [**min** | **max** | **start**] *mtu_byte*

Sets the maximum transmission unit (MTU) size in Bytes for SCTP association between HNB and HNB-GW.

min: This option sets the minimum size of MTU for SCTP association between HNB and HNB-GW. Default minimum MTU size *mtu_byte* is 508 Bytes.

max: This option sets the maximum size of MTU for SCTP association between HNB and HNB-GW. Default maximum MTU size *mtu_byte* is 1500 Bytes.

start: This option sets the size of MTU for SCTP association at the start of session between HNB and HNB-GW. Default MTU size *mtu_byte* at initial state is 508 Bytes.

mtu_byte can be configured to any integer value from 508 to 65535.

rto { **initial** *ini_rto_dur* | **min** *min_rto_dur* | **max** *max_rto_dur* }

Sets the Retransmission TimeOut (RTO) duration parameters for SCTP association between HNB and HNB-GW.

initial *ini_rto_dur*: This option sets the initial retransmission timeout duration for SCTP association between HNB and HNB-GW. *ini_rto_dur* is RTO duration in seconds must be an integer between 1 through 1200. The default timeout value for *ini_rto_dur* is 30.

min *min_rto_dur*: This option sets the minimal retransmission timeout duration for SCTP association between HNB and HNB-GW. *min_rto_dur* is RTO duration in seconds must be an integer between 1 through 50. The default timeout value for *min_rto_dur* is 10.

max *max_rto_dur*: This option sets the maximum retransmission timeout duration for SCTP association between HNB and HNB-GW. *max_rto_dur* is RTO duration in seconds must be an integer between 5 through 1200. The default timeout value for *max_rto_dur* is 600.

sack-frequency *sack_frq*

Default: 2 chunks

Sets the number of chunks received before sending the Selective Acknowledgement chunk HNB from HNB-GW in SCTP association. SACK chunk is sent to the HNB to acknowledge received DATA chunks and to inform the HNB of gaps in the received subsequences of DATA chunks.

sack_frq is the frequency after which SACK chunk is sent to HNB. *sack_frq* must be an integer value from 1 to 5.

sack-period *sack_dur*

Default: 2 sec.

Sets the duration in seconds after which Selective Acknowledgement chunk is sent to HNB from HNB-GW in SCTP association. SACK chunk is sent to the HNB to acknowledge received DATA chunks and to inform the HNB of gaps in the received subsequences of DATA chunks.

sack_dur is the time period in seconds after which SACK chunk is sent to HNB and must be an integer value from 0 to 5. A 'zero' value disables the parameter.

max-in-strms *in_strms*

Default: 4 streams

Sets the maximum number of inward SCTP streams allowed on HNB-GW for associated HNB in an SCTP association.

in_strms is the maximum incoming SCTP streams allowed from an associated HNB to HNB-GW and must be an integer value from 1 to 16.

max-out-strms *out_strms*

Default: 4 streams

Sets the maximum number of outgoing SCTP streams allowed from HNB-GW for associated HNB in an SCTP association.

out_strms is the maximum outgoing SCTP streams allowed from an associated HNB to HNB-GW and must be an integer value from 1 to 16.

Usage

Use this command to configure the SCTP protocol messaging and session management parameters in SCTP association between HNB and HNB-GW.

Example

The following command sets the SCTP COOKIE life to 600 milliseconds on HNB-GW for the SCTP association:

```
default cookie-life
```

sctp bind

This command configures the SCTP IP address and port that is used for binding the SCTP socket to communicate with the Home-NodeB over Iuh interface with an HNB-GW service.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
sctp bind { address address | port port_num }
[ default | no ] sctp bind { address | port }
```

default

Sets the SCTP port to default value of 600 to communicate with the Home-NodeB using Iuh interface.

address *address*

Specifies the IP address of HNB-GW in IPv4 or IPv6 notation for the interface configured as Iuh interface to connect with Home-NodeB.

address must be an IP address in IPv4 or IPv6 notation.

port *port_num*

Specifies the SCTP port number to communicate with the Home-NodeBs using Iuh interface.

port_num must be an integer between 1 through 65535.

Usage

Use this command to assign the SCTP IP address and port with SCTP socket on HNB-GW to communicate with the Home-NodeB using Iuh interface. This SCTP configuration provides the IP-address and listen port where HNB-GW service shall bind to listen for incoming SCTP associations from HNB.

Example

The following command sets the SCTP port number *999* on HNB-GW to listen from Home-NodeB over Iuh interface:

```
sctp bind port 999
```

The following command sets the SCTP address *1.2.3.4* of HNB-GW to use with Home-NodeB over Iuh interface:

```
sctp bind address 1.2.3.4
```

sctp connection-timeout

This command configures the SCTP connection timeout duration in seconds to explicitly remove the SCTP association with not responding HNB from an HNB-GW service.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
sctp connection-timeout dur  
[ default | no ] sctp connection-timeout
```

no

Disables the connection time out configuration on HNB-GW service.

default

Restores the connection timeout duration value to its default value of 10 seconds.

dur

Default: 10 seconds.

Sets the connection timeout duration in seconds after which the association is explicitly removed. In case of an HNB de-registration scenario, the HNB-GW waits for configured amount time before initiating the procedure to clear the SCTP association.

dur is measured in seconds and can be configured to any integer value from 5 to 30.

Usage

Use this command to configure the minimum duration value before removing the SCTP association between a non-responding HNB and HNB-GW. If HNB registration not happened within the configured period after the SCTP association is established then the SCTP association is explicitly removed. In a scenario where an HNB de-registered due to any reason, the HNB-GW waits for the configured amount of time before initiating the procedure to clear the SCTP association.

Example

The following command sets the SCTP connection timeout duration to 15 second on HNB-GW after expiry of which the SCTP association is removed:

```
sctp connection-timeout 15
```

sctp heart-beat-timeout

This command configures the SCTP heartbeat timer parameters for SCTP connection over IuH interface in an HNB-GW service instance.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
sctp heart-beat-timeout dur
```

```
[ default | no ] sctp heart-beat-timeout
```

no

Disables the heartbeat timer configuration for SCTP over IuH in HNB-GW service instance.

default

Restores the default time out value for heartbeat timer to 30 sec. for SCTP over IuH in HNB-GW service instance.

dur

Default: 30 seconds.

Sets the heartbeat timer timeout duration in seconds after which the next heartbeat command is send to HNB from HNB-GW in SCTP over IuH interface. In case of an HNB de-registration scenario, the HNB-GW waits for configured amount time before initiating the procedure to clear the SCTP association.

dur is measured in seconds and can be configured to any integer value from 1 to 300.

Usage

Use this command to configure the minimum duration value before retransmitting the HEARTBEAT chunk to HNB from HNB-GW in SCTP transmission. By default HNB-GW monitors the reachability of the idle HNBs by sending a HEARTBEAT chunk periodically to the HNB address.

Each time the HEARTBEAT timer expires on any address, or when a HEARTBEAT sent to an idle address is not acknowledged within a Retransmission Timeout duration, the error counter of that HNB incremented.

When the value in the error counter exceeds the protocol parameter for maximum retransmission for that destination address, the HNB-GW mark the destination HNB as inactive and a notification is sent to the upper layer.

Example

The following command sets the SCTP HEARTBEAT timeout duration to 15 second on HNB-GW after expiry of which the HNB-GW retransmits the HEARTBAT chunk to HNB over SCTP association:

```
sctp heart-beat-timeout 15
```

security-gateway aaa

This command associates a pre-configured AAA Service group to use authentication parameters for Security Gateway (SeGW) functionality in HNB-GW service. Associated AAA server group is a pre-configured AAA server group configured in Context configuration mode.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
security-gateway aaa authentication { first-phase | second-phase } context
ctx_name aaa-group aaa_grp
```

```
no security-gateway aaa { attribute calling-station-id | authentication { first-
phase | second-phase } }
```

no

Removes previously configured AAA authentication or attribute setting from HNB-GW service while using SeGW functionality.

```
attribute calling-station-id ms_id
```

Specifies the calling station id from where the user placed the call.

```
authentication { first-phase | second-phase } context ctx_name aaa-group
aaa_grp
```

Specifies the AAA authentication parameters to be used while using SeGW functionality in an HNB-GW service.

first-phase specifies the parameters to be used for first phase of authentication while using SeGW functionality in an HNB-GW service. This associates the AAA parameters through AAA server group association with in it.

second-phase specifies the parameters to be used for second phase of authentication while using SeGW functionality in an HNB-GW service. This associates the AAA parameters through AAA server group association with in it.

context *ctx_name* **aaa-group** *aaa_grp* specifies the name of the pre-configured AAA server group and its context to associate AAA parameters to be used for first/second or both phase of authentication while using SeGW functionality in an HNB-GW service.

ctx_name specifies the name of the context in which AAA server group is configured.

aaa_grp specifies the name of the AAA server group configured in Context configuration mode with AAA parameters which need to be used for first/second or both phase of authentication while using SeGW functionality in an HNB-GW service.

Important: For more information on AAA server groups, refer *AAA Server Group Configuration Mode Commands*.

Usage

Use this command to associate or tie the AAA authentication or attribute parameters with an HNB-GW service which is to be used for first/second or both phase of authentication while using SeGW functionality in an HNB-GW service or removing AAA attribute “calling-station-id” from AAA message. This functionality is part of SeGW configuration support in an HNB-GW service.

Caution: This is a critical configuration and need to be configured carefully when Security Gateway (SeGW) functionality required on HNB-GW service.

Example

The following command associates an AAA server group named *sec_gw_grp1* with HNB-GW service to use specific AAA authentication parameters in first phase of authentication and another AAA server group named *sec_gw_grp2* to use different AAA authentication parameter in second phase of authentication. Both AAA server groups are configured in same context named *SeGW_ctx1*:

```
security-gateway aaa authentication first-phase context SeGW1 aaa-group  
sec_gw_grp1security-gateway aaa authentication second-phase context SeGW1  
aaa-group sec_gw_grp2
```

The following command disables a previously configured AAA authentication parameter for first phase of authentication:

```
no security-gateway aaa authentication first-phase
```

security-gateway bind

This command binds the SeGW in HNB-GW service to a logical IP interface serving as an Iuh interface and associates an IPsec IKV2 crypto-map template to the HNB-GW service.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
security-gateway bind address address crypto-template cryp_name [ context ctx_name ]
```

```
no security-gateway bind
```

no

Removes a previously configured IPsec IP address use for binding the IKv2 IPsec tunnel (local bind address) to communicate with the Home-NodeBs using Iuh interface.

bind *address* *address*

Specifies the IP address in IPv4 or IPv6 notation for the interface configured as an Iuh for IPsec tunnel. This is the IP address where the HNB-GW service is bound and shall be provided to Home-NodeB during HNB-GW discovery.

address specifies the IPsec IP address in IPv4/IPv6 notation to be used for binding the IKEv2 IPsec tunnel (local bind address) to communicate with the Home-NodeBs using Iuh interface.

crypto-template *cryp_name*

Specifies the Crypto-map template to be used for IPsec IKEv2 tunneling for the interface configured as an Iuh.

cryp_name specifies the name of the pre-configured Crypto-map template which is configured in *Crypto-Map Template Configuration Mode* and associated with HNB-GW service to create IPsec tunnel with Home-NodeB during HNB-GW discovery procedure on Iuh interface.

context *ctx_name*

Specifies the name of the pre-configured context in which Security Gateway service is configured. By default this command uses HNB-GW service context for Security Gateway configuration.

Usage

Use this command to associate or tie the HNB-GW service to a specific logical IP address that is used for binding the Iuh socket to communicate with the Home-NodeB using IPsec tunnel. A maximum of one IP address can be configured with this command for one HNB-GW service.

The HB-GW passes the IP address during setting up the HNB-GW discovery procedure with the Home-NodeB.

Caution: This is a critical configuration. The HNB-GW service can not be started without this configuration. Any change to this configuration would lead to restarting the HNB-GW service and removing or disabling this configuration stops the HNB-GW service.

Example

The following command binds the logical IP interface with the address of `1.2.3.4` to the HNB-GW service using existing IPsec Crypto-Map template `crypto1` to establish IPsec tunnel with Home-NodeB:

```
security-gateway bind address 1.2.3.4 crypto-template crypto1
```

The following command disables a binding that was previously configured:

```
security-gateway bind address
```

security-gateway username

This command configures the options related to user name received from MS.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] security-gateway username mac-address-stripping
```

no

Disables previously configured option for user name received from MS.

default

Sets the user name option configuration of default setting of “Disable”.

mac-address-stripping

Default: Disabled

This keyword sets the system to strip the MAC address from the user name received from the MS.

Usage

Use this command to set the user name related options. By enabling this option system strips the MAC address from the user name received from MS.

Example

The following command sets the system to strip the MAC address from user name received from user MS:

```
security-gateway username mac-address-stripping
```

tnsf-timer

This command configures the NAS Node Selection Function (NNSF) timer (T-NNSF) which is used by the HNB-GW to store the IMSI and the relevant *Global-CN-ID* in the short term after Paging. This timer is used for Iu-Flex feature support.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
tnsf-timer dur
```

```
[no | default] tnsf-timer
```

no

Disables/removes the configured timer value of NNSF timer (T-NNSF) from HNB-GW service instance.

default

Sets the timer value of NNSF timer (T-NNSF) for HNB-GW service instance to default value of 30 seconds.

tnsf-timer *dur*

Default: 30 secs.

Configures the timer value for NNSF timer (T-NNSF) in seconds, which is used by the HNB-GW to store the IMSI and the relevant *Global-CN-ID* in the short term after Paging.

dur must be an integer between 10 through 60.

Usage

Use this command to configure the NNSF timer value in seconds for Iu-Flex support.

Whenever the MSC sends the paging request with IMSI, the HNB-GW stores the *Global_CN_ID* of the node which issued the paging request message for the given IMSI and HNB-GW starts the **tnsf-timer**. HNBGW stores the mapping of IMSI to *Global_CN_ID* until the **tnsf-timer** expires

Example

The following command sets the NNSF timer value to 30 seconds in an HNB-GW service instance:

```
default tnsf-timer
```

ue registration-timeout

This command configures the UE registration timeout duration in seconds to de-register the connected UE from an HNB-GW service.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
ue registration-timeout dur  
[ default | no ] ue registration-timeout
```

no

Disables the UE registration timeout duration configuration from HNB-GW service and UE is de-registered explicitly from HNB-GW service.

default

Restores the UE registration timeout duration value to its default value of 120 seconds.

dur

Default: 120 seconds.

Sets the UE registration timeout duration in seconds after which the UE is de-registered from HNB-GW. In a scenario when all Iu connections are released for a subscriber the HNB-GW service de-registers the UE after configured period of time only.

dur is measured in seconds and can be configured to any integer value from 60 to 300.

Usage

Use this command to configure the minimum duration value before de-registering the UE when subscriber fails to establish the Iu connection. If subscriber's Iu session does not established before configured period then UE is de-registered. Also in a scenario where all Iu connections are released for a subscriber, the HNB-GW service waits for configured period before starting UE deregistration procedure.

Example

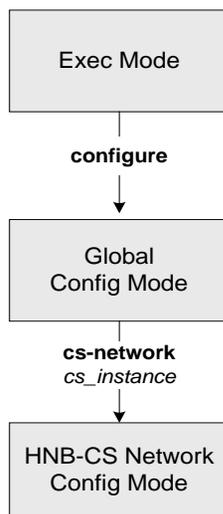

The following command sets the UE registration timeout duration to 150 second on HNB-GW after expiry of which the UE is de-registered:

```
ue registration-timeout 150
```

Chapter 135

HNB-CS Network Configuration Mode Commands

The HNB-CS Network configuration mode provides the commands to create, provide, and manage the circuit switched (CS) network instance allowing the HNB-GW access with the CS core network in a 3G UMTS network.

associate alcap-service

This command associates a previously defined Access Link Control Application Part (ALCAP) service with the CS network instance for multiplexing of different users onto one AAL2 transmission path using channel IDs (CIDs). This configuration is provided to support IuCS-over-ATM functionality

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
associate alcap-service svc_name context ctx_name
```

```
no associate alcap-service
```

no

Removes the associated ALCAP service from this HNB-CS network instance configuration.

svc_name

Identifies the name of the ALCAP service preconfigured in Context configuration mode to associate with an HNB-CS network instance for multiplexing of different users onto one AAL2 transmission path using channel IDs (CIDs).

The *svc_name* must be a preconfigured ALCAP service.

Only one instance of this command can be configured.

 **Caution:** If this CLI is not configured any RAB-ASST-REQ requesting AAL2 connection setup shall be rejected with an appropriate cause.

context *ctx_name*

Specifies the name of the context in which ALCAP service is configured.

The *ctx_name* must be an existing context name in which this ALCAP service is configured.

Usage

Use this command to configure IuCS-over-ATM support. This association of ALCAP protocol service configuration in HNB-CS network instance provides multiplexing of different users onto one AAL2 transmission path using channel IDs (CIDs).

 **Caution:** If this CLI is not configured any RAB-ASST-REQ message requesting AAL2 connection setup shall be rejected with an appropriate cause.

 **Important:** This command must not be used more than once to configure IuCS-over-ATM support.

Example

Following command associates ALCAP service *alcap_svc1* configured in context named *Ctx_alcap1* with specific HNB-CS network instance:

```
associate alcap-service alcap_svc1context ctx_alcap1
```

associate rtp pool

This command associates a previously defined RTP pool (IP pool) with the CS network instance to be used for assignment of IP address/port as RTP streams end point address over IuCS interface. This configuration support is provided for RTP stream management feature in an HNB-GW service.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
associate rtp pool pool_name context ctx_name
```

```
no associate rtp pool
```

no

Removes the associated RTP pool (IP pool) from this HNB-CS network instance configuration.

pool_name

Identifies the name of the RTP IP pool preconfigured in Context configuration mode to associate with an HNB-CS network instance to be used for assignment of IP address/port over the IuCS interface RTP streams. The *pool_name* must be an existing IP pool name configured in Context configuration mode.

Important: For IP pool (RTP pool) configuration, refer *Context Configuration Commands Mode* chapter.

context *ctx_name*

Specifies the name of the context in which RTP pool (IP pool) is configured. The *ctx_name* must be an existing context name in which this IP pool is configured.

Usage

Use this command to associate RTP pool (IP Pool) with an HNB-CS network instance for allotment of IP address/port over IuCS interface for RTP streams across all sessions. A fixed range of RTP ports from 5000 through 65000 shall be used to allocate to RTP stream.

Important: This command must be used to provide IP address/port for RTP streams end point address over IuCS interface.

Important: This configuration support is provided for RTP stream management feature on an HNB-GW service.

Example

Following command associates RTP pool named *rtp_1* with specific HNB-CS network instance:

```
associate rtp pool rtp_1
```

associate sccp-network

This command associates a predefined Signaling Connection Control Part (SCCP) network id with the CS network instance in order to route the messages towards MSC/VLR over IuCS interface.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
associate-sccp-network sccp_net_id
```

```
no associate-sccp-network
```

no

Removes the associated SCCP network id from this HNB-CS network instance configuration.

sccp_network_id

Identifies the predefined SCCP network id to associate with an HNB-CS network instance over IuCS/IuFlex interface to enable connection with MSC/VLR(s).

The *sccp_network_id* must be a predefined SCCP network id in Global configuration mode.

Usage

Use this command to associate a preconfigured SCCP network id over IuCS interface in HNB-GW service to connect with CS network elements; i.e. MSC.

Caution: The SCCP network id must be defined in Global Configuration mode before using it with this command.

Important: A single SCCP network configuration instance can not be shared with multiple HNB-CS network instances.

Example

Following command associates SCCP network 2 with specific HNB-CS network instance:

```
associate-sccp-network 2
```

end

Exits the current mode and returns to the Exec Mode.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

map core-network-id

This command maps/associates the CS core network id to a default MSC in network using MSC point code in HNB-CS network to allow HNBs to access UMTS network.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
map core-network-id cn_id point-code msc_point_code
```

```
no map core-network-id cn_id
```

no

Removes the mapping of a CS core network id with particular MSC point code.

cn_id

Specifies the core network identifier configured to represent a UMTS CS core network.

cn_id must be an integer between 0 through 4095.

Multiple instance of this command can be mapped with different MSC point code.

point-code *msc_point_code*

Specifies SS7 address of default MSC in CS network in point code value to a configured HNB-CS network instance.

point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Only one instance of this MSC point code can be mapped with one CS core network id.

Usage

Use this command to map a UMTS CS core network identifier with a particular MSC point code.

This command can be entered multiple times with same MSC point code to map with one or more CS core network Id, but a particular core network identifier can be mapped to one MSC only.

This command is instrumental in Iu-Flex functionality, whenever HNB-GW receives RESET/RESET-RES messages from MSC with Global CN-ID information element, the response from HNB-GW is sent to the node configured for that particular Global CN-ID.

If the RESET/RESET-RES messages do not have Global CN-ID IE, then the response of those messages is directed to the default MSC which is configured using **msc point-code** command in this mode.

Example

The following command configures the CS core network identifier *101* with an MSC point code *1.2.3*:

```
map core-network-id 101 point-code 1.2.3
```

The following command configures the CS core network identifier *102* with the same MSC point code *1.2.3*:

■ map core-network-id

```
map core-network-id 102 point-code 1.2.3
```

map idnns range

This command configures the mapping of Intra-Domain NAS Node Selector (IDNNS) IE received from UE in RUA connect message towards HNB-GW to MSC point code. This is an important configuration for CS network resource sharing over Iu-Flex interface.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
map idnns range idnns_start to idnns_end point-code msc_point_code [ backup
point-code bkup_msc_point_code]
```

```
no map idnns range idnns_start to idnns_end
```

no

Removes the entries of mapping of range of IDNNS received from UE with particular MSC point code.

range *idnns_start* **to** *idnns_end*

Specifies the range of IDNNS received from UE to map with particular MSC point code during initial CS core network node selection.

idnns_start must be an integer between 0 through 1023 and should be less than *idnns_end*.

idnns_end must be an integer between 0 through 1023 and should be more than *idnns_start*.

The command can be entered more than once to map multiple IDNNS ranges to same MSC, but overlapping and mapping of same range to different MSC point code is not allowed.

point-code *msc_point_code*

Specifies SS7 address of MSC in CS network in point code value to map with range of IDNNS values.

msc_point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

backup point-code *bkup_msc_point_code*

Specifies SS7 address of MSC to be used as backup in CS network in point code value to map with range of IDNNS values.

bkup_msc_point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Usage

Use this command to map a NRI received from UE during initial CS network node selection to MSC point code through NRI range mapping over Iu-Flex interface.

The IDNNS refers to the information element in RUA connect message from UE towards RAN (HNB-GW). In IDNNS IE, if the choice of routing mentioned is other than local P-TMSI, then the value it provides is used against this configuration to map the MSC point code.

■ map idnns range

If backup MSC point-code is specified, then specified MSC works as backup for the IDNS range configured. This Backup MSC is selected if the mapped MSC for a given IDNNS range is going for offloading using **offload-msc point-code** command.

The command can be entered more than once to map multiple IDNNS ranges to same MSC point code, but overlapping and mapping of same range to different MSC point code is not allowed.

Example

The following command maps the IDNNS range from *101* to *201* with MSC point code *1.2.3* and point code *7.8.9* as backup MSC point code :

```
map nri range 101 to 201 point-code 1.2.3 backup point-code 7.8.9
```

The following command removes all IDNNS range matching entries between *301* to *399* from the configuration:

```
no map idnns range 301 to 399
```

map nri range

This command configures the mapping of Network Resource Id (NRI) received from UE to MSC point code. This is an important configuration for CS network resource sharing over Iu-Flex interface.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
map nri range nri_start to nri_end point-code msc_point_code
```

```
no map nri range nri_start to nri_end
```

no

Removes the entries of mapping of range of NRIs received from UE with particular MSC point code.

range *nri_start* **to** *nri_end*

Specifies the range of NRIs received from UE to map with particular MSC point code during initial CS core network node selection.

nri_start must be an integer between 0 through 1023 and should be less than *nri_end*.

nri_end must be an integer between 0 through 1023 and should be more than *nri_start*.

The command can be entered more than once to map multiple NRI ranges to same MSC, but overlapping is not allowed.

point-code *msc_point_code*

Specifies SS7 address of MSC in CS network in point code value to map with range of NRI values.

point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Usage

Use this command to map a NRI received from UE during initial CS network node selection to MSC point code through NRI range mapping over Iu-Flex interface.

This configuration is used during initial CS core network node selection when the network resource identifier (NRI) from the UE is available. The NRI range is mapped to MSC point code. This configuration is used when the core network uses Iu-Flex interface.

The command can be entered more than once to map multiple NRI ranges to same MSC point code.

It is possible to configure multiple ranges to more than one MSC however this configuration is required only when the CS core network is configured as Multi-Operator Core Network (MOCN).

When the CS core network is not MOCN and one range is mapped to more than one MSC then MSC is selected randomly in a non-predictable manner.

Example

The following command maps the NRI range from 101 to 201 with MSC point code 1.2.3:

■ map nri range

```
map nri range 101 to 201 point-code 1.2.3
```

The following command maps the NRI range from 301 to 399 with MSC point code 1.2.3:

```
map nri range 301 to 399 point-code 1.2.3
```

The following command removes all NRI range matching entries between 301 to 399 from the configuration:

```
no map nri range 301 to 399
```

msc deadtime

This command is used to configure a timer on HNB-GW to manage MSC availability in a CS core network on receiving of PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP instance.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
msc deadtime { immediate | dur }  
[ no | default ] msc deaddtime
```

no

Enables the peer node (MSC) available all the time and never be marked down for specific HNB-CS network instance.

default

Default: Enabled

Sets the default action for HNB-GW and provision it as such that peer node (MSC) is marked down as soon as HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP in specific HNB-CS network instance.

immediate

Default: Disabled

Sets the HNB-GW to mark peer node (MSC) down immediately and clears all Iu-CS connections towards MSC is released.

dur

Sets the duration in seconds for a timer which started once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer MSC. On expiry of this timer the peer MSC is marked as dead and all Iu-CS connections towards that MSC shall be released.

dur is timer duration in seconds and must be an integer from 1 through 30.

Only one instance of this command can be configured.

Usage

This command is used to configure a timer on HNB-GW to manage MSC availability in a CS core network on receiving of PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP. This configuration plays important role during RANAP reset procedure as well.

Timer value sets the duration in seconds for a timer which started once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer MSC. On expiry of this timer the peer MSC is marked as dead and all Iu-CS connections towards that MSC shall be released.

Important: This command can be entered only once. Reentering this command overwrites the previous parameters.

Example

The following command configures the deadtime timer value for *10* seconds on HNB-GW. Once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer MSC the HNB-GW waits for configured period and on expiry of timer it marks the sepcific MSC as dead:

```
msc deadtime 10
```

msc point-code

This command is used to configure default MSC point-code with HNB-CS network instance. This command is used when HNB-GW is to be connected to only one MSC with in a CS network or as default MSC for all HNBs connected through specific HNB-CS network instance.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] msc point-code point_code
```

no

Removes the configured default MSC point code from specific HNB-CS network instance.

 **Caution:** Removing the MSC point code is a disruptive operation and affects all HNB sessions which are connected to particular MSC through an HNB-CS network instance.

msc point_code

Specifies SS7 address of default MSC in CS network in point code value to this configured HNB-CS network instance.

point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Only one instance of this command can be configured.

Usage

Use this command to configure a default MSC to which HNB connects for CS network access through HNB-GW service.

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC Range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

 **Important:** This command can be entered only once. If entered again the previous value shall be overwritten.

Example

The following command configures a default MSC with point code *01.201.101* for HNBs to access CS network through HNB-GW service in this HNB-CS network instance:

■ msc point-code

```
msc point-code 101.201.101
```

nri length

This command configures the network resource identifier (NRI) length in bits to identify a specific MSC serving in a pooled area and at least one NRI value has to be assigned to an MSC serving in a pool. The NRI is coded inside of the temporary mobile subscriber identity (TMSI), located within bits 14 to 23 with an variable length between 0 and 10 bits. Operator needs to set this NRI length to indicates the number of bits that shall be used for the NRI field to set the parameters for Iu-Flex (MSC pooling) functionality.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
nri length nri_value
```

```
default nri length
```

default

Sets the NRI length to default value of 0 and disables the Iu-Flex (MSC pooling) functionality.

```
nri length nri_length
```

Default: 0

Specifies the number of bits to be used in the P-TMSI, bits 23 to 18, to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length is of zero length.

length must be an integer from 1 to 10 to identify the number of bits.

When a non-zero value is configured the CS network is considered to be a pool.

Usage

Use this command to enable the Iu-Flex functionality on HNB-GW. This command identifies a unique MSC serving a pooled area for Iu-Flex functionality and at least one NRI value has to be assigned to an MSC serving in a pool. It performs MSC pooling/offloading scenario over Iu-Flex interface. The NRI is stored in the bits 14 to 23 of TMSI. The HNB-GW uses a portion of this NRI to set the parameters for Iu-Flex (MSC pooling) functionality.

If more than one NRI is configured, the HNB-GW service does round-robin between the available NRIs when new subscriber(s) (re)connect.

This command must be used in conjunction with **null nri** command to configured MSC pooling/offloading over Iu-Flex interface.

Example

The following command sets the HNB-GW to use bit length as 6 to derive the values from NRI field (stored in the bits 14 to 23 of TMSI) to set the parameters for Iu-Flex (MSC pooling) functionality:

```
nri length 6
```

■ nri length

null-nri

This command configures the null NRI for load redistribution in Iu-Flex functionality support. The NRI value defined with this command must be unique across the pool areas. This null-NRI is used by HNB-GW for load redistribution during MSC offloading.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
null-nri null_nri_value
```

```
no null-nri null_nri_value
```

no

Disables/removes the configured null-NRI value used for MSC offloading procedure.

null_nri_value

Indicates null-NRI value to be used by HNB-GW for load re-distribution during MSC offloading.

null_nri_value must be an integer between 0 through 1023. Without MOCN configuration this value can be entered only once.

In case of MOCN a unique null-NRI must be assigned to each MOCN operator identify by its PLMN-id (MCC+MNC).

A 0 (zero) value configured as null-NRI indicates the keyword is not to be used. There is no default value for this parameter.

Usage

Use this command to identify the MSC by HNB-GW to be used for load redistribution during MSC offloading over Iu-Flex interface.

There is one unique null-NRI in a PLMN supporting pool functionality.

Without MOCN configuration this command can be entered only once. In case of MOCN a unique null-NRI must be assigned to each MOCN operator identify by its PLMN-id (MCC+MNC).

Example

The following command sets the null-NRI as *1001* to be used by HNB-GW for load redistribution during MSC offloading:

```
null-nri 1001
```

offload-msc

This command is used to provisioning the HNB-GW to enable or disable the exclusion of particular MSC node during NAS Node Selection Function (NNSF) procedure when it needs to be offloaded while using Iu-Flex functionality on HNB-GW node.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] offload-msc point-code msc_point_code
```

no

Removes the particular MSC point code from exclusion list for NNSF function on HNB-GW and re-enable the inclusion of the MSC node to be considered by HNB-GW.

point-code msc_point_code

Specifies SS7 address of MSC in CS network in point code value to be excluded for NNSF function on HNB-GW when it needs to be offloaded in Iu-Flex functionality.

point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Only one instance of this MSC point code can be mapped with one CS core network id.

Usage

Use this command to provision the HNB-GW to enable or disable the exclusion of the MSC node when it needs to be offloaded.

When this command is enabled for exclusion of MSC node during NNSF function in HNB-GW, the HNB-GW excludes the particular node from being considered.

User can re-enable the inclusion of the MSC node to be considered for NNSF functionality by **no offload-msc point-code** command.

Example

The following command configures the HNB-GW to exclude the MSC point code *1.2.3* from being considered in NNSF function for Iu-Flex support:

```
offload-msc point-code 1.2.3
```

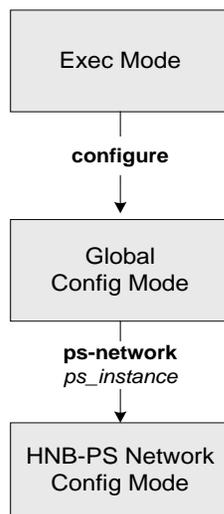

The following command re-enables the inclusion of MSC point code *1.2.3* from being considered in NNSF function for Iu-Flex support:

```
no offload-msc point-code 1.2.3
```

Chapter 136

HNB-PS Network Configuration Mode Commands

The HNB-PS Network Configuration Mode is used to create, provide, and manage the Packet Switched (PS) network instance on HNB-GW service to provide HNB access with PS core network in a 3G UMTS network.

associate gtpu-service

This command associates a previously configured GTP-U service to bind the HNB-GW service to provide a GTP-U tunnel with an SGSN towards the core network side. A GTP-U service must be configured in Context configuration mode before using this configuration.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
associate gtpu-service svc_name context ctx_name
```

```
no associate gtpu-service
```

no

Removes the associated GTP-U service from this HNB-GW service configuration.

svc_name

Identifies the name of the GTP-U service preconfigured in Context configuration mode to associate with an HNB-GW service towards the Home-NodeB side.

The *svc_name* is name of a preconfigured GTP-U service.

context *ctx_name*

Specifies the name of the context in which GTP-U service is configured.

The *ctx_name* must be an existing context name in which this GTP-U service is configured.

Usage

Use this command to configure GTP-U data plan tunnel between HNB-GW service and GSNs in core network. The service defined for GTP-U tunnel must be configured in Context configuration mode.

Important: Another GTP-U service can be used to bind the HNB-GW service to GTP-U tunnel with HNB in HNB access network and can be configured in HNB-GW Service Configuration mode. For more information on GTP-U service configuration, refer *GTP-U Service Configuration Mode Commands*.

Example

Following command associates GTP-U service *gtpu_svc1* configured in context named *Ctx_gtpu1* with specific HNB-PS network instance for GTP-U tunnel towards GSN in core network:

```
associate gtpu-service gtpu_svc1 context Ctx_gtpu1
```

associate-sccp-network

This command associates a previously defined Signaling Connection Control Part (SCCP) network id with the PS network instance in order to route the messages towards SGSN over IuPS interface.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
associate-sccp-network sccp_net_id
```

```
no associate-sccp-network
```

no

Removes the associated SCCP network configuration instance from this HNB-PS network instance configuration.

sccp_net_id

Identifies a predefined SCCP network id to associate with an HNB-PS network instance over IuPS/IuFlex interface to enable connection with SGSN(s).

The *sccp_network_num* must be a predefined SCCP instance in Global configuration mode.

Usage

Use this command to associate a predefined SCCP network id with the IuPS interface in HNB-GW service to connect with PS network elements; i.e. SGSN.

 **Caution:** The SCCP network id must be defined in Global Configuration mode before using it with this command.

 **Important:** A single SCCP network id can not be shared with multiple HNB-PS network instances.

Example

Following command associates SCCP network id 2 with specific HNB-PS network instance:

```
associate-sccp-network 2
```

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

map core-network-id

This command maps/associates the PS core network id to a default SGSN in network using SGSN point code in HNB-PS network to allow HNBS to access UMTS network.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
map core-network-id cn_id point-code sgsn_point_code
```

```
no map core-network-id cn_id
```

no

Removes the mapping of a PS core network id with particular SGSN point code.

cn_id

Specifies the core network identifier configured to represent a UMTS PS core network.

cn_id must be an integer between 0 through 4095.

Multiple instance of this command can be mapped with different SGSN point code.

point-code *sgsn_point_code*

Specifies SS7 address of default SGSN in PS network in point code value to a configured HNB-PS network instance.

point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Only one instance of this SGSN point code can be mapped with one PS core network id.

Usage

Use this command to map a UMTS PS core network identifier with a particular SGSN point code.

This command can be entered multiple times with same SGSN point code to map with one or more PS core network Id, but a particular core network identifier can be mapped to one SGSN only.

This command is instrumental in Iu-Flex functionality, whenever HNB-GW receives RESET/RESET-RES messages from SGSN with Global CN-ID information element, the response from HNB-GW is sent to the node configured for that particular Global CN-ID.

If the RESET/RESET-RES messages do not have Global CN-ID IE, then the response of those messages is directed to the default SGSN which is configured using **sgsn point-code** command in this mode.

Example

The following command configures the PS core network identifier *101* with an SGSN point code *1.2.3*:

```
map core-network-id 101 point-code 1.2.3
```

The following command configures the PS core network identifier *102* with the same SGSN point code *1.2.3*:

```
map core-network-id 102 point-code 1.2.3
```

map idnns range

This command configures the mapping of Intra-Domain NAS Node Selector (IDNNS) IE received from UE in RUA connect message towards HNB-GW to SGSN point code. This is an important configuration for PS network resource sharing over Iu-Flex interface.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
map idnns range idnns_start to idnns_end point-code sgsn_point_code [ backup
point-code bkup_sgsn_point_code]
```

```
no map idnns range idnns_start to idnns_end
```

no

Removes the entries of mapping of range of IDNNS received from UE with particular SGSN point code.

range *idnns_start* **to** *idnns_end*

Specifies the range of IDNNS received from UE to map with particular SGSN point code during initial PS core network node selection.

idnns_start must be an integer between 0 through 1023 and should be less than *idnns_end*.

idnns_end must be an integer between 0 through 1023 and should be more than *idnns_start*.

The command can be entered more than once to map multiple IDNNS ranges to same SGSN, but overlapping and mapping of same range to different SGSN point code is not allowed.

point-code *sgsn_point_code*

Specifies SS7 address of SGSN in PS network in point code value to map with range of IDNNS values.

sgsn_point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

backup point-code *bkup_sgsn_point_code*

Specifies SS7 address of SGSN to be used as backup in PS network in point code value to map with range of IDNNS values.

bkup_sgsn_point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Usage

Use this command to map a NRI received from UE during initial PS network node selection to SGSN point code through NRI range mapping over Iu-Flex interface.

The IDNNS refers to the information element in RUA connect message from UE towards RAN (HNB-GW).

In IDNNS IE, if the choice of routing mentioned is other than local P-TMSI, then the value it provides is used against this configuration to map the SGSN point code.

If backup SGSN point-code is specified, then specified SGSN works as backup for the IDNS range configured. This Backup SGSN is selected if the mapped SGSN for a given IDNNS range is going for offloading using **offload-sgsn point-code** command.

The command can be entered more than once to map multiple IDNNS ranges to same SGSN point code, but overlapping and mapping of same range to different SGSN point code is not allowed.

Example

The following command maps the IDNNS range from *101* to *201* with SGSN point code *1.2.3* and point code *7.8.9* as backup SGSN point code :

```
map nri range 101 to 201 point-code 1.2.3 backup point-code 7.8.9
```

The following command removes all IDNNS range matching entries between *301* to *399* from the configuration:

```
no map idnns range 301 to 399
```

map nri range

This command configures the mapping of Network Resource Id (NRI) received from UE to SGSN point code. This is an important configuration for PS network resource sharing over Iu-Flex interface.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
map nri range nri_start to nri_end point-code sgsn_point_code
```

```
no map nri range nri_start to nri_end
```

no

Removes the entries of mapping of range of NRIs received from UE with particular SGSN point code.

range *nri_start* **to** *nri_end*

Specifies the range of NRIs received from UE to map with particular SGSN point code during initial PS core network node selection.

nri_start must be an integer between 0 through 1023 and should be less than *nri_end*.

nri_end must be an integer between 0 through 1023 and should be more than *nri_start*.

The command can be entered more than once to map multiple NRI ranges to same SGSN, but overlapping is not allowed.

point-code *sgsn_point_code*

Specifies SS7 address of SGSN in PS network in point code value to map with range of NRI values.

point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Usage

Use this command to map a NRI received from UE during initial PS network node selection to SGSN point code through NRI range mapping over Iu-Flex interface.

This configuration is used during initial PS core network node selection when the network resource identifier (NRI) from the UE is available. The NRI range is mapped to SGSN point code. This configuration is used when the core network uses Iu-Flex interface.

The command can be entered more than once to map multiple NRI ranges to same SGSN point code.

It is possible to configure multiple ranges to more than one SGSN however this configuration is required only when the PS core network is configured as Multi-Operator Core Network (MOCN).

When the PS core network is not MOCN and one range is mapped to more than one SGSN then SGSN is selected randomly in a non-predictable manner.

Example

The following command maps the NRI range from *101* to *201* with SGSN point code *1.2.3*:

```
map nri range 101 to 201 point-code 1.2.3
```

The following command maps the NRI range from 301 to 399 with SGSN point code 1.2.3:

```
map nri range 301 to 399 point-code 1.2.3
```

The following command removes all NRI range matching entries between 301 to 399 from the configuration:

```
no map nri range 301 to 399
```

nri length

This command configures the network resource identifier (NRI) length in bits to identify a specific SGSN serving in a pooled area and at least one NRI value has to be assigned to an SGSN serving in a pool. The NRI is coded inside of the temporary mobile subscriber identity (TMSI), located within bits 14 to 23 with an variable length between 0 and 10 bits. Operator needs to set this NRI length to indicates the number of bits that shall be used for the NRI field to set the parameters for Iu-Flex (SGSN pooling) functionality.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
nri length nri_value
```

```
default nri length
```

default

Sets the NRI length to default value of 0 and disables the Iu-Flex (SGSN pooling) functionality.

```
nri length nri_length
```

Default: 0

Specifies the number of bits to be used in the P-TMSI, bits 23 to 18, to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length is of zero length.

length must be an integer from 1 to 10 to identify the number of bits.

When a non-zero value is configured the PS network is considered to be a pool.

Usage

Use this command to enable the Iu-Flex functionality on HNB-GW. This command identifies a unique SGSN serving a pooled area for Iu-Flex functionality and at least one NRI value has to be assigned to an SGSN serving in a pool. It performs SGSN pooling/offloading scenario over Iu-Flex interface. The NRI is stored in the bits 14 to 23 of TMSI. The HNB-GW uses a portion of this NRI to set the parameters for Iu-Flex (SGSN pooling) functionality.

If more than one NRI is configured, the HNB-GW service does round-robin between the available NRIs when new subscriber(s) (re)connect.

This command must be used in conjunction with **null nri** command to configure SGSN pooling/offloading over Iu-Flex interface.

Example

The following command sets the HNB-GW to use bit length as 6 to derive the values from NRI field (stored in the bits 14 to 23 of TMSI) to set the parameters for Iu-Flex (SGSN pooling) functionality:

```
nri length 6
```

null-nri

This command configures the null NRI for load redistribution in Iu-Flex functionality support. The NRI value defined with this command must be unique across the pool areas. This null-NRI is used by HNB-GW for load redistribution during SGSN offloading.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
null-nri null_nri_value
```

```
no null-nri null_nri_value
```

no

Disables/removes the configured null-NRI value used for SGSN offloading procedure.

null_nri_value

Indicates null-NRI value to be used by HNB-GW for load re-distribution during SGSN offloading.

null_nri_value must be an integer between 0 through 1023. Without MOCN configuration this value can be entered only once.

In case of MOCN a unique null-NRI must be assigned to each MOCN operator identify by its PLMN-id (MCC+MNC).

A 0 (zero) value configured as null-NRI indicates the keyword is not to be used. There is no default value for this parameter.

Usage

Use this command to identify the SGSN by HNB-GW to be used for load redistribution during SGSN offloading over Iu-Flex interface.

There is one unique null-NRI in a PLMN supporting pool functionality.

Without MOCN configuration this command can be entered only once. In case of MOCN a unique null-NRI must be assigned to each MOCN operator identify by its PLMN-id (MCC+MNC).

Example

The following command sets the null-NRI as *1001* to be used by HNB-GW for load redistribution during SGSN offloading:

```
null-nri 1001
```

offload-sgsn

This command is used to provisioning the HNB-GW to enable or disable the exclusion of particular SGSN node during NAS Node Selection Function (NNSF) procedure when it needs to be offloaded while using Iu-Flex functionality on HNB-GW node.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] offload-sgsn point-code sgsn_point_code
```

no

Removes the particular SGSN point code from exclusion list for NNSF function on HNB-GW and re-enable the inclusion of the SGSN node to be considered by HNB-GW.

point-code *sgsn_point_code*

Specifies SS7 address of SGSN in PS network in point code value to be excluded for NNSF function on HNB-GW when it needs to be offloaded in Iu-Flex functionality.

point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Only one instance of this SGSN point code can be mapped with one PS core network id.

Usage

Use this command to provision the HNB-GW to enable or disable the exclusion of the SGSN node when it needs to be offloaded.

When this command is enabled for exclusion of SGSN node during NNSF function in HNB-GW, the HNB-GW excludes the particular node from being considered.

User can re-enable the inclusion of the SGSN node to be considered for NNSF functionality by **no offload-sgsn point-code** command.

Example

The following command configures the HNB-GW to exclude the SGSN point code *1.2.3* from being considered in NNSF function for Iu-Flex support:

```
offload-sgsn point-code 1.2.3
```

The following command re-enables the inclusion of SGSN point code *1.2.3* from being considered in NNSF function for Iu-Flex support:

```
no offload-sgsn point-code 1.2.3
```

sgsn deadtime

This command is used to configure a timer on HNB-GW to manage SGSN availability in a PS core network on receiving of PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP instance. .

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
sgsn deadtime { immediate | dur }
```

```
[ no | default ] sgsn deaddtime
```

no

Enables the peer node (SGSN) available all the time and never be marked down for specific HNB-PS network instance.

default

Default: Enabled

Sets the default action for HNB-GW and provision it as such that peer node (SGSN) is marked down as soon as HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP in specific HNB-PS network instance.

immediate

Default: Disabled

Sets the HNB-GW to mark peer node (SGSN) down immediatly and clears all Iu-PS connections towards SGSN is released.

dur

Sets the duration in seconds for a timer which started once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer SGSN. On expiry of this timer the peer SGSN is marked as dead and all Iu-PS connections towards that SGSN shall be released.

dur is timer duration in seconds and must be an integer from 1 through 30.

Only one instance of this command can be configured.

Usage

This command is used to configure a timer on HNB-GW to manage SGSN availability in a PS core network on receiving of PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP.

Timer value sets the duration in seconds for a timer which started once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer SGSN. On expiry of this timer the peer SGSN is marked as dead and all Iu-PS connections towards that SGSN shall be released.

Important: This command can be entered only once. Reentering this command overwrites the previous parameters.

Example

The following command configures the deadtime timer value for *10* seconds on HNB-GW. Once HNB-GW receives PC-STATE-DOWN or SSN-STATE-DOWN (RANAP) indication from SCCP for a peer SGSN the HNB-GW waits for configured period and on expiry of timer it marks the sepcific SGSN as dead:

```
sgsn deadtime 10
```

sgsn point-code

This command is used to configure default SGSN point-code with HNB-PS network instance. This command is used when HNB-GW is to be connected to only one SGSN with in a PS network or as default SGSN for all HNBs connected through specific HNB-PS network instance.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] sgsn point-code point_code
```

no

Removes the configured default SGSN point code from specific HNB-PS network instance.

Caution: Removing the SGSN point code is a disruptive operation and affects all HNB sessions which are connected to particular SGSN through an HNB-PS network instance.

point_code

Specifies SS7 address of default SGSN in PS network in point code value to this configured HNB-PS network instance.

point_code must be in SS7 point code dotted-decimal ###.###.### format or 8-digit decimal ##### format.

Only one instance of this command can be configured.

Usage

Use this command to configure a default SGSN to which HNB connects for PS network access through HNB-GW service.

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC Range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

Important: This command can be entered only once. If entered again the previous value shall be overwritten.

Example

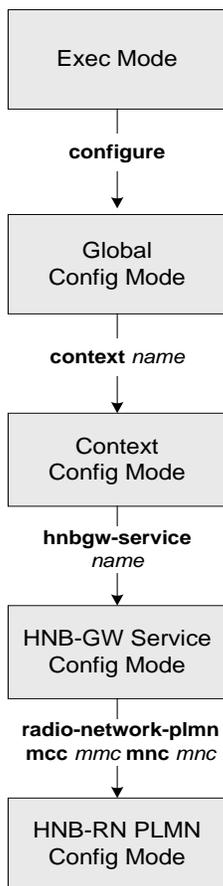

The following command configures a default SGSN with point code *101.201.101* for HNBs to access PS network through HNB-GW service in this HNB-PS network instance:

```
sgsn point-code 101.201.101
```

Chapter 137

HNB-RN PLMN Configuration Mode Commands

This HNB Radio Network PLMN configuration mode provides configuration to define the radio network PLMN parameters related to the HNB-GW connection with UMTS Femto radio network.

associate cs-network

This command associates a preconfigured circuit switched (CS) network within an HNB radio network PLMN with HNB-GW service.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] associate cs-network cs_name [ lac lac ]
```

no

Disassociates/removes the configured CS network with an HNB radio network PLMN configured in HNB-GW service mode.

cs_name

Specifies the name of a preconfigured CS network in Global configuration mode with **cs-network** command and to be associated with an HNB radio network PLMN configured in HNB-GW service mode. To configure CS network, refer *HNB-CS Configuration Mode Commands* chapter.

lac *lac_id*

This keyword defines the granularity level of circuit switch network to a location area code (LAC) level to be associated with radio network PLMN in HNB-GW service.

lac_id must be an integer between 1 and 65535.

Usage

Use this command to associate pre-defined CS networks with a radio network PLMN in an HNB-GW service.

The circuit switched network comprises of one or more MSCs, where CS-domain IU-connections shall be routed. In a typical deployment HNB-GW is connected to only one MSC. However due to Iu-flex and networks-sharing requirements, HNB-GW can be connected to more than one MSCs as well.

Another scenario when HNB-GW can be connected to multiple MSCs is when a set of HNBs should be connected to a particular MSC based on their UTRAN location or geographical location.

This command provides configuration to have one or more MSCs such that these are used in load-shared (IuFlex) or network-shared mode. If location based distribution of HNBs to MSCs is desired then more than one circuit switched network configuration will be required.

This configuration allows association of a circuit switched network with a radio network PLMN and granularity can either be at the PLMN level or at the level of a location area (LAC) in that PLMN.

To configure CS network, refer *HNB-CS Configuration Mode Commands* chapter.

Example

The following command associates a CS network *umts1* with radio network PLMN with a granularity of LAC 234:

```
associate cs-network umts1 lac 234
```

associate ps-network

This command associates a preconfigured packet switched (PS) network within an HNB radio network PLMN with HNB-GW service.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] associate ps-network ps_name [ lac lac [ rac rac ] ]
```

no

Disassociates/removes the configured PS network with an HNB radio network PLMN configured in HNB-GW service mode.

ps_name

Specifies the name of a preconfigured PS network in Global configuration mode with **ps-network** command and to be associated with an HNB radio network PLMN configured in HNB-GW service mode. To configure PS network, refer *HNB PS Configuration Mode Commands* chapter.

lac lac_id

This keyword defines the granularity level of packet switched network to a location area code (LAC) level to be associated with radio network PLMN in HNB-GW service.

lac_id must be an integer between 1 and 65535.

rac rac_id

This keyword defines the granularity level of packet switched network to a radio area code (RAC) level to be associated with radio network PLMN in HNB-GW service.

rac_id must be an integer between 1 and 65535.

Usage

Use this command to associate pre-defined PS networks with HNB radio network PLMN in an HNB-GW service.

The packet switched network comprises of one or more SGSNs where PS-domain IU-connections shall be routed. In a typical deployment HNB-GW is connected to only one SGSN. However with IuFlex and network-sharing functionality, HNB-GW can be connected to more than one SGSNs as well.

Another scenario when HNB-GW can be connected to multiple SGSNs is when a set of HNBs should be connected to a particular SGSN based on their UTRAN location or geographical location.

This command provides configuration to have one or more to have one or more SGSNs such that these are used in load-shared (iu-flex) or network-shared mode. If location based distribution of HNBs to SGSNs is desired then more than one packet switched network configuration will be required.

This command allows association of a packet switched network with a radio network PLMN and granularity could either be at the PLMN level or at the level of a location area code (LAC) in that PLMN or at the level of a routing area code (RAC) in that LAC.

To configure PS network, refer *HNB-PS Configuration Mode Commands* chapter.

Example

The following command associates a PS network *umts_ps1* with radio network PLMN with a granularity of LAC *234* and RAC as *123*:

```
associate ps-network umts_ps1 lac 234 rac 123
```

■ end

end

Exits the configuration mode and returns to the Exec mode.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the configuration mode and returns to the Global configuration mode.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Global configuration mode.

rnc-id

This command configures the Radio Network Concentrator (RNC) identifier in a Radio Network PLMN associated with HNB-GW service to provide RNC identifier to HNB during HNB-REGISTRATION procedure. Depending upon the requirement the RNC Identifier can be provided at the desired granularity.

Product

HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] rnc-id rnc_id [ lac lac_id [ rac rac_id | cell-id cell_id ] ]
```

no

Deletes the LAC and RAC information from the system configuration.

rnc-id

Specified the RNC id to be configured in radio network PLMN associated with HNB-GW and to be provided to HNB during HNB-REGISTRATION procedure from HNB-GW. It also configures RNC Id for all HNBs operating in a particular PLMN.

rnc_id must be an integer between 1 and 65535.

lac *lac_id*

This keyword defines the granularity level of location of HNB to a location area code (LAC) level and configures RNC ID for all HNBs operating in particular location-area.

lac_id must be an integer between 1 and 65535.

rac *rac_id*

This keyword defines the granularity level of location of HNB to a routing area code (RAC) level and configures RNC ID for all HNBs operating in particular routing area.

rac_id must be an integer between 1 and 65535.

cell-id *cell_id*

This keyword defines the granularity level of location of HNB to a UTRAN cell level and configures RNC ID for all HNBs operating in particular UTRAN cell area.

cell_id must be an integer between 1 and 65535.

Usage

Use this command to configure RNC id for Radio Network PLMN which will be sent to HNBs from HNB-GW during HNB-REGISTRATION procedure. Depending upon the requirement the RNC Identifier can be provided at the desired granularity.

When HNB-REGISTRATION request is received the RNC Id is looked up by matching the parameters received in the request. The most specific entry that matches the request shall have the highest priority, for example in the following configuration:

```
rnc-id 257 lac 1 cell-id 3
rnc-id 258 lac 1 rac 2
rnc-id 259 lac 1
rnc-id 260
```

- If request is received with LAC=1, RAC=2, and Cell-Id=3, the selected RNC id will be 257.
- If request is received with LAC=1, RAC=3, and Cell-Id != 3, the selected RNC id will be 258.
- If request is received with LAC=1 and any other values of RAC and Cell-id, the selected RNC id will be 259. For all other requests 260 will be returned.

Example

Following command will configure the HNB-GW service to return RNC id as 102 when HNB-REGISTRATION request is received with LAC 1, and RAC 2:

```
rnc-id 102 lac 1 rac 2
```

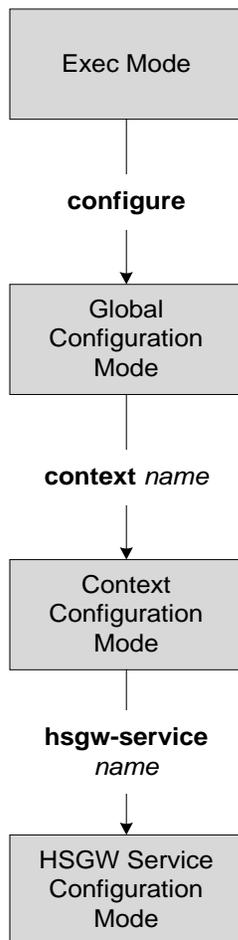

Following command will configure the HNB-GW service to return RNC id as 102 when HNB-REGISTRATION request is received with LAC 1 and cell-id 4:

```
rnc-id 102 lac 1 cell-id 5
```

Chapter 138

HSGW Service Configuration Mode Commands

The HSGW Service Configuration Mode is used to create and manage a configuration allowing the HSGW to communicate, send and receive call data, and session flows to/from a eAN/PCF in an eHRPD network.

 **Important:** This appendix will be added to the CLI Reference when the product releases. Use this appendix in conjunction with the latest release of the Command Line Interface Reference.

associate

Associates accounting policies and QCI-QoS mapping parameters with this HSGW service.

Product

HSGW

Privilege

Administrator

Syntax

```
associate { accounting-policy name | qci-qos-mapping name }
```

```
no associate { accounting-policy [ name ] | qci-qos-mapping }
```

no

Removes the specified associated policy or mapping from the service.

accounting-policy *name*

Specifies the accounting policy to associate with the HSGW service. *name* must be an existing accounting policy and be from 1 to 63 alpha and/or numeric characters.

qci-qos-mapping *name*

Associates the HSGW service with QCI to QoS mapping parameters. *name* must be an existing QCI-QoS mapping configuration and be from 1 to 63 alpha and/or numeric characters. QCI-QoS mapping is configured through the `qci-qos-mapping` command in the Global Configuration Mode.

Usage

Use this command to associate an accounting policy with the HSGW service.

Example

The following command associates an accounting policy named `acct2` to the HSGW service:

```
associate accounting-policy acct2
```

bind address

Binds the service to a logical IP interface serving as the A10 interface and specifies the maximum number of subscribers that can access this service over the configured interface.

Product

HSGW

Privilege

Administrator

Syntax

```
bind address ip_address [ max-subscribers num ]
```

```
no bind address
```

no

Removes the interface binding from this service.

address *ip_address*

Specifies the IPv4 address of the interface configured as the A10/A11 interface. *ip_address* is specified in dotted decimal notation.

max-subscribers *num*

Default: 2500000

Specifies the maximum number of subscribers that can access this service on this interface. *num* must be configured to an integer between 0 and 2,500,000.

Important: The maximum number of subscribers supported is dependant on the license key installed and the number of active PSCs in the system. A fully loaded system with 13 active PSCs can support 3,000,000 total subscribers. Refer to the license key command and the Usage section (below) for additional information.

Usage

Associate the HSGW service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an A10/A11 interface that provides the session connectivity to/from an eAN/PCF. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the **max-subscribers** option, be sure to consider the following:

- The total number of A10/A11 interfaces you will configure
- The total number of subscriber sessions that all of the configured interfaces may handle during peak busy hours
- An average bandwidth per session multiplied by the total number of sessions
- The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to

■ bind address

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Example

The following command would bind the logical IP interface with the address of *112.334.556.778* to the HSGW service and specifies that a maximum of *200,000* simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

```
bind address 112.334.556.778 max-subscribers 200000
```

context-retention-timer

Configures the maximum number of consecutive seconds that a UE session context (which includes the LCP, authentication and A10 session context for a given UE) is maintained by the HSGW before it is torn down.

Product

HSGW

Privilege

Administrator

Syntax

```
context-retention-timer timeout [ sec ]  
  
[ default | no ] context-retention-timer timeout
```

default

Disables the timer.

no

Disables the timer.

timeout [*sec*]

Default: 60

Specifies the amount of time, in seconds, that the session context is maintained before it is disassembled. *sec* must be an integer value from 1 to 3600.

Usage

Use this command to configure a timer to retain session contexts for a specified amount of time before disassembling it.

Example

The following command allows the HSGW to maintain session contexts for 120 seconds before tearing them down:

```
context-retention-timer timeout 120
```

data-available-indicator

Enable sending Data Available Indicator extension in A10/A11 Registration Reply messages.

Product

HSGW

Privilege

Administrator

Syntax

data-available-indicator

Usage

Use this command to enable the sending of the Data Available Indicator extension in A10/A11 Registration Reply messages

data-over-signaling

Enable the data-over-signaling marking feature for A10 packets.

Product

HSGW

Privilege

Administrator

Syntax

```
[ default | no ] data-over-signaling
```

default

Enables the data-over signaling feature for A10 packets.

no

Disable the data-over signaling feature for A10 packets.

Usage

Use this command to enable or disable the data-over signaling feature for A10 packets.

dns-pgw

Identifies to the HSGW service the location of the DNS client. The DNS client is used to identify a FQDN for the peer P-GW. This command defaults to the same context as the HSGW service.

Product

HSGW

Privilege

Administrator

Syntax

```
dns-pgw context name
```

```
[ default | no ] dns-pgw context
```

default

Returns the command to its default setting of the current context.

no

Removes the configured DNS client context name from this service.

context *name*

Specifies the context in which the DNS client is configured. *name* must be an existing context and be from 1 to 63 alpha and/or numeric characters.

Usage

Use this command to identify to the HSGW service the context where the DNS client is configured.

Example

The following command identifies the context where the DNS client is configured as *isp3*:

```
dns-pgw context isp3
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

fqdn

Configures the Fully Qualified Domain Name (FQDN) for this HSGW service.

Product

HSGW

Privilege

Administrator

Syntax

fqdn *domain_name*

[**default** | **no**] **fqdn**

default

Returns the command to the default setting of “null”.

no

Removes the configured FQDN name from this service.

domain_name

Specifies an FQDN for the HSGW service. *domain_name* must be from 1 to 256 alpha and/or numeric characters.

Important: In order to properly interact with other nodes in the network, the FQDN should be 96 alpha and/or numeric characters or less.

Usage

Use this command to configure an FQDN for this HSGW service. The FQDN is used when matching a P-GW with an HSGW.

Topology Matching

You may specify which P-GW you wish an HSGW interface to connect with by enabling topology matching within the FQDNs for both the HSGW service and P-GW service. Topology matching selects geographically closer nodes and reduces backhaul traffic for a specified interface.

The following optional keywords enable or disable topology matching when added to the beginning of an FQDN:

- **topon**.<*interface_name*>.

Beginning an FQDN with **topon** initiates topology matching with available P-GWs in the network. Once this feature is enabled, the rest of the FQDN is processed from right to left until a matching regional designator is found on a corresponding P-GW FQDN.

- **topoff**.<*interface_name*>.

By default, topology matching is disabled. If you enable topology matching for any interfaces within a node, however, all interfaces not using this feature should be designated with **topoff**.

Example

The following command configures this HSGW service with an FQDN of *abc123.com*:

```
fqdn abc123.com
```

The following command configures this HSGW service with an FQDN that enables topology matching:

```
fqdn  
topon.<interface_name>.hsgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppn  
etwork.org
```

Important: The associated P-GW service must have a corresponding FQDN similar to the following:

```
topon.<interface_name>.pgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppn  
etwork.org
```

fragment

Enables/Disables PPP payload fragmentation.

Product

HSGW

Privilege

Administrator

Syntax

```
[ default | no ] fragment ppp-data
```

default

Returns the command to its default setting of enabled.

no

Disables PPP payload fragmentation.

Usage

Use this command to enable or disable PPP payload fragmentation.

gre

Configures Generic Routing Encapsulation (GRE) parameters for the A10 protocol within the HSGW service.

Product

HSGW

Privilege

Administrator

Syntax

```
gre { checksum | checksum-verify | flow control [ action { disconnect-session |
resume-session } ] [ timeout msecs ] + | ip-header-dscp value { all-control-
packets | setup-packets-only } | reorder-timeout msecs | segmentation |
sequence-mode { none | reorder } | sequence-numbers | threegppp2-ext-headers
qos-marking }
```

```
default gre { checksum | checksum-verify | flow-control | ip-header-dscp |
reorder-timeout | sequence-mode | sequence-numbers | threegppp2-ext-headers qos-
marking }
```

```
no gre { checksum | checksum-verify | flow-control | ip-header-dscp |
segmentation | sequence-numbers | threegppp2-ext-headers qos-marking }
```

default

Restores the specified parameter to its default setting.

no

Disables the specified functionality.

checksum

Default: disabled

Enables the introduction of the checksum field in outgoing GRE packets.

checksum-verify

Default: disabled

Enables verification of the GRE checksum (if present) in incoming GRE packets.

```
flow-control [ action { disconnect-session | resume-session } ] [ timeout
msecs ] +
```

Default: no GRE flow-control

Enables 3GPP2 GRE flow control which causes the HSGW to send flow control enabled Normal Vendor Specific Extensions (NVSE) in A11 RRs.

```
action { disconnect-session | resume-session }:
```

Default: disconnect-session

Specifies the action to be taken when timeout is reached:

- **disconnect-session**: Ends the session and releases the call.
- **resume-session**: Switches flow control to XON and resumes delivery of packets to the RAN.

timeout *msecs*

Default: 1000 milliseconds (10 seconds)

Sets the amount of time wait for an XON indicator from the RAN (after receiving an XOFF). Also sets the action to be taken if the timeout limit is reached.

msecs: Specifies the amount of time in milliseconds before the timeout is reached. *msecs* must be an integer from 1 through 1000000.

ip-header-dscp *value* { **all-control-packets** | **setup-packets-only** }

Default: Disabled

Used to configure the QoS Differentiated Services Code Point (DSCP) marking for GRE packets.

- **value**: Represents the DSCP setting. It represents the first six most-significant bits of the ToS field. It can be configured to any hex value from 0x0 through 0x3F.
- **all-control-packets**: Dictates that the DSCP marking is to be provided in all GRE control packets.
- **setup-packets-only**: Dictates that the DSCP marking is to be provided only in GRE setup packets.

reorder-timeout *msecs*

Default: 100

Configures max number of milliseconds to wait before processing reordered out-of-sequence GRE packets. *msecs* must be an integer from 0 through 5000.

segmentation

Default: disabled

Enables GRE Segmentation for the HSGW service.

sequence-mode { **none** | **reorder** }

Default: none

Configures handling of incoming out-of-sequence GRE packets.

none: Specifies that sequence numbers in packets are ignored and all arriving packets are processed in the order they arrive.

reorder: Specifies that out of sequence packets are stored in a sequencing queue until one of the conditions is met:

- The reorder timeout occurs: All queued packets are sent for processing and the accepted sequence number is updated to the highest number in the queue.
- The queue is full (five packets): All packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number in the queue.
- An arriving packet has a sequence number such that the difference between this and the packet at the head of the queue is greater than five. All the packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number that arrived.
- A packet arrives that fills a gap in the sequenced numbers stored in the queue and creates a subset of packets whose sequence numbers are continuous with the current accepted sequence number. This subset of packets in the queue is sent for processing. The reorder timer continues to run and the accepted sequence number is updated to the highest number in the subset delivered.

sequence-numbers

Enables insertion of GRE sequence numbers in data that is about to be transmitted over the A10 interface. Data coming into the system containing sequence numbers but that is out of sequence is not re-sequenced.

threegpp2-ext-headers qos-marking

When threegpp2-ext-headers qos-marking is enabled and the PCF negotiates capability in the A11 RRQ, the HSGW will include the QoS optional data attribute in the GRE 3gpp2 extension header. The **no** keyword, enables qos-marking in the GRE header based on the tos value in the header.

Usage

Use the **no gre sequence-numbers** command to disable the inclusion of GRE sequence numbers in the A10 data path. More Usage....

Example

The following command configures the HSGW service to support the inclusion of GRE sequence numbers in outgoing traffic:

```
gre sequence-numbers
```

ip

Sets the use of Robust Header Compression (RoHC) and enters the HSGW Service ROHC Configuration Mode where RoHC parameters are configured for the service.

Configures the local User Datagram Protocol (UDP) port for the A10/A11 interface IP socket.

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

Product

HSGW

Privilege

Administrator

Syntax

```
ip { header-compression rohc | local-port number | source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num } }
```

```
default ip { local-port | source-violation drop-limit | period | reneg-limit }
```

```
no { header-compression rohc | ip source-violation clear-on-valid-packet }
```

default

Resets the keyword to its default value.

no

header-compression rohc: Removes the RoHC configuration from this service.

ip source-violation clear-on-valid-packet: Disables the ability of the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

header-compression rohc

Specifies that Robust Header Compression will be applied to sessions using this service and enters the HSGW Service RoHC Configuration Mode where RoHC parameters are configured.

local-por *number*

Default: 699

Specifies the UDP port number.

number can be any integer value between 1 and 65535.

```
source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num }
```

clear-on-valid-packet

Default: disabled

Configures the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

drop-limit *num*

Default: 10

Sets the number of allowed source violations within a detection period before forcing a call disconnect. If *num* is not specified, the value is set to the default.

num can be any integer value from 1 to 1000000.

period *secs*

Default: 120

The length of time, in seconds, for a source violation detection period to last. **drop-limit** and **reneg-limit** counters are decremented each time this value is reached.

The counters are decremented in this manner: **reneg-limit** counter is reduced by one (1) each time the period value is reached until the counter is zero (0); **drop-limit** counter is halved each time the period value is reached until the counter is zero (0). If *secs* is not specified, the value is set to the default.

secs must be an integer value from 1 to 1000000.

reneg-limit *num*

Default: 5

Sets the number of allowed source violations within a detection period before forcing a PPP renegotiation. If *num* is not specified, the value is set to the default.

num can be any integer value from 1 to 1000000.

Usage

Header Compression RoHC: Use this command to specify that sessions using this service will have Robust Header Compression applied and configure parameters supporting RoHC.

Entering this command results in the following prompt:

```
[context_name]hostname(config-ip-header-compression-rohc)#
```

HSGW Service RoHC Configuration Mode commands are defined in the HSGW Service RoHC Configuration Mode Commands chapter.

Local Port: Specify the UDP port that should be used for communications between the Packet Control Function (PCF) and the HSGW.

Important: The UDP port setting on the PCF must match the local-port setting for the HSGW service on the system in order for the two devices to communicate.

Source Violation: This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two HSGWs a number of times during a handoff scenario.

This function operates in the following manner:

When a subscriber packet is received with a source address violation, the system increments both the IP source-violation **reneg-limit** and **drop-limit** counters and starts the timer for the IP-source violation period. Every subsequent packet received with a bad source address during the IP-source violation period causes the **reneg-limit** and **drop-limit** counters to increment.

For example, if **reneg-limit** is set to 5, then the system allows 5 packets with a bad source address (source violations), but on the 5th packet, it re-negotiates PPP.

If the **drop-limit** is set to 10, the above process of receiving 5 source violations and renegotiating PPP occurs only once. After the second 5 source violations, the call is dropped. The period timer continues to count throughout this process.

If the configured source-violation period is exceeded at any time before the call is dropped, the **reneg-limit** counter is checked. If the **reneg-limit** counter is greater than zero (0), the **reneg-limit** is decremented by 1. If the **reneg-limit** counter equals zero, the **drop-limit** is decremented by half.

Example

The following command specifies a UDP port of 3950 for the HSGW service to use to communicate with the PCF on the A10/A11 interface:

```
ip local-port 3950
```

The following command sets the drop limit to 15 and leaves the other values at their defaults:

```
ip source-violation drop-limit 15
```

lifetime

Specifies the time that an A10 connection can exist before its registration is considered expired.

Product

HSGW

Privilege

Administrator

Syntax

```
lifetime time
```

```
[ default | no ] lifetime
```

default

Resets the lifetime value to the default setting of 1800 seconds.

no

Specifies that an A10 connection can exist for an infinite amount of time.

time

Default: 1800

Specifies the time that an A10 connection can exist before its registration is considered expired. *time* is measured in seconds and can be configured to any integer value between 1 and 65534.

Usage

Use this command to set a limit to the amount of time that a subscriber session can remain up whether or not the session is active or dormant. If the lifetime timer expires before the subscriber terminates the session, the connection is terminated automatically.

Example

The following command specifies a time of 3600 seconds (1 hour) for subscriber sessions on this HSGW service:

```
lifetime 3600
```

max-retransmissions

Configures the maximum number of times the HSGW service will attempt to communicate with an eAN/PCF before it marks it as unreachable.

Product

HSGW

Privilege

Administrator

Syntax

```
max-retransmissions count
```

```
default max-retransmissions
```

default

Rests the maximum number of allowed retransmissions to the default value of 5.

count

Default: 5

Specifies the maximum number of times the HSGW service will attempt to communicate with an eAN/PCF before it marks it as unreachable.

count can be configured to any integer value between 1 and 1000000.

Usage

Use this command to limit the number of retransmissions to an eAN/PCF before marking it as unreachable. If the value configured is reached, the call is dropped.

Example

The following command configures the maximum number of retransmissions for the HSGW service to 3:

```
max-retransmissions 3
```

mobile-access-gateway

Identifies the mobile access gateway (MAG) context through which MIPv6 calls are to be routed.

Product

HSGW

Privilege

Administrator

Syntax

```
mobile-access-gateway context context_name [ mag-service service_name ]
```

```
no mobile-access-gateway context
```

no

Removes the configured MAG context route from this service.

context *context_name* [**mag-service** *service_name*]

Specifies the name of the context and, optionally, the service through which MIPv6 sessions are to be routed.

context_name must be an existing context and be from 1 to 79 alpha and/or numeric characters.

service_name must be an existing Mag service and be from 1 to 63 alpha and/or numeric characters.

Usage

Use this command to specify where MIPv6 sessions are routed through this service.

Example

The following command identifies the MAG context *MAG1* as the context through which MIPv6 sessions are to be routed and further narrows the route by specifying the service name (*mag_serv3*):

```
mobile-access-gateway context MAG1 mag-service mag_serv3
```

plmn id

Configures Public Land Mobile Network identifiers used to determine if a mobile station is visiting, roaming, or belongs to this network.

Product

HSGW

Privilege

Administrator

Syntax

```
plmn id mcc number mnc number
```

mcc *number* **mnc** *number*

mcc *number*: Specifies the mobile country code (MCC) portion of the PLMN's identifier. *number* is the PLMN MCC identifier and must be an integer value between 100 and 999.

mnc *number*: Specifies the mobile network code (MNC) portion of the PLMN's identifier. *number* is the PLMN MNC identifier and can be configured to any 2 or 3 digit integer value between 00 and 999.

Usage

The PLMN identifier is used to aid the HSGW service in the determination of whether or not a mobile station is visiting, roaming, or home. Multiple P-GW services can be configured with the same PLMN identifier. Up to five PLMN IDs can be configured for each P-GW Service. The configured IDs are used in Diameter-EAP-Request messages (as a Visited-Network-Identifier AVP).

Example

The following command configures the PLMN identifier with an MCC of 462 and MNC of 2:

```
plmn id mcc 462 mnc 02
```

policy overload

Specifies how an HSGW service should handle overload conditions.

Product

HSGW

Privilege

Administrator

Syntax

```
policy overload { redirect address [ weight weight_num ] [ address2 [ weight
weight_num ] ... address16 [ weight weight_num ] ] | reject [ use reject-code {
admin-prohibite | insufficient-resources } ] }
```

```
default policy overload
```

```
no policy overload [ redirect address [ address2 ] ... [ address16 ]
```

default

Returns the command to its default setting of “reject” with the “admin-prohibited” code.

no

Removes a specified “redirect address” from this service.

```
redirect address [ weight weight_num ] [ address2 [ weight weight_num ]
... address16 [ weight weight_num ] ]
```

This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the HSGW service rejects new sessions with an A11 Registration Reply Code of 88H (unknown HSGW address) and provides the IP address of an alternate HSGW. This command can be issued multiple times.

address: The IP address of an alternate HSGW expressed in IPv4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

weight weight_num: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified, the entry is automatically assigned a weight of 1 (default). *weight_num* must be an integer value from 1 through 10.

```
reject [ use reject-code { admin-prohibite | insufficient-resources } ]
```

This option will cause any overload traffic to be rejected. The HSGW sends an A11 Registration Reply Code of 82H (insufficient resources).

use-reject-code admin-prohibited: When this keyword is specified and traffic is rejected, the error code admin prohibited is returned instead of the error code “insufficient resources”. This is the default behavior.

use-reject-code insufficient-resources: When this keyword is specified and traffic is rejected, the error code “insufficient resources” is returned instead of the error code admin prohibited.

Usage

Policies can be implemented to dictate HSGW service behavior for overload conditions. The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system. The system automatically invokes the overload policy when an on-line software upgrade is started. Use the **no policy overload** command to delete a previously configured policy. If after deleting the policy setting you desire to return the policy parameter to its default setting, use the **default policy** command. The chassis is shipped from the factory with the policy options overload disabled

Example

The following command configures the HSGW service to redirect overload traffic to two IPv4 address, one priority weighted 1 and the other priority weighted 5:

```
policy overload redirect 1.2.3.4 weight 1 1.2.3.5 weight 5
```

profile-id-qci-mapping

Associates a configured mapping table for RP QoS Profile ID to LTE QoS Class Index (QCI) mapping with this service.

Product

HSGW

Privilege

Administrator

Syntax

```
profile-id-qci-mapping name
```

```
no profile-id-qci-mapping [ name ]
```

no

Removes all profile maps or a specific profile map from this service.

name

Specifies the name of the table to be associated with this service. *name* must be an existing Profile ID - QCI Mapping table and be from 1 to 63 alpha and/or numeric characters in length.

Usage

Use this command to associate the HSGW service with a configured Profile ID - QCI Mapping table. The table is configured in the Global Configuration Mode using the **profile-id-qci-mapping-table** command.

Example

The following command associates a Profile ID - QCI Mapping table named *table3* with this service:

```
profile-id-qci-mapping table3
```

registration-deny

Configures parameters related to registration rejection.

Product

HSGW

Privilege

Administrator

Syntax

```
registration-deny { handoff connection-setup-record-absent | newcall connection-  
setup-record-absent } [ use-deny-code { poorly-formed-request | reason-  
unspecified } ]
```

handoff connection-setup-record-absent

When enabled, the HSGW denies or discards handoff sessions that do not have an Airlink Connection Setup record in the A11 Registration Request. Default is disabled. Default HSGW behavior is to accept such requests.

newcall connection-setup-record-absent

When enabled, the HSGW denies or discards new sessions that do not have the airlink connection setup record in the RRQ.

[use-deny-code { poorly-formed-request | reason-unspecified }]

Sets the specified Registration Deny Code when denying a new call or handoff because of a missing connection setup record.

Usage

Use this command to configure parameters relating to the rejection of registration requests.

Example

The following command denies registration for registration requests missing the connection setup record and replies with a use deny code of “poorly formed request”:

```
registration-deny handoff connection-setup-record-absent use-deny-code  
poorly-formed-request
```

retransmission-timeout

Configures the maximum allowable time for the HSGW service to wait for a response from the eAN/PCF before it attempts to communicate with the eAN/PCF again (if the system is configured to retry the PCF) or marks the eAN/PCF as unreachable.

Product

HSGW

Privilege

Administrator

Syntax

```
retransmission-timeout time
```

```
{ default | no } retransmission-timeout
```

default

Resets the timeout setting to the default value of 3.

no

Deletes a previously configured timeout value.

time

Default: 3

Specifies the maximum allowable time, in seconds, for the HSGW service to wait for a response from the eAN/PCF before it: a) attempts to communicate with the eAN/PCF again (if the system is configured to retry the PCF) or b) marks the eAN/PCF as unreachable.

time must be an integer value between 1 and 1000000.

Usage

Use the retransmission timeout command in conjunction with the **max-retransmissions** command in order to configure the HSGW services behavior when it does not receive a response from a particular PCF.

Example

The following command configures a retransmission timeout value of 5 seconds:

```
retransmission-timeout 5
```

setup-timeout

The maximum amount of time allowed for session setup.

Product

HSGW

Privilege

Administrator

Syntax

```
setup-timeout seconds
```

```
[ default | no ] setup-timeout
```

default

Rests the command to the default value of enabled with a timeout of 60 seconds.

no

Disables the feature.

seconds

Default: 60

The maximum amount of time, in seconds, to allow for setup of a session in this service. *seconds* must be an integer value from 1 through 1000000.

Usage

Use this command to set the maximum amount of time allowed for setting up a session.

Example

The following command sets the maximum time allowed for setting up a session to 5 minutes (300 seconds):

```
setup-timeout 300
```

spi remote-address

Configures the security parameter index (SPI) between the HSGW service and the eAN/ePCF. This command also configures the redirection of call based on the PCF zone.

Product

HSGW

Privilege

Administrator

Syntax

```
spi remote-address {pcf_ip_address | ip_addr_mask_combo } spi-number number {
encrypted secret enc_secret | secret secret } [ description string ] [ hash-
algorithm { md5 | rfc2002-md5 } ] [ replay-protection { nonce | timestamp } ] [
timestamp-tolerance tolerance ] [ zone zone_id ]
```

```
no spi remote-address pcf_ip_address spi-number number
```

```
{ pcf_ip_address | ip_addr_mask_combo }
```

pcf_ip_address: Specifies the IP address of the ePCF. *pcf_ip_address* is an IP address expressed in IPv4 dotted decimal notation or IPv6 colon separated notation.

ip_addr_mask_combo: Specifies the IP address of the PCF and specifies the IP address network mask bits. *ip_addr_mask_combo* must be specified using the form “IP Address/Mask Bits” where the IP address must either be an IPv4 address expressed in dotted decimal notation or an IPv6 address expressed in colon separated notation and the mask bits are a numeric value which is the number of bits in the subnet mask.

```
spi-number number
```

Specifies the SPI (*number*) which indicates a security context between the PCF and the HSGW. *number* can be configured to any integer value between 256 and 4294967295.

```
encrypted secret enc_secret | secret secret
```

Configures the shared-secret between the HSGW service and the PCF. The secret can be either encrypted or non-encrypted.

encrypted secret *enc_secret*: Specifies the encrypted shared key (*enc_secret*) between the PCF and the HSGW service. *enc_secret* must be between 1 and 254 alpha and/or numeric characters and is case sensitive.

secret *secret*: Specifies the shared key (*secret*) between the PCF and the HSGW services. *secret* must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **secret** keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

```
description string
```

This is a description for the SPI. *string* must be an alpha and/or numeric string from 1 through 31 characters.

```
hash-algorithm { md5 | rfc2002-md5 }
```

Default: md5

Specifies the hash-algorithm used between the HSGW service and the PCF.

md5: Configures the hash-algorithm to implement MD5.

rfc2002-md5: Configures the hash-algorithm to implement keyed-MD5.

```
replay-protection { nonce | timestamp }
```

Default: timestamp

Specifies the replay-protection scheme that should be implemented by the HSGW service.

nonce: Configures replay protection to be implemented using NONCE.

timestamp: Configures replay protection to be implemented using timestamps.

```
timestamp-tolerance tolerance
```

Default: 60

Specifies the allowable difference (*tolerance*) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. If this is set to 0, then time stamp tolerance checking is disabled at the receiving end.

tolerance is measured in seconds and can be configured to any integer value between 0 and 65535.

```
zone zone_id
```

Specifies the different PCF zones to configure in HSGW service. Mapping of a zone-number to a set of HSGWs can be done per HSGW service basis.

zone_id must be an integer value between 1 and 32. A maximum of 32 PCF zones can be configured for a HSGW service.

Usage

An SPI is a security mechanism configured and shared by the PCF and the HSGW service. Please refer to IOS 4.1 and RFC 2002 for additional information.

Multiple SPIs can be configured if the HSGW service is communicating with multiple eAN/PCFs.

Important: The SPI configuration on the PCF must match the SPI configuration for the HSGW service on the system in order for the two devices to communicate properly.

This command used with the **zone** keyword redirects all calls on the basis of PCF zone to the specific HSGW on the basis of parameters configured using the **policy pcf-zone-match** command.

Example

The following command configures the HSGW service to use an SPI of 256 when communicating with a PCF with the IP address 192.168.0.2. The key that would be shared between the PCF and the HSGW service is q397F65.

```
spi remote-address 192.168.0.2 spi-number 256 secret q397F65
```

The following command creates the configured SPI of 400 for an PCF with an IP address of 172.100.3.200 and zone id as 11:

```
spi remote-address 172.100.3.200 spi-number 400 zone 11
```

■ spi remote-address

unauthorized-flows

Configures the service to wait a specified number of seconds before triggering a QoS update to downgrade an unauthorized flow.

Product

HSGW

Privilege

Administrator

Syntax

```
unauthorized-flows qos-update wait-timeout seconds
```

```
[ default | no ] unauthorized-flows qos-update wait-timeout
```

default

Returns the command to its default setting of

no

Removes the configure wait-timeout setting for this service.

qos-update wait-timeout *seconds*

Specifies the number of seconds to wait before triggering the QoS update to downgrade the unauthorized flow. *seconds* must be an integer value from 1 to 65534.

Usage

Use this command to specific a wait timeout trigger for flows that are unauthorized by policy rules received via the Gxa interface from the PCRF. When the wit timer expires, the HSGW triggers a QoS update to downgrade the unauthorized flow.

Example

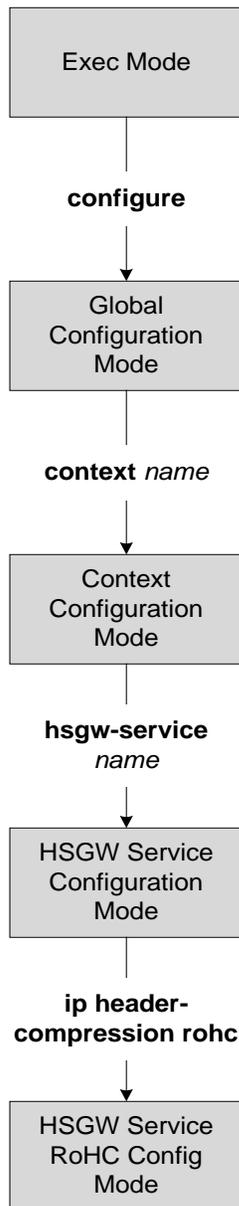

The following command configures the HSGW service to apply the wait time of 30 seconds after receiving an flow unauthorized by the PCRF:

```
unauthorized-flow qos-update wait-timeout 30
```

Chapter 139

HSGW Service RoHC Configuration Mode Commands

The HSGW Service RoHC Configuration Mode is used to configure RoHC parameters for the service.

cid-mode

This mode allows you to configure options that apply during RoHC compression for the service.

Product

HSGW

Privilege

Administrator

Syntax

```
cid-mode { large | small } max-cid integer
```

```
default cid-mode
```

default

Reset all options in the RoHC Profile Compression Configuration mode to their default values.

large

Use large packets with optional information for RoHC

small

This is the default packet size.

Use small RoHC packets.

max-cid *integer*

Default: 15

The highest context ID number to be used by the compressor. *integer* must be an integer from 0 through 15 when small packet size is selected and must be an integer from 0 through 31 when large packet size is selected.

Usage

Use this command to set the RoHC packet size and define the maximum

Example

The following command sets large RoHC packet size and sets the maximum CID to 100:

```
cid-mode large max-cid 100
```

The following command sets the cid-mode to the default settings of small packets and max-cid 0:

```
default cid-mode
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

mrru

This command sets the size of the largest reconstructed reception unit, in octets, that the decompressor is expected to reassemble from segments. The size includes the CRC. If MRRU is negotiated to be 0, no segment headers are allowed on the channel.

Product

HSGW

Privilege

Administrator

Syntax

```
mrru num_octets
```

```
default mrru
```

default

reset the value of this command to its default setting

num_octets

Default: 0

This is the number of octets for the maximum size of the largest reconstructed reception unit allowed. *num_octets* must be an integer from 0 through 65535.

Usage

Use this command to set the size, in octets, of the largest reconstructed reception unit that the decompressor is expected to reassemble from segments.

Example

The following command sets the largest reconstructed reception unit to 1024 octets:

```
mrru 1024
```

The following command resets the MRRU size to its default of 0 octets:

```
default mrru
```

profile

This command specifies the header compression profiles to use. A header compression profile is a specification of how to compress the headers of a specific kind of packet stream over a specific kind of link. At least one profile must be specified.

Product

HSGW

Privilege

Administrator

Syntax

```
profile { [ esp-ip ] [ rtp-udp ] [ udp-ip ] [ uncompressed-ip ] }
```

default profile

default

Default: esp-ip rtp-udp udp-ip uncompressed-ip
Returns the RoHC profile configuration to its default setting.

esp-ip

This enables RoHC Profile 0x0003 which is for ESP/IP compression, compression of the header chain up to and including the first ESP header, but not subsequent subheaders.

rtp-udp

This enables RoHC Profile 0x0001 which is for RTP/UDP/IP compression

udp-ip

This enables RoHC Profile 0x0002 which is for UDP/IP compression, compression of the first 12 octets of the UDP payload is not attempted.

uncompressed-ip

This enables RoHC Profile 0x0000 which is for sending uncompressed IP packets.

Usage

Use this command to specify the RoHC header compression profiles to use.

Example

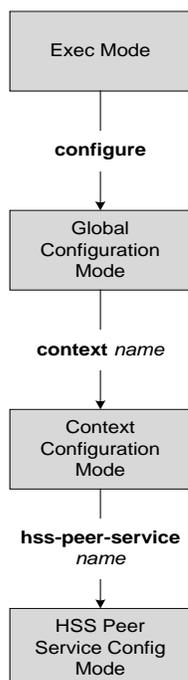

The following command sets the profiles to use as esp-ip and rtp-udp:

```
profile esp-ip rtp-udp
```

Chapter 140

HSS Peer Service Configuration Mode Commands

The HSS Peer Service Configuration Mode is used to create and manage the HSS Peer Service.

auth-request

Configures the number of authentication vectors the MME requests in an Authentication-Information-Request (AIR) message to the HSS for each UE requiring authentication.

Product

MME

Privilege

Administrator

Syntax

```
auth-request num-auth-vectors num
```

```
default auth-request num-auth-vectors
```

```
num-auth-vectors num
```

Specifies the number of vectors the MME is requesting from the HSS. Default = 1. *num* must be an integer value from 1 to 3.

Usage

Use this command to configure the number of authentication vectors the MME requests in an Authentication-Information-Request (AIR) message to the HSS for each UE requiring authentication.

Receiving multiple vectors from the HSS for a given UE helps reduce the number of messages across the diameter connection plus provides the MME with additional vectors for the UE in the event that the connection or the HSS id disabled.

To view the current number of requested vectors, execute the **show hss-peer-service service name** *<name>* command in the Exec mode.

Example

The following command sets the number of requested vectors to 2:

```
auth-request num-auth-vectors 2
```

diameter hss-dictionary

Specifies the Diameter Credit Control dictionary for the HSS peer service.

Product

MME

Privilege

Administrator

Syntax

```
diameter dictionary { custom1 | standard }
```

```
default diameter dictionary
```

default

Sets the dictionary to default for HSS service.

custom1

Default: Disabled

This keyword sets the Diameter dictionary to a customer specific diameter dictionary.

standard

Default: Enabled

This keyword sets the Diameter dictionary to the standard HSS peer dictionary.

Usage

Use this command to select the Diameter dictionary for HSS peer service.

Example

The following command sets the Diameter dictionary to IETF RFC 4006 specific:

```
diameter dictionary standard
```

diameter hss-endpoint

This commands associates a preconfigured Diameter origin endpoint with this HSS peer service.

Product

MME

Privilege

Administrator

Syntax

```
diameter endpoint endpoint_name [ eir-endpoint eir_endpoint_name ]
```

```
no diameter hss-endpoint
```

no

Removes previously associated Diameter origin endpoint from this HSS peer service.

endpoint_name

Identifies a preconfigured Diameter endpoint specific to the HSS interface. The endpoint must be present in all Diameter messages and is the endpoint that originates the diameter message.

endpoint_name must be an preconfigured Diameter endpoint name and be from 1 to 63 alpha and/or numeric characters.

eir-endpoint *eir_endpoint_name*

Identifies a preconfigured Diameter endpoint specific to the S13 Equipment Identity Register (EIR) interface.

eir_endpoint_name must be an existing EIR endpoint and be from 1 to 63 alpha and/or numeric characters.

Usage

Use this command to associated a Diameter origin endpoint to create a Diameter-based interface association in this HSS peer service to provide AAA functionality to the EPS bearer context.

Refer to the *Diameter Endpoint Configuration Mode Commands* chapter for more information on Diameter endpoint configuration parameters.

Example

The following command associates the preconfigured Diameter endpoint `hss_1` with this HSS peer service for HSS interface support.

```
diameter endpoint hss_1
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

failure-handling

This command configures the failure handling behavior in the event of a failure with the HSS peer service. It also defines the action on various error codes on Diameter interface during authentication or session activities.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

```
failure-handling { authentication-information-request | check-identity-request |
notify-request | purge-ue-request | update-location-request } { diameter-result-
code start_error_code [ to end_error_code] | request-timeout } action {
continue | retry-and-terminate | terminate }
```

```
no failure-handling { authentication-information-request | check-identity-
request | notify-request | purge-ue-request | update-location-request }
diameter-result-code start_error_code [ to end_error_code ]
```

```
default failure-handling { authentication-information-request | check-identity-
request | notify-request | purge-ue-request | update-location-request } request-
timeout
```

no

Removes the preconfigured failure handling procedures for calls in an HSS peer service.

default

Sets the default action for failure handling procedure for calls in an HSS peerservice. For default actions on Diameter result/error codes see Usage section of this section.

authentication-information-request

This keyword configures the MME-HSS service to handle the failures in Auth-Information-Request message.

check-identity-request

This keyword configures the MME-HSS service to handle the failures in Check-Identity-Information-Request message.

notify-request

This keyword configures the MME-HSS service to handle the failures in Notify-Request message.

purge-ue-request

This keyword configures the MME-HSS service to handle the failures in Purge-UE-Request message.

update-location-request

This keyword configures the HSS peer service to handle the failures in Update-Location-Request message.

diameter-result-code *start_error_code* [**to** *end_error_code*]

This keyword configures the HSS peer service to handle the failures for various request message having specific single or range of Diameter result code in request message.

start_error_code specifies the individual error code on Diameter protocol and must be an integer from 3000 through 5999. This will be the starting of code if a range of error codes is specified with optional keyword **to** *end_error_code*.

to *end_error_code* is used to specify a range of error codes to handle by this command.

end_error_code specifies the end error code on Diameter protocol and must be an integer from 3000 through 5999.

request-timeout

This keyword configures the HSS peer service to handle the failures for various request messages if response to that message is not received before timeout duration exhausted.

action { **continue** | **retry-and-terminate** | **terminate** }

This keyword specifies the action to be taken on failure of any message as policy of failure handling.

- **continue**: On receipt of any error, this action configuration will allow the HSS peer service to continue with the session procedure without any interruption.
- **retry-and-terminate**: On receipt of any error, this action configuration will instruct the HSS peer service to retry with the procedure. System will retry up to the configured number of attempts and terminate the session/procedure if it received subsequent number of errors after retry attempts.
- **terminate**: This action configuration will allow the HSS peer service to terminate the session procedure without any retry attempt on the event of any failure.

Usage

Use this command to configure the failure handling behavior in the event of a communication failure with the HSS peer service.

Following are the default action for Diameter result codes:

- For all protocol error codes 3000 to 3999 the default action is terminate. For all transient error codes 4000, 4001, 4004 to 4180, and 4182 to 4999 the default action is continue.
- For transient error codes 4002, 4003, and 4181 the default action is retry.
- For error code 4001 the default action is terminate.
- For permanent error codes 5000 to 5999 the default action is terminate

Example

The following command will allow HSS peer service to continue if any failure in Auth-Information-Request message occurred with Diameter error code *3050*:

```
failure-handling authentication-information-request diameter-result-code
3050 action continue
```

request timeout

This command configures the application request timeout between HSS peer service and HSS node. The MME system will wait for this duration before retransmitting the request to corresponding HSS node.

Product

MME

Privilege

Administrator

Syntax

```
request timeout dur
```

```
[ no | default ] request timeout
```

no

Disables the configured application request timeout value.

default

Sets the application request time out duration to default value of 300 seconds.

dur

Default: 300 seconds

Specifies the application request timeout duration in seconds. The MME will wait for this duration before retrying the request with corresponding HSS.

dur must be an integer from 1 through 300.

Usage

Use this command to set the waiting period for HSS peer service in seconds after which the request is deemed to have failed or system will resend the request.

Example

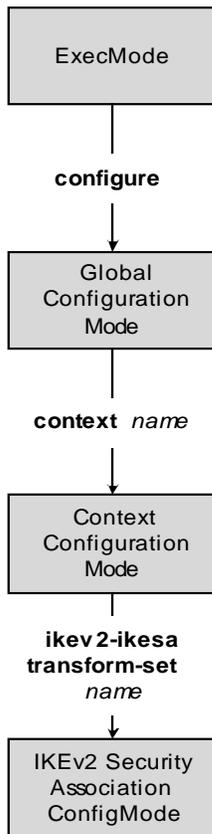

The following example configures the application request timeout duration to 300 seconds:

```
default request timeout
```

Chapter 141

IKEv2 Security Association Configuration Mode Commands

The IKEv2 Security Association Configuration Mode is used to configure a Security Association at the outset of an IPsec session. A security association is the collection of algorithms and parameters (such as keys) that is being used to encrypt and authenticate a particular flow in one direction. In normal bi-directional traffic, the flows are secured by a pair of security associations.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

default

Sets the default properties for the selected parameter.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
default { encryption | group | hmac | lifetime | prf }
```

```
default { encryption | group | hmac | lifetime | prf }
```

Set the defaults for the following parameters:

- **encryption**: Default algorithm for the IKEv2 IKE SA is AES-CBC-128.
- **group**: Default Diffie-Hellman group is Group 2.
- **hmac**: Default IKEv2 IKE SA hashing algorithm is SHA1-96.
- **lifetime**: Default lifetime for SAs derived from this transform-set is 86400 seconds.
- **prf**: Default PRF for the IKEv2 IKE SA is SHA1.

Usage

Configure default parameters for the IKEv2 IKE SA transform-set.

Example

Use the following configuration to set the default encryption algorithm:

```
default encryption
```

encryption

Configure the appropriate encryption algorithm and encryption key length for the IKEv2 IKE security association. AES-CBC-128 is the default.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
encryption { 3des-cbc | aes-cbc-128 | aes-cbc-256 | des-cbc }
```

default encryption

3des-cbc

Data Encryption Standard Cipher Block Chaining encryption applied to the message three times using three different cypher keys (triple DES).

aes-cbc-128

Advanced Encryption Standard Cipher Block Chaining with a key length of 128 bits.

aes-cbc-256

Advanced Encryption Standard Cipher Block Chaining with a key length of 256 bits.

des-cbc

Data Encryption Standard Cipher Block Chaining. Encryption using a 56-bit key size. Relatively insecure.

Usage

IKEv2 requires a confidentiality algorithm to be applied in order to work.

In cipher block cryptography, the plaintext is broken into blocks usually of 64 or 128 bits in length. In cipher block chaining (CBC) each encrypted block is chained into the next block of plaintext to be encrypted. A randomly-generated vector is applied to the first block of plaintext in lieu of an encrypted block. CBC provides confidentiality, but not message integrity.

Because RFC 4307 calls for interoperability between IPsec and IKEv2, the IKEv2 confidentiality algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange. Because of RFC4307, in IKEv2, there is no viable NULL option, it is available for testing only.

Example

The following command configures the encryption to be the default aes-cbc-128:

```
default encryption
```

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec Mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Returns to the previous mode.

group

Configure the appropriate key exchange cryptographic strength by applying a Diffie-Hellman group. Default is Group 2.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
group { 1 | 2 | 5 | 14 }
```

default group

1

Configures crypto strength at the Group 1 level. Lowest security.

2

Configures crypto strength at the Group 2 (default) level. Medium security.
This is the default setting for this command.

5

Configures crypto strength at the Group 5 level. Higher security.

14

Configures crypto strength at the Group 14 level. Highest security

Usage

Diffie-Hellman groups are used to determine the length of the base prime numbers used during the key exchange process in IKEv2. The cryptographic strength of any key derived depends, in part, on the strength of the Diffie-Hellman group upon which the prime numbers are based.

Group 1 provides 768 bits of keying strength, Group 2 provides 1024 bits, Group 5 provides 1536 bits and Group 14 provides 2048 bits of encryption strength.

Configuring a DH group also enables Perfect Forward Secrecy, which is disabled by default.

Example

This command configures security at the default level (Group 2):

```
default group
```

hmac

Configures the IKEv2 IKE SA integrity algorithm. Default is SHA1-96.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
hmac { md5-96 | sha1-96 }
```

```
default hmac
```

md5-96

HMAC-MD5 uses a 128-bit secret key and produces a 128-bit authenticator value.

sha1-96

HMAC-SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. This is the default setting for this command.

Usage

IKEv2 requires an integrity algorithm be configured in order to work.

A keyed-Hash Message Authentication Code, or HMAC, is a type of message authentication code (MAC) calculated using a cryptographic hash function in combination with a secret key to verify both data integrity and message authenticity. A hash takes a message of any size and transforms it into a message of a fixed size: the authenticator value. This is truncated to 96 bits and transmitted. The authenticator value is reconstituted by the receiver and the first 96 bits are compared for a 100 percent match.

Because RFC 4306 calls for interoperability between IPsec and IKEv2, the IKEv2 integrity algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange.

Example

The following command configures the default HMAC value (SHA1-96):

```
default hmac
```

lifetime

Configure the lifetime of a security association (SA) in seconds.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
lifetime sec
```

```
default lifetime
```

```
lifetime sec
```

Default: 86400

Sets the value of the timeout parameter. *sec* must be an integer from 60 to 86400.

Usage

The secret keys that are used for various aspects of a configuration should only be used for a limited amount of time before timing out. This exposes a limited amount of data to the possibility of hacking. If the SA expires, the options are then to either close the SA and open a new one, or renew the existing SA.

Example

The following command sets the lifetime timeout to be the default value (86400):

```
default lifetime
```

prf

Select one of the HMAC integrity algorithms to act as the IKE Pseudo-Random Function. A PRF produces a string of bits that an attacker cannot distinguish from random bit string without knowledge of the secret key. The default is SHA1.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
prf { md5 | sha1 }
```

```
default prf
```

md5

MD5 uses a 128-bit secret key and produces a 128-bit authenticator value.

sha1

SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value.

SHA-1 is considered cryptographically stronger than MD5, but it takes more CPU cycles to compute.

This is the default setting for this command.

Usage

The prf is used for generating keying material for all the cryptographic algorithms used in both the IKE_SA and the CHILD_SAs.

Example

This configuration sets the prf to be the default value (sha1):

```
default prf
```

Chapter 142

IMEI Profile Configuration Mode

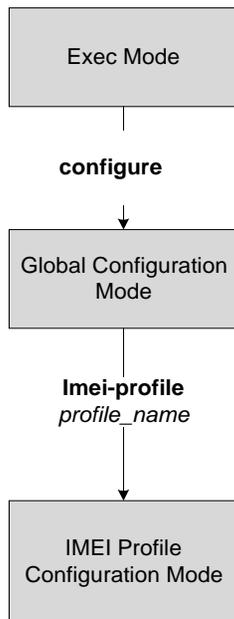

The IMEI profile configuration mode defines a set of parameters controlling the SGSN behavior when a Request is received from a device in the specified IMEI (International Mobile Equipment Identity) range. An IMEI profile is a key element in the Operator Policy feature and an IMEI profile is not used or valid unless it is associated with an IMEI range and this association is specified in an operator policy (see the *Operator Policy Configuration Mode Commands* chapter elsewhere in the *Command Line Interface Reference*).

Essentially, an IMEI profile is a template which groups a set of device-specific commands that may be applicable to one or more IMEIs. The same IMEI profile can be associated with multiple IMEI ranges and multiple operator policies.

An SGSN supports a total of 1000 IMEI profile configurations.

When this mode is accessed, the command prompt should resemble:

```
[local]asr5000(imei-profile-<profile_name>)#
```

associate

Associate an APN remap table with this IMEI profile.

Note that an APN remap table can be associated with an IMEI profile before the table has actually been created/configured.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
associate apn-remap-table table_name
```

```
no associate apn-remap-table
```

no

Disables the configured remap table association.

table_name

Define the name of an APN remap table that is to be associated with this IMEI profile for call routing based in IMEI.

Usage

Use this command to associate an APN remap table with this IMEI profile. With such an association, it is possible to override an APN call-routing based on an IMEI.

For example, with the APN exceptions defined in an APN remap table (refer to the *APN Remap Table Configuration Mode* chapter), a blank APN or an incorrect APN could be overridden. So during PDP Activation for an incoming call, the call could be rerouted based on an IMEI in the range defined for the IMEI profile.

Example

Associate the APN remap table 'remapHO' (remaps all calls with blank APNS to the head-office) to this IMEI profile:

```
associate apn-remap-table remapHO
```

blacklist

Blacklist all mobile devices that fit the IMEI definitions associated with this IMEI profile.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
blacklist
```

```
remove blacklist
```

remove

Including this keyword with the command, removes the blacklist command from the IMEI profile configuration.

Usage

Blacklists subscribers whose devices bear IMEI that match the defined IMEI range for this profile.

Example

Use this command to black list all subscribers with IMEI that fall within the range set for this IMEI profile:

```
blacklist
```

description

Define a descriptive string relevant to the specific APN profile.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
description description
```

```
remove description
```

remove

Removes the configured description from this APN profile.

description

Enter an alphanumeric string of 1 to 100 alphanumeric characters. The string may include spaces, punctuation, and case-sensitive letters if the string is enclosed in double quotes (").

Usage

Define information that identifies this particular APN profile.

Example

Indicate that this IMEI profile *IMEIprof1* is to be used for customers in the United Kingdom and that the profile:

```
description "IMEIprof1 defines routing actions based on IMEI for  
customers in the UK."
```

direct-tunnel

Instruct the SGSN to enable/disable a direct tunnel between the RNC and the GGSN based on the IuPS service configuration.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
direct-tunnel check-iups-service
```

```
no direct-tunnel
```

```
no direct-tunnel
```

This command instructs the SGSN to disable the direct tunnel function between the GGSN and the RNC.

Usage

Direct tunnel is enabled by default on the GGSN and often on the RNC. This leaves it to the SGSN's configuration to actually enable or disable a direct tunnel.

With the SGSN, the options for configuring a direct tunnel are complex -- enable/disable on the basis of APNs, or RNCs, or GGSNs, or on the basis of the IMEI range. Refer to the *Enhanced Feature Configuration Guide* for configuration details.

Example

Assuming the IuPS service configuration has enabled DT for associated RNCs, then use this command to enable DT from the RNC to the GGSN associated with this IMEI profile:

```
direct tunnel check-iups-service
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the context configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Move to the previous configuration mode.

ggsn-address

Identify the target GGSN for traffic being managed by this IMEI profile.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ggsn-address IPv4/IPv6_address
```

IPv4/IPv6_address

Enter the IP address of the target GGSN. Enter the address in either standard IPv4 dotted decimal format or in standard IPv6 colon notation format.

Usage

Use this command to define the IP address of the target GGSN to be associated with this IMEI profile.

Example

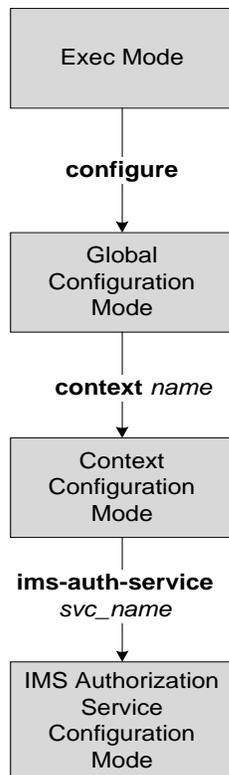

The following command identifies the address of the GGSN associated with this IMEI profile as 123.123.11.1

```
ggsn-address 123.123.11.1
```

Chapter 143

IMS Authorization Service Configuration Mode Commands

IP Multimedia Sub-system (IMS) authorization service is used to configure authorization parameters to manage policy control functions and Gx and Ty interface support with Diameter based procedures for flow based charging within a context. The system uses Gx/Gy andTx/Ty functionality based on the charging policy and rules configured to flow based charging for a subscriber session.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the IMS Authorization Configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to change to the Exec mode.

exit

Exits the current configuration mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

p-cscf discovery

This command defines the method of Proxy-Call Session Control Function (P-CSCF) discovery to be used.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
p-cscf discovery { table { 1 | 2 } [ algorithm { ip-address-modulus | msisdn-
modulus | round-robin } ] | diameter-configured }
[ default | no ] p-cscf discovery
```

default

Sets the P-CSCF discovery to default parameter.

no

Removes/deletes configured parameters for P-CSCF discovery.

table { 1 | 2 }

This keyword specifies that which P-CSCF table is to be used to obtain the primary and secondary P-CSCF addresses. Total 2 tables can be configured for P-CSCF discovery.

algorithm { ip-address-modulus | msisdn-modulus | round-robin }

This keyword specifies the algorithm to select the row from the P-CSCF table to be used for P-CSCF discovery.

- **ip-address-modulus**: This algorithm divides the IP address, in binary, of the subscriber by the number of rows in the table, and the remainder is used as an index into the specified table to select the row.
- **msisdn-modulus**: This algorithm divides the MSISDN value in binary without the leading “+” of the subscriber by the number of rows in the table, and the remainder is used as an index in the specific table to select the row.
- **round-robin**: This algorithm rotates all rows in the active table for selection of the row in round-robin way. If no algorithm is specified this is the default behavior.

Default: round-robin.

diameter-configured

This option enables the table number and algorithm specified by the **diameter host-select table** configuration in Policy Control Configuration mode.

If the primary host in that configuration is down it assumes that the primary P-CSCF in the row of P-CSCF table is also down, and it does not return that IP address in the create PDP context response.

This option also performs the deactivation processing of the PDP contexts when Diameter Policy Control Application (DPCA) switches, host tables as detailed in the **diameter host-select** command description in Policy Control Configuration mode.

Usage

Use this command to configure the table and row selection methods to select IP address/host address for P-CSCF discovery.

Example

The following command specifies **table 1** with **round-robin** algorithm to select the rows with IP address for P-CSCF discovery.

```
p-cscf discovery table 1 algorithm round-robin
```

p-cscf table

This command adds/appends rows with primary and/or secondary IPv4/IPv6 address to a P-CSCF discovery table with precedence for Proxy-Call Session Control Function (P-CSCF) discovery.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
p-cscf table { 1 | 2 } row-precedence precedence_value { address ip_address
| ipv6-address ipv6_address } [ secondary { address ip_address | ipv6-
address ipv6_address } ]
```

```
no p-cscf table { 1 | 2 } row-precedence precedence_value
```

no

Removes/deletes configured row with precedence in specified table for P-CSCF discovery address.

{ 1 | 2 }

Specifies which P-CSCF table is to be used to add/append the primary and secondary P-CSCF addresses. Two tables can be configured for P-CSCF discovery address.

row-precedence *precedence_value*

This keyword adds/appends the row with the specified row-precedence to the P-CSCF address table.

In StarOS 8.1 and later, *precedence_value* must be an integer from 1 through 128, and a maximum of 128 rows can be added to a table.

In StarOS 8.0, *precedence_value* must be an integer from 1 through 100, and a maximum of 16 rows can be added to a table.

secondary

Specifies the secondary IPv4/IPv6 address to be entered in P-CSCF table rows.

address *ip_address*

Specifies the primary and/or secondary IPv4 address for P-CSCF discovery table. This keyword, if used with **secondary** keyword, specifies the secondary IPv4 address.

ip_address must be an IPv4 IP address entered using dotted decimal notation.

ipv6-address *ipv6_address*

Specifies the primary and/or secondary IPv6 address for P-CSCF discovery table. This keyword, if used with **secondary** keyword, specifies the secondary IPv6 address.

ipv6_address must be an IPv6 IP address entered using colon (:) separated notation.

Usage

Use this command to add rows with primary and/or secondary IP addresses for P-CSCF discovery. The row is added with the specified row-precedence.

The operator can add/remove rows to the table that is not currently selected by the **diameter host-select table** command in Policy Control Configuration Mode.

Example

The following command adds a row in **table 2** with primary IP address *1.2.3.4*, secondary IP address as *5.6.7.8*, and row-precedence value as *20* for P-CSCF discovery.

```
p-cscf table 2 row-precedence 20 address 1.2.3.4 secondary 5.6.7.8
```

policy-control

This command enters the Policy Control Configuration mode for Diameter Policy Control Application (DPCA) to configure Diameter authorization and policy control parameter for IMS authorization.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] policy-control
```

no

Disables the pre-configured policy control parameters for IMS authorization in this IMS authorization service.

Usage

Use this command to enter the Policy Control Configuration Mode to configure the policy control parameters for Diameter authorization and charging policy in IMS Authorization Service.

Example

```
policy-control
```

qos-update-timeout

This command is obsolete in release 11.0 and later releases. This command sets the Quality of Service update timeout for a subscriber in IMS authorization service.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
qos-update-timeout timeout_duration
```

```
[ no ] qos-update-timeout
```

no

Disables the pre-configured QoS update timeout parameter in this IMS authorization service.

timeout_duration

Specifies the duration of timeout in seconds, and must be an integer from 0 through 3600.
Default: 60

Usage

Use this command to set the maximum time to wait for a subscriber to initiate the update QoS procedure in IMS authorization service.

Example

The following command sets the QoS update timeout to 90 seconds.

```
qos-update-timeout 90
```

signaling-flag

This command specifies whether a request for a PDP context dedicated to signaling (for IMS sessions) should be granted or denied.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
signaling-flag { deny | permit }
```

```
[ default ] signaling-flag
```

default

Sets the signaling flag to default mode of deny.

deny

When specified this keyword denies the request for a signaling PDP context for IMS session and keeps signaling co-existed with other traffic on PDP contexts.

Default: Enabled

permit

When specified this keyword permit the request for a signaling PDP context for IMS session and a separate signaling context activated.

Default: Disabled

Usage

Use this command to allow or deny the activation of dedicated PDP context for signaling. The user equipment (UE) may indicate that the PDP context should be dedicated for IP multimedia (IM) signaling by setting the IP Multimedia Core Network (IM CN) signaling flag in the Protocol Configuration Options (PCO).

The **deny** option causes the system to inform the UE that the PDP context will not be dedicated for IM signaling and signaling will co-exist with other traffic on PDP context.

The **permit** option is used to activate the signaling context for signal traffic and the other traffic uses other PDP context for traffic with the following destinations:

- Towards the DHCP and DNS servers for the IMS domain.
- Towards the P-CSCF(s).

The UE is not trusted to follow these restrictions, and the system monitors and restricts the traffic from the dedicated PDP context. The **signaling-flow class-map** command is used to configure the restrictions.

Example

The following command denies the request for a signaling PDP context for IMS session.

```
default signaling-flag
```

signaling-flow

This command specifies the packet filters and policy servers for bandwidth control and signaling context enforcement that define the traffic that is allowed through the dedicated signaling context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
signaling-flow permit server-address ip_address [ server-port { port_num | range start_port to end_port } ] [ description STRING ]
```

```
[ no ] signaling-flow permit server-address ip_address [ server-port { port_num | range start_port to end_port } ]
```

no

Disables the signaling flow option configured with this command.

server-address *ip_address*

The server address *ip_address* refers to the destination IP address in uplink packets, and the source IP address in downlink packets.

ip_address is IPv4/IPv6 address in standard notation and can be used with sub-net mask.

A maximum of 16 signaling server address can be configured per IMS Authorization service.

server-port { *port_num* | **range** *start_port to end_port* }

Specifies the TCP/UDP port number(s) of the server and to be used for communication.

port_num must be an integer from 1 through 65535.

range *start_port to end_port* provides the option to configure the range of ports on server for communication.

start_port must be an integer from 1 through 65535 but lesser than *end_num*, and *end_port* must be an integer from 1 through 65535 but greater than *start_num*.

description *STRING*

Specifies the customized description for configured signaling server.

STRING must be an alpha and/or numeric string with maximum of 64 characters.

Usage

Traffic that matches any instance of the signaling-flow command will be forwarded via the signaling PDP context. In addition, the policy server gives policy gates to use for the signaling PDP context.

Example

The following command sets the packet filter server address to *1.2.3.4* with port number *1234* for packet filtering.

```
signaling-flow server-address 1.2.3.4 server-port 1234
```

traffic-policy

This command specifies the action on packets which do not match any policy gates in the general purpose PDP context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
traffic-policy general-pdp-context no-matching-gates direction { downlink |
uplink } { forward | discard }
```

```
default traffic-policy general-pdp-context no-matching-gates direction {
downlink | uplink }
```

default

Sets the default traffic policy for packets without any policy gate match in general purpose PDP context. By default packets which do not have any matching policy gate are forwarded.

no-matching gates

This keyword applies traffic policy for packets which do not match any policy gate.

direction { downlink | uplink }

Specifies the direction of traffic to apply this traffic policy in general PDP context.

downlink: specifies the traffic from system to MN. Default is set to forward.

uplink: specifies the traffic from MN to system. Default is set to forward.

forward

This option forward the packets which do not match any policy gates.

Default: Enabled

discard

This option discards the packets which do not match any policy gates.

Default: Disabled

Usage

This command provides configuration on traffic policy applied on packets which are not matching any policy gate in general PDP context. Packets can either forwarded or discarded on the basis of operators configuration.

This command needs to be configured once for downlink and once for uplink separately.

Example

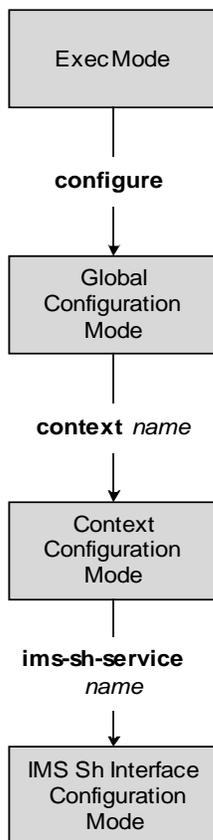

The following command discard uplink packets which do not match any policy gate in general purpose PDP context.

```
traffic-policy general-pdp-context no-matching-gates direction uplink  
discard
```

Chapter 144

IMS Sh Service Configuration Mode Commands

The IMS Sh Interface Configuration Mode is used to configure various Diameter parameters in order for: PDIF to communicate with the HSS server. HSS server is used for MAC address validation in the IKEv2 exchanges to set up SAs and for storing part of the user profile. SCM to communicate with the HSS server. HSS server is used for retrieval and update of call feature parameters and call restriction data.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

diameter

This command configures Diameter parameters.

Product

PDIF, SCM

Privilege

Administrator

Syntax

```
diameter { dictionary { custom1 | standard | endpoint string }
default diameter { dictionary | endpoint }
no diameter endpoint
```

no

Removes previously configured endpoint.

default

Configures parameters to the default value.

dictionary

Specifies the dictionary to use.

- **custom1**: A custom dictionary
- **standard**: The standard dictionary

Important: SCM uses only the standard dictionary.

endpoint *string*

Selects an endpoint to use in the configuration.

string must be the endpoint name, and must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage

The Diameter endpoint contains information on the peer names and IP addresses and port, and the local IP address to use for Diameter.

You can have more than one Diameter endpoint configured on the chassis and the `ims-sh-service` needs to know which Diameter endpoint to use. This command is to select the appropriate Diameter endpoint, even if only one has been configured.

Example

The following example selects a diameter endpoint `diam1`:

```
diameter endpoint diam1
```

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to change to the Exec Mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

failure-handling

This command configures the action to take in the event of an HSS server request failure.

Product

PDIF, SCM

Privilege

Administrator

Syntax

```
[ default ] failure-handling { profile-update-request | user-data-request } { {
diameter-result-code result_code [ to result_code ] } | timeout } action {
continue | retry-and-terminate | terminate } }
```

default

Resets configuration for the specified keyword to the default setting.

profile-update-request

Configures failure-handling as a result of a profile update request error.

user-data-request

Configures failure-handling as a result of a user data request.

diameter-result-code *result_code* [to *result_code*]

The Result-Code data field contains a space representing errors. Diameter provides the following classes of errors, all identified by the thousands digit in the decimal notation:

- 3xxx (Protocol Errors)
- 4xxx (Transient Failures)
- 5xxx (Permanent Failure)

result_code specifies either a result code value (**diameter-result-code 3001**) or a range of result code values (**diameter-result-code 3000 to 9999**) to which the failure-handling applies.

action

Configures the action to take depending on the diameter-result-code:

- Continue the session
- Retry and then terminate
- Terminate the session

request-timeout action

Configures the action to take as a result of a request timeout error:

- Continue the session
- Retry and then terminate
- Terminate the session

Usage

Configures all failure-handling parameters.

Example

The following command configures profile-update-request failure-handling using a result-code configuration with the terminate session option:

```
failure-handling profile-update-request diameter-result-code 3005 to  
3600action terminate
```

request

Configures application request timeout.

Product

PDIF, SCM

Privilege

Administrator

Syntax

```
request timeout secs
```

```
[ no | default ] request timeout
```

no

Disables a configured timeout request.

default

Default: 300 seconds

Resets configuration to the default setting.

request timeout *secs*

Configures the request timeout in seconds.

secs must be an integer from 1 through 300.

Usage

Specifies the session request timeout period in seconds after which the request is deemed to have failed.

Example

The following example configures the default timeout request of 300 seconds:

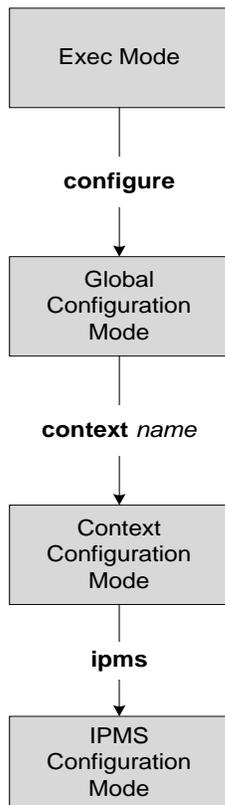

```
default request timeout
```

Chapter 145

IPMS Client Configuration Mode Commands

The IPMS Client Configuration Mode is used to enable the IPMS client service on an Access Gateway and to set basic service wide options in a context.

 **Important:** This is a license enabled external application support. For more information on this product, refer to the IPMS Installation and Administration Guide.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns the CLI session to the previous parent mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the parent CLI mode.

export keys

This command enables the encryption key export in specific key exchange events to IPMS server from IPMS-enabled AGW.

Important: This is a license enabled customer specific command.

Product

IPMS

Privilege

Security Administrator, Administrator

Syntax

no

Removes the configured source IP address from this context for IPMS client communication with IPMS server.

ikev2

This keyword enables the security association (SA) key export for Internet Key Exchange (IKEv2) protocol to IPMS server.

Usage

Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.

Example

The following command assigns the IP address 1.2.3.4 to the IPMS client service in context to communicate with IPMS server. This is the IP address allocated for IPMS client service on chassis.

```
source address 1 . 2 . 3 . 4
```

heartbeat

This command configures the IPMS heartbeating between IPMS-enabled AGW and IPMS server.

Product

IPMS

Privilege

Security Administrator, Administrator

Syntax

```
heartbeat period dur [ permitted-failureno_of_failures ]
[ no | default ] heartbeat
```

default

Configures the heartbeat period and permitted number of failure to default value of 10 seconds and 1 failure respectively.

no

Disables/removes the configured heartbeat period and permitted number of failure.

period *dur*

Default: 10

Specifies the periodicity in seconds of heartbeat messages.

dur is the duration in second between two heartbeat messages and must be an integer value from 1 through 3600.

permitted-failure *no_of_failures*

Default: 1

Specifies the number of errors/failures allowed before declaring an IPMS server as dead/unreachable.

no_of_failures is the number of errors/failure of heartbeat message response and must be an integer value from 1 through 10.

Usage

Use this command to configure the heartbeat message periodicity and permissible failure of heartbeat message response before declaring an IPMS server as dead or unreachable. When an IPMS server is declared down an SNMP trap is sent.

Example

Following command configures the heartbeat message periodicity to 5 second and number of failures allowed as 3 to determine an IPMS server as dead.

```
heartbeat period 5 permitted-failure 3
```

server

This command configures the IPMS server address and ports on which IPMS client on IPMS-enabled AGW communicates. This is the IP address and port range of IPMS server.

Product

IPMS

Privilege

Security Administrator, Administrator

Syntax

```
server address ip_address [ secondary ] [ start-port start_port [ end-port end_port ] ][ secondary ]
```

```
no server address ip_address
```

no

Removes the configured IPMS server IP address and port range from this context.

address *ip_address*

Specifies the IP address of the IPMS server to which the IPMS client service communicates. This is the address which is used by IPMS client service to locate the IPMS server.

A maximum of 4 IPMS servers can be configured with this command in one context.

ip_address must be an IP v4 address in dotted decimal notation.

[**start-port** *start_port* [**end-port** *end_port*]]

Default: 45001 source port

45005 end port

Specifies the range of UDP ports on which IPMS client communicates with IPMS server.

start-port start_port is the starting port number and must be an integer value in the range from 1 through 65535 but less than *end_port*, if end-port is specified.

end-port end_port is the end port number and must be an integer value in the range from 1 through 65535 but more than *start_port*.

secondary

The secondary keyword is used to configure the specified server address as secondary IP address on the IPMS client interface.

Usage

Use this command to configure/remove the IPMS servers. Up to 4 different IPMS servers can be configured with this command. UDP port number can also be configured with this command. IPMS client will search for this IP address to push the event and traffic logs.

Example

The following command configures IPMS server having IP address 1.2.3.4 in the IPMS client service export the event and traffic logs for intelligent packet monitoring functionality. It also specifies the UDP port range from 48000 to 48005 for communication.

```
server address 1.2.3.4 start-port 48000 end-port 48005
```

source

This command configures the source address of IPMS client in this context to communicate with IPMS server. This is the IP address for IPMS client on the chassis.

Product

IPMS

Privilege

Security Administrator, Administrator

Syntax

```
source address ip_address
```

```
address ip_address
```

Specifies the IP address of the IPMS client on the AGW in this context. This is the address which is bound to the IPMS client service in this context.

ip_address must be an IP v4 address in dotted decimal notation.

Usage

Monitor subscribers which have complaints of service availability or to monitor a test user for system verification.

Example

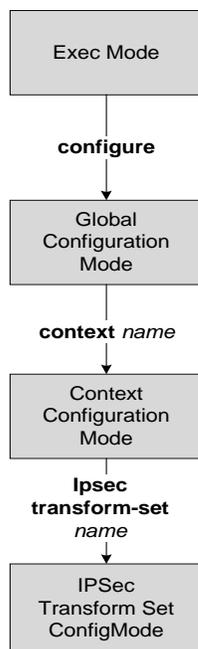

The following command assigns the IP address 1.2.3.4 to the IPMS client service in context to communicate with IPMS server. This is the IP address allocated for IPMS client service on chassis.

```
source address 1.2.3.4
```

Chapter 146

IPSec Transform Set Configuration Mode Commands

The IPSec Transform Set Configuration Mode is used to configure IPsec security parameters. There are two core protocols, the Authentication Header (AH) and Encapsulating Security Payload (ESP). AH may be considered redundant as ESP can provide the same authentication services that AH does.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

default

Set or restore the default mode for a given parameter

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
default { encryption | group | hmac | mode }
```

```
default { encryption | group | hmac | mode
```

Set the defaults for the IPSec transform-set as follows:

- encryption**: Default Child SA IPSec ESP algorithm is AES-CBC-128.
- group**: Default Diffie-Hellman group algorithm is none. This also deactivates PFS.
- hmac**: Default Child SA IPSec hashing algorithm is SHA1-96.
- mode**: Default Child SA IPSec Mode is Tunnel.

Usage

Defines the default values for the Child SA IPSec transform-set.

Example

Use the following configuration to set the default mode to Tunnel:

```
default mode
```

encryption

Configures the appropriate IPsec ESP encryption algorithm and encryption key length. AES-CBC-128 is the default.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
encryption { 3des-cbc | aes-cbc-128 | aes-cbc-256 | des-cbc | null }
```

default encryption

3des-cbc

Data Encryption Standard Cipher Block Chaining encryption applied to the message three times using three different cypher keys (triple DES).

aes-cbc-128

Advanced Encryption Standard Cipher Block Chaining with a key length of 128 bits. This is the default setting for this command.

aes-cbc-256

Advanced Encryption Standard Cipher Block Chaining with a key length of 256 bits.

des-cbc

Data Encryption Standard Cipher Block Chaining. Encryption using a 56-bit key size. Relatively insecure.

null

The NULL encryption algorithm represents the optional use of applying encryption within ESP. ESP can then be used to provide authentication and integrity without confidentiality.

Usage

In cipher block cryptography, the plaintext is broken into blocks usually of 64 or 128 bits in length. In cipher block chaining (CBC) each encrypted block is chained into the next block of plaintext to be encrypted. A randomly generated vector is applied to the first block of plaintext in lieu of an encrypted block. CBC provides confidentiality, but not message integrity.

Because RFC 4307 calls for interoperability between IPsec and IKEv2, the IKEv2 confidentiality algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange. In IKEv2, there is no NULL option.

Example

The following command configures the encryption to be the default aes-cbc-128:

■ encryption

`default encryption`

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec Mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Returns to the previous mode.

group

Configure the appropriate key exchange cryptographic strength and activate Perfect Forward Secrecy by applying a Diffie-Hellman group.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
group { 1 | 2 | 5 | 14 | none }
```

default group

default group

Configures the default crypto strength to be **none** and disables Perfect Forward Secrecy.

1

Configures crypto strength at the Group 1 level. Lowest security.

2

Configures crypto strength at the Group 2 level. Medium security.

5

Configures crypto strength at the Group 5 level. Higher security.

14

Configures crypto strength at the Group 14 level. Highest security.

none

Applies no group and disables Perfect Forward Secrecy. This is the default.

Usage

Diffie-Hellman groups are used to determine the length of the base prime numbers used during the key exchange process. The cryptographic strength of any key derived depends, in part, on the strength of the Diffie-Hellman group upon which the prime numbers are based.

Group 1 provides 768 bits of keying strength, Group 2 provides 1024 bits, Group 5 provides 1536 bits and Group 14 provides 2048 bits. Selecting a group automatically activates Perfect Forward Secrecy. The default value is none, which disables PFS.

Example

This command configures security at Group 2 and activates PFS:

```
■ group
```

```
group 2
```

hmac

Configures the IPsec ESP integrity algorithm.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
hmac { md5-96 | sha1-96 | null }
```

```
default hmac
```

default

Configures the default hmac value of sha1-96.

md5-96

MD5-96 uses a 128-bit secret key and produces a 128-bit authenticator value.

sha1-96

SHA-1 uses a 160-bit secret key and produces a 160-bit authenticator value. This is the default setting for this command.

null

Configures the hmac value to be null. The NULL encryption algorithm represents the optional use of applying encryption within ESP. ESP can then be used to provide authentication and integrity without confidentiality.

Usage

HMAC is an encryption technique used by IPsec to make sure that a message has not been altered. A keyed-Hash Message Authentication Code, or HMAC, is a type of message authentication code (MAC) calculated using a cryptographic hash function in combination with a secret key to verify both data integrity and message authenticity. A hash takes a message of any size and transforms it into a message of a fixed size: the authenticator value. This is truncated to 96 bits and transmitted. The authenticator value is reconstituted by the receiver and the first 96 bits are compared for a 100 percent match. Because RFC 4306 calls for interoperability between IPsec and IKEv2, the IKEv2 integrity algorithms must be the same as those configured for IPsec in order for there to be an acceptable match during the IKE message exchange.

Example

The following command configures the default HMAC value (SHA1-96):

```
default hmac
```

■ hmac

mode

Configures the security of IP datagrams based on header placement. Tunnel mode applies security to a completely encapsulated IP datagram, while Transport does not. Default is Tunnel mode.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
mode { transport | tunnel }
```

```
default mode
```

transport

In Transport mode, the IPSec header is applied only over the IP payload, not over the IP header in front of it. The AH and/or ESP headers appear between the original IP header and the IP payload, as follows: Original IP header, IPSec headers (AH and/or ESP), IP payload (including transport header). Transport mode is used for host-to-host communications and is generally unsuited to PDIF traffic.

tunnel

In Tunnel mode, the original IP header is left intact, so a complete IP datagram is encapsulated, forming a virtual tunnel between IPSec-capable devices. The IP datagram is passed to IPSec, where a new IP header is created ahead of the AH and/or ESP IPSec headers, as follows: New IP header, IPSec headers (AH and/or ESP), old IP header, IP payload. Tunnel mode is used for network-to-network communications (secure tunnels between routers) or host-to-network and host-to-host communications over the Internet. This is the default setting for this command.

Usage

IPSec modes are closely related to the function of the two core protocols, the Authentication Header (AH) and Encapsulating Security Payload (ESP). Both of these protocols provide protection by adding to a datagram a header (and possibly other fields) containing security information. The choice of mode does not affect the method by which each generates its header, but rather, changes what specific parts of the IP datagram are protected and how the headers are arranged to accomplish this.

Example

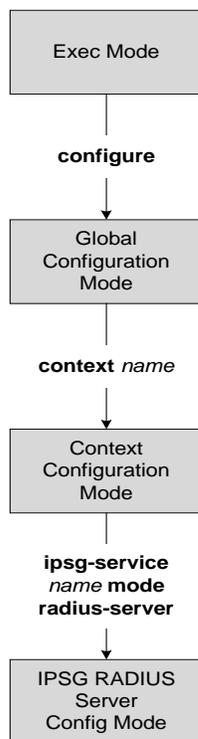

The following command configures the default Tunnel mode:

```
default mode
```

Chapter 147

IPSG RADIUS Server Configuration Mode Commands

The IP Services Gateway (IPSG) RADIUS Server Configuration Mode is used to create and configure IPSG services in the current system context. The IPSG RADIUS Server Mode configures the system to receive RADIUS accounting requests as if it is a RADIUS Accounting Server, and reply after accessing those requests for user information.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

bind

This command binds the IPSG RADIUS Server service to a logical AAA interface and specifies the number of allowed subscriber sessions.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
bind { accounting-proxy address ip_address | address ip_address } [ max-subscribers max_sessions | port port_number | source-context source_context ]
```

```
bind authentication-proxy address ip_address [ acct-port port_number | auth-port port_number | max-subscribers max_sessions | source-context source_context ]
```

```
no bind
```

```
no
```

Removes the binding for the service.

```
accounting-proxy address ip_address | address ip_address } [ max-subscribers max_sessions | port port_number | source-context source_context ]
```

- **accounting-proxy address** *ip_address*: Specifies IP address of the interface where accounting proxy requests are received by this service.
ip_address must be specified using standard IPv4 or IPv6 dotted decimal notation.
- **address** *ip_address*: Specifies IP address of the interface where accounting requests are received by this service.
ip_address must be specified using standard IPv4 or IPv6 dotted decimal notation.
- **max-subscribers** *max_sessions*: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.
On an ASR 5000 chassis, in Release 8.x, *max_sessions* must be an integer from 0 through 3000000. In Release 9.x and later, *max_sessions* must be an integer from 0 through 4000000.
- **port** *port_number*: Specifies the port number of the interface where accounting requests are received by this service.
port_number must be an integer from 0 through 65535.
Default: 1813
- **source-context** *source_context*: Specifies the source context where RADIUS accounting requests are received.
source_context must be an alpha and/or numeric string of 1 through 79 characters in length.

This keyword should be configured if the source of the RADIUS requests is in a different context than the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

```
authentication-proxy address ip_address [ acct-port port_number | auth-port port_number | max-subscribers max_sessions | source-context source_context ]
```

- **authentication-proxy** address *ip_address*: Specifies IP address of the interface where authentication proxy requests are received by this service.

ip_address must be specified using standard IPv4 or IPv6 dotted decimal notation.

Important: Enabling authentication proxy also enables accounting proxy.

- **acct-port** *port_number*: Specifies the port number of the interface where accounting proxy requests are received by this service.

port_number must be an integer from 0 through 65535.

Default: 1813

- **auth-port** *port_number*: Specifies the port number of the interface where authentication proxy requests are received by this service.

port_number must be an integer from 0 through 65535.

Default: 1812

- **max-subscribers** *max_sessions*: Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.

On an ASR 5000 chassis, in Release 8.x, *max_sessions* must be an integer from 0 through 3000000. In Release and 9.0 and later, *max_sessions* must be an integer from 0 through 4000000.

- **source-context** *source_context*: Specifies the source context where RADIUS accounting requests are received.

source_context must be an alpha and/or numeric string of 1 through 79 characters in length.

This keyword should be configured if the source of the RADIUS requests is in a different context than the IPSG service. If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

Usage

Use this command to bind the IPSG RADIUS Server service to a logical AAA interface and specify the number of allowed subscriber sessions. If the AAA interface is not located in this context, configure the **source-context** parameter.

Use the accounting and authentication proxy settings to enable RADIUS proxy server functionality on the IPSG. These commands are used when the NAS providing the RADIUS request messages is incapable of sending them to two separate devices. The IPSG in RADIUS Server mode proxies the RADIUS request and response messages while performing the user identification task in order to provide services to the session.

Example

bind

The following command binds the service to a AAA interface with an IP address of `1.2.3.4` located in the source context named `aaa_ingress`:

```
bind address 1.2.3.4 source-context aaa_ingress
```

connection authorization

This command configures the RADIUS authorization password that must be matched by the RADIUS accounting requests received by this service.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
connection authorization { [ encrypted ] password password }
```

```
no connection authorization
```

no

Removes the RADIUS authorization for the IPSG RADIUS server service.

[encrypted] password *password*

- **encrypted**: Specifies that the RADIUS authorization password is encrypted.
- **password *password***: Specifies the password that must be matched by incoming RADIUS accounting requests.
password must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage

The IPSG RADIUS server service does not terminate RADIUS user authentication so the user password is unknown.

Use this command to configure the authorization password that the RADIUS accounting requests must match in order for the service to examine and extract user information.

Example

The following command sets the RADIUS authorization password that must be matched by the RADIUS accounting requests sent to this service. The password must be encrypted and the example provided is the word “*secret*”.

```
connection authorization encrypted password secret
```

■ end

end

This command exits the IPSG RADIUS Server Configuration Mode and returns the CLI prompt to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to change to the Exec Mode.

exit

This command exits the IPSG RADIUS Server Configuration Mode and returns the CLI prompt to the Context Configuration Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax**exit**

Usage

Use this command to return to the Context Configuration Mode.

profile

This command configures the service to use APN or subscriber profiles.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
profile { APN | subscriber }
```

default profile

default

Configures the default setting for this command.

Default: **APN**

APN

Sets the service to support APN configuration required to enable Gx support.

subscriber

Sets the service to support subscriber profile lookup.

Usage

Use this command to set the service to support APN profiles (supporting Gx through the enabling of **ims-auth-service**) or for basic subscriber profile lookup.

radius accounting

Specifies the IP address and shared secret of the RADIUS accounting client from which RADIUS accounting requests are received. The RADIUS client can be either the access gateway or the RADIUS accounting server depending on which device is sending accounting requests.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
radius accounting { { client { ip_address | ip_address/mask } [ encrypted ] key
secret [ dictionary dictionary ] [ disconnect-message [ dest-port
destination_port ] ] } | { interim create-new-call } }
```

```
no radius accounting client { ip_address | ip_address/mask }
```

```
default radius accounting interim create-new-call
```

no

Removes the RADIUS accounting client address identifier from the service.

```
ip_address | ip_address/mask
```

Specifies the IP address and, optionally, subnet mask of the RADIUS client from which RADIUS accounting requests are received.

ip_address and *ip_address/mask* must be specified using standard IPv4 or IPv6 dotted decimal notation.

Up to 16 addresses can be configured.

dictionary *dictionary*

Specifies what dictionary database to use. The possible values for *dictionary* are described in the following table:

Table 25.

Dictionary	Description
3gpp2	This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.
3gpp2-835	This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835.
customX	These are dictionaries that can be customized to fit your needs. Customization information can be attained by contacting your local service representative. X is the integer value of the custom dictionary.
standard	This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.

Dictionary	Description
starent	This dictionary consists of all of the attributes in the starent-vsa1 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system.
starent-835	This dictionary consists of all of the attributes in the starent-vsa1-835 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system.
starent-vsa1	This dictionary consists not only of the 3gpp2 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.
starent-vsa1-835	This dictionary consists not only of the 3gpp2-835 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.

[**encrypted**] **key** *secret*

- encrypted**: Specifies that the shared key between the RADIUS client and this service is encrypted.

- key** *secret*: Specifies the shared key between the RADIUS client and this service.

secret must be an alpha and/or numeric string of 1 through 127 characters in length, and is case sensitive.

disconnect-message [**dest-port** *destination_port*]

Specifies sending disconnect message.

dest-port *destination_port*: Optionally, the port number to which the disconnect message must be sent can be specified.

destination_port must be an integer from 1 through 65535.

interim create-new-call

Enables the ability to create a new session upon receipt of a RADIUS interim message.

Default: Disabled

Usage

Use this command to configure the communication with the RADIUS client from which RADIUS accounting requests are received.

Example

The following command configures the service to communicate with a RADIUS client with an IP address of 1.2.3.4 and an encrypted shared secret of *secret_1234*:

```
radius accounting client 1.2.3.4 encrypted key secret_1234
```

radius dictionary

Configures the RADIUS database dictionary to use for the IPSG service.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
radius dictionary dictionary
```

```
default radius dictionary
```

```
dictionary dictionary
```

Default: **starent-vsaa1**

Specifies what dictionary database to use. The possible values for *dictionary* are described in the table that follows:

Table 26.

Dictionary	Description
3gpp2	This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.
3gpp2-835	This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835.
customXX	These are dictionaries that can be customized to fit your needs. Customization information can be attained by contacting your local service representative. XX is the integer value of the custom dictionary.
standard	This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.
starent	This dictionary consists of all of the attributes in the starent-vsaa1 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system.
starent-835	This dictionary consists of all of the attributes in the starent-vsaa1-835 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system.
starent-vsaa1	This dictionary consists not only of the 3gpp2 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.
starent-vsaa1-835	This dictionary consists not only of the 3gpp2-835 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.

radius dictionary

Usage

Use this command to specify the RADIUS database dictionary to use for the IPSG service.

Example

The following command configures the IPSG service to use the *custom10* RADIUS database dictionary:

```
radius dictionary custom10
```

setup-timeout

Configures a timeout value for IPSG session set up attempts.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
setup-timeout seconds
```

```
default setup-timeout
```

seconds

Specifies the time period, in seconds, the IPSG session setup is allowed to continue before the set up attempt is terminated.

seconds must be an integer from 1 through 100000.

Default: 60

Usage

Use this command to prevent IPSG session set up attempts from continuing without termination.

Example

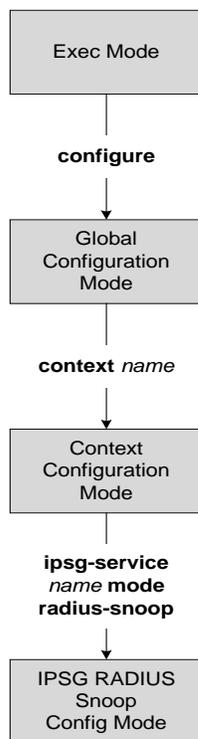

The following command sets the session setup timeout to 20 seconds:

```
setup-timeout 20
```

Chapter 148

IPSG RADIUS Snoop Configuration Mode Commands

The IP Services Gateway (IPSG) RADIUS Snoop Configuration Mode is used to create and configure IPSG services within the current context. The IPSG RADIUS Snoop Mode configures the system to inspect RADIUS accounting requests on the way to the RADIUS accounting server and extract user information.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

bind

Configures the service to accept data on any interface configured in the context. Optionally allows the system to limit the number of sessions processed by this service.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
bind [ max-subscribers max_sessions ]
```

```
no bind
```

no

Removes the binding for the service.

max-subscribers *max_sessions*

Specifies the maximum number of subscriber sessions allowed for the service. If this option is not configured, the system defaults to the license limit.

On an ASR 5000 chassis, in Release 8.x, *max_sessions* must be an integer from 0 through 3000000. In Release 9.0 and later, *max_sessions* must be an integer from 0 through 4000000.

Usage

Use this command to initiate the service and begin accepting data on any interface configured in the context.

Example

The following command prepares the system to receive subscriber sessions on any interface in the context and limits the sessions to *10000*:

```
bind max-subscribers 10000
```

connection authorization

Sets the RADIUS authorization password that must be matched by the RADIUS accounting requests “snooped” by this service.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
connection authorization [ encrypted ] password password
```

```
no connection authorization
```

no

Removes the RADIUS authorization for the IPSG RADIUS snoop service.

```
[ encrypted ] password password
```

- **encrypted**: Specifies that the received RADIUS authorization password is encrypted.

- **password *password***: Specifies the password that must be matched by incoming RADIUS accounting requests.

password must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage

RADIUS accounting requests being examined by the IPSG RADIUS snoop service are destined for a RADIUS Accounting Server. Since the “snoop” service does not terminate user authentication, the user password is unknown.

Use this command to configure the authorization password that the RADIUS accounting requests must match in order for the service to examine and extract user information.

Example

The following command sets the RADIUS authorization password that must be matched by the RADIUS accounting requests “snooped” by this service. The password must be encrypted and the example provided is the word “*secret*”.

```
connection authorization encrypted password secret
```

■ end

end

This command exits the IPSG RADIUS Snoop Configuration Mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to change to the Exec Mode.

exit

This command exits the IPSG RADIUS Snoop Configuration Mode and returns to the Context Configuration Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the Context Configuration Mode.

radius

Specifies RADIUS accounting servers where accounting requests are sent after being “inspected” by this service.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] radius { accounting server ip_address [ port port_number | source-context
name ] | dictionary { 3gpp2 | 3gpp2-835 | custom XX | standard | starent |
starent-835 | starent-vs1 | starent-vs1-835 } }
```

no

Removes the RADIUS accounting server identifier from this service.

radius accounting server *ip_address*

Specifies the IP address of a RADIUS Accounting Server where accounting requests are sent after being “snooped” by this service.

ip_address must be specified using standard IPv4 or IPv6 dotted decimal notation and must be a valid IP address.

Up to 16 addresses can be configured.

port *port_number*

Specifies the port number of the RADIUS Accounting Server where accounting requests are sent after being “snooped” by this service.

port_number must be an integer from 0 through 65535.

Default: 1813

source-context *name*

Specifies the source context where RADIUS accounting requests are received.

name must be an alpha and/or numeric string of 1 through 79 characters in length.

If this keyword is not configured, the system will default to the context in which the IPSG service is configured.

```
dictionary { 3gpp2 | 3gpp2-835 | custom XX | standard | starent |
starent-835 | starent-vs1 | starent-vs1-835 }
```

Specifies what dictionary to use. The possible values are described in the following table:

Table 27.

Dictionary	Description
3gpp	This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in 3GPP 32.015.

Dictionary	Description
3gpp2	This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835-A.
3gpp2-835	This dictionary consists not only of all of the attributes in the standard dictionary, but also all of the attributes specified in IS-835.
customXX	These are dictionaries that can be customized to fit your needs. Customization information can be attained by contacting your local service representative. XX is the integer value of the custom dictionary.
standard	This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.
starent	This dictionary consists of all of the attributes in the starent-vsaa1 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system.
starent-835	This dictionary consists of all of the attributes in the starent-vsaa1-835 dictionary and incorporates additional Starent Networks VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system.
starent-vsaa1	This dictionary consists not only of the 3gpp2 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.
starent-vsaa1-835	This dictionary consists not only of the 3gpp2-835 dictionary, but also includes Starent Networks vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0 - 255). This is the default dictionary.

Usage

Use this command to specify the RADIUS Accounting Servers where accounting requests are sent after being snooped by this service.

Example

The following command specifies the IP address (1.2.3.4) of a RADIUS Accounting Server whose accounting requests are to be “snooped”, and the source context (*aaa_ingress*) where the requests are received on the system:

```
radius accounting server 1.2.3.4 source-context aaa_ingress
```

setup-timeout

Configures a timeout value for IPSG session setup attempts.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
setup-timeout setup_timeout
```

```
default setup-timeout
```

```
setup_timeout
```

Specifies the period of time, in seconds, the IPSG session setup is allowed to continue before the setup attempt is terminated.

setup_timeout must be an integer from 1 through 100000.

Default: 60

Usage

Use this command to prevent IPSG session setup attempts from continuing without termination.

Example

The following command configures the session setup timeout setting to 20 seconds:

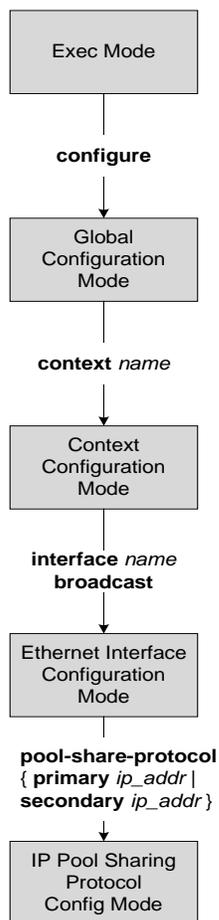

```
setup-timeout 20
```

Chapter 149

IPSP Configuration Mode Commands

The IPSP Configuration Mode is used to configure properties for the IP pool sharing protocol (IPSP).

 **Important:** For information on configuring and using IPSP refer to the System Administration and Configuration Guide.

dead-interval

Configures the retry time to connect to the remote system for the IP Pool Sharing Protocol.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

dead-interval*seconds*

[**no** | **default**] **dead-interval**

no

Disables the dead interval. On loss of connectivity to the remote system, no retries are attempted and the remote system is marked dead immediately on failure.

default

Resets the dead interval to the default of 3600 seconds.

seconds

Default: 3600 seconds

The amount of time in seconds to wait before retrying the remote system. *seconds* must be an integer from 25 through 259200.

Usage

Use this command to set the amount of time to wait before retrying to connect with the remote system for the IP pool sharing protocol.

Example

Use the following command to set the interval to 180 seconds (3 minutes):

```
dead-interval 180
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

■ exit

exit

Exits the current configuration mode and returns to the context configuration mode.

Product

PDNS, HA

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

reserved-free-percentage

This command is used to set the amount of free addresses reserved for use on the primary HA.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
reserved-free-percentage value
```

```
default reserved-free-percentage
```

value

Default: 100

value specifies the percentage of free addresses reserved for the use on the primary HA for IP pool sharing during upgrade.

Usage

This command is used with **pool-sharing-protocol active mode** on primary HA. Before using this command, **pool-sharing-protocol** in Ethernet Interface Configuration Mode must be configured.

For more information, refer to the *Ethernet Interface Configuration Mode Commands* chapter in this guide.

Example

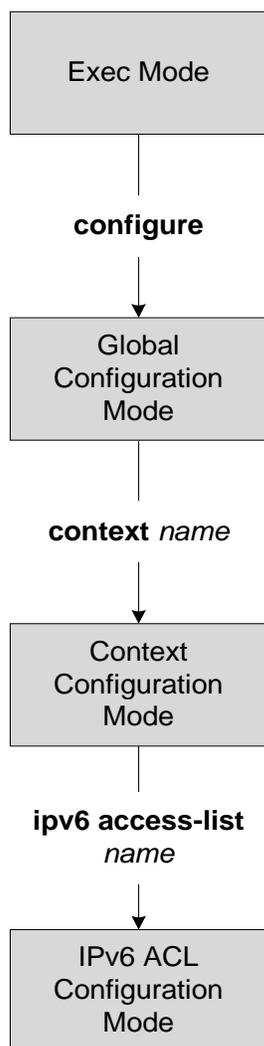

To reserve 40 percent of free addresses in primary HA for IP pool sharing, enter the following command:

```
reserved-free-percentage 40
```

Chapter 150

IPv6 ACL Configuration Mode Commands

The IPv6 Access Control List Configuration Mode is used to create and manage IPv6 access privileges.

deny/permit (by source IP address masking)

Used to filter subscriber sessions based on the IPv6 address mask sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
{ deny | permit } [ log ] source_address source_wildcard
after { deny | permit } [ log ] source_address source_wildcard
before { deny | permit } [ log ] source_address source_wildcard
no { deny | permit } [ log ] source_address source_wildcard
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny:** Indicates the rule, when matched, drops the corresponding packets.
- **permit:** Indicates the rule, when matched, allows the corresponding packets.

log

Default: packets are not logged.

Indicates all packets which match the filter are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

 **Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

Usage

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rules as it does not require a rule for each source and destination pair.

 **Important:** The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example

The following command defines two rules with the second logging filtered packets:

```
permit 1:1:1:1:1:1:1:1
```

```
deny log 1:1:1:1:1:1:1:1
```

The following sets the insertion point to before the first rule defined above:

```
before permit 1:1:1:1:1:1:1:1
```

The following command sets the insertion point after the second rule defined above:

```
after deny log 1:1:1:1:1:1:1:1
```

The following deletes the first rule defined above:

```
no permit 1:1:1:1 1:1:1:1
```

deny/permit (any)

Used to filter subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
{ deny | permit } [ log ] any
after { deny | permit } [ log ] any
before { deny | permit } [ log ] any
no { deny | permit } [ log ] any
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny:** Indicates the rule, when matched, drops the corresponding packets.
- **permit:** Indicates the rule, when matched, allows the corresponding packets.

log

Default: packets are not logged.

Indicates all packets which match the filter are to be logged.

any

Indicates all packets will match the filter regardless of source and/or destination.

Usage

Define a catch all rule to place at the end of the list of ru

Important: It is suggested that any rule which is added to be a catch all should also have the **log** option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example

The following command defines two rules with the second logging filtered packets:

```
permit any
```

```
deny log any
```

The following sets the insertion point to before the first rule defined above:

```
before permit any
```

The following command sets the insertion point after the second rule defined above:

```
after deny log any
```

The following deletes the first rule defined above:

```
no permit any
```

deny/permit (by host IP address)

Used to filter subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
{ deny | permit } [ log ] host source_host_address
after { deny | permit } [ log ] host source_host_address
before { deny | permit } [ log ] host source_host_address
no { deny | permit } [ log ] host source_host_address
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny:** Indicates the rule, when matched, drops the corresponding packets.
- **permit:** Indicates the rule, when matched, allows the corresponding packets.

log

Default: packets are not logged.

Indicates all packets which match the filter are to be logged.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage

Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example

The following command defines two rules with the second logging filtered packets:

```
permit host 1:1:1:1:1:1:1:1:1
deny log host 1:1:1:1:1:1:1:1:1
```

The following sets the insertion point to before the first rule defined above:

```
before permit host 1:1:1:1:1:1:1:1:1
```

The following command sets the insertion point after the second rule defined above:

```
after deny log host 1:1:1:1:1:1:1:1:1
```

The following deletes the first rule defined above:

```
no permit host 1:1:1:1:1:1:1:1:1
```

deny/permit (by source ICMP packets)

Used to filter subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
{ deny | permit } [ log ] icmp { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
after { deny | permit } [ log ] icmp { source_address source_wildcard | any |
host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
before { deny | permit } [ log ] icmp { source_address source_wildcard | any |
host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
no { deny | permit } [ log ] icmp { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny**: Indicates the rule, when matched, drops the corresponding packets.
- **permit**: Indicates the rule, when matched, allows the corresponding packets.

log

Default: packets are not logged.

Indicates all packets which match the filter are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

■ deny/permit (by source ICMP packets)

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

icmp_type

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

icmp_code

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

Usage

Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk. The IP filtering allows flexible controls for pairs of individual hosts or groups by IP masking which allows the filtering of entire subnets if necessary.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example

The following command defines two rules with the second logging filtered packets:

```
permit icmp host 1.2.3.4 any 168
deny log icmp 1.2.3.0 0.0.0.31 host 1.2.4.16 168 11
```

The following sets the insertion point to before the first rule defined above:

```
before permit icmp host 1.2.3.4 any 168
```

The following command sets the insertion point after the second rule defined above:

```
after deny log icmp 1.2.3.0 0.0.0.31 host 1.2.4.16 168 11
```

The following deletes the first rule defined above:

```
no permit icmp host 1.2.3.4 any 168
```

deny/permit (by IP packets)

Used to filter subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
{ deny | permit } [ log ] ip { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ fragment ] [ protocolnum ]
```

```
after { deny | permit } [ log ] ip { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ fragment ] [ protocolnum ]
```

```
before { deny | permit } [ log ] ip { source_address source_wildcard | any |
host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ fragment ] [ protocolnum ]
```

```
no { deny | permit } [ log ] ip { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ fragment ] [ protocolnum ]
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny**: indicates the rule, when matched, drops the corresponding packets.
- **permit**: indicates the rule, when matched, allows the corresponding packets.

log

Default: packets are not logged.

Indicates all packets which match the filter are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

fragment

Indicates packet filtering is to be applied to IP packet fragments only.

protocol num

Indicates that the packet filtering is to be applied to a specific protocol number. *num* can be any integer ranging from 0 to 255.

Usage

Block IP packets when the source and destination are of interest.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example

The following command defines two rules with the second logging filtered packets:

```
permit ip host 1.2.3.4 any fragment
deny log ip 1.2.3.0 0.0.0.31 host 1.2.4.16
```

The following sets the insertion point to before the first rule defined above:

```
before permit ip host 1.2.3.4 any fragment
```

The following command sets the insertion point after the second rule defined above:

```
after deny log ip 1.2.3.0 0.0.0.31 host 1.2.4.16
```

The following deletes the first rule defined above:

```
no permit ip host 1.2.3.4 any fragment
```

deny/permit (by TCP/UDP packets)

Used to filter subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
{ deny | permit } [ log ] { tcp | udp } { { source_address source_wildcard | any
| host source_host_address } [ eq source_port | gt source_port | lt source_port
| neq source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port
] }
```

```
after { deny | permit } [ log ] { tcp | udp } { { source_address source_wildcard
| any | host source_host_address } [ eq source_port | gt source_port | lt
source_port | neq source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port
] }
```

```
before { deny | permit } [ log ] { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port ] } { { dest_address
dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port |
lt dest_port | neq dst_port ] }
```

```
no { deny | permit } [ log ] { tcp | udp } { { source_address source_wildcard |
any | host source_host_address } [ eq source_port | gt source_port | lt
source_port | neq source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dst_port
] }
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

deny | permit

Specifies the rule is either block (deny) or an allow (permit) filter.

- **deny:** Indicates the rule, when matched, drops the corresponding packets.
- **permit:** Indicates the rule, when matched, allows the corresponding packets.

log

Default: packets are not logged.

Indicates all packets which match the filter are to be logged.

tcp | udp

Specifies the filter is to be applied to IP based transmission control protocol or the user datagram protocol.

- **tcp:** Filter applies to TCP packets.
- **udp:** Filter applies to UDP packets.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq *source_port*

Specifies a single, specific source TCP port number to be filtered.

source_port must be configured to any integer value from 0 to 65535.

gt *source_port*

Specifies that all source TCP port numbers greater than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

lt *source_port*

Specifies that all source TCP port numbers less than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

neq *source_port*

Specifies that all source TCP port numbers not equal to the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

eq *dest_port*

Specifies a single, specific destination TCP port number to be filtered.

dest_port must be configured to any integer value from 0 to 65535.

■ deny/permit (by TCP/UDP packets)

gt *dest_port*

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

lt *dest_port*

Specifies that all destination TCP port numbers less than the one specified are to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

neq *dest_port*

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide.

Example

The following command defines four rules with the second and fourth rules logging filtered packets:

```
permit tcp host 1.2.3.4 any
deny log udp 1.2.3.0 0.0.0.31 host 1.2.4.16
permit tcp host 1.2.3.64 gt 1023 any
```

The following sets the insertion point to before the first rule defined above:

```
before permit tcp host 1.2.3.4 any
```

The following command sets the insertion point after the second rule defined above:

```
after deny log udp 1.2.3.0 0.0.0.31 host 1.2.4.16
```

The following deletes the third rule defined above:

```
no permit tcp host 1.2.3.64 gt 1023 any
```

end

Exits the ACL configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

Example

```
end
```

exit

Exits the ACL configuration mode and returns to the context configuration mode.

Privilege

Security Administrator, Administrator

Product

All

Syntax

exit

Usage

Return to the context configuration mode.

Example

exit

readdress server

Alter the destination address and port number in TCP or UDP packet headers to redirect packets to a different server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

redirect_address

The IP address to which the IP packets are redirected. TCP or UDP packet headers are rewritten to contain the new destination address. This must be an IPv6 address specified in either : or :: notation.

port *port_no*

The number of the port at the redirect address where the packets are sent. TCP or UDP packet headers are rewritten to contain the new destination port number.

tcp | **udp**

Specifies the redirect is to be applied to the IP based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq *source_port*

Specifies a single, specific source TCP port number to be filtered.

source_port must be configured to any integer value from 0 to 65535.

gt *source_port*

Specifies that all source TCP port numbers greater than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

lt *source_port*

Specifies that all source TCP port numbers less than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

neq *source_port*

Specifies that all source TCP port numbers not equal to the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

eq *dest_port*

Specifies a single, specific destination TCP port number to be filtered.

dest_port must be configured to any integer value from 0 to 65535.

gt *dest_port*

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.

dest_port must be configured to any integer value from 0 to 65535.

lt *dest_port*

Specifies that all destination TCP port numbers less than the one specified are to be filtered.

dest_port must be configured to any integer value from 0 to 65535.

neq *dest_port*

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.

dest_port must be configured to any integer value from 0 to 65535.

Usage

Use this command to define a rule that redirects packets to a different destination address. The TCP and UDP packet headers are modified with the new destination address and destination port.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the server at *192.168.10.4*, UDP packets coming from any host with a destination of any host are matched:

```
readdress server 192.168.10.4 udp any any
```

The following sets the insertion point to before the rule defined above:

```
before readdress server 192.168.10.4 udp any any
```

The following deletes the rule defined above:

```
no readdress server 192.168.10.4 udp any any
```

redirect context (by IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect context context_id [ log ] source_address source_wildcard
```

```
after redirect context context_id [ log ] source_address source_wildcard
```

```
before redirect context context_id [ log ] source_address source_wildcard
```

```
no redirect context context_id [ log ] source_address source_wildcard
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

Usage

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of redirect rules as it does not require a rule for each source and destination pair.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23 and the source IP and wildcard of 198.162.22.0 and 0.0.0.31:

```
redirect context 23 198.162.22.0 0.0.0.31
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 198.162.22.0 0.0.0.31
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 198.162.22.0 0.0.0.31
```

The following deletes the first rule defined above:

```
no redirect context 23 198.162.22.0 0.0.0.31
```

redirect context (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect context context_id [ log ] any
```

```
after redirect context context_id [ log ] any
```

```
before redirect context context_id [ log ] any
```

```
no redirect context context_id [ log ] any
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

```
context context_id
```

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

any

Indicates all packets will match the redirect regardless of source and/or destination.

Usage

Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

Important: It is suggested that any rule which is added to be a catch all should also have the log option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23 and any source IP:

```
redirect context 23 any
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 any
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 any
```

The following deletes the first rule defined above:

```
no redirect context 23 any
```

redirect context (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect context context_id [ log ] host source_ip_address
```

```
after redirect context context_id [ log ] host source_ip_address
```

```
before redirect context context_id [ log ] host source_ip_address
```

```
no redirect context context_id [ log ] host source_ip_address
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

```
context context_id
```

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage

Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23 and a host IP address of *192.168.200.11*:

```
redirect context 23 host 192.168.200.11
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 host 192.168.200.11
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 host 192.168.200.11
```

The following deletes the first rule defined above:

```
no redirect context 23 host 192.168.200.11
```

redirect context (by source ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect context context_id [ log ] icmp { source_address source_wildcard | any
| host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
after redirect context context_id [ log ] icmp { source_address source_wildcard
| any | host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
before redirect context context_id [ log ] icmp { source_address source_wildcard
| any | host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
no redirect context context_id [ log ] icmp { source_address source_wildcard |
any | host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
 - One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.
-

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

icmp_type

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

icmp_code

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

Usage

Define a rule to block ICMP packets which can be used for address resolution and possibly be a security risk. The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23, and ICMP packets coming from the host with the IP address *198.162.100.25*:

```
redirect context 23 icmp host 198.162.100.25
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 icmp host 198.162.100.25
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 icmp host 198.162.100.25
```

The following deletes the first rule defined above:

```
no redirect context 23 icmp host 198.162.100.25
```

redirect context (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect context context_id [ log ] ip { source_address source_wildcard | any |
host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ fragment ] [ protocol num ]
```

```
after redirect context context_id [ log ] ip { source_address source_wildcard |
any | host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ fragment ] [ protocol num ]
```

```
before redirect context context_id [ log ] ip { source_address source_wildcard |
any | host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ fragment ] [ protocol num ]
```

```
no redirect context context_id [ log ] ip { source_address source_wildcard | any
| host source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ fragment ] [ protocol num ]
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

fragment

Indicates packet redirection is to be applied to IP packet fragments only.

protocol *num*

Indicates that the packet filtering is to be applied to a specific protocol number. *num* can be any integer ranging from 0 to 255.

Usage

Block IP packets when the source and destination are of interest.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23, and IP packets coming from the host with the IP address 198.162.100.25, and fragmented packets for any destination are matched:

```
redirect context 23 ip host 198.162.100.25 any fragment
```

The following sets the insertion point to before the first rule defined above:

```
before redirect context 23 ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule defined above:

```
after redirect context 23 ip host 198.162.100.25 any fragment
```

The following deletes the first rule defined above:

```
no redirect context 23 ip host 198.162.100.25 any fragment
```

redirect context (by TCP/UDP packets)

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect context context_id [ log ] { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port ] } { { dest_address
dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port |
lt dest_port | neq dst_port ] }
```

```
after redirect context context_id [ log ] { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port ] } { { dest_address
dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port |
lt dest_port | neq dst_port ] }
```

```
before redirect context context_id [ log ] { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port ] } { { dest_address
dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port |
lt dest_port | neq dst_port ] }
```

```
no redirect context context_id [ log ] { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port ] } { { dest_address
dest_wildcard | any | host dest_host_address } [ eq dest_port | gt dest_port |
lt dest_port | neq dst_port ] }
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

tcp | **udp**

Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq *source_port*

Specifies a single, specific source TCP port number to be filtered.

source_port must be configured to any integer value from 0 to 65535.

gt *source_port*

Specifies that all source TCP port numbers greater than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

lt *source_port*

Specifies that all source TCP port numbers less than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

neq *source_port*

Specifies that all source TCP port numbers not equal to the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

eq *dest_port*

Specifies a single, specific destination TCP port number to be filtered.

dest_port must be configured to any integer value from 0 to 65535.

■ redirect context (by TCP/UDP packets)

gt *dest_port*

Specifies that all destination TCP port numbers greater than the one specified are to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

lt *dest_port*

Specifies that all destination TCP port numbers less than the one specified are to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

neq *dest_port*

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered. *dest_port* must be configured to any integer value from 0 to 65535.

Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the context with the context ID of 23, and UDP packets coming from any host are matched:

```
redirect context 23 udp any
```

The following sets the insertion point to before the rule defined above:

```
before redirect context 23 udp any
```

The following command sets the insertion point after the rule defined above:

```
after redirect context 23 udp any
```

The following deletes the rule defined above:

```
no redirect context 23 udp any
```

redirect css delivery-sequence

This is a restricted command. In StarOS 9.0 and later, this command is obsoleted.

redirect css service (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] any
```

```
after redirect css service svc_name [ log ] any
```

```
before redirect css service svc_name [ log ] any
```

```
no redirect css service svc_name [ log ] any
```

after

Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definitions which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

any

Indicates all packets will match the redirect regardless of source and/or destination.

Usage

Define a catch all rule definitions to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

 **Important:** It is suggested that any rule definition which is added to be a catch all should also have the **log** option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

 **Important:** A maximum of 16 rule definitions can be configured per ACL.

 **Important:** Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service with the name *chgsvc1* and any source IP:

```
redirect css service chgsvc1 any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 any
```

The following command sets the insertion point after the second rule definitions above:

```
after redirect css service chgsvc1 any
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 any
```

redirect css service (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] host source_host_address
```

```
after redirect css service svc_name [ log ] host source_host_address
```

```
before redirect css service svc_name [ log ] host source_host_address
```

```
no redirect css service svc_name [ log ] host source_host_address
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service with the name *chgsvc1* and a host IP address of *198.162.200.11*:

```
redirect css service chgsvc1 host 198.162.200.11
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 host 198.162.200.11
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 host 198.162.200.11
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 host 198.162.200.11
```

redirect css service (by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ] ]
```

```
after redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ] ]
```

```
before redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ] ]
```

```
no redirect css service svc_name [ log ] icmp { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [icmp_type [ icmp_code ] ]
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

icmp_type

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

icmp_code

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

Usage

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.

The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and ICMP packets coming from the host with the IP address *198.162.100.25*:

```
redirect css service chgsvc1 icmp host 198.162.100.25
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 icmp host 198.162.100.25
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 icmp host 198.162.100.25
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 icmp host 198.162.100.25
```

redirect css service (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
after redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
before redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
no redirect css service svc_name [ log ] ip { any | host source_host_address | source_address source_wildcard } { any | host dest_host_address | dest_address dest_wildcard } [ fragment ]
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

fragment

Indicates packet redirection is to be applied to IP packet fragments only.

Usage

Block IP packets when the source and destination are of interest.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and IP packets coming from the host with the IP address *198.162.100.25*, and fragmented packets for any destination are matched:

```
redirect css service chgsvc1 ip host 198.162.100.25 any fragment
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 ip host 198.162.100.25 any fragment
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 ip host 198.162.100.25 any fragment
```

redirect css service (by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] source_address source_wildcard
```

```
after redirect css service svc_name [ log ] source_address source_wildcard
```

```
before redirect css service svc_name [ log ] source_address source_wildcard
```

```
no redirect css service svc_name [ log ] source_address source_wildcard
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

log

Default: packets are not logged.
Indicates all packets which match the filter are to be logged.

source_address

The IP address(es) from which the packet originated.
This option is used to filter all packets from a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

 **Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

Usage

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

 **Important:** A maximum of 16 rule definitions can be configured per ACL.

Example

The following command defines a rule definition to redirect packets to a charging service named *chgsvc1*:

```
redirect css service chgsvc1 1:1:1:1:1:1:1:1
```

redirect css service (by TCP/UDP packets)

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

Product

source_port | lt source_port | neq source_port | range start_source_port
end_source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port
| range start_dest_port end_dest_port ] }
```

```
no redirect css service svc_name [ log ] { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port | range start_source_port
end_source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port
| range start_dest_port end_dest_port ] }
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

tcp | udp

Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.

- tcp**: Redirect applies to TCP packets.
- udp**: Redirect applies to UDP packets.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq *source_port*

Specifies a single, specific source TCP port number to be filtered.
source_port must be configured to any integer value from 0 to 65535.

gt *source_port*

Specifies that all source TCP port numbers greater than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

lt *source_port*

Specifies that all source TCP port numbers less than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

neq *source_port*

Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

range *start_source_port end_source_port*

Specifies that all source TCP ports within a specific range are to be filtered.
start_source_port is the initial port in the range and *end_source_port* is the final port in the range.
Both *start_source_port* and *end_source_port* can be configured to any integer value from 0 to 65535.

dest_address

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.
The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

 **Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

eq *dest_port*

Specifies a single, specific destination TCP port number to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

gt *dest_port*

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

lt *dest_port*

Specifies that all destination TCP port numbers less than the one specified are to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

neq *dest_port*

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

range *start_dest_port end_dest_port*

Specifies that all destination TCP ports within a specific range are to be filtered.
start_dest_port is the initial port in the range and *end_dest_port* is the final port in the range.
Both *start_dest_port* and *end_dest_port* can be configured to any integer value from 0 to 65535.

Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

 **Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and UDP packets coming from any host are matched:

```
redirect css service chgsvc1 udp any
```

The following sets the insertion point to before the rule definition above:

```
before redirect css service chgsvc1 udp any
```

■ redirect css service (by TCP/UDP packets)

The following command sets the insertion point after the rule definition above:

```
after redirect css service chgsvc1 udp any
```

The following deletes the rule definition above:

```
no redirect css service chgsvc1 udp any
```

redirect css service (for downlink, any)

Used to redirect subscriber sessions based on any packet received in the downlink (from the Mobile Node) direction. This command is also used to set the access control list insertion point.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] downlink any
```

```
after redirect css service svc_name [ log ] downlink any
```

```
before redirect css service svc_name [ log ] downlink any
```

```
no redirect css service svc_name [ log ] downlink any
```

after

Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

■ redirect css service (for downlink, any)

downlink

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

any

Indicates all packets will match the redirect regardless of source and/or destination.

Usage

Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

Important: It is suggested that any rule definition which is added to be a catch all should also have the **log** option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

Important: A maximum of 16 rule definitions can be configured per ACL.

Important: Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service with the name *chgsvc1* and any source IP:

```
redirect css service chgsvc1 downlink any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect service chgsvc1 downlink any
```

The following command sets the insertion point after the second rule definition above:

```
after redirect service chgsvc1 downlink any
```

The following deletes the first rule definition above:

```
no redirect service chgsvc1 downlink any
```

redirect css service (for downlink, by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address in the downlink (from the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] downlink host source_host_address
```

```
after redirect css service svc_name [ log ] downlink host source_host_address
```

```
before redirect css service svc_name [ log ] downlink host source_host_address
```

```
no redirect css service svc_name [ log ] downlink host source_host_address
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

 **Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

 **Important:** If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

```
css service svc_name
```

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

■ `redirect css service (for downlink, by host IP address)`

downlink

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service with the name *chgsvc1* and a host IP address of *198.162.200.11*:

```
redirect service chgsvc1 downlink host 198.162.200.11
```

The following sets the insertion point to before the first rule definition above:

```
before redirect service chgsvc1 downlink host 198.162.200.11
```

The following command sets the insertion point after the second rule definition above:

```
after redirect service chgsvc1 downlink host 198.162.200.11
```

The following deletes the first rule definition above:

```
no redirect service chgsvc1 downlink host 198.162.200.11
```

redirect css service (for downlink, by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets in the downlink (from the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] downlink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

```
after redirect css service svc_name [ log ] downlink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

```
before redirect css service svc_name [ log ] downlink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

```
no redirect css service svc_name [ log ] downlink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code ] ]
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

downlink

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
 - One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.
-

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

icmp_type

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

icmp_code

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

Usage

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.

The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and ICMP packets coming in the downlink (from the Mobile Node) direction from the host with the IP address *198.162.100.25*:

```
redirect css service chgsvc1 downlink icmp host 198.162.100.25
```

■ `redirect css service` (for downlink, by ICMP packets)

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 downlink icmp host 198.162.100.25
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 downlink icmp host 198.162.100.25
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 downlink icmp host 198.162.100.25
```

redirect css service (for downlink, by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets in the downlink (from the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] downlink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
after redirect css service svc_name [ log ] downlink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
before redirect css service svc_name [ log ] downlink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
no redirect css service svc_name [ log ] downlink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

downlink

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
 - One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.
-

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

fragment

Indicates packet redirection is to be applied to IP packet fragments only.

Usage

Block IP packets when the source and destination are of interest.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and downlink IP packets coming from the host with the IP address *198.162.100.25*, and fragmented packets for any destination are matched:

```
redirect css service chgsvc1 downlink ip host 198.162.100.25 any fragment
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 downlink ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule definition above:

■ redirect css service (for downlink, by IP packets)

```
after redirect css service chgsvc1 downlink ip host 198.162.100.25 any
fragment
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 downlink ip host 198.162.100.25 any
fragment
```

redirect css service (for downlink, by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source in the downlink (from the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] downlink source_address source_wildcard
```

```
after redirect css service svc_name [ log ] downlink source_address  
source_wildcard
```

```
before redirect css service svc_name [ log ] downlink source_address  
source_wildcard
```

```
no redirect css service svc_name [ log ] downlink source_address source_wildcard
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

■ redirect css service (for downlink, by source IP address masking)

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

downlink

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the filter are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

Usage

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

Important: A maximum of 16 rule definitions can be configured per ACL.

Example

The following command defines a rule definition to redirect packets to a charging service named *chgsvc1*:

```
redirect css service chgsvc1 downlink 1:1:1:1:1:1:1:1
```

redirect css service (for downlink, by TCP/UDP packets)

Used to redirect subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the downlink (from the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] downlink { tcp | udp } { { source_address
source_wildcard | any | host source_host_address } [ eq source_port | gt
source_port | lt source_port | neq source_port | range start_source_port
end_source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port
| range start_dest_port end_dest_port ] }
```

```
after redirect css service svc_name [ log ] downlink { tcp | udp } { {
source_address source_wildcard | any | host source_host_address } [ eq
source_port | gt source_port | lt source_port | neq source_port | range
start_source_port end_source_port ] } { { dest_address dest_wildcard | any |
host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq
dest_port | range start_dest_port end_dest_port ] }
```

```
after redirect css service svc_name [ log ] downlink { tcp | udp } { {
source_address source_wildcard | any | host source_host_address } [ eq
source_port | gt source_port | lt source_port | neq source_port | range
start_source_port end_source_port ] } { { dest_address dest_wildcard | any |
host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq
dest_port | range start_dest_port end_dest_port ] }
```

```
no redirect css service svc_name [ log ] downlink { tcp | udp } { {
source_address source_wildcard | any | host source_host_address } [ eq
source_port | gt source_port | lt source_port | neq source_port | range
start_source_port end_source_port ] } { { dest_address dest_wildcard | any |
host dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq
dest_port | range start_dest_port end_dest_port ] }
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

downlink

Apply this rule definition only to packets in the downlink (from the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

tcp | udp

Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.

- tcp:** Redirect applies to TCP packets.
- udp:** Redirect applies to UDP packets.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq *source_port*

Specifies a single, specific source TCP port number to be filtered.
source_port must be configured to any integer value from 0 to 65535.

gt *source_port*

Specifies that all source TCP port numbers greater than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

lt *source_port*

Specifies that all source TCP port numbers less than the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

neq *source_port*

Specifies that all source TCP port numbers not equal to the one specified are to be filtered.
source_port must be configured to any integer value from 0 to 65535.

range *start_source_port end_source_port*

Specifies that all source TCP ports within a specific range are to be filtered.
start_source_port is the initial port in the range and *end_source_port* is the final port in the range.
Both *start_source_port* and *end_source_port* can be configured to any integer value from 0 to 65535.

dest_address

The IP address(es) to which the packet is to be sent.
This option is used to filter all packets to a specific IP address or a group of IP addresses.
When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

 **Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

eq dest_port

Specifies a single, specific destination TCP port number to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

gt dest_port

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

lt dest_port

Specifies that all destination TCP port numbers less than the one specified are to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

neq dest_port

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

range start_dest_port end_dest_port

Specifies that all destination TCP ports within a specific range are to be filtered.
start_dest_port is the initial port in the range and *end_dest_port* is the final port in the range.
Both *start_dest_port* and *end_dest_port* can be configured to any integer value from 0 to 65535.

Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

 **Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and UDP packets coming from any host are matched:

■ `redirect css service` (for downlink, by TCP/UDP packets)

```
redirect css service chgsvc1 downlink udp any
```

The following sets the insertion point to before the rule definition above:

```
before redirect css service chgsvc1 downlink udp any
```

The following command sets the insertion point after the rule definition above:

```
after redirect css service chgsvc1 downlink udp any
```

The following deletes the rule definition above:

```
no redirect css service chgsvc1 downlink udp any
```

redirect css service (for uplink, any)

Used to redirect subscriber sessions based on any packet received in the uplink (to the Mobile Node) direction. This command is also used to set the access control list insertion point.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] uplink any
```

```
after redirect css service svc_name [ log ] uplink any
```

```
before redirect css service svc_name [ log ] uplink any
```

```
no redirect css service svc_name [ log ] uplink any
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

 ■ redirect css service (for uplink, any)

uplink

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

any

Indicates all packets will match the redirect regardless of source and/or destination.

Usage

Define a catch all rule definition to place at the end of the list of rule definitions to provide explicit handling of rule definitions which do not fit any other criteria.

Important: It is suggested that any rule definition which is added to be a catch all should also have the **log** option specified. The logged packets may be used to determine if the current list of rule definitions is adequate or needs modification to ensure proper security.

Important: A maximum of 16 rule definitions can be configured per ACL.

Important: Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service with the name *chgsvc1* and any source IP:

```
redirect css service chgsvc1 uplink any
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 uplink any
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 uplink any
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 uplink any
```

redirect css service (for uplink, by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address in the uplink (to the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] uplink host source_host_address
```

```
after redirect css service svc_name [ log ] uplink host source_host_address
```

```
before redirect css service svc_name [ log ] uplink host source_host_address
```

```
no redirect css service svc_name [ log ] uplink host source_host_address
```

uplink

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

after

Indicates all rule definitions defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

■ redirect css service (for uplink, by host IP address)

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

uplink

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage

Define a rule definition when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rule definitions to be very clear and concise.

Important: A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service with the name *chgsvc1* and a host IP address of *192.168.200.11*:

```
redirect service chgsvc1 uplink host 192.168.200.11
```

The following sets the insertion point to before the first rule definition above:

```
before redirect service chgsvc1 uplink host 192.168.200.11
```

The following command sets the insertion point after the second rule definition above:

```
after redirect service chgsvc1 uplink host 192.168.200.11
```

The following deletes the first rule definition above:

```
no redirect service chgsvc1 uplink host 192.168.200.11
```

redirect css service (for uplink, by ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets in the uplink (to the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] uplink icmp { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ icmp_type [ icmp_code
] ]
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

uplink

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
 - One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.
-

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

 **Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

icmp_type

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

icmp_code

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

Usage

Define a rule definition to block ICMP packets which can be used for address resolution and possibly be a security risk.

The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

 **Important:** A maximum of 16 rule definitions can be configured per ACL. Also note that “redirect” rule definitions are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and ICMP packets in the uplink (to the Mobile Node) direction from the host with the IP address *198.162.100.25*:

```
redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following sets the insertion point to before the first rule definition above:

```
before redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 uplink icmp host 198.162.100.25
```

redirect css service (for uplink, by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets in the uplink (to the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] uplink ip { any | host source_host_address
| source_address source_wildcard } { any | host dest_host_address | dest_address
dest_wildcard } [ fragment ]
```

```
after redirect css service svc_name [ log ] uplink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
before redirect css service svc_name [ log ] uplink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

```
no redirect css service svc_name [ log ] uplink ip { any | host
source_host_address | source_address source_wildcard } { any | host
dest_host_address | dest_address dest_wildcard } [ fragment ]
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

Important: If the options specified do not exactly match an existing rule definition, the insertion point does not change.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

uplink

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
 - One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.
-

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

■ redirect css service (for uplink, by IP packets)

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

fragment

Indicates packet redirection is to be applied to IP packet fragments only.

Usage

Block IP packets when the source and destination are of interest.

Example

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and uplink IP packets going to the host with the IP address *198.162.100.25*, and fragmented packets for any destination are matched:

```
redirect css service chgsvc1 uplink ip host 198.162.100.25 any fragment
```

The following sets the insertion point to before the first rule definition above:

```
redirect css service chgsvc1 uplink ip host 198.162.100.25 any fragment
```

The following command sets the insertion point after the second rule definition above:

```
after redirect css service chgsvc1 uplink ip host 198.162.100.25 any fragment
```

The following deletes the first rule definition above:

```
no redirect css service chgsvc1 uplink ip host 198.162.100.25 any fragment
```

redirect css service (for uplink, by source IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source in the uplink (to the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] uplink source_address  
source_wildcard
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

uplink

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the filter are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

■ **redirect css service (for uplink, by source IP address masking)**

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Usage

Define a rule definition when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of filtering rule definitions as it does not require a rule definition for each source and destination pair.

Example

The following command defines a rule definition to redirect packets to a charging service named *chgsvc1*:

```
redirect css service chgsvc1 uplink 1:1:1:1:1:1:1:1
```

redirect css service (for uplink, by TCP/UDP packets)

Used to redirect subscriber sessions to a charging service based on the transmission control protocol/user datagram protocol packets in the uplink (to the Mobile Node) direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address
source_wildcard | any | source_host_address } [ eq source_port | gt source_port
| lt source_port | neq source_port | range start_source_port end_source_port ] }
{ { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port |
gt dest_port | lt dest_port | neq dest_port | range start_dest_port
end_dest_port ] }
```

```
after redirect css service svc_name [ log ] uplink { tcp | udp } { {
source_address source_wildcard | any | source_host_address } [ eq source_port |
gt source_port | lt source_port | neq source_port | range start_source_port
end_source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port
| range start_dest_port end_dest_port ] }
```

```
before redirect css service svc_name [ log ] uplink { tcp | udp } { {
source_address source_wildcard | any | source_host_address } [ eq source_port |
gt source_port | lt source_port | neq source_port | range start_source_port
end_source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port
| range start_dest_port end_dest_port ] }
```

```
no redirect css service svc_name [ log ] uplink { tcp | udp } { { source_address
source_wildcard | any | source_host_address } [ eq source_port | gt source_port
| lt source_port | neq source_port | range start_source_port end_source_port ] }
{ { dest_address dest_wildcard | any | host dest_host_address } [ eq dest_port |
gt dest_port | lt dest_port | neq dest_port | range start_dest_port
end_dest_port ] }
```

after

Indicates all rule definitions subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule definition which matches the exact options specified such that new rule definitions will be added, in order, after the matching rule definition.

before

Indicates all rule definitions subsequent to this command are to be inserted before the command identified by the exact options listed.

 ■ redirect css service (for uplink, by TCP/UDP packets)

This moves the insertion point to be immediately before the rule definition which matches the exact options specified such that new rule definitions will be added, in order, before the matching rule definition.

no

Removes the rule definition which exactly matches the options specified.

css service *svc_name*

The name of the active charging service to which packets are to be redirected. At the executive mode prompt, use the **show active-charging service all** command to display the names of all configured charging services.

svc_name must be a string of 1 through 15 characters in length.

uplink

Apply this rule definition only to packets in the uplink (to the Mobile Node) direction.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

tcp | udp

Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

any

Specifies that the rule definition applies to all packets.

host

Specifies that the rule definition applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq *source_port*

Specifies a single, specific source TCP port number to be filtered.

source_port must be configured to any integer value from 0 to 65535.

gt *source_port*

Specifies that all source TCP port numbers greater than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

lt *source_port*

Specifies that all source TCP port numbers less than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

neq *source_port*

Specifies that all source TCP port numbers not equal to the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

range *start_source_port end_source_port*

Specifies that all source TCP ports within a specific range are to be filtered.

start_source_port is the initial port in the range and *end_source_port* is the final port in the range.

Both *start_source_port* and *end_source_port* can be configured to any integer value from 0 to 65535.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

eq *dest_port*

Specifies a single, specific destination TCP port number to be filtered.

 ■ redirect css service (for uplink, by TCP/UDP packets)

dest_port must be configured to any integer value from 0 to 65535.

gt *dest_port*

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.

dest_port must be configured to any integer value from 0 to 65535.

lt *dest_port*

Specifies that all destination TCP port numbers less than the one specified are to be filtered.

dest_port must be configured to any integer value from 0 to 65535.

neq *dest_port*

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.

dest_port must be configured to any integer value from 0 to 65535.

range *start_dest_port end_dest_port*

Specifies that all destination TCP ports within a specific range are to be filtered.

start_dest_port is the initial port in the range and *end_dest_port* is the final port in the range.

Both *start_dest_port* and *end_dest_port* can be configured to any integer value from 0 to 65535.

Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

Example

The following command defines a rule definition that redirects packets to the charging service named *chgsvc1*, and UDP packets coming from any host are matched:

```
redirect css service chgsvc1 uplink udp any
```

The following sets the insertion point to before the rule definition above:

```
before redirect css service chgsvc1 uplink udp any
```

The following command sets the insertion point after the rule definition above:

```
after redirect css service chgsvc1 uplink udp any
```

The following deletes the rule definition above:

```
no redirect css service chgsvc1 uplink udp any
```

redirect nexthop (by IP address masking)

Used to redirect subscriber sessions based on the IP address mask sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect nexthop nexthop_addr { context context_id | interface interface_name }  
[ log ] source_address source_wildcard
```

```
after redirect nexthop nexthop_addr { context context_id | interface  
interface_name } [ log ] source_address source_wildcard
```

```
before redirect nexthop nexthop_addr { context context_id | interface  
interface_name } [ log ] source_address source_wildcard
```

```
no redirect nexthop nexthop_addr { context context_id | interface interface_name  
} [ log ] source_address source_wildcard
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

nexthop *nexthop_addr*

The IP address to which the IP packets are redirected.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

interface *interface_name*

The name of the logical interface to which the packets should be redirected. *interface_name* must be an alpha and/or numeric string from 1 to 79 characters in length.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

Usage

Define a rule when any packet from the IP addresses which fall into the group of addresses matching the IP address masking. This allows the reduction of redirect rules as it does not require a rule for each source and destination pair.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the next hop host at *192.168.10.4*, the context with the context ID of *23* and the source IP and wildcard of *198.162.22.0* and *0.0.0.31*:

```
redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

The following sets the insertion point to before the first rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

The following command sets the insertion point after the second rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 198.162.22.0 0.0.0.31
```

redirect nexthop (any)

Used to redirect subscriber sessions based on any packet received. This command is also used to set the access control list insertion point.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect nexthop next_hop_addr { context context_id | interface interface_name }
[ log ] any
```

```
after redirect nexthop next_hop_addr { context context_id | interface
interface_name } [ log ] any
```

```
before redirect nexthop next_hop_addr { context context_id | interface
interface_name } [ log ] any
```

```
no redirect nexthop next_hop_addr { context context_id | interface interface_name
} [ log ] any
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

nexthop *next_hop_addr*

The IP address to which the IP packets are redirected.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

interface *interface_name*

The name of the logical interface to which the packets should be redirected. *interface_name* must be an alpha and/or numeric string from 1 to 79 characters in length.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

any

Indicates all packets will match the redirect regardless of source and/or destination.

Usage

Define a catch all rule to place at the end of the list of rules to provide explicit handling of rules which do not fit any other criteria.

Important: It is suggested that any rule which is added to be a catch all should also have the **log** option specified. The logged packets may be used to determine if the current list of rules is adequate or needs modification to ensure proper security. The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the next hop host at *192.168.10.4*, the context with the context ID of *23* and any source IP:

```
redirect nexthop 192.168.10.4 context 23 any
```

The following sets the insertion point to before the first rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 any
```

The following command sets the insertion point after the second rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 any
```

The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 any
```

redirect nexthop (by host IP address)

Used to redirect subscriber sessions based on the targeted host IP address sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect nexthop nexthop_addr { context context_id | interface interface_name }
[ log ] host source_ip_address
```

```
after redirect nexthop nexthop_addr { context context_id | interface
interface_name } [ log ] host source_ip_address
```

```
before redirect nexthop nexthop_addr { context context_id | interface
interface_name } [ log ] host source_ip_address
```

```
no redirect nexthop nexthop_addr { context context_id | interface interface_name
} [ log ] host source_ip_address
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

nexthop *nexthop_addr*

The IP address to which the IP packets are redirected.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

interface *interface_name*

The name of the logical interface to which the packets should be redirected. *interface_name* must be an alpha and/or numeric string from 1 to 79 characters in length.

log

Default: packets are not logged.
Indicates all packets which match the redirect are to be logged.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

Usage

Define a rule when a very specific remote host is to be blocked. In simplified networks where the access controls need only block a few hosts, this command allows the rules to be very clear and concise.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the next hop host at *192.168.10.4*, the context with the context ID of *23* and a host IP address of *192.168.200.11*:

```
redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```

The following sets the insertion point to before the first rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```

The following command sets the insertion point after the second rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```

The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 host 192.168.200.11
```

redirect nexthop (by source ICMP packets)

Used to redirect subscriber sessions based on the internet control message protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect nexthop nexthop_addr { context context_id | interface interface_name }
[ log ] icmp { source_address source_wildcard | any | host source_host_address }
{ dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [
icmp_code ] ]
```

```
after redirect nexthop nexthop_addr { context context_id | interface
interface_name } [ log ] icmp { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
before redirect nexthop nexthop_addr { context context_id | interface
interface_name } [ log ] icmp { source_address source_wildcard | any | host
source_host_address } { dest_address dest_wildcard | any | host
dest_host_address } [ icmp_type [ icmp_code ] ]
```

```
no redirect nexthop nexthop_addr { context context_id | interface interface_name
} [ log ] icmp { source_address source_wildcard | any | host source_host_address
} { dest_address dest_wildcard | any | host dest_host_address } [ icmp_type [
icmp_code ] ]
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

nexthop *nexthop_addr*

The IP address to which the IP packets are redirected.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

interface *interface_name*

The name of the logical interface to which the packets should be redirected. *interface_name* must be an alpha and/or numeric string from 1 to 79 characters in length.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

 ■ redirect nexthop (by source ICMP packets)

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

icmp_type

Specifies that all ICMP packets of a particular type are to be filtered. The type can be any integer value between 0 and 255.

icmp_code

Specifies that all ICMP packets of a particular code are to be filtered. The type can be any integer value between 0 and 255.

Usage

Define a rule to block ICMP packets which can be used for address resolution and possible be a security risk. The IP redirecting allows flexible controls for pairs of individual hosts or groups by IP masking which allows the redirecting of entire subnets if necessary.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the next hop host at *192.168.10.4*, the context with the context ID of *23*, and ICMP packets coming from the host with the IP address *192.168.100.25*:

```
redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```

The following sets the insertion point to before the first rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```

The following command sets the insertion point after the second rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```

The following deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 icmp host 192.168.100.25
```

redirect nexthop (by IP packets)

Used to redirect subscriber sessions based on the internet protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect nexthop next_hop_addr { context context_id | interface interface_name }
[ log ] ip { source_address source_wildcard | any | host source_host_address } {
dest_address dest_wildcard | any | host dest_host_address } [ fragment ] [
protocol num ]
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to be immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

nexthop *next_hop_addr*

The IP address to which the IP packets are redirected.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

interface *interface_name*

The name of the logical interface to which the packets should be redirected. *interface_name* must be an alpha and/or numeric string from 1 to 79 characters in length.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

fragment

Indicates packet redirection is to be applied to IP packet fragments only.

protocol *num*

Indicates that the packet filtering is to be applied to a specific protocol number. *num* can be any integer ranging from 0 to 255.

Usage

Block IP packets when the source and destination are of interest.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

redirect nexthop (by TCP/UDP packets)

Used to redirect subscriber sessions based on the transmission control protocol/user datagram protocol packets sent by the source to the mobile node or the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect nexthop nexthop_addr { context context_id | interface interface_name }
[ log ] { tcp | udp } { { source_address source_wildcard | any | host
source_host_address } [ eq source_port | gt source_port | lt source_port | neq
source_port ] } { { dest_address dest_wildcard | any | host dest_host_address }
[ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

```
after redirect nexthop nexthop_addr { context context_id | interface
interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any
| host source_host_address } [ eq source_port | gt source_port | lt source_port
| neq source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port
] }
```

```
before redirect nexthop nexthop_addr { context context_id | interface
interface_name } [ log ] { tcp | udp } { { source_address source_wildcard | any
| host source_host_address } [ eq source_port | gt source_port | lt source_port
| neq source_port ] } { { dest_address dest_wildcard | any | host
dest_host_address } [ eq dest_port | gt dest_port | lt dest_port | neq dest_port
] }
```

```
no redirect nexthop nexthop_addr { context context_id | interface interface_name
} [ log ] { tcp | udp } { { source_address source_wildcard | any | host
source_host_address } [ eq source_port | gt source_port | lt source_port | neq
source_port ] } { { dest_address dest_wildcard | any | host dest_host_address }
[ eq dest_port | gt dest_port | lt dest_port | neq dest_port ] }
```

after

Indicates all rules defined subsequent to this command are to be inserted after the command identified by the exact options listed.

This moves the insertion point to immediately after the rule which matches the exact options specified such that new rules will be added, in order, after the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

before

Indicates all rules defined subsequent to this command are to be inserted before the command identified by the exact options listed.

This moves the insertion point to be immediately before the rule which matches the exact options specified such that new rules will be added, in order, before the matching rule.

Important: If the options specified do not exactly match an existing rule, the insertion point does not change.

no

Removes the rule which exactly matches the options specified.

nexthop *nexthop_addr*

The IP address to which the IP packets are redirected.

context *context_id*

The context identification number of the context to which packets are redirected. At the executive mode prompt, use the **show context all** command to display context names and context IDs.

interface *interface_name*

The name of the logical interface to which the packets should be redirected. *interface_name* must be an alpha and/or numeric string from 1 to 79 characters in length.

log

Default: packets are not logged.

Indicates all packets which match the redirect are to be logged.

tcp | **udp**

Specifies the redirect is to be applied to IP based transmission control protocol or the user datagram protocol.

- **tcp**: Redirect applies to TCP packets.
- **udp**: Redirect applies to UDP packets.

source_address

The IP address(es) from which the packet originated.

This option is used to filter all packets from a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this option. The range can then be configured using the *source_wildcard* parameter.

source_wildcard

This option is used in conjunction with the *source_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be identical.
- One-bits in this parameter mean that the corresponding bits configured for the *source_address* parameter must be ignored.

 **Important:** The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

any

Specifies that the rule applies to all packets.

host

Specifies that the rule applies to a specific host as determined by its IP address.

source_host_address

The IP address of the source host to filter against expressed in IPv6 colon notation.

dest_host_address

The IP address of the destination host to filter against expressed in IPv6 colon notation.

eq *source_port*

Specifies a single, specific source TCP port number to be filtered.

source_port must be configured to any integer value from 0 to 65535.

gt *source_port*

Specifies that all source TCP port numbers greater than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

lt *source_port*

Specifies that all source TCP port numbers less than the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

neq *source_port*

Specifies that all source TCP port numbers not equal to the one specified are to be filtered.

source_port must be configured to any integer value from 0 to 65535.

dest_address

The IP address(es) to which the packet is to be sent.

This option is used to filter all packets to a specific IP address or a group of IP addresses.

When specifying a group of addresses, the initial address is configured using this parameter. The range can then be configured using the *dest_wildcard* parameter.

dest_wildcard

This option is used in conjunction with the *dest_address* option to specify a group of addresses for which packets are to be filtered.

The mask must be entered as a complement:

- Zero-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be identical.

■ redirect nexthop (by TCP/UDP packets)

- One-bits in this parameter mean that the corresponding bits configured for the *dest_address* parameter must be ignored.

Important: The mask must contain a contiguous set of one-bits from the least significant bit (LSB). Therefore, allowed masks are 0, 1, 3, 7, 15, 31, 63, 127, and 255. For example, acceptable wildcards are 0.0.0.3, 0.0.0.255, and 0.0.15.255. A wildcard of 0.0.7.15 is **not** acceptable since the one-bits are not contiguous.

eq *dest_port*

Specifies a single, specific destination TCP port number to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

gt *dest_port*

Specifies that all destination TCP port numbers greater than the one specified are to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

lt *dest_port*

Specifies that all destination TCP port numbers less than the one specified are to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

neq *dest_port*

Specifies that all destination TCP port numbers not equal to the one specified are to be filtered.
dest_port must be configured to any integer value from 0 to 65535.

Usage

Block IP packets when the source and destination are of interest but for only a limited set of ports.

Important: The maximum number of rules that can be configured per ACL varies depending on how the ACL is to be used. For more information, refer to the Engineering Rules appendix in the System Administration Guide. Also note that “redirect” rules are ignored for ACLs applied to specific subscribers or all subscribers facilitated by a specific context.

Example

The following command defines a rule that redirects packets to the next hop host at *192.168.10.4*, the context with the context ID of *23*, and UDP packets coming from any host are matched:

```
redirect nexthop 192.168.10.4 context 23 udp any
```

The following sets the insertion point to before the rule defined above:

```
before redirect nexthop 192.168.10.4 context 23 udp any
```

The following command sets the insertion point after the rule defined above:

```
after redirect nexthop 192.168.10.4 context 23 udp any
```

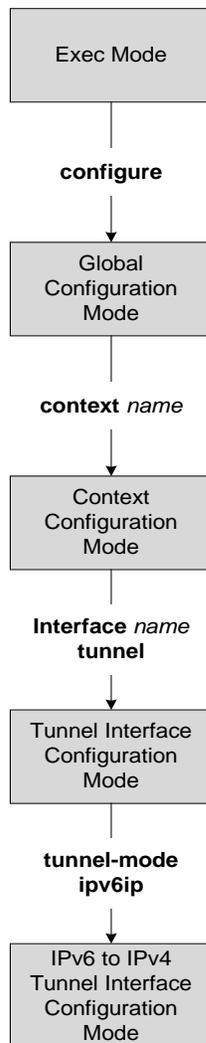

The following command deletes the first rule defined above:

```
no redirect nexthop 192.168.10.4 context 23 udp any
```

Chapter 151

IPv6 to IPv4 Tunnel Interface Configuration Mode Commands

The IPv6 to IPv4 Tunnel Interface Configuration Mode is used to create and manage the IP interfaces for addresses, address resolution options, etc.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

- redirect nexthop (by TCP/UDP packets)

destination address

Configures the destination of the tunnelled packets for a manual tunnel.

Product

All

Privilege

Administrator

Syntax

```
destination address address  
no destination address
```

no

Removes configuration for the specified keyword.

address

Specifies the IP address of the destination device. *address* must be specified in IPv4 dotted decimal notation or IPv6 colon-separated notation.

Usage

Use this command to configure the IP address of the destination end of the tunnel.

Example

The following command sets the destination address for packets on this tunnelled interface to 1.2.3.4:

```
destination address 1.2.3.4
```

■ end

end

Exits the interface configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the Interface Configuration Mode and returns to the Context Configuration Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

mode

Configures the mode of IPv6 to IPv4 tunneling. The default is set to manual mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
mode { 6to4 | manual }  
default mode
```

6to4

Configures automatic 6to4 IPv6 to IPv4 tunnels as specified in RFC 3056.

manual

Configures point-to-point manual IPv6 to IPv4 tunnels by specifying IPv4 address of the tunnel remote end.

default

Resets the mode of IPv6 to IPv4 tunneling to manual mode.

Usage

There can be only one 6to4 tunnel possible in a context. Once a 6to4 tunnel is configured, all subsequent tunnels will be configured as manual tunnels.

Example

The following command configures the mode to 6to4.

```
mode 6to4
```

The following command configures the mode to manual.

```
mode manual
```

source

Configures the source of tunneled packets.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
source { address ip_address | interfaceinterface_name }  
no source { address | interface }
```

address *ip_address*

Specifies the IPv4 address to use as the source address of the tunnel.

ip_address must be expressed in dotted-decimal notation.

interface *interface_name*

Specifies the name of a non-tunnel IPv4 interface, whose address is used as the source address of the tunnel. *interface* must be from 1 to 79 alpha and/or numeric characters.

no source { **address** | **interface** }

Removes configuration for the specified keyword.

Usage

Configures the source IPv4 address of the tunnel by either specifying the IP address (host address) or by specifying another configured non-tunnel IPv4 interface. The source address must be an existing interface address before it is used. State of source address will affect the operational state of the tunnel.

Example

The following command configures the source address of the tunnel.

```
source address 1.2.3.4
```

The following command specifies the source interface as *testsource1*.

```
source interface testsource1
```

tos

Configures the type of service (TOS) settings of the outer IPv4 header of the tunneled packets.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
tos { copy | value tos_value }
```

default tos

copy

Copies the DC octet of IPv6 packet to the TOS octet of IPv4 packet.

default

Configures default setting for the specified keyword.

value tos_value

Configures the raw TOS value ranging from 0 to 255. The default is 0.

Usage

Sets the TOS parameter to be used in the tunnel transport protocol or instructs to copy TOS value from the original IPv6 DC byte to the TOS value of the encapsulating IPv4 header.

Example

The following command sets the tos value to 1:

```
tos value 1
```

ttl

Configures the TTL (Time to live) value of the outer IPv4 header of the tunneled packets.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
ttl value ttl_value
```

default

Configures default setting for the specified keyword.

value *ttl_value*

ttl_value is a range from 1 to 255. The default is 16.

Usage

Configures the TTL parameter to be used in the tunnel transport protocol.

Example

The following command sets the TTL value to 25.

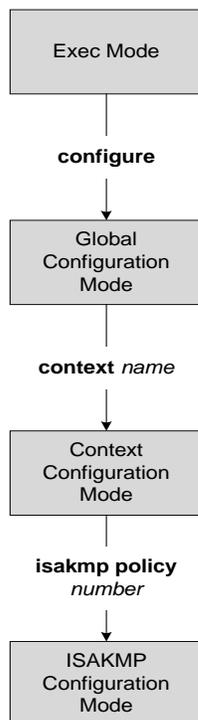

```
ttl value 25
```

Chapter 152

ISAKMP Configuration Mode Commands

The ISAKMP Configuration Mode is used to configure Internet Security Association Key Management Protocol (ISAKMP) policies that are used to define Internet Key Exchange (IKE) security associations (SAs).

Modification(s) to an existing ISAKMP policy configuration will not take effect until the related security association has been cleared. Refer to the clear crypto security-association command located in the Exec Mode Commands chapter of the Command Line Interface Reference for more information.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

authentication

Configures the ISAKMP policy authentication mode.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
authentication preshared-key
```

```
[ default | no ] authentication
```

default

Restores the default setting of this parameter. The command is enabled by default.

no

Disables the preshared key authentication mode.

preshared-key

Specifies that the policy will be authenticated through the use of the pre-shared key.

Usage

When the system is configured to use ISAKMP-type crypto maps for establishing IPsec tunnels, this command is used to indicate that the policy will be authenticated through the use of the pre-shared key configured in the ISAKMP crypto map.

Example

The following command sets policy authentication mode to use a pre-shared key:

```
authentication preshared-key
```

encryption

Configures the encryption protocol to use to protect subsequent IKE SA negotiations.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
encryption { 3des-cbc | des-cbc }  
[ default | no ] encryption
```

default

Restores the default setting of this parameter.

no

Removes a previously configured encryption type.

3des-cbc

Specifies that the encryption protocol is Triple Data Encryption Standard (3DES) in chain block (CBC) mode.

des-cbc

Specifies that the encryption protocol is DES in CBC mode. This is the default setting.

Usage

Once the D-H exchange between the system and the security gateway has been successfully completed, subsequent IKE SA negotiations will be protected using the protocol specified by this command.

Example

The following command sets the IKE encryption method to 3des-cbc:

```
encryption 3des-cbc
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Returns to the Exec mode.

exit

Exits the current configuration mode and returns to the Context configuration mode.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Context Configuration mode.

group

Configures the Oakley group (also known as the Diffie-Hellman (D-H) group) in which the D-H exchange occurs.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
group { 1 | 2 | 5 }
```

```
[ default | no ] group
```

default

Restores the default setting of this parameter.

no

Removes a previously configured group.

```
{ 1 | 2 | 5 }
```

Default: **1**

The number of the Oakley group. The following groups are allowed:

- **1** : Enables Oakley Group 1 using a 768-bit modp as defined in RFC 2409.
- **2** : Enables Oakley Group 2, using a 1024-bit modp as defined in RFC 2409.
- **5** : Enables Oakley Group 5, using a 1536-bit modp as defined in RFC 3526.

Usage

Specifies the Oakley group that determine the length of the base prime numbers that are used during the key exchange process.

Example

The following command sets the group to 5 which specifies 1536-bit base prime numbers:

```
group 5
```

hash

Configures the IKE hash protocol to use during IKE SA negotiations.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator\

Syntax

```
hash { md5 | sha1 }
```

```
[ default | no ] hash
```

default

Restores the default setting of this parameter.

no

Removes a previously configured hash algorithm.

md5

Specifies that the hash protocol is Message Digest 5 truncated to 96 bits.

sha1

Specifies that the hash protocol is Secure Hash Algorithm-1 truncated to 96 bits. This is the default setting for this command.

Usage

Use this command to configure the hash algorithm used during key negotiation.

Example

Set the hash algorithm to Message-Digest 5 by entering the following command:

```
hash md5
```

lifetime

Configures the lifetime of the IKE Security Association (SA).

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
lifetime seconds
```

```
default lifetime
```

default

Restores the default setting of this parameter.

seconds

Default: 86400

The number of seconds for the SA to live. *seconds* must be an integer from 60 to 86400.

Usage

Use this command to set the time that an ISAKMP SA will be valid. The lifetime is negotiated with the peer and the lowest configured lifetime duration is used.

Example

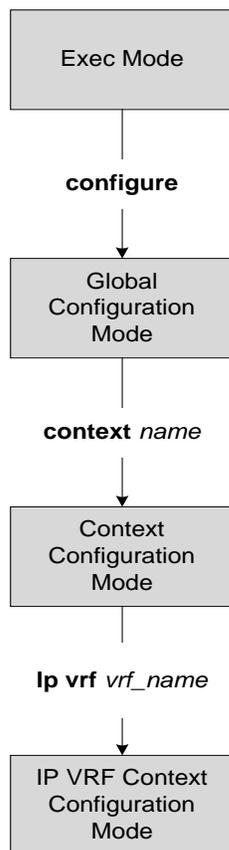

The following command sets the SA lifetime to 100 seconds:

```
lifetime 100
```

Chapter 153

IP VRF Context Configuration Mode Commands

The IP Virtual Routing and Forwarding Context Configuration Mode is used to create and manage the VRF context instance for GRE tunneling interfaces for addresses, address resolution options, etc.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the interface configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the Interface Configuration Mode and returns to the Context Configuration Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

ip maximum-routes

This command configures the maximum number of routes in an IP VRF routing table configured in this context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip maximum-routes max_routes
```

```
no ip maximum-routes
```

no

Disables the configured maximum routes in specific IP VRF context.

max_routes

Sets the maximum number of routes in a specific IP VRF context.

max_routes must be an integer between 1 through 16384 on ASR 5000 system.

Usage

Use this command to configure the maximum number of routes in a particular VRF routing table. When the number of routes in the VRF is more than the maximum limit configured, a critical log is generated indicating that the number of routes is over the limit. Once the number of routes in the VRF goes under the limit, a clear log is generated.

The maximum routes configured using this command will be sent to the threshold configuration logic for appropriate action. For more information on threshold configuration, refer **threshold route-service bgp-routes** and **threshold poll route-service interval** commands in Global configuration mode.

Example

The following command sets *1000* routes as a maximum limit for specific VRF context:

```
ip maximum-routes 1000
```

mpls map-dscp-to-exp

This command provides mapping of final differentiated services code point (DSCP) bit value in IP packet header to final Experimental (EXP) bit value in MPLS header for incoming traffic.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
mpls map-dscp-to-exp dscp dscp_bit_value exp exp_bit_value
```

dscp *dscp_bit_value*

This keyword specifies the final DSCP bit value which is to map with the final EXP bit value in MPLS header for incoming traffic.

dscp_bit_value specifies the value of DSCP bit values separated in 8 groups and represented with integers between 0 through 7.

The default representation of DSCP value in 8 groups is given in the following table:

DSCP Marking Value	DSCP Map Group
0-7	0
8-15	1
16-23	2
24-31	3
32-39	4
40-47	5
48-55	6
56-63	7

exp *exp_bit_value*

This keyword specifies the final EXP bit value in MPLS header to which the final DSCP bit value 0 to 7 (represented in 8 values) coming from incoming traffic will be mapped.

exp_bit_value is the value of EXP bit in MPLS header and must be an integer between 0 through 7.

Usage

Use this command to map the final DSCP value coming from incoming IP traffic to a final EXP value in MPLS header. This mapping determines the QoS and service parameters to which the packet is assigned.

Example

mpls map-dscp-to-exp

The following command maps the DSCP value 3 (24 to 31) to EXP bit 3 in MPLS header:

```
mpl map-dscp-to-exp dscp 3 exp 3
```

mpls map-exp-to-dscp

This command provides mapping of incoming Experimental (EXP) bit value in MPLS header to internal differentiated services code point (DSCP) bit value in IP packet header for outgoing traffic.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
mpls map-exp-to-dscp exp exp_bit_value dscp dscp_bit_value
```

exp *exp_bit_value*

This keyword specifies the incoming EXP bit value in MPLS header to which the internal DSCP bit value 0 to 7 (represented in 8 values) in IP traffic will be mapped.

exp_bit_value is the value of EXP bit in MPLS header and must be an integer between 0 through 7.

dscp *dscp_bit_value*

This keyword specifies the DSCP bit value is to be mapped with the incoming EXP bit value in MPLS header.

dscp_bit_value specifies the value of DSCP bit values separated in 8 groups and represented with integers between 0 through 7.

The default representation of DSCP value in 8 groups is given in the following table:

DSCP Marking Value	DSCP Map Group
0-7	0
8-15	1
16-23	2
24-31	3
32-39	4
40-47	5
48-55	6
56-63	7

Usage

Use this command to map the incoming EXP bit value in MPLS header to DSCP bit value in IP traffic. This mapping determines the QoS and service parameters to which the packet is assigned.

Example

■ mpls map-exp-to-dscp

The following command maps the EXP bit value 4 to DSCP value 6 (48 to 55) in IP header:

```
mpl map-exp-to-dscp exp 4 dscp 6
```

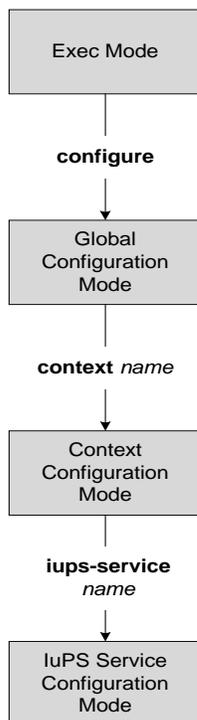

Chapter 154

IuPS Service Configuration Mode Commands

The IuPS Service configuration mode is used to define properties for the IuPS service which controls the Iu-PS interface connections to Radio Network Controllers (RNCs) of the UMTS Terrestrial Radio Access Network (UTRAN).

In this mode, the prompt will appear similar to:

```
[<context_name>]hostname(config-ctx-iups-service)#
```

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

access-protocol

This command configures the access protocol parameters for the IuPS service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] access-protocol sccp-network sccp_net_id
```

no

Removes a previously configured access protocol value.

sccp-network *sccp_net_id*

Specifies the Signaling Connection Control Part (SCCP) for this IuPS service to use. *sccp_net_id* must be an integer from 1 to 16.

Usage

Use this command to configure access protocol parameters for the current IuPS service.

Example

The following command specifies that the current Iu-PS service should use SCCP 1:

```
access-protocol sccp-network 1
```

blacklist-timeout-gtpu-bind-addresses

This command specifies the time period that a GTP-U bind address (loopback address) will not be used (is blacklisted) in RAB-Assignment requests after a RAB assignment request, with that GTP-U bind address, has been rejected by an RNC with the cause - Unspecified Error. This is a failure at the RNC's GTP-U IP interface.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

blacklist-timeout-gtpu-bind-addresses *seconds*

default blacklist-timeout-gtpu-bind-addresses

default

Resets the blacklist time to 60 seconds.

seconds

Number of seconds that the GTP-U bind (loopback) address will not be used in a RAB-Assignment request.
seconds : Must be an integer from 1 to 1800.

Usage

Use this command to configure the blacklist period.

Example

The following command specifies a 15 minutes blacklist period.

```
blacklist-timeout-gtpu-bind-addresses seconds 460
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the previous configuration mode, the context configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

gtpu

This commands configures parameters for the GTP user (GTP-U) dataplane.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpu { bind ip_addr | echo-interval seconds | max-retransmissions number |
retransmission-timeout seconds }
```

```
no gtpu { bind address ip_addr | echo-interval | max-retransmissions |
retransmission-timeout }
```

```
default gtpu { echo-interval | max-retransmissions | retransmission-timeout }
```

no

Removes the configured parameter value.

default

Sets the specified parameter to its default setting.

bind **address** *ip_addr*

This command binds the specified IP address to the Iu-PS GTP-U endpoint.

ip_addr: Must be an IP v4 IP address in dotted decimal notation.

echo-interval *seconds*

Default: 60

Configures the rate, in seconds, at which GTP-U echo packets are sent to the UTRAN over the Iu-PS interface.

seconds : Must be an integer from 60 through 3600.

max-retransmissions *number*

Default: 5

Configures the maximum number of transmission retries for GTP-U packets.

number : Must be an integer from 0 through 15.

retransmission-timeout *seconds*

Default: 5

Configures the retransmission timeout for GTPU packets in seconds.

seconds : Must be an integer from 1 through 20.

Usage

Use this command to configure GTP-U parameters for the Iu-PS interface.

Example

The following command binds the IP address 192.168.0.10 to the Iu-PS interface for communication with the UTRAN:

```
gtpu bind address 192.168.0.10
```

iu-hold-connection

Defines the type and duration of the Iu hold connection.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
iu-hold-connection ( always [ hold-time time ] | requested-by-ms [ hold-time time ] ) ]
```

```
[ default | no ] iu-hold-connection
```

default

Resets the Iu hold connection parameters to requested-by-ms and 100 second duration.

no

Removes the configuration information for the specified Iu hold connection parameter.

always

Specifies that there is always to be an Iu hold connection procedure.

requested-by-ms

Specifies that there is only an Iu hold connection procedure if requested by the MS/UE. This is the default setting for Iu-hold-connection.

hold-time *time*

This variable configures the interval (in seconds) that the SGSN holds the Iu connection.
time: must be an integer from 10 to 3600.
 Default is 100.

Usage

Define the amount of time the Iu connection will be held open.

Example

```
iu-hold-connection always hold-time 120
```

iu-recovery

This command enables the Iu recovery function.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
iu-recovery
```

```
no iu-recovery
```

```
no
```

Disables IU recovery.

Usage

Enable or disable Iu recovery function that should be used whenever sessions are recovered.

Example

The following command disables the Iu Recovery function:

```
no iu-recovery
```

iu-release-complete-timeout

Configures the SGSN's timer for waiting for an Iu Release Complete message from the RNC.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
iu-release-complete-timeout time
```

```
default iu-release-complete-timeout
```

default

Resets the timer to its default setting.

time

This variable defines the amount of time (in seconds) that the SGSN waits to receive an 'Iu Release Complete' message from the RNC.

Default: 10.

time : Must be an integer from 1 to 60.

Usage

Configure the number of seconds that the SGSN waits to receive the Iu Release Complete message.

Example

```
iu-release-complete-timeout 20
```

loss-of-radio-coverage ranap-cause

This command sets the detection cause included in the Iu Release message. This command is unique to releases 9.0 and higher.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
loss-of-radio-coverage ranap-cause cause_number
```

```
default loss-of-radio-coverage ranap-cause
```

default

This keyword resets the configuration to the default cause ID number.

ranap-cause *cause_number*

This number identifies the reason the SGSN has detected, from Iu Release messages, for the loss of radio coverage (LORC). This value is included in the IE messages the SGSN sends to either the GGSN or the GGSN and the peer SGSN to indicate LORC state. The range of reasons is a part of the set defined by 3GPP 25413.

cause_number : Must be an integer from 1 to 512.

Default: 46 (MS/UE radio connection lost)

Usage

By defining a cause code, the SGSN knows to detect the LORC state of the mobile from Iu Release messages it receives for the subscriber. This configuration also instructs the SGSN to include the defined cause code for the LORC state in the IE portion of various messages sent to the GGSN and optionally the peer SGSN. This command is one of the two commands required to enable the SGSN to work with the GGSN and, optionally the peer SGSN, to implement the Overcharging Protection feature (see the *SGSN Overview* in the *SGSN Administration Guide* for feature details. The other command needed to implement the Overcharging Protection feature is the **gtp private extension** command explained in the *SGSN APN Policy Configuration Mode* chapter of the *Command Line Interface Reference*.

Example

Use the following command to set the cause code to indicate that there are no radio resources available in the target cell, cause 53.

```
loss-of-radio-coverage ranap-cause 53
```

plmn

Configures the PLMN (public land mobile network) related parameters for the IuPS service. This command is applicable to releases 8.1 and higher.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
plmn id mcc mcc_num mnc mnc_num [ network-sharing common-plmn mcc mcc_num mnc mnc_num [ plmn-list mcc mcc_num mnc mnc_num [ mcc mcc_num mnc mnc_num+ ] ] ]
```

```
no plmn id
```

no

Removes the PLMN ID from the configuration.

id

Creates a PLMN configuration instance based on the PLMN ID (comprised of the MCC and MNC). In accordance with TS 25.413, the SGSN supports up to 32 PLMN configurations for shared networks.

mcc *mcc_num*

Specifies the mobile country code (MCC) portion of the PLMN's identifier.

mcc_num: The PLMN MCC identifier and can be configured to any integer value between 100 and 999.

mnc *mnc_num*

Specifies the mobile network code (MNC) portion of the PLMN's identifier.

mnc_num: The PLMN MNC identifier and can be configured to any 2-digit or 3-digit value between 00 and 999.

network-sharing common-plmn **mcc** *mcc_num* **mnc** *mnc_num*

When network sharing is employed, this set of keywords is required to define the PLMN ID of the common PLMN. The common PLMN is usually not the same as the local PLMN.

plmn-list **mcc** *mcc_num* **mnc** *mnc_num*

When network sharing is employed and more than two PLMNs are available, then use the **plmn-list** keyword to begin a list of all additional PLMNs.

Usage

Use this command to configure the PLMN associated with the SGSN. There can only be one PLMN associated with an SGSN unless one of the following features is enabled and configured: network sharing or multiple PLMN.

For network sharing, use of the **network-sharing** keywords make it possible to identify more than one PLMN. Including the PLMN identified initially. None have precedence. They are all treated equally but they must each be unique. In a MOCN configuration, the PLMN list will not be used as there would only be one local PLMN.

For multiple PLMN support, the SGSN can support up to 8 Iu-PS configurations for PLMNs. These Iu-PS service configurations must be associated with the SGSN via the **ran-protocol** command in the SGSN Service configuration mode.

Example

Use the following command to identify a PLMN and instruct the SGSN to perform network sharing with a single PLMN:

```
plmn id mcc 313 mnc 23 network-sharing common-plmn mcc 404 mnc 123
```

rab-assignment-response-timeout

Configures the RAB assignment timer.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
rab-assignment-response-timeout time
```

```
default rab-assignment-response-timeout
```

default

Resets the timer to its default setting.

time

This variable configures the amount of time (in seconds) that the SGSN waits to receive a RAB assignment from the RNC.

time : must be an integer from 1 to 60.

Default: 8.

Usage

This command defines time the SGSN waits for the completion of the RAB assignment procedure.

Example

Change the timer setting to 11 seconds.

```
rab-assignment-response-timeout
```

radio-network-controller

This command creates an instance of an RNC configuration to associate with the IuPS service for the SGSN. This command is only available in release 8.0; use the **rnc** command for releases 8.1 and higher.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
radio-network-controller id rnc_id mcc mcc_num mnc mnc_num
```

```
no radio-network-controller id rnc_id mcc mcc_num mnc mnc_num
```

no

Removes the configuration information for the specified RNC.

id *rnc_id*

Define the instance number of the RNC configuration.

rnc_id : Must be an integer from 0 to 4095.

mcc *mcc_num*

Specifies the mobile country code (MCC).

mcc_num : Must be an integer between 100 and 999.

mnc *mnc_num*

Specifies the mobile network code (MNC).

mnc_num : Must be an integer between 00 and 999.

Usage

Use this command to configure information for the IuPS service to use to contact specific RNCs.

This command also provides access to the RNC configuration mode.

Example

The following command creates or accesses an instance of an RNC configuration.

```
radio-network-controller id 1 mcc 131 mnc 22
```

relocation-complete-timeout

This command specifies the maximum time for the SGSN to wait for a Relocation Completion from the core network.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
relocation-complete-timeout timeout_value
```

```
default relocation-complete-timeout
```

default

Resets the configuration to a 5 second wait time.

timeout_value

Time in seconds that the SGSN waits for relocation to be completed.

timeout_value : Must be an integer from 1 to 60.

Default : 5 seconds.

Usage

Use this command to configure the number of seconds the SGSN will wait for a relocation to be completed. This timeout needs to be set with sufficient time so that SRNS procedure aborts can be avoided if the peer fails to respond in a timely fashion in the case of a hard handoff.

Example

The following command sets the wait time for 10 seconds.

```
relocation-complete-timeout 10
```

reset

Defines the configuration specific to the RESET procedure.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
reset ( ack-timeout time | guard-timeout time | max-retransmissions retries |
sgsn-initiated }
```

```
default reset ( ack-timeout | guard-timeout | max-retransmissions | sgsn-
initiated }
```

```
no reset sgsn-initiated
```

default

Returns to the default settings for the Reset procedure.

no

Removes the SGSN-initiated reset procedure from the configuration.

ack-timeout *time*

Configures the interval (in seconds) for which the SGSN waits for RESET-ACK from the RNC.
time must be an integer from 5 to 10.
Default: 10.

guard-timeout

Configures the interval (in seconds) after which the SGSN sends RESET-ACK to the RNC.
time must be an integer from 5 to 10.
Default : 10

max-retransmissions

Configures maximum retries for RESET message.
retries must be an integer from 0 to 2.
Default: 1.

sgsn-initiated

Enables SGSN initiated RESET procedure.
Default: disabled.

Usage

Configures the parameters that determine a RESET.

■ reset

Example

Use the following to have the SGSN initiate the RESET procedure:

```
reset sgsn-initiated
```

rnc

This command creates or accesses an instance of an RNC (radio network controller) configuration.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
rnc id rnc_id
```

```
no rnc id rnc_id
```

no

Removes the configuration information for the specified RNC.

```
id rnc_id
```

Set the identification number of the RNC configuration instance.

rnc_id : Must be an integer from 0 to 4095 for 8.1 releases. Must be an integer from 0 to 65535 for releases 9.0 and higher.

Usage

Use this command to configure information for the IuPS service to use to contact specific RNCs. This command also provides access to the RNC configuration mode.

Example

The following command creates an RNC configuration instance

```
rnc id 1
```

security-mode-complete-timeout

This command configures the security mode timer.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
security-mode-complete-timeout time
```

```
default security-mode-complete-timeout
```

default

Resets the timer configuration to the default settings.

time

Configures the interval (in seconds) the SGSN waits for the security mode from the MS to complete.

time must be an integer from 1 to 60.

Default is 5

Usage

Use this command to configure the timer that determines how long the SGSN waits for a Security Mode Complete message from the MS (mobile station).

Example

```
security-mode-complete-timeout 7
```

srns-context-response-timeout

This command configures the SGSN context response timer.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
srns-context-response-timeout time
```

```
default srns-context-response-timeout
```

default

Resets the timer configuration to the default setting.

time

Configures the interval (in seconds) for which the SGSN waits for an SRNS Context Request message.

time must be an integer from 1 to 60.

Default: 5.

Usage

Configures the time to wait before the SGSN sends a response to the SRNS 'context request' message.

Example

```
srns-context-response-timeout 7
```

tigoc-timeout

This command configures the TigOc interval.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
tigoc-timeout time
```

```
default tigoc-timeout
```

default

Resets the timer configuration to the default setting.

time

This command sets the time in seconds.

time : Must be an integer from 1 to 10.

Default: 5.

Usage

Define the amount of time that the SGSN ignores any overload messages for TigOc interval after receiving one overload message from the RNC.

Example

Use the following command to change the default TigOc interval:

```
tigoc-timeout 4
```

tintc-timeout

This command configures the TinTc interval..

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
tintc-timeout time
```

```
default tintc-timeout
```

default

Resets the timer configuration to the default setting.

time

Set the number of seconds to wait.

time : Must be an integer from 1 to 10.

Default: 5.

Usage

Define the number of seconds that the SGSN waits before decrementing (by one) the traffic level of the RNC.

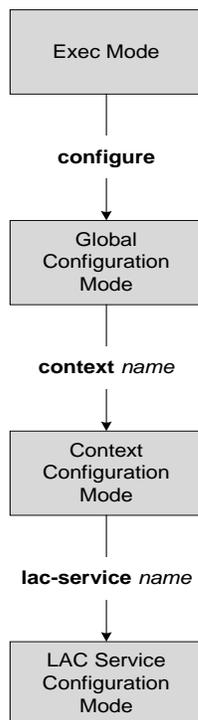

Example

```
tintc-timeout 4
```

Chapter 155

LAC Service Configuration Mode Commands

The LAC Service Configuration Mode is used to create and manage L2TP services within contexts on the system. L2TP Access Concentrator (LAC) services facilitate tunneling to peer L2TP Network Servers (LNSs).

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

allow

This command configure the system to allow different attributes in the LAC Hostname AVP and Called-Number AVP for L2TP messages exchanged between LAC and LNS.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
allow {aaa-assigned-hostname | called-number value apn}
```

```
[ no | default ] allow {aaa-assigned-hostname | called-number value apn}
```

no

Disable the configured attribute and returns to the behavior that uses the LAC-Service name as the HostName AVP.

aaa-assigned-hostname

When enabled if AAA assigns a valid Tunnel-Client-Auth-ID attribute for the tunnel, it is used as the HostName AVP in the L2TP tunnel setup message.

This keyword works in conjunction with **local-hostname** *hostname* keyword applied with **tunnel 12tp** command in APN configuration mode.

When Tunnel parameters are not received from the RADIUS Server, Tunnel parameters configured in APN are considered for the LNS peer selection. When APN configuration is selected, local-hostname configured with **tunnel 12tp** command in the APN for the LNS peer will be used as a LAC Hostname.

called-number value apn

This keyword configures the system to send APN name in Called-Number AVP as a part of ICRQ message sent to the LNS. If this keyword is not configured, Called-Number AVP will not be included in ICRQ message sent to the LNS.

Usage

Use this command to configure the attribute for the HostName AVP for L2TP messages exchanged between LAC and LNS.

LAC Hostname will be different for the subscribers corresponding to the different corporate APNs. In the absence of a AAA assigned HostName, the LAC-Service name is used as HostName. By default the LAC-Service name is used as the HostName AVP.

Example

The following command enables the use of the value of Tunnel-Client-Auth-ID attribute for the HostName AVP:

```
allow aaa-assigned-hostname
```

Use the following command to reset the behavior so that the LAC-Service uses the LAC-Service name as the HostName AVP:

```
no allow aaa-assigned-hostname
```

bind

This command assigns a local end point address to the LAC service in the current context.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
bind ip_address [max-subscribers]
```

```
no bind ip_address
```

no

Unassign, or unbind, the local end point to the LAC service.

ip_address

This must be a valid IPv4 address, using dotted-decimal notation.

max-subscribers

The maximum number of subscribers that can use the endpoint for this LAC service. Must be an integer from 1 to 2500000.

Usage

Use this command to bind a local end point IP address to the LAC service.

Example

The following command binds the local end point IP address *10.10.10.100* to the LAC service in the current context:

```
bind 10.10.10.100
```

The following command removes the binding of the local end point to the LAC service:

```
no bind
```

data sequence-number

Enables data sequence numbering for sessions that use the current LAC service. Data sequence numbering is enabled by default.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
data sequence-number
```

```
no data sequence-number
```

```
no
```

Disables data sequence numbering for sessions.

Usage

An L2TP data packet header has an optional data sequence numbers field. The data sequence number may be used to ensure ordered delivery of data packets. This command is used to re-enable or disable the use of the data sequence numbers for data packets.

Example

Use the following command to disable the use of data sequence numbering:

```
no data sequence-number
```

Use the following command to re-enable data sequence numbering:

```
data sequence-number
```

default

This command sets the specified LAC service parameter to its default value or setting.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
default {data sequence-number | hide-attributes | keepalive-interval | load-
balancing | local-receive-window | max-retransmission | max-session-per-tunnel |
max-tunnel-challenge-length | max-tunnels | proxy-lcp-authentication |
retransmission-timeout-first | retransmission-timeout-max | trap all | tunnel-
authentication}
```

data sequence-number

Enables data sequence numbering for sessions.

hide-attributes

Disables hiding attributes in control messages sent from the LAC to the LNS.

keepalive-interval

Sets the interval for send L2TP Hello keepalive if there is no control or data transactions to the default value of 60 secs.

load-balancing

Sets the load balancing algorithm to be used when many LNS peers have been configured to the default of round robin.

local-receive-window

Sets the window size to be used for the local side for the reliable control transport to the default of 16.

max-retransmission

Sets the maximum number of retransmissions to the default of 5.

max-session-per-tunnel

Sets the maximum number of sessions per tunnel at any point in time to the default of 512.

max-tunnel-challenge-length

Sets the maximum length of the tunnel challenge to the default of 16 bytes.

max-tunnels

Sets the maximum number of tunnels for this service to the default of 32000.

proxy-lcp-authentication

Sets sending of proxy LCP authentication parameters to the LNS to the default state of enabled.

retransmission-timeout-first

Sets the first retransmit interval to the default of 1 second.

retransmission-timeout-max

Sets the maximum retransmit interval to the default of 8 seconds.

trap all

Generates all supported SNMP traps.

tunnel-authentication

Sets tunnel authentication to the default state of enabled.

Usage

Use the default command to set LAC service parameters to their default states.

Example

Use the following command to set the keep alive interval to the default value of 60 seconds:default

```
keepalive-interval
```

Use the following command to set the maximum number of sessions per tunnel to the default value of 512:

```
default max-session-per-tunnel
```

hide-attributes

Enables hiding certain attributes (such as proxy-auth-name and proxy-auth-rsp) in control messages sent from the LAC to the LNS. The LAC hides such attributes only if tunnel authentication is enabled between the LAC and the LNS.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

hide-attributes

no hide-attributes

no

Disable hiding attributes.

Usage

Use this command to hide certain attributes from control messages when tunnel authentication is enabled between the LAC and the LNS.

Example

The following command enables hiding attributes:

hide-attributes

keepalive-interval

This command specifies the amount of time to wait before sending a Hello keep alive message.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
keepalive-interval seconds
```

```
no keepalive-interval
```

no

Disables the generation of Hello keep alive messages on the tunnel.

seconds

Default: 60

The number of seconds to wait before sending a Hello keep alive message. The number can be configured to any integer value from 30 to 2147483648.

Usage

Use this command to set the amount of time to wait before sending a Hello keep alive message or disable the generation of Hello keep alive messages completely. A keep alive mechanism is employed by L2TP in order to differentiate tunnel outages from extended periods of no control or data activity on a tunnel. This is accomplished by injecting Hello control messages after a specified period of time has elapsed since the last data or control message was received on a tunnel. As for any other control message, if the Hello message is not reliably delivered then the tunnel is declared down and is reset. The transport reset mechanism along with the injection of Hello messages ensures that a connectivity failure between the LNS and the LAC is detected at both ends of a tunnel.

Example

Use the following command to set the Hello keep alive message interval to *120* seconds:

```
keepalive-interval 120
```

Use the following command to disable the generation of Hello keep alive messages:

```
no keepalive-interval
```

load-balancing

Configures how LNSs are selected for this LAC service.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
load-balancing {balanced | prioritized | random}
```

balanced

LNS selection is made without regard to prioritization, but in a sequential order that balances the load across the total number of LNS nodes available.

prioritized

LNS selection is made based on the priority assigned in the Tunnel-Preference attribute. An example of this method is three LNS nodes, with preferences of 1, 2, and 3 respectively. In this example, the RADIUS server always tries the tunnel with a preference of 1 before using any of the other LNS nodes.

random

Default: Enabled

LNS selection is random in order, wherein the RADIUS server does not use the Tunnel-Preference attribute in determining which LNS to select.

Usage

Use this command to configure the load-balancing algorithm that defines how the LNS node is selected by the LAC when there are multiple peer LNSs configured in the LAC service.

Example

The following command sets the LAC service to connect to LNSs in a sequential order;

```
load-balancing balanced
```

The following command sets the LAC service to connect to LNSs according to the priority assigned through the Tunnel-Preference attribute:

```
load-balancing prioritized
```

local-receive-window

Specifies the number of control messages the remote peer LNS can send before waiting for an acknowledgement.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
local-receive-window integer
```

integer

Default: 4

The number of control messages to send before waiting for an acknowledgement. The number can be configured to any integer value from 1 to 256.

Usage

Use this command to set the size of the control message receive window being offered to the remote peer LNS. The remote peer LNS may send the specified number of control messages before it must wait for an acknowledgment.

Example

The following command sets the local receive window to 10 control messages:

```
local-receive-window 10
```

max-retransmission

Sets the maximum number of retransmissions of a control message to a peer before the tunnel and all sessions within it are cleared.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-retransmission integer
```

integer

Default: 5

The maximum number of retransmissions of a control message to a peer. This value must be an integer in the range of 1 to 10.

Usage

Each tunnel maintains a queue of control messages to be transmitted to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. If no peer response is detected after the number of retransmissions set by this command, the tunnel and all sessions within are cleared.

Use this command to set the maximum number of retransmissions that the LAC service sends before closing the tunnel and all sessions within. it.

Example

The following command sets the maximum number of retransmissions of a control message to a peer to 7:

```
max-retransmissions 7
```

max-session-per-tunnel

Sets the maximum number of sessions that can be facilitated by a single a tunnel at any time.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-sessions-per-tunnel integer
```

integer

Default: 512

The maximum number of sessions. This value must be in the range of 1 to 65535.

Usage

Use this command to set the maximum number of sessions you want to allow in a tunnel.

Example

The following command sets the maximum number of sessions in a tunnel to *5000*:

```
max-sessions-per-tunnel 5000
```

max-tunnel-challenge-length

Sets the maximum length of the tunnel challenge in bytes. The challenge is used for tunnel authentication purposes during tunnel creation.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-tunnel-challenge-length bytes
```

bytes

Default: 16

The number of bytes to set the maximum length of the tunnel challenge. This must be a value from 4 to 32.

Usage

Use this command to set the maximum length, in bytes, for the tunnel challenge that is used during tunnel creation.

Example

The following command sets the maximum length of the tunnel challenge to 32 bytes:

```
max-tunnel-challenge-length 32
```

max-tunnels

The maximum number of tunnels that the current LAC service can support.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-tunnels integer
```

integer

Default: 32000

The maximum number of tunnels. This value must be an integer from 1 to 32000.

Usage

Use this command to set the maximum number tunnels that this LAC service can support at any on time.

Example

Use the following command to set the maximum number of tunnels for the current LAC service to *20000*:

```
max-tunnels 20000
```

peer-lns

Adds a peer LNS address for the current LAC service. Up to 8 peer LNSs can be configured for each LAC service.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
peer-lns ip_address [encrypted] secret secret [crypto-map map_name { [encrypted]
isakmp-secret secret } ] [ description text ] [ preference integer]
```

```
no peer-lns ip_address
```

```
no peer-lns ip_address
```

Deletes the peer LNS at the IP address specified by *ip_address*. *ip_address* must be entered in standard IPv4 dotted decimal notation.

```
ip_address
```

The IP address of the peer LNS for the current LAC service. *ip_address* must be entered in standard IPv4 dotted decimal notation.

```
[encrypted] secret secret
```

Designates the secret which is shared between the current LAC service and the peer LNS. *secret* must be a string from 1 to 256 alpha and/or numeric characters and is case sensitive.

encrypted secret *secret*: Specifies that encryption should be used when communicating the secret with the peer LNS.

```
crypto-map map_name { [encrypted] isakmp-secret secret }
```

map_name is the name of a crypto map that has been configured in the current context. *map_name* must be a string from 1 to 127 alpha and/or numeric characters and is case sensitive.

isakmp-secret *secret*: The pre-shared key for IKE. *secret* must be a string from 1 to 127 alpha and/or numeric characters and is case sensitive.

encrypted isakmp-secret *secret*: The pre-shared key for IKE. Encryption must be used when sending the key. *secret* must be a string from 1 to 127 alpha and/or numeric characters.

```
description text
```

Specifies the descriptive text to use to describe the specified peer LNS. *text* must be 0 to 79 alpha and/or numeric characters with no spaces or a quoted string of printable characters.

```
preference integer
```

This sets the priority of the peer LNS if multiple peer LNSs are configured. *integer* must be a value ranging from 1 to 128.

Usage

Use this command to add a peer LNS address for the current LAC service.

Example

The following command adds a peer LNS to the current LAC service with the IP address of *10.10.10.100*, sets encryption on, specifies the shared secret to be *1b34nnf5d*, and sets the preference to *3*:

```
peer-lns 10.10.10.100 encrypted secret 1b34nnf5d preference 3
```

The following command removes the peer LNS with the IP address of *10.10.10.200* for the current LAC service:

```
no peer-lns 10.10.10.200
```

proxy-lcp-authentication

Enables and disables the sending of proxy LCP authentication parameters to the LNS.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
proxy-lcp-authentication
```

```
no proxy-lcp-authentication
```

no

Disables the sending of proxy LCP authentication parameters to the LNS.

proxy-lcp-authentication

Default: Enabled

Enables the sending of proxy LCP authentication parameters to the LNS.

Usage

Use this feature in situations where the peer LNS does not understand the proxy LCP Auth AVPs that the system sends and does not do an LCP renegotiation and tears down the call.

Example

Use the following command to disable the sending of proxy LCP authentication parameters to the LNS;

```
no proxy-lcp-authentication
```

Use the following command to re-enable the sending of proxy LCP authentication parameters to the LNS:

```
proxy-lcp-authentication
```

retransmission-timeout-first

Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted. This command sets the initial timeout for retransmission of control messages.

Privilege

Security Administrator, Administrator

Syntax

```
retransmission-timeout-first integer
```

integer

Default: 1

The amount of time to wait before sending the first control message retransmission. This value is measured in seconds and must be an integer from 1 to 100.

Usage

Use this command to set the initial timeout before retransmitting control messages to the peer.

Example

The following command sets the initial retransmission timeout to 3 seconds:

```
retransmission-timeout-first 3
```

retransmission-timeout-max

This command configures maximum amount of time between two retransmission of control messages.

Privilege

Security Administrator, Administrator

Syntax

```
retransmission-timeout-max integer
```

integer

Default: 8

integer is the maximum time in seconds to wait before retransmitting control messages and must be an integer between 1 through 100.

Usage

Use this command to set the maximum amount of time that can elapse before retransmitting control messages.

Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval.

Example

The following command sets the maximum retransmission time-out to *10* seconds:

```
retransmission-timeout-max 10
```

single-port-mode

This command enables/disables the L2TP LAC service always to use standard L2TP port 1701 as source port for all L2TP control and data packets originated from LAC node.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[no | default] single-port-mode
```

no

Disables the configured single source port configuration from this LAC service.

default

Default: Enabled

Sets this command to default state of disabled. By default single source port configuration for L2TP LAC packets is disabled.

Usage

Use this command to enable or disable the single port mode for L2TP LAC service.

If this feature is enabled, then L2TP LAC service will always use standard L2TP port 1701 as source port for all L2TP control/data packets originated from LAC (instead of the default scheme in which each L2TPMgr uses a dynamic source port). L2TPMgr instance 1 will handle all L2TP calls for the service.

Caution: Changing this configuration, while the service is already running, will cause restart of the service.

Example

The following command enables the LAC service to use port 1701 as source port for all L2TP control and data packets:

```
single-port-mode
```

snoop framed-ip-address

When enabled, this feature allows the LAC to detect IPCP packets exchanged between the mobile node and the LNS and extract the framed-ip-address assigned to the mobile node. The address will be reported in accounting start/stop messages and will be displayed for subscriber sessions.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[no | default] snoop framed-ip-address
```

no

Disables the feature. Accounting start/stop will occur before the PPP session is established and the framed IP address field will be reported as 0.0.0.0.

default

Disabled.

Usage

This feature is available to address simple IP roaming scenarios. If this feature is enabled, the accounting start will be sent only after the framed-ip-address is detected. If the framed-ip-address is not detected within 16 seconds, an accounting start will be sent for the session with the 0.0.0.0 address. If the session is disconnected during the detection attempt, accounting start/stop will be sent for the session. If the session renegotiates IPCP, an accounting stop will be generated with a framed-ip-address from the old session and an accounting start will be generated with an IP address for the new session. IPv6 address detection is not supported.

Important: When this feature is enabled and the show subscribers all command is invoked, the framed-IP-address is displayed for the PDSN Simple IP subscriber in the output display.

trap

This command generates SNMP traps.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[no] trap all
```

no

Disables SNMP traps.

Usage

Use this command to enable/disable all supported SNMP traps.

Example

To enable all supported SNMP traps, enter the following command:

```
trap all
```

tunnel-authentication

Enables tunnel authentication. When tunnel authentication is enabled, a configured shared secret is used to ensure that the LAC service is communicating with an authorized peer LNS. The shared secret is configured by the **peer-lns** command in the LAC service configuration mode, the **tunnel l2tp** command in the subscriber configuration mode, or the **Tunnel-Password** attribute in the subscribers RADIUS profile.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] tunnel-authentication

no

Disables tunnel authentication.
Tunnel authentication is enabled by default.

Usage

Disable or enable the usage of secrets to authenticate a peer LNS when setting up a tunnel.

Example

To disable tunnel authentication, use the following command:

```
no tunnel-authentication
```

To re-enable tunnel authentication, use the following command:

```
tunnel-authentication
```

tunnel selection-key

This command enables the support to create tunnels between L2TP service and an LNS server on the basis of value of attribute “Tunnel-Server-Auth-ID” received from AAA server.

Privilege

Security Administrator, Administrator

Syntax

```
tunnel selection-key { tunnel-server-auth-id | none }
```

```
[default] tunnel selection-key
```

default

This keyword disables the creation of tunnel between LAC service and LNS based on key value received in attribute, “Tunnel-Server-Auth-ID” from AAA server.

tunnel-server-auth-id

Default: Enabled

This keyword enables the creation of tunnels between LAC service on GGSN and an LNS server on the basis of domain attribute, “Tunnel-Server-Auth-ID”, value received from AAA server.

none

Default: Enabled

This keyword disables the creation of multiple tunnels between a pair of LAC service on GGSN and LNS server. LAC will not make use of key to choose a tunnel with LNS in this setup.

Usage

Use this command to enable or disable the creation of additional L2TP tunnels between LAC service on GGSN and LNS server on the basis of “Tunnel-Server-Auth-ID” attribute value received from AAA Server in Access-Accept message. This value of attribute is treated as a key for tunnel selection and creation.

When the LAC needs to establish a new L2TP session, it would first check if there is already an existing L2TP tunnel with the peer LNS based on the value of key configured. If no such tunnel exists for the key, it will create a new Tunnel with the LNS.

Default configuration have selection-key as **none**. Hence, LAC will not make use of key to choose a tunnel with LNS, in default setup.

Maximum number of session as configured with **max-sessions-per-tunnel** command will be applicable for each tunnel created through this command. By default each tunnel supports 512 sessions.

If LAC service needs to establish a new tunnel for new L2TP session with LNS and the tunnel create request fails because maximum tunnel creation limit is reached, LAC will try other LNS addresses received from AAA server in Access-Accept message for the APN/subscriber. If all available peer-LNS are exhausted, LAC service will reject the call.

Example

The following command enables the use of “Tunnel-Server-Auth-ID” attribute value received from AAA Server in Access-Accept message as a key for tunnel selection and creation:

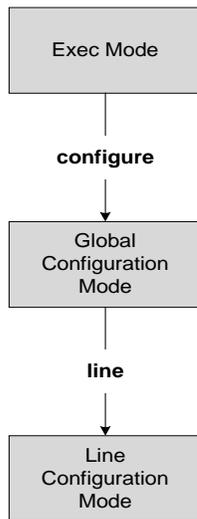

■ tunnel selection-key

```
tunnel selection-key tunnel-server-auth-id
```

Chapter 156

Line Configuration Mode Commands

The Line Configuration Mode is used to manage the terminal line characteristics for output formatting.

i **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

default

Restores the default length or width for the output to the display terminal.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
default { length | width }
```

length | width

length: restores the default value for the number of rows (length) of the output for display.

width: restores the default value for the number of columns (width) of the output for display as the number of characters.

Usage

Reset the output display properties if they had been changed during a session.

Example

```
default length
```

```
default width
```

end

Exits the line configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the line configuration mode and returns to the global configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

length

Configures the output for the displays length (number of rows).

Privilege

Security Administrator, Administrator

Syntax

```
length number
```

number

Specifies the number of rows (lines) of output that can be displayed at one time for the display (output) terminal. *number* must have a value of 0 or be in the range from 5 through 512 where the special value 0 implies an infinite number of rows.

Usage

Set the current session's display terminal has different display characteristics than the defaults. The special infinite value (0) is typically used when logging the output of a session from a remote machine since this will result in no pagination of output.

Example

The following commands set the length of the display to infinite and 33, respectively.

```
length 0
```

```
length 33
```

width

Configures the output for the displays width (number of columns/characters wide).

Privilege

Security Administrator, Administrator

Syntax

```
width number
```

number

Specifies the number of columns (characters) of output that can be displayed at one time for the display (output) terminal. *number* must have a value in the range from 5 through 512.

Usage

Set the current session's display terminal has different display characteristics than the defaults.

Example

```
width 160
```

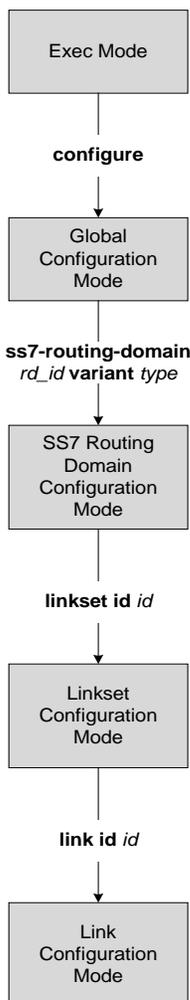

Chapter 157

Link Configuration Mode Commands

The Link configuration mode defines the MTP3 link parameters for a specific link in a linkset of an SS7 routing domain instance.

In this mode, the prompt will be similar to:

```
[local]hostname(config-ss7-rd-linkset-<#>-link-<#>)#
```

■ width

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

arbitration

This command configures link arbitration.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
arbitration { active | passive }
```

```
no arbitration
```

no

Removes the arbitration configuration for the link.

active

The SSCOP initiates the transmission of PDUs.

passive

The SSCOP waits to receive PDUs.

Usage

Sets the configuration to initiate transmission of PDUs.

Example

```
arbitration active
```

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec Mode.

exit

Exits the current mode and returns to the previous mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Returns to the previous mode.

mtp2-aerm-emergency-threshold

Configure the alignment error rate monitor (AERM) emergency threshold value.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp2-aerm-emergency-threshold value
```

```
default mtp2-aerm-emergency-threshold
```

default

Resets the parameter to the default value of 1.

value

value : Enter an integer from 1 to 50. Default: 1.

Usage

This command sets the emergency threshold for the MTP2 alignment error rate monitor.

Example

Set the emergency AERM threshold to 17:

```
mtp2-aerm-emergency-threshold 17
```

mtp2-aerm-normal-threshold

Configure the alignment error rate monitor (AERM) normal threshold value.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp2-aerm-normal-threshold value
```

```
default mtp2-aerm-normal-threshold
```

default

Resets the parameter to the default value of 4.

value

value : Enter an integer from 4 to 100. Default: 4.

Usage

This command sets the normal threshold for the MTP2 alignment error rate monitor.

Example

Set the normal AERM threshold to 55:

```
mtp2-aerm-normal-threshold 55
```

mtp2-eim-decrement

Configure the errored interval monitor (EIM) emergency decrement value.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp2-eim-decrement value
```

```
default mtp2-eim-decrement
```

default

Resets the parameter to the default value of 1.

value

value : Enter an integer from 1 to 2. Default: 1.

Usage

This command sets the emergency decrement value for the EIM.

Example

Reset the EIM emergency decrement to 1:

```
default mtp2-eim-decrement
```

mtp2-eim-increment

Configure the errored interval monitor (EIM) emergency increment value.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp2-eim-increment value
```

```
default mtp2-eim-increment
```

default

Resets the parameter to the default value of 1.

value

value : Enter an integer from 1 to 2. Default: 1.

Usage

This command sets the emergency increment value for the EIM.

Example

Set the EIM emergency increment to 2:

```
mtp2-eim-increment 2
```

mtp2-eim-threshold

Configure the errored interval monitor (EIM) emergency threshold value.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp2-eim-threshold value
```

```
default mtp2-eim-threshold
```

default

Resets the parameter to the default value of 100.

value

value : Enter an integer from 100 to 200. Default: 100.

Usage

This command sets the emergency threshold value for the EIM.

Example

Set the EIM emergency threshold to 154:

```
mtp2-eim-threshold 154
```

mtp2-error-correction

Configure the error correction method to be used.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp2-error-correction { basic | preventive-cyclic-retransmission }  
default mtp2-error-correction
```

default

Resets the parameter to the default value.

basic

Basic error correction (BEC) is a positive / negative acknowledgement method that uses backwards retransmission. This method is best for links with less than 30 ms one-way propagation delays.

preventive-cyclic-retransmission

PCR is recommended for links with 125 ms, or higher, propagation delays.

Usage

Set the method of MTP2 layer error correct to be used on the link.

Example

Set error correction for a link with 15 ms propagaion delay::

```
mtp2-error-correction basic
```

mtp2-lssu-len

This command sets the length of the link status signal unit (LSSU) which carries link status information used to manage link alignment and indicate the status of the signaling points to each other.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp2-lssu-len #_octets
```

```
default mtp2-lssu-len
```

default

Using this keyword with the command resets the length to the default of 1 octet.

#_octets

Sets the number of octets for the length of the LSSU.

#_octets: Must be either 1 or 2.

Usage

Use this command to define the maximum amount of link status information that is to be shared between signaling points.

Example

You can use the following command to set the LSSU length to 2 octets - the maximum length:

```
mtp2-lssu-len 2
```

mtp3-discard-priority

Configure MTP3 message discard priority.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp3-discard-priority priority
```

```
default mtp3-discard-priority
```

default

Resets the priority to the default value.

priority

priority: must be an integer between 0 and 3.

Default is 0.

Usage

Use this command to manage MTP3 messaging.

Example

```
mtp3-discard-priority 2
```

mtp3-max-slt-try

Configure maximum number of times to retry SLT (signaling link test).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp3-max-slt-try retries
```

```
default mtp3-max-slt-try
```

default

Resets the number of retries to the default value.

retries

retries: must be an integer between 1 to 65535.

Default is 10.

Usage

Use this command to troubleshoot MTP3 link mismatch.

Example

```
mtp3-max-slt-try 35
```

mtp3-msg-priority

Configures the priority for sending MTP3 management messages.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp3-msg-priority priority
```

```
default mtp3-msg-priority
```

default

Resets the number of priority to the default value.

priority

priority: must be an integer from 0 to 3.

Default: 0

Usage

Use this command to set the priority for sending MTP3 management messages.

Example

Use the following to set the message priority to 3:

```
mtp3-msg-priority 3
```

mtp3-msg-size

Configures the size of messages from layer 3 to layer 2..

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp3-msg-size size
```

```
default mtp3-msg-size
```

default

Resets the the size to the default value which is 4096 (for q.2140) or 272 (for MTP2)

size

size: must be an integer from 1 to 4096.

Usage

Use this command to set the maximum message size, in bytes.

Example

Use this command to set the MTP3 message size to 4096 bytes:

```
mtp3-msg-size 4096
```

mtp3-p1-qlen

Configure the size for the MTP3 p1 queue length.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp3-p1-qlen size
```

```
default mtp3-p1-qlen
```

default

Resets the number of size of the priority 1 queue to the default value.

size

size: integer from 1 to 65535. Size should be less than MTP3 p2 qlen and p3 qlen.

Default: 1024

Usage

Use this command to configure the queue length threshold for raising the congestion priority to level 1.

Example

Use this command to set the queue length priority to 128:

```
mtp3-p1-qlen 128
```

mtp3-p2-qlen

Configure the size of the priority 2 queue.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp3-p2-qlen size
```

```
default mtp3-p2-qlen
```

default

Resets the number of size of the priority 2 queue to the default value.

size

size: integer from 1 to 65535. Size should be less than MTP3 p3 qlen and greater than p1 qlen.

Default: 1024

Usage

Use this command to configure the queue length threshold for raising the congestion priority to level 2.

Example

Use this command to set the queue length threshold to 256:

```
mtp3-p2-qlen 256
```

mtp3-p3-qlen

Configure the size of the priority 3 queue.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp3-p3-qlen size
```

```
default mtp3-p3-qlen
```

default

Resets the number of size of the priority 3 queue to the default value.

size

size: integer from 1 to 65535. Size should be greater than MTP3 p1 qlen and p2 qlen .

Default: 1024

Usage

Use this command to configure the queue length threshold for raising the congestion priority to level 3.

Example

```
mtp3-p3-qlen 1024
```

mtp3-test-pattern

Configures the character string for the test message.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mtp3-test-pattern pattern
```

```
default mtp3-test-pattern
```

default

Resets the pattern to the default value.

pattern

pattern: 1 to 15 alphanumeric characters.

Default: SGSN-ORIGINATED

Usage

Use this command to define a test pattern string for the signalling link test match (SLTM).

Example

```
mtp3-test-pattern TEST1-HomeOffice
```

priority

Configures the MTP3 Link Priority.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
priority pri_value
```

```
no priority
```

no

Removes the priority configuration.

pri_value

pri_value: 0 represents highest priority and 15 represents the lowest priority.

Usage

Use this command to configure the link priority within the MTP3 link set.

Example

```
priority 2
```

signaling-link-code

Configures the signaling link code (SLC).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
signaling-link-code code
```

```
no signaling-link-code
```

no

Removes the SLC configuration.

code

code : integer from 0 to 15.

Usage

Use this command to uniquely identify the signaling link to be used for MTP3 management messages.

Example

```
signaling-link-code 4
```

timeout

This command enables configuration of an array of signaling and flow control timers - for MTP, SSCF, and SSCOP.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] timeout timer
```

no

Adding **no** to the **timeout** command removes the timer configuration.

timer

Repeat the command as needed to configure all required timers.

- **mtp2-tmr-t1** - alignment ready timer; granularity is 100 ms. Range 250 to 3500 for high-speedhigh-speed (HS) and 400 to 500 for low-speed (LS); default value 3000 (HS) or 400 (LS)
- **mtp2-tmr-t2** - not aligned timer; granularity is 100 ms. Range 50 to 150; default value 50
- **mtp2-tmr-t4e** - emergency providing period timer. Once set this timer can be reset but it can not be disabled. Granularity is 100 ms. Range 4 to 6; default value 5
- **mtp2-tmr-t4n** - normal providing period timer. Once set this timer can be reset but it can not be disabled. Granularity is 100 ms. Range 30 to 700 for high-speed (HS) and 79 to 95 for low-speed (LS); default value 300 (HS) or 82 (LS)
- **mtp2-tmr-t5** - sending status indication busy (SIB) timer; granularity is 100 ms. Range 1 to 2; default value 1
- **mtp2-tmr-t5** - sending status indication busy (SIB) timer; granularity is 100 ms. Range 1 to 2; default value 1
- **mtp2-tmr-t7** - excessive delay of acknowledgement timer; granularity is 100 ms. Range 5 to 20; default value 10
- **mtp2-tmr-t8** - interval timer for error interval monitor - high-speed only; granularity is 100 ms. Range 1 to 2; default value 1
- **mtp3-tmr-t1** - mtp3 t1 timer, default value is 500ms
- **mtp3-tmr-t12** - mtp3 t12 timer, default value is 800ms
- **mtp3-tmr-t13** - mtp3 t13 timer, default value is 800ms
- **mtp3-tmr-t14** - mtp3 t14 timer, default value is 2000ms
- **mtp3-tmr-t17** - mtp3 t17 timer, default value is 800ms
- **mtp3-tmr-t2** - mtp3 t2 timer, default value is 700ms
- **mtp3-tmr-t22** - mtp3 t22 timer, default value is 180s
- **mtp3-tmr-t23** - mtp3 t23 timer, default value is 180s
- **mtp3-tmr-t24** - mtp3 t24 timer, default value is 500ms

- **mtp3-tmr-t3** - mtp3 t3 timer, default value is 500ms
- **mtp3-tmr-t31** - mtp3 t31 timer, default value is 5s
- **mtp3-tmr-t32** - mtp3 t32 timer, default value is 10s
- **mtp3-tmr-t33** - mtp3 t33 timer, default value is 20s
- **mtp3-tmr-t34** - mtp3 t34 timer, default value is 60s
- **mtp3-tmr-t4** - mtp3 t4 timer, default value is 500ms
- **mtp3-tmr-t5** - mtp3 t5 timer, default value is 500ms
- **mtp3-tmr-t7** - mtp3 t7 timer, default value is 1000ms
- **sscf-nni-tmr-t1** - sscf nni t1 timer. default value is 5s
- **sscf-nni-tmr-t2** - sscf nni t2 timer. default value is 30s
- **sscf-nni-tmr-t3** - sscf nni t2 timer. default value is 10ms
- **sscop-tmr-cc** - sscop cc timer. default value is 200ms
- **sscop-tmr-idle** - sscop idle timer (UNI 3.1 only). default value is 100ms
- **sscop-tmr-keep-alive** - sscop keep alive timer. default value is 100ms. For stability purposes, `tmrKeepAlive >= tmrPoll` and `tmrKeepAlive < tmrNoResponse`
- **sscop-tmr-no-rsp** - sscop no response timer. default value is 1.5s. For stability purposes, `tmrNoResponse > tmrKeepAlive`
- **sscop-tmr-poll** - sscop poll timer. default value is 100ms. For stability purposes, `tmrPoll <= tmrKeepAlive`

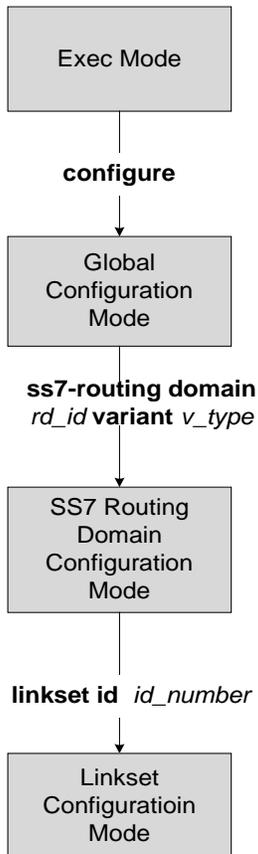

Important: For timers having different ranges for high speed (HS) and low speed (LS) links, the appropriate ranges will be displayed based on the link-type configured.

Chapter 158

Linkset Configuration Mode Commands

The Linkset configuration mode defines the MTP3 linkset parameters for a specific SS7 routing domain instance. In this mode, the prompt will appear similar to:

```
[local]hostname(config-ss7-rd-linkset-<#>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

adjacent-point-code

This command defines the point-code for the adjacent (next) network element in the SS7 network.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
adjacent-point-code point-code
```

```
no adjacent-point-code
```

point-code

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

no

Removes the adjacent-point-code configuration for this linkset in the SS7 routing domain

Important: Removing the linkset configuration will result in the termination of all of the links within the linkset.

Usage

Use this command to define the point-code for the adjacent element in the SS7 network.

Example

```
adjacent-point-code 6.202.7
```

end

Exits the current mode and returns to the Exec Mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec Mode.

exit

Exits the current mode and returns to the previous mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Returns to the previous mode.

link

This command creates an MTP3 link configuration for the SS7 linkset and enters the Link configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
link id id [ link-type [ atm-broadband | highspeed-narrowband | lowspeed-narrowband ]
```

```
no link id id
```

no

Disables the specified link configuration.

Important: Removing the link configuration will result in the termination of traffic on the specified link.

#_octets

Sets the number of octets for the length of the LSSU.

id

This number uniquely identifies the link in the linkset.

id: an integer between 1 and 16.

link-type

Identifies the signalling type for this link; options include:

- ATM broadband -- ATM AAL5 over an optical line card (OLC2)
- high speed-narrowband -- 64 kbps over a channelized optical line card (CLC2)
- low speed-narrowband -- 4.8 kbps over a channelized optical line card (CLC2)

Important: Be default link-type is ATM-broadband. To support narrowband SS7, one of the other options must be set.

Usage

Access the Link configuration mode to configure the parameters for the the link.

Example

Access configuration for link 4:

■ link

link id 4

self-point-code

This command defines the SS7 network point-code to identify this SGSN.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
self-point-code point-code
```

```
no self-point-code
```

point-code

Point-code is an SS7 address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Format options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

no

Removes the self-point-code configuration for this linkset in the SS7 routing domain.

Important: Removing the self-point-code will result in the termination of all traffic on this link.

Usage

Use this command to define the SS7 point-code to identify this system.

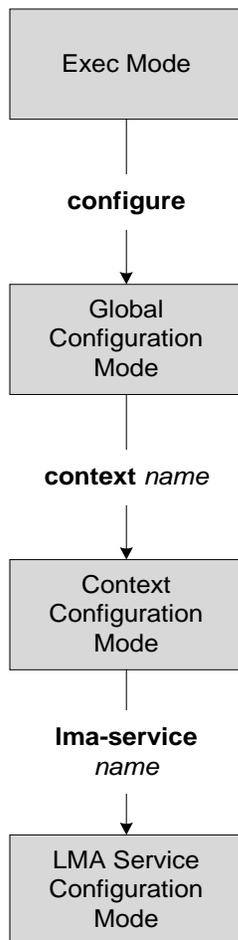

Example

```
self-point-code 6.192.7
```

Chapter 159

LMA Service Configuration Mode Commands

The LMA Service Configuration Mode is used to create and manage the Local Mobility Anchor configuration supporting Proxy Mobile IP on a PDN Gateway in an eHRPD and E-UTRAN/EPC network.

aaa accounting

Enables the LMA to send AAA accounting information for subscriber sessions.

Product

P-GW

Privilege

Administrator

Syntax

```
[ default | no ] aaa accounting
```

default

Sets the command to the default condition of enabled.

no

Disables the ability of the LMA to send AAA accounting information.

Usage

Use this command to enable the LMA service to send all accounting data (start, stop, and interim) to the configured AAA servers.

Important: In order for this command to function properly, AAA accounting must be enabled for the context in which the LMA service is configured using the **aaa accounting subscriber radius** command.

Example

The following command disables aaa accounting for the LMA service:

```
no aaa accounting
```

bind address

Binds the LMA service to a logical IP interface serving as the S2a (HSGW) or S5/S8 (S-GW) interface and specifies the maximum number of subscribers that can access this service over the configured interface.

Product

P-GW

Privilege

Administrator

Syntax

```
bind address ipv6_address [ ipv4-address ipv4_address ] [ max-subscribers num ]
```

```
no bind address
```

no

Removes the interface binding from this service.

ipv6_address

Specifies the IPv6 address of the interface configured as the S2a or S5/S8 interface. *ipv6_address* is specified in colon separated notation.

ipv4-address *ipv4_address*

Specifies optional IPv4 HA/P-GW address to support DSMIP6 session using IPv4 transport. *ipv4_address* must be entered as a standard IPv4 address in dotted decimal notation.

max-subscribers *num*

Default: 3000000

Specifies the maximum number of subscribers that can access this service on this interface. *num* must be configured to an integer between 0 and 3,000,000.

Important: The maximum number of subscribers supported is dependant on the license key installed and the number of active PSCs in the system. A fully loaded system with 13 active PSCs can support 3,000,000 total subscribers. Refer to the license key command and the Usage section (below) for additional information.

Usage

Associate the LMA service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an S2a or S5/S8 interface that provides the session connectivity to an HSGW (S2a) or S-GW (S5/S8). Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the **max-subscribers** option, be sure to consider the following:

- The total number of S2a or S5/S8 interfaces you will configure

bind address

- The total number of subscriber sessions that all of the configured interfaces may handle during peak busy hours
- An average bandwidth per session multiplied by the total number of sessions
- The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Example

The following command would bind the logical IP interface with the address of `4551:0db8:85a3:08d3:3319:8a2e:0370:1344` to the LMA service and specifies that a maximum of `300,000` simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

```
bind address 4551:0db8:85a3:08d3:3319:8a2e:0370:1344 max-subscribers  
300000
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax`end`

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

refresh-advice-option

Configures inclusion of a refresh advice option in the binding acknowledgement message sent by the LMA.

Product

P-GW

Privilege

Administrator

Syntax

```
[ default | no ] refresh-advice-option
```

default

Returns the command setting to the default setting of disabled.

no

Disables the inclusion of the refresh advice option in the binding acknowledgement message sent by the LMA

Usage

Use this command to enable the LMA to include this option in a binding acknowledgment sent to the requesting MAG. The option provides a “hint” to the MAG of when it should refresh the binding. As defined in RFC 3775 “Mobility Support in IPv6”, the binding refresh advice option can only be present in the binding acknowledgement sent from the mobile node's home agent in reply to a registration request. A refresh interval parameter determines the amount of time until the mobile node must send a new registration to the home agent to avoid de-registration and loss of session.

Important: Refer to the refresh-interval-percent and reg-lifetime commands for a complete understanding of registration (binding) lifetimes and refresh intervals.

refresh-interval-percent

Configures percentage of the granted registration lifetime to be used in the refresh interval mobility option in a binding acknowledgement message sent by the LMA service.

Product

P-GW

Privilege

Administrator

Syntax

```
refresh-interval-percent number
```

```
default refresh-interval-percent
```

default

Resets the command value to the default setting of 75.

number

Default: 75

Sets the percent value for session lifetimes for this service.

number must be an integer value from 1 to 99.

Usage

Use this command to configure the amount of the granted registration lifetime to be used in the refresh interval mobility option in the binding acknowledgement message sent by the LMA service to the requesting MAG.

Refreshing a binding or registration is based on the granted registration lifetime. Since a refresh request must be within the granted range of a registration lifetime, this command provides a method of setting the interval of when a refresh request is sent.

As described in RFC 3775 “Mobility Support in IPv6”, if a binding refresh advice option is present in the binding acknowledgement, the refresh interval field in the option must be a value less than the binding lifetime (also returned in the binding acknowledgement). The mobile node then should attempt to refresh its registration at the shorter refresh interval. The home agent will still honor the registration for the lifetime period, even if the mobile node does not refresh its registration within the refresh period.

Important: Refer to the refresh-advice-option and reg-lifetime commands for a complete understanding of registration (binding) lifetimes and refresh intervals.

Example

The following command sets the refresh interval percent to 90:

```
refresh-interval-percent 90
```

reg-lifetime

Configures the Mobile IPv6 session registration lifetime for this service.

Product

P-GW

Privilege

Administrator

Syntax

```
reg-lifetime seconds
```

```
default reg-lifetime
```

default

Resets the command value to the default setting of 600.

seconds

Default: 600

Sets the time value for session lifetimes for this service.
seconds must be an integer value from 1 to 262140.

Usage

Use this command to limit PMIPv6 lifetime on this service. If the PBU contains a lifetime shorter than what is specified, it is granted. If the lifetime is longer, then HA service will limit the granted lifetime to the configured value.

Important: Refer to the refresh-interval-percent and refresh-advice-option commands for a complete understanding of registration (binding) lifetimes and refresh intervals.

Example

The following command sets the registration lifetime for Mobile IPv6 sessions using this service to 1200 seconds (20 minutes):

```
reg-lifetime 1200
```

revocation

Enables the MIP revocation feature and configures revocation parameters.

Product

P-GW

Privilege

Administrator

Syntax

```
revocation { enable | max-retransmission number | retransmission-timeout msecs }
```

```
default revocation { enable | max-retransmission | retransmission-timeout }
```

```
no revocation enable
```

default

Resets the keyword to its default value.

no

Disables revocation for this service.

enable

Default: disabled

Enables the MIP registration revocation feature for the LMA service. When enabled, if revocation is negotiated with a MAG and a MIP binding is terminated, the LMA can send a Revocation message to the MAG. This feature is disabled by default.

max-retransmission *number*

Default: 3

The maximum number of retransmissions of a Revocation message before the revocation fails. *number* must be an integer value from 0 through 10.

retransmission-timeout *msecs*

Default: 3000

The number of milliseconds to wait for a Revocation Acknowledgement from the MAG before retransmitting the Revocation message. *msecs* must be an integer value from 500 through 10000.

Usage

Use this command to enable or disable the MIP revocation feature on the LMA or to change settings for this feature.

Example

The following command sets the maximum number of retries for a Revocation message to 6:

```
revocation max-retransmission 6
```

The following command sets the timeout between retransmissions to *10*:

```
revocation retransmission-timeout 10
```

sequence-number-validate

Configures sequence number validation of the received MIPv6 control packets by the LMA service according to RFC 3775.

Product

P-GW

Privilege

Administrator

Syntax

```
[ default | no ] sequence-number-validate
```

default

Resets the command value to the default setting of enabled.

no

Disables the feature.

Usage

Use this command to configure the sequence number validation of the received MIPv6 control packets (PBUs) by the LMA service. This feature validates MIPv6 control packets and insures that any incoming packets with a sequence number prior to the last number received is consider invalid. If this service has no cache entry of the home address included in the PBU, it will accept any sequence value in the initial PBU from the mobile node.

setup-timeout

The maximum amount of time allowed for session setup.

Product

P-GW

Privilege

Administrator

Syntax

```
setup-timeout seconds
```

```
default setup-timeout
```

default

Resets the command value to the default setting of 60.

seconds

Default: 60 seconds

The maximum amount of time, in seconds, to allow for setup of a session in this service. *seconds* must be an integer value from 1 through 1000000.

Usage

Use this command to set the maximum amount of time allowed for setting up a session.

Example

The following command sets the maximum time allowed for setting up a session to 5 minutes (300 seconds):

```
setup-timeout 300
```

simul-bindings

Specifies the maximum number of “care-of” addresses that can simultaneously be bound for the same user as identified by NAI and Home address.

Product

P-GW

Privilege

Administrator

Syntax

```
simul-bindings number
```

```
default simul-bindings
```

default

Resets the command value to the default setting of 1.

number

Default: 1

Configures maximum number of “care of” addresses that can be simultaneously bound for the same user as identified by their NAI and home address. *number* must be an integer value between 1 and 3.

Usage

Per RFC 5213 (and 3775), the LMA service creates a binding record known as a binding cache entry (BCE) for each subscriber session it is facilitating. Each BCE is associated with a care-of address. As the mobile node roams, it is possible that the session will be associated with a new care of address.

Typically, the LMA service will delete an old binding and create a new one when the information in the registration request changes. However, the mobile node could request that the LMA maintains previously stored BCEs. This command allows you to configure the maximum number of BCEs that can be stored per subscriber if more than one is requested.

Example

The following command configures the service to support up to 2 addresses per subscriber:

```
simul-bindings 2
```

standalone

Configures the LMA service to start in standalone mode.

Product

P-GW

Privilege

Administrator

Syntax

```
[ default | no ] standalone
```

default

Resets the command value to the default setting.

no

Disables the feature.

Usage

Use this command to start the LMA service in standalone mode.

timestamp-option-validation

Configures validation of timestamp option in binding update messages. By default, timestamp option is mandatory.

Product

P-GW

Privilege

Administrator

Syntax

```
[ default | no ] timestamp-option-validation
```

default

Resets the command value to the default setting of enabled.

no

Disables the feature.

Usage

Use this command to configure timestamp validation in binding update messages.

timestamp-replay-protection

Designates timestamp replay protection scheme as per RFC 4285.

Product

P-GW

Privilege

Administrator

Syntax

```
timestamp-replay-protection tolerance seconds
```

```
[ default | no ] timestamp-replay-protection tolerance
```

default

Resets the command value to the default setting of 7.

no

Disables the timestamp replay protection feature.

seconds

Default: 7

Defines the acceptable difference in timing (between timestamps) before rejecting packet, in seconds.

seconds must be an integer value between 0 and 65535.

Usage

Use this command to define the acceptable difference in timing (between timestamps) before rejecting packet.

Example

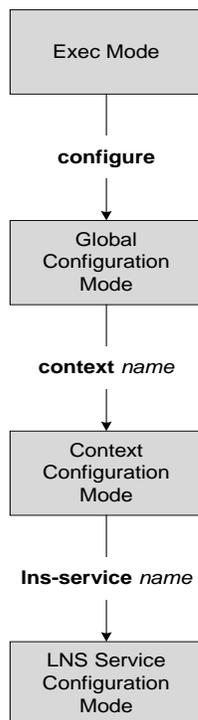

The following command sets the acceptable difference for timestamps to 10 seconds:

```
timestamp-replay-protection tolerance 10
```

Chapter 160

LNS Service Configuration Mode Commands

The LNS Service Configuration Mode is used to create and manage L2TP services within contexts on the system. LNS services facilitate tunneling with peer LACs.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

aaa accounting

Enables the sending of AAA accounting information by the LNS.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] aaa accounting

no

Disables this option.

Usage

Use this command to enable the sending of AAA accounting information by the LNS. By default this is enabled.

Example

The following command enables the sending of AAA accounting information by the LNS:

aaa accounting

authentication

Configures the type of subscriber authentication for PPP sessions terminated at the current LNS.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
authentication { { [ allow-noauth ] [ chap chap_priority ] [ mschap
mschap_priority ] [ pap pap_priority ] } | msid-auth }
```

allow-noauth

Default: Disabled

This option configures the LNS to allow PPP sessions access even though they have not been authenticated.

This command issued by itself causes the LNS to not attempt authentication for any PPP sessions.

When the allow-noauth option is used in conjunction with commands specifying other authentication protocols and priorities to use, then if attempts to use those protocols fail, the system will treat the allow-noauth option as the lowest priority.

If no authentication is allowed, then NAI construct will be implemented in order to provide accounting records for the PPP session.

chap *chap_priority*

Default: 1

This option configures the LNS to attempt to use the Challenge Handshake Authentication Protocol (CHAP) to authenticate the PPP session.

A *chap_priority* must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.

chap_priority must be an integer from 1 through 1000. The lower the integer, the higher the preference. CHAP is enabled by default as the highest preference.

mschap *mschap_priority*

Default: Disabled

This option configures the LNS to attempt to use the Microsoft Challenge Handshake Authentication Protocol (MSCHAP) to authenticate the PP session.

A *mschap_priority* must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.

mschap_priority must be an integer from 1 through 1000. The lower the integer, the higher the preference.

pap *pap_priority*

Default: 2

This option configures the LNS to attempt to use the Password Authentication Protocol (PAP) to authenticate the PPP session.

A *pap_priority* must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.

pap_priority must be an integer from 1 through 1000. The lower the integer, the higher the preference. PAP is enabled by default as the second highest preference.

msid-auth

Default: Disabled

This option configures the LNS to attempt to authenticate the PPP session based on the Mobile Station Identity (MSID).

Usage

Use to specify how the LNS service should handle authentication and what protocols to use. The flexibility is given to configure this option to accommodate the fact that not every mobile will implement the same authentication protocols.

The chassis is shipped from the factory with the LNS authentication options set as follows:

- allow-noauth disabled
- chap enabled with a priority of 1
- mschap disabled
- msid-auth disabled
- pap enabled with a priority of 2

Important: At least one of the keywords must be used to complete the command.

Example

The following command configures the LNS service to allow no authentication for PPP sessions and would perform accounting using the default NAI-construct of username@domain:

```
authentication allow-noauth
```

The following command configures the system to attempt authentication first using CHAP, then MSCHAP, and finally PAP. If the allow-noauth command was also issued, when all attempts to authenticate the subscriber using these protocols failed, then the subscriber would be allowed access:

```
authentication chap 1 mschap 2 pap 3
```

avp map called-number apn

This command maps an incoming AVP to a GGSN APN for authentication and authorization of the call.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
{ default | no } avp map called-number apn
```

default

Disables mapping.

no

Disables mapping.

Usage

For LNS calls received through a LAC, the ICRQ message includes an APN name in the Called Number AVP. This mapping function enables a GGSN system to provide RADIUS authentication/authorization via a defined APN in place of an LNS configuration. If the mapped APN has not been defined within the GGSN configuration then the call will be rejected.

Example

Enter the following command to enable mapping:

```
avp map called-number apn
```

Enter the following command to disable mapping:

```
no avp map called-number apn
```

bind

This command assigns the IP address of an interface in the current context to the LNS service.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
bind ip_address [max-subscribers max_value ]
```

```
no bind ip_address
```

no

Unassign, or unbind, the local end point to the LNS service.

ip_address

The IP address of an interface in the current context. This must be a valid IPv4 address, using dotted-decimal notation.

max-subscribers *max_value*

Default: 10000

The maximum number of subscribers that can be connected to this service at any time. *max_value* must be an integer from 1 through 2500000.

Usage

Use this command to bind the IP address of an interface in the current context to the LNS service.

Example

The following command binds the current context interface IP address 192.168.100.10 to the current LNS service:

```
bind 192.168.100.10
```

The following command removes the binding of the IP address from the LNS service:

```
no bind
```

data sequence-number

Enables data sequence numbering for sessions that use the current LNS service. Data sequence numbering is enabled by default.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] data sequence-number

no

Disables data sequence numbering for sessions.

Usage

An L2TP data packet header has an optional data sequence numbers field. The data sequence number may be used to ensure ordered delivery of data packets. This command is used to re-enable or disable the use of the data sequence numbers for data packets.

Example

Use the following command to disable the use of data sequence numbering:

no data sequence-number

Use the following command to re-enable data sequence numbering:

data sequence-number

default

This command sets the specified LAC service parameter to its default value or setting.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
default { authentication | data sequence-number | ip source-violation |
keepalive-interval | load-balancing | local-receive-window | max-retransmission
| max-session-per-tunnel | max-tunnel-challenge-length | max-tunnels | proxy-
lcp-authentication | retransmission-timeout-first | retransmission-timeout-max |
setup-timeout| single-port-mode | subscriber| trap all tunnel-authentication}
```

authentication

Sets the authentication parameters for PPP sessions to the following defaults:

- allow-noauth disabled
- chap enabled with a priority of 1
- mschap disabled
- msid-auth disabled
- pap enabled with a priority of 2

data sequence-number

Enables data sequence numbering for sessions.

ip source-violation

Sets the IP source violation parameters to the following defaults:

- drop-limit 10
- period 120 seconds
- reneg-limit 5

keepalive-interval

Sets the interval for send L2TP Hello keepalive if there is no control or data transactions to the default value of 60 secs.

local-receive-window

Sets the window size to be used for the local side for the reliable control transport to the default of 4.

max-retransmission

Sets the maximum number of retransmissions to the default of 5.

max-session-per-tunnel

Sets the maximum number of sessions per tunnel at any point in time to the default of 65535.

max-tunnel-challenge-length

Sets the maximum length of the tunnel challenge to the default of 16 bytes.

max-tunnels

Sets the maximum number of tunnels for this service to the default of 32000.

proxy-lcp-authentication

Sets sending of proxy LCP authentication parameters to the LNS to the default state of enabled.

retransmission-timeout-first

Sets the first retransmit interval to the default of 1 second.

retransmission-timeout-max

Sets the maximum retransmit interval to the default of 8 seconds.

setup-timeout

Sets the maximum time allowed for session setup to the default of 60 seconds.

single-port-mode

Disables assignment of only port 1107 for incoming tunnels and allows dynamic assignment of ports.

subscriber

Sets the name of the default subscriber configuration to use.

tunnel-authentication

Sets tunnel authentication to the default state of enabled.

trap all

Generates all supported SNMP traps.

tunnel-switching

Sets the ability of the LNS to create subsequent tunnels to the default of enabled.

Usage

Use the default command to set LAC service parameters to their default states.

Example

Use the following command to set the keep alive interval to the default value of 60 seconds:

```
default keepalive-interval
```

■ default

Use the following command to set the maximum number of sessions per tunnel to the default value of 512:

```
default max-session-per-tunnel
```

ip source-violation

This command configures settings related to IP source-violation detection.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip source-violation { clear-on-valid-packet | drop-limit num | period secs |
reneg-limit num }
```

```
no ip source-violation clear-on-valid-packet
```

clear-on-valid-packet

Default: disabled

Configures the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

drop-limit num

Default: 10

Sets the number of allowed source violations within a detection period before forcing a call disconnect. If *num* is not specified, the value is set to the default. *num* can be any integer value from 1 to 1000000.

period secs

Default: 120

The length of time, in seconds, for a source violation detection period to last. drop-limit and reneg-limit counters are decremented each time this value is reached.

The counters are decremented in this manner: reneg-limit counter is reduced by one (1) each time the period value is reached until the counter is zero (0); drop-limit counter is halved each time the period value is reached until the counter is zero (0). If *secs* is not specified, the value is set to the default.

secs can be any integer value from 1 to 1000000.

reneg-limit num

Default: 5

Sets the number of allowed source violations within a detection period before forcing a PPP renegotiation. If *num* is not specified, the value is set to the default.

num can be any integer value from 1 to 1000000.

Usage

This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two PDSNs a number of times during a handoff scenario.

This function operates in the following manner:

When a subscriber packet is received with a source address violation, the system increments both the IP source-violation renege-limit and drop-limit counters and starts the timer for the IP-source violation period. Every subsequent packet received with a bad source address during the IP-source violation period causes the renege-limit and drop-limit counters to increment.

For example, if renege-limit is set to 5, then the system allows 5 packets with a bad source address (source violations), but on the 5th packet, it re-negotiates PPP.

If the drop-limit is set to 10, the above process of receiving 5 source violations and renegotiating PPP occurs only once. After the second 5 source violations, the call is dropped. The period timer continues to count throughout this process.

If at any time before the call is dropped, the configured source-violation period is exceeded, the counters for drop-limit is decremented by half and renege-limit is decremented by 1. See period definition above.

Example

To set the maximum number of source violations before dropping a call to 100, enter the following command:

```
ip source-violation drop-limit 100
```

keepalive-interval

This command specifies the amount of time to wait before sending a Hello keep alive message.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
keepalive-interval seconds
```

```
no keepalive-interval
```

no

Disables the generation of Hello keep alive messages on the tunnel.

seconds

Default: 60

The number of seconds to wait before sending a Hello keep alive message. The number can be configured to any integer value from 30 to 2147483648.

Usage

Use this command to set the amount of time to wait before sending a Hello keep alive message or disable the generation of Hello keep alive messages completely. A keep alive mechanism is employed by L2TP in order to differentiate tunnel outages from extended periods of no control or data activity on a tunnel. This is accomplished by injecting Hello control messages after a specified period of time has elapsed since the last data or control message was received on a tunnel. As for any other control message, if the Hello message is not reliably delivered then the tunnel is declared down and is reset. The transport reset mechanism along with the injection of Hello messages ensures that a connectivity failure between the LNS and the LAC is detected at both ends of a tunnel.

Example

Use the following command to set the Hello keep alive message interval to 120 seconds:

```
keepalive-interval 120
```

Use the following command to disable the generation of Hello keep alive messages:

```
no keepalive-interval
```

local-receive-window

Specifies the number of control messages the remote peer LAC can send before waiting for an acknowledgement.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
local-receive-window integer
```

integer

Default: 4

The number of control messages to send before waiting for an acknowledgement. The number can be configured to any integer value from 1 through 256.

Usage

Use this command to set the size of the control message receive window being offered to the remote peer LAC. The remote peer LAC may send the specified number of control messages before it must wait for an acknowledgment.

Example

The following command sets the local receive window to 10 control messages:

```
local-receive-window 10
```

max-retransmission

Sets the maximum number of retransmissions of a control message to a peer before the tunnel and all sessions within it are cleared.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-retransmission integer
```

integer

Default: 5

The maximum number of retransmissions of a control message to a peer. This value must be an integer from 1 through 10.

Usage

Each tunnel maintains a queue of control messages to be transmitted to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. If no peer response is detected after the number of retransmissions set by this command, the tunnel and all sessions within are cleared.

Use this command to set the maximum number of retransmissions that the LAC service sends before closing the tunnel and all sessions within. it.

Example

The following command sets the maximum number of retransmissions of a control message to a peer to 7:

```
max-retransmissions 7
```

max-session-per-tunnel

Sets the maximum number of sessions that can be facilitated by a single tunnel at any time.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-sessions-per-tunnel integer
```

integer

Default: 512

The maximum number of sessions. This value must be from 1 through 65535.

Usage

Use this command to set the maximum number of sessions you want to allow in a tunnel.

Example

The following command sets the maximum number of sessions in a tunnel to 5000:

```
max-sessions-per-tunnel 5000
```

max-tunnel-challenge-length

Sets the maximum length of the tunnel challenge in bytes. The challenge is used for tunnel authentication purposes during tunnel creation.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-tunnel-challenge-length bytes
```

bytes

Default: 16

The number of bytes to set the maximum length of the tunnel challenge. This must be a value from 4 through 32.

Usage

Use this command to set the maximum length, in bytes, for the tunnel challenge that is used during tunnel creation.

Example

The following command sets the maximum length of the tunnel challenge to 32 bytes:

```
max-tunnel-challenge-length 32
```

max-tunnels

The maximum number of tunnels that the current LNS service can support.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-tunnels integer
```

integer

Default: 32000

The maximum number of tunnels. This value must be an integer from 1 to 32000.

Usage

Use this command to set the maximum number tunnels that this LNS service can support at any one time.

Example

Use the following command to set the maximum number of tunnels for the current LNS service to *20000*:

```
max-tunnels 20000
```

nai-construction domain

Designates the alias domain name to use for Network Access Identifier (NAI) construction.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
nai-construction domain domain_name { @ | % | - | \ | # | / }
```

```
no nai-construction domain
```

```
no
```

Deletes the NAI construction domain alias.

```
domain_name { @ | % | - | \ | # | / }
```

The desired domain name alias followed immediately by a separator from the valid list. *domain_name* must be a string of from 1 through 79 alphanumeric characters.

Usage

Use this command to specify the domain alias and separator to use for NAI construction. The specified domain name must be followed by a valid separator (@ | % | - | \ | # | /).

Example

To specify a domain alias of mydomain with a separator of @, enter the following command:

```
nai-construction domain mydomain@
```

To delete the current setting for the NAI construction domain alias, enter the following command:

```
no nai-construction domain
```

peer-lac

Adds a peer LAC address for the current LNS service. Up to 8 peer LACs can be configured for each LNS service.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
peer-lac { ip_address / ip_address/mask } [ encrypted ] secret secret [
description text ]
```

```
no peer-lac ip_address
```

```
no peer-lac ip_address
```

Deletes the peer LAC IP address specified by *ip_address*. *ip_address* must be entered in standard IPv4 dotted decimal notation.

```
ip_address
```

The IP address of a specific peer LAC for the current LNS service. *ip_address* must be entered in standard IPv4 dotted decimal notation.

```
ip_address/mask
```

A network prefix and mask enabling communication with a group of peer LACs. *ip_address* is the network prefix expressed in dotted decimal notation. *mask* is the number of bits that defines the prefix.

```
[encrypted]
```

Specifies the encrypted shared key between the LAC and the LNS service.

This keyword is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the secret keyword is the encrypted version of the plain text secret. Only the encrypted secret is saved as part of the configuration file.

```
secret secret
```

Designates the secret which is shared between the current LNS service and the peer LAC. *secret* must be a string from 1 to 127 alpha and/or numeric characters and is case sensitive.

```
description text
```

Specifies the descriptive text to use to describe the specified peer LAC. *text* must be 0 to 79 alpha and/or numeric characters with no spaces or a quoted string of printable characters.

Usage

Use this command to add a peer LAC address for the current LNS service.

Specific peer LACs can be configured by specifying their individual IP addresses. In addition, to simplify configuration, communication with a group of peer LACs can be enabled by specifying a network prefix and a mask.

Example

The following command adds a peer LAC to the current LNS service with the IP address of 10.10.10.100, and specifies the shared secret to be *1b34nnf5d*:

```
peer-lac 10.10.10.100 secret 1b34nnf5d
```

The following command enables communication with up to 16 peer LACs on the 192.168.1.0 network each having a secret of *abc123*:

```
peer-lac 192.168.1.0/28 secret abc123
```

The following command removes the peer LAC with the IP address of 10.10.10.200 for the current LNS service:

```
no peer-lac 10.10.10.200
```

proxy-lcp-authentication

Enables/disables proxy LCP authentication.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] proxy-lcp-authentication

no

Disables the processing of proxy LCP authentication parameters from the LAC.

proxy-lcp-authentication

Default: Enabled

Enables the processing proxy LCP authentication parameters from the LAC.

Usage

When enabled, if proxy LCP authentication parameters are received from the LAC and are acceptable, the LNS resumes the PPP session from the authentication phase and goes to the IPCP phase.

When disabled, PPP is always started from the LCP phase, ignoring and discarding any proxy LCP authentication parameters received from the LAC. Disable this feature in situations where accept proxy LCP Auth AVPs that the peer LAC sends should not be expected.

Example

Use the following command to disable the processing of proxy LCP authentication parameters from the LAC:

```
no proxy-lcp-authentication
```

Use the following command to re-enable the processing of proxy LCP authentication parameters from the LAC:

```
proxy-lcp-authentication
```

retransmission-timeout-first

Configures the initial timeout for the retransmission of control messages to the peer LAC.

Privilege

Security Administrator, Administrator

Syntax

```
retransmission-timeout-first integer
```

integer

Default: 1

The amount of time to wait before sending the first control message retransmission. This value is measured in seconds and must be an integer from 1 to 100.

Usage

Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted.

Example

The following command sets the initial retransmission timeout to 3 seconds:

```
retransmission-timeout-first 3
```

retransmission-timeout-max

Configures the maximum amount of time that can elapse before retransmitting control messages to the peer LAC.

Privilege

Security Administrator, Administrator

Syntax

```
retransmission-timeout-max integer
```

integer

Default: 8

The maximum time to wait before retransmitting control messages. If this limit is reached, the tunnel, and all sessions within it, is cleared. This value is measured in seconds and must be an integer in the range of 1 to 100.

Usage

Each tunnel maintains a queue of control messages to transmit to its peer. After a period of time passes without acknowledgement, a message is retransmitted. Each subsequent retransmission of a message employs an exponential backoff interval. For example; if the first retransmission occurs after 1 second, the next retransmission occurs after 2 seconds has elapsed, then the next after 4 seconds. This continues until the limit set by this command is reached. If this limit is reached, the tunnel, and all sessions within it, is cleared.

Example

Use the following command to set the maximum retransmission time-out to 10 seconds:

```
retransmission-timeout-max 10
```

setup-timeout

Configures the maximum amount of time, in seconds, allowed for session setup.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
setup-timeout seconds
```

seconds

Default: 60

The maximum time to wait, in seconds, for the setup of a session. *seconds* must be an integer from 1 through 1000000.

Usage

This command controls the amount of time allowed for tunnel establishment with a peer LAC. If this timer is exceeded the tunnel setup is aborted.

Example

The following command configures a maximum setup time of 120 seconds:

```
setup-timeout 120
```

single-port-mode

When enabled, this command sets the LNS to use only the default local UDP port (port 1701) for the life of a tunnel.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[no | default] single-port-mode
```

no

Disable single port mode

Usage

Use this command to control the L2TP LNS tunnel local UDP port assignment mode. If `single-port-mode` is enabled, the LNS-service uses the standard UDP port (port 1701) for the life of the incoming tunnel. Otherwise, it assigns a new local UDP port number for a tunnel when it responds to a tunnel create request received on the standard port number. This is done for load distributing the tunnel processing between multiple tasks within the system to increase the capacity and performance. Even though all L2TP LACs are required to support such dynamic port assignments during tunnel establishments, there exist some LACs that do not support port assignment other than port 1701. This `single-port-mode` feature can be enabled to support such LAC peers. This configuration must be applied for the LNS-Service before the `bind` command is executed.

Example

The following command enables single port mode for the current LNS service:

```
single-port-mode
```

trap

This command generates SNMP traps.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[no] trap all
```

no

Disables SNMP traps.

Usage

Use this command to enable/disable all supported SNMP traps.

Example

To enable all supported SNMP traps, enter the following command;

```
trap all
```

tunnel-authentication

Enables/disables L2TP tunnel authentication for the LNS service.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[no] tunnel-authentication
```

no

Disables tunnel authentication
Tunnel authentication is enabled by default.

Usage

When tunnel authentication is enabled, a configured shared secret is used to ensure that the LNS service is communicating with an authorized peer LAC. The shared secret is configured by the **peer-lac** command, the **tunnel l2tp** command in the Subscriber Configuration mode, or the **Tunnel-Password** attribute in the subscribers RADIUS profile.

Example

To disable tunnel authentication, use the following command:

```
no tunnel-authentication
```

To re-enable tunnel authentication, use the following command:

```
tunnel-authentication
```

tunnel-switching

Enables/disables the LNS service from creating tunnels to another LAC for an existing tunnel.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[no] tunnel-switching
```

no

Disable tunnel switching.
Tunnel switching is enabled by default.

Usage

Tunnel switching is when the LNS has a tunnel connected to a LAC and creates a tunnel to a different LAC and routes the data from the original LAC through the new tunnel to the other LAC.

Example

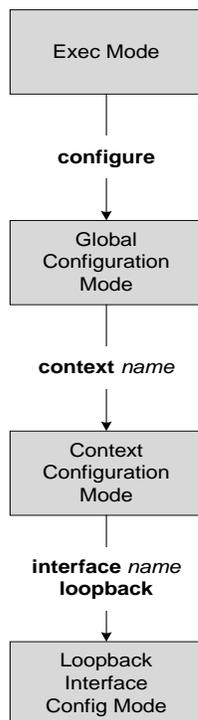

To disable tunnel switching in the LNS, enter the following command;

```
no tunnel-switching
```

Chapter 161

Loopback Interface Configuration Mode Commands

Use the Loopback Interface Configuration mode to create and manage loopback interfaces that provide IP addresses that are always available and reachable from any interface within a given context.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ description

description

Use this command to configure the descriptive text for the current interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

description *text***no description**

no

Clears the description for the interface.

text

Specifies the descriptive text to use. For *text*, enter 0 to 79 alpha and/or numeric characters with no spaces, or a string of printable characters within quotes.

Usage

Set the description to provide any useful information on the interface's primary function, services, end users.

Example

```
description sampleInterfaceDescriptiveText
```

end

Enter this command to exit the interface configuration mode and return to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Enter this command to exit the interface configuration mode and return to the context configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

ip address

Use this command to configure the IP options for the current interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip address { ip_address ip_mask / ip_address/bitmask } [ secondary | srp-activate ]
```

```
no ip address ip_address
```

no

Deletes the IP address you specify from the interface configuration.

```
address {ip_address ip_mask / ip_address/bitmask} [ secondary | srp-activate ]
```

Configures the IP address and network mask for the interface.

Enter an *ip_address ip_mask* to specify an IP address and the subnet mask pair that identifies the IP address of the interface. For *ip_address*, specify with standard IPv4 dotted decimal notation. Currently, the only value accepted for *ip_mask* is 255.255.255.255.

For the network mask, *ip_address/net_mask*, enter the IP address and the length in bits of the network mask in dotted decimal notation and a mask (192.168.1.0/32). Currently, the only value accepted for *bit_mask* is 32.

Use the **secondary** keyword to configure a secondary IP address on the interface. This is referred to as multi-homing of the interface.

Use the **srp-activate** keyword to activate the IP address for Interchassis Session Redundancy.

Usage

Create and manage loopback interfaces for the current context.

Example

The following command configures IP address to associate with the interface:

```
ip address 1.2.3.4 255.255.255.255
```

The following command removes the associated IP address for the interface:

```
no ip address 1.2.3.4
```

ip vrf

Use this command to configure the IP VPN routing/forwarding instance for the current interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip vrf forwarding vrf_nameno vrf forwarding
```

no

Deletes the IP VPN routing/forwarding instance you specify from the interface configuration.

vrf_name

Specifies the preconfigured IP VPN routing/forwarding instance name to be used with this interface. For *vrf_name*, enter a preconfigured VPN routing/forwarding instance name with the **ip vrf forwarding** command in Context Configuration mode.

Usage

Use this command to associate a preconfigured IP VPN routing/forwarding instance for the current interface.

Example

The following command associates a preconfigured IP routing/forwarding instance named *vrf_1* with this interface:

```
ip vrf forwarding vrf_1
```

ipv6 address

Use this command to configure the IPv6 options for the current interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ipv6 address ipv6_address ip_mask [ srp-activate ]
```

```
no ipv6 address ipv6_address
```

no

Deletes the specified IPv6 address from the interface configuration.

```
address ipv6_address ip_mask [ srp-activate ]
```

Configures the IP address and network mask for the interface.

ipv6_address ip_mask specifies an IP address and the subnet mask pair that identifies the IPv6 address of the interface. Specify *ipv6_address* in standard IPv6 dotted decimal notation.

The **srp-activate** keyword activates the IPv6 address for Session Recovery.

Usage

Create and manage loopback interfaces for the current context and enable Session Redundancy Protocol (SRP) when appropriate.

Example

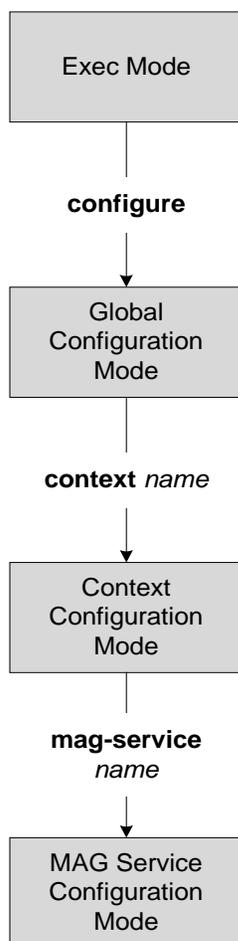

The following command configures an IPv6 address to associate with the interface and enables SRP:

```
ipv6 address 2001:268:2008:b::1021/128 srp-activate
```

Chapter 162

MAG Service Configuration Mode Commands

The MAG Service Configuration Mode is used to create and manage a Mobility Access Gateway service in an HSGW (eHRPD network) or a P-MIP S-GW (LTE-SAE network). The MAG is the PMIP client and communicates with the Local Mobility Anchor (LMA) configured on a PDN Gateway.

bind address

Binds the service to a logical IP interface serving as the S2a (HSGW) or S5/S8 (S-GW) interface and specifies the maximum number of subscribers that can access this service over the configured interface.

Product

HSGW, S-GW

Privilege

Administrator

Syntax

```
bind address ip_address [ max-subscribers num ]
```

```
no bind address
```

no

Removes the interface binding from this service.

ip_address

Specifies the IPv6 address of the interface configured as the S5/S8 interface. *ip_address* is specified in colon separated notation.

max-subscribers *num*

Default: 1500000

Specifies the maximum number of subscribers that can access this service on this interface. *num* must be configured to an integer between 0 and 3000000.

Important: The maximum number of subscribers supported is dependant on the license key installed and the number of active PSCs in the system. A fully loaded system with 13 active PSCs can support 3,000,000 total subscribers. Refer to the license key command and the Usage section (below) for additional information.

Usage

Associate the MAG service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an S2a or S5/S8 interface that provides the session connectivity to/from a PDN gateway. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the **max-subscribers** option, be sure to consider the following:

- The total number of S2a or S5/S8 interfaces you will configure
- The total number of subscriber sessions that all of the configured interfaces may handle during peak busy hours
- An average bandwidth per session multiplied by the total number of sessions
- The type of physical port (10/100Base-T or 1000Base-Tx) that these interfaces will be bound to

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Example

The following command would bind the logical IP interface with the address of `4551:0db8:85a3:08d3:3319:8a2e:0370:1344` to the MAG service and specifies that a maximum of `300,000` simultaneous subscriber sessions can be facilitated by the interface/service at any given time:

```
bind address 4551:0db8:85a3:08d3:3319:8a2e:0370:1344 max-subscribers  
300000
```

encapsulation

Configures data encapsulation type to be used for specific MAG service.

Product

HSGW, S-GW

Privilege

Administrator

Syntax

```
encapsulation { gre | ipip }
```

```
default encapsulation
```

default

Resets the encapsulation type to be used by this service to the default option of GRE.

```
{ gre | ipip }
```

gre: Specifies that GRE encapsulation is to be used for PMIPv6 tunnel data between the MAG and the LMA. This is the default for this command.

ipip: Specifies that IP-in-IP encapsulation is to be used for PMIPv6 tunnel data between the MAG and the LMA.

Usage

Use this command to select the encapsulation type to be used for PMIPv6 tunnel data between the MAG and the LMA.

Example

The following command sets the encapsulation data to IP-in-IP:

```
encapsulation ipip
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

information-element-set

Identifies the information element set of mobility options to be used in Proxy Binding Update (PBU) messages sent by the MAG to the LMA.

Product

HSGW, S-GW

Privilege

Administrator

Syntax

```
information-element-set { custom1 | standard }
```

```
default information-element-set
```

default

Resets the command to the default value of “standard”.

{ custom1 | standard }

custom1: Specifies that a custom set of mobility options to be used in proxy binding update messages that are sent in Vendor Specific Mobility Options. These options are:

- User Location Info
- Hardware Identifier
- Access Network Charging Identifier

standard: Specifies that a standard set of mobility options are to be used in proxy binding update messages. The 3GPP specification, 29.275 defines these as Protocol Configuration Options.

Usage

Use this command to identify the type of information element set of mobility options to be used in PBU messages sent from the MAG to the LMA. The mobility options can be either standards-based (3GPP 29.275) or custom (vendor-specific as defined by 3GPP 29.275).

Example

The following command identifies the information element set of mobility options to use in PBU messages as custom:

```
information-element-set custom1
```

max-retransmissions

Configures maximum number of retransmissions of Proxy MIP control messages to the LMA.

Product

HSGW, S-GW

Privilege

Administrator

Syntax

```
max-retransmissions num
```

```
default max-retransmissions
```

default

Rests the maximum number of allowed retransmissions to the default value of 5.

num

Default: 5

Specifies the maximum number of times the MAG service will attempt to communicate with the LMA before it marks it as unreachable.

count can be configured to any integer value between 1 and 4294967295.

Usage

Use this command to limit the number of retransmissions to LMA before marking it as unreachable. If the value configured is reached, the call is dropped.

Example

The following command configures the maximum number of retransmissions for the MAG service to 3:

```
max-retransmissions 3
```

reg-lifetime

Configures the Mobile IPv6 session registration lifetime for this service.

Product

HSGW, S-GW

Privilege

Administrator

Syntax

```
reg-lifetime seconds
```

```
default reg-lifetime
```

default

Resets the command value to the default setting of 600.

seconds

Default: 600

Sets the time value for session lifetimes for this service.
seconds must be an integer value from 1 to 262140.

Usage

Use this command to limit PMIPv6 lifetime on this service. If the PBA from the LMA contains a lifetime shorter or longer than what is specified, it is used instead.

Example

The following command sets the registration lifetime for Mobile IPv6 sessions using this service to 1200 seconds (20 minutes):

```
reg-lifetime 1200
```

renew-percent-time

Configures percentage of lifetime at which a registration renewal is sent to the LMA.

Product

HSGW, S-GW

Privilege

Administrator

Syntax

```
renew-percent-time percent
```

```
default renew-percent-time
```

default

Resets the command to the default value of 75.

percent

Default: 75

Specifies the time when the registration renewal is sent to the LMA. *percent* is a percentage value of the registration lifetime and must be an integer value from 1 to 100.

Usage

Use this command to specify when a registration renewal is sent to the LMA for subscribers using this service.

If the registration lifetime is 600 seconds (10 minutes) and this command is set to 75 (percent), then the registration renewal message is sent after 450 seconds of the registration lifetime has expired.

Example

The following command sets the registration renewal time for subscribers using this service to 90 percent of the registration lifetime:

```
renew-percent-time 90
```

retransmission-policy

Configures the retransmission policy for Proxy MIP control message retransmissions.

Product

HSGW

Privilege

Administrator

Syntax

```
retransmission-policy { exponential-backoff | normal }  
default retransmission-policy
```

default

Returns the command to its default setting of exponential-backoff.

```
{ exponential-backoff | normal }
```

Sets the retransmission timeout behavior for this service.

exponential-backoff: Specifies that the Proxy Binding Update retransmission uses an exponential backoff to increase the retransmission timeout for each retry.

normal: Specifies that the Proxy Binding Update retransmission uses the configured retransmission timeout value for all PBU retransmission retries.

Usage

Use this command to specify the retransmission policy for PMIP control messages.

Example

The following command sets the retransmission timeout policy for PMIP control packets to “normal”:

```
retransmission-policy normal
```

retransmission-timeout

Configures the maximum allowable time for the MAG service to wait for a response from the LMA before it attempts to communicate with the LMA again (if the system is configured to retry the LMA) or marks the LMA as unreachable.

Product

HSGW, S-GW

Privilege

Administrator

Syntax

```
retransmission-timeout time
```

```
{ default | no } retransmission-timeout
```

default

Resets the timeout setting to the default value of 3.

no

Deletes a previously configured timeout value.

time

Default: 3 seconds (300)

Specifies the maximum allowable time, in milliseconds, for the MAG service to wait for a response from the LMA before it: a) attempts to communicate with the LMA again (if the system is configured to retry the LMA) or b) marks the LMA as unreachable.

time must be an integer value between 100 and 100000.

Usage

Use the retransmission timeout command in conjunction with the **max-retransmissions** command in order to configure the MAG services behavior when it does not receive a response from a particular LMA.

Example

The following command configures a retransmission timeout value of 5 seconds:

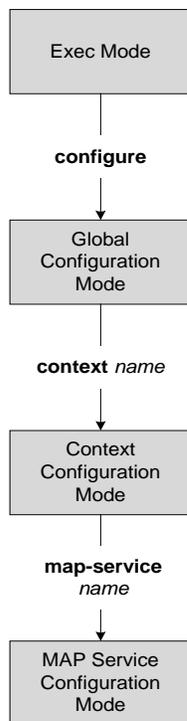

```
retransmission-timeout 5
```

Chapter 163

MAP Service Configuration Mode Commands

The MAP Service Configuration Mode is used to configure properties for Mobile Application Part (MAP) service. Mobile Application Part (MAP) is a protocol which provides an application layer for the various nodes in the core mobile network and GPRS and UMTS core network to communicate with each other in order to provide services to mobile phone users. The MAP service provides the application-layer protocol support used to access the Home Location Register (HLR).

```
[ <context_name> ] hostname ( config-map-service- <svc_name> ) #
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

access-protocol

Configures access protocol parameters for the MAP service as defined for a specific SCCP network instance.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
access-protocol sccp-network sccp_id
```

```
no access-protocol
```

```
sccp-network sccp_id
```

Specifies the ID number of the SCCP network to use for the SGSN connection.
sccp_id : Must be an integer from 1 to 16.

```
no
```

Removes the access protocol SCCP network instance ID from the configuration.

Usage

Use this command to associate access protocol parameters to a specific instance of the MAP service for an SCCP network.

Example

The following command associates the access protocols with the SCCP network ID #10:

```
access-protocol sccp-network 10
```

application-context-name

Configure the operation timer(s) for one or more MAP application contexts.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
application-context-name application operation-timer value
```

```
default application-context-name application operation-timer
```

default

Resets the operation timers for all applications to system defaults.

application

Select one of the following applications to enable the application:

- **authentication-failure-report** : Sets the reporting operation timer for authentication failure. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
- **cancel-location** : Sets the cancel location operation timer. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
- **check-imei** : Sets the check-IMEI operation timer. The setting range for this timer is 15 to 30 seconds for releases 8.0 and 8.1 and 1 to 30 seconds for releases 9.0 and higher. The default setting is 15 seconds.
- **delete-subscriber-data** : Sets the delete subscriber data operation timer. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
- **mo-fwd-sm** : Sets the operation timer for forwarding mobile-originated SMS. The setting range for this timer is 1 to 10 minutes and the default setting is 1 minute (60 seconds).
- **ms-purge** : Sets the operation timer for MS-purge function. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
- **mt-fwd-sm** : Sets the operation timer for forwarding mobile-terminated SMS. The setting range for this timer is 1 to 10 minutes and the default setting is 1 minute (60 seconds).
- **ready-for-sm** : Sets the operation timer for the ready for SMS operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
- **send-authentication-info** : Sets the operation timer for the sending authentication information operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
- **stand-alone-insert-subscriber-data** : Sets the operation timer for the standalone insert subscriber data operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.

■ application-context-name

- **ugl-insert-subscriber-data** : Sets the operation timer for the insert subscriber data portion of the update GPRS location operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.
- **update-gprs-location** : Sets the operation timer for the update GPRS location operation. The setting range for this timer is 15 to 30 seconds and the default setting is 15 seconds.

operation-timer *value*

Configures the operation timer for the selected application. Timer values are indicated above.

Usage

Repeat this command entering a different application each time to enable multiple applications.

Example

```
application-context-name stand-alone-insert-subscriber-data operation-timer operation-timer 20
```

auth-vectors

Configures the number of authorization vectors to be requested from the home location register (HLR) during call setup to provide subscriber authentication.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
auth-vectors number-to-request number
```

```
default auth-vectors number-to-request
```

default

Resets the number of vectors requested from the HLR to the system default.

number-to-request *number*

number: Must be an integer from 1 to 5 to define the number of authorization vectors be requested from the HLR.

Default is 5.

Usage

Set the number of requests to be received from the HLR.

Example

```
auth-vectors number-to-request 4
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

equipment-identity-register

Defines the information relevant to the equipment-identity-register (EIR) used by the SGSN.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
equipment-identity-register { isdn E.164_num | point code pt_code } [ source-ssn ssn | check-imei-every-n-events times ]
```

```
no equipment-identity-register { isdn E.164_num | point code pt_code }
```

no

Deletes the EIR configuration.

isdn *number*

Enter the E.164 number of the EIR.

number: must be a string of 1 to 15 digits.

point code *pt_code*

Enter SS7 point code address of the EIR in dotted-decimal format according to variant settings:

- ITU Range 0.0.1 to 7.255.7
- ANSI Range 0.0.1 to 255.255.255
- TTC Range 0.0.1 to 15.31.255
- or a string of 1 to 11 characters

source-ssn *ssn*

Identifies the subsystem number (SSN) to be used.

ssn must be an integer from 1 to 255.

check-imei-every-n-events *times*

Configures the frequency with which a 'check IMEI' message is sent to the EIR. When set, the SGSN skips sending the 'check IMEI' message for the first N-1 where IMDI/IMEISV is received.

times :

- For releases 8.0 and 8.1, the value must be an integer from 1 to 15.
- For releases 9.0 and higher, the value must be an integer from 1 to 255.

 **Important:** This feature requires the enabling of **verify-equipment-identity** for IMEI or IMEISV as specified with the the **gmm retrieve-equipment-identity imei** command of the SGSN Operator Policy configuration mode.

■ equipment-identity-register

Usage

Configure the identity of the EIR that the SGSN uses and the interaction parameters.

Increasing the **check-imei-every-n-events** frequency enables the EIR to avoid overload as the number of data-only devices attaching to the network increases.

Example

Configure EIR with point code 1.255.1 to perform IMEI check after every 61st received Attach Request message:

```
equipment-identity-register point code 1.255.1 check-imei-every-n-events  
62
```

exit

Exits the current configuration mode and returns to the global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

hlr

This command enters the configuration mode for the home location register (HLR). The HLR is a database containing the subscriber profile information for all mobile stations (MS) / user equipment (UE) connecting to a specific GPRS or UMTS core network.

Important: The commands and options for this mode are documented in the HLR Configuration Mode chapter.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

hlr

policy

This command configures the Transaction Capabilities Application Part (TCAP) -specific MAP policy for either ANSI or ITU SS7 variants.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] policy tcap { use-received-destination-address | use-received-source-address }
```

use-received-destination-address

Selecting this keyword overwrites stored CG and CD addresses with a new address received in first TC CNT msg

use-received-source-address

Selecting this keyword instructs the MAP service to use the received source address for the dialog.

Usage

Use this command to determine how TCAP will handle MAP messages.

Example

```
policy tcap use-received-destination-address
```

short-message-service

This command enables and disables the short message service (SMS service) and provides access to the SMS service configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] short-message-service
```

no

Disables the SMS service.

Usage

Enter the command to access the SMS service configuration mode to fine tune the SMS functionality.

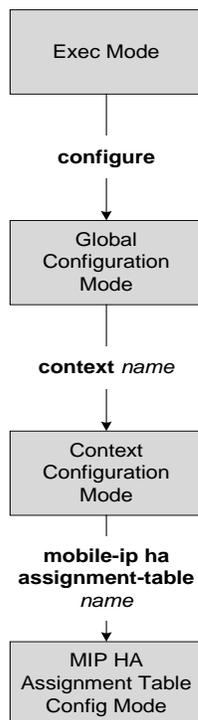

Example

```
short-message-service
```

Chapter 164

MIP HA Assignment Table Configuration Mode Commands

The Mobile IP HA Assignment Table Configuration Mode is used to assign specific HA IP addresses to ranges of Mobile Node IP addresses.

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Returns to the Exec mode.

exit

Exits the current configuration mode and returns to the Context configuration mode.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Return to the Context Configuration mode.

hoa-range

This command assigns ranges of Mobile Node (MN) IP addresses to specific Home agent IP addresses.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
hoa-range ip_address ip_address2 ha ip_address3
```

```
no hoa-range ip_address ip_address2 ha ip_address3
```

no

Remove the specified Home Agent assignment from the assignment table.

```
ip_address ip_address2
```

Specifies a range of MN IP addresses. *ip_address* and *ip_address2* must be specified in either IPv4 dotted decimal notation or IPv6 colon notation.

```
ha ip_address3
```

Specifies the IP address of the Home Agent to assign to MNs that are within the specified range. *ip_address3* must be specified in either IPv4 dotted decimal notation or IPv6 colon notation.

Usage

Use this command to assign ranges of MN IP addresses to specific HAs.

Important: A maximum of 8 MIP HA assignment tables can be configured per context with a maximum of 8 MIP HA assignment tables across all contexts.

Important: A maximum of 256 non-overlapping hoa-ranges can be configured per MIP HA Assignment table with a maximum of 256 non-overlapping hoa-ranges across all MIP HA Assignment tables.

Example

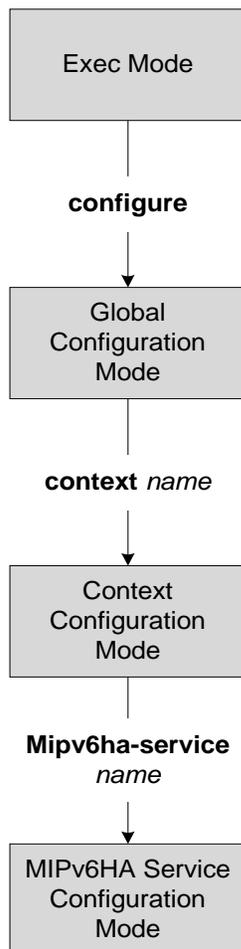

The following command assigns any MN IP address that falls in the range of *192.168.100.0* through *192.168.101.0* to the HA with the IP address of *192.168.200.10*:

```
hoa-range 192.168.100.0 192.168.101.0 ha 192.168.200.10
```

Chapter 165

MIPv6HA Service Configuration Mode Commands

The MIPv6 HA Service Configuration Mode is used to create and manage MIPv6 access privileges.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

aaa accounting

Configures the sending of subscriber session AAA accounting by the HA service.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
aaa accounting
no aaa accounting
```

Usage

Enabling the HA service will send all accounting data (start, stop, and interim) to the configured AAA servers.

The chassis is shipped from the factory with the AAA accounting enabled.

Important: In order for this command to function properly, AAA accounting must be enabled for the context in which the HA service is configured using the `aaa accounting subscriber radius` command.

AAA accounting for the HA service can be disabled using the **no** version of the command.

Example

The following command disables aaa accounting for the HA service:

```
no aaa accounting
```

bind

Designates the address of the MIPv6HA service and specifies the maximum number of subscribers that can access this service over the interface.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
bind address IPv6_address [ max-subscribers count ]
```

```
no bind address
```

address

Specifies the IPv6 address (*address*) of the MIPv6HA service. The IPv6 *address* size is 128 bits. The preferred IPv6 address representation is: *xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx* where each x is a hexadecimal digit representing 4 bits.

max-subscribers *count*

Default: 3000000

Specifies the maximum number of subscribers that can access this service on this interface. *count* can be configured to any integer value between 0 and 4000000.

default

Restore default values assigned for specified parameter.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
default { aaa | refresh-advice-option | refresh-interval-percent | reg-lifetime
| sequence-number-validate | setup-timeout | simul-bindings | subscriber |
timestamp-replay-protection }
```

aaa

Restores the aaa setting configured by the aaa command to its default of enabled.

refresh-advice-option

Restores the refresh-advice-option setting to its default of disabled.

refresh-interval-percent

Restores the refresh-interval-percent setting to its default of 75.

reg-lifetime

Restores the Mobile IP session registration lifetime setting configured by the reg-lifetime command to its default: 600 seconds.

sequence-number-validate

Restores the sequence-number-validate setting to its default of enabled.

setup-timeout

Restore the maximum amount of time allowed for setting up a session to the default: 60 seconds.

simul-bindings

Restores the simultaneous bindings setting to its default: 1.

subscriber

Configures settings for the default subscriber.

timestamp-replay-protection

Restores the timestamp-replay-protection scheme according to RFC 4285.

Usage

After the system has been modified from its default values, this command is used to set/restore specific parameters to their default values.

Example

The following command is used to return the simultaneous bindings setting parameter to its default value:

```
default simul-bindings
```

■ end

end

Exits the HA service configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the HA service configuration mode and returns to the context configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Return to the context configuration mode.

refresh-advice-option

Configures inclusion of refresh advice option in Binding Acknowledgement sent by Home Agent (HA).

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
refresh-advice-option
```

Usage

Includes the refresh advice option in the binding acknowledgements sent by the home agent. Default is disabled.

refresh-interval-percent

Configures percentage of the granted lifetime to be used in the refresh interval mobility option in Binding Acknowledgement sent by Home Agent (HA).

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
refresh-interval-percent value
```

value

value represents a percentage, value should be integer between 1 and 99. Default is 75.

Usage

Use this command to configure the amount of the granted lifetime to be used in the refresh interval mobility option in Binding Acknowledgement sent by Home Agent (HA).

Example

The following command sets the refresh-interval-percent value to 50%:

```
refresh-interval-percent 50
```

reg-lifetime

Specifies the longest registration lifetime that the HA service will allow in any Registration Request message from the mobile node.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
reg-lifetime time
```

no

Sets the registration lifetime to infinite.

time

Specifies the registration lifetime.

time is measured in seconds and can be configured to any integer value between 1 and 262140. Default is 600.

Usage

Use to limit a mobile nodes lifetime. If the mobile node requests a shorter lifetime than what is specified, it is granted. However, Per RFC 2002, should a mobile node request a lifetime that is longer than the maximum allowed by this parameter, the HA service will respond with the value configured by this command as part of the Registration Reply.

The chassis is shipped from the factory with the registration lifetime set to 600 seconds.

Example

The following command configures the registration lifetime for the HA service to be 2400 seconds:

```
reg-lifetime 2400
```

The following command configures an infinite registration lifetime for MIPv6 calls:

```
no reg-lifetime
```

sequence-number-validate

Configures sequence number validation of the received MIPv6 control packet by the Home Agent (HA) according to RFC 3775.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
sequence-number-validate
```

Usage

Use this command to configure the sequence number validation of the received MIPv6 control packet by the Home Agent (HA) as per RFC 3775. Default is enabled.

setup-timeout

The maximum amount of time allowed for session setup.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
setup-timeout seconds
```

seconds

Default: 60 seconds

The maximum amount of time, in seconds, to allow for setup of a session. must be an integer from 1 through 1000000. Default is 60 seconds.

Usage

Use this command to set the maximum amount of time allowed for setting up a session.

Example

To set the maximum time allowed for setting up a session to 5 minutes (300 seconds), enter the following command:

```
setup-timeout 300
```

simul-bindings

Specifies the maximum number of “care-of” addresses that can simultaneously be bound for the same user as identified by NAI and Home address.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
simul-bindings number
```

number

Configures maximum number of "care of" addresses that can be simultaneously bound for the same user as identified by their NAI and home address.

number can be configured to any integer value between 1 and 3. Default is 1.

Usage

The chassis is shipped from the factory with the simultaneous sessions set to 1.

Per RFC 2002, the HA service creates a mobile binding record (MBR) for each subscriber session it is facilitating. Each MBR is associated with a care-of address. As the mobile node roams, it is possible that the session will be associated with a new care of address.

Typically, the HA service will delete an old binding and create a new one when the information in the Registration Request changes. However, the mobile could request that the HA maintains previously stored MBRs. This command allows you to configure the maximum number of MBRs that can be stored per subscriber if the requested.

Example

The following command configures the service to support up to 2 addresses per subscriber:

```
simul-bindings 2
```

timestamp-replay-protection tolerance

Designates timestamp replay protection scheme as per RFC 4285.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
timestamp-replay-protection tolerance
```

seconds

tolerance *seconds*

Defines the acceptable difference in timing (between timestamps) before rejecting packet, in seconds. tolerance must be an integer between 0 and 65535. The default is 7 seconds.

Usage

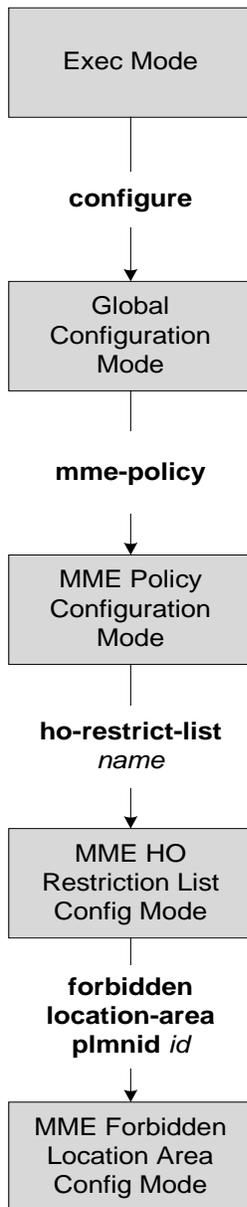

Use this command to define the acceptable difference in timing (between timestamps) before rejecting packet.

Chapter 166

MME Forbidden Location Area Configuration Mode Commands

The MME Forbidden Location Area Configuration Mode is used to create and manage forbidden 3G location area code configurations.

■ timestamp-replay-protection tolerance

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

lac

Configures a 3G location area code or area codes where a UE, associated with this MME policy, is restricted from participating in a handover scenario.

Product

MME

Privilege

Administrator

Syntax[**no**] **lac** { *area_code* } +

no

Removes a configured forbidden handover area code or area codes from this policy. If no location area code is specified, then all location area codes are removed.

area_code

Specifies an area code or area codes from which UEs are restricted from participating in a handover. *area_code* must be an integer value from 0 to 65535. Multiple area codes can be entered (up to 128 in a single line).

Usage

Use this command to configure 3G location-based area codes that will be forbidden to UEs associated with this MME policy.

Example

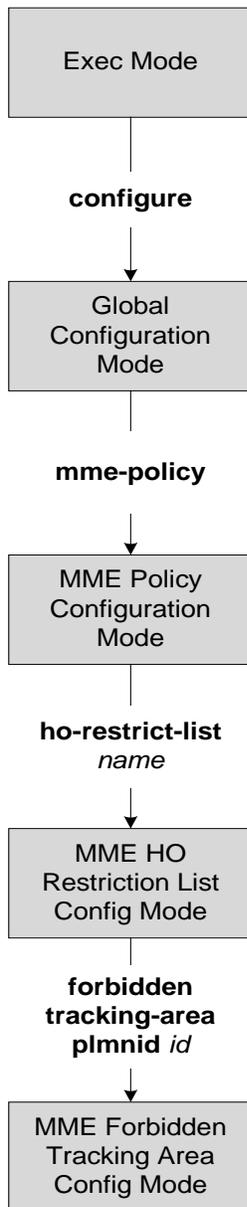

The following command configures eight location-based area codes (1, 2, 3, 4, 5, 6, 7, 8) where a UE, associated with this MME policy, is restricted from participating in a handover scenario:

```
lac 1 2 3 4 5 6 7 8
```

Chapter 167

MME Forbidden Tracking Area Configuration Mode Commands

The MME Forbidden Tracking Area Configuration Mode is used to create and manage forbidden tracking area code configurations.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntaxend

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Syntax

exit

Usage

Return to the previous mode.

tac

Configures a tracking area code or area codes where a UE, associated with this MME policy, is restricted from participating in a handover scenario.

Product

MME

Privilege

Administrator

Syntax [**no**] **tac** *area_code*

no

Removes a configured forbidden handover area code or area codes from this policy. If no tracking area code is specified, then all tracking area codes are removed.

area_code

Specifies a tracking area code or area codes from which UEs are restricted from participating in a handover. *area_code* must be an integer value from 0 to 65535. Multiple area codes can be entered (up to 128 in a single line).

Usage

Use this command to configure tracking area codes that will be forbidden to UEs associated with this MME policy.

Example

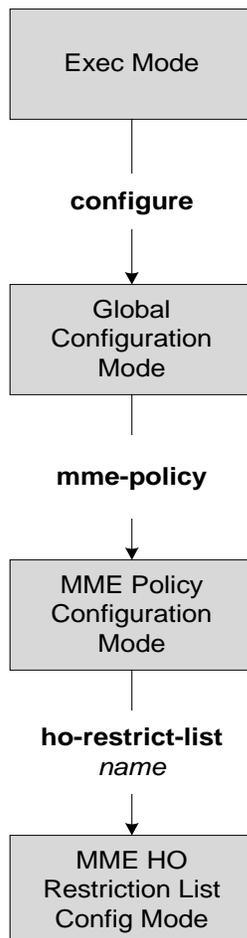

The following command configures two tracking area codes (1, 2, 3, 4, 5, 6, 7, 8) where a UE, associated with this MME policy, is restricted from participating in a handover *scenario*:

```
tac 1 2 3 4 5 6 7 8
```

Chapter 168

MME Handover Restriction List Configuration Mode Commands

The MME Handover Restriction List Configuration Mode is used to create and manage the LTE Mobility Management Entity (MME) handover restriction lists for LTE/SAE networks. Handover restriction lists are used to restrict user equipment (UE) from participating in specified handovers. The MME creates the handover restriction lists as part of its local policy and provides them to the eNodeB where the restrictions are enforced.

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

forbidden

Configures the handover restriction lists provided to eNodeBs where handover restrictions are enforced for UEs.

Product

MME

Privilege

Administrator

Syntax

```
[ no ] forbidden { inter-rat { all | cdma2000 | geran | utran } | location-area
plmnid id | tracking-area plmnid id }
```

default forbidden inter-rat

default forbidden inter-rat

Removes the forbidden inter-rat configuration from the MME policy.

no

Removes the forbidden configuration from the MME policy.

inter-rat { all | cdma2000 | geran | utran }

Specifies that one or all Radio Access Technology (RAT) handovers are to be prohibited for UEs associated with the MME policy.

all: Specifies that all inter-RAT handovers are to be prohibited for UEs associated with the MME policy.

cdma2000: Specifies that all CDMA2000 handovers are to be prohibited for UEs associated with the MME policy.

geran: Specifies that all GSM EDGE Radio Access Network (GERAN) handovers are to be prohibited for UEs associated with the MME policy.

utran: Specifies that all UMTS Terrestrial Radio Access Network (UTRAN) handovers are to be prohibited for UEs associated with the MME policy.

location-area plmnid id

Specifies that handovers to 3G location area codes defined through this keyword and subsequent configuration mode are to be prohibited for UEs associated with the MME policy. Enters the MME Forbidden Location Area Configuration Mode. *id* must be a valid PLMN ID and be an integer value comprising an MCC and MNC (five-digit minimum, six-digit maximum).

Entering this command results in the following prompt:

```
[ context_name ] hostname ( forbidden_la ) #
```

MME Forbidden Location Area Configuration Mode commands are defined in the *MME Forbidden Location Area Configuration Mode Commands* chapter.

tracking-area plmnid id

Specifies that handovers to 4G tracking area codes defined through this keyword and subsequent configuration mode are to be prohibited for UEs associated with the MME policy. Enters the MME

Forbidden Tracking Area Configuration Mode. *id* must be a valid PLMN ID and be an integer value comprising an MCC and MNC (five-digit minimum, six-digit maximum).

Entering this command results in the following prompt:

```
[context_name]hostname(forbidden_ta)#
```

MME Forbidden Tracking Area Configuration Mode commands are defined in the *MME Forbidden Tracking Area Configuration Mode Commands* chapter.

Usage

Use this command to create the list of restricted handover types that apply to all UEs associated with the MME policy.

Example

The following command prohibits UEs associated with this MME policy from participating in a handover to a GERAN network type:

```
forbidden inter-rat geran
```

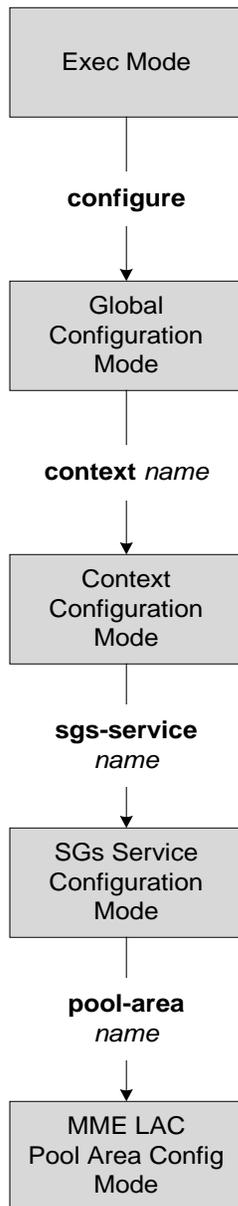

The following command prohibits UEs, associated with this MME policy and a mobile network with a PLMN ID of *12345*, from participating in a handover to location area codes defined in the Location Area Configuration Mode:

```
forbidden location-area plmnid 12345
```

Chapter 169

MME LAC Pool Area Configuration Mode Commands

The MME LAC Pool Area Configuration Mode is used to create and manage the Local Area Code (LAC) pool areas.

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

hash-value

Configures the Visitor Location Register hash value mapping for this pool area.

Product

MME

Privilege

Administrator

Syntax

```
hash-value { value | non-configured-values | range value to value } use-vlr
vlr_name
```

```
no hash-value { value | non-configured-values | range value to value }
```

no

Removes the configured hash-value from the pool-area configuration.

value

Specifies the VLR hash value to be used with the configured VLR. *value* must be an integer from 0 to 999.

non-configured-values

Specifies that the VLR configured in this command is to be used non-configured hash values.

range *value* **to** *value* *vlr_name*

Specifies a range of hash values to use with the configured VLR. *value* must be an integer from 0 to 999.

use-vlr

Specifies the VLR to be used with the hash value configuration in this command.

Usage

Use this command to configure hash values to be used with VLRs.

Example

The following command configures all hash values within a range of 0 to 500 to use a VLR named *vlr1*:

```
hash-value range 0 to 500 use-vlr vlr1
```

The following command configures hash values of 501 to use a VLR named *vlr2*:

```
hash-value 501 use-vlr vlr2
```

The following command configures all non-configured hash values to use a VLR named *vlr3*:

```
hash-value non-configured-values use-vlr vlr3
```

lac

Configures a 3G location area code or area codes that define this pool area.

Product

MME

Privilege

Administrator

Syntax[**no**] **lac** { *area_code* } +

no

Removes a configured forbidden handover area code or area codes from this policy. If no location area code is specified, then all location area codes are removed.

area_code

Specifies an area code or area codes from which UEs are restricted from participating in a handover.

area_code must be an integer value from 0 to 65535. Multiple area codes can be entered (up to 128 in a single line).

Usage

Use this command to configure 3G location-based area codes that define this pool area.

Example

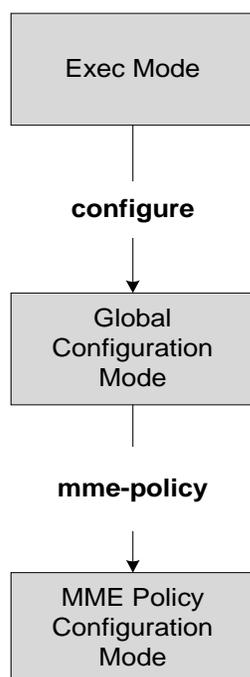

The following command configures eight location-based area codes (1, 2, 3, 4, 5, 6, 7, 8) that define this pool area:

```
lac 1 2 3 4 5 6 7 8
```

Chapter 170

MME Policy Configuration Mode Commands

The MME Policy Configuration Mode is used to create and manage the LTE Mobility Management Entity (MME) policies for LTE/SAE networks.

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

ho-restrict-list

Creates a handover (HO) restriction list or specifies an existing HO restriction list and enters the Handover Restriction List Configuration Mode.

Product

MME

Privilege

Administrator

Syntax

```
[ no ] ho-restrict-list list_name[ -noconfirm ]
```

no

Removes the specified restriction list from the system.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

list_name

Specifies the name of the HO restriction list. If *list_name* does not refer to an existing list, a new list is created. *list_name* must be from 1 to 64 alpha and/or numeric characters.

Usage

Use this command to enter the Handover Restriction List Configuration Mode for an existing list or for a newly defined list. This command is also used to remove an existing list. Entering this command results in the following prompt:

```
[ context_name ]hostname(ho-restrict-list)#
```

Handover Restriction List Configuration Mode commands are defined in the *MME Handover Restriction List Configuration Mode Commands* chapter.

Example

The following command enters the Handover Restriction List Configuration Mode for a new or existing list named *ho_restricit_list1*:

```
ho-restrict-list ho_restrict_list1
```

subscriber-map

Creates a subscriber map or specifies an existing subscriber map and enters the Subscriber Map Configuration Mode.

Product

MME

Privilege

Administrator

Syntax

```
[ no ] subscriber-map map_name [ -noconfirm ]
```

no

Removes the specified subscriber map from the system.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

map_name

Specifies the name of the subscriber map. If *map_name* does not refer to an existing map, a new map is created. *map_name* must be from 1 to 64 alpha and/or numeric characters.

Usage

Enter the Subscriber Map Configuration Mode for an existing or newly defined map. This command is also used to remove an existing map.

Entering this command results in the following prompt:

```
[ context_name ] hostname (subscriber-map) #
```

Subscriber Map Configuration Mode commands are defined in the *Subscriber Map Configuration Mode Commands* chapter.

Example

The following command enters the existing Subscriber Map Configuration Mode (or creates it if it doesn't already exist) for the map named *map1*:

```
subscriber-map map1
```

tai-mgmt-db

Creates a Tracking Area Identifier (TAI) Management Database or specifies an existing database and enters the TAI Management Database Configuration Mode.

Product

MME

Privilege

Administrator

Syntax

```
[ no ] tai-mgmt-db db_name[ -noconfirm ]
```

no

Removes the specified management database from the system.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

db_name

Specifies the name of the management database. If *db_name* does not refer to an existing database, a new database is created. *db_name* must be from 1 to 64 alpha and/or numeric characters.

Usage

Enter the TAI Management Database Configuration Mode for an existing or newly defined database. This command is also used to remove an existing database.

Entering this command results in the following prompt:

```
[ context_name ]hostname (tai-mgmt-db) #
```

TAI Management Database Configuration Mode commands are defined in the *TAI Management Database Configuration Mode Commands* chapter.

Example

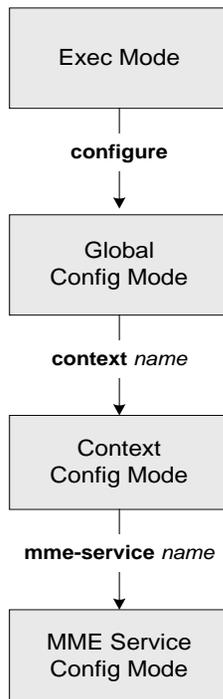

The following command enters the existing TAI Management Database configuration mode (or creates it if it doesn't already exist) for the database named *tai_db1*:

```
tai-mgmt-db tai_db1
```

Chapter 171

MME Service Configuration Mode Commands

The MME Service Configuration Mode is used to create and manage the LTE Mobility Management Entity (MME) services for the LTE/SAE network. This service works in conjunction with MME-HSS Service and eGTP Service.

associate

This command associates/disassociates the supportive services and policies like an Evolved GPRS Tunnelling Protocol (eGTP) service, an MME-HSS service, or an MME policy subscriber map with an MME service.

Product

MME

Privilege

Administrator

Syntax

```
associate { { egtp-service egtp_svc_name | hss-peer-service hss_svc_name | sgs-
service sgs_svc_name | sgtpc-service sgtpc_svc_name } [ context ctx_name ] |
subscriber-map map_name | tai-mgmt-db database_name }
```

```
no associate { egtp-service | hss-peer-service | sgs-service | sgtpc-service |
subscriber-map | tai-mgmt-db }
```

no

Disassociates a previously associated service with this MME service.

egtp-service egtp_svc_name

Associates an eGTP service with MME service.

egtp_svc_name specifies the name for a pre-configured eGTP service in a context to associate with this MME service. For more information on eGTP service, refer egtp-service command in Context Configuration Mode Commands chapter.

hss-peer-service hss_svc_name

Associates an HSS peer service with this MME service.

hss_svc_name specifies the name for a pre-configured HSS peer service in a context to associate with this MME service and must be from 1 to 64 alpha and/or numeric characters. For more information on the HSS peer service, refer to the **hss-peer-service** command in the *Context Configuration Mode Commands* chapter and refer to the *HSS Peer Service Configuration Mode Commands* chapter.

sgs-service sgs_svc_name

Associates an SGs service with this MME service.

sgs_svc_name specifies the name for a pre-configured SGs service in a context to associate with this MME service and must be from 1 to 64 alpha and/or numeric characters. For more information on the SGs service, refer to the **sgs-service** command in the *Context Configuration Mode Commands* chapter and refer to the *MME SGs Service Configuration Mode Commands* chapter.

sgtpc-service sgtpc_svc_name

Associates an SGTPC service with this MME service.

sgtpc_svc_name specifies the name for a pre-configured SGTPC service in a context to associate with this MME service and must be from 1 to 64 alpha and/or numeric characters. For more information on the SGTPC service, refer to the **sgtpc-service** command in the *Context Configuration Mode Commands* chapter and/or refer to the *SGTPC Service Configuration Mode Commands* chapter.

context *ctx_name*

Identifies a specific context name where eGTP or HSS peer service is configured. If this keyword is omitted, the named eGTP or HSS peer service must exist in the same context as the MME service.

ctx_name is name of the configured context of the eGTP or HSS peer service. This can be from 1 to 63 alpha and/or numeric characters and is case sensitive.

subscriber-map *map_name*

Associates this MME service with a pre-configured subscriber map.

map_name specifies the name of a pre-configured subscriber map to associate with this MME service and must be from 1 to 64 alpha and/or numeric characters. For more information on subscriber maps, refer to the **subscriber-map** command in the *MME Policy Configuration Mode Commands* chapter and refer to the *MME Subscriber Map Configuration Mode Commands* chapter.

tai-mgmt-db *database_name*

Associates this MME service with a pre-configured TAI Management Database.

database_name specifies the name of a pre-configured TAI Management Database to associate with this MME service and must be from 1 to 64 alpha and/or numeric characters. For more information on subscriber maps, refer to the **tai-mgmt-db** command in the *MME Policy Configuration Mode Commands* chapter and refer to the *MME TAI Management Database Configuration Mode Commands* chapter.

Usage

Use this command to associate a pre-configured service or policy with an MME service.

The eGTP service provides eGTP-U and eGTP-C protocol interface support between EPS nodes. For more information on eGTP service and supported interface type, refer eGTP Service Configuration Mode Commands chapter in Command Line Interface Reference.

Important: Only one eGTP service can be associated to a service. The eGTP service should be configured prior to issuing this command.

The HSS peer service provides S6a interface support via the Diameter protocol between the MME and HSS. For more information on HSS peer service and other parameters, refer to the *HSS Peer Service Configuration Mode Commands* chapter.

Important: Only one HSS peer service can be associated to a service in this release. The eGTP service should be configured prior to issuing this command.

Caution: This is a critical configuration. The MME service can not be started without this configuration. Any change to this configuration would lead to restarting the MME service and removing or disabling this configuration will stop the MME service.

Example

The following command associates a pre-configured eGTP service called *egtp1* in *dst_ctx* context to an MME service:

```
associate egtp-service egtp1 context dst_ctx
```

■ **associate**

The following command associates a pre-configured HSS peer service called *hss1* in the same context as MME service to an MME service:

```
associate hss-peer-service hss1
```

bind s1-mme

This command binds the MME service to a logical IP interface serving as the S1-MME interface.

Product

MME

Privilege

Administrator

Syntax

```
bind s1-mme { ipv4-address address [ ipv4-address secondary_address ] | ipv6-
address address [ ipv6-address secondary_address ] } [ max-subscribers number ]
```

```
no bind s1-mme
```

no

Removes a previously configured IP address used for binding the SCTP (local bind address) to communicate with the eNodeBs using an S1-MME interface.

```
{ ipv4-address address [ ipv4-address secondary_address ] | ipv6-address
address [ ipv6-address secondary_address ] }
```

Specifies the IP address in IPv4 or IPv6 notation for the interface configured as an S1-MME interface. For IPv4, address must be specified in dotted decimal notation. For IPv6, address must be specified in colon separated notation. Optionally configure a secondary IP address for either address type.

max-subscribers *number*

Specifies the maximum number of subscribers that can access this service on this interface. *number* must be an integer from 0 and 4,000,000.

Usage

Use this command to associate or tie the MME service to a specific logical IP address that will be used for binding the SCTP socket to communicate with the eNodeB using S1AP. A maximum of one IP address can be configured with this command for one MME service.

The MME passes the IP address during setting up the SCTP association with the eNodeB.

 **Caution:** This is a critical configuration. The MME service can not be started without this configuration. Any change to this configuration would lead to restarting the MME service and removing or disabling this configuration will stop the MME service.

Example

The following command would bind the logical IP interface with the address of `192.168.3.1` to the MME service to interact with eNodeB:

```
bind s1-mme ipv4-address 192.168.3.1
```

■ bind s1-mme

The following command disables a binding that was previously configured:

```
no bind s1-mme ipv4address
```

dns

This command associates/disassociates the Domain Name System (DNS) client service configured for DNS query in a context to select P-GW and S-GW in an MME service.

Product

MME

Privilege

Administrator

Syntax

```
dns { peer-mme | pgw | sgw } [ context ctx_name ]
```

```
no dns { peer-mme | pgw | sgw }
```

no

Disassociates a previously associated context having DNS client service configured for DNS query to select peer MME, P-GW or S-GW with this MME service.

peer-mme

This keyword associates the named context with a DNS client service for a DNS query for selection of a peer MME with this MME service.

pgw

This keyword associates the named context with a DNS client service for DNS query for selection of a P-GW with this MME service.

sgw

This keyword associates the named context with a DNS client service for DNS query for selection of an S-GW with this MME service.

context *ctx_name*

This optional keyword associates the specific context name where DNS client service is configured to select a peer MME, a P-GW and/or an S-GW for this MME service. If this keyword is omitted DNS client service must be configured in the same context as this MME service.

ctx_name is name of the configured context of the DNS client service. This can be from 1 to 63 alpha and/or numeric characters and is case sensitive.

Usage

Use this command to associate a pre-configured context where a DNS client service is configured with an MME service.

The DNS Client service configured in a context provides the DNS query support to locate peer MMEs, P-GWs, or S-GWs from an MME service. For more information on DNS Client service and support, refer to the *DNS Client Service Configuration Mode Commands* chapter in the *Command Line Interface Reference*.

A maximum of one DNS client service for a peer MME, one DNS client service for a P-GW, and one DNS client service for S-GW can be associated with an MME service.

Example

The following command associates a pre-configured context *dns_ctx1* where a DNS client service is configured for DNS query to P-GW from an MME service:

```
dns pgw context dns_ctx1
```

The following command associates a pre-configured context *dns_ctx2* where a DNS client service is configured for DNS query to S-GW from an MME service:

```
dns sgw context dns_ctx2
```

emm

This command defines the Evolved Mobility Management timer parameters like timeout durations for timers for the NAS message retransmission in MME service.

Product

MME

Privilege

Administrator

Syntax

```
default emm { mobile-reachable-timeout | t3412-timeout | t3413-timeout | t3422-  
timeout | t3423-timeout | t3450-timeout | t3460-timeout | t3470-timeout }
```

```
no emm implicit-detach-timeout
```

default

Resets the specified timer timeout to the system default value.

no

Removes the specified EMM timeout definition from the configuration.

implicit-detach-timeout *detach_dur*

Default: 5640

Sets the timer timeout duration after which subscriber will implicitly detached from the network if there is no activity. Generally this timer value is 240 seconds (4 minutes) more than the timeout value of T3423 timer. This timer starts when mobile reachable timer expires while the network is in EMM-IDLE mode and ISR is activated and stops when NAS signalling connection established.

detach_dur is timeout duration in seconds and must be an integer from 1 through 12000.

mobile-reachable-timeout *mob_reach_dur*

Default: 5640

Sets the timeout timer duration after which reachability procedure will be discarded and reattempt starts.

mob_reach_dur is timeout duration in seconds and must be an integer from 1 through 12000.

t3412-timeout *t3412_dur*

Default: 5400

Sets the timeout duration for T3412 timer. This timer is used for periodic tracking area update (P-TAU).

When this timer expires, the periodic tracking area updating procedure starts and the timer is set to its initial value for the next start.

This timer starts when the UE goes from EMM-CONNECTED to EMM-IDLE mode and stops when the UE enters EMM-CONNECTED mode.

t3412_dur is timeout duration in seconds and must be an integer from 1 through 11160.

t3413-timeout *t3413_dur*

Default: 10

Sets the timeout duration for T3413 timer. The timer starts when MME initiates the EPS paging procedure to the EMM entity in the network and requests the lower layer to start paging. This timer stops for the paging procedure when a response received from the UE.

t3413_dur is timeout duration in seconds and must be an integer from 1 through 20.

t3422-timeout *t3422_dur*

Default: 10

Sets the timeout duration for T3422 timer. This timer starts when MME initiates the detach procedure by sending a DETACH REQUEST message to the UE and stops upon receipt of the DETACH ACCEPT message.

t3422_dur is timeout duration in seconds and must be an integer from 1 through 20.

t3423-timeout *t3423_dur*

Default: 5400

Sets the timeout duration for T3423 timer. This timer starts when UE enters the EMM-DEREGISTERED state or when entering EMM-CONNECTED mode. It stops while the UE is in EMM-REGISTERED.NO-CELL-AVAILABLE state and Idle mode Signalling Reduction (ISR) is activated.

t3423_dur is timeout duration in seconds and must be an integer from 1 through 11160.

t3450-timeout *t3450_dur*

Default: 6

Sets the timeout duration for T3450 timer. This timer starts when MME initiates the Globally Unique Temporary Identifier (GUTI) reallocation procedure by sending a GUTI REALLOCATION COMMAND message to the UE and stops upon receipt of the GUTI REALLOCATION COMPLETE message. This timer is also used for Tracking area update procedure.

t3450_dur is timeout duration in seconds and must be an integer from 1 through 20.

t3460-timeout *t3460_dur*

Default: 6

Sets the timeout duration for T3460 timer. The timer starts when the network initiates the authentication procedure by sending an AUTHENTICATION REQUEST message to the UE and stops upon receipt of the AUTHENTICATION RESPONSE message.

t3460_dur is timeout duration in seconds and must be an integer from 1 through 20.

t3470-timeout *t3470_dur*

Default: 6

Sets the timeout duration for T3470 timer. The MME starts this timer when the network initiates the identification procedure by sending an IDENTITY REQUEST message to the UE and stops upon receipt of the IDENTITY RESPONSE message.

t3470_dur is timeout duration in seconds and must be an integer from 1 through 20.

Usage

Use this command to set EMM timers.

The following tables describe the triggers and states for timers:

Table 28. EPS mobility management timers – UE side

Timer	State	Cause of Start	Normal Stop	On Expiry
T3402	<ul style="list-style-type: none"> • EMM-DEREGISTERED • EMM-REGISTERED 	<ul style="list-style-type: none"> • At attach failure and the attempt counter is equal to 5. • At tracking area updating failure and the attempt counter is equal to 5. 	<ul style="list-style-type: none"> • ATTACH REQUEST sent • TRACKING AREA UPDATE REQUEST sent 	Initiation of the attach procedure or TAU procedure

T3442	EMM-REGISTERED	SERVICE REJECT received with EMM cause #39	TRACKING AREA UPDATE REQUEST sent	None

NOTE 1: The default value of this timer is used if the network does not indicate another value in an EMM signalling procedure.

NOTE 2: The value of this timer is provided by the network operator during the attach and tracking area updating procedures.

NOTE 3: The value of this timer may be provided by the network in the ATTACH ACCEPT message and TRACKING AREA UPDATE ACCEPT message. The default value of this timer is identical to the value of T3412.

NOTE 4: The value of this timer is provided by the network operator when a service request for CS fallback is rejected by the network with EMM cause #39 "CS domain temporarily not available".

Table 29. EPS mobility management timers – network side

Timer	State	Cause of Start	Normal Stop	On Expiry 1st, 2nd, 3rd, 4th EXPIRY (NOTE 1)
T3413	EMM-REGISTERED	Paging procedure initiated	Paging procedure completed	Network dependent
T3422	EMM-DEREGISTERED-INITIATED	DETACH REQUEST sent	DETACH ACCEPT received	Retransmission of DETACH REQUEST
T3450	EMM-COMMON-PROC-INIT	<ul style="list-style-type: none"> ATTACH ACCEPT sent TRACKING AREA UPDATE ACCEPT sent with GUTI GUTI REALLOCATION COMMAND sent 	<ul style="list-style-type: none"> ATTACH COMPLETE received TRACKING AREA UPDATE COMPLETE received GUTI REALLOCATION COMPLETE received 	Retransmission of the same message type, i.e. ATTACH ACCEPT, TRACKING AREA UPDATE ACCEPT or GUTI REALLOCATION COMMAND
T3460	EMM-COMMON-PROC-INIT	<ul style="list-style-type: none"> AUTHENTICATION REQUEST sent SECURITY MODE COMMAND sent 	<ul style="list-style-type: none"> AUTHENTICATION RESPONSE received AUTHENTICATION FAILURE received SECURITY MODE COMPLETE received SECURITY MODE REJECT received 	Retransmission of the same message type, i.e. AUTHENTICATION REQUEST or SECURITY MODE COMMAND
T3470	EMM-COMMON-PROC-INIT	IDENTITY REQUEST sent	IDENTITY RESPONSE received	Retransmission of IDENTITY REQUEST
Mobile reachable timer	All except EMM-DEREGISTERED	Entering EMM-IDLE mode	NAS signalling connection established	Network dependent, but typically paging is halted on 1st expiry
Implicit detach timer	All except EMM-DEREGISTERED	The mobile reachable timer expires while the network is in EMM-IDLE mode and ISR is activated	NAS signalling connection established	Implicitly detach the UE on 1st expiry
NOTE 1: Typically, the procedures are aborted on the fifth expiry of the relevant timer. Exceptions are described in the corresponding procedure description.				
NOTE 2: The value of this timer is network dependent.				

Table 30. EPS session management timers – UE side

Timer	State	Cause of Start	Normal Stop	On Expiry 1st, 2nd, 3rd, 4th EXPIRY (NOTE 1)
T3480	PROCEDURE TRANSACTION PENDING	BEARER RESOURCE ALLOCATION REQUEST sent	ACTIVATE DEDICATED EPS BEARER CONTEXT REQUEST received or MODIFY EPS BEARER CONTEXT REQUEST received or BEARER RESOURCE ALLOCATION REJECT received	Retransmission of BEARER RESOURCE ALLOCATION REQUEST
T3481	PROCEDURE TRANSACTION PENDING	BEARER RESOURCE MODIFICATION REQUEST sent	ACTIVATE DEDICATED EPS BEARER CONTEXT REQUEST received or MODIFY EPS BEARER CONTEXT REQUEST received or DEACTIVATE EPS BEARER CONTEXT REQUEST received or BEARER RESOURCE MODIFICATION REJECT received	Retransmission of BEARER RESOURCE MODIFICATION REQUEST
T3482	PROCEDURE TRANSACTION PENDING	An additional PDN connection is requested by the UE which is not combined in attach procedure	ACTIVE DEFAULT EPS BEARER CONTEXT REQUEST received or PDN CONNECTIVITY REJECT received	Retransmission of PDN CONNECTIVITY REQUEST
T3492	PROCEDURE TRANSACTION PENDING	PDN DISCONNECT REQUEST sent	DEACTIVATE EPS BEARER CONTEXT REQUEST received or PDN DISCONNECT REJECT received	Retransmission of PDN DISCONNECT REQUEST
NOTE 1: Typically, the procedures are aborted on the fifth expiry of the relevant timer. Exceptions are described in the corresponding procedure description.				

This command can be repeated to set each timer as needed.
The retransmission of all type of NAS messages can be configured through **nas-max-retransmissions** command.

Example

The following command sets the timeout value for EPS paging procedure timer T3413 for 10 seconds.

```
emm t3413-timeout 10
```

encryption-algorithm-lte

This command configures the precedence for LTE encryption algorithms to use for security procedures through this MME service.

Product

MME

Privilege

Administrator

Syntax

```
encryption-algorithm-lte priority1 { 128-eea0 | 128-eea1 | 128-eea2 } [
priority2 { 128-eea0 | 128-eea1 | 128-eea2 } ] [ priority3 { 128-eea0 |
128-eea1 | 128-eea2 } ]
default encryption-algorithm-lte
```

default

Sets the default LTE encryption algorithm for security procedures with configured priority *value*. Default configuration of LTE encryption algorithm is:

- priority1 with 128-eea0 encryption algorithm
- priority2 with 128-eea1 encryption algorithm
- priority3 with 128-eea2 encryption algorithm

priority1

Specifies the preference of integrity algorithm for security procedures on this MME service as priority 1. Least value has highest preference.

priority2

Specifies the preference of integrity algorithm for security procedures on this MME service as priority 2. Least value has highest preference.

priority3

Specifies the preference of integrity algorithm for security procedures on this MME service as priority 3. Least value has highest preference.

128-eea0

Default: Enabled

This keyword sets the Null ciphering algorithm (128-EEA0) for LTE encryption as the encryption algorithm for security procedures.

128-eea1

Default: Disabled

This keyword sets the SNOW 3G synchronous stream ciphering algorithm (128-EEA1) for LTE encryption as the encryption algorithm for security procedures. SNOW 3G is a stream cipher that forms the base of the 3GPP confidentiality algorithm UEA2 and the 3GPP integrity algorithm UIA2.

128-eea2

Default: Disabled

This keyword sets the Advance Encryption Standard (AES) ciphering algorithm (128-EEA2) for LTE encryption as the encryption algorithm for security procedures.

Usage

Use this command to set the LTE encryption algorithms for security procedures to use with this MME service.

Caution: When this command is executed, all the existing priority to algorithm mappings will be removed and the newly configured ones will be applicable for security procedures.

Caution: Configuration of same algorithm to multiple priorities is prohibited.

Example

The following command sets the 128-EEA1 as the LTE encryption algorithm with priority 2 for security procedures with an MME service:

```
encryption-algorithm-lte priority2 128-eea1
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

esm

This command defines the Evolved Session Management timer parameters like timeout durations for timers for the retransmission of NAS messages in MME service.

Product

MME

Privilege

Administrator

Syntax

```
default esm { t3485-timeout | t3486-timeout | t3489-timeout | t3495-timeout }
```

default

Resets the specified Evolved Session Management timer timeout to the system default value.

t3485-timeout *t3485_dur*

Default: 6

Sets the timeout duration for T3485 timer. This timer is used for default EPS bearer context activation procedure.

This timer starts when the MME sends ACTIVATE DEFAULT EPS BEARER CONTEXT REQUEST message to UE and stops when receives ACTIVATE DEFAULT EPS BEARER CONTEXT ACCEPT or ACTIVATE DEFAULT EPS BEARER CONTEXT REJECT message from UE.

t3485_dur is timeout duration in seconds and must be an integer from 1 through 60.

t3486-timeout *t3486_dur*

Default: 6

Sets the timeout duration for T3486 timer. This timer is used for the default EPS bearer context modification procedure.

This timer starts when the MME sends a MODIFY EPS BEARER CONTEXT REQUEST message to the UE and stops whenit receives a MODIFY EPS BEARER CONTEXT ACCEPT received or a MODIFY EPS BEARER CONTEXT REJECT message from UE.

t3485_dur is timeout duration in seconds and must be an integer from 1 through 60.

t3489-timeout *t3489_dur*

Default: 4

Sets the timeout duration for T3489 timer. This timer is used for the default EPS bearer context deactivation procedure.

This timer starts when the MME sends an ESM INFORMATION REQUEST message to the UE and stops when receives a ESM INFORMATION RESPONSE message from the UE.

t3495_dur is timeout duration in seconds and must be an integer from 1 through 60.

t3495-timeout *t3495_dur*

Default: 6

Sets the timeout duration for T3495 timer. This timer is used for default EPS bearer context deactivation procedure.

This timer starts when the MME sends a DEACTIVATE EPS BEARER CONTEXT REQUEST message to UE and stops when receives DEACTIVATE EPS BEARER CONTEXT ACCEPT or DEACTIVATE EPS BEARER CONTEXT REJECT message from UE.

t3495_dur is timeout duration in seconds and must be an integer from 1 through 60.

Usage

Use this command to set Evolved Session Management timers.
Following tables describe the triggers and states for timers:

Table 31. EPS session management timers – Network side

Timer	State	Cause of Start	Normal Stop	On Expiry1st, 2nd, 3rd, 4th EXPIRY (NOTE 1)
T3485	BEARER CONTEXT ACTIVE PENDING	<ul style="list-style-type: none"> ACTIVATE DEFAULT EPS BEARER CONTEXT REQUEST sent ACTIVATE DEDICATED EPS BEARER CONTEXT REQUEST sent 	<ul style="list-style-type: none"> ACTIVATE DEFAULT EPS BEARER CONTEXT ACCEPT received or ACTIVATE DEFAULT EPS BEARER CONTEXT REJECT received or ACTIVATE DEDICATED EPS BEARER CONTEXT ACCEPT received or ACTIVATE DEDICATED EPS BEARER CONTEXT REJECT received 	Retransmission of the same message
T3486	BEARER CONTEXT MODIFY PENDING	MODIFY EPS BEARER CONTEXT REQUEST sent	<ul style="list-style-type: none"> MODIFY EPS BEARER CONTEXT ACCEPT received or MODIFY EPS BEARER CONTEXT REJECT received 	Retransmission of MODIFY EPS BEARER CONTEXT REQUEST

Timer	State	Cause of Start	Normal Stop	On Expiry 1st, 2nd, 3rd, 4th EXPIRY (NOTE 1)
T3489	PROCEDURETRANSACTION PENDING	ESM INFORMATION REQUEST sent	ESM INFORMATION RESPONSE received	Retransmission of ESM INFORMATION REQUEST on 1st and 2nd expiry only
T3495	BEARER CONTEXT INACTIVE PENDING	DEACTIVATE EPS BEARER CONTEXT REQUEST sent	DEACTIVATE EPS BEARER CONTEXT ACCEPT received	Retransmission of DEACTIVATE EPS BEARER CONTEXT REQUEST

NOTE 1: Typically, the procedures are aborted on the fifth expiry of the relevant timer. Exceptions are described in the corresponding procedure description.

This command can be repeated to set each timer as needed.
 The retransmission of all type of NAS messages can be configured through **nas-max-retransmissions** command.

Example

The following command sets the timeout value for default EPS bearer context activation procedure timer T3485 for 10 seconds.

```
esm t3485-timeout 10
```

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax`exit`

Usage

Return to the previous mode.

gtpv2

Configures GTPv2 piggybacking support from the MME to the P-GW. A piggybacking flag is sent by the MME to a P-GW in the S11 “Create Session Request” message and determines whether dedicated bearer creation (Create Bearer Request) is piggybacked onto the “Create Session Response” message or not.

Product

MME

Privilege

Administrator

Syntax

```
[ default | no ] gtpv2 piggybacking
```

default

Returns the command to its default value of enabled.

no

Disables the feature.

piggybacking

Specifies that piggybacking is to be performed by the P-GW.

Usage

Use this command to enable the sending of a piggybacking flag to the P-GW over the S11 interface requesting that the Create Bearer Request message is piggybacked on the Create Session Response message (sent from the P-GW to the MME).

Example

The following command disables this feature:

```
no gtpv2 piggybacking
```

integrity-algorithm-lte

This command configures the precedence of LTE integrity algorithms to use for security procedures through this MME service. By default integrity algorithm is enabled on MME service, which cannot be disabled.

Product

MME

Privilege

Administrator

Syntax

```
default integrity-algorithm-lte
```

default

Removes the preconfigured integrity algorithm and sets the default LTE integrity algorithm for security procedures. Default configuration of LTE integrity algorithm is:

- priority1 with 128-eia1 integrity algorithm
- priority2 with 128-eia2 integrity algorithm

priority1

Specifies the preference of integrity algorithm for security procedures on this MME service as priority 1. This is the mandatory and default priority keyword.

priority2

Specifies the preference of integrity algorithm for security procedures on this MME service as priority 2.

128-eia1

Default: Disabled

This keyword sets the SNOW 3G synchronous stream ciphering algorithm (128-EIA1) for LTE integrity as the integrity algorithm for security procedures. SNOW 3G is a stream cipher that forms the base of the 3GPP confidentiality algorithm UEA2 and the 3GPP integrity algorithm UIA2.

128-eia2

Default: Enabled

This keyword sets the Advance Encryption Standard (AES) ciphering algorithm (128-EIA2) for LTE integrity as the integrity algorithm for security procedures.

Usage

Use this command to set the LTE integrity algorithms for security procedures to use with this MME service.

WARNING: Integrity algorithm is a mandatory aspect and can not be disabled in MME service.

Caution: When this command is executed, all the existing priority to algorithm mappings will be removed and the newly configured ones will be applicable for security procedures.

Caution: Configuration of same algorithm to multiple priorities is prohibited.

Example

The following command sets the AES ciphering algorithms (128-EIA2) as the LTE integrity algorithm with priority as 1 for security procedures with an MME service:

```
integrity-algorithm-lte priority1 128-eia2
```

location-reporting

This command enables the location reporting functionality for UE on MME service.

Product

MME

Privilege

Administrator

Syntax

```
[ no | default ] location-reporting
```

default

Disables the location reporting feature on MME service.

no

Disables the location reporting feature on MME service.

Usage

Use this command to enable/disable the UE location reporting feature on MME service.

Example

The following command sets the MME service to provide the location reporting functionality for UE:

```
location-reporting
```

max-bearers per-subscriber

This command specifies the maximum number of EPS bearers that a subscriber may simultaneously use to access this MME service.

Product

MME

Privilege

Administrator

Syntax

```
max-bearers per-subscriber max_bearer
```

```
default max-bearers per-subscriber
```

default

Configures the maximum EPS bearers for a subscriber to use simultaneously to default value of 11.

max_bearer

Default: 11

Specifies the maximum number of EPS bearers for a subscriber may simultaneously use to access this MME service.

max_bearer can be configured to any integer value between 1 and 11.

Usage

Use this command to set the maximum number of EPS bearers that a subscriber may simultaneously use to access this MME service.

Example

The following command specifies that a maximum of 6 simultaneous EPS bearers can be facilitated for a subscriber at any given time:

```
max-bearers per-subscriber 6
```

max-paging-attempts

This command configures the maximum number of paging attempt retransmission allowed for network requested service creation to a subscriber while first attempt failed.

Product

MME

Privilege

Administrator

Syntax

```
max-paging-attempt max_paging_retry
```

```
default max-paging-attempt
```

default

Configures the maximum number of retransmission of paging request to default value of 3.

max_paging_retry

Default: 3

Specifies the maximum number of paging attempt retransmission allowed for network requested service creation to a subscriber while first attempt failed.

max_paging_retry can be configured to any integer value between 1 and 10.

Usage

Use this command to set the maximum number of paging attempt retransmission allowed for network requested service creation to a subscriber while first attempt failed.

Example

The following command specifies that a maximum of 6 paging attempt retransmission allowed for network requested service creation to a subscriber while first attempt failed for a subscriber at any given time:

```
max-paging-attempt 6
```

max-pdns per-subscriber

This command specifies the maximum number of PDNs that a subscriber may simultaneously access through this MME service.

Product

MME

Privilege

Administrator

Syntax

```
max-pdns per-subscriber max_pdn
```

```
default max-pdns per-subscriber
```

default

Configures the maximum PDNs for a subscriber simultaneously access through this MME service to default value of 3 PDNs.

max_pdn

Default: 3

Specifies the maximum number of PDNs that a subscriber may simultaneously access through this MME service.

max_pdn can be configured to any integer value between 1 and 11.

Usage

Use this command to set the maximum number of PDNs that a subscriber may simultaneously access through this MME service.

Example

The following command specifies that a maximum of 2 simultaneous PDNs can be accessed by a subscriber at any given time through this MME service:

```
max-pdns per-subscriber 6
```

mme-id

This command configures the MME identifier with an MME service. MME identifier is constructed with MME group ID and MME Code.

Product

MME

Privilege

Administrator

Syntax

```
mme-id group-id grp_id mme-code mme_code
```

```
no mme-id
```

```
no
```

Removes the configured MME identifier for this MME service.

Caution: Removing the MME identifier is a disruptive operation; the MME service shall be removed from the service.

```
group-id grp_id
```

Specifies the group identifier for the group of which this MME belongs.
grp_id must be an integer value from 0 through 65535.

```
mme-code mme_code
```

Specifies the unique code for this MME service.
mme_code must be an integer value from 0 through 255.

Usage

Use this command to set the MME identifier for this MME service. This MME identifier will be the identity of this MME in network.

Caution: Changing or removing the MME identifier is a disruptive operation; the MME service shall be restarted or removed from service.

Example

The following command configures the MME identifier with group id as *1025* and MME code as *101* for this MME service:

```
mme-id group-id 1025 mme-code 101
```

mmemgr-recovery

Configures the recovery action for the MME manager.

Product

MME

Privilege

Administrator

Syntax

```
mmemgr-recovery { no-reset | reset }
```

```
default mmemgr-recovery
```

default

Resets the command to its default value.

no-reset

Specifies that the recovery action is to NOT reset S1 peers.

reset

Specifies that the recovery action is TO reset S1 peers.

Usage

Use this command to set a recovery action for the MME Manager.

Example

The following command configures the MME Manager recovery action to reset all S1 peers:

```
mmemgr-recovery reset6
```

nas-max-retransmission

This command sets the retransmission counter for all type of NAS messages in an MME service.

Product

MME

Privilege

Administrator

Syntax

```
nas-max-retransmissions nas_retrans_count
```

```
default nas-max-retransmissions
```

default

Resets the retransmission counter to the system default value of 4.

nas_retrans_count

Default: 4

Sets the maximum number of retransmission of NAS messages permitted during any procedure after which activation procedure will be discarded.

nas_retrans_count is number of retransmission allowed and must be an integer from 1 through 10.

Usage

Use this command to set maximum number of retries allowed for any type of NAS messages.

NAS Messages send by the MME which require a response from the UE for procedure completion are retransmitted. Retransmission happens based on timer expiry. The timers are configured through **emm** and **esm** command. The NAS messages are retransmitted as per configuration, and if no response from the UE is received, the pending transaction is abandoned. If the transaction is a DETACH or PDN DISCONNECT REQUEST, the transaction is completed without further UE signaling.

The timeout duration configured through **emm** and **esm** command will be applicable between two retries.

Example

The following command sets the maximum number of retries allowed as 4 for all type of NAS messages in an MME service.

```
default nas-max-retransmissions
```

peer-mme

Configures parameters that, when matched by another MME, specifies that MME as a peer for inter-MME relocations.

Product

MME

Privilege

Administrator

Syntax

```
peer-mme { gummei mcc number mnc number group-id id mme-code code address
ipv4_address | tai-match priority value mcc number mnc number tac { area_code |
any | start_area_code to end_area_code } address ipv4_address }
```

```
no peer-mme { gummei mcc number mnc number group-id id mme-code code | tai-match
priority value
```

no

Removes the configured peer MME GUMMEI or TAI match priority from this service.

```
gummei mcc number mnc number group-id id mme-code code address
ipv4_address
```

Specifies that an MME with values matching those configured in this Globally Unique MME Identifier (GUMMEI) is to be considered a peer MME. This variable supports the lookup of an IP address for a peer MME based on the exact match of the supporting keyword below (which make up the GUMMEI).

mcc number: Sets the mobile country code (MCC) for peer match. *number* must be an integer value between 100 and 999.

mnc number: Sets the mobile network code (MNC) for this peer match. *number* must be an integer value between 00 and 999.

group-id id: Specifies the group identifier for the group to which this MME belongs. *id* must be an integer value from 0 through 65535.

mme-code code: Specifies the unique code for an MME service. *code* must be an integer value from 0 through 255.

address ipv4_address: Specifies the IPv4 address of the peer MME. *ipv4_address* must be entered in dotted decimal notation.

```
tai-match priority value mcc number mnc number tac { area_code | any |
start_area_code to end_area_code } address ipv4_address
```

Specifies that an MME with values matching those configured in this Tracking Area Identifier (TAI) match, is to be considered a peer MME. This keyword provides a priority-ordered list of TAI descriptions where the TAC field may be either an exact value, a range of values, or a “wildcard” value. It also provides an IP address of the peer MME corresponding to the TAI description.

priority value:

mcc number: Sets the mobile country code (MCC) for peer match. *number* must be an integer value between 100 and 999.

mnc number: Sets the mobile network code (MNC) for this peer match. *number* must be an integer value between 00 and 999.

tac *area_code*: Sets a specific Tracking Area Code (TAC) for the peer MME match. *area_code* must be an integer value from 1 to 65535.

tac any: Specifies that any TAC value can be considered for a peer MME.

tac *start_area_code to end_area_code*: Specifies a range of TACs. MMEs within this range and matching the rest of the criteria in this command are to be considered peer MMEs. *start_area_code* and *end_area_code* must be integer values from 1 to 268435455.

address *ipv4_address*: Sets a specific IPv4 address for this TAI peer MME match. *ipv4_address* must be entered in dotted decimal notation.

Usage

Use this command to configure parameters that, when matched by another MME, specifies that MME as a peer for inter-MME relocations.

This command allows configuration for two relocation scenarios:

- **gummei**: an MME receives either an Attach or a TAU request with a GUTI that originated from another MME.
- **tai-match**: an MME receives an S1 Handover Required message and must select a new MME based on the TAI.

Up to 32 peer-mme gummei or tai-match entries may be configured per MME service.

Example

The following command identifies a peer MME with GUMMEI parameters:

```
peer-mme gummei mcc 123 mnc 12 group-id 40000 mme-code 100 address  
1.2.3.4
```

pgw-address

This command configures the PDN Gateway (P-GW) address to use P-MIP protocol for S5 and S8 interface and other parameters with MME service. By default S5 and S8 use GTP protocol for this.

Product

MME

Privilege

Administrator

Syntax

```
pgw-address address [ s5-s8-protocol pmip ] [ weight value ]
```

```
no pgw-address address [ s5-s8-protocol pmip ]
```

no

Removes a previously configured IP address of P-GW along with S5 and S8 interface of P-MIP protocol type and other parameters from this MME service.

address

Specifies the IP address of the P-GW.

address must be an IP address in IPv4 or IPv6 notation.

s5-s8-protocol pmip

Specifies that P-MIP type of protocol to use for S5 and S8 interfaces with P-GW. By default S5 and S8 interface uses GTP protocol.

pmip Sets the protocol to Proxy-MIP for S5 and S8 interface as by default GTP is the applicable protocol.

weight value

Assigns the weight to P-GW address to use as a preferred P-GW.

value must be an integer from 1 through 100. Lowest value has the least preference.

Usage

Use this command to configure the PDN Gateway (P-GW) addresses to use with MME service. This command also changes the default protocol or GTP to P-MIP for the S5 and S8 interface and weight to share the load between associated P-GWs. A maximum of 16 P-GW addresses can be configured with this command.

This command only changes the use of protocol in S5 and S8 interface. By default P-GW uses GTP protocol for S5 and S8 interfaces. By this command user can change the protocol to P-MIP for S5 and S8 interface. When weight is used, the weights of the P-GW(s) (that are operational) are totaled and then weighted round-robin selection is used to distribute new default bearer context among the P-GW(s) according to their weights.

Example

The following command associates the P-GW IP address of *192.168.3.1* to the MME service with S5 and S8 protocol as P-MIP and weight as *90*:

```
pgw-address 192.168.3.1 s5-s8-protocol pmip weight 90
```

The following command removes the above configured P-GW IP address and other parameters:

```
no pgw-address 192.168.3.1 s5-s8-protocol pmip
```

plmn-id

This command configures the Public Land Mobile Network (PLMN) identifier for this MME service. PLMN identifier is made of Mobile Country Code (MCC) and Mobile Network Code (MNC). A maximum of 16 PLMN id can be configured in an MME service.

Product

MME

Privilege

Administrator

Syntax

```
plmn-id mcc mcc_value mnc mnc_value
```

```
no plmn-id mcc mcc_value mnc mnc_value
```

no

Removes the configured PLMN identifier for this MME service.

Caution: Removing the PLMN identifier is a disruptive operation; the MME service shall be re-started.

mcc *mcc_value*

Specifies the mobile country code (MCC) part of PLMN identifier.
mcc_value must be an integer value from 101 through 998.

mnc *mnc_value*

Specifies the mobile network code (MNC) part of PLMN identifier.
mnc_value must be an integer value from 01 through 99 or 100 through 998.

Usage

Use this command to set the PLMN identifier for this MME service.

Caution: Changing or removing the PLMN identifier is a disruptive operation; the MME service shall be re-started.

A maximum of 16 PLMN identifiers are supported for an MME service.

Example

The following command configures the PLMN identifier with MCC value as *102* and MNC value as *20* for this MME service:

```
plmn-id mcc 102 mnc 20
```

policy attach

Configures parameters for the UE attach procedure.

Product

MME

Privilege

Administrator

Syntax

```
policy attach { imei-query-type { imei | imei-sv | none } [ verify-equipment-identity [ deny-greylisted ] ] | set-ue-time { disable | enable } default policy attach { imei-query-type | set-ue-time }
```

default

Returns the command to its default setting of **none** for **imei-query-type** and **disabled** for **set-ue-time**.

```
imei-query-type { imei | imei-sv | none } [ verify-equipment-identity [ deny-greylisted ] ]
```

Configures the IMEI query type for UE attach.

imei: Specifies that the MME is required to query the UE for its International Mobile Equipment Identity (IMEI).

imei-sv: Specifies that the MME is required to query the UE for its International Mobile Equipment Identity - Software Version (IMEI-SV).

none: Specifies that the MME does not need to query for IMEI or IMEI-SV.

verify-equipment-identity [deny-greylisted]: Specifies that the identification (IMEI or IMEI-SV) of the UE is to be performed by the Equipment Identity Register (EIR) over the S13 interface.

deny-greylisted: Configures the MME to deny grey-listed equipment during the attach procedure.

```
set-ue-time { disable | enable }
```

Configures the MME to set the time in the UE during the attach procedure. Default: **disabled**.

Usage

Use this command to configure various MME settings used during the UE attach procedure.

Example

The following command configures the MME to query the UE for its IMEI and to verify the UEs equipment identity over the S13 interface with an EIR:

```
policy attach imei-query-type imei verify-equipment-identity
```

policy idle-mode

This command configures the user-defined policies of session management for LTE subscriber in an MME service.

Product

MME

Privilege

Administrator

Syntax

```
policy idle-mode detach { explicit | implicit }  
[ default ] policy idle-mode detach
```

default

Sets the policy of idle mode detach for a subscriber to its default behavior as implicit.

idle-mode detach

This keyword configures the IDLE mode detach behavior of a UE.

detach

This keyword defines the detach procedure while UE is in IDLE mode.

explicit

Default: disabled

This keyword enables the explicit detach while a UE is in IDLE mode. System will page UE before detach procedure started and then perform explicit detach procedure.

implicit

Default: Enabled

This keyword enables the implicit detach while a UE is in IDLE mode. System never send any message to UE before detach and performs explicit detach procedure immediately.

Usage

Use this command to set the user-defined policies for session management in this MME service.

Example

The following command sets the idle mode detach policy to explicit for a user in this MME service:

```
policy idle-mode detach explicit
```

policy network

This command configures the MME to indicate to the P-GW that all peer SGSNs support dual-addressing for bearers and, subsequently, dual-addressing must be supported for all IPv4 and IPv6 PDNs. Dual-addressing on SGSNs is based on UE capability to support inter-rat roaming.

Product

MME

Privilege

Administrator

Syntax

```
[ default | no ] policy network dual-addressing-supported
```

default

Returns the command to its default setting of disabled.

no

Removes the ability to send dual-addressing support messaging from the MME to the P-GW.

dual-addressing-supported

Specifies that the MME shall indicate to the P-GW that dual-addressing is supported.

Usage

Use this command to configure the MME to send messaging to the P-GW that indicate that all peer SGSNs support dual-addressing for bearers and, subsequently, dual-addressing must be supported for all IPv4 and IPv6 PDNs.

Conversely, when Pre-release 8 SGSNs exist in the network, this command should be disabled. Pre-release 8 SGSNs do not support dual-addressing.

policy overload

This command configures the traffic overload policy to control congestion in this service.

Product

MME

Privilege

Administrator

Syntax

```
policy overload { drop | reject }
```

```
default policy overload
```

default

Sets the traffic overload policy action to default behavior of reject.

drop

Default: Disabled

Specifies that the system is to drop the incoming packets with new session requests to avoid overload on MME node.

reject

Default: Enabled

This keyword configures the system to reject the new session/call request and responds with a reject message when threshold for allowed call session is crossed on MME node.

Usage

Use this command to set the user-defined policies for new call connection attempted during overload in an MME service.

Congestion policies at the service-level can be configured for service. When congestion control functionality is enabled at service level, these policies dictate how services respond should the system detect that a congestion condition threshold has been crossed.

Example

The following command sets the nw call connect policy to reject the new session/call request in an MME service:

```
policy overload reject
```

policy pdn-reconnection

This command configures the action by MME when a PDN connection request to an already connected APN is being processed by MME service.

Product

MME

Privilege

Administrator

Syntax

```
policy pdn-reconnection { multiple | reject | restart }
[ default ] policy pdn-reconnection
```

default

Sets the policy of PDN reconnection to its default behavior of reject.

multiple

Default: Disabled

This keyword allows multiple connections to a PDN with same APN and PDN Type. In this case, the existing connection is left unchanged, and the MME attempts to establish an additional connection to the PDN.

reject

Default: Enabled

This keyword configures set the action of MME to deny or reject the request, by sending a PDN connection reject command. This is the default behavior.

restart

Default: Disabled

This keyword deletes the existing connection and initiate an attempt to establish a new connection.

Usage

Use this command to set the user-defined policies for PDN reconnection attempt procedures initiated by UE in an MME service.

While a UE is attached, the UE can request connections to PDNs. The PDNs are identified by APN (Access Point Name) and PDN Type (ipv4, ipv6 or ipv4v6).

If the UE requests connection to a PDN for which a connection with the same APN name and PDN type already exists, the MME can; 1) deny or Reject the request, by sending a PDN connection reject command; 2) allow multiple connections to a PDN with same APN and PDN Type; or 3) delete the existing connection, and attempt to establish a new connection.

Example

The following command sets the PDN reconnect policy to delete the existing PDN and start the attempt to establish a new connection in an MME service:

■ policy pdn-reconnection

```
policy pdn-reconnection restart
```

policy s1-reset

This command configures how the MME responds to an S1 interface reset.

Product

MME

Privilege

Administrator

Syntax

```
policy s1-reset { detach-ue | idle-mode-entry }  
default policy s1-reset
```

default

Returns the command to its default setting of **idle-mode-entry**.

{ detach-ue | idle-mode-entry }

Specifies the action to perform when the S1 interface is reset.

detach-ue: Specifies that UEs are to be detached from the service upon S1 interface reset.

idle-mode-entry: Specifies that UEs are to be placed into an idle mode condition during S1 interface reset.

Usage

Use this command to configure how the MME reacts to an S1 interface reset condition.

Example

The following command configures the MME to place UEs into an idle state while the S1 interface is being reset:

```
s1-reset idle-mode-entry
```

policy sctp-down

This command configures how the MME responds to a failure of the SCTP connection from the eNodeB.

Product

MME

Privilege

Administrator

Syntax

```
policy sctp-down { detach-ue | idle-mode-entry }
```

```
default policy sctp-down
```

default

Returns the command to its default setting of **idle-mode-entry**.

```
{ detach-ue | idle-mode-entry }
```

Specifies the action to perform when the SCTP connection from the eNodeB fails.

detach-ue: Specifies that UEs are to be detached from the service upon SCTP failure.

idle-mode-entry: Specifies that UEs are to be placed into an idle mode condition upon SCTP failure.

Usage

Use this command to configure how the MME reacts to an SCTP connection failure condition.

Example

The following command configures the MME to place UEs into an idle state while the SCTP connection from the eNodeB fails:

```
sctp-down idle-mode-entry
```

policy tau

Configures parameters for the tracking area update (TAU) procedure.

Product

MME

Privilege

Administrator

Syntax

```
policy tau { imei-query-type { imei | imei-sv | none } [ verify-equipment-identity [ deny-greylisted ] ] | set-ue-time { disable | enable } default policy tau { imei-query-type | set-ue-time }
```

default

Returns the command to its default setting of **none** for **imei-query-type** and **disabled** for **set-ue-time**.

```
imei-query-type { imei | imei-sv | none } [ verify-equipment-identity [ deny-greylisted ] ]
```

Configures the IMEI query type for TAUs.

imei: Specifies that the MME is required to query the UE for its International Mobile Equipment Identity (IMEI).

imei-sv: Specifies that the MME is required to query the UE for its International Mobile Equipment Identity - Software Version (IMEI-SV).

none: Specifies that the MME does not need to query for IMEI or IMEI-SV.

verify-equipment-identity [deny-greylisted]: Specifies that the identification (IMEI or IMEI-SV) of the UE is to be performed by the Equipment Identity Register (EIR) over the S13 interface.

deny-greylisted: Configures the MME to deny grey-listed equipment during the TAU procedure.

```
set-ue-time { disable | enable }
```

Configures the MME to set the time in the UE during the TAU procedure. Default: **disabled**.

Usage

Use this command to configure various MME settings used during the tracking area update (TAU) procedure.

Example

The following command configures the MME to query the UE for its IMEI and to verify the UEs equipment identity over the S13 interface with an EIR:

```
policy tau imei-query-type imei verify-equipment-identity
```

relative-capacity

Configures a relative capacity variable that is sent to the ENodeB for use in selecting an MME from a pool in order to load balance the pool.

Product

MME

Privilege

Administrator

Syntax

```
relative-capacity number
```

default

Returns the command to its default setting of 255.

number

Specifies the relative capacity or weight of an MME compared to others in an MME pool. *number* must be an integer value from 0 to 255. Default: 255

Usage

Use this command to configure the relative capacity or weight of this MME in comparison to other MMEs in a pool. This value is sent to the ENodeB in the S1AP S1 SETUP RESPONSE message.

If this value is changed after the S1 interface is initialized, the MME CONFIGURATION UPDATE message is used to update the ENodeB with the change.

Example

The following command sets this MME with a relative capacity or weight of 100:

```
relative-capacity 100
```

setup-timeout

This command configures the timeout duration for call setup of MME calls in this MME service.

Product

MME

Privilege

Administrator

Syntax

```
setup-timeout dur
```

```
default setup-timeout
```

default

Sets the call setup timeout duration to default value of 60 seconds.

dur

Default: 60

Specifies the call setup timeout duration for MME calls after which attempt will be discarded. *dur* must be an integer between 1 through 10000.

Usage

Use this command to configured the timeout duration in seconds to setup an MME call with an MME service. One this duration exhausted Call setup procedure will be discarded with this MME service.

Example

The following command sets the default setup timeout duration of 60 seconds for MME calls:

```
default setup-timeout
```

snmp trap

Enables or disables the SNMP trap for S1 interface connection establishment.

Product

MME

Privilege

Administrator

Syntax

```
[ default | no ] snmp trap s1-initial-establishment
```

default

Returns the command to it's default setting of disabled.

no

Disables the SNMP trap.

s1-initial-establishment

Specifies that the SNMP trap for S1 interface connection establishment is to be enabled or disabled.

Usage

Use this command to enable or disabled the SNMP trap for S1 interface connection establishment.

ue-db

This command configures the UE database which is maintained by MME as cache of EPS context per UE keyed by IMSI/GUTI to allow UE to attach by GUTI and reuse previously established security parameters. This cache will be maintained in each session manager where the first attach occurred for an UE.

Product

MME

Privilege

Administrator

Syntax

```
ue-db purge-timeout dur_mins
```

```
default ue-db purge-timeout
```

default

Resets the UE database purge timer timeout to the system default value of 10080 mins.

purge-timeout *dur_mins*

Default: 10080

Sets the timeout duration for MME to store UE database in cache memory.

This timer starts when UE goes in dormant.

dur_mins is timeout duration in minutes and must be an integer from 1 through 20160.

Usage

Use this command to set timeout duration for MME to hold UE database information in cache memory. The MME DB acts as a cache for storing subscriber related information. This subscriber related information helps in reducing signaling traffic. The MME DB is a part of the Session Manager and interfaces between the Session Manager Application and Evolved Mobility Management Manager to provide access to the cached data.

Example

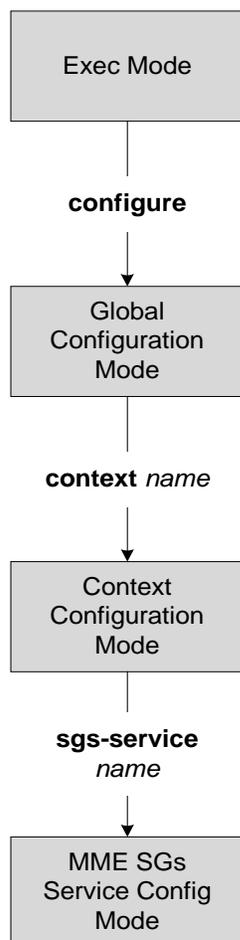

The following command configures the MME database cache timer to hold the UE information up to 7 days (10080 minutes) in MME Database:

```
default ue-db purge-timeout
```

Chapter 172

MME SGs Service Configuration Mode Commands

The MME SGs Service Configuration Mode is used to create and manage the LTE Mobility Management Entity (MME) SGs services on this system. The SGs service creates an SGs interface between the MME and a MSC/VLR.

bind

Binds the service to a logical IP interface serving as the SGs interface.

Product

MME

Privilege

Administrator

Syntax

```
bind ipv4-address ip_address
```

```
no bind ipv4-address
```

```
no bind ipv4-address
```

Removes the interface binding from this service.

```
ip_address
```

Specifies the IPv4 address of the SGs interface. *ip_address* must be specified in IPv4 dotted decimal notation.

Usage

Associate the SGs service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an SGs interface that provides the session connectivity for circuit switched fallback (CSFB) to/from a Mobile Switching Center/Visitor Location Register (MSC/VLR). Only one interface can be bound to a service. The interface should be configured prior to issuing this command

Example

The following command binds the logical IP interface with the IPv4 address of 111.223.334.445 to the SGs service:

```
bind ipv4-address 111.223.334.445
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

non-pool-area

Configures a non-pool area where a group of LAC values use a specific VLR.

Product

MME

Privilege

Administrator

Syntax

```
non-pool-area name use-vlr vlr_name lac value(s)
```

```
no non-pool-area name [ lac value(s) ]
```

```
no non-pool-area name [ lac value(s) ]
```

Removes the configured non-pool-area from this service. Optionally, removes a specific LAC or LACs from this non-pool area. *name* must be the name of an existing non-poll-area and be from 1 to 63 alpha and/or numeric characters. *value(s)* must be existing LAC integer values and be from 1 to 65535.

name

Specifies the name of the non-pool area. *name* must be from 1 to 63 alpha and/or numeric characters.

```
use-vlr vlr_name
```

Specifies the Visitor Location Register (VLR) to be used in this non-pool area configuration. *vlr_name* must be from 1 to 63 alpha and/or numeric characters.

```
lac value(s)
```

Specifies the local area code or codes to be used with the configured VLR in this non-pool area configuration. *value(s)* must be from 1 to 65535. Multiple area codes can be entered (up to 128 in a single line).

Usage

Use this command to configure a non-pool area where LAC values are associated with a specific VLR.

Example

The following command creates a non-pool area named svlr1 associated with a VLR named vlr1 and containing LAC values of 1, 2, 3, 4, 5, 6, 7, 8, and 9:

```
non-pool-area svlr1 use-vlr vlr1 lac 1 2 3 4 5 6 7 8 9
```

pool-area

Creates a LAC pool area configuration or specifies an existing pool area and enters the LAC Pool Area Configuration Mode.

Product

MME

Privilege

Administrator

Syntax

```
[ no ] pool-area pool_name [ -noconfirm ]
```

no

Removes the selected pool area configuration from the SGs service.

pool_name

Specifies the name of the LAC pool area configuration. If *pool_name* does not refer to an existing pool, a new pool is created. *pool_name* must be from 1 to 64 alpha and/or numeric characters.

Usage

Use this command to enter the LAC Pool Area Configuration Mode for an existing pool area configuration or for a newly defined pool area configuration. This command is also used to remove an existing pool area configuration.

Entering this command results in the following prompt:

```
[ context_name ] hostname ( config-sgs-pool-area ) #
```

LAC Pool Area Configuration Mode commands are defined in the *MME LAC Pool Area Configuration Mode Commands* chapter.

Example

The following command enters the LAC Pool Area Configuration Mode for a new or existing pool area configuration named *pool1*:

```
pool-area pool1
```

sctp

Configures the Stream Control Transmission Protocol (SCTP) port number for this service.

Product

MME

Privilege

Administrator

Syntax

```
sctp port port_number
```

```
no sctp
```

no

Removes the SCTP configuration for this service.

```
port port_number
```

Specifies the SCTP port number used to communicate with the MSC/VLR using the SGs interface. *port_number* must be an integer value from 1 to 65535.

Usage

Use this command to assign the SCTP port with SCTP socket to communicate with the MSC/VLR through the SGs interface. A maximum of one SCTP port can be associated with one SGs service.

Example

The following command sets the SCTP port to *29118* for this service:

```
sctp port 29118
```

tac-to-lac-mapping

Maps any TAC value or a specific TAC value to a LAC value.

Product

MME

Privilege

Administrator

Syntax

```
tac-to-lac-mapping { any-tac | tac value } map-to lac value
no tac-to-lac-mapping { any-tac | { tac value } + }
```

any-tac | tac value

Specifies the TAC to map to the LAC.

any-tac: Specifies that any TAC value is to be mapped to the specified LAC.

tac value: Maps a specific TAC value to a LAC value. *value* must be an integer value from 1 to 65535. For specific TAC values, multiple mappings can be entered on the same line (see Example).

map-to lac value

Specifies the LAC value that the selected TAC value, or any TAC value is mapped. *value* must be an integer value from 1 to 65535. For specific TAC values, multiple mappings can be entered on the same line (see Example).

Usage

Use this command to map TAC values to LAC values.

Enter up to eight mappings per line. A maximum of 256 mappings can be entered.

If no mapping is entered, the default behavior is TAC equals LAC.

Example

The following command maps a TAC value of 2 to a LAC value of 3, a TAC value of 4 to a LAC value of 5, and a TAC value of 6 to a LAC value of 7:

```
tac-to-lac-mapping tac 2 map-to lac 3 tac 4 map-to lac 5 tac 6 map-to lac
7
```

vlr

Configures the Visitor Location Register (VLR) to be used by this service.

Product

MME

Privilege

Administrator

Syntax

```
vlr vlr_name ipv4-address ip_address port port_number
```

```
no vlr vlr_name
```

no

Removes the configured VLR from this service.

vlr_name

Specifies the name of the VLR. *vlr_name* must be from 1 to 63 alpha and/or numeric characters.

ipv4-address *ip_address*

Specifies the IPv4 address of the VLR. *ip_address* must be entered in dotted decimal notation.

port *port_number*

Specifies the port number of the VLR. *port_number* must be an integer value from 1 to 65535.

Usage

Use this command to configure the VLR used by this SGs service.

Example

The following command configures a VLR to be used by this service with a name of *vlr1*, an IPv4 address of *1.2.3.4*, and a port number of *29118*:

```
vlr vlr1 ipv4-address 1.2.3.4 port 29118
```

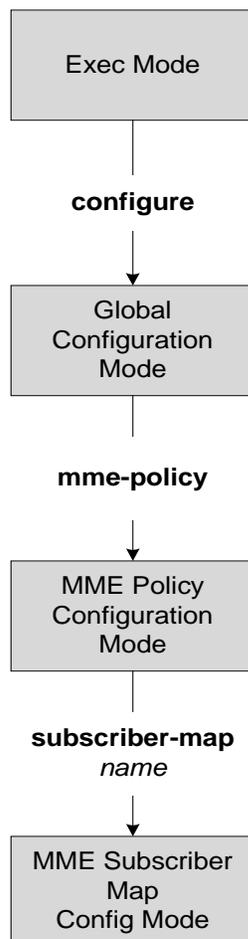

Chapter 173

MME Subscriber Map Configuration Mode Commands

The MME Subscriber Map Configuration Mode is used to create and manage subscriber maps for applying operator policy templates to individual subscribers and/or groups of subscribers.

Subscriber mappings are ordered lists containing explicit UE matching criteria. In order to match a UE with a subscriber map, the maps are examined in order criteria defined in the map is match to specific UE identity information such as the UE's IMSI. The first map that matches the criteria is used to associated an operator policy with the UE.

Subscriber maps can be modified but will only affect future subscribers and not subscribers already attached to the system.

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

precedence

Sets the order of precedence, the matching criteria and the association to an operator policy for subscribers meeting the match criteria.

Product

MME

Privilege

Administrator

Syntax

```
precedence number match-criteria all operator-policy-name policy_name
```

```
precedence number match-criteria imsi mcc mcc_num mnc mnc_num [ msin first start_range last end_range | service-plmnid id ] operator-policy-name policy_name
```

```
precedence number match-criteria service-plmnid id operator-policy-name policy_name
```

```
no precedence number
```

no

Removes the selected precedence number from the subscriber map. *number* must be an integer value from 1 to 1024.

number

Specifies the order of precedence for the subscriber map. 1 is the highest precedence. *number* must be an integer value from 1 to 1024.

match-criteria

Specifies that the keyword following this keyword is the criteria to be used to match a UE.

all

Specifies that all UEs are to be associated with the operator policy.

```
imsi mcc mcc_num mnc mnc_num [ msin first start_range last end_range | service-plmnid id ]
```

Specifies that UEs with criteria matching the International Mobile Subscriber Identifier (IMSI) information (MCC and MNC) are to be associated with a specified operator policy.

mcc *mcc_num*: Specifies the mobile country code (MCC) portion of the IMSI identifier. *mcc_num* must be an integer value between 100 and 999.

mnc *mnc_num*: Specifies the mobile network code (MNC) portion of the IMSI identifier. *mnc_num* can be configured to any 2 or 3 digit integer value between 00 and 999.

msin first *start_range* **last** *end_range*: Optionally specifies a range of Mobile Subscriber Identification Numbers that further narrows the match criteria for the IMSI match configuration. *start_range* and *end_range* must each be an integer value of 10 digits.

service-plmnid *id*: Optionally specifies a local service PLMN ID number used further narrow the IMSI-based operator policy selection. *id* must be an integer value of five digits minimum and six digits maximum (the combination of the MCC and MNC).

service-plmnid *id*

Specifies a local service PLMN ID number used in for PLMN ID-based operator policy selection. *id* must be an integer value of five digits minimum and six digits maximum (the combination of the MCC and MNC). This command

operator-policy-name *policy_name*

Sets the operator policy to which the matching criteria is associated. *policy_name* must be an existing operator policy and be from 1 to 64 alpha and/or numeric characters. Operator policies are configured in the Operator Policy Configuration Mode. More information about operator policies can be found in the *Operator Policy Configuration Mode Commands* chapter.

Usage

The MME operator policy provides mechanisms to fine tune the behavior of subsets of subscribers above and beyond the behaviors described in the user profile. It is also used to control the behavior or visiting subscribers in roaming scenarios, enforce roaming agreements and provide a measure of local protection against foreign subscribers.

Example

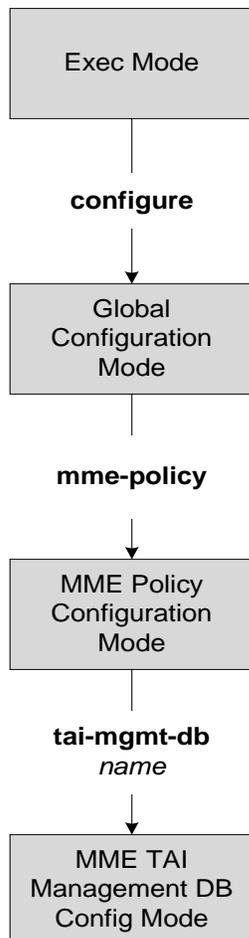

The following command associates the operator policy named *op_pol1* with UEs associated with an IMSI MCC of *111*, an MNC of *222*, and a service PLMN ID of *123456*:

```
precedence 100 match-criteria imsi mcc 1111 mnc 222 service-plmnid 123456
operator-policy-name op_pol1
```

Chapter 174

MME TAI Management Database Configuration Mode Commands

The MME TAI Management Database Configuration Mode is used to create and manage the LTE Mobility Management Entity (MME) TAI management database configuration for MME polices configured on this system.

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax **exit**

Usage

Return to the previous mode.

tai-mgmt-obj

Creates new, or removes/enters existing, MME Tracking Area Identifier (TAI) object configurations.

Product

MME

Privilege

Administrator

Syntax

```
[ no ] tai-mgmt-obj object_name [ -noconfirm ]
```

no

Removes a configured TAI management object from the TAI management database.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

object_name

Specifies the name of the TAI management object and enters the MME TAI Management Object Configuration Mode. *object_name* must be from 1 to 64 alpha and/or numeric characters.

Usage

Use this command to enter the MME TAI Management Object Configuration Mode for an existing object or for a newly defined object. This command is also used to remove an existing object.

Entering this command results in the following prompt:

```
[ context_name ] hostname ( tai-mgmt-obj ) #
```

MME TAI Management Object Configuration Mode commands are defined in the *MME TAI Management Object Configuration Mode Commands* chapter.

Example

The following command creates a TAI management object called tai-obj3 and enters the MME TAI Management Object Configuration Mode:

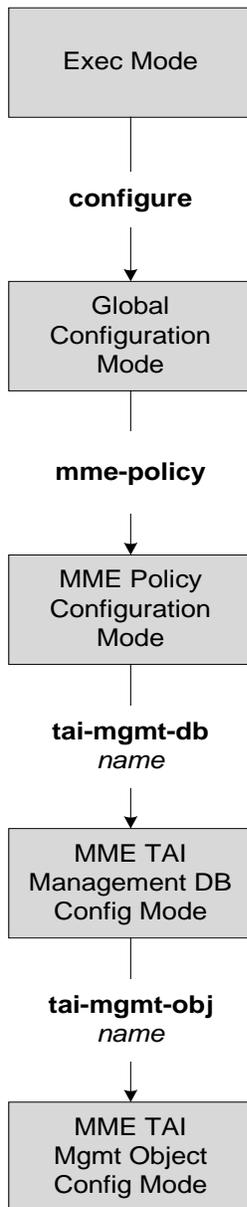

```
tai-mgmt-obj tai-obj3
```

Chapter 175

MME TAI Management Object Configuration Mode

Commands

The MME TAI Management Object Configuration Mode is used to create and manage the LTE Mobility Management Entity (MME) Tracking Area Identifiers for the TAI database.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

sgw-address

Configures an S-GW IP address, supported S5/S8 protocol type, and selection weight used in a pool for S-GW selection.

Product

MME

Privilege

Administrator

Syntax

```
sgw-address ipv4_or_ipv6_address s5-s8-protocol { both | gtp | pmip } weight
number
```

```
no sgw-address ipv4_or_ipv6_address s5-s8-protocol { both | gtp | pmip }
```

```
no sgw-address ipv4_or_ipv6_address s5-s8-protocol { both | gtp | pmip }
```

Removes the configured S-GW address from this TAI management object.

ipv4_or_ipv6_address

Specifies the IP address of the S-GW in the selection pool. *ipv4_or_ipv6_address* must be entered in dotted decimal notation (for IPv4 addresses) or colon-separated hexadecimal notation (for IPv6 addresses). Up to 32 S-GW address can be configured per TAI management object.

s5-s8-protocol { **both** | **gtp** | **pmip** }

Specifies the S5/S8 interface type found between the configured S-GW and the P-GW.

both: Specifies that both the GTP and PMIP protocols are supported over the S5/S8 interface.

gtp: Specifies that the GTP protocol is supported over the S5/S8 interface.

pmip: Specifies that the PMIP protocol is supported over the S5/S8 interface.

weight *number*

Specifies the priority or weight of the S-GW address used during weighted round-robin selection within this TAI management object. *number* must be an integer value from 1 to 100.

Usage

Use this command to configure a pool of S-GW addresses used for S-GW selection.

Example

The following command configures an S-GW with an IPv4 address of 1.2.3.4, a supported S5/S8 protocol type of GTP, and a selection weight of 3:

```
sgw-address 1.2.3.4 s5-s8-protocol gtp weight 3
```

tai

Configures a Tracking Area Identifier (TAI) for this TAI management object.

Product

MME

Privilege

Administrator

Syntax

```
[ no ] tai mcc number mnc number { tac value } +
```

no

Removes a configured TAI from the TAI database.

mcc *number*

Specifies the mobile country code (MCC) portion of a PLMN's identifier. *number* must be an integer value between 100 and 999.

mnc *number*

Specifies the mobile network code (MNC) portion of a PLMN's identifier. *number* can be configured to any 2 or 3 digit integer value between 00 and 999

tac *value* +

Specifies the Tracking Area Code portion of the TAI. *value* must be an integer from 1 to 65535. Up to 16 TAC values can be entered on a single line.

Usage

Use this command to configure one or more TAIs for this management object. Up to 16 TAIs can be configured per management object.

Example

The following command adds a TAI to this management object with an MCC of *111*, an MNC of *22*, and a TAC value of *1001*:

```
tai mcc 122 mnc 22tac 1000
```

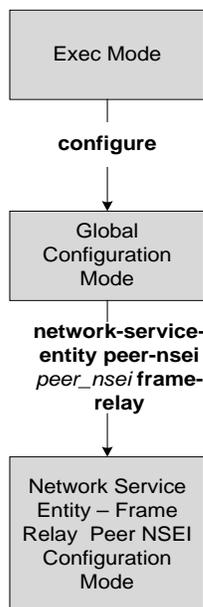

Chapter 176

Network Service Entity - Peer NSEI Configuration Mode Commands

The Network Service Entity (NSE) - Peer NSEI configuration mode configures the Frame Relay parameters for the peer NSE. This mode is a sub-mode of the Global Configuration mode. This sub-mode provides the commands and parameters to define the management functionality for the Gb interface between a BSS and an SGSN over a 2.5G GPRS Frame Relay network connection.

Upon accessing this mode, the prompt should be similar to:

```
[local]hostname(nse-fr-peer-nsei-<nse_id>)#
```

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ bssgp-timer

bssgp-timer

This command has been deprecated.

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

■ exit

exit

Exits the current configuration mode and returns to the previous configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

ns-reset-mode

The command configures automatic NS-Reset for a specific Frame Relay peer NSE (network service entity).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ns-reset-mode { active | passive }
```

```
default ns-reset-mode
```

default

Resets the configuration to the passive mode.

active

Configures active mode so that the SGSN is enabled to initiate NS-Reset without manual intervention.

passive

Configures passive mode which means the SGSN continues *not* to initiate NS-Reset. This is the default mode.

Usage

Use this command to configure the SGSN for active mode regarding the peer NSE, so that the SGSN will initiate:

- NS-Reset when NSVC-DLCI binding is done.
- NS-Reset when the link goes down and then comes back.
- NS-Unblock upon receipt of NS-Reset-Ack message.

Active mode is useful in the following scenarios:

- if the SGSN detects LMI down but the BSC does not detect any link failure so does not send NS-Reset.
- if the NS layer can go down and the SGSN will mark the link as 'Blocked-Dead'. If the link comes up later, the NS layer state for that link will remain in the Blocked state.

Example

Configure active mode to perform NS-Reset when the link goes down and comes back up:

```
ns-reset-mode active
```

ns-vc

This command creates a network service virtual circuit (NSVC) for this frame relay NSE and enters the configuration sub-mode to define the NSVC parameters. These parameters are described in the NSVC Configuration Mode chapter elsewhere in this CLI Reference Guide.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ns-vc id ns-vc_id
```

no

Removes the specified NSVC configuration.

id *ns-vc_id*

This keyword defines the NSVC configuration identifier.

ns-vc_id: Must be an integer from 0 to 65535

Usage

Access the NSVC configuration mode.

Example

Gain access to the NSVC configuration mode to change the 4th instance.

```
ns-vc id 4
```

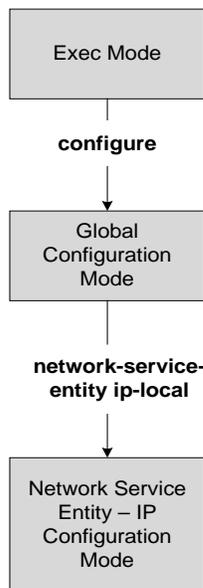

Chapter 177

Network Service Entity- IP Local Configuration Mode Commands

The Network Service Entity (NSE) - IP Local configuration mode is a sub-mode of the Global Configuration mode. This sub-mode configures the local endpoint for NS/IP with the commands and parameters to define the management functionality for the Gb interface between a BSS and an SGSN over a 2.5G GPRS IP network connection.

Upon entering this mode, the prompt will appear in a manner similar to:

```
[local]hostname(nse-ip-local)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

all-nsvc-failure-action

Configure how the SGSN handles the NSE when all NSVCs go down.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
all-nsvc-failure-action clear-nse
```

```
default all-nsvc-failure-action
```

default

By default, the NSE is not cleared if all NSVCs go down.

clear-nse

Instructs the SGSN to clear NSEs if all NSVCs to the BSC are down.

Usage

Enable the SGSN to clear NSE information when all NSVCs go down.

Example

Use the following command to configure the SGSN to clear NSEs when all NSVCs go down.

```
all-nsvc-failure-action clear-nse
```

bssgp-timer

This command has been deprecated.

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Returns to the global configuration mode.

max-ns-retransmissions

This command configures the maximum number of transmission retries counter.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] max-ns-retransmissions { alive count | sns-proc count }
```

default

Resets the specified counter configuration to the default value.

alive count

Sets the maximum number of alive retries.

count : Must be an integer between 0 and 10. Default is 3.

sns-proc count

Sets the maximum number of retries for the SNS procedure

count : Must be an integer between 0 and 5. Default is 3.

Usage

Sets the maximum for NS transmission retries.

Example

```
max-ns-retransmission alive 4
```

ns-timer

This command sets the network service (NS) counters for the SNS procedure and testing.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ns-timer { sns-prov timeout_val | test timeout_val }
```

```
default ns-timer { sns-prov | test }
```

default

Resets the selected timer configuration to its default value.

sns-prov *timeout_val*

Sets the SNS procedure timeout value in seconds.

timeout_val: Enter an integer from 1 to 10. Default is 5.

test *timeout_val*

Sets the test procedure timeout value in seconds.

timeout_val: Enter an integer from 1 to 60. Default is 30 seconds.

Usage

Set NS timers to help manage the NSE-IP connection.

Example

The following example sets the test timer to 4 seconds:

```
ns-timer test 4
```

nsvc-failure-action

This command enables and disables the sending of an NS-STATUS message with cause 'ip-test fail' when NSVC goes down.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
nsvc-failure-action send-ns-status
```

```
default nsvc-failure-action
```

default

Resets the command configuration to its default value. The default action is not to send an NS-STATUS message. This is applicable only to NSVCs that are auto-learned and not configured.

send-ns-status

Enables the sending of the NS-STATUS message.

Usage

Use this command to enable or disable sending an NS-STATUS messages when an NSVC goes down.

Example

Enable sending of the message:

```
nsvc-failure-action send-ns-status
```

nsvl

This command creates and instance of a network service virtual link (NSVL) and enters the NSVL configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] nsvl instance nsvl_id
```

no

Removes the identified NSVL definition from the configuration.

instance *nsvl_id*

Identifies a specific NSVL configuration instance.

nsvl_id: Must be an integer from 0 to 3.

Usage

Access the NSVL configuration mode.

Example

Enter the NSVL configuration sub-mode to modify the configuration for NSVL instance 2:

```
nsvl instance 2
```

■ peer-network-service-entity

peer-network-service-entity

This command has been replaced by the Network Service Entity - Peer NSEI Frame Relay configuration mode.

retry-count

This command has been replaced by the **max-ns-retransmissions** command.

■ timer

timer

This command has been replaced by the **ns-timer** command.

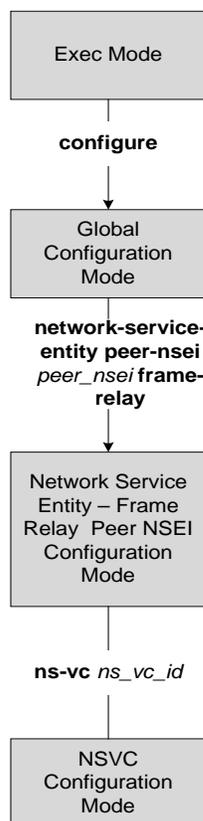

Chapter 178

Network Service Virtual Connection Configuration Mode Commands

The Network Service Virtual Connection (NSVC) configuration mode is a sub-mode of the Network Service Entity (NSE) - Peer NSEI (for Frame Relay) configuration mode. The NSVC sub-mode creates a configuration instance for a specific NSVC, within the Gb interface, between a BSS and an SGSN in a 2.5G GPRSFrame Relay network connection.

Upon accessing this mode, the prompt will appear similar to:

```
[local]hostname(nse-fr-peer-nsei-<nse_id>-nsvci-<nsvc_id>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the previous configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Returns to the network service entity - frame relay configuration mode.

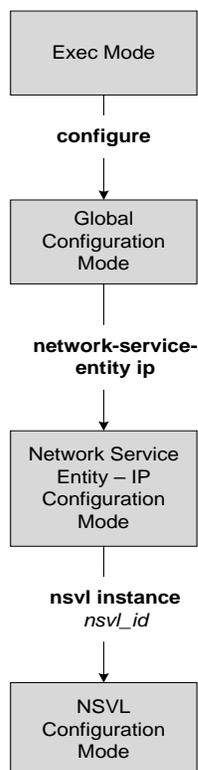

Chapter 179

Network Service Virtual Link Configuration Mode Commands

The Network Service Virtual Link configuration mode is a sub-mode of the Network Service Entity - IP configuration mode. This sub-mode provides the commands and parameters to define the NSVL of the Gb interface between a BSS and an SGSN in a 2.5G GPRS IP network connection.

Upon entering this mode, the prompt should appear similarly to the following:

```
[local]hostname(nse-ip-local-nsvl-<nsvl_id>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the previous configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the network service entity - IP configuration mode. mode.

nsvl-address

This command configures the IP address of the NSVL end-point.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
nsvl-address ip-address ip_address context ctxt_name port port_num
```

ip-address *ip_address*

Identifies the address of the NSVL.

ip_address: Must be specified using the standard IPv4 dotted decimal notation or colon notation for IPv6.

context *ctxt_name*

Identifies the specific context associated with this NSVL address.

ctxt_name: Enter up to 79 alphanumeric characters.

port *port_num*

Specifies the UDP port to associate with the NSVL end-point.

port_num: Must be an integer from 1 to 65535.

Usage

Use this command to configure the IP address, context name and port number for the NSVL end-point.

Example

```
nsvl-address ip-address 1.1.1.1 context sgsn2 port 3735
```

weight

This command configures the signaling or data weight for NSVL.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
weight { data data_weight | signaling signaling_weight }
```

data *data_weight*

Defines the data weight for the NSVL.

data_weight: Must be an integer from 0 to 255. Default is 1.

signaling *signaling_weight*

Defines the signaling weight for the NSVL.

signaling_weight: Must be an integer from 0 to 255. Default is 1.

Usage

Configure the weight of the signaling or data for the NSVL.

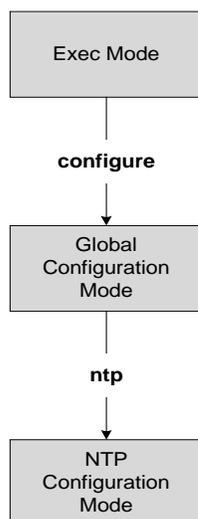

Example

```
weight data 234
```

Chapter 180

NTP Configuration Mode Commands

The Network Timing Protocol Configuration Mode is used to manage the NTP options for the entire system.

enable

Enables the use of the network timing protocol for updating the system clock.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
enable [ context ]
```

context

Default: local

Specifies the context for which NTP is to be enabled. *name* must refer to a previously configured context.

Usage

Set the NTP server to be used for the system. Only one NTP server may be active at any given time. If this command were issued in a different context followed by the current context, the prior context's NTP server would be disabled and the current context's NTP server would be used.

If any NTP server is enabled, the chassis system clock will be synchronized to the active NTP server which covers all contexts for timing synchronization.

The use of a given context for NTP server assignment is to inherit the domain and IP routing options of the configured context.

Example

```
enable sampleContext
```

end

Exits the NTP configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the NTP configuration mode and returns to the global configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

server

Configures an NTP server for use by the local NTP client in synchronizing the system clock.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
server ip_address [ prefer ] [ version number ] [ minpoll poll_period ] [ maxpoll poll_period ]
```

```
no server ip_address
```

no

Indicates the server specified is to be removed from the list of NTP servers for clock synchronization.

ip_address

Specifies the IP address of the NTP server to allow for clock synchronization. *ip_address* must be specified using the standard IPv4 dotted decimal notation.

prefer

Indicates the NTP server specified to be the preferred server. Only one server can be set to preferred. The preferred server is first contacted for clock synchronization.

Important: Use of the prefer keyword is not recommended.

version *number*

Default: 4

Specifies the network timing protocol version to use for server communications. *number* must be a value in the range from 1 to 4.

minpoll *poll_period*

Default: 6

Specifies the minimum polling interval for NTP messages, in seconds, as a power of 2. *poll_period* is the power or exponent. For example, if you specify the number 10, the value is 2¹⁰ and the resultant poll period is 1024 seconds. *poll_period* must be an integer from 6 through 17.

maxpoll *poll_period*

Default: 10

Specifies the maximum polling interval for NTP messages, in seconds, as a power of 2. *poll_period* is the power or exponent. For example, if you specify the number 10, the value is 2¹⁰ and the resultant poll period is 1024 seconds. *poll_period* must be an integer from 6 through 17.

Usage

Configure the network timing protocol servers in the network as changes occur.

Important: Adding, removing, or modifying an NTP server configuration entry causes the NTP client to restart and restart the synchronization process with all configured NTP servers.

Example

The following command adds the NTP server with address `1.2.3.4` to the list of NTP servers.

```
server 1.2.3.4
```

The following marks the server with IP address 1.2.3.4 as the preferred NTP server.

```
server 1.2.3.4 prefer
```

Chapter 181

Operator Policy Configuration Mode

Operator Policy configuration mode associates APNs, APN profiles, IMEI ranges, IMEI profiles, an APN remap table and a call-control profile to an operator policy. These profiles and tables are created and defined within their own configuration modes to generate sets of rules and instructions that can be reused and assigned to multiple policies.

- A maximum of 1000 operator policies can be defined, this includes the ‘default’ operator policy.
- A maximum of 50 APN profiles can be associated with a single operator policy.
- A maximum of 10 IMEI profiles can be associated with a single operator policy.
- Only one APN remap table can be associated with a single operator policy.
- Only one call-control profile can be associated with a single operator policy.

Using the Operator Policy feature enables the operator to fine-tune any desired restrictions or limitations needed to control call handling per subscriber or for a group of callers across IMSI ranges.

apn

This command identifies an APN (access point name) and associates it with an APN profile (created separately in the APN Profile configuration mode).

Product

MME, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
apn { default-apn-profile apn_profile_name | network-identifier apn_net_id apn-profile apn_profile_name | operator-identifier apn_op_id apn-profile apn_profile_name }
```

```
no apn { default-apn-profile | network-identifier apn_net_id | operator-identifier apn_op_id }
```

no

Disables the specified APN to APN Profile correspondence.

default-apn-profile *apn_profile_name*

Enables the use of a default APN profile comprised of default values for all parameters. this profile will be used when none of the configured APNs match the APN in the incoming Request.

apn_profile_name : Enter a string of 1 to 64 alphanumeric characters.

apn-profile *apn_profile_name*

apn_profile_name : Enter a string of 1 to 64 alphanumeric characters.

network-identifier *apn_net_id*

Links the specified APN network ID with the specified APN profile.

apn_net_id : Enter a string of 1 to 63 alphanumeric characters, including dots (.) and dashes (-).

operator-identifier *apn_op_id*

Links the specified APN operator ID with the specified APN profile.

apn_op_id : Enter a string of 1 to 18 alphanumeric characters including dots (.). The entry must be in the following format, where # represents a digit: : MNC###.MCC###.GPRS.

Usage

Use this command, to associate APNs with APN profiles. This command can be repeated to associate multiple APNs with profiles.

Example

Associate the APN profile named *apnprof1* to APN network ID *starflash.com: cust1-net*:

```
apn network-identifier starflash.com
```

associate

Associate an APN remap table and a call-control profile with the operator policy.

Product

MME, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
associate { apn-remap-table table_id | call-control-profile profile_id }
```

```
no associate { apn-remap-table | call-control-profile }
```

no

Removes the association definition from the policy configuration.

apn-remap-table *table_id*

Identifies the APN remap table to be associated with the operator policy.

table_id: Enter a string of 1 to 65 alphanumeric characters.

call-control-profile *profile_id*

Identifies a call-control profile to be associated with the operator policy.

profile_id: Enter a string of 1 to 64 alphanumeric characters.

Usage

Use this command to associate an APN remap table and/or a call-control profile with this Operator Policy. The APN remap table and the call-control profile contain the definitions that instruct the SGSN or MME how to handle calls. Only one of each of these can be associated with an operator policy.

Example

Associate the *stardust.net_APNremap1* APN remap table with this operator policy:

```
associate apn-remap-table stardust.net_APNremap1
```

description

Set to a relevant descriptive string.

Product

MME, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
description description
```

```
no description
```

description

Enter an alphanumeric string of 1 to 100 alphanumeric characters. The string may include spaces, punctuation, and case-sensitive letters if the string is enclosed in double quotes (").

no

Removes the description configuration from this operator policy.

Usage

Define information that identifies this particular operator policy.

Example

```
description "sgsn1 operator policy carrier1"
```

■ end

end

Exits the configuration mode and returns to the Exec mode.

Product

MME, SGSN

Privilege

Security Administrator, Administrator

Syntax

end

exit

Exits the configuration mode and returns to the previous configuration mode.

Product

MME, SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

imei

Defines a range of IMEI (International Mobile Equipment Identity) numbers and associates an IMEI profile with the range definition.

Product

MME, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
imei range IMEI_number to IMEI_number { imei-profile profile_name | sv ## imei-profile profile_name }
```

```
no imei range IMEI_number to IMEI_number sv ##
```

no

Removes the IMEI definition from the policy configuration.

range *IMEI_number* **to** *IMEI_number*

Defines the beginning and end of a range of IMEIs.

IMEI_number : Enter up to 14 digits.

sv

Identifies the software version to fine-tune the IMEI definition. This keyword should only be included if the IMEISV is retrievable.

: Enter 2 digits.

imei-profile *profile_name*

Identify the IMEI profile that defines the actions appropriate to the devices identified within the specified range.

profile_name : Enter a string of 1 to 64 alphanumeric characters.

Usage

This command defines the IMEI ranges that will be used by the operator policy to determine if the device is appropriately selected for actions defined in the specified IMEI profile.

Example

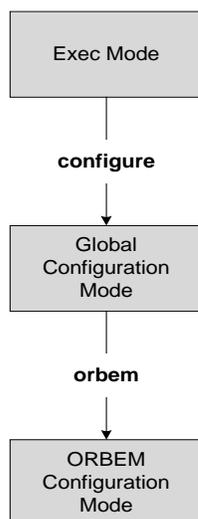

All devices with an IMEI of 123123* requesting Attach shall be subject to actions in the *blacklist_profile1*

```
imei range 1231230 to 1231239 imei-profile name blacklist_profile1
```

Chapter 182

ORBEM Configuration Mode Commands

The ORB Element Manager Configuration Mode is used to manage the ORBEM server options for the current context.

activate

Activates/deactivates a client for the ORB element management system interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
active client id
```

```
no active client id
```

no

Indicates the client specified is to be deactivated. When omitted, the client is activated.

id *name*

Specifies the client to be activated. *name* must refer to a previously configured client.

Usage

Activate clients after they have been configured or deactivated by the system or by configuration.

Example

```
active client sampleClient
```

```
no active client sampleClient
```

client

Configures/removes a client from the ORB element manager system interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
client id name [ encrypted ] password pwd
```

```
no client id name
```

no

Indicates the client specified is to be removed from the configuration.

id *name*

Specifies the client to be configured. *name* must be from 1 to 10 alpha and/or numeric characters in length.

encrypted

Indicates password specified is encrypted.

The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **password** keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

password *pwd*

Specifies the password for the client. *pwd* must be from 1 to 35 alpha and/or numeric characters.

Usage

Clients for ORB element manager access must be configured prior to being activated.

Example

The following commands set the password for client *sampleClient* specifying a plain text password and an encrypted password as well.

```
client id sampleClient password secretPassword
```

```
client id sampleClient encrypted password f54gj801sd
```

The following deletes *sampleClient* from the configuration.

```
no client id sampleClient
```

default

Restores the system default values for the option specified.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
default { event-notif-iiop-port | event-notif-service filter | event-notif-siop-
port | iiop-port | iop-address | max-attempt | session-timeout | siop-port }
```

event-notif-iiop-port

Restores the port number for the inter-ORB event notifications to the system default: 7778.

event-notif-service filter

Restores the ORB Notification Service filter to its default behavior of sending all “error” level and higher events, and “info” level events for the orbs facility, CLI command logs, and license change logs.

event-notif-siop-port

Restores the port to use for secure socket layer inter-ORB event communication to the system default: 7777.

iiop-port

Restores the port number for the inter-ORB communications to the system default: 14132.

iop-address

Restores the IP address for the inter-ORB communications to the system default: IP address of current context.

max-attempt

Restores the maximum number of failed login attempts before which the client is deactivated to the system default: 3 attempts.

session-timeout

restores the amount of idle time (no activity) before a session is terminated to the system default: 300 seconds.

siop-port

Restores the secure socket layer I/O port for inter-ORB events to the system default: 14131.

Usage

Restore the ORB element manager options to a well known values, the system defaults.

Example

```
default event-notif-iiop-port
```

```
default max-attempt
```

■ end

end

Exits the ORBEM configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

event-notif-iiop-port

Configures the port number for the Internet inter-ORB event notifications.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
event-notif-iiop-port number
```

number

Default: 7778

Specifies the port number to use as a number between 1 and 65535.

Usage

Explicitly set the port number when the default port number is not the desired port value for integrating multiple products together for standardized inter-ORB communications.

Event notification port configured is only used if the Internet inter-ORB transport is enabled via the **iiop-transport** command with the event notification service being enabled as well.

Example

```
event-notif-iiop-port 25466
```

event-notif-service

Enables/disables the ORB Notification Service and allows the configuration of filters dictating which event notifications are sent.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
event-notif-service [ filter { event-id event_id [ to final_event_id ] | facility event_facility level event_level } ]
```

```
no event-notif-service [ filter { event-id event_id [ to final_event_id ] | facility event_facility level event_level } ]
```

no

Indicates the event notification service is to be disabled.

filter

Allows the specification of a filter dictating which events the system sends notifications for.

event-id *event_id* [**to** *final_event_id*]

Specifies an event filter based on event identification (event ID) number.

event_id is a specific event ID to filter or is the initial event ID in range if the **to** keyword is used. It can be configured to any integer value between 1 to 100,000.

to allows the specification of a range of event IDs to filter. When used, *final_event_id* specifies the last event ID in the range to be filtered. It can be configured to any integer value between 1 to 100,000 but should be a value greater than the initial event ID.

facility *event_facility* **level** *event_level*

Specifies an event filter based on facility type and notification severity level.

event_facility specifies the facility type and can be any one of the following:

- **a10**: A10 interface facility
- **a11**: A11 interface facility
- **a11mgr**: A11 Manager facility
- **aaa-client**: AAA client facility
- **aaamgr**: AAA manager logging facility
- **aaaproxy**: AAA Proxy facility
- **acl-log**: Access Control List logging facility
- **acsctrl**: Active Charging Service (ACS) Controller facility
- **acsmgr**: Active Charging Service (ACS) Manager facility
- **alarmctrl**: Alarm Controller facility

- **all**: All facilities
- **asf**: Voice Application Server Framework logging facility
- **asfprt**: ASF Protocol Task (SIP) logging facility
- **asngwmgr**: ASN Gateway Manager facility
- **asnrmgr**: ASN Paging/Location-Registry Manager facility
- **bgp**: Border Gateway Protocol (BGP) facility
- **cli**: CLI logging facility
- **cscf**: IMS/MMD CSCF
- **cscfmgr**: SIP CSCF Manager facility
- **csp**: Card Slot Port controller facility
- **css**: Content Service Selection (CSS) facility
- **css-sig**: Content Service Selection (CSS) RADIUS Signaling facility
- **dcardctrl**: IPSEC Daughtercard Controller logging facility (not used at this time)
- **dcardmgr**: IPSEC Daughtercard Manager logging facility (Not used at this time)
- **dhcp**: DHCP facility (GGSN product only)
- **dhost**: Distributed Host logging facility
- **diameter**: Diameter endpoint logging facility
- **diameter-ecs**: ECS Diameter signaling facility
- **dpath**: IPSEC Data Path facility
- **drvctrl**: Driver Controller facility
- **evlog**: Event log facility
- **famgr**: Foreign Agent manager logging facility
- **gss-gcdr**: GTPP Storage Server GCDR facility
- **gtpc**: GTP-C protocol logging facility (GGSN product only)
- **gtpcmgr**: GTP-C protocol Manager logging facility (GGSN product only)
- **gtpp**: GTP-PRIME protocol logging facility (GGSN product only)
- **gtpu**: GTP-U protocol logging facility (GGSN product only)
- **h248prt**: H.248 Protocol logging facility
- **hamgr**: Home Agent manager logging facility
- **hat**: High Availability Task (HAT) process facility
- **ims-authorization**: IMS Authorization Service facility
- **ip-arp**: IP Address Resolution Protocol facility
- **ip-interface**: IP interface facility
- **ip-route**: IP route facility
- **ipsec**: IP Security logging facility
- **ipsgmgr**: IP Services Gateway facility
- **ipsp**: IP Pool Sharing Protocol logging facility

- **l2tp-control**: L2TP control logging facility
- **l2tp-data**: L2TP data logging facility
- **l2tpdemux**: L2TP Demux Manager logging facility
- **l2tpmgr**: L2TP Manager logging facility
- **li**: Refer to the *Cisco ASR 5000 Lawful Intercept Configuration Guide* for a description of this command.
- **mobile-ip**: Mobile IP processes
- **mobile-ip-data**: Mobile IP data facility
- **multicast-proxy**: Multicast Proxy logging facility
- **netwstrg**: Network Storage facility
- **npuctrl**: Network Processor Unit Control facility
- **npumgr**: Network Processor Unit Manager facility
- **nsctrl**: Charging Service Controller facility (supported in conjunction with ECSv1)
- **nsmgr**: Charging Service Manager facility
- **nsproc**: Charging Service process facility
- **orbs**: Object Request Broker System logging facility
- **ospf**: OSPF logging facility
- **ppp**: PPP link and packet facilities
- **radius-acct**: RADIUS accounting logging facility
- **radius-auth**: RADIUS authentication logging facility
- **radius-coa**: RADIUS change of authorization and radius disconnect
- **rct**: Recovery Control Task logging facility
- **rdt**: Redirect Task logging facility
- **resmgr**: Resource Manager logging facility
- **rip**: RIP logging facility (RIP is not supported at this time.)
- **rohc**: ROust Header Compression facility
- **rsvp**: Reservation Protocol logging facility
- **sct**: Shared Configuration Task logging facility
- **sessctrl**: Session Controller logging facility
- **sessmgr**: Session Manager logging facility
- **sft**: Switch Fabric Task logging facility
- **sipcdprt**: Sip Call Distributor facility
- **sitmain**: System Initialization Task main logging facility
- **snmp**: SNMP logging facility
- **srdb**: Static Rating Database
- **srp**: Service Redundancy Protocol (SRP) logging facility
- **ssh-ipsec**: SSH IP Security logging facility **stat**: Statistics logging facility

- **stat**: Statistics logging facility
- **system**: System logging facility
- **tacacsplus**: TACACS+ Protocol logging facility
- **threshold**: threshold logging facility
- **udr**: User detail record facility (used with the Charging Service)
- **user-data**: User data logging facility
- **user-l3tunnel**: User layer-3 tunnel logging facility
- **vpn**: Virtual Private Network logging facility
- **wimax-data**: WiMAX DATA
- **wimax-r6**: WiMAX R6

event_level

specifies the severity level of the event notification to filter and can be configured to one of the following:

- **critical** : display critical events
- **error** : display error events and all events with a higher severity level
- **warning** : display warning events and all events with a higher severity level
- **unusual** : display unusual events and all events with a higher severity level
- **info** : display info events and all events with a higher severity level
- **trace** : display trace events and all events with a higher severity level
- **debug** : display all events

Usage

This command is used to enable or disable the ORB Notification Service. Additionally, it can be used to configure filters dictating which events are sent. This service is disabled by default. Filters can be configured for a specific event identification number (event ID), a range of event IDs, or specific severity levels for events for particular facilities. When no filters are configured and the service is enabled, the ORB Notification Service sends all “error” level and higher events, and “info” level events for the orbs facility, CLI command logs, and license change logs. Multiple instance of this command can be executed to configure multiple filters.

Example

The following command enables the ORB Notification service:

```
event-notif-service
```

The following command disables the ORB Notification service:

```
no event-notif-service
```

The following command configures a filter for the ORB Notification Service allowing only event IDs 800 through 805 to be sent:

```
event-notif-service filter event-id 800 to 805
```

■ event-notif-service

The following command configures a filter for the ORB Notification Service allowing only “critical” level notifications for the A11 facility:

```
event-notif-service filter facility a11 level critical
```

event-notif-siop-port

Configures the port to use for secure socket layer inter-ORB event communication.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
event-notif-siop-port number
```

number

Default: 7777

Specifies the port number to use as a number between 1 and 65535.

Usage

Explicitly set the port number when the default port number is not the desired port value for integrating multiple products together for inter-ORB communications using SSL.

Example

```
event-notif-siop-port 25466
```

exit

Exits the ORBEM configuration mode and returns to the global configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

iiop-port

Configures the port number for the internet inter-ORB communications.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] iiop-port number
```

no

Disables the iiop port.

number

Default: 14132

Specifies the port number to use as a number between 1 and 65535.

Usage

Explicitly set the port number when the default port number is not the desired port value for integrating multiple products together for standardized inter-ORB communications.

Internet inter-ORB port is only used if the Internet inter-ORB transport is enabled via the **iiop-transport** command.

Example

```
iiop-port 25466
```

iiop-transport

Enables/disables use of the Internet Inter-ORB Protocol for management across the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
iiop-transport
```

```
no iiop-transport
```

```
no
```

Indicates no internet inter-ORB protocol communication is to take place across the network.

Usage

Enable the transport of Internet Inter-ORB Protocol messages to support remote management across the network.

The chassis is shipped from the factory with the Internet Inter-ORB transport disabled.

Example

The following commands enable and disable the ORB-based management across the network, respectively.

```
iiop-transport
```

```
no iiop-transport
```

iop-address

Enables/disables use of the Internet Inter-ORB Protocol for management across the network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
iop-address ip_address
```

ip_address

Specifies the IP address to use for inter-ORB communications for the current context. *ip_address* must be specified using the standard IPv4 dotted decimal notation.

Usage

Change the inter-ORB IP address when the IP address of the current context should not be used. The IP address of the local context may not be appropriate when the ORB configuration across nodes would cause conflicts with the IP addresses.

The chassis is shipped from the factory with the inter-ORB IP address defaulted to the IP address of the current context.

Example

```
iop-address 1.2.3.4
```

max-attempt

Configures the maximum number of failed login attempts before which the client is deactivated.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
max-attempt count
```

count

Default: 3 attempts

Specifies the number of failed login attempts prior to deactivating a client. The value must be within the range of 1 through 10.

Usage

Adjust the maximum number of attempts to a smaller value to increase the security level of the system.

Example

```
max-attempt 3
```

session-timeout

Configures the amount of idle time (no activity) before a client session is terminated.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
session-timeout seconds
```

seconds

Default: 300 seconds

Specifies the number of seconds of idle time before a client session is terminated. The value must be in the range of 1 through 86400.

Usage

Reduce the session timeout when the maximum number of sessions allowed is frequently being reached. Setting this to a lower value will help release idle sessions faster to allow use by other clients.

Example

```
session-timeout 1800
```

siop-port

Configures the secure socket layer I/O port for inter-ORB events.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
siop-port number
```

number

Default: 14131

Specifies the port number to use as a number between 1 and 65535.

Usage

Explicitly set the port number when the default port number is not the desired port value for integrating multiple products together for inter-ORB communications.

Example

```
siop-port 25466
```

ssl-auth-policy

Configures the secure socket layer peer authentication policy used by the ORBEM server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ssl-auth-policy { auth-none | auth-once | auth-once-fail | auth-peer | auth-  
peer-fail }
```

auth-none | auth-once | auth-once-fail | auth-peer | auth-peer-fail

Default: **auth-none**

auth-none: ORBEM server does not authenticate the peer

auth-once: ORBEM server authenticates the peer once (no fail)

auth-once-fail: ORBEM server authenticates the peer once (fail if no certificate)

auth-peer: ORBEM server authenticates the peer every time (no fail)

auth-peer-fail: ORBEM server authenticates the peer every time (fail if no certificate)

Usage

Use to configure the peer authentication policy used by the SSL transport of ORBEM.

Example

The following command sets the policy to authenticate the peer once without failure.

```
ssl-auth-policy auth-once
```

ssl-certificate

Defines the certificate to be used by the SSL transport of ORBEM.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ssl-certificate { string certificate | file url }
```

string *certificate*

Specifies an ORBEM SSL certificate. *certificate* is a string of up to 4096 alpha and/or numeric characters.

file *url*

Default: /usr/ssl/certs/orbscert.pem

Specifies an ORBEM SSL certificate file and location. *url* is a string of up to 1024 alpha and/or numeric characters.

Usage

Use to configure the certificate to be used by the SSL transport of ORBEM. Note that if file option is used, the certificate content is read from the url and converted into quoted string.

Example

The following command defines the certificate cert3.pem file as being located in the /usr/ssl/certs directory:

```
ssl-certificate file /usr/ssl/certs/cert3.pem
```

The following command defines the certificate string (the string shown is abbreviated):

```
ssl-certificate string
```

```
"-----BEGIN CERTIFICATE-----\n

```

ssl-private-key

Configures the SSL private key used by the ORBEM server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ssl-private-key { string key | file url }
```

string *key*

Specifies an ORBEM SSL private key. *key* is a string of up to 4096 alpha and/or numeric characters.

file *url*

Default: /usr/ssl/certs/orbscert.pem

Specifies the ORBEM SSL private key file location. *url* is a string of up to 1024 alpha and/or numeric characters.

Usage

Use to configure the private key to be used by the SSL transport of ORBEM. Note that if file option is used, the private key is read from the url and converted into quoted string.

Example

The following command defines the private-key cert3.pem file as being located in the /usr/ssl/certs directory:

```
ssl-private-key file /usr/ssl/certs/cert3.pem
```

The following command defines the private-key string (the string shown is abbreviated):

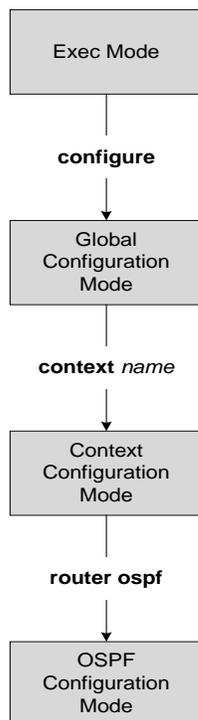

```
ssl-private-key string
```

```
"-----BEGIN RSA PRIVATE KEY-----\n\

```

Chapter 183

OSPF Configuration Mode Commands

The OSPF Configuration sub-mode is used to configure the OSPF routing protocol. This mode includes commands that configure OSPF routing parameters.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

area authentication

Enables authentication for the specified OSPF area.

Product

PDSN, HA GGSN

Privilege

Security Administrator, Administrator

Syntax

```
area { ipaddress | decimal_value } authentication [ message-digest ]  
no area { ipaddress | decimal_value } authentication [ message-digest ]
```

no

Disables authentication for the specified area.

ipaddress

IP address in IPv4 dotted-decimal notation of the area where authentication will be enabled.

decimal-value

The identification number of the area where authentication will be enabled. This must be an integer from 0 through 4294967295.

message-digest

Sets the OSPF authentication type to use the message digest 5 (MD5) authentication method.

Usage

Use this command to enable authentication of OPSF areas.

Example

The following command enables authentication for an OSPF area defined by the IP address *192.168.100.10* and the OSPF authentication type to MD5:

```
area 192.168.100.10 authentication message-digest
```

area default-cost

This command configures the default cost for an area.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
area { ipaddress | decimal_value } default-cost cost_value
```

```
no area { ipaddress | decimal_value } default-cost cost_value
```

no

Deletes the default cost for the area.

ipaddress

The IP address, in IPv4 dotted-decimal notation, of the area.

decimal-value

The identification number of the area. This must be an integer from 0 through 4294967295.

cost_value

The default cost to be configured for the specified area. This must be an integer from 0 through 16777215.

Usage

Use this command to configure the default cost for an OSPF area.

Example

The following command sets the default cost for an OSPF area defined by the IP address *192.168.100.10* to *300*:

```
area 192.168.100.10 default-cost 300
```

area nssa

Define an area as an NSSA (Not So Stubby Area) and configure OSPF parameters for it.

Product

PDSN, HA GGSN

Privilege

Security Administrator, Administrator

Syntax

```
area { ipaddress | decimal_value } nssa [ default-information-originate | no-
redistribution | no-summary | translate-always | translate-candidate |
translate-never ] [ no-redistribution ] [ no-summary ] [ translate-always ] [
translate-candidate ] [ translate-never ]
```

```
no area { ipaddress | decimal_value } nssa [ default-information-originate | no-
redistribution | no-summary | translate-always | translate-candidate |
translate-never ] [ no-redistribution ] [ no-summary ] [ translate-always ] [
translate-candidate ] [ translate-never ]
```

ipaddress

The IP address, in IPv4 dotted-decimal notation, of the NSSA area.

decimal-value

The identification number of the NSSA area. This must be an integer from 0 through 4294967295.

default-information-originate

Originate default information to the NSSA area

no-redistribution

Do not redistribute external routes to the NSSA area

no-summary

Do not inject inter-area routes into NSSA

translate-always

Configure NSSA-ABR to always translate

translate-candidate

Configure NSSA-ABR for translate election (This is enabled by default.)

translate-never

Configure NSSA-ABR to never translate

Usage

Use this command to define NSSA areas.

Example

The following command defines the area designated by the IP address *192.168.100.10* as an NSSA area:

```
area 192.168.100.10 nssa
```

area stub

This command defines an area as a stub area.

Product

PDSN, HAGGSN

Privilege

Security Administrator, Administrator

Syntax

```
area { ipaddress | decimal_value } stub [ no-summary ]  
no area { ipaddress | decimal_value } stub [ no-summary ]
```

ipaddress

The IP address, in IPv4 dotted-decimal notation, of the stub area.

decimal-value

The identification number of the stub area. This must be an integer from 0 through 4294967295.

no-summary

Disables (stops) the ABR from sending summary LSAs into the stub area.

Usage

Use this command to define an OPSF area as a stub area.

Example

The following command defines the OSPF area defined by the IP address *192.168.100.10* as a stub area:

```
area 192.168.100.10 stub
```

area virtual-link

This command configures a virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
area { ipaddress | decimal_value } virtual-link router_id_address  
no area { ipaddress | decimal_value } virtual-link router_id_address
```

no

Disables area virtual-link.

ipaddress

The IP address, in IPv4 dotted-decimal notation, of the transit area.

decimal-value

The identification number of the transit area. This must be an integer from 0 through 4294967295.

router_id_address

The router id, in dotted-decimal notation, of the ABR to be linked to.

Usage

Use this command to create a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.

Example

The following command creates a virtual link between the OSPF areas defined by the IP address *192.168.100.10* and the IP address *192.168.200.20*:

```
area 192.168.100.10 virtual-link 192.168.200.20
```

area virtual link authentication

This command configures the OSPF authentication method to be used by the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
area { ipaddress | decimal_value } virtual-link router_id_address authentication  
{ message-digest | null | text }
```

```
no area { ipaddress | decimal_value } virtual-link router_id_address  
authentication { message-digest | null | text }
```

no

Disables area virtual link authentication.

ipaddress

The IP address, in IPv4 dotted-decimal notation, of the transit area.

decimal-value

The identification number of the transit area. This must be an integer from 0 through 4294967295.

router_id_address

The router id, in dotted-decimal notation, of the ABR to be linked to.

message-digest

Set the OSPF authentication type to use the message digest (MD) authentication method.

null

Set the OSPF authentication type to use no authentication, thus disabling either MD or clear text methods.

text

Set the OSPF authentication type to use the clear text authentication method.

Usage

Use this command to set the authentication method for a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.

Example

The following command sets the authentication method for a virtual link between the OSPF areas defined by the IP address *192.168.100.10* and the IP address *192.168.200.20* to use no authentication:

```
area 192.168.100.10 virtual-link 192.168.200.2 null
```

area virtual-link authentication-key

This command configures the authentication password for the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
area { ipaddress | decimal_value } virtual-link router_id_address
authentication-key [ encrypted password encrypted_authentication_key] password
authentication_key
```

```
no area { ipaddress | decimal_value } virtual-link router_id_address
authentication-key [ encrypted password encrypted_authentication_key] password
authentication_key
```

no

Disables area virtual link authentication key.

ipaddress

The IP address, in IPv4 dotted-decimal notation, of the transit area.

decimal-value

The identification number of the transit area. This must be an integer from 0 through 4294967295.

router_id_address

The router id, in dotted-decimal notation, of the ABR to be linked to.

encrypted password

encrypted_authentication_key is a string variable of size 1 to 523.

Use this if you are pasting a previously encrypted authentication key into the CLI command.

password *authentication_key*

The password to use for authentication. *authentication_key* is a string variable, from 1 through 16 alphanumeric characters, that denotes the authentication password. This variable is entered in clear text format.

Usage

Use this command to specify the authentication password for a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.

Example

The following command creates an authentication password of *123456* for a virtual link between the OSPF areas defined by the IP address *192.168.100.10* and the IP address *192.168.200.20*:

```
area 192.168.100.10 virtual-link 192.168.200.20 authentication-key password  
123456
```

area virtual link intervals

This command configures the interval or delay type, and the delay time in seconds, for the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
area { ipaddress | decimal_value } virtual-link router_id_address [ dead-interval value ] [ hello-interval value ] [ retransmit-interval value ] [ transmit-delay value ] [ dead-interval value ] [ hello-interval value ] [ retransmit-interval value ] [ transmit-delay value ]
```

```
no area { ipaddress | decimal_value } virtual-link router_id_address [ dead-interval value ] [ hello-interval value ] [ retransmit-interval value ] [ transmit-delay value ] [ dead-interval value ] [ hello-interval value ] [ retransmit-interval value ] [ transmit-delay value ]
```

no

Disables area virtual link intervals.

ipaddress

The IP address, in IPv4 dotted-decimal notation, of the area.

decimal-value

The identification number of the transit area. This must be an integer from 0 through 4294967295.

router_id_address

The router id, in dotted-decimal notation, of the ABR to be linked to.

dead-interval *value*

The interval, in seconds, that the router should wait, during which time no packets are received and after the router considers a neighboring router to be off-line. *value* must be an integer from 1 through 65535.

hello-interval *value*

The interval, in seconds before sending a hello packet. *value* must be an integer from 1 through 65535.

retransmit-interval *value*

The interval, in seconds, that router should wait before retransmitting a packet. *value* must be an integer from 1 through 3600.

transmit-delay *value*

The interval, in seconds, that the router should wait before transmitting a packet. *value* must be an integer from 1 through 3600.

Usage

Use this command to set the intervals or delay types for a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.

Example

The following command sets the retransmit interval for a virtual link between the OSPF areas defined by the IP address *192.168.100.10* and the IP address *192.168.200.20* to *60* seconds:

```
area 192.168.100.10 virtual-link 192.168.200.20 retransmit-interval 60
```

area virtual link message-digest-key

This command enables the use of MD5-based OSPF authentication for the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
area { ipaddress | decimal_value } virtual-link router_id_address message-digest-key key_id md5 [ encrypted password encrypted_authentication_key ] password authentication_key
```

```
no area { ipaddress | decimal_value } virtual-link router_id_address message-digest-key key_id md5 [ encrypted password encrypted_authentication_key ] password authentication_key
```

no

Disables area virtual link message digest key.

ipaddress

The IP address, in IPv4 dotted-decimal notation, of the transit area.

decimal-value

The identification number of the transit area. This must be an integer from 0 through 4294967295.

router_id_address

The router id, in dotted-decimal notation, of the ABR to be linked to.

message-digest-key *key_id*

Specifies the key identifier number. *key_id* must be an integer from 1 through 255.

encrypted password

encrypted_authentication_key is a string variable of size 1 to 523.

Used this if you are pasting a previously encrypted authentication key into the CLI command.

password *authentication_key*

The password to use for authentication. *authentication_key* is a string variable, from 1 through 16 alphanumeric characters, that denotes the authentication password. This variable is entered in clear text format.

Usage

Use this command to enable the use of MD5-based OSPF authentication for a virtual link between an area that is connected to the network backbone and an area that cannot be connected to the network backbone.

Example

The following command enables the use of MD5-based OSPF authentication for a virtual link between the OSPF areas defined by the IP address *192.168.100.10* and the IP address *192.168.200.20*, sets the MD5 Key ID to *25*, and the password to *123456*:

```
area 192.168.100.10 virtual-link 192.168.200.20 message-digest-key 25 md5  
password 123456
```

capability graceful-restart

This command configures graceful-restart. By default, capability is set to enabled.

Product

PDFN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
capability graceful-restart
```

```
no capability graceful-restart
```

no

Disables capability graceful-restart.

Usage

Use this command to configure graceful-restart.

Example

The following command configure capability graceful-restart:

```
capability graceful-restart
```

default-information originate

This command creates a default external route into an OSPF routing domain.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
default-information originate [ always ] [ metric metric_value ] [ metric-type {  
1 | 2 } ] [ route-map route_map_name ]
```

always

Indicates that the route should always be advertised, regardless of whether the software has a default route or not.

metric *metric_value*

Sets the OSPF metric used in creating the default route. This must be an integer from 1 through 16777214.

metric-type { 1 | 2 }

Sets the default route metric type.

1 : Sets the OSPF external link type for default routes to Type 1.

2 : Sets the OSPF external link type for default routes to Type 2.

route-map *route_map_name*

Specifies the name of the default route-map to be use. This must be specified as a string of 1 through 79 alphanumeric characters.

Usage

Use this command to set the default external route into an OSPF routing domain.

Example

The following command sets the default external route to originate from the routemap named *rmap1*:

```
default-information originate route-map rmap1
```

default metric

This command configures the default metric value for the OSPF routing protocol.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
default-metric metric_value
```

```
no default-metric
```

metric-value

The metric value to set. This must be an integer from 1 through 16777214. The default metric value setting is 26385.

no

Enables/Disables the followed option

Usage

Use this command to set the default metric for routes.

Example

The following command sets the default metric to 235:

```
default-metric 235
```

distance

This command configures the OSPF route administrative distances for all OSPF route types or based on specific route type.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
distance { distance_value | ospf { [ external distance_value ] [ inter-area
distance_value ] [ intra-area distance_value ] } }
```

```
no distance { distance_value | ospf { [ external distance_value ] [ inter-area
distance_value ] [ intra-area distance_value ] } }
```

distance_value

is an integer, ranging from 1 to 255, that sets OSPF route administrative distances. The default distance value is 110.

```
ospf { [ external distance_value ] [ inter-area distance_value ] [ intra-
area distance_value ] }
```

Set the distance value for the specified route type.

external *distance_value*: Set the OSPF route administrative distance for routes from other routing domains, learned by redistribution. This must be an integer from 1 through 255. The default is 110.

inter-area *distance_value*: sets the OSPF route administrative distance for routes from one routing area to another. This must be an integer from 1 through 255. The default is 110.

intra-area *distance_value*: sets the OSPF route administrative distance for all routes within an area. This must be an integer from 1 through 255. The default is 110.

no

Enables/Disables the followed option.

Usage

Use this command to set the administrative distance for OSPF routes.

Example

The following command sets the administrative distance for all OSPF route types to 30:

```
distance 30
```

distribute-list

This command enables the filtering of networks in outgoing routing updates.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
distribute-list route_access_list out { connected | rip | static }
```

```
nodistribute-list route_access_list out { connected | rip | static }
```

route_access_list

The name of the OSPF route access list to use. This is an alphanumeric string up to 63 characters in length.

connected

Filter connected routes.

rip

Filter RIP routes. (RIP is not supported at this time.)

static

Filter static routes.

no

Enables/Disables the followed option.

Usage

Use this command to enable the filtering of outgoing route updates by using the specified route access list.

Example

The following command uses the route access list named *ral1* to filter outgoing routing updates for all connected routes:

```
distribute-list ral1 out connected
```

end

Exits the NTP configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the NTP configuration mode and returns to the global configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

ip vrf

This command configures the VRF instances for OSPF routing protocol.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip vrf vrf_name
```

```
no ip vrf vrf_name
```

no

Disables the VRF instances and removes the configured VRF context association for OSPF routing.

vrf_name

vrf_name is name of a preconfigured virtual routing and forwarding (VRF) context configured in Context Configuration Mode through **ip vrf** command.

Usage

Use this command to configure the IP VRF forwarding also to associate the preconfigured VRF context with the specific tunnel interface.

This command creates and enters the OSPF VRF Configuration Mode if required to configure the VRF context instances for OSPF routing.

Example

The following command enables preconfigured VRF context instance *ospf_vrf1* for OSPF routing and enters the OSPF VRF Configuration mode:

```
ip vrf ospf_vrf1
```

neighbor

This command configures OSPF routers that interconnect to non-broadcast networks.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
neighbor ip_address [ poll-interval poll_interval_value ] [ priority  
priority_value ]
```

ip_address

The interface IP address of the OSPF neighbor. This must be an IP address entered in dotted-decimal notation.

poll-interval *poll_interval_value*

Default: 120

Set the number of seconds in the dead neighbor polling interval. This must be an integer from 1 through 65535

priority *priority_value*

Default: 0

Set the 8-bit number that represents the router priority value of the non-broadcast neighbor associated with the IP address specified. This must be an integer from 0 through 255. This keyword does not apply to point-to-multipoint interfaces.

Usage

Use this command to configure OSPF routers that connect to non-broadcast networks.

Example

The following command specifies an OSPF router neighbor with the IP address of *192.168.100.10*:

```
neighbor 192.168.100.10
```

network area

This command enables OSPF on an interface and defines the OSPF area for that network.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
network network_ip_address / network_mask area { area_id | area_ip_address }
```

network_ip_address/network_mask

The network address and mask that specify the interface on which OSPF will be enabled. This is entered in dotted-decimal notation, followed by the “/” and the mask. Example: 192.168.1.0/24.

area_id

The OSPF area identification number for the specified network. This must be an integer from 0 through 4294967295.

area_ip_address

The IP address of the OSPF area for the specified network. This must be entered in dotted-decimal notation.

Usage

Use this command to specify the IP address of the network interface that the OSPF router will use.

Example

The following command specified that the OSPF router will use the interface at IP address *192.168.1.0* with a netmask of *24*:

```
network 192.168.1.0/24
```

ospf graceful-restart

This command helps configure graceful-restart specific settings.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
ospf graceful-restart { grace-period grace_period / helper { never | policy {  
only-reload | only-upgrade } }
```

```
grace-period grace-period
```

OSPF graceful restart grace period (seconds) is the time in which OSPF restarts, it should be an integer between 1 to 1800. Default grace period is 60 seconds.

```
helper { never | policy }
```

Helps configure OSPF helper settings.

never: Specifies never as helper.

policy { only-reload | only-upgrade }: Allows ospf graceful-restart helper policy.

- only-reload: Allows ospf graceful-restart helper policy only-reload.

- only-upgrade: Allows ospf graceful-restart helper policy only-upgrade.

Default is ospf graceful-restart grace-period.

Usage

Use this command to configure graceful-restart specific settings.

Example

The following command sets the graceful restart grace period to 60 seconds:

```
ospf graceful-restart grace-period 60  
  
ospf graceful-restart helper policy only-reload  
  
ospf graceful-restart helper policy only-upgrade
```

ospf router-id

This command configures the router ID for the OSPF process.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
ospf router-id ip_address
```

```
no ospf router-id ip_address
```

ip_address

The router ID for the OSPF process. This must be an IP address entered in dotted-decimal notation

no

Disables the router ID for the OSPF process.

Usage

Use this command to set the router ID for the current OSPF router process.

Example

The following command sets the router ID to *192.168.200.1*:

```
ospf router-id 192.168.200.1
```

passive-interface

This command enables the suppression of OSPF routing updates on the specific interface.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
passive-interface interface_name
```

```
no passive-interface interface_name
```

interface_name

The name assigned to a logical interface within the specific context. An interface name can be from 1 through 79 alphanumeric characters.

no

Disables the name assigned to a logical interface within the specific context.

Usage

Use this command to suppress router updates on an interface in the current context.

Example

The following command suppresses OSPF routing updates on the interface named *Intfc1*:

```
passive-interface Intfc1
```

redistribute

This command redistributes routes into OSPF. This means that any routes from another protocol are redistributed to OSPF neighbors using the OSPF protocol.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
redistribute { bgp | connected | rip | static } [ metric metric_value ] [
metric-type { 1 | 2 } ] [ route-map route_map_name ]
no redistribute { bgp | connected | rip | static }
```

bgp

Specifies that BGP routes will be redistributed.

Important: BGP routing is only supported for use with the HA.

no

Disables the redistributed.

connected

Specifies that connected routes will be redistributed.

rip

Specifies that RIP routes will be redistributed. (RIP is not supported at this time.)

static

Specifies that static routes will be redistributed.

metric *metric_value*

Sets the OSPF metric used in the redistributed route. This must be an integer from 1 through 16777214.

metric-type { 1 | 2 }

Default: 2

Sets route metric type that is applied to redistributed routes.

1 : Sets the OSPF external link type for routes to Type 1.

2 : Sets the OSPF external link type for routes to Type 2.

■ redistribute

route-map *route_map_name*

Filter routes through the specified route map before redistribution. *route_map_name* specifies the name of the route-map to use and must be specified as a string of 1 through 79 alphanumeric characters.

Usage

Use this command to define what routing protocols should have their routes redistributed into OSPF.

Example

The following command defines that BGP routes should be redistributed:

redistribute bgp

refresh timer

This command adjusts the OSPF refresh timer.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
refresh timer value
```

```
no refresh timer value
```

no

Disables refresh timer.

value

Default: 10

The minimum amount of time, in seconds, to wait before refreshing an LSA. This must be an integer from 10 through 1800.

Usage

Use this command to define the amount of time to wait before refreshing an LSA.

Example

The following command sets the refresh timer to *90* seconds:

```
refresh timer 90
```

router-id

This command configures the router ID for the OSPF process.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
router-id ip_address
```

```
no router-id ip_address
```

no

Disables router ID for the OSPF process.

ip_address

The router ID for the OSPF process. This must be an IP address entered in dotted-decimal notation.

Usage

Use this command to set the router ID for the current OSPF router process.

Example

The following command sets the router ID to *192.168.200.1*:

```
router-id 192.168.200.1
```

timers spf

This command adjusts the SPF timers.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
timers spf delay_value hold_time_value
```

```
no timers spf
```

no

Disables SPF timers.

delay_value

Default: 5

The delay time, in seconds, between receiving changes to an SPF calculation. This must be an integer from 0 through 4294967295.

hold_time_value

Default: 10

The hold time, in seconds, between consecutive SPF calculations. This must be an integer from 0 through 4294967295.

Usage

Use this command to set the SPF delay and hold timers for the current OSPF router process.

Example

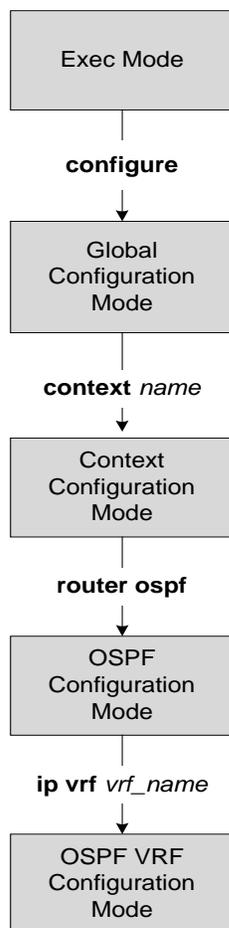

The following command sets the delay timer to *15* and the hold timer to *15*:

```
timers spf 15 15
```

Chapter 184

OSPF VRF Configuration Mode Commands

The OSPF VRF Configuration sub-mode is used to configure the virtual routing and forwarding (VRF) context instances for OSPF routing protocol. This mode includes commands that configure VRF instance for OSPF routing parameters.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

area

This command configures the various parameters, including authentication, area identification, virtual link id, delay/interval values for the specified OSPF area using specific VRF instance.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[no] area { decimal_value | ip_address } {authentication [ message-digest ] |
default-cost cost_value | nssa [default-information-originate] [no-
redistribution] [no-summary] [translate-always] [translate-candidate]
[translate-never] | stub [no-summary] | virtual-link router_ip_address
[authentication {message-digest | null | text}| authentication-key {encrypted
password encrypted_string | password password_string}| message-digest-key key_id
md5 [encrypted password encrypted_string | password password_string]} [dead-
interval] [hello-interval] [retransmit-interval] [transmit-delay]
```

no

Disables/removes configured parameters for the specified OSPF area using specific VRF instance.

ip_address

Specifies the IP address in IPv4 dotted-decimal notation, of the area where authentication will be enabled.

decimal_value

Specifies the identification number of the area where parameters to be configured. This must be an integer from 0 through 4294967295.

message-digest

Sets the OSPF authentication type to use the message digest 5 (MD5) authentication method.

default-cost *cost_value*

Sets the default cost for an OSPF area.

cost_value is the default cost to be configured for the specified area and must be an integer from 0 through 16777215.

nssa [default-information-originate] [no-redistribution no-summary] [translate-always] [translate-candidate] [translate-never]

Configures and defines an area as an NSSA (Not So Stubby Area) and configures OSPF parameters for it. **default-information-originate:** This optional keyword configures the OSPF VRF instances to originate default information to the NSSA area.

no-redistribution: This optional keyword configures the OSPF VRF instance to not to redistribute external routes to the NSSA area.

no-summary: This optional keyword configures the OSPF VRF instance to not to inject the inter-area routes into NSSA.

translate-always: This optional keyword configures the NSSA-ABR always to translate. By default this is disabled.

translate-candidate: This optional keyword configures the NSSA-ABR always to translate election. By default this is enabled.

translate-never: This optional keyword configures the NSSA-ABR never to translate. By default this is disabled.

stub [no-summary]

This keyword specifies an OSPF area as an stub area configures the NSSA-ABR never to translate. By default this is disabled.

no-summary: This optional keyword disables (stops) the ABR from sending summary LSAs into the stub area.

virtual-link *router_id*

Specifies the router identifier which provides a virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

router_id must be an IP address in IPv4 dotted-decimal notation of the ABR to be linked to.

authentication {message-digest | null | text}

Configures the OSPF authentication method to be used by the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

message-digest: Set the OSPF authentication type to use the message digest (MD) authentication method.

null: Set the OSPF authentication type to use no authentication, thus disabling either MD or clear text methods.

text: Set the OSPF authentication type to use the clear text authentication method.

authentication-key

Configures the authentication password for the virtual link between an area that cannot be physically connected to the network backbone and an area that is physically connected to the network backbone.

message-digest-key *key_id*

Specifies the MD key identifier number for virtual link connection.

key_id must be an integer from 1 through 255.

md5

Sets the message digest to MD5 for virtual link connection.

[encrypted] password *passwd_string*

Specifies the password required for virtual link connection authentications. The keyword **password** is optional and if specified *passwd_string* must be from 1 to 63 alpha and/or numeric characters. The password specified must be in an encrypted format if the optional keyword **encrypted** was specified. The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **password** keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file. *encrypted_string* is a string of size 1 to 523.

dead-interval *value*

Specifies the dead interval, in seconds, that the router should wait, during which time no packets are received and after the router considers a neighboring router to be off-line. *value* must be an integer from 1 through 65535.

hello-interval *value*

Specifies the hello interval, in seconds before sending a hello packet. *value* must be an integer from 1 through 65535.

retransmit-interval *value*

Specifies the delay between retransmission, in seconds, that router should wait before retransmitting a packet. *value* must be an integer from 1 through 3600.

transmit-delay *value*

Specifies the interval, in seconds, that the router should wait before transmitting a packet. *value* must be an integer from 1 through 3600.

Usage

Use this command to configure/set the various network/connection/authentication parameters of OSPF areas using specific VRF instance.

Example

The following command enables authentication for an OSPF area defined by the IP address `192.168.100.10` and the OSPF authentication type to MD5:

```
area 192.168.100.10 authentication message-digest
```

The following command sets the default cost for an OSPF area defined by the IP address `192.168.100.10` to `300`:
The following command defines the area designated by the IP address `192.168.100.10` as an NSSA area where translation of NSSA candidate is enabled by default:

```
area 192.168.100.10 nssa
```

The following command defines the OSPF area defined by the IP address `192.168.100.10` as a stub area:

```
area 192.168.100.10 stub
```

The following command creates a virtual link between the OSPF areas defined by the IP address `192.168.100.10` and the IP address `192.168.200.20`:

```
area 192.168.100.10 virtual-link 192.168.200.20
```

The following command sets the authentication method for a virtual link between the OSPF areas defined by the IP address `192.168.100.10` and the IP address `192.168.200.20` to use no authentication:

```
area 192.168.100.10 virtual-link 192.168.200.2 null
```

The following command creates an authentication password of `123456` for a virtual link between the OSPF areas defined by the IP address `192.168.100.10` and the IP address `192.168.200.20`:

```
area 192.168.100.10 virtual-link 192.168.200.20 authentication-key password 123456
```

The following command enables the use of MD5-based OSPF authentication for a virtual link between the OSPF areas defined by the IP address `192.168.100.10` and the IP address `192.168.200.20`, sets the MD5 Key ID to `25`, and the password to `123456`:

```
area 192.168.100.10 virtual-link 192.168.200.20 message-digest-key 25 md5 password 123456
```

The following command sets the retransmit interval for a virtual link between the OSPF areas defined by the IP address `192.168.100.10` and the IP address `192.168.200.20` to `60` seconds:

```
area 192.168.100.10 virtual-link 192.168.200.20 retransmit-interval 60
```

default-information originate

This command creates a default external route into an OSPF routing domain.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
default-information originate [always] [ metric metric_value ] [ metric-type { 1 | 2 } ] [ route-map route_map_name ]
```

```
nodefault-information originate [always] [ metric metric_value ] [ metric-type { 1 | 2 } ] [ route-map route_map_name ]
```

no

Disables **default-information**.

always

Indicates that the route should always be advertised, regardless of whether the software has a default route or not.

metric *metric_value*

Sets the OSPF metric used in creating the default route. This must be an integer from 1 through 16777214.

metric-type { 1 | 2 }

Sets the default route metric type.

1: Sets the OSPF external link type for default routes to Type 1.

2: Sets the OSPF external link type for default routes to Type 2.

route-map *route_map_name*

Specifies the name of the default route-map to be use. This must be specified as a string of 1 through 79 alphanumeric characters.

Usage

Use this command to set the default external route into an OSPF routing domain.

Example

The following command sets the default external route to originate from the routemap named *rmap1*:

```
default-information originate route-map rmap1
```

default metric

This command configures the default metric value for the OSPF routing protocol.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
default-metric metric_value
```

```
no default-metric
```

metric_value

The metric value to set. This must be an integer from 1 through 16777214. The default metric value setting is 26385.

no

Disables **default-metric**.

Usage

Use this command to set the default metric for routes.

Example

The following command sets the default metric to 235:

```
default-metric 235
```

■ end

end

Exits the NTP configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the NTP configuration mode and returns to the global configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

neighbor

This command configures OSPF routers that interconnect to non-broadcast networks.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
neighbor ip_address [poll-interval poll_inter_value] [priority priority_value]
```

```
no neighbor ip_address [poll-interval poll_inter_value] [priority priority_value]
```

no

Disables **neighbor** IP address.

ip_address

The interface IP address of the OSPF neighbor. This must be an IP address entered in dotted-decimal notation.

poll-interval *poll_inter_value*

Default: 120

Set the number of seconds in the dead neighbor polling interval. This must be an integer from 1 through 65535

priority *priority_value*

Default: 0

Set the 8-bit number that represents the router priority value of the non-broadcast neighbor associated with the IP address specified. This must be an integer from 0 through 255. This keyword does not apply to point-to-multipoint interfaces.

Usage

Use this command to configure OSPF routers that connect to non-broadcast networks.

Example

The following command specifies an OSPF router neighbor with the IP address of *192.168.100.10*:

```
neighbor 192.168.100.10
```

network area

This command enables OSPF on an interface and defines the OSPF area for that network.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
network ip_address/ip_mask area { area_id | area_ip_address }  
no network ip_address/ip_mask area { area_id | area_ip_address }
```

no

Disables **network** *ip_address*.

ip_address/ip_mask

The network address and mask that specify the interface on which OSPF will be enabled. This is entered in dotted-decimal notation, followed by the “/” and the mask. Example: 192.168.1.0/24.

area_id

The OSPF area identification number for the specified network. This must be an integer from 0 through 4294967295.

area_ip_address

The IP address of the OSPF area for the specified network. This must be entered in dotted-decimal notation.

Usage

Use this command to specify the IP address of the network interface that the OSPF router will use.

Example

The following command specified that the OSPF router will use the interface at IP address *192.168.1.0* with a netmask of *24*:

```
network 192.168.1.0/24
```

ospf router-id

This command configures the router ID for the OSPF process.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
ospf router-id ip_address
```

```
no ospf router-id ip_address
```

no

Disables **ospf router-id**.

ip_address

The router ID for the OSPF process. This must be an IP address entered in dotted-decimal notation

Usage

Use this command to set the router ID for the current OSPF router process.

Example

The following command sets the router ID to *192.168.200.1*:

```
ospf router-id 192.168.200.1
```

passive-interface

This command enables the suppression of OSPF routing updates on the specific interface.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
passive-interface interface_name
```

```
no passive-interface interface_name
```

no

Disables **passive-interface**.

interface_name

The name assigned to a logical interface within the specific context. An interface name can be from 1 through 79 alphanumeric characters.

Usage

Use this command to suppress router updates on an interface in the current context.

Example

The following command suppresses OSPF routing updates on the interface named *Intfc1*:

```
passive-interface Intfc1
```

redistribute

This command redistributes routes into OSPF. This means that any routes from another protocol are redistributed to OSPF neighbors using the OSPF protocol.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
redistribute {connected | rip | static} [metric value] [metric-type {1 | 2} ] [
route-map route_map_name ]
```

```
no redistribute {connected | rip | static} [metric value ] [metric-type {1 | 2}
] [ route-map route_map_name ]
```

no

Disables **redistribute**.

connected

Specifies that connected routes will be redistributed.

rip

Specifies that RIP routes will be redistributed. (RIP is not supported at this stage.)

static

Specifies that static routes will be redistributed.

metric value

Sets the OSPF metric used in the redistributed route.
value must be an integer from 1 through 16777214.

metric-type {**1** | **2**}

Default: 2

Sets route metric type that is applied to redistributed routes.

1: Sets the OSPF external link type for routes to Type 1.

2: Sets the OSPF external link type for routes to Type 2.

route-map *route_map_name*

Filter routes through the specified route map before redistribution. *route_map_name* specifies the name of the route-map to use and must be specified as a string of 1 through 79 alphanumeric characters.

Usage

Use this command to define what routing protocols should have their routes redistributed into OSPF.

Example

The following command defines that static routes should be redistributed in an OSPF area:

```
redistribute static
```

refresh timer

This command adjusts the OSPF refresh timer.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
refresh timer value
```

```
no refresh timer value
```

no

Disables **refresh timer**.

value

Default: 10

The minimum amount of time, in seconds, to wait before refreshing an LSA. This must be an integer from 10 through 1800.

Usage

Use this command to define the amount of time to wait before refreshing an LSA.

Example

The following command sets the refresh timer to 90 seconds:

```
refresh timer 90
```

router-id

This command configures the router ID for the OSPF process.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
router-id ip_address
```

```
no router-id ip_address
```

no

Disables **router-id** *ip_address*.

ip_address

The router ID for the OSPF process. This must be an IP address entered in dotted-decimal notation

Usage

Use this command to set the router ID for the current OSPF router process.

Example

The following command sets the router ID to *192.168.200.1*:

```
router-id 192.168.200.1
```

timers spf

This command adjusts the Shortest Path First (SPF) timers.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
timers spf delay_value hold_time_value
```

no timers spf

no

Disables **timers spf**.

delay_value

Default: 5

The delay time, in seconds, between receiving changes to an SPF calculation. This must be an integer from 0 through 4294967295.

hold_time_value

Default: 10

The hold time, in seconds, between consecutive SPF calculations. This must be an integer from 0 through 4294967295.

Usage

Use this command to set the SPF delay and hold timers for the current OSPF router process.

Example

The following command sets the delay timer to *15* and the hold timer to *15*:

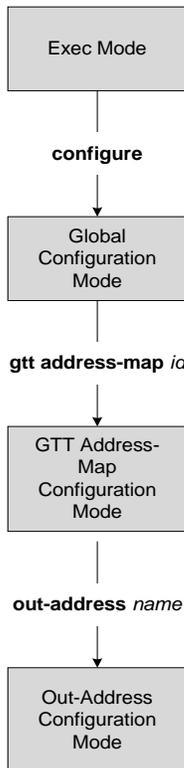

```
timers spf 15 15
```

Chapter 185

Out-Address Configuration Mode Commands

The Out-Address configuration mode provides the commands to configure the outgoing addresses for SCCP entities. In this mode, the prompt line will appear similar to:

```
[local]hostname(config-gtt-addrmap-outaddr-<name>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the configuration mode and returns to the Global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Global configuration mode.

gt-address

Configures the SCCP short address.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gt-address gt_address
```

gt_address

A string of 1 to 15 digits to define the GT-address

Usage

Define the GT-address

Example

```
gt-address 010405525397
```

gt-format

The GT-format provides four formats that can be used during GTT.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gt-format format_num
```

format_num

1: Selects GT-format 1 options which include **nature-of-address** and **odd/even**. Once selected, the system enters GT-Format1 configuration mode.

2: Selects GT-format2 options which include **translation-type**. Once selected, the system enters GT-Format2 configuration mode.

3: Selects GT-format3 options which include **encoding-scheme**, **numbering-plan3** and **translation-type**. Once selected, the system enters GT-Format1 configuration mode.

4: Selects GT-format4 options which include **encoding-scheme**, **nature-of-address**, **numbering-plan**, and **translation-type**. Once selected, the system enters GT-Format4 configuration mode.

Usage

Select the a GT-format that include encoding-scheme as part of the GTT process.

Example

```
gt-format 3
```

ni-indicator

Configures the National and International indicator to use during the GTT process.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ni-indicator ni_ind
```

ni_ind

Select one of the following as the appropriate type of national indicator for the address structure:

- national**
- international**

Usage

Select the international indicator to be used for out-going addresses.

Example

```
ni-indicator international
```

point-code

Selects and configures the SS7-type point code for use with the out-going address.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
point-code pt_code
```

pt_code

Enter 1 to 11 digits in the point code format predefined during variant selection of GTT association.

Usage

Define an ITU point code to be used for out-going address processing.

Example

```
point-code 6.255.6
```

routing-indicator

Selects the type of routing and the indicator to be included in the out-going message.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
routing-indicator routing_ind
```

routing_ind

Select one of the following options:

- **gt**: Inserts an indicator that identifies routing based on global title.
- **ssn**: Inserts an indicator that identifies routing based on the subsystem number.

Usage

Select global title as the appropriate routing indicator.

Example

```
routing-indicator gt
```

ssf

Selects the subservice field as factor in the out-going address processing. **ssf** sets the network indicator in the subservice field for SS7 Message Signal Units (MSUs). The indicator carried in the message's routing information typically identifies the structure of the point code as a message from within a nation or as a message coming from outside the national - international.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ssf sub_svc_fld
```

sub_svc_fld

Select one of the following options:

- **international**: The network indicator identifies the message as international with a point code structure that does not match the national point code structure,
- **national**: The network indicator identifies the messages as having a national point code structure.
- **reserved**: Provides an alternate network indicator for national messages.
- **spare**: Provides an alternate network indicator for international messages.

Usage

Select the international NI for inclusion in out-going address subservice fields.

Example

```
ssf international
```

ssn

Selects the subsystem number to be included in the out-going message.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ssn sub_sys_num
```

sub_sys_num

Enter an integer from 1 to 255.

Usage

Use subsystem number 44 in the out-going address.

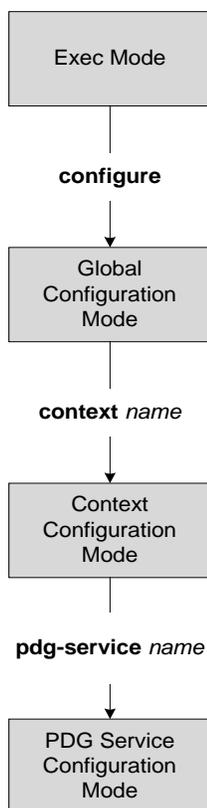

Example

```
ssn 44
```

Chapter 186

PDG Service Configuration Mode Commands

The PDG Service Configuration Mode is used to specify the properties required for the UEs in the WLAN (Wireless Local Access Network) to interface with the PDG/TTG.

aaa attribute

Sets the attributes that the system uses in AAA messages.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
aaa attribute { 3gpp-negotiated-qos-profile string }
```

```
no aaa attribute
```

```
3gpp-negotiated-qos-profile string
```

Specifies the 3GPP negotiated QoS profile to use in AAA messages during IMS emergency call handling. *string* must be in the range of 1 to 31 characters.

```
no aaa attribute
```

Removes a previously configured AAA attribute.

Usage

Specifies the 3GPP negotiated QoS profile to use in AAA messages during IMS emergency call handling.

Example

The following command specifies the 3GPP negotiated QoS profile to use during IMS emergency call handling:

```
aaa attribute 3gpp-negotiated-qos-profile 100
```

associate sgtp-service

Identifies the SGTP service to be associated with the PDG service to enable TTG functionality on the PDG/TTG. TTG functionality supports GTP-C (GTP control plane) messaging and GTP-U (GTP user data plane) messaging between the TTG and the GGSN over the Gn' interface.

Important: This command can be used before the associated service instance is created and configured but care should be used to match the service names.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] associate sgtp-service sgtp_service_name [ context sgtp_context_name ]
```

no

Removes the service association definition from the configuration.

sgtp-service *sgtp_service_name*

Specifies which SGTP service configuration, by naming the SGTP service instance, to associate with this PDG service.

sgtp_service_name must be a string of 1 through 63 alpha and/or numeric characters with no spaces.

context *sgtp_context_name*

Defines the context in which the SGTP service was created. If no context is specified, the current context is used.

sgtp_context_name must be a string of 1 through 63 alpha and/or numeric characters with no spaces.

Usage

Use this command to associate the SGTP service to be associated with the PDG service to enable TTG functionality on the PDG/TTG.

Example

The following command associates SGTP service *sgtp_service_1* with this PDG service:

```
associate sgtp-service sgtp_service_1 context sgtp_context_1
```

certificate-selection

Configures the PDG/TTG to select the trusted certificate (and the private key for calculating the AUTH payload) to be included in the first IKE_AUTH message from the PDG/TTG based on the APN (Access Point Name). The selected certificate is associated with the APN included in the IDr payload of the first IKE_AUTH message from the UE.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] certificate-selection apn-based
```

```
default certificate-selection
```

```
certificate-selection apn-based
```

Selects a trusted certificate for the first IKE-AUTH message based on the APN.

```
no certificate-selection
```

Disables APN-based certificate selection and resumes sending a certificate bound to a crypto template.

```
default certificate-selection
```

Sets the default certificate selection method to a certificate bound to a crypto template.

Usage

Configures the PDG/TTG to select the trusted certificate to be included in the first IKE_AUTH message based on the APN.

Example

Use the following example to enable APN-based certificate selection:

```
certificate-selection apn-based
```

bind

Binds the PDG service IPv4 address to a crypto template and specifies the maximum number of sessions the PDG service supports.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] bind address ipv4_address { crypto-template string } mode { ttg | pdg } [
max-sessions number ]
```

no

Removes a previously configured binding.

bind address ipv4_address

Specifies the IPv4 address of the PDG service with which the UE attempts to establish an IKEv2/IPSec tunnel. This address must be a valid IP address within the context.

This is a mandatory parameter.

crypto-template string

Specifies the name of the crypto template to be bound to the PDG service. This is the name of the IPsec policy to be used as a template for PDG/TTG subscriber session IPsec policies. The crypto template includes most of the IPsec and IKEv2 parameters for keepalive, lifetime, NAT-T, and cryptographic and authentication algorithms. There must be one crypto template per PDG service.

This is a mandatory parameter.

string is any value from 0 - 127 alpha and/or numeric characters.

mode { ttg | pdg }

Default: There is no default value.

Specifies whether the PDG service provides TTG or PDG functionality, as follows:

- In TTG mode, PDN connectivity is provided through the GGSN. PDG functionality is provided by the combined TTG and GGSN.
- In PDG mode, PDN connectivity and PDG functionality are provided directly through the PDG service.

This is a mandatory parameter.

Important: PDG mode is not supported in this software release.

Dependencies:

When you configure the PDG service to be in TTG mode, you must also configure the SGTP service using the **associate sgtp-service** command, as the TTG needs to connect with the GGSN to complete the PDG functionality.

The following behaviors occur when the PDG service operates in TTG mode:

- If the SGTP service associated with PDG service is not configured, the PDG service is not started.
- If the SGTP service associated with PDG service is not started, the PDG service is not started.
- If the SGTP service associated with PDG service is stopped, the PDG service is stopped.
- If the SGTP service associated with PDG service is re-started, the PDG service is re-started.
- If the SGTP service is not yet configured, whenever the SGTP service is started, the PDG service is started.

Note that starting or stopping the PDG service has no impact on the SGTP service.

max-sessions *number*

Default: 1000000

Specifies the maximum number of sessions to be supported by the PDG service.

number can be any integer value from 0 - 1000000.

If the max-sessions value is changed on an existing system, the new value takes effect immediately if it is higher than the current value. If the new value is lower than the current value, existing sessions remain established, but no new sessions are permitted until usage falls below the newly-configured value.

Usage

Use this command in PDG Service Configuration Mode to bind the IP address used as the connection point for establishing IKEv2/IPSec sessions to a crypto template. You can also use it to define the maximum number of sessions the PDG service supports.

Example

The following command binds a PDG service with an IP address of *1.2.3.4* to the crypto template *crypto_template_1*, sets the mode to TTG, and sets the maximum number of sessions to *500000*:

```
bind address 1.2.3.4 crypto-template crypto_template_1 mode ttg max-sessions 500000
```

ip gnp-qos-dscp

Configures the quality of service (QoS) differentiated service code point (DSCP) used when sending data packets over the Gn' interface in the uplink direction.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip gnp-qos-dscp { background dscp | conversationaldscp | interactive dscp | streaming dscp | interactive [ traffic-handling-priority traffic_priority ] { allocation-retention-priority allocation_retention_priority } } +
```

```
default ip gnp-qos-dscp
```

no

Disables the overriding of the ToS (Type of Service) field and enables the pass-through option.

background dscp

Specifies the DSCP marking to be used for packets of sessions subscribed to the 3GPP background class, in which the data transfer is not time-critical (for example, in e-mail exchanges). This traffic class is the lowest QoS.

dscp : Set the DSCP for the specified traffic class. See the *dscp* section below.

conversational dscp

Specifies the DSCP marking to be used for packets of sessions subscribed to the 3GPP conversational class, in which there is a constant flow of traffic in both the uplink and downlink direction. This traffic class is the highest QoS.

dscp: Set the DSCP for the specified traffic pattern. See the *dscp* section below.

interactive [traffic-handling-priority traffic_priority]

Specifies the DSCP marking to be used for packets of sessions subscribed to three possible traffic priorities in the 3GPP interactive class, in which there is an intermittent flow of packets in the uplink and downlink direction. This traffic class has a higher QoS than the background class, but not as high as the streaming class. *traffic_priority* is the 3GPP traffic handling priority and can be the integers 1,2 or 3.

allocation-retention-priority allocation_retention_priority

Specifies the DSCP for the interactive class if the allocation priority is present in the QoS profile.

allocation-retention-priority can be the integers 1, 2, or 3.

DSCP uses the values in the following table based on the traffic handling priority and allocation/retention priority if the allocation priority is present in the QOS profile.

Allocation Priority	1	2	3
Traffic Handling Priority			

Allocation Priority	1	2	3
1	ef	ef	ef
2	af21	af21	af21
3	af21	af21	af21

Important: If you only configure DSCP marking for interactive traffic classes without specifying ARP, it may not properly take effect. The CLI allows this scenario for backward compatibility however, it is recommended that you configure all three values.

streaming *dscp*

Specifies the DSCP marking to be used for packets of sessions subscribed to the 3GPP streaming class, in which there is a constant flow of data in either in the uplink or downlink direction. This traffic class has a higher QoS than the interactive class, but not as high as the conversational class.

dscp: Set the DSCP for the specified traffic pattern. See the *dscp* section below.

dscp

Default:

- background: be
- interactive
- Traffic Priority 1: ef
- Traffic Priority 1: af21
- Traffic Priority 1: af21
- streaming: af11
- conversational: ef

Specifies the DSCP for the specified traffic pattern. *dscp* can be configured to any one of the following:

• af11: Assured Forwarding 11 per-hop-behavior (PHB)	• af33: Assured Forwarding 33 PHB
• af12: Assured Forwarding 12 PHB	• af41: Assured Forwarding 41 PHB
• af13: Assured Forwarding 13 PHB	• af42: Assured Forwarding 42 PHB
• af21: Assured Forwarding 21 PHB	• af43: Assured Forwarding 43 PHB
• af22: Assured Forwarding 22 PHB	• be: Best effort forwarding PHB
• af23: Assured Forwarding 23 PHB	• ef: Expedited forwarding PHB

<ul style="list-style-type: none"> af31: Assured Forwarding 31 PHB 	
<ul style="list-style-type: none"> af32: Assured Forwarding 32 PHB 	

+

More than one of the above keywords can be entered within a single command.

Usage

DSCP levels can be assigned to specific traffic patterns in order to ensure that data packets are delivered according to the precedence with which they're tagged. The diffserv markings are applied to the IP header of every subscriber data packet transmitted over the Gn' interface(s).

The four traffic patterns have the following order of precedence: background (lowest), interactive, streaming, and conversational (highest). Data packets falling under the category of each of the traffic patterns are tagged with a DSCP that further indicate their precedence as shown in the following tables:

Drop Precedence	Class			
	Class 1	Class 2	Class 3	Class 4
Low	af11	af21	af31	af41
Medium	af12	af22	af32	af41
High	af13	af23	af33	af43

Precedence (low to high)	DSCP
1	Best Effort (be)
2	Class 1
3	Class 2
4	Class 3
5	Class 4
6	Express Forwarding (ef)

The DSCP level can be configured for multiple traffic patterns within a single instance of this command.

Example

The following command configures the DSCP level for the streaming traffic pattern to be ef:
`ip gnp-qos-dscp streaming ef`

The following command configures the DSCP levels for the conversational, streaming, interactive and background traffic patterns to be ef, ef, af22, and af41, respectively:
`ip gnp-qos-dscp conversational ef streaming ef interactive af22 background af41`

ip qos-dscp

Configures the quality of service (QoS) differentiated service code point (DSCP) used when sending data packets over the Wu interface in the downlink direction.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
ip qos-dscp { qci { 1 { dscp-pt } | 2 { dscp-pt } | 3 { dscp-pt } | 4 { dscp-pt }
| 5 { allocation-retention-priority 1..3 | dscp-pt } | 6 { allocation-
retention-priority 1..3 | dscp-pt } | 7 { allocation-retention-priority 1..3dscp
| dscp-pt } | 8 { allocation-retention-priority 1..3 | dscp-pt } | 9 { dscp-pt }
+ }
```

```
no ip qos-dscp { qci { 1 | 2 | 3 | 4 | 5 { allocation-retention-priority 1..3 |
dscp-pt } | 6 { allocation-retention-priority 1..3 | dscp-pt } | 7 { allocation-
retention-priority 1..3 | dscp-pt } | 8 { allocation-retention-priority 1..3 |
dscp-pt } | 9 {+
```

allocation-retention-priority

Specifies the DSCP for interactive class if the allocation priority is present in the QoS profile.

allocation-retention-priority can be the integers 1, 2, or 3.

DSCP values use the following matrix to map based on traffic handling priority and Alloc/Retention priority if the allocation priority is present in the QoS profile.

The following table shows the DSCP value matrix for *allocation-retention-priority*.

Table 32. Default DSCP Value Matrix

	Allocation Priority 1	Allocation Priority 2	Allocation Priority 3
Traffic Handling Priority			
1	ef	ef	ef
2	af21	af21	af21
3	af21	af21	af21

qci

Configures the qci attribute of QoS. Here the *qci_val* is the QCI for which the negotiate limit is being set, it ranges from 1 to 9.

dscp

Default QCI:

- 1: ef
- 2: ef
- 3: af11
- 4: af11
- 5: ef
- 6: ef
- 7: af21
- 8: af21
- 9: be

Specifies the DSCP for the specified traffic pattern. *dscp* can be configured to any one of the following:

• af11: Assured Forwarding 11 per-hop-behavior (PHB)	• af32: Assured Forwarding 32 PHB
• af12: Assured Forwarding 12 PHB	• af33: Assured Forwarding 33 PHB
• af13: Assured Forwarding 13 PHB	• af41: Assured Forwarding 41 PHB
• af21: Assured Forwarding 21 PHB	• af42: Assured Forwarding 42 PHB
• af22: Assured Forwarding 22 PHB	• af43: Assured Forwarding 43 PHB
• af23: Assured Forwarding 23 PHB	• be: Best effort forwarding PHB
• af31: Assured Forwarding 31 PHB	• ef: Expedited forwarding PHB

+

More than one of the above keywords can be entered within a single command.

Usage

You can assign DSCP to specific traffic patterns to ensure that data packets are delivered according to the precedence with which they are tagged. The diffserv markings are applied to the outer IP header of every GTP data packet. The diffserv marking of the inner IP header is not modified. The traffic patterns are defined by QCI (1 to 9). Data packets falling under the category of each of the traffic patterns are tagged with a DSCP that further indicate their precedence as shown in the following tables :

Table 33. Class structure for assured forwarding (af) levels

Drop Precedence	Class			
	Class 1	Class 2	Class 3	Class 4
Low	af11	af21	af31	af41
Medium	af12	af22	af32	af41

■ ip qos-dscp

Drop Precedence	Class			
	Class 1	Class 2	Class 3	Class 4
High	af13	af23	af33	af43

Table 34. DSCP Precedence

Precedence (low to high)	DSCP
0	Best Effort (be)
1	Class 1
2	Class 2
3	Class 3
4	Class 4
5	Express Forwarding (ef)

The DSCP level can be configured for multiple traffic patterns within a single instance of this command. The no ip qos command can be issued to remove a QOS setting and return it to its default setting.

Example

The following command configures the DSCP level for QCI to be Expedited Forwarding, **ef**:

```
ip qos-dscp qci 1 ef
```

ip source-violation

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
ip source-violation { clear-on-valid-packet | drop-limit num period secs }
```

```
default ip source-violation { drop-limit num period secs }
```

```
no ip source-violation clear-on-valid-packet
```

clear-on-valid-packet

Default: disabled

Configures the service to reset the drop-limit counters upon receipt of a properly addressed packet.

drop-limit num

Default: 10

Sets the maximum number of allowed IP source violations within the detection period before dropping a call. If *num* is not specified, the value is set to the default value.

num can be any integer value from 1 to 1000000.

period secs

Default: 120

Sets the detection period in seconds for IP source violations. If *secs* is not specified, the value is set to the default value.

secs can be any integer value from 1 to 1000000.

default ip source-violation { drop-limit num period secs }

Sets or restores the IP source violation detection defaults, as follows:

- **drop-limit:** Sets or restores the maximum number of IP source violations within the detection period before dropping the call to the default value of 10.
- **period:** Sets or restores the detection period for IP source violations to the default value of 120 seconds.

no ip source-violation clear-on-valid-packet

The drop-limit counters are not reset upon receipt of a properly addressed packet.

Usage

Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

This function operates in the following manner: When a subscriber packet is received with a source IP address violation, the system increments the IP source violation drop-limit counter and starts the timer for the IP source violation period. Every subsequent packet received with a bad source address during the IP source violation period causes the drop-limit counter to increment. For example, if the drop-limit is set to 10, after 10 source violations, the call is dropped. The detection period timer continues to count throughout this process.

Example

The following command sets the drop limit to 15 and leaves the other values at their default values:

```
ip source-violation drop-limit 15
```

max-tunnels-per-ue

The maximum number of IKEv2/IPSec tunnels allowed per UE by the PDG/TTG. This maximum number is specified per PDG service.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
max-tunnels-per-ue integer
```

```
default max-tunnels-per-ue
```

integer

Default: 11

The maximum number of IKEv2/IPSec tunnels allowed per UE. This value must be an integer from 1 to 11.

```
default max-tunnels-per-ue
```

Sets the maximum number of IKEv2/IPSec tunnels allowed per UE to its default value, which is 11.

Usage

Use this command to set the maximum number of IKEv2/IPSec tunnels allowed per UE.

Example

Use the following command to set the maximum number of IKEv2/IPSec tunnels allowed per UE to 2:

```
max-tunnels-per-ue 2
```

plmn id

Configures location specific mobile network identifiers used to help translate local emergency and service-related numbers. Default is disabled.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
plmn id mcc mcc_number mnc mnc_number
```

```
no plmn id mcc mcc_number mnc mnc_number
```

```
mcc mcc_number
```

Specifies the mobile country code (MCC) portion of the PLMN's identifier.
mcc_number is the PLMN MCC identifier and can be configured to any integer value between 200 and 999.

```
mnc mnc_number
```

Specifies the mobile network code (MNC) portion of the PLMN's identifier.
mnc_number is the PLMN MNC identifier and can be configured to any 2 or 3 digit integer value between 00 and 999.

```
no plmn id mcc mcc_number mnc mnc_number
```

Removes a previously configured PLMN identifier for the PDG service.

Usage

The PLMN ID is included in the RAI (Routing Area Identity) field of the PDP Create Request messages sent to the GGSN. Multiple PDG services can be configured with the same PLMN identifier. Up to five PLMN IDs can be configured for each PDG service.

Example

The following command configures the PLMN identifier with an MCC of 462 and MNC of 2:

```
plmn id mcc 462 mnc 02
```

setup-timeout

Specifies the maximum time allowed to set up a session in seconds.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
setup-timeout integer
```

```
default setup-timeout
```

```
setup-timeout integer
```

Default: 60

Sets the session setup timeout value.

integer is a value in the range of 2 - 300 seconds.

```
default setup-timeout
```

Sets or restores the default session setup timer value to 60 seconds.

Usage

The PDG/TTG clears both the user session and tunnels if a call does not initiate successfully before the session setup timer expires.

Example

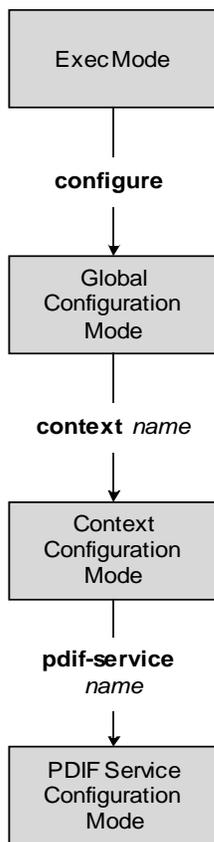

The following command sets the session setup timeout value to the default value of 60 seconds:

```
default setup-timeout
```

Chapter 187

PDIF Service Configuration Mode Commands

The PDIF Service Configuration Mode is used to configure the properties required for a mobile station to interface with a PDIF.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

aaa attribute

Sets the system attributes for AAA messages.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
aaa attribute { 3gpp2-bsid string | 3gpp2-service-option integer | calling-
station-id integer | 3gpp2-serving-pcf ip-address }
```

```
no aaa attribute
```

```
default aaa attribute 3gpp2-service-option integer
```

no

Removes a previously configured AAA attribute.

default

Returns the specified aaa attribute to the original default system settings.

3gpp2-bsid *string*

Specifies the base-station ID and consists of the SID + NID + CELLID.
string must contain 12 hexadecimal upper-case ASCII characters.

3gpp2-service-option *integer*

Default: 4095

Specifies the radius attribute value when sending authentication and accounting messages.
integer can be configured to any value in the range 0 - 32767

calling-station-id *integer*

Calling station phone number.

integer can be configured to any value from 1 - 15 numbers.

3gpp2-serving-pcf *ip-address*

Use this command to generate attribute values without creating a new ASR 5000 image.

Usage

If the RADIUS protocol is being used, accounting messages can be sent over a AAA interface to the RADIUS server.

3gpp2-serving-pcf attribute value (if configured) is sent in both RADIUS authentication and accounting messages. If the attribute value is not configured (or explicitly 'not configured' using no command), radius

attributes are still included with just type and length. This is because inclusion/exclusion of radius attributes are still controlled through the dictionary, not with CLI.

Example

The following command identifies the base station ID:

```
aaa attribute 3gpp2-bsid 0ab23289acb3
```

aaa authentication

Sets the aaa authentication for first and second phase authentication when multiple authentication is configured on the system.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
aaa authentication { { first-phase | second-phase } | { context-name name aaa-group name } }
```

```
no aaa authentication { first-phase | second-phase }
```

```
no aaa authentication { first-phase | second-phase }
```

Removes any existing authentication configuration.

```
first-phase context-name name aaa-group name
```

Specifies the context name and the aaa group name configured in the context for the first authentication phase.

- **context-name** *name*: Context where aaa server group is defined. *name* must be a string of size 1-79.
- **aaa-group** *name*: Name of the aaa-group to be used for authentication. *name* must be a string of size 1-63.

```
second-phase context-name name aaa-group name
```

Specifies the context name and the aaa group name configured in the context for the second authentication phase.

- **context-name** *name* : Context where aaa server group is defined. *name* must be a string of size 1-79.
- **aaa-group** *name*: Name of the aaa-group to be used for authentication. *name* must be a string of size 1-63.

Usage

Two phase-authentication happens in IKEv2 setup for setting up the IPSec session. The first authentication uses Diameter AAA EAP method and second authentication uses RADIUS AAA authentication. The same AAA context may be used for both authentications. PDIF service allows you to specify only a single AAA group, which could normally be used for the first authentication method.

A given AAA group only supports either Diameter or RADIUS authentication. If the NAI in the first authentication is different from NAI in the second authentication each NAI can point to a different domain profile in the PDIF. Each domain profile may be configured with each AAA group, one for Diameter and the other for RADIUS.

Example

Use the following to configure first-phase authentication for an aaa group named *aaa-10* in the pdif context:

```
first-phase context-name pdif aaa-group aaa-10
```

bind

Binds the service IP address to crypto template and configures the number of sessions the PDIF can support.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
bind address address { crypto-template string } [ max-sessions number ]
```

```
no bind
```

no

Removes a previously configured binding.

address

Specifies the IP address of the service.

crypto-template *string*

Specifies the name of the crypto template to be bound to the service.
string is any value from 0 - 127 alpha and/or numeric characters.

max-sessions *number*

Default is 3000000.

Specifies the maximum number of sessions to be supported by the service.
number can be any integer value from 0 to 3000000.

Usage

Binds the IP address used as the connection point for establishing the IKEv2 sessions to the crypto template. It can also define the number of sessions the PDIF can support.

Example

The following command binds a service with the ip address `13.1.1.1` to the crypto template `T1` and sets the maximum number of sessions to `2000000`:

```
bind address 13.1.1.1 crypto-template T1 max-sessions 2000000
```

default

Sets or restores the default condition for the selected parameter.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
default { { aaa attribute 3gpp2-service-option } | duplicate-session-detection |
hss { failure-handling mac-address-validation-failure | mac-address-validation |
update-profile } | ip source-violation { drop-limit | period } | setup-timeout |
subscriber name | username mac-address-stripping } }
```

aaa attribute 3gpp2-service-option

Configures the default value 4095.

duplicate-session-detection

Configures the default to be NAI-based.

hss { failure-handling mac-address-validation-failure | mac-address-validation | update-profile }

Configures the HSS server defaults:

failure-handling mac-address-validation-failure: By default, the MAC address is validated by IMS-Sh interface.

- mac-address-validation**: By default, validating the MAC address is disabled.
- update-profile**: By default, updating the PDIF profile is disabled.

ip source-violation (drop-limit | period }

Configures IP source-violation detection defaults.

- drop-limit**: Default number of ip source violations permitted in detection period before the call is dropped is 10.
- period**: Default detection period is 120 seconds.

setup-timeout

Default call setup time limit is 60 seconds.

subscriber name

Configures the default subscriber name. *name* is a string of 1-127 characters.

username mac-address-stripping

Default is to disable stripping the MAC address from the username.

■ default

Usage

Configures the default settings for a given parameter.

Example

Use the following example to configure the default call setup time limit:

```
default setup-timeout
```

duplicate-session-detection

Configures the PDIF to detect duplicate call sessions using old IMSI or NAI addresses and clear old call information.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] duplicate-session-detection { imsi-based | nai-based }
```

no

Stops duplicate session detection.

default

Configures the default setting, which is NAI-based detection.

imsi-based

Configures the PDIF to detect duplicate call sessions based on the IMSI address.

nai-based

Configures the PDIF to detect duplicate call sessions based on the NAI address. This is the default setting.

Usage

If an MS leaves the Wi-Fi coverage area and subsequently comes back online, it may initiate a new session setup procedure. After both the device authentication with HSS and the subscriber authentication with AAA server are completed, PDIF runs the internal mechanism to see whether there was any other session bound with the same IMSI. If an old session is detected, PDIF starts clearing this old session by sending a proxy-MIP Deregistration request to the HA. PDIF resumes new session setup by sending a proxy-MIP registration request. When the old session is aborted, PDIF sends Diameter STR messages and RADIUS Acct STOP messages to corresponding AAA servers.

PDIF allows duplicate session detection based on either the NAI or IMSI addresses. When detecting based on NAI, it is the first-phase (device authentication) NAI that is used.

Example

The following command configures duplicate session detection to use IMSI addressing:

```
duplicate-session-detection imsi
```

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec Mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Returns to the previous mode.

hss

Configures the HSS server parameters.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
hss { failure-handling { { mac-address-validation-failure | update-profile }
action { terminate | continue } } | update-profile | mac-address-validation }

[ no | default ] hss { failure-handling | update-profile | mac-address-
validation }
```

no

Removes a previously configured HSS profile.

default

Resets the defaults for this command.

failure-handling mac-address-validation-failure

Configures the way the HSS server is to handle errors.

If HSS returns a list of MAC addresses and if PDIF fails to match the subscriber MAC address against the list, then the session is always terminated.

action { continue | terminate }

Configures the action to be performed depending on the failure type.

- **continue:** Ignore a mac-address-validation-failure and continue the session.
- **terminate:** Terminate the session on a mac-address-validation-failure.

mac-address-validation

Default: disabled.

If mac-address-validation is enabled, the PDIF queries the HSS server for a list of MAC addresses associated with the Mobile Directory Number (MDN).

update-profile

Default: disabled.

Update the HSS server with the subscriber profile.

Usage

An HSS server is used to provide MAC address validation and store part of the subscriber profile. This command enables or disables validation and profile updates, and configures how the system responds to failures: terminate or continue a session.

An `ims-sh-service` and Diameter interface needs to be configured to communicate with the HSS server.

Example

The following example enables mac-address validation:

```
hss mac-address-validation
```

ims-sh-service

Associates the IMS-Sh-service parameters.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
ims-sh-service name name
```

```
no ims-sh-service name name
```

no

Removes a previously configured IMS-Sh-service.

name

Names the IMS-Sh-service in the pdif-service context.

Usage

This command is used to name the IMS-Sh-service.

Example

The following command names the IMS-Sh-service ims1:

```
ims-sh-service name ims1
```

ip source-violation

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
ip source-violation { clear-on-valid-packet | drop-limit num | period secs }  
no ip source-violation clear-on-valid-packet
```

clear-on-valid-packet

Default: disabled

Configures the service to reset the renege-limit and drop-limit counters after receipt of a properly addressed packet.

drop-limit num

Default: 10

Sets the number of allowed source violations within a detection period before forcing a call disconnect. If *num* is not specified, the value is set to the default. *num* can be any integer value from 1 to 1000000.

period secs

Default: 120

The length of time, in seconds, for a source violation detection period to last. If *secs* is not specified, the value is set to the default. *secs* can be any integer value from 1 to 1000000.

Usage

This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two PDIFs a number of times during a handoff scenario.

This function operates in the following manner:

When a subscriber packet is received with a source address violation, the system increments the IP source-violation drop-limit counter and starts the timer for the IP-source violation period. Every subsequent packet received with a bad source address during the IP-source violation period causes the drop-limit counter to increment.

For example, if the drop-limit is set to 10, after 10 source violations, the call is dropped. The period timer continues to count throughout this process.

ip source-violation

Example

The following command sets the drop limit to *15* and leaves the other values at their defaults:

```
ip source-violation drop-limit 15
```

mobile-ip

Sets the MIP FA context for the specific PDIF service.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
mobile-ip foreign-agent context string [ fa-service string ]
```

```
no mobile-ip
```

no

Removes previously configured parameters.

foreign-agent context *string*

Provides the context name in which the FA is configured. *string* is any value in the range 1 - 79 alpha and/or numeric characters.

fa-service *string*

Designates the name of the FA service in the FA context. *string* is any value in the range 1 - 79 alpha and/or numeric characters.

Usage

Shows in which context the FA is located and names the FA service.

Example

This command configures MIP for the FA context named fa1:

```
mobile-ip foreign-agent context fa1
```

setup-timeout

Configures the maximum time allowed to set up a session.

Product

PDIF

Privilege

Security-Administrator, Administrator

Syntax

```
setup-timeout integer
```

```
default setup-timeout
```

```
setup-timeout integer
```

This command manually sets the session setup timer. *integer* is a value in the range 2 - 300 seconds.

```
default setup-timeout
```

Default session setup timer: 60 seconds.

Usage

PDIF clears both user session and tunnels if a call does not initiate successfully before the timer expires.

Example

The following command sets the setup-timeout to the default 30 seconds:

```
default setup-timeout
```

username

Configures mac-address-stripping on a username coming in from a mobile station session.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
username mac-address-stripping
```

```
[ default | no ] username mac-address-stripping
```

```
username mac-address-stripping
```

Configures mac-address stripping from the Network Access Identifier (NAI).

```
default
```

Configures the parameter default, which is disabled.

```
no
```

Returns the configuration to the default condition.

Usage

When enabled, PDIF strips the MAC address from a mobile username NAI before sending to the RADIUS AAA server.

Example

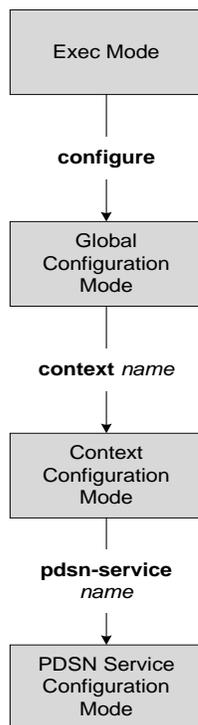

The following example disables mac-address-stripping.

```
no username mac-address-stripping
```

Chapter 188

PDSN Service Configuration Mode Commands

The PDSN Service Configuration Mode is used to create and manage PDSN service instances for the current context.

aaa 3gpp2-service-option

Specifies the value for the 3gpp2-service option.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
aaa 3gpp2-service-option number
```

```
no aaa 3gpp2-service-optionnumber
```

```
default aaa 3gpp2-service-option
```

no

Disables the aaa 3gpp2-service option configuration.

default

Sets / Restores default value assigned for specified parameter **aaa 3gpp2-service-option**.

number

Service option *number* is integer and should be between 0 to 32767.

Usage

Allows the configuration of a default service option value to be sent in accounting when service option values are not received from PCF. The PDSN will default the service option value to the configured value if the value is not specified by the PCF.

Example

The following command sets the service option to be 40:

```
aaa 3gpp2-service-option 40
```

access-flow traffic-validation

If **access-flow traffic-validation** is enabled for the service and the subscriber then the flows are checked against the filter rules. If the packets does not match the filter rules, and N violations occur in K seconds, the rp connection is downgraded to best-effort flow, if it is not already a best-effort flow

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
access-flow traffic-validation threshold [ interval seconds | violationslimit ]  
[no | default] access-flow traffic-validation
```

```
[ no | default ]
```

Disable traffic validation for the service.

```
threshold { [ violations limit ] [ interval seconds ] }
```

violations limit: Sets the parameters that determine traffic access violations. This is determined by setting the maximum number of violations within a set time period. must be an integer from 1 through 100000.
interval seconds Sets the time interval, in seconds. must be an integer from 1 through 100000.

Usage

Use this command to enable traffic validation for the current PDSN service.

Example

The following command enables traffic validation for the current PDSN service and sets the limit allowed to 100 violations within 5 seconds:

```
access-flow traffic-validation threshold violations 100 interval 5
```

access-network

Configures access network parameters.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
access-network { accounting identifier | realm realm_name }
```

```
no access-network { accounting identifier | realm }
```

no

Disables the **access-network**.

accounting identifier

Configures accounting for the access-network. This value must be a string from 1 to 128 characters in length.

realm *realm_name*

Configures the realm for the access-network. *realm_name* must be a string from 1 to 128 characters in length.

Usage

Use this command to configure access-network parameters for accounting and realms.

Example

The following command creates an **access-network realm** named *realm2*.

```
access-network realm realm2
```

airlink bad-sequence-number

Configures PDSN behavior for airlink related parameters.

Product

PDSN

Privilege

Security Administrator, Administrator

```
airlink bad-sequence-number { accept | deny [use-deny-code { poorly-formed-
request | unsupported-vendor-id} ]}
```

```
[ no | default ] airlink bad-sequence-number
```

[no | default]

Disables the deny of bad-sequence number and accept it.
It is the default behavior.

accept

Accepts the A11 RRQ messages that have an Airlink Sequence number less than or equal to a previously received sequence number.
It is the default behavior.

deny

Rejects the A11 RRQ messages that have an Airlink Sequence number less than or equal to a previously received sequence number.
It uses **poorly-formed-request** option by default to deny a request.

```
use-deny-code {poorly-formed-request | unsupported-vendor-id}
```

These are optional keywords that used with **deny** sub-command to deny the A11 RRQ messages that have either an unsupported vendor Id or A11 Requests with bad/poor formation.
unsupported-vendor-id denies request on the basis of vendor Id.
poorly-formed-request will deny the A11 request on the basis of request formation or structure. It is the default deny code for **deny** sub-command.

Usage

This command is used to configure the airlink parameters for A11 RRQs. .
When configured it denies the A11 RRQ messages that have an Airlink Sequence number less than or equal to a previously received sequence number.

Example

The following command would configure the system to deny all A11 RRQ messages having unsupported vendor Id or bad structure of message, including those having arilink sequence number less than or equal to a previously received sequence number:

```
airlink bad-sequence-number deny
```

■ `airlink bad-sequence-number`

allow alt-ppp

Allows proprietary modified versions of PPP type sessions to connect this PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
allow alt-ppp
```

```
no allow alt-ppp
```

```
no
```

Disables the allowed alternate PPP feature.

Usage

This command is used to deviate from standard PPP protocol and use a proprietary modified version of PPP with a pre-defined non-negotiable PPP parameters. It is a vendor-specific licensed feature command.

always-on-indication

Enables/disables the inclusion of 3GPP2 Always On Indicators in messages to the PCF.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

always-on-indication

no always-on-indication

no

Disables the sending of 3GPP2 Always On Indication messages.

Usage

This command is available when the 3GPP2 Always-On RP Extensions feature-use license is installed. When enabled, this command causes the PDSN service to include the Always On Indicators in the Normal Vendor Specific Extension (NVSE) part of an A11 Session Update message to the PCF. The indicator will only be sent for those subscriber sessions in which Always On functionality is enabled as determined after a successful authentication: the 3GPP2-Always-On attribute is set to a value of 1 (Active) for subscribers configured on a AAA server, or the always-on parameter is set for locally configured subscribers. This functionality is enabled by default.

authentication

Configures the PDSN service authentication parameters.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
authentication { { [ allow-noauth ] [ chap chap_priority ] [ mschap
mschap_priority ] [ msid-auth ] } | pap pap_priority }
```

default authentication

default

Configures authentication parameters for specific PDSN service.

allow-noauth

Default: Disabled

This option configures the system to provide subscribers with network access even though they have not been authenticated. This command issued by itself would cause the system to not attempt to authenticate subscribers.

When the allow-noauth option is used in conjunction with commands specifying other authentication protocols and priorities to use, then if attempts to use those protocols fail, the system will treat the allow-noauth option as the lowest priority.

If no authentication is allowed, then NAI construct will be implemented in order to provide accounting records for the subscriber.

chap *chap_priority*

Default: 1

This option configures the system to attempt to use the Challenge Handshake Authentication Protocol (CHAP) to authenticate the subscriber.

A *chap_priority* must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.

chap_priority must be an integer from 1 through 1000. The lower the integer, the higher the preference. CHAP is enabled by default as the highest preference.

mschap *mschap_priority*

Default: Disabled

This option configures the system to attempt to use the Microsoft Challenge Handshake Authentication Protocol (MSCHAP) to authenticate the subscriber.

A *mschap_priority* must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.

mschap_priority must be an integer from 1 through 1000. The lower the integer, the higher the preference.

pap pap_priority

Default: 2

This option configures the system to attempt to use the Password Authentication Protocol (PAP) to authenticate the subscriber.

A *pap_priority* must be specified in conjunction with this option. Priorities specify which authentication protocol should be attempted first, second, third and so on.

pap_priority must be an integer from 1 through 1000. The lower the integer, the higher the preference. PAP is enabled by default as the second highest preference.

msid-auth

Default: Disabled

This option configures the system to attempt to authenticate the subscriber based on their Mobile Station Identity (MSID).

Usage

Use to specify how the PDSN service should handle authentication and what protocols to use. The flexibility is given to configure this option to accommodate the fact that not every mobile will implement the same authentication protocols.

The chassis is shipped from the factory with the authentication options set as follows:

- allow-noauth disabled
- chap enabled with a priority of 1
- mschap disabled
- msid-auth disabled
- pap enabled with a priority of 2

Important: At least one of the keywords must be used to complete the command.

Example

The following command would configure the system to allow no authentication for subscribers and would perform accounting using the default NAI-construct of *username@domain*:

```
authentication allow-noauth
```

The following command would configure the system to attempt subscriber authentication first using CHAP, then MSCHAP, and finally PAP. If the allow-noauth command was also issued, if all attempts to authenticate the subscriber using these protocols fail, then the subscriber would be allowed access:

```
authentication chap 1 mschap 2 pap 3
```

bind

Binds the PDSN service to a logical IP interface serving as the R-P interface. Specifies the maximum number of subscribers that can access this service over the interface.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
bind address address [ max-subscribers count ]
```

```
no bind address address
```

no

Removes a previously configured binding.

address

Specifies the IP address (*address*) of the interface configured as the R-P interface. *address* is specified in dotted decimal notation.

max-subscribers *count*

Default: 500000

Specifies the maximum number of subscribers that can access this service on this interface. *count* can be configured to any integer value between 0 and 2500000.

Important: The maximum number of subscribers supported is dependant on the license key and the number of active PACs/PSCs installed in the system. A fully loaded system with 13 active PACs/PSCs can support 2500000 total subscribers. Refer to the license key command for additional information.

Usage

Associate or tie the PDSN service to a specific logical IP address. The logical IP address or interface takes on the characteristics of an R-P interface. Only one interface can be bound to a service. The interface should be configured prior to issuing this command.

This command also sets a limit as to the number of simultaneous subscribers sessions that can be facilitated by the service/interface at any given time.

When configuring the **max-subscribers** option, be sure to consider the following:

- The total number of interfaces that you will configure for use as R-P interfaces
- The maximum number of subscriber sessions that all of the interfaces may handle during peak busy hours
- The average bandwidth for each of the sessions
- The type of physical port (10/100Base-Tx or 1000Base-T) to which these interfaces will be bound

Taking these factors into account and distributing your subscriber session across all available interfaces will allow you to configure your interfaces to optimally handle sessions without degraded performance.

Example

The following command would bind the logical IP interface with the address of *192.168.3.1* to the PDSN service and specifies that a maximum of *600* simultaneous subscriber sessions can be facilitated by the interface/service at any given time.

```
bind address 192.168.3.1 max-subscribers 600
```

The following command disables a binding that was previously configured:

```
no bind address
```

bcmcs

Sets the BCMCS group username and password for RADIUS access.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
bcmcs [ custom ptt | flow-id value [flow-id-type { flow-id | program-id } ] | [
encrypted ] grppasswd group_passwd | grpusrname group_name | ptt { destination-
context dest_name | disconnect-dscp-label dscp_label | mtu transmission_unit |
rohc-profile-name rohc_profile_name } ]
```

```
default bcmcs [ custom ptt | ptt { disconnect-dscp-label | mtu | rohc-profile-
name } ]
```

```
no bcmcs [ custom ptt | flow-id value [flow-id-type { flow-id | program-id } ] |
grppasswd | grpusrname | ptt { destination-context | disconnect-dscp-label | mtu
| rohc-profile-name } ]
```

custom

Customise the BCMCS configuration.

flow-id *value*

Set the BCMCS flow-id. This value must be a hex string between *0x1000* and *0xFFFFFFFF*.

Making this entry opens a new mode: *bcmcs-flow-id*.

rohc-profile name : Configure ROHC parameters name, name should be string of size 1 to 63.

grpusrname *group_name*

Sets the BCMCS group name for RADIUS access requests. This value must be a string from 1 to 127 characters in length.

[**encrypted**] **grppasswd** *group_passwd*

Set the BCMCS group password for RADIUS access requests. This value must be a string from 1 to 63 characters in length.

Password can be encrypted or clear.

ptt { **destination-context** *dest_name* | **disconnect-dscp-label** *dscp_label* | **mtu** *transmission_unit* | **rohc-profile-name** *rohc_profile_name* }

destination-context: Specify the intended destination context name. This value must be string of 1 to 79 characters in length.

disconnect-dscp-label: Configures the DSCP label to be present in the In Call Signalling packet based on which In Call Signalling and Media Flows will be disconnected. This value must be a Hexadecimal number between *0x0* and *0xF*.

mtu transmission_unit: Configures maximum transmission unit, This value must be ranging from 100 to 2000. Default is 1500.

rohc_profile_name rohc_profile_name: Profile name of the ROHC compressor and decompressor. This value should be a string of 1 to 63.

Usage

Use this command to set the BCMCS group username and password for RADIUS access requests.

Example

```
bcmcs grpusername group_namebcmcs grpasswd group_password
```

data-available-indicator

Enable sending Data Available Indicator extension in R-P Registration Reply.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] data-available-indicator
```

no

Default: Disabled

Disable the sending of the Data Available Indicator extension in R-P Registration Reply.

default

Sets / Restores default value assigned for specified parameter for **data-available-indicator**.

Usage

Use this command to enable or disable the sending of the Data Available Indicator extension in R-P Registration Reply

Example

Use the following command to enable sending the Data Available Indicator extension in R-P Registration Reply:

```
data-available-indicator
```

Use the following command to disable sending the Data Available Indicator extension in R-P Registration Reply

```
no data-available-indicator
```

data-over-signaling

Enable the data-over-signaling marking feature for A10 packets.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] data-over signaling
```

default

Sets / Restores default value assigned for specified parameter for **data-over signaling**

no

Default: Enabled

Disable the data-over signaling feature for A10 packets.

Usage

Use this command to enable or disable the data-over signaling feature for A10 packets.

Important: This is a customer-specific command.

Example

```
no data-over-signaling
```

default subscriber

Specifies the name of a subscriber profile configured within the same context as the PDSN service from which to base the handling of all other subscriber sessions handled by the PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
default subscriberprofile_name
```

```
no default subscriber profile_name
```

no

Enables/Disables the option **default subscriber** *profile_name*

profile_name

Specifies the name of the configured subscriber profile. *profile_name* can be between 1 and 63 alpha and/or number characters and is case sensitive.

Usage

Each subscriber profile specifies “rules” such as permissions, PPP settings, and timeout values.

By default, the PDSN service will use the information configured for the subscriber named default within the same context. This command allows for multiple PDSN services within the same context to apply different “rules” to sessions they process. Each set of rules can be configured under a different subscriber name which is pointed to by this command.

Use the **no default subscriber** *profile_name* command to delete the configured default subscriber.

Example

To configure the PDSN service to apply the rules configured for a subscriber named *user1* to every other subscriber session it processes, enter the following command:

```
default subscriber user1
```

dormant-transition

Configures the PDSN behavior to terminate A10 session, when the PDSN receives the A11-RRQ (Type 4) before the session for the original MN is established completely.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

[no | default] dormant-transition initial-session-setup

no

Terminates the A10 session, when PDSN receives the A11-RRQ (Type 4) before the original session established completely.

default

Keeps the A10 session live in case of A11-RRQ (Type 4) is received before the original session is established completely.

Usage

When the status of A10 session goes to dormant before the session for the original MN is established completely, the different MN may possibly send the A11-RRQ (Type 4) to the PDSN and PPP renegotiation may start.

This command is used to terminate the A10 session when the PDSN receives the A11-RRQ (Type 4) before the session for original MN is established completely.

Example

Following command is used to release the A10 session in case of receiving A11-RRQ (Type 4) before the original session is established completely

no dormant-transition initial-session-setup

end

Exits the PDSN service configuration mode and returns to the Exec mode.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the PDSN service configuration mode and returns to the context configuration mode.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

fragment

It enables/disables fragmentation of PPP data.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] fragment ppp-data
```

no

Disables the fragmentation of ppp data.

default

Default enables ppp data fragmentation.

Usage

This command is to indicate to the RP module to NOT fragment PPP payloads being sent to the PCF, if the total packet size (PPP+GRE+IP) exceeds 1500 bytes.

Disabling fragmentation may cause the **sessmgr** to perform outer IP fragmentation of the outgoing packet, if the resulting packet exceeds the MED MTU.

gre

Configures Generic Routing Encapsulation (GRE) parameters for the A10 protocol within the PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
gre { checksum | checksum-verify | flow-control [ action { disconnect-session |
resume-session } ] [ timeout msec ] [ action { disconnect-session | resume-
session } ] [ timeout msec ] | ip-header-dscp value { all-control-packets |
setup-packets-only } | protocol-type { any | byte-stream | ppp } | reorder-
timeout value | segmentation | sequence-mode { none | reorder } | sequence-
numbers | threegppp2-ext-header qos-marking }
```

```
no gre { checksum | checksum-verify | flow-control | ip-header-dscp | segmentation |
sequence-numbers | threegppp2-ext-headers qos-marking }
default gre { checksum | checksum-verify | flow-control ip-header-dscp | protocol-type
| segmentation | sequence-mode | sequence-numbers | threegppp2-ext-headers qos-marking
}
```

no

Disables the specified functionality.

default

Restores the specified parameter to its default setting.

checksum

Default: disabled

Enables the introduction of the checksum field in outgoing GRE packets.

```
flow-control[ action { disconnect-session | resume-session } ] [ timeout
msec ] [ action { disconnect-session | resume-session } ] [ timeout
msec ]
```

Default: no gre flow-control

Enables 3GPP2 GRE flow control which causes the PDSN to send flow control enabled Normal Vendor Specific Extensions (NVSE) in A11 RRs.

disconnect-session: (default): Ends the session and releases the call.

resume-session: Switches flow control to XON and resumes delivery of packets to the RAN.

msec: Specifies the amount of time in milliseconds before the timeout is reached. It must be an integer from 1 through 1000000

checksum-verify

Default: disabled

Enables verification of the GRE checksum (if present) in incoming GRE packets.

```
ip-header-dscp value { all-control-packets | setup-packets-only }
```

Default: Disabled

Used to configure the QoS Differentiated Services Code Point (DSCP) marking for GRE packets.

- **value** : Represents the DSCP setting. It represents the first six most-significant bits of the ToS field. It can be configured to any hex value from 0x0 through 0x3F.
- **all-control-packets** : Dictates that the DSCP marking is to be provided in all GRE control packets.
- **setup-packets-only** : Dictates that the DSCP marking is to be provided only in GRE setup packets.

```
protocol-type { any | byte-stream | ppp }
```

Specifies the protocol used for GRE encapsulation that is acceptable to

any: Specifies that the PDSN service will accept GRE packets encapsulated using any protocol.

byte-stream: Specifies that the PDSN service will accept GRE packets only encapsulated using byte stream. Using byte stream encapsulation, PPP packets are framed at different intervals and sent.

ppp: Specifies that the PDSN service will accept GRE packets only encapsulated using the Point-to-Point Protocol (PPP). Using PPP encapsulation, PPP packets are framed at regular intervals and sent.

```
reorder-timeout
```

Default: 100

Configures max number of milliseconds to wait before processing reordered out-of-sequence GRE packets. *milliseconds* must be an integer from 0 through 5000.

```
segmentation
```

Default: disabled

Enables GRE Segmentation for the PDSN service.

```
sequence-mode { none | reorder }
```

Default: none

Configures handling of incoming out-of-sequence GRE packets.

none: Specifies that sequence numbers in packets are ignored and all arriving packets are processed in the order they arrive.

reorder: Specifies that out of sequence packets are stored in a sequencing queue until one of the conditions is met:

- The reorder timeout occurs: All queued packets are sent for processing and the accepted sequence number is updated to the highest number in the queue.
- The queue is full (five packets): All packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number in the queue.
- An arriving packet has a sequence number such that the difference between this and the packet at the head of the queue is greater than five. All the packets in the queue are sent for processing, the reorder timer is stopped and the accepted sequence number is updated to the highest number that arrived.
- A packet arrives that fills a gap in the sequenced numbers stored in the queue and creates a subset of packets whose sequence numbers are continuous with the current accepted sequence number. This subset of packets in the queue is sent for processing. The reorder timer continues to run and the accepted sequence number is updated to the highest number in the subset delivered.

sequence-numbers

Enables insertion of GRE sequence numbers in data that is about to be transmitted over the A10 interface. Data coming into the system containing sequence numbers but that is out of sequence is not re-sequenced.

threegpp2-ext-headers qos-marking

When `threegpp2-ext-headers qos-marking` is enabled and the PCF negotiates capability in the A11 RRQ, the PDSN will include the qos optional data attribute in the GRE 3gpp2 extension header. The `no` keyword, enables qos-marking in the gre header based on the tos value in the header.

Usage

The `gre protocol-type` command can be used to prevent the PDSN service from servicing PCFs that use a specific form of encapsulation.

Use the `no gre sequence-numbers` command to disable the inclusion of GRE sequence numbers in the A10 data path.

The chassis is shipped from the factory with the authentication options set as follows:

- `protocol-type any`
- `sequence-numbers enabled`

Example

Use this command to configure the PDSN service to exclude byte stream encapsulated GRE traffic:

```
gre protocol-type ppp
```

inter-pdsn-handoff mobility-event-indicator

Configures the PDSN to support the Mobility Event Identifier (MEI) during inter-PDSN handoffs. The presence of the Mobility Event Indicator (MEI) and Access Network Identifier (ANID) elements in a A11 handoff request represents an Inter-PDSN handoff.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
inter-pdsn-handoff mobility-event-indicator  
no inter-pdsn-handoff mobility-event-indicator  
default inter-pdsn-handoff mobility-event-indicator
```

no

Disables support for the MEI during inter-PDSN handoffs.

default

Sets / Restores default value assigned for **inter-pdsn-handoff mobility-event-indicator**. By default it is disabled.

Usage

Use this command to configure support for the MEI during inter-PDSN handoffs.

Example

Use the following command to enable support for the MEI during inter-PDSN handoffs

```
inter-pdsn-handoff mobility-event-indicator
```

ip header-compression rohc

This command enters PDSN Service ROHC Configuration Mode. The ROHC configuration mode lets you configure ROHC parameters that PDSN conveys to the PCF in the initial A11 RRP message before PPP authentication.

By default, ROHC is disabled for a PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
ip header-compression rohc
```

```
default ip header-compression rohc
```

```
no ip header-compression rohc
```

default

Sets all PDSN Service ROHC Configuration Mode values back to the defaults and disable ROHC for this PDSN service.

no

Disable IP header compression for this PDSN Service.

Usage

Use this command to enter the PDSN Service ROHC Configuration Mode or disable ROHC for the current PDSN service.

Example

The following command enters PDSN Service ROHC Configuration Mode:

```
ip header-compression rohc
```

The following command disables ROHC for the current PDSN service and sets all of the values for commands in PDSN Service ROHC Configuration Mode back to their default settings:

```
default ip header-compression rohc
```

ip local-port

Configures the local User Datagram Protocol (UDP) port for the R-P interfaces' IP socket.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
ip local-portnumber
```

```
default ip local-port
```

number

Default: 699

Specifies the UDP port number.

number can be any integer value between 1 and 65535.

default

Designates UDP port, default value as 699.

Usage

Specify the UDP port that should be used for communications between the Packet Control Function (PCF) and the PDSN.

Important: The UDP port setting on the PCF must match the local-port setting for the PDSN service on the system in order for the two devices to communicate.

Example

Use the following command to specify a UDP port of 3950 for the PDSN service to use to communicate with the PCF on the R-P interface:

```
ip local-port 3950
```

ip source-violation

Sets the parameters for IP source validation. Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

Product

PDSN, PDIF

Privilege

Security Administrator, Administrator

Syntax

```
ip source-violation { clear-on-valid-packet | drop-limit num | period secs | reneg-limit num }
```

```
no ip source-violation clear-on-valid-packet
```

```
default ip source-violation { drop-limit num | period secs | reneg-limit num }
```

no

Enables/Disables **ip source-violation clear-on-valid-packet**.

default

Configure default settings related to **ip source-violation**.

clear-on-valid-packet

Default: disabled

Configures the service to reset the reneg-limit and drop-limit counters after receipt of a properly addressed packet.

drop-limit *num*

Default: 10

Sets the number of allowed source violations within a detection period before forcing a call disconnect. If *num* is not specified, the value is set to the default. *num* can be any integer value from 1 to 1000000.

period *secs*

Default: 120

The length of time, in seconds, for a source violation detection period to last. drop-limit and reneg-limit counters are decremented each time this value is reached.

The counters are decremented in this manner: reneg-limit counter is reduced by one (1) each time the period value is reached until the counter is zero (0); drop-limit counter is halved each time the period value is reached until the counter is zero (0). If *secs* is not specified, the value is set to the default.

secs can be any integer value from 1 to 1000000.

reneg-limit *num*

Default: 5

Sets the number of allowed source violations within a detection period before forcing a PPP renegotiation. If *num* is not specified, the value is set to the default.

num can be any integer value from 1 to 1000000.

Usage

This function is intended to allow the operator to configure a network to prevent problems such as when a user gets handed back and forth between two PDIFs PDSNs a number of times during a handoff scenario. This function operates in the following manner:

When a subscriber packet is received with a source address violation, the system increments both the IP source-violation *reneg-limit* and *drop-limit* counters and starts the timer for the IP-source violation period. Every subsequent packet received with a bad source address during the IP-source violation period causes the *reneg-limit* and *drop-limit* counters to increment.

For example, if *reneg-limit* is set to 5, then the system allows 5 packets with a bad source address (source violations), but on the 5th packet, it re-negotiates PPP.

If the *drop-limit* is set to 10, the above process of receiving 5 source violations and renegotiating PPP occurs only once. After the second 5 source violations, the call is dropped. The period timer continues to count throughout this process.

If the configured source-violation period is exceeded at any time before the call is dropped, the *reneg-limit* counter is checked. If the *reneg-limit* counter is greater than zero (0), the *reneg-limit* is decremented by 1. If the *reneg-limit* counter equals zero, the *drop-limit* is decremented by half.

Example

The following command sets the drop limit to 15 and leaves the other values at their defaults:

```
ip source-violation drop-limit 15
```

lifetime

Specifies the time that an A10 connection can exist before its registration is considered expired.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
lifetime time
```

```
no lifetime
```

default lifetime

```
no lifetime
```

Specifies that an A10 connection can exist for an infinite amount of time.

```
default lifetime
```

Sets / Restores default value assigned for **lifetime** as 1800.

```
time
```

Default: 1800

Specifies the time that an A10 connection can exist before its registration is considered expired. *time* is measured in seconds and can be configured to any integer value between 1 and 65534.

Usage

Set a limit to the amount of time that a subscriber session can remain up whether or not the session is active or dormant. If the lifetime timer expires before the subscriber terminates the session, their connection will be terminated automatically.

Use the **no lifetime** command to delete a previously configured lifetime setting. If after deleting the lifetime setting you desire to return the lifetime parameter to its default setting, use the **default lifetime** command.

Example

The following command specifies a time of 3600 seconds (1 hour) for subscriber sessions on this PDSN service:

```
lifetime 3600
```

max-retransmissions

Configures the maximum number of times the PDSN service will attempt to communicate with a PCF before it marks it as unreachable.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
max-retransmissions count
```

```
default max-retransmissions
```

default

Sets / Restores default value assigned for **max-retransmissions** as 5.

count

Specifies the maximum number of times the PDSN service will attempt to communicate with a PCF before it marks it as unreachable.

count can be configured to any integer value between 1 and 1,000,000.

Usage

If the value configured for the max-retransmissions is reached the call will be dropped.

The chassis is shipped from the factory with the Internet maximum number of retransmissions set to 5.

Example

The following command configures the maximum number of retransmissions for the PDSN service to 3:

```
max-retransmissions 3
```

mobile-ip foreign-agent context

For Mobile IP support, specifies the context in which the FA service(s) are configured.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
mobile-ip foreign-agent context context_name [fa-service name]
```

```
no mobile-ip foreign-agent context context_name [fa-service name]
```

no

Enables/Disables **mobile-ip foreign-agent context**

context_name

Specifies the name of the previously configured context that facilitates the FA service(s). *context_name* must be between 1 and 79 alpha or numeric characters and is case sensitive.

[**fa-service** *name*]

This optional keyword allows you to link the PDSN service to a particular FA service in the specified context. *name* is the name of the FA service to link to. *name* is a string of size 1 to 63

Usage

FA services on the system can be configured either in the same or different contexts from those facilitating PDSN services. When they are configured in separate contexts, this command configured with a PDSN service instructs the PDSN service to route traffic to the context facilitating the FA service.

Use the **no mobile-ip foreign-agent context** to delete a previously configured destination context.

Example

The following command instructs the PDSN service to use the context named FA-destination for FA functionality:

```
mobile-ip foreign-agent context fa-destination
```

msid length

Specifies the allowed configurable Mobile Station Identifier (MSID) length.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] msid length { min min_length | max } max_length
```

default

Specifies the default length of MSID (10 to 15) as per standard. By default **msid** is disabled.

min *min_length*

Specifies the minimum length for MSID.

min_length is any Integer value between 10 to 15, but should be less than *max_length* specified with **max**. Default is 10.

max *max_length*

Specifies the maximum length for MSID.

max_length is any Integer value between 10 to 15, but should be more than *min_length* specified with **min**. Default is 15.

Usage

MSID length can be configured either in the standard length or different customized length form. This command is used to specify the allowed length of MSID.

Example

The following command specifies an MSID length between 12 and 15:

```
msid length min 12 max 15
```

nai-construction

Specifies a domain alias that will be used to represent the context which the PDSN service should use for AAA functionality.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
nai-construction domain alias
```

```
no nai-construction domain
```

domain alias

alias represents the “domain” name that you would like to associate with the context in which AAA functionality is configured. alias can be between 1 and 79 alpha and/or numeric characters and is case-sensitive.

Usage

Enabling NAI will be constructed for the subscriber in the event that their mobile station (MS) does not negotiate CHAP, PAP, or MSCHAP. If this option is selected, no further attempts will be made to authenticate the user. Instead, the constructed NAI will be used for accounting purposes.

The context specified by this command would be used to provide the communication with the RADIUS accounting server.

Use the **no nai-constructed** domain command to delete a configured alias.

Important: This command should only be used if the PDSN service is configured to allow no authentication using the authentication allow-noauth command.

Additionally, the **aaa constructed-nai** command in the Context Configuration mode can be used to configure a password for constructed NAIs.

Example

The following command configured a domain alias of aaa_context for the PDSN service to use when an NAI is constructed for a subscriber session:

```
nai-construction domain aaa_context
```

new-call conflict

Enable or disable to send A11-RUPD to current PCF, when system receives the A11-RRQ(Type1) from new PCF during the session exists.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[no | default] new-call conflict terminate-session-old-pcf
```

no

Disable to send A11-RUPD to current PCF, when system receives the A11-RRQ(Type1) from new PCF during the session exists.

default

Enable to send A11-RUPD to current PCF, when system receives the A11-RRQ(Type1) from new PCF during the session exists.

Usage

This configuration supports to enable or disable to send A11-RUPD to current PCF, when the system receives the A11-RRQ(Type1) from new PCF during the session exists.

If the configuration is **no new-call conflict terminate-session-old-pcf** system will not send registration update to old PCF on receiving a new call (A11-RRQ(Type1)) request for an existing active/dormant session. The default behavior is to send registration updates.

Example

The following command configured a system to send a registration update on receiving an A11-RRQ (Type 1) request for an existing active/dormant session:

```
new-call conflict terminate-session-old-pcf
```

pcf-monitor

When this is enabled, the PDSN monitors all the PCFs that have sessions associated with it. The PDSN stops monitoring a PCF if it is determined to be down. Once a PCF is determined to be down, the PDSN tears down all sessions that correspond to the PCF and generates AAA Accounting Stop messages. All the PCFs that are connected to the PDSN service are monitored.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
pcf-monitor [ interval seconds | max-inactivity-time seconds | num-retry num | timeout seconds ]
```

```
[ no | default ] pcf-monitor
```

pcf-monitor

Entering the command with no keywords enables the PCF monitoring function with all parameters set to the defaults.

no

Disables the pcf monitoring function.

default

Sets / Restores default value assigned for **pcf-monitor**.

interval *seconds*

Default: 60 seconds

Sets the amount of time to wait between ping request messages.
seconds must be an integer in the range from 60 through 3600.

max-inactivity-time *seconds*

Default: 120 seconds

The maximum amount of time (seconds) with no A10 traffic from a PCF before the ICMP-ping mechanism is triggered.

seconds must be an integer from 1 through 3600.

num-retry *num*

Default: 5

Sets the number of times that the PDSN retries to ping the PCF. When num-retry for a given PCF has been exhausted with no response, sessions that correspond to the non-responsive PCF are terminated and Accounting Stop records for each terminated session are generated.

num must be an integer in the range from 0 through 100.

timeout *seconds*

Default: 3 seconds

The amount of time to wait for a response before retrying.
seconds must be in the range from 1 through 10.

Usage

Use this command to enable the PDSN service to monitor the PCFs that have sessions associated with the PDSN service.

Example

The following command enables PCF monitoring with parameters set to the defaults:

```
pcf-monitoring
```

The following command enables PCF monitoring and sets the timeout to *10* seconds:

```
pcf-monitor timeout 10
```

The following command disables pcf-monitoring:

```
no pcf-monitor
```

pcf-session-id-change restart-ppp

This feature manages current session and PPP renegotiation on GRE-key change without any change in PCF/PANID/CANID. This command disables or enables the PPP renegotiation restart on receiving an RP registration request from the current PCF with GRE key (PCF session Id) change. With this command the PDSN aborts and restarts the call causing PPP renegotiation.

This is enabled by default.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] pcf-session-id-change restart-ppp
```

no

Disables the pcf-session-id-change restart-ppp function.

With this option PDSN does not restart the PPP renegotiation on GRE key change from current PCF in an RP registration request, unless it indicates change in PCF/PANID/CANID.

default

Set the pcf-session-id-change function to the default state on enabled.

Usage

GRE key (PCF session ID) is used to identify the data packet for a session and is negotiated through the A11 signaling messages between PCF and PDSN. By default PDSN aborts and restarts the PPP renegotiation on receipt of any RP registration request with change in GRE key or PCF session Id.

With use of no pcf-session-id-change restart-ppp command PDSN is configured to disable the restart of call or PPP renegotiation on receipt of any RP registration request with changed GRE key, unless it has any PCF/PANID/CANID change. PDSN silently switches the GRE key for the session, retaining the existing PPP session.

Example

The following command disables the PPP renegotiation restart action on receipt of any RP RRQ with changed GRE key from same PCF/PANID/CANID.

```
no pcf-session-id-change restart-ppp
```

pdsn type0-tft attempt-inner-match

Configures a type0 traffic flow template (tft) to a type1 traffic flow template.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] pdsn type0-tft attempt-inner-match
```

no

Disables **pdsn type0-tft attempt-inner-match**.

default

Sets / Restores default value assigned for **pdsn type0-tft attempt-inner-match**.

Usage

This CLI is used make PDSN match inner IP packets for an AIMS call. When enabled, the PDSN tries to match a type-0 tft to match both outer and inner packet, so that MN can use a Type-0 filter for HoA traffic which are tunneled.

This is disabled by default.

Example

The following command enables type0 tft:

```
pdsn type0-tft attempt-inner-match
```

peer-pcf

Configures settings for any PCF that has a connection with this PDSN.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
peer-pcf ip_address bcmcs-framing { hdlc-like | segment-based }
```

ip_address

ip_address must be specified using the standard IPv4 dotted decimal notation or colon notation for IPv6.

```
bcmcs_framing { hdlc-like | segment-based }
```

Specifies the type of `bcmcs_framing` to use for this PCF connection.

- `hdlc-like`: applies HDLC-like framing for all BCMCS flows
- `segment-based`: applies segment-based framing for all BCMCS flows

Usage

Use this command to configure the settings for any PCF that is connected to this PDSN. You can also specify `bcmcs` framing settings to use for the connection.

Example

The following command configures the `peer-pcf` for an IP address of `131.2.3.4`:

```
peer-pcf 131.2.3.4
```

policy

Configures PDSN service policies.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] policy msid-match msid_with_wildcards { redirect address [ weight
weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight
weight_num ] ] }
```

```
[ default | no ] policy overload { redirect address [ weight weight_num ] [
address2 [ weight weight_num ] ... address16 [ weight weight_num ] ] } | {
reject [ use-reject-code { admin-prohibited | insufficient-resources } ] }
```

```
[ no ] policy pcf-zone-match zone_number { redirect address [ weight weight_num
] [ address2 [ weightweight_num ] ... address16 [ weight weight_num ] ] }
```

```
[ default | no ] policy rrq mei-from-current-pcf suppress-ppp-restart
```

```
[ default | no ] policy service-option enforce
```

```
[ default | no ] policy unknown-cvse enforce
```

```
no policy { overload [ redirect address [ address2...address16 ] ] | rrq
mei-from-current-pcf {suppress-ppp-restart} | service-option | unknown-
cvse enforce }
```

Deletes a previously set policy or removes a redirect IP address.

overload: This keyword without any options deletes the complete overload policy from the PDSN service.

overload redirect address [address2 ... address16]: deletes up to 16 IP addresses from the overload redirect policy. The IP addresses must be expressed in IP v4 dotted decimal notation

rrq mei-from-current-pcf suppress-ppp-restart: suppresses the PPP restart, when RRQ containing MEI comes from the current PCF. This is disabled by default.

service-option: Resets the PDSN service to accept calls that do not contain the service option(s) configured using the service option command.

unknown-cvse enforce: When unknown-cvse policy is enforced, PDSN will deny RRQs with unknown CVSEs (unknown vendor id, unknown app type or unknown app subtype) with an error code.

When disabled, PDSN will process the CVSE like an NVSE. If an unknown vendor-id, app-type or app-subtype is encountered during the processing of a CVSE, the entire CVSE will be ignored and rest of the RRQ will be processed.

```
policy overload { redirect address [ weight weight_num ] [ address2 [
weight weight_num ] ... address16 [ weight weight_num ] ] } | { reject [
use-reject-code { admin-prohibited | insufficient-resources } ] }
```

Specifies how a PDSN service should handle an overload condition.

redirect: This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the PDSN service rejects new sessions with an A11 Registration Reply Code of 88H (unknown PDSN address) and provides the IP address of an alternate PDSN. This command can be issued multiple times.

address: The IP address of an alternate PDSN expressed in IP v4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

weight *weight_num*: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. *weight_num* must be an integer from 1 through 10.

reject: This option will cause any overload traffic to be rejected. The PDSN will send an A11 Registration Reply Code of 82H (insufficient resources).

use-reject-code admin-prohibited: When this keyword is specified and traffic is rejected, the error code admin prohibited is returned instead of the error code insufficient resources. This is the default behavior.

use-reject-code insufficient-resources: When this keyword is specified and traffic is rejected, the error code insufficient resources is returned instead of the error code admin prohibited.

```
policy msid-match msid_with_wildcards { redirect address [ weight
weight_num ] [ address2 [ weight weight_num ] ... address16 [ weight
weight_num ] ] }
```

Specifies how a PDSN service should handle an incoming call that matches a list of wildcard MSIDs.

msid_with_wildcards: An MSID in which up to 16 digits have been replaced with the wildcard '\$'.

This defines the list of possible matches for incoming calls.

redirect: This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the PDSN service rejects new sessions with an A11 Registration Reply Code of 88H (unknown PDSN address) and provides the IP address of an alternate PDSN. This command can be issued multiple times.

address: The IP address of an alternate PDSN expressed in IP v4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

weight *weight_num*: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. *weight_num* must be an integer from 1 through 10.

```
policy pcf-zone-match zone_number { redirect address [ weight weight_num
] [ address2 [ weight weight_num ] ... address16 [ weight weight_num ] ]
}
```

Specifies how a PDSN service should handle an incoming call that matches a predefined zone number.

zone_number: An integer between 1 and 32 that defines the zone incoming calls must match for redirection.

redirect: This option enables a redirect policy for overloading conditions. When a redirect policy is invoked, the PDSN service rejects new sessions with an A11 Registration Reply Code of 88H (unknown PDSN address) and provides the IP address of an alternate PDSN. This command can be issued multiple times.

address: The IP address of an alternate PDSN expressed in IP v4 dotted decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.

weight *weight_num*: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. *weight_num* must be an integer from 1 through 10.

Usage

Policies can be implemented to dictate PDSN service behavior for various conditions such as overloading. The system invokes the overload policy if the number of calls currently being processed exceeds the licensed limit for the maximum number of sessions supported by the system.

The system automatically invokes the overload policy when an on-line software upgrade is started.

Use the **no policy { overload | service-option }** command to delete a previously configured policy. If after deleting the policy setting you desire to return the policy parameter to its default setting, use the **default policy** command.

The chassis is shipped from the factory with the policy options set as follows:

- overload disabled
- sequence-numbers enforced enabled

 **Caution:** Incorrect configuration of the **policy msid-match** and **policy pcf-zone-match** keywords could result in sessions failing to be established. For example, if PDSN1 is configured to redirect sessions to PDSN2 while PDSN2 is configured to redirect sessions to PDSN1, a loop is created in which all sessions would fail to be connected. In addition, sessions will not be established if the PDSN to which the sessions are being redirected is unavailable.

Example

The following command configures the PDSN service to redirect traffic to two different destinations with weights of 1 and 10 respectively:

```
policy overload redirect 192.168.1.100 weight 1 192.168.1.200 weight 10
```

ppp

Sets PPP tunneling parameters for subscribers in the current PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
ppp { tunnel-context context_name | tunnel-type { l2tp | l2tp-secure | none } }
no ppp tunnel-context
```

no

Clears the configured tunnel context entry.

tunnel-context *context_name*

The name of the context that has a LAC service configured to handle all tunnels from this PDSN service.

tunnel-type { l2tp | l2tp-secure | none }

l2tp: Force all subscriber sessions in this PDSN service to use L2TP tunneling.

l2tp-secure: Force all subscriber sessions in this PDSN service to use L2TP tunneling and use IPSEC to ensure a secure connection.

none: Do not force L2TP tunneling. This is the default.

 **Important:** If the context specified by the **ppp tunnel-context *context_name*** command does not have a LAC service configured and **tunnel-type** is set to **l2tp** or **l2tp-secure**, the call is rejected.

 **Important:** If the PPP tunnel context has not been set or has been cleared with the **no ppp tunnel-context** command and **tunnel-type** is set to **l2tp** or **l2tp-secure**, the context where the current PDSN service resides is used. If that context does not have a LAC service configured the call is rejected.

Usage

Use this command to enable or disable forced L2TP tunneling for all subscribers using this PDSN service. Also use this command to define which context defines the L2TP tunneling parameters.

Example

To set the tunnel context to the context named *context1* and enable forced L2TP tunneling, use the following commands;

```
ppp tunnel-context context1 ppp tunnel-type l2tp
```

To enable forced L2TP tunneling with IPSEC security, use the following commands;

```
ppp tunnel-type l2tp-secure
```

To disable forced tunneling, use the following command;

```
ppp tunnel-type none
```

To clear the setting for the tunnel context, use the following command;

```
no ppp tunnel-context
```

qos-profile-id-mapping

This command creates the customized QoS profile identifier to QoS mapping for IMS authorization support through a Ty interface at the PDSN service level.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
qos-profile-id-mapping profile-id id_num { description desc | downlink-bw dl_bw
| drop-rate drop_percentage | latency latency_duration | qos-class {class-A |
class-B | class-C | class-D | class-E | class-F } uplink-bw ul_bw }+
```

```
[ default | no ] qos-profile-id-mapping profile-id id_num
```

default

Configures the specified QoS profile ID for QoS mapping with default values in this PDSN service.

no

Removes the configured QoS profile ID mapping in this PDSN service.

profile-id *id_num*

Specifies the profile identifier for QoS parameters to be used as the customized profile ID or modifies the QoS parameters in a profile ID (*id_num*) coming from RAN.

id_num must be an integer between 0 and 65535.

description *desc*

Specifies the user defined description for profile identifier.

desc must be an alpha and/or numeric string between 1 and 32 characters.

downlink-bw *dl_bw*

Default: 32

Specifies the downlink (towards the MN) data traffic bandwidth in kilo-bits per second for this QoS profile.

dl_bw must be an integer value between 0 and 100000.

drop-rate *drop_percentage*

Default: 0

Specifies the permitted packet drop rate in percentage for traffic flow to this QoS profile.

drop_percentage must be an integer value between 0 and 1000.

latency *latency_duration*

Default: 1000

Specifies the permitted latency duration in milli-seconds for this QoS profile.

latency_duration must be an integer value between 0 and 1000.

```
qos-class {class-A | class-B | class-C | class-D | class-E | class-F }
```

Default: Class-C

Specifies the type of QoS class associated with this QoS profile

class-A: Specifies the A type of QoS class.

class-B: Specifies the B type of QoS class.

class-C: Specifies the C type of QoS class.

class-D: Specifies the D type of QoS class.

class-E: Specifies the E type of QoS class.

class-F: Specifies the F type of QoS class.

```
uplink-bw ul_bw
```

Default: 32

Specifies the uplink (from the MN) data traffic bandwidth in kilo-bits per second for this QoS profile.

ul_bw must be an integer value between 0 and 100000.

+

More than one of the above keywords can be entered within a single command.

Usage

Use this command to define the values associated with the profile ID on the PDSN. This profile ID is used during the mapping to and from the authorized QoS to the QoS parameters for the A10 link. This mapping is required because the PDSN only knows the profile IDs and not the actual configured values for the profile ID in the RAN. Also this configuration allows the use of custom profile IDs for the subscribers.

If no values are defined with a QoS profile ID, the values from matching QoS profile ID from RAN will be applicable to the subscriber traffic.

Example

The following command sets the downlink bandwidth to 32 kbps, latency duration as 1000 ms, uplink bandwidth to 32 kbps, and QoS class to Class-C for the QoS profile ID 11 in a PDSN service:

```
default qos-profile-id-mapping profile-id 11
```

qos update

Use this command to set QoS update parameters for policy mismatches or wait timeouts.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
qos-update [ policy-mismatch | wait-timeout seconds action [ disconnect-session
| downgrade-to-best-effort | drop-packets ] ]
```

```
[ no | default ] qos-update [ policy-mismatch | wait-timeout ]
```

no

Enables/Disables the `qos-update [policy-mismatch | wait-timeout]`.

default

Sets / Restores default value for `qos-update [policy-mismatch | wait-timeout]`.

policy-mismatch

PDSN raises a TFT violation if there is a QoS policy mismatch.

```
wait-timeout action [ drop-packets | disconnect-session | downgrade-to-
best-effort ]
```

Sets the wait time for A11 RRQ for QoS changes. *seconds* must be an integer from 1 through 1000.

action: configures the action on the wait-timeout

- **disconnect-session:** Drops the call if the A11 RRQ has not been received for the QoS update. This includes all of the IP flows for the session.
- **downgrade-to-best-effort:** Drops packets if the A11 RRQ has not been received for the QoS update. Sends the forward traffic over best effort (flow FF or FE if available).
- **drop-packets:** Drops packets if the A11 RRQ has not been received for the QoS update.

Usage

This command provides a PDSN service level configurable to configure an action, if the PCF ignores the QoS Update request from PDSN. It sets the amount of time to wait and the action to take, if no RRQ is received before the timeout. The action can be to drop packets for the flow, disconnect the session or to downgrade to best effort.

Example

```
qos-update policy mismatch
```

The following command sets **wait-timeout** to 60 seconds and invokes **downgrade-to-best-effort** if the A11 RRQ has not been received for the QoS update:

```
qos-update wait-timeout 60 action downgrade-to-best-effort
```

registration-accept

When the PDSN is tearing down a session and the MN moves over to a new PCF and initiates a new session, the PDSN by default does not accept the handoff until it tears down the old session. This command allows the PDSN to accept registration requests when a handoff disconnect is in progress.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

registration-accept handoff session-disconnect-in-progress

[**no** | **default**] **registration-accept handoff session-disconnect-in-progress**

no

Disable accepting of registration requests when a handoff disconnect is still in progress.

default

Default is disabled.

Sets / Restores default value assigned for **registration-accept handoff session-disconnect-in-progress**.

Usage

Use this command to allow the PDSN service to accept registration requests when a handoff disconnect is still in progress.

Example

```
registration-accept handoff session-disconnect-in-progress
```

registration-ack-deney terminate-session-on-error

Configure the PDSN service to terminate an A11 session when a Registration ACK received from the PCF has an error status.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
registration-ack-deney terminate-session-on-error
```

```
[ no | default ] registration-ack-deney terminate-session-on-error
```

no

Disable terminating A11 sessions on a Registration ACK error from the PCF.

default

Sets / Restores default value assigned to **registration-ack-deney terminate-session-on-error**.

Usage

Use this command to enable the PDSN service to terminate A11 sessions on a Registration ACK error from the PCF.

Example

Use the following command to enable this functionality in the PDSN:

```
registration-ack-deney terminate-session-on-error
```

registration-deny

Configures parameters related to registration rejection.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
registration-deny { handoff { closedrp-rp handoff-in-progress | onnection-setup-
record-absent [ use-deny-code { poorly-formed-request | reason-unspecified } |
max-deny-reply-limit num | mismatched-coa-source-address | new-call {
connection-setup-record-absent | reverse-tunnel-unavailable } | session-already-
active | session-already-closed | session-already-dormant | terminate-session-
on-error | use-zero-gre-key
```

```
no registration-deny { handoff { closedrp-rp handoff-in-progress | connection-
setup-record-absent } | mismatched-coa-source-address | new-call { connection-
setup-record-absent | reverse-tunnel-unavailable } | session-already-active |
session-already-closed | session-already-dormant | terminate-session-on-error |
use-zero-gre-key
```

```
default registration-deny { handoff { closedrp-rp handoff-in-progress |
connection-setup-record-absent } | mismatched-coa-source-address | new-call {
connection-setup-record-absent | reverse-tunnel-unavailable } | session-already-
active | session-already-closed | session-already-dormant | terminate-session-
on-error | use-zero-gre-key
```

default

Sets / Restores default value for **registration-deny**.

no

Disables the specified option.

```
handoff { closedrp-rp handoff-in-progress | connection-setup-record-
absent [ use-deny-code { poorly-formed-request | reason-unspecified
```

This command configures the handoff behavior.

closedrp-rp handoff-in-progress: Configures parameters related to denying handoffs from Closed-RP to RP systems. When enabled the PDSN rejects retransmitted handoff R-P requests when a handoff is already in progress from Closed RP to RP. The deny code used is 'Reason Unspecified'. The default is disabled meaning that the PDSN simply discards such requests.

connection-setup-record-absent [use-deny-code { poorly-formed-request | reason-unspecified }: When enabled the PDSN denies or discards handoff R-P sessions that do not have an Airlink Connection Setup record in the A11 Registration Request. Default is disabled. Default PDSN behavior is to accept such requests.

[use-deny-code { poorly-formed-request | reason-unspecified }: Sets the specified Registration Deny Code when denying a handoff because of a missing connection setup record.

max-deny-reply-limit *num*

Default: 3

Configures max number of retries of erroneous registration request message from PCF for a session before PDSN terminates the session. *num* can be from 1 to 10.

mismatched-coa-source-address

Default: disabled

Denies RP requests which have a care-of-address field that is different from the request source address.

new-call { **connection-setup-record-absent** [**use-deny-code** { **poorly-formed-request** | **reason-unspecified** } | **reverse-tunnel-unavailable** }**connection-setup-record-absent**: Configures the PDSN to reject calls that do not have the airlink connection setup record in the RRQ.**use-deny-code** { **poorly-formed-request** | **reason-unspecified** } When rejecting calls that do not have the airlink setup record, use the the specified deny code.**reverse-tunnel-unavailable**: Configures the PDSN to reject calls if the GRE key for a user collides with that of another user.

session-already-active

PDSN denies Registration requests for sessions that are already active with the error code “poorly formed request” .

session-already-closed

PDSN denies RP renew and dereg requests with error code 0x8E for absent R-P sessions.

session-already-dormant

PDSN denies Registration requests for sessions that are already dormant with the error code “poorly formed request” .

terminate-session-on-error

Default: Disabled.

Configures PDSN to terminate session if erroneous registration request message is received for the session.

use-zero-gre-key

Configures the PDSN to set the GRE key to zero (0) when denying a new R-P session.

Usage

Use this command to configure parameters relating to the rejection of registration requests.

Example

To reject calls that do not have the airlink setup record in the RRQ, enter the following command:

```
registration-deny new-call connection-setup-record-absent
```

To reject calls if the GRE key collides with that of another user, enter the following command:

■ registration-deny

```
registration-deny new-call reverse-tunnel-unavailable
```

To set the GRE key to 0 (zero) when a new R-P session is denied, enter the following command:

```
registration-deny new-call use-zero-gre-key
```

registration-discard

Configures the PDSN service to discard any Registration Request message containing multiple information elements of the same type or a different GRE key for existing IMSI session.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
registration-discard { bad-extension | gre-key-change | handoff connection-  
setup-record-absent }
```

```
no registration-discard { bad-extension | gre-key-change | handoff connection-  
setup-record-absent }
```

```
default registration-discard { bad-extension | gre-key-change | handoff  
connection-setup-record-absent }
```

default

Sets / Restores default value assigned for **registration-discard** .

no

Disables the discarding of Registration request messages containing multiple information elements or different GRE keys.

bad-extension

Default: Disabled

Configures the PDSN to discard Registration Request message containing multiple information elements of same type.

gre-key-change

Default: Disabled

Configures PDSN to discard Registration Request message containing different GRE key for existing IMSI session. Default is disable

handoff connection-setup-record-absent

Default: Disabled

When enabled, discards A11 Handoff requests that do not contain the Airlink Setup record.

Usage

Use this command to configure the PDSN service to discard and Registration Requests that contain multiple information elements of the same type or discard Registration Requests that contain GRE keys that have different GRE keys for the existing IMSI session.

■ registration-discard

Example

To configure the PDSN service to discard of Registration Requests that have multiple information elements of the same type, enter the following command:

```
registration-discard bad-extension
```

To configure the PDSN service to discard registration Requests that contain a GRE key that is different than the existing one for the existing IMSI session, enter the following command:

```
registration-discard gre-key-change
```

registration-update

Configures registration update related parameters for the PDSN.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
registration-update { pdsn-code-nvse | wait-timeout secs }  
no registration-update { pdsn-code-nvse | wait-timeout }  
default registration-update { pdsn-code-nvse | wait-timeout }
```

no

If this option is used with the **pdsn-code-nvse** keyword, then pdsn-code-nvse configuration is disabled. If this option is used with the **wait-timeout** keyword, a separate A11 timer is not used. The PDSN waits for the ppp retransmit-timeout and then sends the A11 Update. If a value is provided, then the "ppp retransmit-timeout" is ignored and a separate A11 timeout is started immediately upon sending the LCP Term-Ack. The A11 Update is then sent when the timer expires. A value of 0 sends the A11 Update immediately after sending the LCP Term-Ack.

default

Sets / Restores default value assigned for **registration-update { pdsn-code-nvse | wait-timeout }**

pdsn-code-nvse

Adds the PDSN code NVSE in all A11 registration update messages.

secs

The number of seconds to wait. *secs* must be an integer in the range from 0 through 16.

wait-timeout

After the Mobile Node terminates a PPP session between the PDSN and the Mobile Node, the PDSN service waits for the specified time period to receive an A11 RRQ from the PCF before it sends out a Registration-Update to clear the Session from the PCF.

Usage

Use this command to configure registration update related. The **wait-timeout** keyword configures the PDSN to wait the specified amount of time before sending out a Registration-Update to clear the Session from the PCF.

■ registration-update

Example

Use the following command to set the registration wait-timeout to 16 seconds:

```
registration-update wait-timeout 16
```

retransmission-timeout

Configures the maximum allowable time for the PDSN service to wait for a response from the PCF before it a) attempts to communicate with the PCF again (if the system is configured to retry the PCF) or b) marks the PCF as unreachable.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
retransmission-timeout time
```

```
no retransmission-timeout
```

```
default retransmission-timeout
```

no

Enables/Disables the **retransmission-timeout**.

default

Sets / Restores default value assigned for **retransmission-timeout**.

time

Specifies the maximum allowable time for the PDSN service to wait for a response from the PCF before it a) attempts to communicate with the PCF again (if the system is configured to retry the PCF) or b) marks the PCF as unreachable.

time is measured in seconds and can be configured to any integer value between 1 and 1,000,000.

Usage

Use the retransmission timeout command in conjunction with the **max-retransmissions** command in order to configure the PDSN services behavior when it does not receive a response from a particular PCF. Use the **no retransmission-timeout** command to delete a previously configured timeout value. If after deleting the lifetime setting you desire to return the lifetime parameter to its default setting, use the **default retransmission-timeout** command.

The chassis is shipped from the factory with the retransmission timeout set to 3 seconds.

Example

The following command configures a retransmission timeout value of 5 seconds:

```
retransmission-timeout 5
```

The following command deletes a previously configured retransmission-timeout setting:

```
no retransmission-timeout
```

■ retransmission-timeout

sdb-indication

Configures parameters pertaining to Short Data Burst (SDB) functionality.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
sdb-indication { echo-request | server-address ipaddress/mask packet-length-range min min_range max max_range }
```

```
no sdb-indication { echo-request | server-address ipaddress/mask }
```

no

Disables short-databurst indication.

echo-request

Default: Disabled

Enables the inclusion of the SDB indicator in the LCP Echo Request message(s).

server-address *ipaddress/mask*

Configures the IP address of the PTT server.

ipaddress is the IP address expressed in dotted decimal notation.

mask is the number of mask bits.

packet-length-range min *min_range* max *max_range*

Configures the packet length associated with the specified server.

min *min_range* configures the minimum packet length as an integer value between 1 and 65535.

max *max_range* configures the maximum packet length as an integer value between 1 and 65535.

Usage

This command controls the use of Short Data Burst functionality between the PDSN, PCF, and Push-to-Talk (PTT) servers.

Important: This command is for use with a customer-specific implementation and requires a valid Short Data Burst feature-use license to be installed.

Example

The following command configures a PTT server address of 192.168.1.200 with a mask of 16, a minimum packet size of 200, and a maximum packet size of 400:

■ sdb-indication

```
sdb-indication server-address 192.168.1.200/16 packet-length-range min  
200 max 400
```

service-option

If the service option policy is enabled, this command specifies the service options supported by the PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
service-option number
```

```
no service-option number
```

```
default service-option
```

no

Enables/Disables the **service-option** *number*

default

Sets / Restores default value assigned for **service-option**.

number

Default: 7, 15, 22, 23, 24, 25, 33, 59, 67

Specifies a specific Service Option (SO) number that this PDSN service is allowed to support. number can be configured to any integer value between 1 and 1000.

Usage

Use the service option command in conjunction with the policy service option enforce command to configure specific SO numbers that are supported. If a particular SO number is not configured, then any subscriber session received with that SO number will be rejected and an A11 Registration Reply Code of 86 (poorly formed request) will be sent.

By default, PDSN services are configured to support the following service option numbers:

- 7: PCF specific
- 15: PCF specific
- 22: High Speed Packet Data Service: Internet or ISO Protocol Stack (RS1 forward, RS1 reverse)
- 23: High Speed Packet Data Service: Internet or ISO Protocol Stack (RS1 forward, RS2 reverse)
- 24: High Speed Packet Data Service: Internet or ISO Protocol Stack (RS2 forward, RS1 reverse)
- 25: High Speed Packet Data Service: Internet or ISO Protocol Stack (RS2 forward, RS2 reverse)
- 33: 3G High Speed Packet Data
- 59: High Rate Packet Data
- 67: RP A10 connection

Important: Option 67 is used for auxiliary connections for Rev-A calls. PPP encapsulation of data packets does not flow over this service option connection. ROHC can be performed without PPP for this service option.

Use the **no service-option *number*** command to delete a previously configured service option. If after deleting the service option setting you desire to return the service option parameter to its default setting, use the **default service-option command**.

Example

The following command enables a service option of 12:

```
service-option 12
```

The following command disables the default service option 59 :

```
no service-option 59
```

setup-timeout

The maximum amount of time allowed for session setup.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
setup-timeout seconds
```

```
default setup-timeout
```

default

Sets / Restores default value assigned for **setup-timeout**.

seconds

Default: 60 seconds

The maximum amount of time, in seconds, to allow for setup of a session. *seconds* must be an integer from 1 through 1000000

Usage

Use this command to set the maximum amount of time allowed for setting up a session.

Example

Use the following command to set the maximum time allowed for setting up a session to 300 seconds:

```
setup-timeout 300
```

simple-ip allow

This command is used to disable or re-enable Simple-IP sessions from making a connection before authorization takes place.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[no|default] simple-ip allow
```

no

When a session attempts PPP authentication, it is assumed that it is a Simple-IP session and it is disconnected before the user is authenticated (RADIUS or local authentication). Also, if **allow-noauth** is enabled and PPP authentication is not performed, after IPCP the session is disconnected if it is discovered that it is a Simple-IP session.

default

Reset this command to allow Simple-IP sessions to connect.

Usage

Use this command to prevent Simple-IP sessions from connecting to a PDSN service.

Example

The following command configures the PDSN service so that it will reject any Simple-IP sessions:

```
no simple-ip allow
```

The following command configures the PDSN service to allow Simple-IP sessions:

```
simple-ip allow
```

spi

Configures the security parameter index (SPI) between the PDSN service and the PCF. This command also configures the redirection of call based on PCF zone.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
spi remote-address { pcf_ip_address | ip_addr_mask_combo } } spi-number
number { encrypted secret enc_secret | secret secret } [ description string
} ] [ hash-algorithm { md5 | rfc2002-md5 } ] [ replay-protection { nonce |
timestamp } ] [ timestamp-tolerance tolerance ] [ zone zone_id ]
```

```
no spi remote-address pcf_ip_address spi-number number
```

```
remote-address { pcf_ip_address | ip_addr_mask_combo }
```

pcf_ip_address: Specifies the IP address of the PCF. *pcf_ip_address* is an IP address expressed in IP v4 dotted decimal notation.

ip_addr_mask_combo: Specifies the IP address of the PCF and specifies the IP address network mask bits. *ip_addr_mask_combo* must be specified using the form 'IP Address/Mask Bits' where the IP address must either be an IPv4 address expressed in dotted decimal notation or an IPv6 address expressed in colon notation and the mask bits are a numeric value which is the number of bits in the subnet mask.

```
spi-number number
```

Specifies the SPI (number) which indicates a security context between the PCF and the PDSN in accordance with IOS 4.1 and RFC 2002.

number can be configured to any integer value between 256 and 4294967295.

```
encrypted secret enc_secret | secret secret
```

Configures the shared-secret between the PDSN service and the PCF. The secret can be either encrypted or non-encrypted.

encrypted secret *enc_secret*: Specifies the encrypted shared key (*enc_secret*) between the PCF and the PDSN service. *enc_secret* must be between 1 and 254 alpha and/or numeric characters and is case sensitive.

secret *secret*: Specifies the shared key (*secret*) between the PCF and the PDSN services. *secret* must be between 1 and 127 alpha and/or numeric characters and is case sensitive.

The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **secret** keyword is the encrypted version of the plain text secret key. Only the encrypted secret key is saved as part of the configuration file.

```
description string
```

This is a description for the SPI. *string* must be an alpha and or numeric string of from 1 through 31 characters.

```
hash-algorithm { md5 | rfc2002-md5 }
```

Default: md5

Specifies the hash-algorithm used between the PDSN service and the PCF.

md5: Configures the hash-algorithm to implement MD5 per RFC 1321.

rfc2002-md5: Configures the hash-algorithm to implement keyed-MD5 per RFC 2002.

```
replay-protection { nonce | timestamp }
```

Default: timestamp

Specifies the replay-protection scheme that should be implemented by the PDSN service.

nonce: Configures replay protection to be implemented using NONCE per RFC 2002.

timestamp: Configures replay protection to be implemented using timestamps per RFC 2002.

```
timestamp-tolerance tolerance
```

Default: 60

Specifies the allowable difference (tolerance) in timestamps that is acceptable. If the difference is exceeded, then the session will be rejected. If this is set to 0, then time stamp tolerance checking is disabled at the receiving end.

tolerance is measured in seconds and can be configured to any integer value between 0 and 65535.

```
zone zone_id
```

Specifies the different PCF zones to configure in PDSN service. Mapping of a zone-number to a set of PDSNs can be done per PDSN service basis.

zone_id must be an integer value between 1 and 32. A maximum of 32 PCF zones can be configured for a PDSN service.

Usage

An SPI is a security mechanism configured and shared by the PCF and the PDSN service. Please refer to IOS 4.1 and RFC 2002 for additional information.

Multiple SPIs can be configured if the PDSN service is communicating with multiple PCFs.

Important: The SPI configuration on the PCF must match the SPI configuration for the PDSN service on the system in order for the two devices to communicate properly.

Use the **no** version of this command to delete a previously configured SPI.

This command used with **zone zone_id** redirects all calls on the basis of PCF zone to the specific PDSN on the basis of parameters configured at policy pcf-zone-match command.

Example

The following command configures the PDSN service to use an SPI of 256 when communicating with a PCF with the IP address 192.168.0.2. The key that would be shared between the PCF and the PDSN service is q397F65.

```
spi remote-address 192.168.0.2 spi-number 256 secret q397F65
```

The following command deletes the configured SPI of 400 for an PCF with an IP address of 172.100.3.200:

```
no spi remote-address 172.100.3.200 spi-number 400
```

The following command creates the configured SPI of 400 for an PCF with an IP address of 172.100.3.200 and zone id as 11:

```
spi remote-address 172.100.3.200 spi-number 400 zone 11
```

spi zone

Configures the security parameter index (SPI) between the PDSN service and the PCF with mapping between a zone number to a set of PDSNs per PDSN service to redirect call on the basis of PCF zone.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
spi zone zone_id
```

```
no spi zone zone_id
```

```
zone zone_id
```

Default: 60

Specifies the different PCF zones to configure in PDSN service. Mapping of a zone-number to a set of PDSNs can be done per PDSN service basis.

zone_id must be an integer value between 1 and 32. A maximum of 32 PCF zones can be configured for a PDSN service.

Usage

An SPI is a security mechanism configured and shared by the PCF and the PDSN service. Please refer to IOS 4.1 and RFC 2002 for additional information.

Multiple SPIs can be configured if the PDSN service is communicating with multiple PCFs.

This PCF zone option is used for call redirection on the basis of PCF zone. When a new call arrives the PDSN, it checks whether the PCF, from which the call arrived, belongs to a particular zone. If

Important: The SPI configuration on the PCF must match the SPI configuration for the PDSN service on the system in order for the two devices to communicate properly.

Use the **no** version of this command to delete a previously configured SPI.

Example

The following command configures the PDSN service to use an SPI of 256 when communicating with a PCF with the IP address 192.168.0.2. The key that would be shared between the PCF and the PDSN service is q397F65.

```
spi remote-address 192.168.0.2 spi-number 256 secret q397F65
```

The following command deletes the configured SPI of 400 for an PCF with an IP address of 172.100.3.200:

```
no spi remote-address 172.100.3.200 spi-number 400
```

threshold a11-rrp-failure

Set an alarm or alert based on the number of A11 Registration Response failures for the PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold a11-rrp-failure high_thresh [ clear low_thresh ]
```

```
no threshold a11-rrp-failure
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of A11 Registration Response failures that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear *low_thresh*

Default:0

The low threshold number of A11 Registration Response failures that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of A11 Registration Response failures is equal to or greater than a specified number.

Alerts or alarms are triggered for the number of A11 Registration Response failures based on the following rules:

- **Enter condition:** Actual number of A11 Registration Response failures > High Threshold
- **Clear condition:** Actual number of A11 Registration Response failures £ Low Threshold

Example

The following command configures a number of A11 Registration Response failures threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold a11-rrp-failure 1000 clear 500
```

■ threshold a11-rrp-failure

threshold a11-rrq-msg-discard

Set an alarm or alert based on the number of Discarded A11 Registration Requests for the PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold all-rrq-msg-discard high_thresh [ clear low_thresh ]  
no threshold all-rrq-msg-discard
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of Discarded A11 Registration Requests that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear *low_thresh*

Default:0

The low threshold number of Discarded A11 Registration Requests that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of Discarded A11 Registration Requests is equal to or greater than a specified number.

Alerts or alarms are triggered for the number of Discarded A11 Registration Requests based on the following rules:

- **Enter condition:** Actual number of Discarded A11 Registration Requests > High Threshold
- **Clear condition:** Actual number of Discarded A11 Registration Requests \leq Low Threshold

Example

The following command configures a number of Discarded A11 Registration Requests threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold all-rrq-msg-discard 1000 clear 500
```

■ threshold a11-rrq-msg-discard

tft-validation wait-timeout

This command configures the TFT validation wait timeout value for QoS changes. The QoS update timer triggers automatic QoS updates based on dynamic policies.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
tft-validation wait-timeout seconds
```

```
[ no | default ] tft-validation wait-timeout
```

no

Removes the wait-timeout timer.

default

Sets / Restores default value assigned for **tft-validation wait-timeout**.

Usage

Configures the TFT validation wait time value for All RRQ for QoS changes. *seconds* must be an integer from 1 through 65535.

Example

Use the following command to set the TFT validation wait-timeout to 5 seconds:

```
tft-validation wait-timeout 5
```

threshold a11-rac-msg-discard

Set an alarm or alert based on the number of Discarded A11 Registration Acknowledgements for the PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold a11-rac-msg-discard high_thresh [ clear low_thresh ]
```

```
no threshold a11-rac-msg-discard
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of Discarded A11 Registration Acknowledgements that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear *low_thresh*

Default:0

The low threshold number of Discarded A11 Registration Acknowledgements that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of Discarded A11 Registration Acknowledgements is equal to or greater than a specified number.

Alerts or alarms are triggered for the number of Discarded A11 Registration Acknowledgements based on the following rules:

- **Enter condition:** Actual number of Discarded A11 Registration Acknowledgements > High Threshold
- **Clear condition:** Actual number of Discarded A11 Registration Acknowledgements £ Low Threshold

Example

The following command configures a number of Discarded A11 Registration Acknowledgements threshold of *1000* and a low threshold of *500* for a system using the Alarm thresholding model:

```
threshold all-rac-msg-discard 1000 clear 500
```

threshold all-ppp-send-discard

Set an alarm or alert for the PDSN service based on the number of packets that the PPP protocol processing layer internally discarded on transmit for any reason.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold all-ppp-send-discard high_thresh [ clear low_thresh]
```

```
no threshold all-ppp-send-discard
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold number of discarded PPP send packets that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 100000.

clear *low_thresh*

Default:0

The low threshold number of discarded PPP send packets that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 100000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the number of discarded PPP send packets is equal to or greater than a specified number.

Alerts or alarms are triggered for the number of discarded PPP send packets is based on the following rules:

- **Enter condition:** Actual number of discarded PPP send packets > High Threshold
- **Clear condition:** Actual number of discarded PPP send packets £ Low Threshold

Example

The following command configures a number of discarded PPP send packets threshold of *1000* and a low threshold of *500* for a system using the Alarm thresholding model:

```
threshold all-ppp-send-discard 1000 clear 500
```

threshold init-rrq-rcvd-rate

Set an alarm or alert based on the average number of calls setup per second for the context.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
threshold init-rrq-rcvd-rate high_thresh [ clear low_thresh ]
```

```
no threshold init-rrq-rcvd-rate
```

no

Deletes the alert or alarm.

high_thresh

Default: 0

The high threshold average number of calls setup per second must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured to any integer value between 0 and 1000000.

clear low_thresh

Default:0

The low threshold average number of calls setup per second that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured to any integer value between 0 and 1000000.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the average number of calls setup per second is equal to or greater than a specified number of calls per second.

Alerts or alarms are triggered for the number of calls setup per second based on the following rules:

- **Enter condition:** Actual number of calls setup per second > High Threshold
- **Clear condition:** Actual number of calls setup per second £ Low Threshold

Example

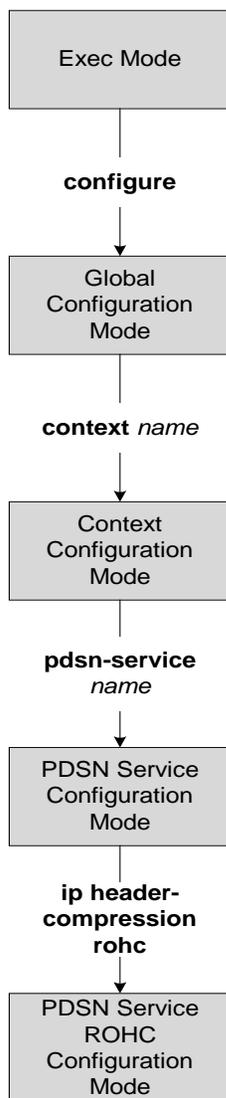

The following command configures a number of calls setup per second threshold of 1000 and a low threshold of 500 for a system using the Alarm thresholding model:

```
threshold init-rrq-rcvd-rate 1000 clear 500
```

Chapter 189

PDSN Service RoHC Configuration Mode Commands

The PDSN Service RoHC Configuration Mode is used to configure RoHC (Robust Header Compression) parameters the PDSN service conveys to the PCF in the initial A11 RRP message before PPP authentication.

 **Important:** The commands, keywords and variables in this mode are available dependent on platform type, product version, and installed license(s).

■ threshold init-rrq-rcvd-rate

cid-mode

This command enters the RoHC Profile Compression Options Configuration mode. This mode allows you to configure options that apply during RoHC compression for the current RoHC profile.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
cid-mode { large | small } max-cid integer
```

```
default cid-mode
```

default

Reset all options in the RoHC Profile Compression Configuration mode to their default values.

large

Use large packets with optional information for RoHC

small

This is the default packet size.
Use small RoHC packets.

max-cid *integer*

Default: 15

The highest context ID number to be used by the compressor. *integer* must be an integer from 0 through 15 when small packet size is selected and must be an integer from 0 through 31 when large packet size is selected.

Usage

Use this command to set the RoHC packet size and define the maximum

Example

The following command sets large RoHC packet size and sets the maximum CID to 100:

```
cid-mode large max-cid 100
```

The following command sets the cid-mode to the default settings of small packets and max-cid 0:

```
default cid-mode
```

■ end

end

Returns the CLI prompt to the Exec mode.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits this configuration mode and returns to the PDSN Service configuration mode.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the PDSN Service configuration mode.

mrru

This command sets the size of the largest reconstructed reception unit, in octets, that the decompressor is expected to reassemble from segments. The size includes the CRC. If MRRU is negotiated to be 0, no segment headers are allowed on the channel.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
mrru num_octets
```

```
default mrru
```

default

reset the value of this command to its default setting

num_octets

Default: 0

This is the number of octets for the maximum size of the largest reconstructed reception unit allowed. *num_octets* must be an integer from 0 through 65535.

Usage

Use this command to set the size, in octets, of the largest reconstructed reception unit, in octets, that the decompressor is expected to reassemble from segments.

Example

The following command sets the largest reconstructed reception unit to 1024 octets:

```
mrru 1024
```

The following command resets the mrru size to its default of 0 octets:

```
default mrru
```

profile

This command specifies the header compression profiles to use. A header compression profile is a specification of how to compress the headers of a specific kind of packet stream over a specific kind of link. At least one profile must be specified.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
profile { [ esp-ip ] [ rtp-udp ] [ udp-ip ] [ uncompressed-ip ] }
```

```
default profile
```

default

Default: esp-ip rtp-udp udp-ip uncompressed-ip

This command sets the RoHC profile configuration back to its default setting.

esp-ip

This enables RoHC Profile 0x0003 which is for ESP/IP compression, compression of the header chain up to and including the first ESP header, but not subsequent subheaders.

rtp-udp

This enables RoHCProfile 0x0001 which is for RTP/UDP/IP compression

udp-ip

This enables RoHC Profile 0x0002 which is for UDP/IP compression, compression of the first 12 octets of the UDP payload is not attempted.

uncompressed-ip

This enables RoHC Profile 0x0000 which is for sending uncompressed IP packets.

Usage

Use this command to specify the RoHC header compression profiles to use.

Example

The following command sets the profiles to use as esp-ip and rtp-udp:

```
profile esp-ip rtp-udp
```

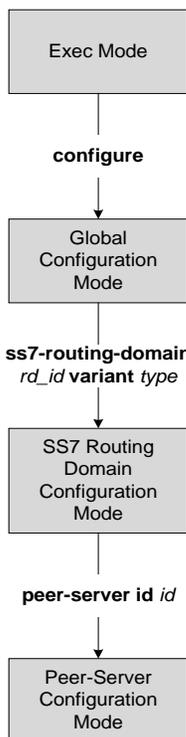

Chapter 190

Peer-Server Configuration Mode Commands

The Peer-Server configuration mode provides the commands to define and manage the peer server configuration part of the SS7 routing on an SGSN.

In this mode, the prompt line usually appears similar to:

```
[local]hostname(config-ss7-rd-<ss7rd_id>-ps-id-<ps_id>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the configuration mode and returns to the Global configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Global configuration mode.

mode

Configures the operational mode of the peer-server.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mode ( loadshare | standby )
```

loadshare

Sets the peer-server to load share. This is the default.

standby

Sets the peer-server to be in standby mode.

Usage

Configure the operational mode of the peer-server.

Example

Configure the peer-server for standby mode.

```
mode standby
```

name

Defines the unique identification - the name - of the peer-server in the SS7 routing domain.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

name *name*

no name

no

Removes the peer server's name from this configuration instance.

name

name : Must be a string of 1 to 64 alphanumeric characters to define a unique identification for the peer-server within the specific SS7 routing domain. Double quotes must be used to create a name that includes spaces.

Usage

Create peer server names that are easy to remember and uniquely identify the PSP.

Example

Use this command to create an easily remembered alphanumeric name for the peer-server:

```
name "Berlin West"
```

psp

Creates the peer-server-process (PSP) instance and enters the PSP configuration mode. See the PSP Configuration Mode chapter in this guide for information on the configuration commands.

Important: This command configures a mandatory parameter in the configuration of the peer server.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] psp instance id
```

no

Removes the PSP instance from the peer server configuration.

id

id Uniquely identifies the specific peer-server-process configuration. The Id must be an integer from 1 to 4.

Usage

Use this command to define the peer-server-process (PSP) instance ID number for the SGSN configuration.

Example

Use this command to create instance #3 for the PSP configuration:

```
psp instance 3
```

routing-context

Defines the ID of the routing context for the peer-server to use.

Important: This command configures a mandatory parameter in the configuration of the peer server.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
routing-context id
```

```
no routing-context
```

id

id Uniquely identifies a specific routing context for the peer-server-process to use. The Id must be an integer from 1 to 65535.

no

Removes the routing-context definition from the peer server configuration.

Usage

Use this command to define routing contexts for the peer server.

Example

Define routing-context instance 15:

```
routing-context 15
```

self-point-code

This command defines the point-code to identify the SGSN as a peer server.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
self-point-code point-code
```

```
no self-point-code
```

point-code

Point-code is an SS7-type address for an element in the SS7 network. Point-codes must be defined in dotted-decimal format in a string of 1 to 11 digits. Options include:

- 0.0.1 to 7.255.7 for point-code in the ITU range.
- 0.0.1 to 255.255.255 for point-code in the ANSI range.
- 0.0.1 to 15.31.255 for point-code in the TTC Range.
- a string of 1 to 11 digits in dotted-decimal to represent a point-code in a different range.

no

Removes the self-point-code configuration for this linkset in the peer server.

Important: Removing the self-point-code will result in the termination of all traffic on this link.

Usage

Use this command to define the point-code to identify the SGSN.

Example

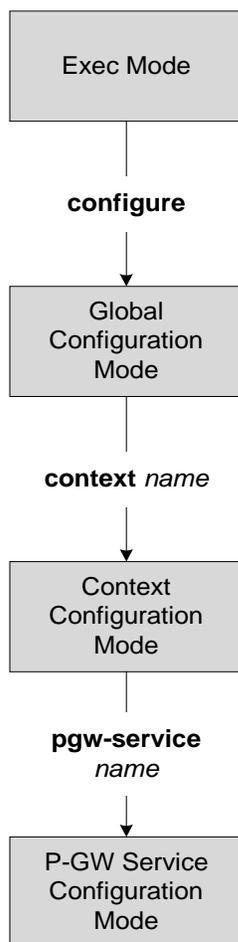

Use the following command to remove the self-point-code definition from the peer-server configuration:

```
no self-point-code
```

Chapter 191

P-GW Service Configuration Mode Commands

The P-GW (PDN Gateway) Service Configuration Mode is used to create and manage the relationship between specified services used for either GTP or PMIP network traffic.

associate

Associates the P-GW service with specific pre-configured services and/or policies configured in the same context.

Product

P-GW

Privilege

Administrator

Syntax

```
associate { egtp-service name [ lma-service name ] | ggsn-service name | lma-
service name [ egtp-service name ] | qci-qos-mapping name }
```

```
no associate { egtp-service | lma-service | qci-qos-mapping }
```

no

Removes the selected association from this service.

```
{ egtp-service name [ lma-service name ] | lma-service name [ egtp-
service name ] }
```

egtp-service *name* [**lma-service** *name*]: Specifies that the P-GW service is to be associated with an existing eGTP service within this context. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing eGTP service.

Configure an associated LMA service name to support handoffs between PMIPv6 and GTP. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing LMA service.

lma-service *name* [**egtp-service** *name*]: Specifies that the P-GW service is to be associated with an existing LMA service within this context. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing LMA service.

Configure an associated eGTP service name to support handoffs between PMIPv6 and GTP. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing eGTP service.

ggsn-service *name*

Specifies that the P-GW service is to be associated with an existing GGSN service within this context. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing GGSN service.

qci-qos-mapping *name*

Specifies that the P-GW service is to be associated with an existing QCI-QoS mapping configuration within this context. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing QCI-QoS mapping configuration.

QCI-QoS mapping is typically configured in a AAA context. Refer to the QCI-QoS Mapping Configuration Mode Commands chapter for more information.

Usage

Use this command to associate the P-GW service with other pre-configured services and/or policies configured in the same context.

Example

The following command associates this service with an eGTP service called *egtp1*:

```
associate egtp-service egtp1
```

authorize-with-hss

Identifies the function to use for subscriber authorization.

Product

P-GW

Privilege

Administrator

Syntax

```
[ default | no ] authorize-with-hss
```

```
[ default | no ]
```

Resets the command to the default setting of “authorize locally” from an internal APN authorization configuration.

Usage

Use this command to specify that the system will use the S6b interface to acquire subscriber authorization from a 3GPP AAA server and the HSS.

dns-client

Specifies the context to use where the DNS client resides to send DNS queries.

Product

P-GW

Privilege

Administrator

Syntax

```
dns-client context name
```

```
[ default | no ] dns-client context
```

default

Returns the command to the default setting of targeting the DNS client in the context where the P-GW service resides.

no

DNS query is disabled.

name

Specifies the name of the context where the DNS client is used for the resolution of PCSCF-FQDN received from S6b interface. *name* must be an existing context and be from 1 to 79 alpha and/or numeric characters.

Usage

Use this command to specify the context where the DNS client resides to perform P-CSCF-FQDN resolution from the S6b interface.

Example

The following command identifies the *egress1* context as the context where the DNS client resides:

```
dns-client context egress1
```

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax`exit`

Usage

Return to the previous mode.

fqdn

Configures a Fully Qualified Domain Name for this P-GW service used in messages between the P-GW and a 3GPP AAA server over the S6b interface.

Product

P-GW

Privilege

Administrator

Syntax

```
fqdn host domain_name realm realm_name
```

```
[ default | no ] fqdn
```

default

Returns the command to the default setting of “null”.

no

Remove the configured FQDN from this services configuration.

host*domain_name*

Specifies the domain name of the P-GW service. *domain_name* must be from 1 to 255 alpha and/or numeric characters.

realm*realm_name*

Specifies the realm name of the P-GW service. *realm_name* must be from 1 to 255 alpha and/or numeric characters.

Usage

Use this command to identify the P-GW service using an FQDN required when sending messages over the S6b interface to a 3GPP AAA server.

Important: In order to properly interact with other nodes in the network, the FQDN should be 96 alpha and/or numeric characters or less.

Topology Matching (eHRPD only)

You may specify which P-GW you wish an HSGW interface to connect with by enabling topology matching within the FQDNs for both the HSGW service and P-GW service. Topology matching selects geographically closer nodes and reduces backhaul traffic for a specified interface.

The following optional keywords enable or disable topology matching when added to the beginning of an FQDN:

- **topon**.<*interface_name*>.

Beginning an FQDN with **topon** initiates topology matching with available HSGWs in the network. Once this feature is enabled, the rest of the FQDN is processed from right to left until a matching regional designator is found on a corresponding HSGW FQDN.

- **topoff**.<interface_name>.

By default, topology matching is disabled. If you enable topology matching for any interfaces within a node, however, all interfaces not using this feature should be designated with **topoff**.

Example

The following command configures the FQDN for this P-GW service as *123abc.all.com* with a realm name of *all.com*:

```
fqdn host 123abc.all.com realm all.com
```

The following command configures this P-GW service with an FQDN that enables topology matching:

```
fqdn host
topon.<interface_name>.pgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppnetwork.org realm node.epc.<mnc>.<mcc>.3gppnetwork.org
```

Important: The associated HSGW service must have a corresponding FQDN similar to the following:

```
topon.<interface_name>.hsgw01.bos.ma.node.epc.mnc<value>.mcc<value>.3gppnetwork.org
```

■ gx-li

gx-li

Refer to the *ASR 5000 Lawful Intercept Configuration Guide* for a description of this command.

newcall

Configures the P-GW to accept or reject requests for a static IP address if the address is already in use by another session.

Product

P-GW

Privilege

Administrator

Syntax

```
newcall duplicate-subscriber-requested-address { accept | reject }
```

```
no newcall duplicate-subscriber-requested-address
```

no

Returns the command to the default setting of “reject”.

duplicate-subscriber-requested-address { accept | reject }

Default: reject

accept: Specifies that the old session with the requested address will be ended to accept the new session with the same address.

reject: Specifies that the new session requesting the same address will be rejected.

Usage

Use this command to configure the behavior of the P-GW service when receiving requests for static IP address already in use by other sessions.

Important: This command is only applicable to sessions using services supporting duplicate address abort. These services include HA, GGSN, and P-GW.

Example

The following command allows for the acceptance of requests for static IP addresses already in use by other sessions:

```
newcall duplicate-subscriber-requested-address accept
```

plmn

Configures Public Land Mobile Network identifiers used to determine if a mobile station is visiting, roaming, or belongs to this network.

Product

P-GW

Privilege

Administrator

Syntax

```
plmn id mcc number mnc number [ primary ]
```

mcc *number* **mnc** *number*

mcc *number*: Specifies the mobile country code (MCC) portion of the PLMN's identifier. *number* is the PLMN MCC identifier and must be an integer value between 100 and 999.

mnc *number*: Specifies the mobile network code (MNC) portion of the PLMN's identifier. *number* is the PLMN MNC identifier and can be configured to any 2 or 3 digit integer value between 00 and 999.

primary

When multiple PLMN IDs are configured, the **primary** keyword can be used to designate one of the PLMN IDs to be used for the AAA attribute.

Usage

The PLMN identifier is used to aid the P-GW service in the determination of whether or not a mobile station is visiting, roaming, or home. Multiple P-GW services can be configured with the same PLMN identifier. Up to five PLMN IDs can be configured for each P-GW Service.

Example

The following command configures the PLMN identifier with an MCC of *462* and MNC of *02*:

```
plmn id mcc 462 mnc 02
```

session-delete-delay

Configures a delay in terminating a session.

Product

P-GW

Privilege

Administrator

Syntax

```
session-delete-delay timeout [ msec ]  
[ default | no ] session-delete-delay timeout
```

default

Resets the command to the default setting of 10000 msec.

no

Disables the feature.

timeout msec

Default: 10000

Specifies the time to retain the session before terminating it. *msec* must be an integer from 1000 to 60000.

Usage

Use this command to set a delay to provide session continuity in case of break-before-make scenario.

Example

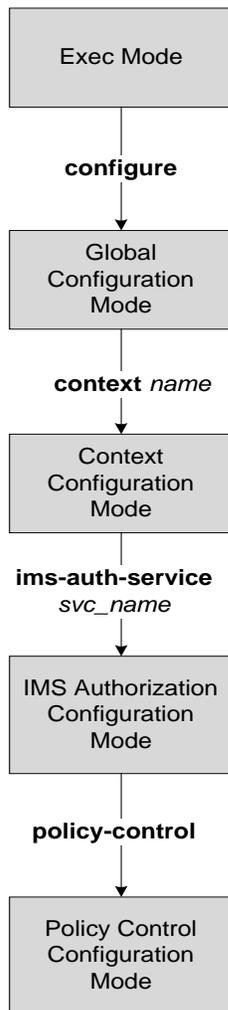

The following command sets the session delete delay to the default setting of 10,000 msec:

```
session-delete-delay timeout
```

Chapter 192

Policy Control Configuration Mode Commands

Policy Control Configuration mode is used to configure the Diameter dictionary, origin host, host table entry and host selection algorithm for IMS Authorization service.

apn-name-to-be-included

This command configures the APN name to be included in CCR Gx messages.

Product

GGSN, IPSP, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
apn-name-to-be-included { gn | virtual }
```

```
default apn-name-to-be-included
```

default

Applies the default setting for this command.

Default: **gn**

gn | virtual

Specifies which APN name must be sent in the Gx messages.

gn: Send the real APN name.

virtual: Send the virtual APN name if present, else send the real APN name.

Usage

Use this command to configure the APN name to be included in the CCR Gx messages to the PCRF — the real APN name or the virtual APN name.

Example

The following command configures sending the real APN name in Gx messages:

```
apn-name-to-be-included gn
```

custom-reauth-trigger

This command enables custom reauth event triggers.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
custom-reauth-trigger { none | { preservation-changed | reactivation-changed } +  
}
```

```
default custom-reauth-trigger
```

default

Configures the default setting for this command.

none

Disables all custom event triggers.
This is the default setting.

preservation-changed

Enables preservation-changed event trigger.

 **Important:** This keyword is for use with a customer-specific implementation, and will be available only if a valid license is installed.

reactivation-changed

Enables reactivation-changed event trigger.

 **Important:** This keyword is for use with a customer-specific implementation, and will be available only if a valid license is installed.

Usage

Use this command to enable/disable custom reauth event triggers.

It is recommended that the preservation-changed and reactivation-changed triggers both be enabled. As, when the bearer goes into preservation mode with the preservation-changed trigger, the reactivation-changed trigger must also be enabled for the bearer to get reactivated subsequently.

If only the preservation-changed trigger is enabled, and the bearer goes into preservation mode, the bearer will never get reactivated. The reactivation triggers will be ignored. If only the reactivation-changed trigger is enabled, reactivation of the already active bearer does not take place, and the reactivation triggers are ignored.

■ custom-reauth-trigger

Example

The following command disables all custom event triggers:

```
custom-reauth-trigger none
```

diameter dictionary

Specifies the Diameter Policy Control Application dictionary for the IMS Authorization Service through Gx/Ty interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter dictionary { Standard | dpca-custom1 | dpca-custom10 | dpca-custom11 |
dpca-custom12 | dpca-custom13 | dpca-custom14 | dpca-custom15 | dpca-custom16 |
dpca-custom17 | dpca-custom18 | dpca-custom19 | dpca-custom2 | dpca-custom20 |
dpca-custom3 | dpca-custom4 | dpca-custom5 | dpca-custom6 | dpca-custom7 | dpca-
custom8 | dpca-custom9 | gxa-3gpp2-standard | gxc-standard | pdsn-ty | r8-gx-
standard | std-pdsn-ty | ty-plus | ty-standard }
```

default diameter dictionary

default

Sets the Diameter dictionary to standard for Gx or Ty interface.

dpca-custom1

Custom-defined Diameter dictionary for the Gx interface.

dpca-custom2

Custom-defined Diameter dictionary for Rel. 7 Gx interface.

dpca-custom3

Custom-defined Diameter dictionary for the Gx interface in conjunction with IP Services Gateway (IPSG).

dpca-custom4

Standard Diameter dictionary for 3GPP Rel. 7 Gx interface.

dpca-custom5

Custom-defined Diameter dictionary for Rel. 7 Gx interface.

dpca-custom6 ... dpca-custom20

Custom-defined Diameter dictionaries.

gxa-3gpp2-standard

Gxa 3GPP2 standard dictionary.

■ diameter dictionary

gxc-standard

Gxc standard dictionary.

pdsn-ty

Custom-defined Diameter dictionary for Ty interface.

r8-gx-standard

R8 Gx standard dictionary.

standard

Standard Diameter dictionary for the 3GPP Rel. 6 Gx interface.

Default: Enabled for Gx support in 3GPP networks.

std-pdsn-ty

Standard Diameter dictionary for Ty interface.

Default: Enabled for Ty support in 3GPP2 networks.

ty-plus

Enhanced custom-defined Diameter dictionary for Ty interface.

ty-standard

Specifies standard Diameter dictionary for Ty attributes.

Usage

Use this command to specify the Diameter dictionary for IMS Authorization Service.

Example

The following command sets the **standard** dictionary for Diameter Policy Control functions in 3GPP network:

```
diameter dictionary standard
```

diameter host-select reselect

This command controls pacing of the reselection or switching of the PCRF after a change occurs in table configuration for an IMS Authorization Service.

Default: Disabled

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter host-select reselect subscriber-limit subs_limit time-interval duration  
{ default | no } diameter host-select reselect
```

default

Applies the default setting for this command.
Sets the PCRF reselection or switching to default state.

no

Removes the configured PCRF reselection method and disables the reselection or switching of PCRF.

subscriber-limit *subs_limit*

Specifies the limit of subscribers to switch or reselect the PCRF for subscribers not more than *subs_limit* in time duration of *duration* second(s).
subs_limit must be an integer from 1 through 10000000.

time-interval *duration*

Specifies the time duration, in seconds, to reselect PCRF for subscribers not more than *subs_limit* in time duration of *duration* second(s).
duration must be an integer from 1 through 3600.

Usage

Use this command to specify the pacing of reselection or switching of the PCRF in an IMS authorization service..

In case IMS authorization session have been opened on certain PCRF on the basis of the current selection table, and the current active table configuration is changed, the IMSA starts selection procedure for the PCRF. Existing sessions on current PCRF from earlier table is required to close and reopened on the selected PCRF from the new table. This reselection periodicity is controlled by this command and it indicates the number of subscriber sessions *subs_limit* to be reselected or moved in *duration* seconds.

For example, if this command is configured with 100 subscribers and 2 seconds, then the system reselects the PCRF for no more than 100 subscribers per 2 seconds.

■ diameter host-select reselect

Example

The following command sets the system to reselect the new PCRF for no more than *1000* subscriber in *15* seconds:

```
diameter host-select reselect subscriber-limit 1000 time-interval 15
```

diameter host-select row-precedence

This command adds/appends rows with precedence to a Diameter host table or MSISDN prefix range table.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter host-select row-precedence precedence_value table { { { 1 | 2 } host
host_name [ realm realm_id ] [ secondary host host_name [ realm realm_id ] ] } |
{ prefix-table { 1 | 2 } msisdn-prefix-from msisdn_prefix_from msisdn-prefix-to
msisdn_prefix_to host host_name [ realm realm_id ] [ secondary host
sec_host_name [ realm sec_realm_id ] algorithm { active-standby | round-robin }
} } [ -noconfirm ]
```

```
no diameter host-select row-precedence precedence_value table { { 1 | 2 } |
prefix-table { 1 | 2 } }
```

```
no diameter host-select row-precedence precedence_value table { 1 | 2 }
```

Removes the row with the specified precedence from the specified Diameter host table.

```
diameter host-select row-precedence precedence_value table { 1 | 2 } host
host_name [ realm realm_id ] [ secondary host sec_host_name [ realm
sec_realm_id ] ]
```

This command adds/appends a row in the specified Diameter host table.

In StarOS 8.0, a maximum of 16 rows can be added to a table. In StarOS 8.1 and later releases, a maximum of 128 rows can be added per table.

row-precedence *precedence_value*: Specifies precedence of the row in the Diameter host table.

Important: In StarOS 8.1 and later releases, *precedence_value* must be an integer from 1 through 128. In StarOS 8.0 and previous releases, *precedence_value* must be an integer from 1 through 100.

table { 1 | 2 }: Specifies the Diameter host table to add/append the primary and secondary Diameter host addresses.

host *host_name*: Specifies the primary host name. *host_name* must be an alpha and/or numeric string of 1 through 127 characters in length.

realm *realm_id*: Specifies the primary realm ID. *realm_id* must be an alpha and/or numeric string of 1 through 127 characters in length.

secondary host *sec_host_name* [**realm** *sec_realm_id*]: Specifies the secondary host name and realm ID:

host *sec_host_name*: Specifies the secondary host name. *host_name* must be an alpha and/or numeric string of 1 through 127 characters in length.

realm *sec_realm_id*: Specifies the secondary realm ID. *realm_name* must be an alpha and/or numeric string of 1 through 127 characters in length.

```
no diameter host-select row-precedence precedence_value table prefix-table { 1 | 2 }
```

Removes the row with the specified precedence from the specified MSISDN prefix range table.

```
diameter host-select row-precedence precedence_value table prefix-table { 1 | 2 } msisdn-prefix-from msisdn_prefix_from msisdn-prefix-to msisdn_prefix_to host host_name [ realm realm_id ] [ secondary host sec_host_name [ realm sec_realm_id ] algorithm { active-standby | round-robin } ] [ -noconfirm ]
```

Use this command to configure the MSISDN prefix range based PCRF selection mechanism for Rel. 7 Gx interface support, wherein the PCEF is required to discover and select an appropriate PCRF to establish control relationship at primary PDP context activation.

This command adds a row in the specified MSISDN prefix range table. A maximum of 128 rows can be added per prefix range table.

row-precedence *precedence_value*: Specifies precedence of the row in the table.

Important: In StarOS 8.1 and later releases, *precedence_value* must be an integer from 1 through 128. In StarOS 8.0 and previous releases, *precedence_value* must be an integer from 1 through 100.

prefix-table { 1 | 2 }: Specifies the MSISDN prefix range table to add the primary and/or secondary Diameter host addresses.

msisdn-prefix-from *msisdn_prefix_from*: For a range of MSISDNs, specifies the starting MSISDN.

msisdn-prefix-to *msisdn_prefix_to*: For a range of MSISDNs, specifies the ending MSISDN.

Important: To enable the Gx interface to connect to a specific PCRF for a range of MSISDNs/subscribers configure *msisdn_prefix_from* and *msisdn_prefix_to* with the starting and ending MSISDNs respectively. The MSISDN ranges must not overlap between rows. To enable the Gx interface to connect to a specific PCRF for a specific MSISDN/subscriber, configure both *msisdn_prefix_from* and *msisdn_prefix_to* with the same MSISDN.

host *host_name*: Specifies the primary host name. *host_name* must be an alpha and/or numeric string of 1 through 127 characters in length.

realm *realm_id*: Specifies the primary realm ID. *realm_id* must be an alpha and/or numeric string of 1 through 127 characters in length.

secondary host *sec_host_name* [**realm** *sec_realm_id*]: Specifies the secondary host name and realm ID: **host** *sec_host_name*: Specifies the secondary host name. *sec_host_name* must be an alpha and/or numeric string of 1 through 127 characters in length.

realm *sec_realm_id*: Specifies the secondary realm ID. *sec_realm_id* must be an alpha and/or numeric string of 1 through 127 characters in length.

algorithm { active-standby | round-robin }: Specifies the algorithm for selection between primary and secondary servers in the MSISDN prefix range table.

Default: **active-standby**

active-standby: Specifies selection of servers in the Active-Standby fashion.

round-robin: Specifies selection of servers in the Round-Robin fashion.

Important: The Round Robin algorithm for PCRF selection is effective only over a large number of PCRF selections, and not at a granular level.

-noconfirm

Specifies that the command is to execute without any additional prompt and confirmation from the user.

Usage

Use this command to add, update, or delete rows specified with a precedence from a Diameter host table or MSISDN prefix range table.

In the Rel. 7 Gx implementation, when the Gateway interworks with multiple PCRFs, the Gateway can configure the primary and secondary server based on the MSISDN-prefix range in the MSISDN prefix range table. Using this command, you can add a new prefix row into the MSISDN prefix table.

If a row with the precedence that you add already exists in a table, the existing prefix row is removed and the new row is inserted with the same precedence.

Example

The following command adds a row with precedence *12* in table **2** with primary host name as *star_ims1* and secondary host name as *star_ims2* to Diameter host table.

```
diameter host-select row-precedence 12 table 2 host star_ims1 secondary
host star_ims2
```

diameter host-select table

This command selects the Diameter host table or the MSISDN prefix range table, and the algorithm to select rows from the Diameter host table.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter host-select table { { 1 | 2 } algorithm { ip-address-modulus [ prefer-
ipv4 | prefer-ipv6 ] | msisdn-modulus | round-robin } | prefix-table { 1 | 2 } }
{ default | no } diameter host-select table
```

default

Applies the default setting for this command.

no

Removes previous configuration.

When no table is selected, the system will not communicate with any PCRF for new sessions.

```
diameter host-select table { 1 | 2 } algorithm { ip-address-modulus |
msisdn-modulus | round-robin }
```

table { 1 | 2 }: Specifies the Diameter host table to obtain the primary and secondary host name for PCRF.

algorithm { ip-address-modulus [prefer-ipv4 | prefer-ipv6] | msisdn-modulus | round-robin }: Specifies the algorithm to select row from the Diameter host table.

Default: **round-robin**

- **ip-address-modulus [prefer-ipv4 | prefer-ipv6]**: This algorithm divides the IP address, in binary, of the subscriber by the number of rows in the table, and the remainder is used as an index into the specified table to select the row.
- **prefer-ipv4**: Specifies that IPv4 addresses are to be used, if an IPv4v6 call is received, for selecting the rows in the host table.
- **prefer-ipv6**: Specifies that IPv6 addresses are to be used, if an IPv4v6 call is received, for selecting the rows in the host table.
- **msisdn-modulus**: This algorithm divides the MSISDN value in binary without the leading “+” of the subscriber by the number of rows in the table, and the remainder is used as an index in the specific table to select the row.
- **round-robin**: This algorithm rotates all rows in the active table for selection of the row in round-robin fashion. If no algorithm is specified this is the default behavior.

Important: The Round Robin algorithm is effective only over a large number of selections, and not at a granular level.

```
diameter host-select table prefix-table { 1 | 2 }
```

Specifies the MSISDN Prefix Range table to be used in case of MSISDN prefix range based PCRF discovery mechanism.

Usage

Use this command to configure the Diameter host table and row selection methods to select host name or realm for PCRF.

When this command is used to change which table the system should be using, user must re-determine which E-PDF the system should be using for each subscriber. If a different E-PDF results from the configuration change in the table, the system will wait for all of the IMS sessions for the subscriber to be no longer active and then the system either closes/opens Gx sessions with the old/new PDFs respectively, or the system deactivates the PDP contexts of the subscriber.

Here is an example of how row selection is configured for three hosts that the system will use for load-balancing. Operator can configure six rows in a table, as follows.

Modulo 6	Primary Host	Secondary Host
0	1	2
1	1	3
2	2	1
3	2	3
4	3	1
5	3	2

In the above table, the three hosts are named 1, 2, and 3. When all hosts are working, the load will be distributed among all the three hosts. If host 1 fails, then the load will be distributed between the remaining two hosts. In this scenario, the modulo 6 results of 2 and 4 will return rows that have primary hosts but no working back-up host.

In the Rel. 7 Gx implementation, the GGSN/PCEF is required to discover and select an appropriate PCRF to establish control relationship at primary PDP context activation. The ip-address-modulus, msisdn-modulus, and round-robin algorithms are supported by the GGSN/PCEF for PCRF discovery. In addition, the active/standby and round-robin algorithms are used for selection between primary and secondary servers based on the MSISDN Prefix Range Table.

Example

The following command specifies **table 1** with **round-robin** algorithm to select the rows with host name for E-PDF in Diameter host table.

```
diameter host-select table 1 algorithm round-robin
```

diameter origin endpoint

This command binds the origin endpoint configured in Context Configuration mode to the IMS Authorization service for Diameter Policy Control Application (DPCA).

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter origin endpoint endpoint_name
```

```
no diameter origin
```

```
no
```

Removes the binding of Diameter origin endpoint with IMS Authorization service.

```
endpoint endpoint_name
```

endpoint_name is the Diameter endpoint configured in Context Configuration Mode to bind with IMS authorization service, and must be an alpha/numeric string of 1 through 63 characters in length.

Usage

Use this command to bind a configured Diameter origin endpoint to the IMS Authorization service for DPCA. This IMS authorization service searches all system contexts until it finds one with a matching Diameter origin endpoint name specified.

Example

The following command binds a configured endpoint named test to the IMS authorization service:

```
diameter origin endpoint test
```

diameter request-timeout

This command configures the request-timeout setting for Diameter-IMSA Gx interface.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
diameter request-timeout timeout
```

```
default diameter request-timeout
```

default

Applies the default setting for this command.

timeout

Specifies the timeout period in seconds.

timeout must be an integer from 1 through 300.

Default: 10 seconds

Usage

Use this command to configure the request-timeout setting for Diameter-IMSA Gx interface.

Example

The following command configures the Diameter request-timeout setting to 20 seconds:

```
diameter request-timeout 20
```

■ end

end

Exits the current mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to change to the Exec mode.

event-report-indication

This command enables event report indication.

Product

P-GW

Privilege

Security Administrator, Administrator

Syntax

```
event-report-indication { all | pgw-trace-control | qos-change | rai-change |
rat-change | sgsn-change | ue-timezone-change | user-loc-change } [ pgw-trace-
control ] [ qos-change ] [ rai-change ] [ rat-change ] [ sgsn-change ] [ ue-
timezone-change ] [ user-loc-change ]
```

```
{ default | no } event-report-indication
```

```
all | pgw-trace-control | qos-change | rai-change | rat-change | sgsn-
change | ue-timezone-change | user-loc-change
```

Specifies which types of changes will trigger an event report from the PCRF.

- **all**: all triggers
- **pgw-trace-control**: P-GW trace control change trigger
- **qos-change**: QoS change trigger
- **rai-change**: RAI change trigger
- **rat-change**: RAT change trigger
- **sgsn-change**: SGSN change trigger
- **ue-timezone-change**: UE time zone change trigger
- **user-loc-change**: User location change trigger

```
default | no
```

Event report indication disabled.

Usage

Use this command to determine what type of event changes are reported from the PCRF.

Example

The following command enables event report indication for all triggers.

```
event-report-indication all
```

event-update

This command configures sending usage information in event updates.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
event-update send-usage-report [ reset-usage ]  
{ default | no } event-update
```

default

Configures the default setting for this command.
Default: Usage report is not sent in event update.

no

Disables sending usage report in event update.

send-usage-report

Specifies to send volume usage report in event update.

reset-usage

Specifies to reset the usage at PCEF after reporting in event update.

Usage

Use this command to send volume usage information when an event change is reported to the PCRF in a CCR-U message.

Example

The following command specifies to send volume usage report in event updates to the PCRF:

```
event-update send-usage-report
```

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

failure-handling

This command configures Diameter failure handling behavior.

Product

All

Privilege

Security Administrator, Administrator

Syntax

In StarOS 8.0:

```
failure-handling { continue | retry-and-terminate | terminate | diameter-result-
code { any-error | result_code } ccfh { continue | retry-and-terminate |
terminate } [ cc-request-type { initial-request | terminate-request | update-
request } ] }
```

```
no failure-handling diameter-result-code { any-error | integer result_code } [
cc-request-type { initial-request | terminate-request | update-request } ]
```

In StarOS 8.1 and later releases:

```
failure-handling cc-request-type { any-request | initial-request | terminate-
request | update-request } { diameter-result-code { any-error | result_code [ to
end_result_code ] } } { continue | retry-and-terminate | terminate }
```

```
no failure-handling cc-request-type { any-request | initial-request | terminate-
request | update-request } [ diameter-result-code { any-error | result_code [ to
end_result_code ] } ]
```

no

Disables previous failure-handling configuration.

continue

Specifies that in the event of a failure the user session continues. DPCA/Diameter will make periodic request and/or connection retry attempts and/or will attempt to communicate with a secondary peer depending on the peer config and session-binding setting.

retry-and-terminate

Specifies that in the event of a failure the user session continues for the duration of one retry attempt with the server. If this retry attempt also fails, the session is terminated.

terminate

Specifies that in the event of a failure the user session be terminated.

```
diameter-result-code { any-error | result_code [ to end_result_code ] }
```

Specifies failure handling behavior for any/specific result-code(s) to identify the type of failure and failure handling action for specific credit control request type.

any-error: Specifies failure handling behavior for those result-codes for which failure-handling behavior has not been specified.

result_code: Specifies a Diameter failure result code. *result_code* is the code returned for a failure handling action and must be an integer from 3000 through 4999.

to end_result_code: Use to specify a range of Diameter failure result codes. *end_result_code* must be an integer from 3000 through 4999, and must be greater than *result_code*.

continue | retry-and-terminate | terminate

As in StarOS 8.1 and later releases.

Specifies the credit control failure handling action.

- **continue:** In the event of a failure the user session continues. DPCA/Diameter will make periodic request and/or connection retry attempts and/or will attempt to communicate with a secondary peer depending on the peer config and session-binding setting.
- **retry-and-terminate:** In the event of a failure the user session continues for the duration of one retry attempt with the server. If this retry attempt also fails, the session is terminated.
- **terminate:** In the event of a failure the user session is terminated.

ccfh { continue | retry-and-terminate | terminate }

As in StarOS 8.0 release:

Specifies the credit control failure handling (CCFH) action with or without credit control request type.

- **continue:** In the event of a failure the user session continues. DPCA/Diameter will make periodic request and/or connection retry attempts and/or will attempt to communicate with a secondary peer depending on the peer config and session-binding setting.
- **retry-and-terminate:** In the event of a failure the user session continues for the duration of one retry attempt with the server. If this retry attempt also fails, the session is terminated.
- **terminate:** In the event of a failure the user session is terminated.

cc-request-type

As in StarOS 8.0 release:

This optional keyword defines the type of credit control request with failure result code and credit control failure handling action for a session.

- **any-request:** Specifies the request type as any request for a new session.
- **initial-request:** Specifies the request type as initial request for a new session.
- **terminate-request:** Specifies the request type as terminate request for a session.
- **update-request:** Specifies the request type as update request for an active session.

Usage

Use this command to configure the Diameter Policy Control Application (DPCA) failure handling behavior. When an unknown rulebase comes in CCA, changing of rulebase and failure handling is managed in the following manner:

- If the new and existing rulebases have the same CCA policy, then switch to the new rulebase is successful.
- If the new rulebase is valid and has CCA-enabled, in CCA-Initial/Update request, switch to the new rulebase is successful.

- If the new rulebase is valid and does NOT have CCA enabled, whereas the existing rulebase has credit enabled, or vice versa, in CCA-Initial/Update request:
 - CCFH-Continue: Goes offline immediately after sending the CCR-T with termination cause as BAD_ANSWER.
 - CCFH-RETRY&TERMINATE: Goes offline immediately after sending the CCR-T with termination cause as BAD_ANSWER.
 - CCFH-TERMINATE: Goes offline immediately after sending the CCR-T with termination cause as BAD_ANSWER.
- If the new rulebase is invalid, in CCA-Initial/Update request:
 - CCFH-Continue: Goes offline immediately after sending the CCR-T with termination cause as BAD_ANSWER.
 - CCFH-RETRY&TERMINATE: Terminates on successful CCA-T, or terminates after successful/failed retry to secondary.
 - CCFH-TERMINATE: Terminates on successful/failed CCR-T to Primary.

The default failure handling behavior is:

```
failure-handling diameter-result-code any-error ccfh terminate
```

Example

The following command sets the DPCA failure handling to **retry-and-terminate** and return a result code of 3456 for credit control request type **initial-request**:

As in StarOS 8.0 release:

```
failure-handling diameter-result-code 3456 ccfh retry-and-terminate cc-  
request-type initial-request
```

As in StarOS 8.1 and later releases:

```
failure-handling cc-request-type initial-request diameter-result-code  
3456 retry-and-terminate
```

li-secret

Refer to the *Cisco ASR 5000 Lawful Intercept Configuration Guide* for a description of this command.

reauth-trigger

This command specifies the trigger events to initiate re-authorization for a subscriber in IMS authorization service.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] reauth-trigger { all | { an-gw-change | bearer-loss | bearer-
recovery | plmn-change | policy-failure | qos-change | rat-change | sgsn-change
| tft-change | tft-delete } + }
```

Default

Applies the default setting for this command.

all

Sets the IMS authorization service to initiate re-authorization process for a subscriber on all events listed in this command.

an-gw-change

Sets the IMS authorization service to initiate re-authorization process for a subscriber whose access network gateway changed.

bearer-loss

Sets the IMS authorization service to initiate re-authorization process for a subscriber on loss of bearer or service.

bearer-recovery

Sets the IMS authorization service to initiate re-authorization process for a subscriber when a bearer or service recovered after loss of bearer or service.

default-bearer-qos-change

Sets the IMS authorization service to initiate re-authorization process when QoS is changed and DEFAULT_EPS_BEARER_QOS_CHANGE event triggered for the default EPS bearer context of a subscriber in LTE network.

plmn-change

Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in Public Land Mobile Network (PLMN) of subscriber.

policy-failure

Sets the IMS authorization service to initiate re-authorization process for a subscriber on failure of credit and charging policy for subscriber.

qos-change

Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in Quality of Service level/rating of subscriber.

rat-change

Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in Radio Access Type (RAT) of subscriber node.

sgsn-change

Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in SGSN for subscriber node.

tft-change

Sets the IMS authorization service to initiate re-authorization process for a subscriber on change in Traffic Flow Template (TFT) of subscriber session.

tft-delete

Sets the IMS authorization service to initiate re-authorization process for a subscriber when Traffic Flow Template (TFT) of subscriber session is deleted by a system administrative user.

Usage

Use this command to set the triggers to initiate QoS re-authorization process for a subscriber in IMS authorization service.

Example

Following command sets the re-authorization trigger to **bearer-loss**, so that re-authorization of subscriber session is initiated on loss of bearer.

```
reauth-trigger bearer-loss
```

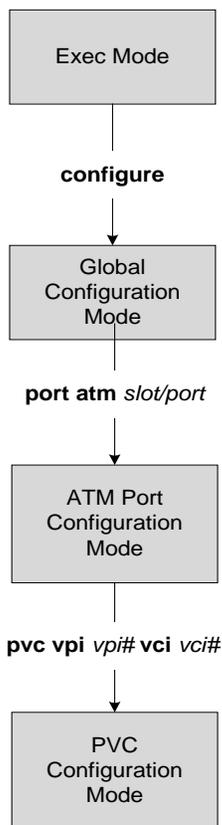

Chapter 193

PVC Configuration Mode Commands

The Permanent Virtual Connection (PVC) configuration mode commands bind IP interfaces or SS7-Frame Relay links a PVC as well as configure PVC operational parameters for a specific port.

In this mode, the prompt line should appear similar to:

```
[local]hostname(config-port-<slot#>/<port#>-pvc-<pvc_num>/<vci_num>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, version, and installed license(s).

bind

This command binds an IP interface or an SS7 link to the PVC.

Important: Prior to attempting the binding, the interface and context or the SS7 routing information and link must have been configured.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] bind { interface interface_name context_name | link ss7-routing-domain
rd_id linkset-id id link-id id }
```

no

Removes the binding from the configuration.

interface_name

Defines the name of the virtual interface to be bound to the PVC. *interface_name*: Must be a unique string consisting of 1 to 79 alphanumeric characters.

context_name

Specifies the name of the context to be bound to the virtual interface. *context_name*: Must be a unique string consisting of 1 to 79 alphanumeric characters.

ss7-routing-domain *rd_id*

Identifies a specific SS7 routing domain. *rd_id* must be an integer from 1 to 12

linkset-id *id*

Identifies a specific linkset within the routing domain. *id*: must be an integer from 1 to 33

link-id *id*

Identifies a specific link within the linkset. *id*: must be an integer value 1 - 16

Usage

Use this command to bind the PVC to an interface or a specific link.

Example

Use a command similar to the following to bind a PVC to a link ID #2:

```
bind ss7-routing-domain 1 linkset-id 23 link-id 2
```

encapsulation aal5

Specify the data encapsulation type for the ATM adaptation layer 5 (AAL5) frames for the PVC.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
encapsulation aal5 { llc-snap | vc-mux }
```

llc-snap

Frames protocol is identified in the AAL5 using logical link control (LLC) encapsulation.

vc-mux

Frames are not encapsulated and use virtual circuit multiplexing (VC-MUX) to identify the protocols used for the AAL5 frames.

Usage

Use this command to identify the protocol type for the circuit.

Example

```
encapsulation aal5 vc-mux
```

end

Exits the PVC configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the PVC configuration mode and returns to the ATM port configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the port configuration mode.

shaping

Specify the type of traffic shaping (rates) for this PVC.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
shaping { cbr pcr prc_num | ubr pcr prc_num | ubr+ pcr prc_num mrc mrc_num | vbr
pcr prc_num scr src_num mbs mbs_num }
```

cbr

Constant bit rate

pcr - peak cell rate = cells per second

prc_num: Must be an integer from 75 to 1412830

ubr

Unspecified Bit Rate

pcr - peak cell rate = cells per second

prc_num: Must be an integer from 75 to 1412830

ubr+

Unspecified Bit Rate with Minimum Cell Rate.

The PCR and MCR values should be set to maintain the following relationship: $PCR \geq (MCR + \text{minRate})$, where the current recommend *minRate* is 75.

pcr - peak cell rate = cells per second

prc_num: Must be an integer from 75 to 1412830

mcr - minimum cell rate

mrc_num: Must be an integer from 75 to 1412830

vbr

Variable Bit Rate, NRT (not real time) type.

The PCR and MCR values should be set to maintain the following relationship: $PCR \geq (MCR + \text{minRate})$, where the current recommend *minRate* is 75.

pcr - peak cell rate = cells per second

prc_num must be an integer from 75 to 1412830

scr - sustained cell rate

src_num must be an integer from 75 to 1412830

mbs - maximum burst size

mbs_num must be an integer from 75 to 1412830

Usage

Use this command to configure the shaping for egress traffic on this PVC.

Example

■ shaping

```
shaping cbr pcr 56000
```

shutdown

Disables/enables traffic over the current VLAN.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

shutdown

no shutdown

no

Enables the VLAN. When omitted the VLAN is non-functional.

Usage

Enables/ Disables specified VLAN.

This command is necessary to bring a VLAN into service by enabling it via the **no** keyword.

Example

To disable a VLAN from sending or receiving network traffic use the following command:

shutdown

To enable a VLAN use the following command:

no shutdown

Chapter 194

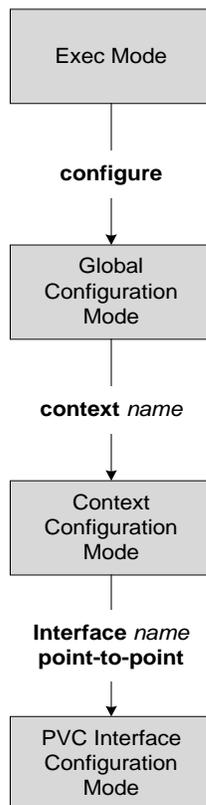

PVC Interface Configuration Mode Commands

The PVC (permanent virtual connection) Interface configuration mode is used to create and manage the IP parameters for PVC interface(s) associated with an OLC (ATM-type) for a specific context.

In this mode, the prompt line should appear similar to:

```
[ <context_name> ] hostname <config-if-pvc> #
```

All configuration information specified with these commands is displayed using the Exec mode.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

description

Defines descriptive text to provide useful information about the current interface.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

description *text*

no description

no

Erases the port's description from the configuration file.

text

text: Must be a string of 1 to 79 alphanumeric characters with no spaces or a string within double quotes that includes printable characters. The description is case-sensitive.

Usage

Set the description to provide helpful information, for example the port's primary function, services, end users. Define any information, the only limit is the number of characters, 79.

Example

description "PVC12 connects server 1 to home office."

end

Exits the PVC interface configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the interface configuration mode and returns to the context configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

ip

The commands in this section are used to configure the IP parameters for the PVC interface.

 **Important:** Before configuring the OSPF parameters in this section, you need to enable OSPF using the router command and OSPF configuration sub-mode commands accessed in the Context configuration mode and documented in the Context Configuration Mode chapter of this Command Line Interface Reference.

ip access-group

This command identifies the access control list (ACL) to be associated with this PVC interface in this context.

 **Important:** Prior to using this command, the access list must be created for this context with the `ip access-list` command in the Context configuration mode and then the ACL must be configured using the commands described in CLI chapter ACL Configuration Mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip access-group name { in | out }
```

```
no ip access-group name { in | out }
```

no

Indicates the specified access group to be removed from the access list.

name

Specifies the access control list (ACL) rule to be added or removed from the group.
name : Must be a string of 1 to 79 alphanumeric characters with no spaces.

 **Important:** Up to 8 ACLs can be applied to a group provided that the number of rules configured within the ACL(s) does not exceed the 128 rule limit for the interface.

in | out

in: Specifies list is for in-bound access control.

out: Specifies the list is for out-bound access control.

 **Important:** Even though “in” or “out” can be specified, context-level ACL rules are automatically applied to both directions.

Usage

Use this command to add IP access lists configured for the same context to an IP access-group. The list can be configured to apply to all inbound and/or outbound traffic.

Example

The following adds ACL access-list-1 to the IP access-group associated with this PVC for this context.

```
ip access-group access-list-1 in
```

ip address

Defines the primary IP address and the network mask to be associated with this PVC interface for this context. This command can also be used to configure the secondary IP address.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip address ip_address ip_mask [ secondary ]
```

```
no ip address ip_address
```

no

Removes the IP address information for this PVC from the configuration. It is not necessary to include the subnet mask with the command.

The command must first be issued with the secondary IP address if one exists and then re-issued with the primary IP address.

address *ip_address ip_mask*

Configures the IP address and the network mask for this PVC interface. The first time this command is entered, it automatically defines the primary IP address for this interface.

ip_address and *ip_mask* must be specified using the standard IPv4 or IPv6 dotted decimal notation.

secondary

secondary: Including this keyword indicates the IP address and subnet mask being defined are to be used as the secondary IP address for this PVC interface. This is referred to as multi-homing of the interface.

Usage

Configures or deletes the IPv4 or IPv6 addresses and subnet mask to be associated with this PVC.

Example

The following configures the secondary IP address to associate with the interface.

```
ip address 131.2.3.4 255.255.255.0 secondary
```

The following set of commands removes the primary IP address from the PVC interface configuration for this context.

```
no ip address secondary address
```

```
no ip address primary address
```

ip mtu

Configures the maximum transmission unit (MTU) to be supported on this interface.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip mtu value
```

```
no ip mtu
```

no

Disables and/or restores the option to the system default.

mtu *value*

Configures the maximum transmission unit in octets.

value : Enter an integer between 576 and 1600. Default is 1500.

Usage

Change the maximum transmission unit size to 1300.

Example

```
ip mtu 1300
```

ip ospf authentication-key

This command configures the password or key to be used for OSPF (Open Shortest Path First) authentication with neighboring routers.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf authentication-key [ encrypted ] password auth_key
```

```
no ip ospf authentication-key
```

no

Deletes the authentication key.

encrypted

Enter this keyword if you are pasting a previously encrypted authentication key into the **password** *auth_key* for this command.

password*auth_key*

auth_key is a string variable, from 1 through 16 alphanumeric characters, that denotes the authentication key (password). This variable is entered in clear text format.

Usage

Use this command to set the authentication key used when authenticating with neighboring routers.

Example

To set the authentication key to 123abc, use the following command;

```
ip ospf authentication-key password 123abc
```

Use the following command to delete the authentication key;

```
no ip ospf authentication-key
```

ip ospf authentication-type

This command configures the OSPF authentication method to be used with OSPF neighbors over the logical interface.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf authentication-type { message-digest | null | text }  
no ip ospf authentication-type { message-digest | null | text }
```

no

Disable this function.

message-digest

Set the OSPF authentication type to use the message digest (MD) authentication method.

null

Set the OSPF authentication type to use no authentication, thus disabling either MD or clear text methods.

text

Set the OSPF authentication type to use the clear text authentication method.

Usage

Use this command to set the type of authentication to use when authenticating with neighboring routers.

Example

To set the authentication type to use clear text, enter the following command;

```
ip ospf authentication-type text
```

ip ospf cost

This command configures the cost associated with sending a packet over this logical interface.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf cost value
```

```
no ip ospf cost
```

no

Disable this function.

value

Default: 10

The cost to assign to OSPF packets. This must be an integer from 1 through 65535.

Usage

Use this command to set the cost associated with routes from the interface.

Example

Use the following command to set the cost to 20;

```
ip ospf cost 20
```

Use the following command to disable the cost setting;

```
no ip ospf cost
```

ip ospf dead-interval

This command configures the dead-interval and the delay time in seconds, for OSPF communications.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf dead-interval value
```

```
no ip ospf dead-interval
```

no

Deletes the value set and returns the value to its default.

value

The interval, in seconds, that the router should wait. During this interval, if no packets are received then the system considers the neighboring router to be off-line. This interval is typically 4 times the duration of the hello-interval.

value must be an integer from 1 through 65535. Default: 40

Usage

Use this command to set the dead-intervals or delays for OSPF communications.

Example

To set the dead-interval to 100, use the following command;

```
ip ospf dead-interval 100
```

To delete the setting for the dead-interval and reset the dead-interval value to its default of 40, use the following command'

```
no ip ospf dead-interval
```

ip ospf hello-interval

This command configures the delay time in seconds, for OSPF hello interval.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf hello-interval value
```

```
no ip ospf hello-interval
```

no

Deletes the value set and returns the value to its default.

value

The interval, in seconds, between sending hello packets. This value is typically set to be 1/4 of the value of the **dead-interval**.

value must be an integer from 1 through 65535. Default: 10

Usage

Use this command to set the delays for the hello-interval.

Example

To set the hello-interval to 25, use the following command;

```
ip ospf hello-interval 25
```

To delete the setting for the hello-interval and reset the hello-interval value to its default of 10, use the following command:

```
no ip ospf hello-interval
```

ip ospf message-digest-key

This command enables the use of MD5-based OSPF authentication.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf message-digest-key key_id md5 [ encrypted ] password authentication_key  
no ip ospfmessage-digest-key key_id
```

no

Deletes the key.

message-digest-key *key_id*

Specifies the key identifier number. *key_id* must be an integer from 1 through 255.

encrypted

Use this if you are pasting a previously encrypted authentication key into the CLI command.

password *authentication_key*

The password to use for authentication. *authentication_key* is a string variable, from 1 through 16 alphanumeric characters, that denotes the authentication password. This variable is entered in clear text format.

Usage

Use this command to create an authentication key that uses MD5-based OSPF authentication.

Example

To create a key with the ID of 25 and a password of 123abc, use the following command;

```
ip ospf message-digest-key 25 md5 password 123abc
```

To delete the same key, enter the following command;

```
no ip ospf message-digest-key 25
```

ip ospf network

Configures the OSPF network type.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf network { broadcast | non-broadcast | point-to-multipoint | point-to-point }
```

```
no ip ospf network
```

no

Disable this function.

broadcast

Sets the network type to broadcast.

non-broadcast

Sets the network type to non-broadcast multi access (NBMA).

point-to-multipoint

Sets the network type to point-to-multipoint.

point-to-point

Sets the network type to point-to-point.

Usage

Use this command to specify the OSPF network type.

Example

To set the OSPF network type to broadcast, enter the following command;

```
ip ospf network broadcast
```

To disable the OSPF network type, enter the following command;

```
no ip ospf network
```

ip ospf priority

This command designates the OSPF router priority.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf priority value
```

```
no ip ospf priority value
```

no

Disable this function.

value

The priority value to assign. This must be an integer from 0 through 255.

Usage

Use this command to set the OSPF router priority.

Example

To set the priority to 25, enter the following command:

```
ip ospf priority 25
```

To disable the priority, enter the following command:

```
no ip ospf priority
```

ip ospf retransmit-interval

This command configures the retransmit-interval and the delay time in seconds, for OSPF communications.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf dead-interval value
```

```
no ip ospf dead-interval
```

no

Deletes the value set and returns the value to its default.

value

The interval, in seconds, between LSA (Link State Advertisement) retransmissions. *value* must be an integer from 1 through 65535. Default: 5

Usage

Use this command to set the retransmit-intervals or delays for OSPF communications.

Example

To set the dead-interval to 25, use the following command;

```
ip ospf retransmit-interval 25
```

ip ospf transmit-delay

This command configures the transmit-delay the OSPF communications parameters.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf transmit-delay value
```

```
no ip ospf transmit-delay
```

no

Deletes the value set and returns the value to its default.

transmit-delay *value*

The interval, in seconds, that the router should wait before transmitting a packet. *value* must be an integer from 1 through 65535. Default: 1

Usage

Use this command to set the transmit-delay.

Example

To set the transmit delay to 5 seconds, use the following command;

```
ip ospf transmit-delay 5
```

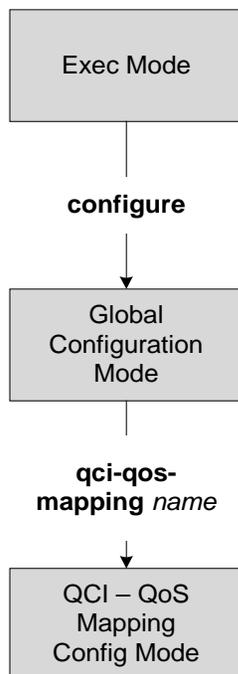

To delete the setting for the transmit-delay or reset the transmit-delay value to its default of 1, use the following command'

```
no ip ospf transmit-delay
```

Chapter 195

QCI - QoS Mapping Configuration Mode Commands

The QoS Class Index (QCI) to QoS Mapping Configuration Mode is used to map QoS Class Indexes to enforceable QoS parameters. Mapping can occur between the RAN and the Serving Gateway (S-GW), the Mobility Management Entity (MME), and/or the PDN Gateway (P-GW) in an LTE network or between the RAN and the eHRPD Serving Gateway (HSGW) in an eHRPD network.

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

qci

Creates and maps QCI values to enforceable QoS parameters.

Product

HSGW, P-GW, S-GW

Privilege

Administrator

Syntax

```
qci num [ delay-class num precedence-class num reliability-class num [ downlink
{ encaps-header { copy-inner | dscp-marking hex } | user-datagram dscp-marking
hex [ encaps-header { copy-inner | dscp-marking hex } ] } ] [ gbr ] [ max-
packet-delay num max-error-rate num [ non-gbr ] [ uplink { encaps-header { copy-
inner | dscp-marking hex } | user-datagram dscp-marking hex [ encaps-header {
copy-inner | dscp-marking hex } ] } ]
[ default | no ] qci num
```

default

Resets the default values for the select QCI value.

no

Disables the selected QCI value.

num

Specifies the QCI value to be enabled. *num* must be an integer value between 1 and 32. QCI values 1 through 9 are standard values. Only undefined values (10 through 32) can be defined.

Important: QCI values 1 through 9 are defined in the 3GPP Specification TS 23.203 “Policy and charging control architecture”.

delay-class num precedence-class num reliability-class num

delay-class num: Pre-release 8 value for configuring packet delay. *num* must be an integer value between 1 and 32.

precedence-class num: Pre-release 8 value for configuring packet precedence. *num* must be an integer value between 1 and 32.

reliability-class num: Pre-release 8 value for configuring packet reliability. *num* must be an integer value between 1 and 32.

```
downlink { encaps-header { copy-inner | dscp-marking hex } | user-
datagram dscp-marking hex [ encaps-header { copy-inner | dscp-marking hex
} ] }
```

Configures parameters for downlink traffic.

encaps-header: Specifies that the DSCP marking must be set on the encapsulation header for IP-in-IP, GRE, or GTP encapsulation.

user-datagram dscp-marking hex: Specifies that the UDP DSCP marking is to be defined by this keyword. *hex* must be expressed as a hexadecimal value from 0x00 through 0x3F.

{ **copy-inner** | **dscp-marking hex** }

- **copy-inner**: Specifies that the DSCP marking is to be acquired from the UDP headers within the encapsulation.
- **dscp-marking hex**: Specifies that the DSCP marking is to be defined by this keyword. *hex* must be expressed as a hexadecimal value from 0x00 through 0x3F.

gbr

Specifies that this QCI type is Guaranteed Bit Rate (GBR).

max-packet-delay num max-error-rate num

max-packet-delay num: Specifies the maximum packet delay in milliseconds that can be applied to the data with the QCI. *num* must be an integer value from 10 through 1000. Default is 10ms for QCI values greater than 9.

max-error-rate num: Specifies the maximum error loss rate of non-congestion related packet loss. *num* must be an integer value from 1 through 6 specifying 10-1 through 10-6. Default is 3 (or 10-3) for QCI values greater than 9.

Important: Defaults for QCI values less than 9 are defined in the 3GPP Specification TS 23.203 “Policy and charging control architecture”.

non-gbr

Specifies that this QCI type is non-Guaranteed Bit Rate (non-GBR).

uplink { encaps-header { copy-inner | dscp-marking hex } | user-datagram dscp-marking hex [encaps-header { copy-inner | dscp-marking hex }] }

Configures parameters for uplink traffic.

encaps-header: Specifies that the DSCP marking must be set on the encapsulation header for IP-in-IP, GRE, or GTP encapsulation.

user-datagram dscp-marking hex: Specifies that the UDP DSCP marking is to be defined by this keyword. *hex* must be expressed as a hexadecimal value from 0x00 through 0x3F.

{ **copy-inner** | **dscp-marking hex** }

- **copy-inner**: Specifies that the DSCP marking is to be acquired from the UDP headers within the encapsulation.
- **dscp-marking hex**: Specifies that the DSCP marking is to be defined by this keyword. *hex* must be expressed as a hexadecimal value from 0x00 through 0x3F.

Usage

Use this command to create and map QCI values to enforceable QoS parameters.

Example

The following command creates a QCI value of 15 and defines the uplink encapsulation header as using the DSCP marking from the encapsulated UDP header:

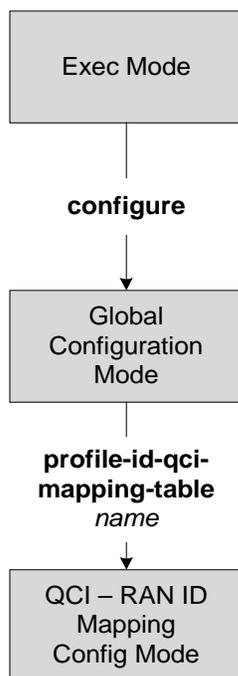

```
qci 15 uplink encaps-header copy-inner
```

■ qci

Chapter 196

QCI - RAN ID Mapping Configuration Mode Commands

The QoS Class Index (QCI) Mapping Configuration Mode is used to map RAN profile IDs to QoS Class Indexes via the HRPD Serving Gateway (HSGW) in an eHRPD network.

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

profile-id

Maps a QCI ID to a RAN profile ID and modifies data flow bit rate ranges.

Product

HSGW

Privilege

Administrator

Syntax

```
profile-id id qci num [ uplink { gbr rate [ mbr rate ] | mbr rate [ gbr rate ] }
downlink { gbr rate [ mbr rate ] | mbr rate [ gbr rate ] }
```

```
no profile-id id
```

no

Removes the specified profile ID entry from this map.

id

Specifies the profile ID to which a QCI ID will be mapped. *id* must be an integer value from 1 to 65535.

qci *num*

Specifies the QCI number to which the profile ID will be mapped. *num* must be an integer value from 1 to 255.

uplink

Specifies that the guaranteed bit rate (GBR) and/or maximum bite rate (MBR) setting that follow this keyword will be applied to the uplink data flow.

downlink

Specifies that the guaranteed bit rate (GBR) and/or maximum bite rate (MBR) settings that follow this keyword will be applied to the downlink data flow.

gbr *rate*

Specifies the guaranteed bit rate for the uplink or downlink data flow. *rate* must be an integer value from 0 to 4294967295.

mbr *rate*

Specifies the maximum bit rate for the uplink or downlink data flow. *rate* must be an integer value from 0 to 4294967295.

Usage

Use this command to map a QCI ID to a RAN profile ID and, optionally, modify data flow bit rate ranges.

Example

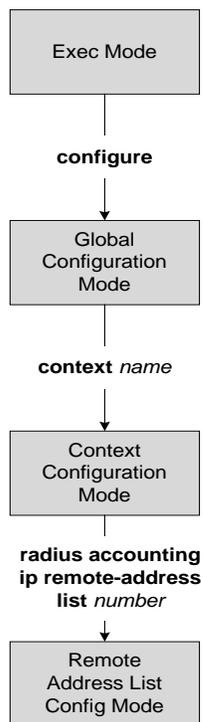

The following command maps a QCI ID (1) to a profile ID (10) and sets the uplink guaranteed bite rate to 10000 and the downlink guaranteed bit rate to 20000:

```
profile-id 10 qci 1 uplink gbr 10000 downlink gbr 20000
```

Chapter 197

Remote Address List Configuration Mode Commands

The Remote Address List Configuration Mode is used to configure address lists for the Remote Address-based Accounting feature on a per-context basis.

address

This command configures addresses for the Remote Address List.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
address ip_address netmask subnet
```

```
no address ip_address netmask subnet
```

no

Removes a previously configured address.

address *ip_address*

Specifies the IP address of the remote device.

ip_address is the IPv4 address expressed in dotted-decimal notation.

netmask *subnet*

Specifies the subnet mask of the remote device.

subnet is the netmask expressed in dotted-decimal notation.

Usage

Use this command to configure remote address lists for use with the Remote Address-based accounting feature. A maximum of 10 address can be configured per list.

Example

The following command adds an IP address of *192.168.100.1* with a subnet mask of *255.255.255.0* to the list:

```
address 192.168.100.1 netmask 255.255.255.0
```

end

This command exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to change to the Exec mode.

exit

This command exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

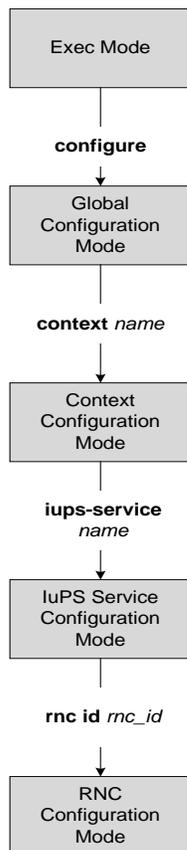

Chapter 198

RNC Configuration Mode Commands

The RNC (radio network controller) configuration mode defines the parameters related to the SGSN connection with an RNC.

This mode is access from the IuPS Service configuration mode and the command prompt for this mode will appear similar to:

```
[<context_name>]hostname(config-ctx-iups-service-rnc)#
```

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

associate-gtpu-bind-address

This command defines the GTP-U loopback address and associates (binds) this address with a particular interface (non-loopback) address.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] associate-gtpu-bind-address ip_address to-interface-address ip_address
```

no

Removes the loopback address definition and interface association from the current RNC configuration.

ip_address

ip_address: Must be specified using the standard IPv4 dotted decimal notation.

Usage

Use this command to setup associations between loopback GTP-U addresses and a non-loopback addresses.

Example

```
associate-gtpu-bind-address 123.1.1.1 to-interface-address 222.1.1.1
```

description

This command defines an alphanumeric string that is intended to provide descriptive information about the radio network controller (RNC). This is used for operator reference only.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

description *string*

no description

no

Removes the description string from the current RNC configuration.

string

Specifies the alphanumeric string that is stored. must be from 1 through 255 alphanumeric characters. Strings with spaces must be enclosed in double-quotes. See the example below.

Usage

Use this command to set a description for reference by operators.

Example

The following command sets the description to identify a particular RNC and carrier in Uganda:

```
description "RNC1 Carrier2 Uganda"
```

direct-tunnel

This command enables/disables the direct tunnel feature through the interface to the radio network controller (RNC).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
direct-tunnel not-permitted-by-rnc
```

```
default direct-tunnel
```

default

Sets the direct tunnel support on RNC to default mode; i.e. enabling direct tunnel.

not-permitted-by-rnc

Default: enabled

Disables the direct-tunnel support on radio network controller (RNC).

Usage

Use this command to disable/enable the direct-tunnel function through the interface to the RNC.

Example

Following command disables the direct tunnel support to the RNC:

```
direct-tunnel not-permitted-by-rnc
```

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode to the Exec mode.

■ exit

exit

Exits the current configuration mode and returns to the IuPS Service configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous configuration mode.

lac

This command identifies a Local Area Concentrator (LAC) and a Remote Area Concentrator (RAC) and associates them with this RNC definition.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] lac lac_id rac rac_id
```

no

Deletes the LAC and RAC information from the system configuration.

lac_id

A unique numeric identifier for the LAC associated with the RNC.

lac_id must be an integer between 1 and 65535.

rac_id

A unique numeric identifier for the RLAC associated with the RNC.

rac_id must be an integer between 1 and 255.

Usage

Creates an association with a specific LAC and RAC.

Example

```
lac 545 rac 23
```

mbms

Configures RNC options for multimedia broadcast multicast service.

Important: This feature and command are currently under development and not yet operational.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

mbms

Usage

Information will be provided when this command has been fully developed and released.

overload-action disable

This command maps an action to be taken if traffic reaches or exceeds defined levels.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
overload-action disable { activate | attach | auth-challenge | modify-request |
paging-downlink-data | ptmsi-reallocation | service-request-data | sms }
traffic-level traffic-level
```

```
[ no | default ] overload-action disable { activate | attach | auth-challenge |
modify-request | paging-downlink-data | ptmsi-reallocation | service-request-
data | sms }
```

no

Removes the defined overload action from configuration.

default

Resets the traffic level to the default level for the associated overload action.

activate traffic-level *traffic-level*

The system rejects new requests to activate PDP contexts if the defined traffic-level is exceeded.

traffic-level: An integer 1 to 15.

Default: 14

attach traffic-level *traffic-level*

The system rejects new requests for GPRS attach if the defined traffic-level is exceeded.

traffic-level: An integer 1 to 15.

Default: 15

auth-challenge traffic-level *traffic-level*

The system skips performing authentication challenges if the defined traffic-level is exceeded.

traffic-level: An integer 1 to 15.

Default: 4

modify-request traffic-level

The system rejects requests to modify a PDP context if the defined traffic-level is exceeded.

traffic-level: An integer 1 to 15.

Default: 12

paging-downlink-data traffic-level *traffic-level*

If the defined traffic-level is exceeded, then paging is not performed for data during downlinks if RABs are not available.

traffic-level: An integer 1 to 15.

Default: 11

ptmsi-reallocation traffic-level *traffic-level*

The system skips performing ptmsi-reallocation if the defined traffic-level is reached or exceeded.

traffic-level: An integer from 1 to 15.

Default: 4

service-request-data traffic-level *traffic-level*

The system rejects service requests to accept data and establish new RABs if the defined traffic-level is reached or exceeded.

traffic-level: An integer from 1 to 15.

Default: 10

sms traffic-level *traffic-level*

The system rejects SMS signaling if the defined traffic-level is reached or exceeded.

traffic-level: An integer 1 to 15.

Default: 8

Usage

This command defines traffic levels and the actions to take if traffic exceeds the defined levels. The command can be re-entered multiple times to create individual definitions for each type of traffic level and action.

Example

Use the following to instruct the system to reject service requests to establish new RABs if the traffic level reaches 3.\
:

```
overload-action disable service-request-data traffic-level 3
```

paging-non-searching-indication

This command instructs the SGSN to include the non-searching indicator flag in the page-request message.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
paging-non-searching-indication { non-searching | searching }
```

```
[ no | default ] paging-non-searching-indication
```

no | default

This is the default. Entering no or default with this command disables the inclusion of the flag.

non-searching

Set the non-searching-indication to non-searching in the page-request message.

searching

Set the non-searching-indication to searching in the page-request message.

Usage

Use this command to determine which type of search indicator flag will be included in the page-request message.

Example

Use this command to include the non-searching flag in page-request messages:

```
paging-non-searching-indication non-searching
```

pointcode

Configures the point code of the RNC.

The access protocol that is part of the IuPS Service configuration mode must be configured prior to defining the RNC's point code.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] pointcode pt_code
```

no

Deletes the RNC's point code information from the system configuration.

pt_code

Point code in dotted-decimal format :

- ITU Range 0.0.1 to 7.255.7
- ANSI Range 0.0.1 to 255.255.255
- TTC Range 0.0.1 to 15.31.255
- string of 1 to 11 characters

Usage

Use this command to identify the point code of the associated RNC.

Example

```
pointcode 1.234.2
```

pooled

Configure an RNC as either 'pooled' or 'non-pooled'.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
pooled
```

```
[ default | no ] pooled
```

```
default | no
```

Entering either **default** or **no** returns the RNC configuration to the default 'non-pooled' state.

Usage

Each RNC, one-at-a-time, can be identified as 'pooled' -- as participating within an SGSN pool -- or 'non-pooled'. Pooled RNCs can co-exist with non-pooled RNCs.

Example

Identify this RNC as being part of an SGSN pool:

```
pooled
```

rab-modify-procedure

This command configures how the RAB (radio access bearer) assignment procedure will be modified

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
rab-modify-procedure { normal-modify | release-and-establish }
```

```
default rab-modify-procedure
```

default

Returns the configuration to the default setting for this command parameter.

normal-modify

Selects the normal RAB modify procedure.

release-and-establish

Instructs the system to release and establish the RAB procedure.

Usage

Set the procedure to establish the radio access bearer (RAB).

Example

```
rab-modify-procedure normal-modify
```

ranap paging-cause-ie

This command sets the paging cause value and either includes or suppresses the Paging Cause IE in responses to Paging Requests due to various sources. This command is available in releases 8.1 and higher.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ranap { paging-cause-ie { all | background-data [ value ] | conversational-data
[ value ] | gmm-signalling [ value ] | gs-signalling [ value ] | interactive-
data [ value ] | sm-signalling [ value ] | sms-signalling [ value ] | streaming-
data [ value ] }
```

```
[ default | no ] ranap { paging-cause-ie { all | background-data |
conversational-data | gmm-signalling | gs-signalling | interactive-data | sm-
signalling | sms-signalling | streaming-data }
```

default

Resets the specific parameters value to default.

no

Suppresses the Paging Cause IE so that it is not included in responses to Paging Requests from respective sources.

all

Using **all** sets the action for the Paging Cause IE value for all paging due to all sources.

background-data [value]

Default: 3 (terminating background call)

Set the Paging Cause IE value for paging due to background data.

value : Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

conversational-data [value]

Default: 5 (terminating high priority signaling)

Set the Paging Cause IE value for paging due to conversational data.

value : Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

gmm-signalling [value]

Default: 5 (terminating high priority signaling)

Set the Paging Cause IE value for paging due to gmm-signaling.

value : Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

gs-signalling [*value*]

Default: 5 (terminating high priority signaling)

Set the Paging Cause IE value for paging due to VLR Paging Request.

value : Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

interactive-data [*value*]

Default: 2 (terminating interactive call)

Set the Paging Cause IE value for paging due to interactive data.

value : Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

sm-signalling [*value*]

Default: 5 (terminating high priority signaling)

Set the Paging Cause IE value for paging due to SM signaling.

value : Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

sms-signalling [*value*]

Default: 4 (terminating low priority signaling)

Set the Paging Cause IE value for paging due to SMS signaling.

value : Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

streaming-data [*value*]

Default: 5 (terminating high priority signaling)

Set the Paging Cause IE value for paging due to streaming data.

value : Must be an integer from 0 to 5. See Paging Cause value mapping in Usage section.

Usage

This command can be used to set the value (meaning) of the Paging Cause IE included in responses to Paging Requests or it can be used to suppress the inclusion of the Paging Cause IE in the responses. These actions can be configured for paging for all sources or for a specified source.

The following values are applicable to all Paging Cause IEs:

- 0 - Terminating conversational call
- 1 - Terminating streaming call
- 2 - Terminating interactive call
- 3 - Terminating background call
- 4 - Terminating low priority signaling
- 5 - Terminating high priority signaling

Example

Use the following command to set Paging Cause value to 3 for paging due to GMM signaling without affecting cause values for other sources:

```
ranap paging-cause-ie gmm-signalling 3
```

Use the following command to suppress the Paging Cause IE from all Paging Requests to the RNC:

```
no ranap paging-cause-ie all
```

Either of the following commands will cause the Paging Cause IE to be included in Paging Requests with the default value for SM signaling without affecting the cause for other sources:

```
ranap paging-cause-ie sm-signalling
```

```
default ranap paging-cause-ie sm-signalling
```

ranap signalling-indication-ie

This command enables/disables the inclusion of the Signaling Indication IE in either or both the RAB Assignment Request and/or the Relocation Request RANAP messages.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ranap signalling-indication-ie { rab-assignment-request [ relocation-request ] |
relocation-request [ rab-assignment-request ] }
```

```
no ranap signalling-indication-ie
```

```
default ranap signalling-indication-ie
```

no

Sets the configuration so that the SGSN never includes the IE.

default

Resets the configuration to the default - the SGSN includes the IE in the messages if preconditions are met (see Usage section).

rab-assignment-request | relocation-request

Including one or both of these keywords configures what type of RANAP message will include the IE.

Usage

The command enables the operator to determine whether the signalling indication information element is included in either or both the RAB Assignment Request and Relocation Request messages during the PDP context setup procedure.

For this command configuration to work so that the IE is included, two preconditions must be met:

- Received QoS traffic class for the context must be interactive
- Received QoS has a signalling indication value as optimized

When an RNC receives this IE, the RNC assumes that the customer is using IMS signaling and allocates massive amounts of bandwidth, potentially causing cell congestion. This command enables the operator to determine the usage of this IE which provides the operator with additional session management control.

Example

Use the following command to include the signalling indication IE in the RAB Assignment Request:

```
ranap signalling-indication-ie rab-assignment-request
```

release-compliance

This command allows the SGSN to support 3GPP release 6 HSPA or release 7 HSPA+.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
release-compliance { pre-release-7 | release-7 }
```

```
default release-compliance
```

default

Returns the configuration to the default value, which is **release-7**.

pre-release-7

Identifies 3GPP Release 6 (R6) as the release the RNC is compliant with.

release-7

Identifies 3GPP Release 7 (R7) as the release the RNC is compliant with.

Usage

Use this command to match the 3GPP release support by the RNC. As the 3GPP releases each support differing data rate options - R6 supports HSPA and R7 supports HSPA+ - then selecting the compliance is a method of performing data rate management on a per RNC basis.

Example

Enable HSPA fallback to R6 compliance:

```
release-compliance pre-release-7
```

reset-resource

This command enables the operator to control message length by configuring the number of IuConIDs sent in each RANAP Reset Resource messages.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
reset-resource max-iuconid-per-msg number
```

```
default reset-resource max-iuconid-per-msg
```

default

Resets the number of Iu connection Ids included in the Reset Resource messages. Default is 250.

max-iuconid-per-msg *number*

Sets the number of Iu connection Ids to be included in the Reset Resource messages.

number: Integer from 1 to 250.

Default : 250

Usage

Id numbers for each Iu connection are included in the RANAP Reset Resource messages. Including this potentially long stream of numbers can make the message very long. With this command, the operator can control the size of the messages by controlling the number of Id messages included in the messages.

Example

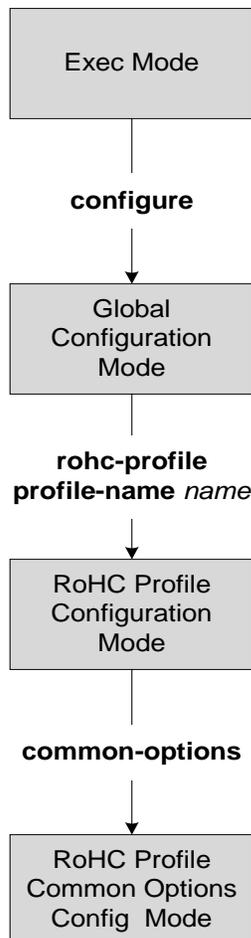

Limit the number of Iu connection Ids to 30:

```
reset-resource max-iuconid-per-msg30
```

Chapter 199

RoHC Profile Common Options Configuration Mode Commands

The RoHC Profile Common Options Configuration Mode is used to set timers that, upon expiration, release header compression contexts.

delay-release-hc-context-timer

Sets a delay in releasing RoHC contexts allowing for context continuation during intra-gateway handoffs.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
delay-release-hc-context-timer seconds
```

```
no delay-release-hc-context-timer
```

no

Removes previously configured value for this command. No value disables the feature.

seconds

Specifies the number of seconds the system delays before releasing the header compression context. *seconds* must be an integer value from 0 to 65535.

Usage

Use this command to set a delay in releasing a header compression context. This command is necessary when employing RoHC and mobility. Typically, when an RP connection is released, the header compression context is also released immediately. However, in mobility situations, such as intra-PDSN handoffs, the header compression context should be preserved. Adding a delay to cover the handoff time allows the context to be maintained.

A header compression context contains the compression/decompression configuration and statistics for the session.

Example

The following command sets the header compression release delay to 20 seconds:

```
delay-release-hc-context-timer 20
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

inactive-traffic-release-hc-context-timer

Set an inactivity timer that is checked when inactivity is detected on an SO67 A10 bearer connection with negotiated RoHC parameters. If the inactivity continues to the end of the configured time, the header compression context is released.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
inactive-traffic-release-hc-context-timer seconds
```

```
no inactive-traffic-release-hc-context-timer
```

no

Removes previously configured value for this command. No value disables the feature.

seconds

Specifies the time, in seconds, the system waits for activity on the bearer channel before releasing the header compression context. *seconds* must be an integer value from 1 to 65535.

Usage

Use this command to set a timer that is started upon detecting inactivity on the bearer channel. Upon expiry, the header compression context is released. Enable this feature to allow for efficient memory utilization.

Example

The following command sets the bearer channel inactivity timer to 60 seconds:

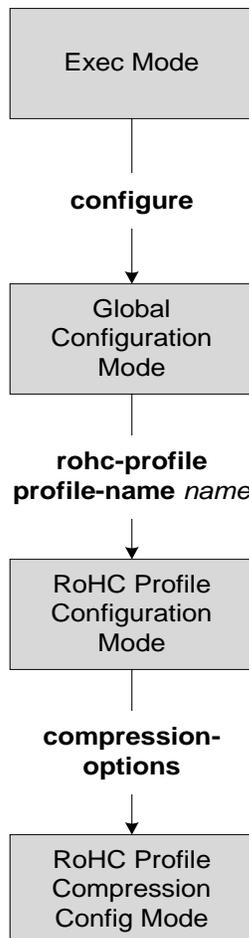

```
inactive-traffic-release-hc-context-timer 60
```

Chapter 200

RoHC Profile Compression Configuration Mode

Commands

The RoHC Profile Compression Configuration Mode is used to configure RoHC (Robust Header Compression) Compressor parameters. RoHC is not supported on GGSN.

 **Important:** The availability of commands, keywords and variables in this mode are dependent on platform type, product version, and installed license(s).

context-timeout

Context timeout in seconds.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
context-timeout seconds
```

```
default context-timeout
```

default

Returns the command to its default value.

seconds

Default: 20 seconds

The context timeout value in seconds. *seconds* must be an integer from 0 through 100.

Usage

Use this command to set the context timeout.

Example

The following command sets the context timeout to 10 seconds:

```
context-timeout-period 10
```

end

Returns the CLI prompt to the Exec mode.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits this configuration mode and returns to the previous mode.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

Usage

Return to the previous mode.

ipid-history-size

The number of IP-IDs of previously sent packets to store. An IP ID is a 16-bit header field that stores IPv4 Identification information.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
ipid-history-size number
```

```
default ipid-history-size
```

default

Returns the command to its default value.

number

Default: 8

The number of IP IDs to store. *number* must be an integer from 1 through 32.

Usage

Use this command to set the number of IP IDs to store in the history.

Example

The following command sets the history size to 24 IP-IDs:

```
ipid-history-size 24
```

max-jitter-cd

The upper boundary of jitter expected on the communication channel between the compressor and decompressor.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
max-jitter-cd num_ms
```

```
default max-jitter-cd
```

default

Returns the command to its default value.

num_ms

Default: 150

The number of milliseconds for the maximum jitter setting. *num_ms* must be an integer from 0 through 999999999.

Usage

Use this command to set the maximum amount of jitter allowed on the communication channel between compressor and decompressor.

Example

The following command sets the jitter limit to 1000ms (1 second):

```
max-jitter-cd 1000
```

max-sliding-window

The width of the sliding window for W-LSB (Windows-based Least Significant Bits) encoded values.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
max-sliding-window size
```

```
default max-sliding-window
```

default

Returns the command to its default value.

size

Default: 6

Set the size of the sliding window. *size* must be an integer from 1 through 1000.

Usage

Use this command to set the size of the sliding window used to compute jitter for W-LSB encoded values.

Example

The following command sets the sliding window size to 500:

```
max-sliding-window 500
```

multiple-ts-stride

Enables or disables the use of repeated transmission of RTS_STRIDE for timer-based compression.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ no ] multiple-ts-stride
```

no

Disables the use of repeated transmission of RTS_STRIDE for time-based compression.

multiple-ts-stride

Enables the repeated transmission of RTS_STRIDE for timer-based compression.

Usage

Use this command to enable or disable a gateway's ability to repeatedly transmit RTS_STRIDE for timer-based compression.

new-context-blocking-time

Time period in seconds for blocking the establishment of new contexts after the compressor has received a feedback reject.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
new-context-blocking-time seconds
```

```
default context-timeout
```

default

Returns the command to its default value.

seconds

Default: 20 seconds

The context blocking time in seconds. *seconds* must be an integer from 0 through 100.

Usage

Use this command to set the context blocking time after the compressor has received a feedback reject.

Example

The following command sets the context blocking time to 10 seconds:

```
new-context-blocking-time 10
```

num-pkts-ts

The number packets per RTP timestamp (TS).

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
num-pkts-ts num_pkts
```

```
default num-pkts-ts
```

default

Returns the command to its default value.

num_pkts

Default: 6

The number of packets for the timestamp. *num_pkts* must be an integer from 0 through 999.

Usage

Use this command to set the number of packets for each RTP timestamp (TS).

Example

The following command sets the number of packets per timestamp to 50:

```
num-pkts-ts 50
```

num-pkts-u-mode

The number packets sent when operating in U-Mode (unidirectional mode).

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
num-pkts-u-mode num_pkts
```

```
default num-pkts-u-mode
```

default

Returns the command to its default value.

num_pkts

Default: 1

The number of packets sent in U-Mode. *num_pkts* must be an integer from 0 through 999.

Usage

Use this command to set the number of packets sent when in U-Mode.

Example

The following command sets the number of packets for U-Mode to 50:

```
num-pkts-u-mode 50
```

num-updates-ir

This command configures the number of IR (Initiation and Refresh state) updates.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
num-updates-ir num_pkts
```

```
default num-updates-ir
```

default

Returns the command to its default value.

num_pkts

Default: 4

The number of packets sent in U-Mode. *num_pkts* must be an integer from 0 through 999.

Usage

Use this command to set the number of packets sent when in U-Mode.

Example

The following command sets the number of packets for U-Mode to 50:

```
num-updates-ir 50
```

optimistic-repeats

For transition from the FO (First Order) to the SO (Second Order) state, the compressor should be confident that the decompressor has all the parameters needed to decompress according to a fixed pattern. The compressor obtains its confidence about decompressor status by sending several packets with the same information according to the lower compression state. If the decompressor receives any of these packets, it is in sync with the compressor. This command defines the number of repeated packets to send to the decompressor.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
optimistic-repeats num_pkts
```

```
default optimistic-repeats
```

default

Returns the command to its default value.

num_pkts

Default: 6

The number of packets to repeat with the same information to assure synchronization with the decompressor. *num_pkts* must be an integer from 0 through 10.

Usage

Use this command to set the number of packets to repeat to the decompressor to assure synchronization before transition states.

Example

The following command sets the number of repeated packets to 5:

```
optimistic-repeats 5
```

rtp-sn-p

The value of *p* in RTP SN (RTP Sequence Number) calculation. Least Significant Bits (LSB) encoding is used for header fields whose values are usually subject to small changes. With LSB encoding, the *k* least significant bits of the field value are transmitted instead of the original field value, where *k* is a positive integer. After receiving *k* bits, the decompressor derives the original value using a previously received value as reference (*v_ref*). The scheme is guaranteed to be correct if the compressor and the decompressor each use interpretation intervals as follows:

- In which the original value resides
- And in which the original value is the only value that has the exact same *k* least significant bits as those transmitted.

The interpretation interval can be described as a function:

$f(v_ref, k)$. Let $f(v_ref, k) = [v_ref - p, v_ref + (2^k - 1) - p]$

Where *p* is an integer.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
rtp-sn-p p_value
```

```
default rtp-sn-p
```

default

Returns the command to its default value.

p_value

Default: 6

The number to use for the value of *p* in the RTP SN calculation. *p_value* must be an integer from 0 through 999.

Usage

Use this command to set the value to use for *p* when performing the RTP SN calculation.

Example

The following command sets the value of *p* to 100:

```
rtp-sn-p 100
```

rtp-sn-p-override

Allow an override of p in RTP SN calculation. This is disabled by default.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] rtp-sn-p-override
```

default

Returns the command to its default value of disabled.

no

Disables overriding p in RTP SN calculation.

Usage

Use this command to enable an override of p in RTP SN calculation.

Example

The following command enables the override of p in the RTP SN calculation:

```
rtp-sn-p-override
```

rtp-time-stride

This command sets the time interval used for one TS (RTP Time Stamp) stride. This is used when timer-based encoding is enabled.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
rtp-time-stride num_ms
```

```
default rtp-time-stride
```

default

Returns the command to its default value.

num_ms

Default: 20

The number of milliseconds to use for TS_STRIDE. *num_ms* must be an integer from 0 through 999999999.

Usage

Use this command to set the length of the TS_STRIDE in milliseconds.

Example

The following command sets TS_STRIDE to 100ms:

```
rtp-time-stride 100
```

rtp-ts-deviation

This command sets the maximum percentage of deviation allowed for input RTP packets for timer-based compression.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
rtp-ts-deviation percentage
```

```
default rtp-ts-deviation percentage
```

default

Returns the command to its default value.

percentage

Default: 25

Specifies the maximum percentage of deviation allowed for input RTP packets for timer-based compression. *percentage* must be an integer value from 0 through 100.

Usage

Use this command to set the maximum percentage of deviation allowed for input RTP packets for timer-based compression.

Example

The following command sets the time increment to 1000:

```
rtp-ts-deviation 25
```

rtp-ts-stride

Amount by which TS (RTP time stamp) is incremented. This is used for Scaled RTP TS encoding.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
rtp-ts-stride num_ms
```

```
default rtp-ts-stride
```

default

Returns the command to its default value.

num_ms

Default: 160

The number of milliseconds to use incrementing TS. *num_ms* must be an integer from 0 through 999999999.

Usage

Use this command to set the amount by which TS is incremented for Scaled RTP TS encoding.

Example

The following command sets amount by which TS is incremented to 100ms:

```
rtp-ts-stride 100
```

sliding-window-ts

DescriptionThe sliding window used to compute jitter.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
sliding-window-ts size
```

```
default sliding-window-ts
```

default

Returns the command to its default value.

size

Default: 4

Set the size of the sliding window. *size* must be an integer from 1 through 1000.

Usage

Use this command to set the size of the sliding window used to compute jitter for the current RoHC profile.

Example

The following command sets the sliding window size to 500:

```
sliding-window-ts 500
```

total-jitter-ipv4

The total jitter experienced after compression for IPV4.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
total-jitter-ipv4 time
```

```
default total-jitter-ipv4
```

default

Returns the command to its default value.

time

Default: 270

Specifies the time interval to use in milliseconds. *time* must be an integer from 0 through 999999999.

Usage

Use this command to set the jitter limit after compression.

Example

The following command sets the jitter after compression limit to 900ms:

```
total-jitter-ipv4 900
```

total-jitter-ipv6

The total jitter experienced after compression for IPV6.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
total-jitter-ipv6 time
```

```
default total-jitter-ipv6
```

default

Returns the command to its default value.

time

Default: 580

Specifies the time interval to use in milliseconds. *time* must be an integer from 0 through 999999999.

Usage

Use this command to set the jitter limit after compression.

Example

The following command sets the jitter after compression limit to 900 ms:

```
total-jitter-ipv6 900
```

unimode-timeout-to-fo-state

The time period in seconds before falling back to the FO (First Order) state.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
unimode-timeout-to-fo-state num_ms
```

```
default unimode-timeout-to-fo-state
```

default

Returns the command to its default value.

num_ms

Default: 3

Timeout period in seconds. *num_ms* must be an integer from 0 through 10.

Usage

Use this command to set the timeout before falling back to the FO state when in Unimode.

Example

The following command sets the fall back timeout to 3 seconds:

```
unimode-timeout-to-fo-state 3
```

unimode-timeout-to-ir-state

The time period in seconds before falling back to the IR (Initiation and Refresh) state.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
unimode-timeout-to-ir-state num_ms
```

```
default unimode-timeout-to-ir-state
```

default

Returns the command to its default value.

num_ms

Default: 5

Timeout period in seconds. *num_ms* must be an integer from 0 through 20.

Usage

Use this command to set the timeout before falling back to the IR state when in Unimode.

Example

The following command sets the fall back timeout to 3 seconds:

```
unimode-timeout-to-ir-state 3
```

use-calculated-rtp-time-stride

This command overrides the configured value of rtp-time-stride with a calculated value.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-calculated-rtp-time-stride
```

default

Returns the command to its default value of enabled.

no

Disables the use of calculated RTP time stride override.

Usage

This command overrides the configured value of rtp-time-stride with a calculated value.

Example

The following command overrides the configured value of rtp-time-stride.

```
use-calculated-rtp-time-stride
```

use-calculated-rtp-ts-stride

This command overrides the configured value of rtp-ts-stride with a calculated value.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-calculated-rtp-ts-stride
```

default

Returns the command to its default value of enabled.

no

Disables the use of calculated RTP TS time stride override.

Usage

This command overrides the configured value of rtp-ts-stride with a calculated value.

Example

The following command overrides the configured value of rtp-ts-stride.

```
use-calculated-rtp-ts-stride
```

use-ipid-override

Enable and disable overriding the IP-ID (IPv4 Identification header field).

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-ipid-override
```

default

Returns the command to its default value of disabled.

no

Disables the IP-ID override.

Usage

Use this command to enable overriding the IP-ID.

Example

The following command enables the IP-ID override feature:

```
use-ipid-override
```

The following command disables the IP-ID override feature:

```
no use-ipid-override
```

The following command also disables the IP-ID override feature:

```
default use-ipid-override
```

use-optimized-talkspurt

Disable and enable the use of optimized talkspurt.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-optimized-talkspurt
```

default

Returns the command to its default value of enabled.

no

Disable the use of optimized talkspurt.

Usage

Use this command to enable and disable the use of optimized talkspurt

Example

The following command enables the use of optimized talkspurt:

```
use-optimized-talkspurt
```

The following command disables the use of optimized talkspurt:

```
no use-optimized-talkspurt
```

use-optimized-transience

Enable or disable the use of optimized transience.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-optimized-transience
```

default

Returns the command to its default value of enabled.

no

Disables the use of optimized transience.

Usage

Use this command to enable or disable the use of optimized transience.

Example

The following command enables the use of optimized transience.

```
use-optimized-transience
```

The following command disables the use of optimized transience.

```
no use-optimized-transience
```

use-timer-based-compression

Enables timer-based compression of the RTP time stamp (TS) at the compressor.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-timer-based-compression
```

default

Returns the command to its default value of enabled.

no

Disables the use of timer-based compression.

Usage

Use this command to enable or disable the use of timer-based compression.

Example

The following command enables the use of timer-based compression.

```
use-timer-based-compression
```

The following command disables the use of timer-based compression.

```
no use-timer-based-compression
```

use-uncomp-profile

Uses the Uncompressed Profile (0x0000) if required at the compressor.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[default | no ] useS-uncomp-profile
```

default

Returns the command to its default value of disabled.

no

Disables the use of the Uncompressed Profile.

Usage

Use this command to enable or disable the use of the Uncompressed Profile.

Example

The following command enables the use of the Uncompressed Profile.

```
use-uncomp-profile
```

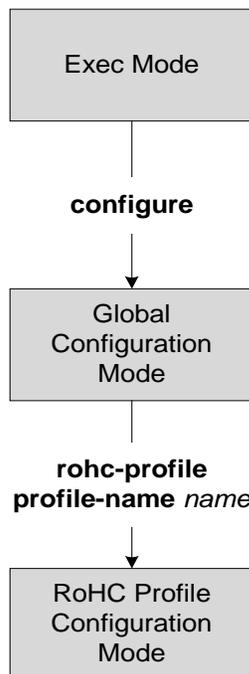

The following command disables the use of the Uncompressed Profile.

```
no use-uncomp-profile
```

Chapter 201

RoHC Profile Configuration Mode Commands

The RoHC Profile Configuration Mode is used to configure RoHC (Robust Header Compression) Compressor and Decompressor parameters. The profiles can then be assigned to specific subscriber sessions when RoHC header compression is configured. RoHC is not supported on GGSN.

 **Important:** The availability of commands, keywords and variables in this mode is dependent on platform type, product version, and installed license(s).

common-options

Enters the RoHC Profile Common Options Configuration Mode where inactivity and delay timers are set to support dynamic header compression contexts and context preservation during handoffs.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default ] common-options
```

default

Reset all parameters in the RoHC Profile Common Options Configuration Mode to default values.

Usage

Use this command to enter the RoHC Profile Common Options Configuration Mode where parameters for maintaining header compression contexts and inactivity timers can be configured.

Entering this command results in the following prompt:

```
[context_name]host(config-rohcprofile-<profile_name>-common)#
```

RoHC Profile Common Options Configuration Mode commands are defined in the RoHC Profile Common Options Configuration Mode Commands chapter.

compression-options

Enters the RoHC Profile Compression Options Configuration Mode allowing configuration of options applied during RoHC compression for the current RoHC profile.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default ] compression-options
```

default

Reset all options in the RoHC Profile Compression Configuration Mode to their default values.

Usage

Use this command to enter RoHC Profile Compression Configuration Mode to set the compression options that are used for subscriber sessions using the current RoHC profile.

Entering this command results in the following prompt:

```
[context_name]host(config-rohcprofile-<profile_name>-comp)#
```

RoHC Profile Compression Options Configuration Mode commands are defined in the RoHC Profile Compression Configuration Mode Commands chapter.

Example

The following command enters RoHC Profile Compression Options Configuration Mode:

```
compression-options
```

The following command sets all compression options to their default values:

```
default compression-options
```

decompression-options

Enters the RoHC Profile Decompression Options Configuration Mode allowing configuration of options applied during RoHC decompression for the current RoHC profile.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[default ] decompression-options
```

default

Reset all options in the RoHC Profile Decompression Options Configuration Mode to their default values.

Usage

Use this command to enter RoHC Profile Decompression Options Configuration Mode to set the decompression options used for subscriber sessions using the current RoHC profile.

Entering this command results in the following prompt:

```
[context_name]host(config-rohcprofile-<profile_name>-decomp)#
```

RoHC Profile Decompression Options Configuration Mode commands are defined in the RoHC Profile Decompression Configuration Mode Commands chapter.

Example

The following command enters RoHC Profile Decompression Options Configuration Mode:

```
decompression-options
```

The following command sets all decompression options to their default values:

```
default decompression-options
```

end

Returns the CLI prompt to to the Exec mode.

Product

HSGW, PDSN

Privilege

Administrator

Syntax`end`

Usage

Change the mode back to the Exec mode.

■ exit

exit

Exits this configuration mode and returns to the previous mode.

Product

HSGW, PDSN

Privilege

Administrator

Syntax `exit`

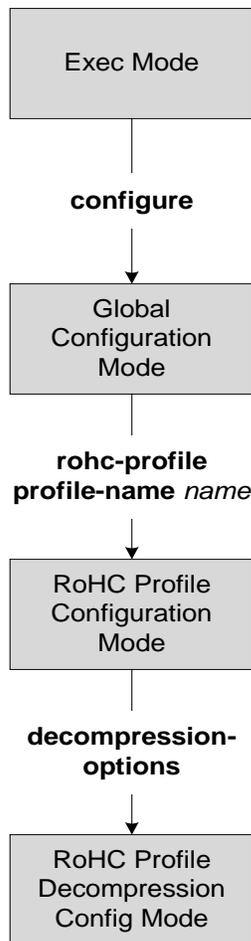

Usage

Return to the previous mode.

Chapter 202

RoHC Profile Decompression Configuration Mode Commands

The RoHC Profile Decompression Configuration Mode is used to configure RoHC (Robust Header Compression) Decompressor parameters.

 **Important:** The availability of commands, keywords and variables in this mode are dependent on platform type, product version, and installed license(s).

accept-delayed-pkts

Accepts delayed packets

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default ] accept-delayed-pkts
```

default

Returns the command to its default value of disabled.

Usage

This command helps reduce packet loss during context repair.

Example

Use the following command to enable the system to accept delayed packets:

```
accept-delayed-pkts
```

context-timeout

Ensures that no expired contexts are used for data compression.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
context-timeout seconds
```

```
default context-timeout
```

default

Returns the command to its default value.

seconds

Default: 20 seconds

The context timeout value in seconds. *seconds* must be an integer from 0 through 100.

Usage

The RoHC stack should periodically clean up expired contexts and release memory in case there is no data activity for the call on this context. The context cleanup period is internally calculated to be set to half of the value of the *context-timeout* value. This will ensure that no expired contexts are used for data compression.

Example

The following command sets the context-timeout parameter to 30 seconds:

```
context-timeout 30
```

crc-errors-fo

This command sets the limits for when a NACK message is sent when in the FO (First Order) state. A NACK is sent when out of a specified number of packets a specified number of them have CRC errors.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
crc-errors-fo-k num_errors
```

```
crc-errors-fo-n num_packets
```

```
default crc-errors-fo-k
```

```
default crc-errors-fo-n
```

default

Returns the command to its default value.

```
crc-errors-fo-k num_errors
```

Default: 1

The number of received packets within a specified number of received packets that triggers the sending of a NACK. *num_errors* must be an integer from 1 through 10.

Important: *num_errors* must be less than or equal to the value specified with the `crc-errors-fo-n` command.

```
crc-errors-fo-n num_packets
```

Default: 1

The number of packets to check for CRC errors. *num_packets* must be an integer from 1 through 10.

Usage

Use this command to set the parameters that trigger sending a NACK message when in the FO state.

Example

To configure a NACK to be sent when 4 out of the last 10 packets have CRC errors when in the FO state, use the following commands:

```
crc-errors-fo-k 4
```

```
crc-errors-fo-n 10
```

crc-errors-so

This command sets the limits for when a NACK message is sent when in the SO (Second Order) state. A NACK is sent when out of a specified number of packets a specified number of them have CRC errors.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
crc-errors-so-k num_errors
```

```
crc-errors-so-n num_packets
```

```
default crc-errors-so-k
```

```
default crc-errors-so-n
```

default

Returns the command to its default value.

```
crc-errors-so-k num_errors
```

Default: 1

The number of received packets within a specified number of received packets that triggers the sending of a NACK. *num_errors* must be an integer from 0 through 10.

Important: *num_errors* must be less than or equal to the value specified with the `crc-errors-so-n` command.

```
crc-errors-so-n num_packets
```

Default: 1

The number of packets to check for CRC errors. *num_packets* must be an integer from 1 through 10.

Usage

Use this command to set the parameters that trigger sending a NACK message when in the SO state.

Example

To configure a NACK to be sent when 4 out of the last 10 packets have CRC errors when in the SO state, use the following commands:

```
crc-errors-so-k 4
```

```
crc-errors-so-n 10
```

■ end

end

Returns the CLI prompt to to the Exec mode.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the this configuration mode and returns to the previous mode.

Product

HSGW, PDSN

Privilege

Administrator

Syntax`exit`

Usage

Return to the previous mode.

nack-limit

Sets the number of unsuccessful decompressions allowed before a NACK is sent.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
nack-limit limit
```

```
default nack-limit
```

default

Returns the command to its default value.

limit

Default: 0

Specifies the number of unsuccessful decompressions allowed. *limit* must be an integer from 0 through 20.

Usage

Use this command to set the maximum number of unsuccessful decompressions before a NACK message is sent.

Example

The following command sets the number of unsuccessful decompressions allowed to 10:

```
nack-limit 10
```

optimistic-mode-ack

When this is enabled, if a type 2 IR-DYN packet is successfully decompressed, an optional ACK is sent in U-mode.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] optimistic-mode-ack
```

default

Returns the command to its default value of enabled.

no

Disables the sending of the optional ACK.

Usage

Use this command to enable and disable the sending of an optional ACK in U-mode when a type 2 IR-DYN packet is successfully decompressed.

Example

To enable the sending of the optional ACK, enter the following command:

```
optimistic-mode-ack
```

To disable the sending of the optional ACK, enter the following command:

```
no optimistic-mode-ack
```

optimistic-mode-ack-limit

When enabled, this command sets the number of packets to send ACKs for.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
optimistic-mode-ack-limit num_pkts
```

```
default optimistic-mode-ack-limit
```

default

Returns the command to its default value.

num_pkts

Default: 3

The number of packets to send ACKs for . *num_pkts* must be an integer from 0 through 20.

Usage

Use this command to set the number of packets to send the optional ACK for when a type 2 IR-DYN packet is successfully decompressed.

Example

Enter the following command to set the number of packets to send and ACK for to 6:

```
optimistic-mode-ack-limit 6
```

Use the following command to set the number of packets to send an ACK for back to the default of 3:

```
default optimistic-mode-ack-limit
```

piggyback-wait-time

The time in milliseconds to wait for a feedback packet to be picked up as piggybacked feedback by the associated compressor.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
piggyback-wait-time m_secs
```

```
default piggyback-wait-time
```

default

Returns the command to its default value.

m_secs

Default: 80ms

Specifies the time in milliseconds to wait for a feedback packet to be picked up. *m_secs* must be an integer value from 0 through 1000.

Usage

Use this command to set the time in milliseconds to wait for a feedback packet to be picked up as piggybacked feedback by the associated compressor.

Example

The following command sets the wait time to 120 ms:

```
piggyback-wait-time 120
```

preferred-feedback-mode

Specifies the preferred feedback mode to use between the compressor and the decompressor

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
preferred-feedback-mode { bidirectional-optimistic | bidirectional-reliable |
unidirectional }
```

default preferred-feedback-mode

default

Default: bidirectional-optimistic
Returns the command to its default setting.

bidirectional-optimistic

This mode is similar to the Unidirectional mode, with the exception of a feedback channel used to send error recovery requests from the decompressor to compressor.

bidirectional-reliable

Reliable mode makes extensive use of a feedback channel to avoid packet loss from context invalidation. A secure reference model is used instead of the optimistic approach used in the other modes. With the secure reference model, the confidence of the compressor depends on acknowledgements from the decompressor for every context updating packet. Periodically the compressor sends context updating packets repeatedly until an acknowledgement is received from the decompressor.

unidirectional

Packets are sent in only one direction, from the compressor to the decompressor.

Usage

Use this command to specify the preferred feedback method to use between the compressor and the decompressor for the current RoHC profile.

Example

Use the following command to set the preferred feedback mode to bidirectional-reliable:

```
preferred-feedback-mode bidirectional-reliable
```

rtp-sn-p

The value of *p* in RTP SN (RTP Sequence Number) calculation. Least Significant Bits (LSB) encoding is used for header fields whose values are usually subject to small changes. With LSB encoding, the *k* least significant bits of the field value are transmitted instead of the original field value, where *k* is a positive integer. After receiving *k* bits, the decompressor derives the original value using a previously received value as reference (*v_ref*). The scheme is guaranteed to be correct if the compressor and the decompressor each use interpretation intervals as follows:

- In which the original value resides
- And in which the original value is the only value that has the exact same *k* least significant bits as those transmitted.

The interpretation interval can be described as a function:

$f(v_ref, k)$. Let $f(v_ref, k) = [v_ref - p, v_ref + (2^k - 1) - p]$

Where *p* is an integer.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
rtp-sn-p value
```

```
default rtp-sn-p
```

default

Returns the command to its default value.

value

Default:

Specifies the number to use for the value of *p* in the RTP SN calculation. *value* must be an integer from 0 through 999.

Usage

Use this command to set the value to use for *p* when performing the RTP SN calculation.

Example

The following command sets the RTP Sequence Number integer “*p*” value to 100:

```
rtp-sn-p 100
```

rtp-sn-p-override

Allow an override of p in RTP SN calculation. This is disabled by default.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] rtp-sn-p-override
```

default

Returns the command to its default value of disabled.

no

Disables overriding p in RTP SN calculation.

Usage

Use this command to allow an override of p in RTP SN calculations.

Example

The following command enables the override of p in the RTP SN calculation:

```
rtp-sn-p-override
```

sliding-window-ts

Computes jitter as described in RFC 3095,[4.5.4]

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
sliding-window-ts size
```

```
default sliding-window-ts
```

default

Returns the command to its default value.

size

Default: 4

Set the size of the sliding window. *size* must be an integer from 1 through 1000.

Usage

Use this command to set the size of the sliding window used to compute jitter for the current RoHC profile.

Example

The following command sets the sliding window size to 500:

```
sliding-window-ts 500
```

use-clock-option

Controls usage of RoHC clock option. The clock option informs the compressor of the clock resolution of the decompressor. This is needed to allow the compressor to estimate the jitter introduced by the clock of the decompressor when doing timer-based compression of the RTP timestamp.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-clock-option
```

default

Returns the command to its default value of enabled.

no

Disable use of the RoHC clock option.

Usage

Use this command to enable and disable the use of the RoHC clock option.

Example

The following command enables RoHC clock option usage:

```
use-clock-option
```

The following command disables RoHC clock option usage:

```
no use-clock-option
```

use-crc-option

Controls usage of the RoHC crc option. The CRC option contains an 8-bit CRC computed over the entire feedback payload, without the packet type and code octet, but including any CID fields,

Product

HSGW, PDSN

Product

Administrator

Syntax

```
[ default | no ] use-crc-option
```

default

Returns the command to its default value of enabled.

no

Disable use of the CRC option.

Usage

Use this command to enable and disable the use of the RoHC CRC option.

Example

The following command enables RoHC CRC option usage:

```
use-crc-option
```

The following command disables RoHC CRC option usage:

```
no use-crc-option
```

use-feedback

Controls use of the feedback channel. A feedback channel sends error recovery requests and (optionally) acknowledgments of significant context updates from the decompressor to the compressor.

Product

HSGW, PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] use-feedback
```

default

Returns the command to its default value of disabled.

no

Disable use of the feedback channel.

Usage

Use this command to enable and disable the use of the RoHC feedback channel.

Example

The following command enables RoHC feedback channel usage:

```
use-feedback
```

The following command disables RoHC feedback channel usage:

```
no use-feedback
```

use-jitter-option

Controls usage of RoHC jitter option. The jitter option allows the decompressor to report the maximum jitter it has observed

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-jitter-option
```

default

Returns the command to its default value of enabled.

no

Disable use of the jitter option.

Usage

Use this command to enable and disable the use of the RoHC jitter option.

Example

The following command enables RoHC jitter option usage:

```
use-jitter-option
```

The following command disables RoHC jitter option usage:

```
no use-jitter-option
```

use-reject-option

Controls usage of RoHC reject option. The reject option informs the compressor that the decompressor does not have sufficient resources to handle the flow.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-reject-option
```

default

Returns the command to its default value of disabled.

no

Disable use of the reject option.

Usage

Use this command to enable and disable the use of the RoHC reject option.

Example

The following command enables RoHC reject option usage:

```
use-reject-option
```

The following command disables RoHC reject option usage:

```
no use-reject-option
```

use-sn-not-valid-option

Controls usage of the RoHC SN not valid option. The sn-not-valid option indicates that the SN of the feedback is not valid. A compressor must not use the SN of the feedback to find the corresponding sent header when this option is present.

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-sn-not-valid-option
```

default

Returns the command to its default value of enabled.

no

Disable use of the sn-not-valid option.

Usage

Use this command to enable and disable the use of the RoHC sn not valid option.

Example

The following command enables RoHC sn not valid option usage:

```
use-sn-not-valid-option
```

The following command disables RoHC sn not valid option usage:

```
no use-sn-not-valid-option
```

use-sn-option

Controls usage of RoHC sn option. The sn option provides 8 additional bits of SN (Sequence Number. Usually RTP Sequence Number.)

Product

HSGW, PDSN

Privilege

Administrator

Syntax

```
[ default | no ] use-sn-option
```

default

Returns the command to its default value of enabled.

no

Disable use of the sn option.

Usage

Use this command to enable and disable the use of the RoHC sn option.

Example

The following command enables RoHC sn option usage:

```
use-sn-option
```

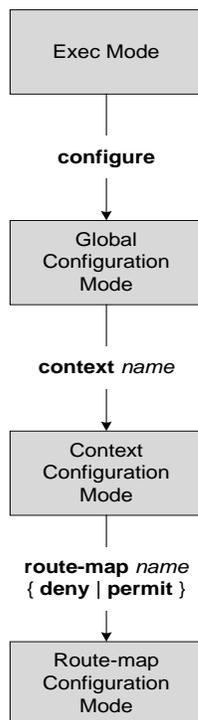

The following command disables RoHC sn option usage:

```
no use-sn-option
```

Chapter 203

Route-map Configuration Mode Commands

The Route-Map Configuration sub-mode is used for the OSPFv2 and BGP-4 routing protocols. This mode includes commands that configure matching rules and set actions to perform on matched routes.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the context configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the context configuration mode and returns to the global configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

match as-path

Match an AS path access list

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
match as-path AS_list
```

```
no match as-path AS_list
```

no

Disables matching the specified AS path access list.

AS_list

Specifies the name of an AS path access list for matching. *AS_list* must be from 1 to 79 alphanumeric characters in length.

Usage

This command is used for BGP-4 routing to specify an AS path access list to be matched. Refer to the **ip as-path access-list** command for more information.

Example

To match entries in an AS path access list named *ASlist1*, enter the following command;

```
match as-path ASlist1
```

match interface

Specifies the next-hop interface name of a route to be matched.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
match interface interface-name
```

```
no match interface interface-name
```

no

Disables matching the specified interface name.

interface-name

Specifies the name of the virtual interface for matching. This variable can be from 1 to 79 alphanumeric characters in length.

Usage

Use this command to specify the next hop interface name for routes to be matched.

Example

To match routes that have the next hop interface specified as *Interface123*, enter the following command:

```
match interface Interface123
```

To disable matching routes that have the next hop interface specified as *Interface123*, enter the following command:

```
no match interface Interface123
```

match ip address

This command matches routes with entries in a route-access-list or prefix-list.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
match ip address { prefix-list | route-access-list } list_name
```

```
no match ip address { prefix-list | route-access-list } list_name
```

no

Disable matching from the specified prefix list or route access list.

prefix-list

This command matches any routes with entries in a prefix-list.

route-access-list

This command matches any routes with entries in a route-access-list

list_name

The name of the IP prefix list or IP route access-list. This variable can be a string from 1 to 63 alphanumeric characters in length.

Usage

Use this command to match routes specified in a route-access-list or prefix-list.

Example

To match routes that are specified in a prefix list named *Prefix100*, enter the following command:

```
match ip address prefix-list Prefix100
```

To disable matching routes that are specified in a prefix list named *Prefix100*, enter the following command:

```
no match ip address prefix-list Prefix100
```

match ip next-hop

This command matches next-hop IP addresses with entries in specified standard prefix-list or route-access-list.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
match ip address next-hop { prefix-list | route-access-list } list_name
```

```
no match ip address next-hop { prefix-list | route-access-list } list_name
```

prefix-list

This command matches any routes that have a next-hop router address that has an entry in the specified prefix list.

route-access-list

This command matches any routes that have a next-hop router address that has an entry in the specified route-access-list.

list_name

The name of the IP prefix-list or IP route-access-list. This variable is a string from 1 through 63 alphanumeric characters in length.

Usage

Use this command to match next-hop IP addresses that have entries in the specified prefix-list or route-access-list.

Example

To match next-hop addresses with entries in a prefix-list named *Prefix100*, enter the following command:

```
match ip address next-hop prefix-list Prefix100
```

To disable matching next-hop addresses with entries in a prefix-list named *Prefix100*, enter the following command:

```
no match ip address next-hop prefix-list Prefix100
```

match metric

This command matches routes that have the specified route metric.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
match metric metric_value
```

```
no match metric metric_value
```

no

Disables matching of the specified route metric.

metric_value

This is the route metric to match. This must be an integer ranging from 0 through 4294967295.

Usage

Use this command to match routes that have the specified route metric.

Example

To match routes with the route metric of *1200*, enter the following command:

```
match metric 1200
```

To disable matching routes with a route metric of *1200*, enter the following command:

```
no match metric 1200
```

match origin

This command matches the origin code learned from BGP. This command is for route maps that are used with BGP routing only.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] match origin { egp | igp | incomplete }
```

no

Disables matching of the origin code.

egp

Match origins learned from learned from the External Gateway Protocol (EGP)

igp

Match origins learned from learned from the local Interior Gateway Protocol (IGP)

incomplete

Match origins with unknown heritage.

Usage

Use this command to match origin codes for BGP routing.

Example

To match origin codes learned from EGP, enter the following command:

```
match origin egp
```

match route-type external

Match external OSPF routes of the specified type.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] match route-type external { type-1 | type-2 }
```

type-1

Only match type-1 external routes.

type-2

Only match type-2 external routes.

Usage

Use this command to match external routes of a specific type.

Example

The following command matches all external routes that are type-2:

```
match route-type external type-2
```

The following command disables matching external routes that are type-2:

```
no match route-type external type-2
```

match tag

This command matches routes with the specified route tag value.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] match tag tag_value
```

no

Disable matching routes with the specified route tag value.

tag_value

The route tag value to match. This must be an integer from 0 through 4294967295.

Usage

Use this command to match routes that have the specified route tag value.

Example

Use the following command match routes that have a route tag value of *1234*:

```
match tag 1234
```

Use the following command to disable matching routes that have a route tag value of *1234*:

```
no match tag 1234
```

set as-path

Modify an AS path for a route by adding the specified AS numbers to the front of the path.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] set as-path prepend ASN
```

no

Disable prepending the AS path. Any previously set prepends are removed.

prepend

Prepends the autonomous system path.

ASN

AS number(s) to be prepended to the AS path. You can specify up to 16 different AS numbers to be prepended in the order specified. Each AS number must be separated by a space. *ASN* must be an integer from 1 through 65535.

Usage

Use this command to add up to 16 specified AS numbers to the front of the AS path.

Example

The following command prepends the AS numbers *100*, *200*, and *1000* to matching AS paths:

```
set as-path prepend 100 200 1000
```

set ip next-hop

Set the IP address that is applied as the next hop for routes.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] set ip next-hop ip_address
```

no

Disable the specified next hop address.

ip_address

This is the IP address of the next hop to which packets are output.

Usage

Use this command to set the IP address that is used as the next hop for routes.

Example

To set the next hop for routes to the IP address *192.168.2.100*, use the following command:

```
set ip next-hop 192.168.2.100
```

To disable setting the next hop for routes to the IP address *192.168.2.100*, use the following command:

```
no set ip next-hop 192.168.2.100
```

set metric

This command sets the route metric for matched routes to the specified value.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] set metric metric_value
```

metric_value

This is the metric value that is set for routes. This must be an integer from 1 through 4294967295.

Usage

Use this command to set the route metric for matched routes.

Example

To set the route metric to *12345*, use the following command;

```
set metric 12345
```

To disable setting the route metric to *12345*, enter the following command;

```
no set metric 12345
```

set metric-type

This command sets the route metric type to either Type-1 or Type-2 in the AS-external-LSA.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] set metric-type { type-1 | type-2 }
```

type-1

Set the route metric to external type-1.

type-2

Set the route metric to external type-2

Usage

Use this command to set the route metric to either external type-1 or external type-2.

Example

To set the route metric to type-1, enter the following command:

```
set metric type-1
```

To disable setting the metric to type, enter the following command:

```
no set metric type-1
```

set origin

This command sets the BGP origin code to the specified value. This command is for route maps that are used with BGP routing only.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] set origin {egp | igp | incomplete}
```

no

Disables setting the origin code.

egp

Set the origin code to specify that the path is from a remote External Gateway Protocol (EGP) system.

igp

Set the origin code to specify that the path is from a local Interior Gateway Protocol (IGP) system.

incomplete

Set the origin code to specify that the path is from an unknown system.

Usage

Use this command to set a specified origin code for BGP.

Example

To the origin code to EGP, enter the following command:

```
set origin egp
```

set tag

This command sets the route tag value for matched routes.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] set tag tag_value
```

no

Disable setting the route tag to the specified value.

tag_value

The route tag value to set. This must be an integer from 0 through 4294967295.

Usage

Use this command to set the route tag value that is applied to all matched routes.

Example

To set the route tag value to *12345*, enter the following command:

```
set tag 12345
```

To disable setting the route tag value to *12345*, enter the following command:

```
no set tag 12345
```

set weight

Set the weight in the routing table for matching routes to the specified value.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] set weight value
```

no

Disable setting the routing weight value.

value

The weight in the routing table to assign. must be an integer from 1 through 4294967295.

Usage

Use this command to set the routing table weight on matched routes.

Example

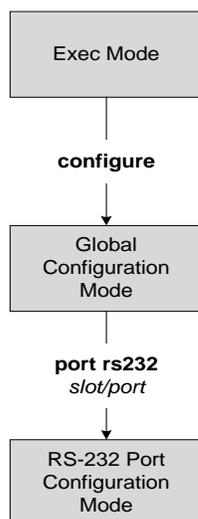

The following command sets the routing table weight for matched routes to *1000*:

```
set weight 1000
```

Chapter 204

RS-232 Port Configuration Mode Commands

The RS-232 Port Configuration Mode is used to manage the RS-232 ports on the SPIO cards.

default

Restores the port's default speed and communication mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
default { preferred slot | terminal { all | databits | flowcontrol | parity |  
speed | stopbits }
```

preferred slot

Sets the port for non-revertive operation for port redundancy auto-recovery; requiring an administrative user to manually issue a port switch to command to return service to the original port.

```
terminal { all | databits | flowcontrol | parity | speed | stopbits }
```

Sets the terminal settings for the rs-232 port to their default settings.

all: Restore all settings to their default values.

databits: Restore the databits setting to its default value of 8.

flowcontrol: Restore the flowcontrol setting to its default value of none.

parity: Restore the parity setting to its default value of none.

speed: Restore the speed setting to its default value of 9600.

stopbits: Restore the stopbits setting to its default value of 1.

Usage

Restores port-level parameters to their default values.

Example

The following command restores all terminal settings to their default values:

```
default terminal all
```

end

Exits the port configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the port configuration mode and returns to the global configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

preferred slot

Assigns revertive or non-revertive control to port redundancy auto-recovery.

Default: non-revertive operation

Product

PDSN, FA, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
preferred slot slot#
```

```
no preferred slot slot#
```

no

Disables revertive, or auto-recovery, operation for selected port.

slot#

Identifies the physical chassis slot where the SPIO card is installed.

Usage

This command enables or disables revertive port redundancy, wherein after a port failover, when the original port is restored to service (i.e. link up) the system will return service to that port automatically.

Disabled, which is the default setting, causes non-revertive operation; requiring an administrative user to manually issue a port switch to command to return service to the original port.

This command must be issued on a per port basis, allowing you to configure specific ports to be used on individual LCs or SPIO cards. For example, ports 1 through 4 could be configured as “preferred” on the LC in slot 17 while ports 5 through 8 are “preferred” on the LC in slot 33. In this scenario, both LCs would be in an Active operational state while still providing LC and port redundancy for the other.

Important: This command is not supported on all platforms.

Example

```
preferred slot 24
```

snmp trap link-status

Enables/disables the generation of an SNMP trap for link status changes.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
snmp trap link-status
```

```
no snmp trap link-status
```

```
no
```

Disables the sending of traps for link status changes.

Usage

Enable link status change traps when a monitoring facility can use the information or if there are trouble shooting activities are in progress.

Example

```
snmp trap link-status
```

```
no snmp trap link-status
```

terminal

Configures the console port on the SPIO.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
terminal { carrierdetect { off | on } | databits { 7 | 8 } | flowcontrol {
hardware | none } | parity { even | none | odd } | speed { 115200 | 19200 |
38400 | 57600 | 9600 } | stopbits { 1 | 2 } }
```

```
carrierdetect { off | on }
```

Default:

Specifies whether or not the console port is to use carrier detect when connecting to a terminal.

```
databits { 7 | 8 }
```

Default: 8

Specifies the number of data bits used to transmit and receive characters.

```
flowcontrol { hardware | none }
```

Default: none

Specifies how the flow of data is controlled between the SPIO and a terminal.

```
parity { even | none | odd }
```

Default: none

Specifies the type of error checking used on the port.

even - Enables error checking by setting the parity bit to 1 (if needed) making the number of 1s in the data bits even.

none - Disables error checking.

odd - Enables error checking by setting the parity bit to 1 (if needed) making the number of 1s in the data bits odd.

```
speed { 115200 | 19200 | 38400 | 57600 | 9600 }
```

Default: 9600

Specifies the flow of data in bits per second between the console port and terminal.

```
stopbits { 1 | 2 }
```

Default: 1

Specifies the number of stop bits between each transmitted character.

Usage

Sets the SPIO's console port parameters for communication with the terminal device.

■ terminal

Example

The following command sets the SPIO's console port. The terminal must support these values.

```
terminal carrierdetect off databits 7 flowcontrol hardware parity even  
speed 115200 stopbits 1
```

Chapter 205

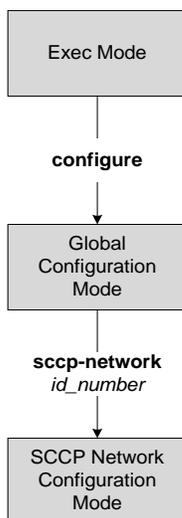

SCCP Network Configuration Mode Commands

The SCCP Network Configuration Mode is used to configure properties for Signaling Connection Control Part (SCCP) services for SS7.

In this mode, the command prompt should be similar to:

```
[local]hostname(config-sccp-network-<sccp_id>)#
```

Signaling Connection Control Part (SCCP) is a routing protocol in the SS7 protocol suite in layer 4, which provides end-to-end routing for TCAP messages to their proper database.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

associate

Associates an SS7 routing domain with the SCCP network.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
associate ss7-routing-domain rd_id
```

```
no associate
```

no

Removes the association with the SS7 routing domain from the system configuration.

rd_id

This number identifies an already defined SS7 routing domain.

rd_id: enter an integer from 1 through 12.

Usage

Use this command to associate SS7 routing domain configurations with SCCP network configurations.

Example

The following command associates the SCCP network with SS7 routing domain 2:

```
associate ss7-routing-domain 2
```

description

This command defines a string that describes the SCCP network. The description is used for operator reference.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
description string
```

```
no description
```

string

This is a string to describe the SCCP network.

string must be an alphanumeric string from 1 through 127 characters in length. If there are spaces in the string the string must be enclosed in double-quotes. For example; "This is a Description".

no

Removes the description from the system configuration.

Usage

Use this command to configure a description of this SCCP service for operator reference.

Example

The following command sets the description to "This is the SCCP Service Number 1":

```
description "This is the SCCP Service Number 1."
```

destination

This command configures the SCCP network destination information. Use this command multiple times to set all of the destination information required.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
destination dpc pt_code { name route_name | next-hop | ssn subsys_num | version sccp_ver }
```

```
no destination dpc p_code [ name route_name | ssn ssn_num | version sccp_ver ]
```

no

Deletes the specified destination information from the SCCP network configuration.

dpc *pt_code*

Specifies the SCCP destination point code.

pt_code: Must be in SS7 point code dotted-decimal ###.###.### format or decimal ##### format.

name *route_name*

The name of the SCCP destination route.

route_name: enter an alphanumeric string from 1 through 64 characters in length.

next-hop

Associates the next destination defined in the SS7 routing domain.

ssn *subsys_num*

The destination subsystem number.

subsys_num: enter an integer from 1 through 255.

version *sccp_ver*

sccp_ver: enter one of the following to select the SCCP variant:

- ANSI88
- ANSI92
- ANSI96
- BELL05
- GSM0806
- ITU88
- ITU92

- ITU96

Usage

Use this command to configure the destination information for the SCCP network.

Example

The following commands set the name of the destination route to `default_route`, the subsystem number to 1, and the variant version to ITU96, all with a destination point code of 1:

```
destination dpc 1 name default_routedestination dpc 1 ssn 1destination  
dpc version ITU96
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN , HNB-GW

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the global configuration mode.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

global-title-translation

This command associates a GTT address-map with this SCCP network.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
global-title-translation address-map instance instance
```

```
no global-title-translation address-map instance instance
```

no

Deletes the GTT address-map instance associated with this SCCP network.

instance

This value uniquely identifies a specific previously defined instance of a GTT address-map.

instance : enter an integer from 1 to 4096.

Usage

Use this command to link a GTT address-map, configured with the GTT Address Map configuration mode, to a specific SCCP network configuration.

Example

```
global-title-translation address-map instance gtt-map1
```

hop-count

This command specifies the hop count for this SCCP network.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
hop-count hop_cnt
```

```
default hop-count
```

default

Resets the hop-count value to the system default of 5.

hop_cnt

The hop count to assign to this SCCP network.

hop_cnt : enter an integer from 1 to 5.

Usage

Use this command to define the hop count for this SCCP network.

Example

The following command sets the hop count to 3:

```
hop-count 3
```

self-point-code

This command specifies the SS7 point code for this SCCP service.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
self-point-code point_code
```

```
no self-point-code
```

no

Deletes the configured self point code.

point_code

Defines the point code to assign to this SCCP network service.

point_code: value entered must adhere to the point code variant selected when the SCCP network instance was defined:

- ITU Range 0.0.1 to 7.255.7
- ANSI Range 0.0.1 to 255.255.255
- TTC Range 0.0.1 to 15.31.255
- a string of 1 to 11 combined digits ad period.

Usage

Use this command to assign the self point code to use for this SCCP service.

Example

The following command sets an ITU-based point code for this SCCP service:

```
self-pointcode 4.121.5
```

The following command removes the configured self-point code:

```
no self-pointcode
```

timeout

This command configures the timeout parameters for this SCCP network.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
timeout { attack-timer | congestion-timer | conn-est-timer | crd-timer | decay-  
timer | iar-timer | ias-timer | interval-timer | reassembly-timer | release-  
timer | repeat-release-timer | reset-timer | sst-timer } +
```

```
default timeout
```

```
no timeout timer
```

attack-timer *time*

Defines the time before the attack timer expires.
time: enter an integer between 1 and 10.

congestion-timer *time*

Defines the time before the congestion timer expires.
time: enter an integer between 1 and 10.

conn-est-timer *time*

Defines the time before the connection timer expires.
time: enter an integer between 6 and 12.

crd-timer *time*

Defines the time before the coordinated-state-change timer expires.
time: enter an integer between 60 and 120.

decay-timer *time*

Defines the time before the decay timer expires.
time: enter an integer between 1 and 10.

iar-timer *time*

Defines the time before the inactivity-receive timer expires.
time: enter an integer between 60 and 120.

ias-timer *time*

Defines the time before the inactivity-send timer expires.
time: enter an integer between 30 and 60.

interval-timer *time*

Defines the time before the interval timer expires.

time: enter an integer between 6 and 12

reassembly-timer *time*

Defines the time before the reassembly-timer expires.

time: enter an integer between 10 and 20.

release-timer *time*

Defines the time before the release-assembly timer expires.

time: enter an integer between 1 and 2.

repeat-release-timer *time*

Defines the time before repeat-release timer expires.

time: enter an integer between 1 and 2

reset-timer *time*

Defines the amount of time before the reset timer expires.

time: enter an integer between 1 and 2

sst-timer *time*

Defines the amount of time before the subsystem status test timer expires.

time: enter an integer between 5 and 1200.

default

Resets the timeout parameter to the system default.

no

Deletes the specified timer configuration.

Usage

Use this command to assign timeout timers and timeout values for this SCCP service.

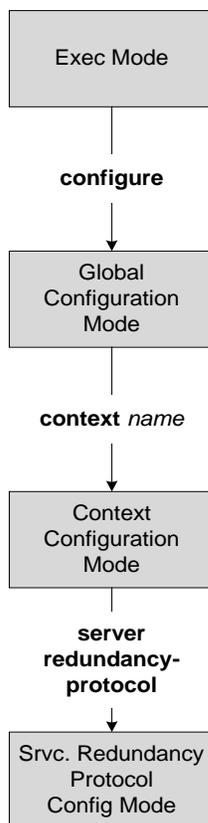

Example

```
timeout reset-timer 75
```

Chapter 206

Service Redundancy Protocol Configuration Mode Commands

The Service Redundancy Protocol Mode is used to configure properties for Interchassis Session Recovery services.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

bind address

Binds the service to the IP address of the local chassis.

Product

HA, GGSN,

Privilege

Security Administrator, Administrator

Syntax

```
bind address { IPv4 _address | IPv6_address }
```

```
[ no ] bind address
```

no

Removes the IP bind address.

IPv4 _address | *IPv6_address*

The system IP address.

Usage

Defines the IP address of the local chassis defined as part of the Interchassis Session Recovery configuration.

Example

The following example binds the service to the IP address 1.1.1.1:

```
bind address 1.1.1.1
```

chassis-mode

Defines the chassis's operational mode - primary or backup - for Interchassis Session Recovery.

Product

HA, GGSN,

Privilege

Security Administrator, Administrator

Syntax

```
chassis-mode { primary | backup }  
  
[ default ] chassis-mode
```

default

Resets the chassis mode to the default setting of backup.

primary

Configures the system as the primary chassis operating in active state.

backup

Configures the system as the backup chassis operating in standby state.

Usage

Sets the chassis mode (primary or backup) for the system within the framework of Interchassis Session Recovery.

Example

The following example configures the system as the primary chassis operating in active state

```
chassis-mode primary
```

checkpoint session duration

Configures check pointing for Interchassis Session Recovery.

Product

HA, GGSN,

Privilege

Security Administrator, Administrator

Syntax

```
checkpoint session duration duration
```

```
[default ] checkpoint session duration
```

default

Resets the checkpoint session duration to the default setting of 60 seconds.

duration

The amount of time (in seconds) that a call must be active before it is check pointed. **duration** must be an integer from 1 through 65535.

Usage

Sets the amount of time the chassis waits before check pointing an existing call session.

Example

The following example configures sets the checkpoint session duration to 6500 seconds:

```
checkpoint session duration 6500
```

configuration-interval

Defines the configuration validation interval.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
configuration-interval interval
```

```
[default] configuration-interval
```

default

Resets the configuration interval to the default setting of 3600 seconds.

interval

The amount of time (number of seconds) between one configuration validation and the next configuration validation. *interval* must be an integer from 1 through 65535.

Usage

This configures the interval between configuration validations of the primary and backup chassis.

Example

The following example sets the configuration interval to 34 seconds:

```
configuration-interval 34
```

dead-interval

The timeout interval before a peer is determined to be down.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
dead-interval interval
```

```
[default] dead-interval
```

default

Resets the dead interval to the default setting of 30 seconds.

interval

The amount of time (in seconds) for the dead interval. *interval* must be an integer from 1 through 65535.

Usage

This command specifies the amount of time that one chassis waits to receive a communication from a peer before the listening chassis determines that the peer chassis is down.

Example

The following example sets the dead interval to 65 seconds:

```
dead-interval 65
```

delay-interval

Configure the delay time, for starting the dead timer, after configuration files are loaded.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
delay-intervalinterval
```

```
[default] delay-interval
```

default

Sets / Restores default value assigned for specified parameter.

interval

The amount of time (in seconds) for the delay interval. *interval* must be an integer from 1 through 65535.

Usage

This configures interval for starting the dead timer, after configuration files are loaded.

Example

The following example sets the delay interval to 65 seconds after the configuration files are loaded:

```
delay interval 65
```

■ end

end

Exits the service recovery mode and returns to the Exec mode.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the Context Configuration mode.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Return to the context configuration mode.

hello-interval

Defines the lapse time between sending the hello message.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
hello-interval interval
```

```
[default] hello-interval
```

default

Resets the hello interval to the default setting of 10 seconds.

interval

The lapse time (in seconds) between sending the hello message. *interval* must be an integer from 1 through 65535.

Usage

This command configures the hello interval - the amount of time that lapses between the sending of each hello message. Each chassis sends the other chassis a hello message at the expiration of every hello interval.

Example

The following example sets the hello interval to 35 seconds:

```
hello-interval 35
```

monitor authentication probe

Enables the monitoring of the connection between the primary chassis and a specified RADIUS server.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] monitor authentication probe context context_name { IPv4_address | IPv6_address } port port_number
```

no

Turns off the monitoring.

context *context_name*

Identifies the context being used.

IPv4 _address | **IPv6_address**

Defines the IP address of the RADIUS server to be monitored.

port *port_number*

Identifies a specific port for the authentication probe. *port_number* must be the port for the AAA server.

Usage

This command initiates monitoring of the connection between the primary chassis and the specified AAA server through the use of authentication probe packets. If the connection drops, the standby chassis becomes active.

Example

The following example initiates the connection monitoring between the primary chassis and AAA server 1.1.1.1 at port 1025:

```
monitor authentication probe context test1 1.1.1.1 port 1025
```

monitor bgp

Enables monitoring of the connection between the specified BGP peer and the primary chassis.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] monitor BGP context context_name IPv4_address vrf vrf_name
```

no

Disables monitoring.

context context_name

Identifies the context being used.

IPv4 _address | IPv6_address

Defines the IP address of the BGP peer to be monitored.

vrf vrf_name

Defines the VPN Routing/Forwarding instance.

Usage

This command initiates monitoring of the connection between the primary chassis and the specified BGP peer through the use of authentication probe packets. If the connection drops, the standby chassis becomes active.

Example

The following example initiates the connection monitoring between the primary chassis and BGP peer 125.2.1.56:

```
monitor bgp context test 125.2.1.56
```

peer-ip-address

Specifies the IP address for the peer chassis.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
peer-ip-address { IPv4_address | IPv6_address }
```

```
[no] peer-ip-address
```

no

Removes the peer IP address of the backup chassis.

IPv4_address | *IPv6_address*

The IP address of the backup chassis.

Usage

This command is used to identify the peer chassis in the Interchassis Session Recovery configuration. From the primary's perspective, the peer is the backup and from the backup's perspective, the peer is the primary.

Example

The following example specifies 1.1.1.1 as a backup peer system to the primary system:

```
peer-ip-address 1.1.1.1
```

priority

Sets the initial Interchassis Session Recovery priority of each peer chassis.

Important: `priority` takes affect only during simultaneous initializing of all chassis in an Interchassis Session Recovery configuration, and only if a misconfiguration has both chassis in the same mode (both Primary or both Backup).

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
priority priority_value
```

```
[default] priority
```

default

Resets the priority to the default setting of 125.

priority_value

The priority for the HA. *priority_value* must be an integer from 1 through 255.

Usage

This command determines which chassis transitions to the Active state when all chassis have the same mode configuration. **priority** acts as a tie breaker for the state determination only when all chassis initialize simultaneously. The chassis with the higher priority (higher number) becomes Active while the chassis with the lower priority (lower number) becomes Standby.

Once chassis become operational (after initialization), if there is an event requiring a chassis change of state, then each chassis returns to its previous state (Active or Standby) after both chassis recover.

Example

The following example sets the priority value to 5:

```
priority 5
```

route-modifier

Sets the route modifier for the peer chassis.

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
route-modifier threshold threshold_value
```

```
[default] route-modifier
```

default

Resets the route modifier to the default setting of 16.

threshold_value

The value that causes the route-modifier counter to be reset to the initial value. *threshold_value* must be an integer from 2 through 32.

Usage

This command is used to determine when the route modifier should be reset to its initial value to avoid rollover.

Example

The following example sets the route modifier threshold to 10:

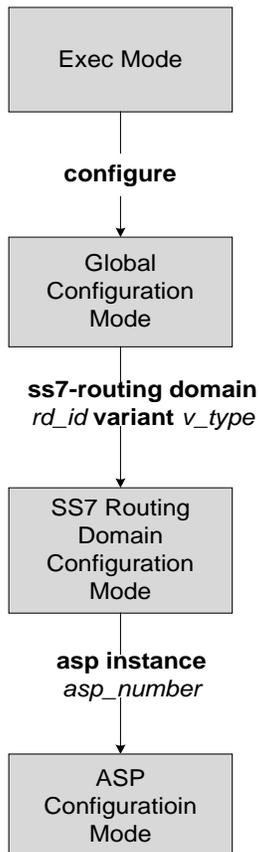

```
route-modifier threshold 10
```

Chapter 207

SGSN ASP Configuration Mode Commands

The ASP (application server process) configuration mode defines the M3UA end-point parameters for a specific SS7 routing domain instance. The ASP instance is generated and accessed via the SS7 routing domain configuration mode commands.

```
[local]hostname(config-ss7-rd-<ss7rd_id>-asp-inst-<asp_inst>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec Mode.

end-point

This command defines or deletes the IP address and/or port number to be associated with the local SCTP end-point for this ASP. At least one address needs to be configured before the end-point can be activated.

When using the **bind** keyword, this command also activates the end-point once the address has been defined. Once bound, it cannot be reconfigured until it is unbound with the **no end-point bind** command.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
end-point { address ip_address context context_id | bind | port port_number }
```

```
no end-point { address ip_address context context_id | bind }
```

address ip_address context context_id:

Specifies the IP address and the context associated with the address for this end-point.

ip_address: must be defined using the standard IPv4 dotted decimal notation or the colon notation of IPv6.

context context_id: a string of 1 to 79 alphanumeric characters to identify the specific context associated with the end-point address.

bind

Activates (binds) the end-point.

Important: Only use **bind** after you have configured other parameters.

port port_number

Identifies the M3UA's SCTP port associated with this end-point.

port_number: must be an integer from 1 to 65535. Default is 2905.

no

Removes the end-point configuration or deactivates the end-point.

Caution: Entering this command will terminate all current subscriber sessions for associated peers.

Usage

Use this command to manage the ASP end-point. Once the ASP end-point is bound the end-point configuration can not be changed until it is unbound.

Example

Activate the end-point with the following command:

■ end-point**end-point bind**

Deactivate or unbind the end-point with the following command:

```
no end-point bind
```

Set the end-point port to default for ASP 1 with the following command:

```
default asp instance 1 end-point port
```

exit

Exits the current mode and returns to the previous mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Returns to the previous mode.

Chapter 208

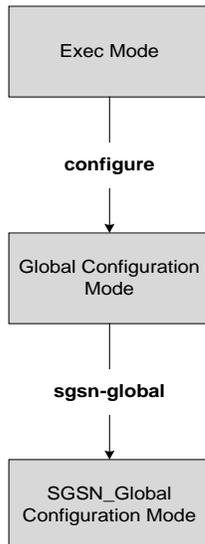

SGSN-Global Configuration Mode Commands

The commands in this mode configure SGSN-specific parameters that will independent of the GPRS or the IuPS services.

In this mode, your prompt will look similar to:

```
[local]hostname(config-sgsn-global)#
```

The SGSN-Global configuration mode is a sub-mode derived from the Global Configuration Mode.

bssgp-timer

Configures the T2 and TH timers for the BVCs (BSSGP virtual connections) of the NSE (network service entities).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
bssgp-timer { t2 T2_time | th TH_time }
```

```
default bssgp-timer { t2 | th }
```

default

Resets the specified timers to default settings.

t2 *T2_time*

Configures the BVC reset guard timer (at the BSSGP layer) in units of 1 second.

T2_time : Enter an integer from 1 to 120. Default is 30 seconds.

th *TH_time*

Configures, at the BSSGP layer, the MS flow control parameter validity timeouts in units of 1 second.

TH_time : Enter an integer from 5 to 6000. Default is 500 seconds.

Usage

Use this command to configure timer timeout values for MS flow control and BVC reset timers that control BVCs for the NSEs.

Example

Set the TH timeout for 20 seconds:

```
bssgp-timer th 20
```

bvc-unblock

This command enables (disabled by default) or disables the SGSN to unblock blocked BVCs based on the receipt of uplink packets from the BSC.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
bvc-unblock { data-or-flow-control | flow-control | ul-data }
[ default | no ] bvc-unblock
```

default

Include **default** with the command to disable the function.

no

Include **no** with the command to disable this function.

data-or-flow-control

Enables the BVC-Unblock function when the SGSN receives either a FLOW-CONTROL-BVC packet or a UL-UNITDATA packet.

flow-control

Enables the BVC-Unblock function when the SGSN receives a FLOW-CONTROL-BVC packet.

ul-data

Enables the BVC-Unblock function when the SGSN receives a UL-UNITDATA packet.

Usage

Configurations defined with this command are common to all NSE defined for the SGSN.

This command is useful if there is a BVC status mismatch across different SGSN managers (such as the Session Manager and the Link Manager) when the BSC sends BVC-Block (SGSN should move to BLOCKED) followed by a BVC-Reset (SGSN should move to UNBLOCKED). Such mismatches can easily occur, particularly on Gb-IP network connection, when one link receives the BVC-Block and a different link receives the BVC-Reset with little delay between the two.

If BVC-Unblock function is enabled, the SGSN ensures that BVCs which are in the BLOCKED state move to the UNBLOCKED state upon receipt of the configured packet type(s).

Example

Instruct the SGSN to perform BVC-Unblock when a mismatch occurs and the SGSN receives a FLOW-CONTROL-BVC packet:

■ bvc-unblock

```
bvc-unblock flow-control
```

end

Exits the current mode and returns to the Exec Mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec Mode.

■ exit

exit

Exits the current mode and returns to the previous configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode to the Global Configuration Mode.

imsi-range

Configure an IMSI range or a PLMN ID to associate with an Operator Policy.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
imsi-range mcc mcc_num mnc mnc_num { msin first start_number last stop_number [ operator-policy policy_name ] | plmnid plmn_id operator-policy policy_name } +
no imsi-range mcc mcc_num mnc mnc_num { msin first start_number last stop_number | plmnid plmn_id }
```

no

Using **no** in the command deletes the definition from the SGSN-Global configuration.

mcc *mcc_num*

mcc defines the mobile country code (MCC) of an IMSI.

mcc_num: Enter a 3-digit number from 100 to 999 - 000 to 099 are reserved.

mnc *mnc_num*

mnc defines the mobile network code (MNC) of an IMSI.

mnc_num: Enter a 2 or 3-digit number from 00 to 999.

msin

MSIN (mobile subscriber international number) portion of the IMSI.

first start_num: Defines first MSIN prefix number in a range

last stop_num: Defines the last or final MSIN prefix number in a range.

operator-policy *policy_name*

Identify the operator policy that the IMSI range definition and/or the PLMN-ID is to be associated.

policy_name: Enter a string of 1 to 64 alphanumeric characters.

If a PLMN-ID is to be included in the definition, enter the **plmnid** before entering the operator policy name.

plmnid *plmn_id*

The 5-6 digit PLMN-ID consists of the MCC (mobile country code) plus the MNC (mobile network code) to identify the public land mobile network (PLMN) for a specific operator. This keyword associates a specific PLMN with this specific SGSN operator policy.

plmn_id: Enter 5 to 6 digits.

+

This symbol indicates that command can be repeated to create repeated definitions.

Usage

An IMSI = maximum of 15 digits. An IMSI consists of the MCC (3 digits) + the MNC (2 or 3 digits) + the MSIN (the remaining 10 or 9 digits depending on the length of the MNC).

MCC and MNC are the minimum amount of information required to identify a unique operator policy with IMSI filtering. The MCC and MNC combine uniquely to identify the country and the network operator, for example: Cingular Wireless in the United States = **mcc 311mnc 180**

To improve the granularity of call handling, an operator policy with additional IMSI filtering parameters can be defined, to include filtering based on the MSIN, by defining a MSIN range - first (or start-of-range) MSIN and last (or end-of-range) MSIN. The range numbers do not include the maximum allowed for the MSIN but should include a sufficient number to enable the operator policy to filter effectively.

For the most efficient IMSI filter, the operator policy should include all of the above parameters and the PLMN ID which defines the current location of the MS -- this parameter is particularly useful for highlighting which calls are roaming.

And if none of the operator policies contain useful filtering information, then the default operator policy will be applied as the information in this command is never defined for the default operator policy.

The following table will illustrate how these filtering parameters determine which operator policy will govern a call:

Operator Policy ID	MCC	MNC	MSINfirst	MSINlast	PLMN ID
OpPol-1	123	45	67890	67898	
OpPol-2	123	45			
OpPol-3	123	45	67890	67898	23232
OpPol-4	123	45			23232
OpPol-5	123	45	6789012	6789019	
OpPol-6	123	45	6789012	6789019	23232
default					

The filtering selects which operator policy will be used to determine how a call is handled - the operator policy that best matches the IMSI. So, a call with IMSI 123456789012345 PLMNID 23232 is best matched with OpPol-6.

In most cases, the operator policy with the most information defined will be used as a combination of PLMNID and IMSI provides the best match. But OpPol-6 won't always be the best match. Using the table above:

OpPol-1 is the best match for IMSI 12345678901111

OpPol-2 is the best match for IMSI 123456789099999

OpPol-5 is the best match for IMSI 123456789012345 if the PLMNID is 12344

Example

The following associates operator policy *oppol1* with country code 310, mobile network code of 33, and IMSI range 1231234 - 1231244:

```
imsi-range mcc 310 mnc 33 msin first 1231234 last 1231244 operator-policy oppol1
```

max-pending-attaches

Configure the maximum pending attach queue length.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

max-pending-attaches *limit*

default max-pending-attaches

default

Resets the SGSN's Attach queue to a maximum pending value of 10,000.

limit

Set the a maximum limit to the pending Attach/RAU messages queue in the LinkMgr. When the limit is reached a message is sent to the IMSIMgr.

limit : Enter an integer from 5000 - 50000. Default is 10000.

Usage

With this command, configure the maximum limit to the pending ATTACH/RAU messages queue in the LinkMgr. When the limit is reached, the LinkMgr sends the Query/Forward messages to the IMSIMgr. As the IMSIMgr gets busier and does not responded to Query/Forward requests, the response to the requests will get slower and slower and the queue size continues inflating if the incoming message rate is high. To avoid this situation, set the **max-pending-attaches** for the pending queue for Attach and RAU messages. All other messages from the HLR will be added to the queue as they cannot be dropped. High and low watermarks are set to the queue at 80% of **max-pending-attaches** " and 60% of **max-pending-attaches** respectively.

Once a high watermark is reached, the new Attach and RAU requests are dropped and relevant statistics are incremented. Once a low watermark is hit, the new Attach/RAU requests are accepted and added to the pending queue. The entries are added to the pending queue only when the window-size between IMSIMgr and LinkMgr becomes zero. This is a very rare occurrence and will not affect the current behavior in normal circumstances.

Example

Set the queue length to a maximum of 15000 requests:

```
max-pending-attaches 15000
```

tlli-cb-audit

This command enable (default is disabled) or disables a periodic (hourly) audit of TLLI-CBs in the BSSGP layer.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
tlli-cb-audit
```

```
[ default | no ] tlli-cb-audit
```

default

Include **default** with the command to disable the audit function.

no

Include **no** with the command to disable the audit function.

Usage

This command is used to clean-up hanging or unassociated TLLI in the BSSGP layer. This configuration defined with this command will be common to all NSE configured for this SGSN. Independent of this command configuration, the SGSN triggers and audit when the number of TLLI-CBs reaches 35,000.

Example

Use the following command to enable the hourly audit for unassociated TLLI-CBs:

```
tlli-cb-audit
```

umts-aka-r99

This command enables the operator to authenticate mobile equipment (MEs) with R99+ USIMs and capable of UMTS AKA.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
umts-aka-r99
```

```
no umts-aka-r99
```

```
no
```

Including **no** with the command disables the authentication.

Usage

This command enables operators to authenticate MEs that are attempting to connect to a 2.5G network with R99+ USIMs if the MEs are UMTS AKA capable.

Example

Use the following command to disable UMTS AKA authentication for MEs with R99+ USIMs:

```
no umts-aka-r99
```

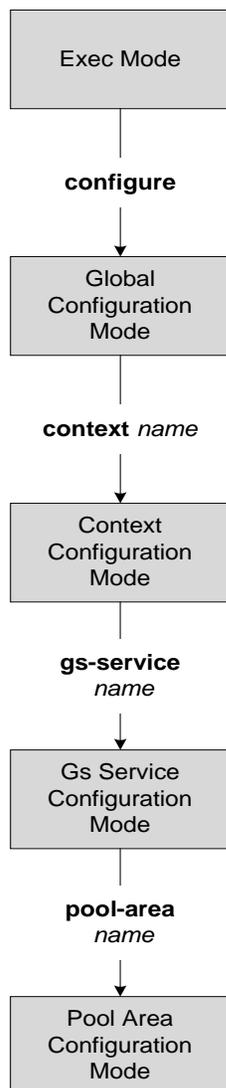

Chapter 209

SGSN Pool Area Configuration Mode Commands

The Pool Area configuration mode configures the parameters used to setup the VLRs to use with a pool area in a Gs service.

With this mode, the command prompt will be similar to:

```
[ctx_name]hostname(config-gs-pool-area)#
```

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

■ exit

exit

Exits the current configuration mode and returns to the previous configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous configuration mode.

hash-value

This command configures the load distribution for the VLRs that service this pool area.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
hash-value { hash_value | range start_value to end_value | non-configured-values } use-vlr vlr_name
```

```
no hash-value { hash_value | range start_value to end_value | non-configured-values }
```

no

Removes the configured Gs procedures from this Gs service.

hash_value

Specifies the specific hash value for VLR(s).

hash_value must be an integer value from 0 through 999.

range *start_value* **to** *end_value*

Specifies the range of hash values for a VLR.

start_value specifies the start value for range of hash and is an integer value from 0 through 999.

start_value must be lower than *end_value*.

end_value specifies the end value for range of hash and is an integer value from 0 through 999.

end_value must be higher than *start_value*.

non-configured-values

This keyword assign all non-configured hash values to use the named VLR.

use-vlr *vlr_name*

Specifies the name of the VLR to be associated with this pool area.

vlr_name is the name of VLR and must be an alpha and/or numeric string of 1 to 63 characters.

Usage

Use this command to command configures the load distribution for the VLRs that service this pool area as defined in TS 23.236.

The algorithm for selection of VLR from a pool area is based on the hash value computed on the IMSI digits. The SGSN derives a hash value (V) using procedure as defined in TS 23.236. Every hash value from the range 0 to 999 corresponds to a single MSC/VLR node. Typically many hash values may point to the same MSC/VLR node.

This command can be entered multiple times for different hash value.

■ hash-value

Example

Following command configure the all non configured hash values to use VLR named *starvlr1* in this pool area:

```
hash-value non-configured-values use-vlr starvlr1
```

lac

This command defines a set of location area code (LAC) values for a pool area.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
lac lac_id +
```

```
no lac lac_id
```

no

Removes the configured LAC value from this pool area configuration.

```
lac lac_id
```

Specifies the subscribers' location area code (LAC) to be associated with this pool area and a specific VLR. This LAC is obtained from the radio area indicator (RAI).

lac_id: Must be an integer from 1 through 65535.

+

More than one *lac_id*, separated by a space, can be entered within a single command.

Usage

Use this command to specify a set of LACs to use for a pool area.

This command can be entered multiple times, subject to a limit of 32 LAC definitions (total for **non-pool-area** and **pool-area** configuration) per Gs service.

Important: LAC values across multiple pool areas and non-pool-areas must be unique within the Gs service.

Example

The following command configures LACs *101*, *301*, and *222* for the pool area.

```
lac 101 301 222
```

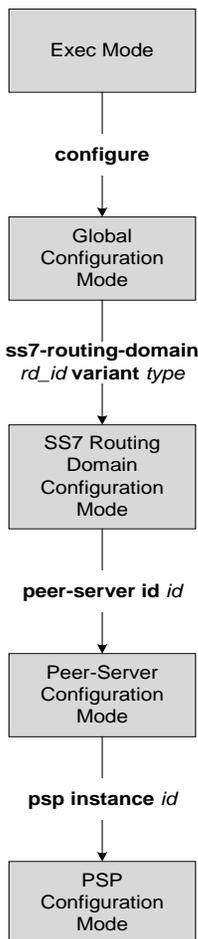

Chapter 210

SGSN PSP Configuration Mode Commands

The Peer-Server Process (PSP) configuration mode provides the commands to create, configure, bind, and manage a specific PSP instance included in an SS7 routing domain configuration.

In this mode, where information in italics is customer-defined, the command prompt should appear similar to:

```
[local]hostname(config-ss7-rd-1-ps-1-psp-1)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

■ lac

associate

Defines an association between the PSP instance and an application server process (ASP) instance.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
associate asp instance asp_num
```

```
no associate
```

no

Removes the association between the PSP and the ASP from the routing domain configuration.

Important: Using this command will probably result in the termination of all current subscriber sessions active through the peer-server.

asp_num

Identifies a specific ASP configuration. Up to four ASP instances can be configured for a single SS7 routing domain.

asp_num must be an integer from 1 through 4.

Usage

Use this command to create an association between a specific peer-server process (PSP) and a specific application server process (ASP) instance.

Before using the **associate** command, the values for the **psp-mode** and **end-point** commands must be configured.

Before using the **associate** command, the M3UA end-point of the ASP must be configured. Use the commands defined in the *ASP Configuration Mode* chapter of the *Command Line Interface Reference*.

Example

Associate this PSP instance with an ASP configuration instance:

```
associate asp instance 2
```

■ end

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

end-point

This command defines or deletes the IP address to be associated with the local SCTP end-point for the application server process (ASP).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
end-point { address ip_address | port port_number }
```

```
no end-point [ address ip_address ]
```

port *port_number*

Configures the M3UA's SCTP port number for the end-point.

port_number: Must be an integer from 1 to 65535.

Default: 2905.

no

Removes the ASP end-point association configuration from the PSP configuration.

Important: This command can not be used as long as the PSP and the ASP are associated.

Usage

Use this command to manage the ASP end-point. At least one address needs to be configured for the ASP before the end-point can be associated with the PSP.

Example

Set the ASP end-point to IP address 192.168.1.1 with the following command:

```
end-point address 192.168.1.1
```

exchange-mode

Configures the exchange-mode for the PSP communication.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
exchange-mode [ double-ended | single-ended ]
```

Usage

Use this command to toggle the exchange modes for the PSP to match the exchange mode supported by the ASP. The exchange mode specifies what type of ASP messages exchange is used in an IPSP communication. The **exchange-mode** must be configured for 'single-ended' if the **psp-mode** has been configured for 'client'.

Example

Change the exchange mode from the standard double-ended to single-ended:

```
exchange-mode single-ended
```

exit

Exits the current configuration mode and moves to the previous configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Peer-Service configuration mode.

psp-mode

Configures either client-mode or server-mode as the PSP's operational mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
psp-mode { client | server }
```

client

The PSP operates as a client.

server

The PSP operates as a server.

Usage

Instruct the peer-server process to operate in either client or server mode.

Example

Configure the PSP to operate in server mode:

```
psp-mode server
```

routing-context

Configures the behavior of the routing context in M3UA messages.

Important: This keyword function is only available in releases 8.1 and higher.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
routing-context { discard-inbound | process-inbound { insert-outbound |
suppress-outbound } }
```

default routing-context

default

Include this keyword with the command, to reset the configuration to the system default for routing-context which is a combination of process-inbound and insert-outbound.

discard-inbound

Sets the routing context received in M3UA messages to be discarded.

process-inbound

Sets the routing context received in M3UA messages to be processed.

insert-outbound

Sets the routing context so that it is added in the M3UA messages.

suppress-outbound

Sets the routing context so that it is suppressed in the M3UA messages.

Usage

In PSP (singled-ended) configuration mode, the settings for both the local routing context (the SGSN's routing context) and the peer routing context (the RNC's routing context) should be the same. If the routing contexts created at the SGSN and on the peer are different then this can cause the M3UA link to fail.

Routing context is an optional parameter when an M3UA association has only one associated peer-server.

Example

If the peer does not support routing context, then disable the routing context feature:

```
routing-context discard-inbound suppress-outbound
```

■ routing-context

sctp-alpha

This stream control transmission protocol (SCTP) retransmission time out (RTO) parameter defines the RTO-Alpha value.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-alpha value
```

```
default sctp-alpha
```

value

Defines a percentage (%) that represents the RTO portion of the round-trip time (RTT) calculation. This percentage value must be an integer between 0 and 65535.

default

Resets the **sctp-alpha** to the default value of 5%.

Usage

sctp-alpha is used in conjunction with other commands, such as the **sctp-beta** command, to determine the round-trip time (RTT) calculations. The Alpha parameter is used to manage load balancing within the SS7 environment for multi-homed peers.

Example

Set the SCTP RTO-Alpha value to 256% of the RTT calculation:

```
sctp-alpha 256
```

sctp-beta

This stream control transmission protocol (SCTP) retransmission time out (RTO) parameter defines the RTO-Beta value.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

sctp-beta *value*

default sctp-beta

value

Defines a percentage (%) that represents the RTO portion of the round-trip time (RTT) calculation. This percentage value must be an integer between 0 and 65535.

default

Resets the **sctp-beta** to the default value of 10%.

Usage

Use this command in conjunction with other commands, such as the **sctp-alpha** command, to determine the round-trip time (RTT) calculations. The Beta parameter is used to manage load balancing within the SS7 environment for multi-homed peers.

Example

Set the SCTP RTO-Alpha value to 512% of the RTT calculation:

```
sctp-beta 512
```

sctp-checksum-type

This command selects the type of checksum algorithm to be used.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-checksum-type { adler32 | crc32 }
```

```
default sctp-checksum-type
```

adler32

Selects the Adler-32 type of algorithm as a faster checksum function.

crc32

Selects the CRC-32, a slower but more reliable 32-bit cyclic redundancy check.

default

Resets the **sctp-checksum-type** to the default of CRC-32.

Usage

Use this command to set which type of checksum algorithm the SGSN is to use to validate SCTP packets.

Example

```
sctp-checksum-type crc32
```

sctp-cookie-life

This command sets the SCTP valid cookie life.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-cookie-life value
```

```
default sctp-cookie-life
```

value

Sets the valid cookie life value in increments of 100 milliseconds. The range is 50 to 1200 .

default

Resets the **sctp-cookie-life** value to the default, 600 (= .6 seconds).

Usage

Use this command to set the SCTP cookie life.

Example

Set the SCTP cookie life to 1 second (1000 milliseconds):

```
sctp-cookie-life 1000
```

sctp-max-assoc-retx

This command sets the maximum number of datagram retransmissions to be associated with this peer server configuration.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-max-assoc-retx value
```

```
default sctp-max-assoc-retx
```

value

Defines the maximum number of datagram retransmissions for an association. The value must be an integer between 0 and 255.

default

Resets the default for **sctp-max-assoc-retx** to 10.

Usage

Use this command to configure the maximum number of datagram retransmissions for an association. The endpoint will be declared unreachable after **sctp-max-assoc-retx** number of consecutive retransmissions to an endpoint on any transport address.

Example

```
sctp-max-assoc-retx 3
```

sctp-max-init-retx

This command sets the maximum number of retries to send the INIT datagram.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-max-init-retx value
```

```
default sctp-max-init-retx
```

value

Sets the maximum number of retries. This value must be an integer between 0 and 255.

default

Resets the default for **sctp-max-init-retx** to 5.

Usage

Use this command to set the maximum number of retries the SCTP layer should make to send the INIT datagram to the peer to open an association.

Example

```
sctp-max-init-retx 3
```

sctp-max-mtu size

This command sets the number of bytes that comprise the maximum MTU size.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-max-mtu-size value
```

```
default sctp-max-mtu-size
```

value

Sets the maximum number of bytes for the Sctp MTU size. This value must be an integer between 508 and 65535.

default

Resets the default for **sctp-max-mtu-size** to 1500 bytes.

Usage

Use this command to configure the size of the MTU.

Example

Set the maximum size of the MTU to 3000 bytes:

```
sctp-max-mtu-size 3000
```

sctp-max-out-strms

This command sets the maximum number of outgoing streams through the PSP going towards the peer server.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-max-out-strms max#_out_streams
```

```
default sctp-max-out-strms
```

default

Resets the SGSN's **sctp-max-out-strms** value to the default of 16.

max#_out_streams

The value must be an integer between 1 and 65535. The value should match the peer node's (STP/SG/RNC/HLR) number of in-bound streams.

Usage

Use this command to balance the stream throughput from the PSP to the peer server. The value for this command is used to validate the incoming packets in the SCTP layer.

Example

```
sctp-max-out-strms 3500
```

sctp-max-path-retx

This command sets the maximum number of datagram retransmissions for this path.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-max-path-retx value
```

```
default sctp-max-path-retx
```

value

Sets the maximum number of datagram retransmission to a destination transport address. This value must be an integer from 0 to 255.

default

Resets the **sctp-max-path-retx** default to 5.

Usage

Use this command to set the maximum number of datagram retransmissions to a destination transport address. The destination transport address will be declared unreachable after the SGSN exhausts the **sctp-max-path-retx** number of consecutive retransmissions to a destination transport address.

Depending upon network conditions, lower values typically means faster detection of Sctp-Path failure.

Example

```
sctp-max-path-retx 10
```

sctp-rto-initial

This command sets the initial retransmission timeout for the SCTP.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-rto-initial value
```

```
default sctp-rto-initial
```

value

Sets the timeout in increments of 100 milliseconds. The value must be an integer between 1 and 1200.

default

Resets the system to the **sctp-rto-initial** default of 30 (3 seconds).

Usage

Use this command to define the initial retransmission timer.

The value set for **sctp-rto-initial** should be greater than or equal to the minimum value set with **sctp-rto-min** (**sctp-rto-initial** => **sctp-rto-min**).

The value set for **sctp-rto-initial** should be less than or equal to the maximum value set with **sctp-rto-max** (**sctp-rto-initial** <= **sctp-rto-max**).

Example

```
sctp-rto-initial 240
```

sctp-rto-max

This command sets the maximum retransmission timeout value for the SCTP.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-rto-max value
```

```
default sctp-rto-max
```

default

Resets the system to the **sctp-rto-max** default of 600 (60 seconds).

value

Set the maximum retransmission timeout value in increments of 100 milliseconds (0.1 seconds) and the value must be an integer between 5 and 1200.

Usage

Use this command to configure the maximum time for retransmissions.

The value set for **sctp-rto-max** should be greater than or equal to the value set for **sctp-rto-initial** (**sctp-rto-max** => **sctp-rto-initial**).

Example

The following sets the timeout for 45 seconds:

```
sctp-rto-max 450
```

sctp-rto-min

This command sets the minimum retransmission timeout (RTO) value for the Sctp.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-rto-min value
```

```
default sctp-rto-min
```

default

Resets the **sctp-rto-min** to the default of 10 (1 second).

value

Sets the minimum retransmission timeout in increments of 100 milliseconds. The value must be an integer from 1 to 50.

Usage

Use this command to set the minimum time for retransmission before timeout.

The value set for **sctp-rto-min** should be less than or equal to the value set for **sctp-rto-initial** (**sctp-rto-min** <= **sctp-rto-initial**)

Example

The following sets the timeout for 2 seconds:

```
sctp-rto-min 20
```

sctp-sack-frequency

This command sets the frequency of transmission of SCTP selective acknowledgements (SACK).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-sack-frequency value
```

```
default sack-frequency
```

value

Sets the maximum number of datagrams to be received prior to sending a SACK to the peer. The value must be an integer between 1 and 5.

default

Resets the **sctp-sack-frequency** default value of 2.

Usage

Use this command to set the maximum number of datagrams to be received before a SACK must be sent to the peer. The **sctp-sack-frequency** is used in conjunction with the **sctp-sack-period** to control the generation of SACK, depending on which one occurs first.

Example

```
sctp-sack-frequency 3
```

sctp-sack-period

This command sets the delay before sending an SCTP selective acknowledgement (SACK).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sctp-sack-period value
```

```
default sack-period
```

value

Sets the maximum time, in increments of 100 milliseconds, before the system must send a SACK to the peer. The value must be an integer from 0 to 5.

default

Resets the system to the **sctp-sack-period** default value, 2 (=200 milliseconds).

Usage

Use this command to set the time the SCTP waits to send a SACK.

Example

```
sctp-sack-period 3
```

sctp-suppress-alarm

This command enables/disables the suppression of alarms for SCTP path failure between two peer endpoints.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] sctp-suppress-alarm path-failure self-end-point-address  
orig_ipv4_address peer-end-point-address peer_ipv4_address
```

no

Disables the pre-configured alarm suppression for SCTP path failure.

path-failure

This keyword specifies that the alarm suppression is for SCTP path failure between two peer nodes.

self-end-point-address *orig_ipv4_address*

This keyword specifies the IP address of the originating endpoint.

orig_ipv4_address is the IP address of originating endpoint in IPv4 dotted decimal notation.

peer-end-point-address *peer_ipv4_address*

This keyword specifies the IP address of the peer endpoint.

peer_ipv4_address is the IP address of peer endpoint in IPv4 dotted decimal notation.

Usage

Use this command to configure the path failure alarm suppression. This command ignores the alarms generated on SCTP path failure.

Example

The following command suppresses the path failure alarms occurred in SCTP path between originating peer address 1.2.3.4 and peer endpoint 6.7.8.9:

```
sctp-suppress-alarm path-failure self-end-point-address 1.2.3.4 peer-end-  
point-address 6.7.8.9
```

timeout

This command sets the times for various timeout timers.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
timeout {m3ua-periodic-dest-audit dest_timeout | sctp-bundle bundle_time | sctp-heart-beat hrt_bt_timeout}
```

```
default timeout sctp-heart-beat
```

default

Resets the system to the default value for the SCTP heartbeat interval.

m3ua-periodic-dest-audit *dest_timeout*

Sets the period (in increments of seconds) between the DAUD messages while auditing a destination state.
dest_timeout: Must be an integer from 1 to 65535. Default is 2.

sctp-bundle *bundle_time*

Enables SCTP bundling and sets the SCTP bundle timeout value in increments of 100 milliseconds. SCTP bundling provides better bandwidth utilization and less traffic, however, there is a 100 millisecond packet transmission delay.

Important: Peer end should also be configured to support SCTP bundling.

Default: SCTP bundling is disabled.

bundle_time : Enter an integer from 1 to 65535.

sctp-heart-beat *hrt_bt_timeout*

Sets the number of seconds in the SCTP heart-beat timer

hrt_bt_timeout: This value is an integer between 1 and 300. Default is 30.

Usage

Use this command to configure timers. Repeat the command with each of the keywords to set values for each.

Example

```
timeout m3ua-periodic-dest-audit 120
```

Chapter 211

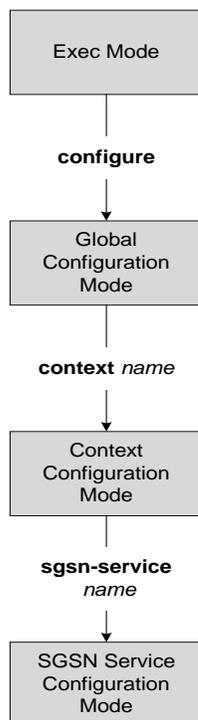

SGSN Service Configuration Mode Commands

The SGSN Service configuration mode is used within the global configuration mode to specify the 3G operations of the SGSN and the available SGSN services for a specific context.

SGSN Service works with MAP Service, SGTP Service, GTPP Group, and IuPS Service. All five of these services must be configured to enable a 3G SGSN to communicate with other elements within a UMTS network.

In this mode, the command prompt should appear like:

```
[<ctx_name>]hostname(config-sgsn-service)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

accounting

This command defines the accounting context name and enables/disables specific types of CDR generation for the accounting in the SGSN service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
accounting ( cdr-types { mcdcr | scdr | sms { mo-cdr | mt-cdr } } + | context
cntx_name }
```

```
default accounting cdr-types
```

```
no accounting ( cdr-types | context }
```

default

Returns the system to default settings for the selected type of CDR.

no

Removes the pre-configured type of CDR generation for accounting from the SGSN service.

```
cdr-types { mcdcr | scdr | sms { mo-cdr | mt-cdr } +
```

Default: enabled

Defines the types of CDRs to be generated within the specified SGSN service for accounting:

- **mcdcr** Enables generation of M-CDRs.
- **scdr** : Enables generation of S-CDRs.
- **sms** : Enables generation of SMS-type CDRs based on one of the following:
 - **mo-cdr** : SMS CDRs originate from the mobile.
 - **mt-cdr** : SMS CDRs terminate at the mobile.

+

Specifies that the specified keywords within the group can be entered multiple times with a single command.

```
context cntx_name
```

Specifies an accounting context to be associated with the SGSN service.

cntx_name: Define a string of 1 to 79 alphanumeric characters.

Usage

Use this command to define the type of CDRs to generate for SGSN service. By default all type of CDRs are generated. Note that change of this configuration will be applied to new call and/or to new PDP contexts only.

By default, generation of the S-CDR, M-CDR, SMS-MT-CDR, and SMS MO-CDR types is enabled.

Example

The following command configures the system to generate CDRs of M-CDR type for accounting in the current SGSN service:

```
accounting cdr-types mcdr
```

admin-disconnect-behavior

This command defines some of the actions the SGSN will take during an Admin-Disconnect procedure.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
admin-disconnect-behavior { clear-subscription | detach-type { reattach-not-
required | reattach-required } }
```

```
[ default | no ] admin-disconnect-behavior { clear-subscription | detach-type }
```

clear-subscription

Including this keyword in the configuration instructs the SGSN to clear subscriber contexts and the subscription data database whenever the **clear subscribers all** command is issued (from the Exec mode) for attached subscribers. As well, the SGSN will issue an appropriate Map-Purge-MS-Req to the HLR if needed.

Default: disabled

detach-type

Including this keyword defines which type of detach instruction to include in the Detach-Request message during an Admin-Disconnect procedure. One of the following options must be included when this command is entered:

- **reattach-not-required**
- **reattach-required**

Default: reattach-required

default | no

Including either **default** or **no** keyword in the command, instructs the SGSN to use the default value for the specified parameter.

Usage

Include the **clear-subscription** keyword with this command configuration to ensure that more than attached MM-context and active PDP-contexts are cleared when the **clear subscribers all** command is issued for attached subscribers.

To clear subscription data for detached subscribers, refer to the **sgsn clear-detached-subscriptions** command described in the *Exec* mode chapter.

Including the **detach-type** keyword with this command instructs the SGSN to include either a 'reattach-required' or a 'reattach-no-required' instruction in the Detach-Request message.

Example

Configure the SGSN to clear data such as PTMSI allocated, auth-vectors received, and NGAF flag values stored in the subscriber database for attached subscribers:

```
admin-disconnect-behavior clear-subscription
```

cc profile

Configures the charging characteristic (CC) profile with the triggers for generating various types of CDR as defined with the **accounting** command.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
cc profile profile_bits [ buckets number | interval time | tariff time1 mins
hours [ time2 mins hours ] [ time3 mins hours ] [ time4 mins hours ] | volume {
downlink down_vol uplink up_vol | total total_vol } ] +

[ no | default ] cc profile profile_bits [ buckets | interval | tariff | volume
]
```

no

Removes a previously configured CC profile.

default

Returns the specified CC profile to the original default system settings.

profile_bits

Defines the value of the profile bits for the SGSN service.

index can be configured to any integer value from 0 to 15. Some of the values have been predefined according to 3GPP standard:

- 1 for hot billing
- 2 for flat billing
- 4 for prepaid billing
- 8 for normal billing

buckets *number*

Specifies the number of statistics container changes in the CDR due to QoS changes or tariff times that can occur before an accounting record (CDR) is closed

Default: 4

number : Must be integer from 1 to 4.

interval *time*

Specifies the normal time duration (in seconds) that must elapse before closing an accounting record (CDR) provided that any or all of the following conditions occur:

time : Enter any integer from 60 to 40000000.

```
tariff time1 mins hours [ time2 mins hours time3 mins hours time4 mins
hours ]
```

Specifies the time-of-day (based on a 24-hour clock) to close the current statistics container in the CDR, but not necessarily the CDR itself. One tariff time must be defined and up to four tariff times can be specified.

Important: The system assumes that the billing system uses the day/date to determine if the statistics container represents an actual tariff period.

- *mins*: The minutes of the hour. Enter an integer from 0 to 59.
- *hours*: The hour of the day. Enter an integer from 0 to 23.

```
volume { downlink down_vol uplink up_vol | total total_vol }
```

Specifies the downlink, uplink, and total volumes octet counts that must be met for the closure of the CDR.

down_vol : Enter any integer from 100000 to 1345294336.

up_vol : Enter any integer from 100000 to 400000000.

total_vol : Enter any integer from 100000 to 400000000.

Usage

Charging characteristics consist of a profile index and behavior settings. This command configures the profile index for the SGSN's charging characteristics. The SGSN supports up to 16 profile indexes.

Example

The following command configures a profile index of 10 with tariff times of 7:00 AM and 7:30 PM:

```
cc profile 10 tariff time1 0 7 time2 30 19 time3 0 7 time4 30 19
```

check-imei-timeout-action

This command configures the action to be taken if a Check-IMEI fails due to a timeout. This command is available in releases 8.1 and higher.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
check-imei-timeout-action [ continue | reject ]
```

```
default check-imei-timeout-action
```

default

Rejects the Attach or ISRAU procedure if a Check-IMEI timeout occurs.

continue

Instructs the SGSN to continue the Attach or ISRAU procedure if a Check-IMEI timeout occurs because the EIR is not reachable. This functionality matches standard call flow.

reject

Instructs the SGSN to reject the Attach or ISRAU procedure if a Check-IMEI timeout occurs.

Usage

Use this command only if the Gf interface (EIR) is available in the network. This command controls the SGSN reaction if the Check-IMEI procedure fails due to a timeout.

The **continue** option allows the SGSN to go forward with the MS Attach or RAU, if the first Check-IMEI fails to reach the EIR due to a timeout. Any subsequent activity (such as a RAU or Service Request) would force another Check-IMEI towards the EIR. If this subsequent MAP Check-IMEI should fail, then the same policy of continuing the procedure would apply.

Example

```
check-imei-timeout-action continue
```

core-network

This command specifies the numeric ID for a core network to identify which CN is to be used by the SGSN service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
core-network id cn_id
```

```
no core-network id
```

no

Removes the currently configured core network ID from the current SGSN configuration.

id *cn_id*

This number identifies the core network to connect the SGSN service.

cn_id : Must be an integer from 0 through 65535.

Usage

Use this command to set a global ID to identify this SGSN in the core network.

Example

The following command sets the core network ID for the current SGSN service to 127:

```
core-network id 127
```

disable/enable super-charger

This command has been deprecated and replaced by the **super-charger** command. For the commands to configure the SuperCharger feature, refer to the *SGSN Operator Policy Configuration Mode* chapter.

dns israu-mcc-mnc-encoding

Configures either decimal or hexadecimal format for the MCC and MNC values in the DNS query which is sent during the ISRAU.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
dns israu-mcc-mnc-encoding { decimal | hexadecimal }
```

```
default dns israu-mcc-mnc-encoding
```

default

Resets the SGSN to send the MCC and MNC values in decimal format for DNS queries.

decimal

Default.

Instructs the SGSN to send the MCC and MNC in decimal format in the DNS query.

hexadecimal

Instructs the SGSN to send the MCC and MNC in hexadecimal format in the DNS query.

Usage

Use this command to determine the type of encoding for the MCC and MNC to be included in the DNS query sent during the inter-SGSN RAU (ISRAU). The choice must match the format of the DNS server. For example:

In decimal, the MNC/MCC in a DNS query would appear like:

```
rac0017.lac42e3.mnc310.mcc722.gprs
```

In hexadecimal, the MNC/MCC in a DNS query would appear like:

```
rac0017.lac42e3.mnc0136.mcc02d2.gprs
```

Example

Use hexadecimal values for the MCC/MNC in the DNS query.

```
dns israu-mcc-mnc-encoding hexadecimal
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the context configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

gmm

This command defines the GPRS mobility management parameters for the SGSN service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gmm { T3302-timeout t3302_dur | T3312-timeout t3312_dur | T3313-timeout initial
t3313_init [ decrease t3313_decrement | increase t3313_increment ] | T3322-
timeout t3322_dur | T3350-timeout t3350_dur | T3360-timeout t3360_dur | T3370-
timeout t3370_dur | implicit-detach-timeout impli_detach_dur | max-auth-
retransmission auth_retrans | max-identity-retransmission id_retrans | max-page-
retransmission page_retrans | max-ptmsi-reloc-retransmission ptmsi_reloc_retrans
| mobile-reachable-timeout ms_reach_dur | perform-identity-on-auth-failure |
purge-timeout purge_dur | trau-timeout trau_dur }
```

```
default gmm { T3302-timeout | T3312-timeout | T3313-timeout | T3322-timeout |
T3350-timeout | T3360-timeout | T3370-timeout | implicit-detach-timeout | max-
auth-retransmission | max-identity-retransmission | max-page-retransmission |
max-ptmsi-reloc-retransmission | mobile-reachable-timeout | perform-identity-on-
auth-failure | purge-timeout | trau-timeout }
```

```
no gmm { implicit-detach-timeout | max-auth-retransmission | max-identity-
retransmission | perform-identity-on-auth-failure }
```

default

Sets the default value for the specified parameter.

T3302-timeout *t3302_dur*

Default: 10

Specifies the retransmission timer value to guard the GPRS attach or RAU procedure on MS side.

t3302_dur is the waiting duration in minutes before retransmitting the specific message and must be an integer from 1 through 186.

T3312-timeout *t3312_dur*

Default: 54

Specifies the retransmission timer value to guard the RAU procedure initiation on network side.

t3312_dur is the waiting duration in minutes before retransmitting the specific message and must be an integer from 1 through 186.

T3313-timeout initial *t3313_init* [decrease *t3313_decrement* | increase *t3313_increment*]

Default: 5

Specifies the retransmission timer value to guard the for paging request procedure initiation on network side.

initial *t3313_init* - Specifies the initial waiting duration in seconds before retransmitting the specific message. *t3313_init* must be an integer from 1 through 60.

decrease *t3313_decrement* - Specifies the decrement of the initial timer value in seconds. *t3313_decrement* must be an integer from 1 through 5.

increase *t3313_increment* - Specifies the increment of the initial timer value in seconds. *t3313_decrement* must be an integer from 1 through 5.

T3322-timeout *t3322_dur*

Default: 6

Specifies the retransmission timer value to guard the GPRS detach request procedure on network side. *t3322_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 20.

T3350-timeout *t3350_dur*

Default: 6

Specifies the retransmission timer value to guard the GPRS attach accept/RAU accept/realloc request procedure sent with P-TMSI and/or TMSI on network side. *t3350_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 20.

T3360-timeout *t3360_dur*

Default: 6

Specifies the retransmission timer value to guard the authentication and cipher request procedure on network side. *t3360_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 20.

T3370-timeout *t3370_dur*

Default: 6

Specifies the retransmission timer value to guard the identity request procedure on network side. *t3370_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 20.

implicit-detach-timeout *impli_detach_dur*

Default: 3600

Specifies the retransmission timer value to guard the implicit detach procedure on network side. *impli_detach_dur* is the waiting duration in seconds before retransmitting the specific message and must be an integer from 1 through 3600.

max-auth-retransmission *auth_retrans*

Default: 4

Specifies the maximum retransmission of authentication requests allowed. *auth_retrans* is the number of retries before declaring the authentication failure and must be an integer from 1 through 10.

max-identity-retransmission *id_retrans*

Default: 4

Specifies the maximum retransmission of identity requests allowed.

id_retrans is the number of retries before declaring the identity failure and must be an integer from 1 through 10.

max-page-retransmission *page_retrans*

Default: 5

Specifies the maximum retransmission of page requests allowed.

id_retrans is the number of retries before declaring the paging request failure and must be an integer from 1 through 5.

max-ptmsi-reloc-retransmission *ptmsi_reloc_retrans*

Default: 5

Specifies the maximum retransmission for P-TMSI relocation procedure allowed.

id_retrans is the number of retries before declaring the P-TMSI relocation procedure failure and must be an integer from 1 through 10.

mobile-reachable-timeout *ms_reach_dur*

Default: 58

Specifies the retransmission timer value to guard the mobile reachability procedure on network side.

impli_detach_dur is the waiting duration in minutes before retransmitting the specific message and must be an integer from 4 through 1440.

perform-identity-on-auth-failure

Default: Enabled

Configures the SGSN service to perform an identity check to ascertain the IMSI after an authentication failure on a PTMSI-based message.

purge-timeout *purge_dur*

Default: 10080 (7 days)

Specifies the timer value to guard the detach of MM context procedure on network side.

impli_detach_dur is the waiting duration in minutes before retransmitting the specific message and must be an integer from 1 through 20160.

Define the purge timer to hold detached mm-contexts. Default is 10080 mins (7 days).

trau-timeout *trau_dur*

This timer is available in releases 9.0 and higher.

Default: 30

Specifies the number of seconds the “old” 3G SGSN waits to purge the MS’s data. This timer is started by the “old” SGSN after completion of the inter-SGSN RAU.

trau_dur : Must be an integer from 5 to 60.

Usage

Repeat this command as needed to configure multiple parameters for GPRS mobility management in a UMTS network. This command provides the configuration of timers for mobility procedures and retries for different messages. GMM layer is defined in the 3GPP TS 24.008 (Release 7).

Example

Following command configures the timer to wait for 5 mins before retransmitting the message for GPRS attach or RAU procedure on MS side with maximum number of retries as 6 for authentication:

```
gmm T3302-timeout 5 max-auth-retransmission 6
```

gs-service

This command associates a previously defined Gs service interface to MSC/VLR along with its associated context with an SGSN service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gs-service gs_srvc_name context ctx_name
```

```
no gs-service gs_srvc_name
```

no

Removes/disassociates the named Gs service from this SGSN service.

gs_srvc_name

Specifies the name of a specific Gs service for which to display information.

svc_name is the name of a configured Gs service and can be from 1 to 63 alpha and/or numeric characters and is case sensitive.

context *ctx_name*

Specifies the specific context name where Gs service is configured. If this keyword is omitted, the named Gs service must exist in the same context as the SGSN service.

ctx_name is name of the configured context of Gs service. This can be from 1 to 63 alpha and/or numeric characters and is case sensitive.

Usage

Use this command to associate a specific Gs service interface with this SGSN service instance.

Important: A single Gs service can be used with multiple SGSN and/or GPRS service.

Example

Following command associates a Gs service instance named *stargs1*, which is configured in context named *star_ctx*, with an SGSN service:

```
gs-service stargs1 context star_ctx
```

lac

This command defines the location area code (LAC in hexadecimal format).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

lac *hex*

no lac

no

Erases the **lac** configuration statement.

hex

Enter a hexadecimal number between 0x0 and 0xFFFF

max-pdp-contexts

Configures the maximum number of PDP contexts for a MS (mobile station) that will be supported on this SGSN service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
max-pdp-contexts per-ms number
```

```
default max-pdp-contexts per-ms
```

default

Resets the maximum number of PDP contexts per mobile station to the default of 11 for the Gs service configuration

per-ms *number*

Default: 11

Defines the combined total number of primary and secondary PDP contexts for the SGSN service. *number* can be an integer from 2 to 11.

Usage

The following example defines 5 as the maximum number of primary and secondary PDP contexts that this SGSN will support for any connected MS.

Example

```
max-pdp-contexts per-ms 5
```

mobile-application-part

This command identifies an already defined MAP service (Mobile Application Part service) to associate with the SGSN service. Although the MAP service does not need to be defined in the same context as the SGSN service, there is a one-to-one relationship between a MAP service and an SGSN service.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
mobile-application-part service map_srvc [ context ctx_name ]
```

```
no mobile-application-part service
```

no

Remove the MAP service association from the SGSN service configuration.

service *map_srvc*

Specifies the name of the MAP service to be associated with this SGSN service. *map_srvc* must be the name of a MAP service previously configured on the system.

context *ctx_name*

Specifies the name of the context where the MAP service is configured. If the MAP service is not configured in the current context, then the context where it is configured must be specified to enable the SGSN to reach the MAP service.

If this keyword is not specified, the current context is used.

ctx_name : Must be the name of the context where the specified MAP service is configured.

Usage

Use this command to identify the MAP service configuration to be used by the SGSN service configuration. Also use this command to specify the context in which the MAP service configuration was created.

If the MAP service is not identified or if the correct context is not identified, then the SGSN service will not START.

Example

The following command specifies a MAP service named *map1* that is configured in the same context as the current SGSN service:

```
mobile-application-part service map1
```

network-sharing cs-ps-coordination

Enables/disables the SGSN service to perform a CS-PS coordination check.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
network-sharing cs-ps-coordination
```

```
default network-sharing cs-ps-coordination
```

```
no network-sharing cs-ps-coordination
```

default

Including this keyword resets the SGSN service to allow the check to be performed.

no

Disables this feature for the SGSN service.

Usage

Use this command to facilitate the network sharing functionality. With this command, the SGSN can be instructed to perform a check to determine if CS-PS coordination is needed. 3GPP TS 25.231 section 4.2.5 describes the functionality of the SGSN to handle CS-PS (circuit-switching/packet-switching) coordination for attached networks not having a Gs-interface. In compliance with the standard, the SGSN rejects an Attach in a MOCN configuration with cause 'CS-PS coordination required', after learning the IMSI, to facilitate the RNC choosing the same operator for both CS and PS domains.

Example

Use the following syntax to disable the CS-PS coordination check:

```
no network-sharing cs-ps-coordination
```

nri length

This command defines the Network Resource Identifier (NRI) of the SGSN that is stored in the P-TMSI (bits 23 to 18).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
nri length nri_length { nri-value nri_value | null-nri-value null_nri_value
non-broadcast mcc mcc mnc mnc lac lac_id rac rac_id [ nri-value value ] }
```

```
no nri
```

no

Removes the configured NRI value and location in P-TMSI for retrieval by this SGSN operator policy.

nri length *nri_length*

Specifies the number of bits to be used in the P-TMSI, bits 23 to 18, to define the network resource identifier (NRI). The NRI length configuration also sets the maximum size of the pool. If not configured, the NRI length will be of zero length.

nri_length: Must be an integer from 1 to 6 to identify the number of bits.

null-nri-value *null_nri_value*

This keyword is only available in releases 8.1 and higher.

Configures the null NRI value which must be unique across the pool areas. This keyword is used for the offloading procedure for SGSN pooling (enabled with the **sgsn offloading** command, see the Exec Mode chapter).

null_nri_value: 0 (zero) indicates the keyword is not to be used and 1 to 63 are used to identify the SGSN to be used for the offloading procedure for SGSN pooling. There is no default value for this parameter.

non-broadcast **mcc** *mcc* **mnc** *mnc* **lac** *lac_id* **rac** *rac_id*

This keyword set is only available in releases 8.1 and higher.

Defines the non-broadcast LAC/RAC to be used in combination with the null-NRI for the offloading procedure. Including the MCC and MNC to specify the PLMN because the Iu-Flex feature supports multiple IuPS Services.

mcc identifies the mobile country code, the first part of the PLMN ID. Must be an integer between 100 and 999.

mnc identifies the mobile network code portion of the PLMN ID. Must be a 2- or 3-digit integer between 01 and 999.

lac_id defines a location area code associated with an RNC. Must be an integer between 1 and 65535.

rac_id defines the remote area code to be associated with an RNC. Must be an integer between 1 and 255.

nri-value *nri_value*

Specifies the MS-assigned value of the NRI to retrieve from the P-TMSI. This value must not exceed the maximum possible value specified by the NRI length. The NRI value must be unique across the pool or across all overlapping pools.

nri_value must be an integer from 1 to 63 to identify a specific SGSN in a pool. Use of 0 (zero) value is not recommended.

Multiple NRI values can be identified by providing multiple **nri-values** separated by a blank space for example: **nri length 6 nri-value 29 43 61**

Usage

Use this command to identify the SGSN identified with the NRI in the MS generated P-TMSI.

This command adds or removes the Iu Flex configuration for this SGSN service. When using Iu Flex, all keywords must be defined. The command can be repeated to specify different values for any of the keyword parameters. If more than one NRI is configured, the SGSN service will round-robin between the available NRIs when new subscribers (re)connect.

Use this command to retrieve the NRI (identity of an SGSN) stored in bits 23 to 18 of the packet-temporary mobile subscriber identity (P-TMSI). If more than one NRI value is configured, the SGSN service will round-robin between the available NRIs when new subscribers (re)connect.

When using MOCN mode for network sharing without SGSN pooling, the NRI length and the NRI value should both be used.

Example

The following command specifies the NRI length as 5 bits, identifies SGSN 23 with LAC 222 and RAC 12 for offloading procedure with NRIs 6 and 41:

```
nri length 5 null-nri-value 34 non-broadcast lac 222 rac 12 nri-value 6  
41
```

override-lac-li

Refer to the *ASR 5000 Lawful Intercept Guide* for a description of this command.

override-rac-li

Refer to the *ASR 5000 Lawful Intercept Configuration Guide* for a description of this command.

rac

Refer to the *ASR 5000 Lawful Intercept Configuration Guide* for a description of this command.

ran-protocol

This command specifies the IuPS service for the SGSN service to use for communication with the RAN.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
ran-protocol iups-service iups_srvc [ context ctx_name ]
```

```
no ran-protocol iups-service
```

no

Removes the IuPS service information from the SGSN service configuration.

iups-service *iups_srvc*

Specifies the name of an IuPS service already configured on the system.

iups_srvc : Enter an alphanumeric string of 1 to 63 characters.

ctx_name

ctx_name : Enter the name of the IuPS context, an alphanumeric string of 1 to 63 characters.

Usage

Use this command to configure the IuPS service context that the current SGSN service will use to communicate with the RAN. Up to 8 definitions can be defined for a single SGSN service to allow for multiple PLMNs support.

Example

The following command configures the SGSN service to use an IuPS service named **iups1** that has been configured. in the same context as the SGSN service:

```
ran-protocol iups-service iups1
```

sgsn-number

This command defines the E.164 number that identifies this particular SGSN service context.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sgsn-number E.164_number
```

```
no sgsn-number
```

no

Removes the SGSN number configuration from the SGSN service configuration.

E.164_number

Enter a maximum of 15 digits to define the 'phone' number associated with this SGSN service in the specified context.

Usage

The SGSN supports multiple SGSN numbers – different numbers in the 2G GPRS service configuration and the the 3G SGSN service configuration. If an HLR-initiated dialog is received, the SGSN will perform a lookup based on the IMSI and find the correct SGSN number with which the MS is associated. Subsequent messaging will use this address.

Example

To delete the sgsn-number associated with this SGSN service context, enter:

```
no sgsn-number
```

sgtp-service

This command creates an instance of an SGTP service.

Product

SGSN

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
sgtp-service sgtp_srvc_name
```

```
no sgtp-service
```

sgtp_srvc_name

Enter the name of an SGTP service that will be used by this SGSN service

sgtp_srvc_name : Enter a string of 1 to 63 alphanumeric characters.

Usage

Use this command to access the SGTP Service configuration mode to configure SGTP parameters.

Example

```
sgtp-service sgtp1
```

sm

This command configures session management parameters for this SGSN service. This command can be repeated multiple times to configure each parameter individually.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sm { T3385-timeout time | T3386-timeout time | T3395-timeout time | max-actv-
retransmission number | max-deactv-retransmission number | max-modf-
retransmission number }
```

```
default sm timer
```

default

Resets the selected timer to the system default value.

T3385-timeout

Retransmission timer for network-initiated Activate Request. Default is 8 sec

T3386-timeout

Retransmission timer for network-initiated Modify Request. Default is 8 sec

T3395-timeout

Retransmission timer for network-initiated Deactivate Request. Default is 8 sec

max-actv-retransmission

Configures maximum retries for activate PDP ctxt request. Default is 4

max-deactv-retransmission

Configures maximum retries for deactivate PDP ctxt request. Default is 4

max-modf-retransmission

Configures maximum retries for modify PDP ctxt request. Default is 4

Usage

Repeat the command to configure multiple session management parameters for the SGSN service.

Example

■ sm

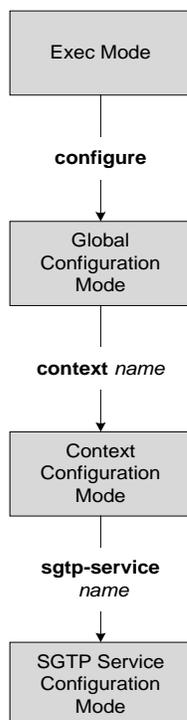

```
sm T3385-timeout 5
```

Chapter 212

SGTP Service Configuration Mode Commands

The SGSN GPRS Tunneling Protocol (SGTP) Service configuration mode provides the configuration of GTP-C and GTP-U related parameters.

```
[<ctx_name>]hostname(config-sgtp-service)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

direct-tunnel-disabled-ggsn

This command makes it possible for the operator to disable direct tunneling on the basis of a GGSN.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
direct-tunnel-disabled-ggsn IPv4/IPv6_address
```

```
no direct-tunnel-disabled-ggsn [ IPv4/IPv6_address ]
```

no

Deletes the direct-tunnel-disabled-ggsn configuration which results in re-enabling direct tunneling to the GGSN.

- Including an IPv4 or IPv6 address for a specific GGSN, re-enables direct tunneling for that specific GGSN.
- Excluding any IPv4 or IPv6 address from this command removes all direct-tunnel-disabled-ggsn definitions from the SGTP service configuration.

Usage

By default, GGSNs and RNCs are assumed to be capable of direct tunneling.

This command disables direct tunneling for a specified GGSN. The command can be repeated to disable direct tunneling for multiple GGSNs, thereby creating a 'disabled GGSN' list. Checking for a direct-tunnel-disabled GGSN is actually the last step in the PDP Activation procedure.

Restricting direct tunneling by a GGSN for an entire APN would be configured with the appropriate command in the APN profile configuration mode.

Restricting direct tunneling at the RNC level would be configured with the appropriate command in the IuPS service configuration mode.

This command can only be used if:

- The Direct Tunnel license has been purchased and applied.
- The Direct Tunnel feature is appropriately enabled via configurations of the IMEI profile and/or the Call-Control and APN profiles.
- The RNC does not restrict direct tunnel.
- The subscriber is not requesting CAMEL services.

Example

Use the following command to disable direct tunnel for the GGSN with the IP address of 141.21.4.20:

```
direct-tunnel-disabled-ggsn 141.21.4.20
```

end

Exits the configuration mode and returns to the Exec mode.

Product

SGSN

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Changes the mode to the Exec mode.

■ exit

exit

Exits the SGTP Service configuration mode and returns to the Context configuration mode.

Product

SGSN

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

gtpc

Configure the GPRS Tunneling Protocol Control (GTP-C) settings for the SGTP service.

Product

SGSN

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
gtpc { bind address ip_address | dns-sgsn context cntxt_name | echo-interval
seconds | guard-interval seconds | ignore response-port-validation | max-
retransmissions num | retransmission-timeout seconds | send { common flags |
rab-context } }
```

```
no gtpc { bind address ip_address | dns-sgsn context cntxt_name | echo-interval
seconds | send { common flags | rab-context } }
```

```
default gtpc { echo-interval | guard-interval | ignore response-port-validation
| max-retransmissions | retransmission-timeout | send { common flags | rab-
context } }
```

no

Disables the configured GTPC setting.

default

Resets the specified parameter to its default value.

bind address *ip_address*

Binds SGTP service to the IP address of the interface.

The bind address for the **gtpc** and **gtpu** commands should be the same.

ip_address: Enter a standard dotted-quad IPv4 address.

dns-sgsn context *cntxt_name*

Enter a string of 1 to 79 alphanumeric characters to identify the context.

echo-interval *seconds*

Configures the duration between echos.

seconds: Enter an integer from 0 through 3600.

Default: 60

guard-interval *seconds*

Configures the interval (in seconds) for which the SGTP maintains responses sent to SGSN. This optimizes the handling of retransmitted messages. This value should be configured to be greater than the SGSN's configuration for max-retries multiple by retry-interval.

seconds: Enter an integer from 10 to 3600.
Default: 100

ignore response-port-validation

This keyword instructs the SGSN to ignore the response port validation. For the SGSN to process incoming GTP responses to an *incorrect* port,

- this keyword must be entered, and

- the same **bind address** must be configured for GTPC and GTPU in the SGTP service.

Default: disabled. To reset the default for *this* parameter, you must enter the following command: **no gtpc ignore response-port-validation**.

max-retransmissions *num*

Configures the maximum number of retries for packets.

num: Enter an integer from 0 to 15.

Default: 4

retransmission-timeout *seconds*

Configures the control packet retransmission timeout in GTP, in seconds.

seconds: Enter an integer value from 1 through 20.

Default: 5

send { **common-flags** | **rab-context** }

common-flags: This option configures the SGTP service to include or exclude the common flags IE during an Inter-SGSN RAU. When selected, the default is to send the common flags IE.

rab-context: This option configures the SGTP service to include/exclude the radio access bearer (RAB) context IE in SGSN 'context response' message during Inter-SGSN Routing Area Update procedure. Default is to send the RAB context IE.

Usage

Use this command to configure GTP-C settings for the current SGTP service.

Example

Following command excludes the radio access bearer (RAB) context IE in the SGSN Context Response message during the inter-SGSN RAU procedure:

```
no gtpc send rab-context
```

gtpu

This command configures the GPRS Tunneling Protocol user data plane parameters (GTP-U) for this SGTP service.

Product

SGSN

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
gtpu { bind address ip_address | echo-interval | max-retransmissions |
retransmission-timeout } +
no gtpu { bind | echo-interval }
default gtpu { echo-interval | max-retransmissions | retransmission-timeout }
```

no

Removes the configuration for the specified parameter from the current SGTP service configuration.

default

Resets the specified GTP-U parameter to its factory default.

bind address ip_address

Defines the GTP-U Gn interface IP address that binds to this SGTP service.

The **gtpu** and the **gtpc** commands should be configured with the same bind address.

ip_address: Enter a standard dotted-quad IPv4 address.

echo-interval seconds

Configures the echo interval.

seconds: Enter an integer from 60 through 3600.

Default: 60

max-retransmissions num

Configures the maximum number of retries for retransmitting packets.

num: Enter an integer from 0 through 15.

Default: 4

retransmission-timeout seconds

Configures the retransmission timeout of packets, in seconds.

seconds: Enter an integer from 1 through 20.

Default: 5

Usage

■ gtpu

Use this command to configure the GTP-U settings for the SGTP service.

Example

```
gtpu echo-interval 5
```

mbms

Enables / disables the Multimedia Broadcast Multicast Service

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

mbms

Usage

Important: The **mbms** command and parameter-configuring keywords are under development for future release and should not be used or included in your configuration at this time.

path-failure

This command specifies the method for determining if path failure has occurred.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
path-failure detection-policy gtp type
```

```
[ no | default ] path-failure detection-policy
```

no

Deletes the path-failure definition from the configuration.

default

Resets the specified path failure parameter to default.

detection-policy gtp *type*

Specifies the policy to be used, value options include:

- **echo** - When set to 'echo', path failure is detected when the retries of echo messages time out.
- **non-echo** - When set to 'non-echo', path failure is detected when the retries of non-echo messages time out.

Default: echo (for both GTPC and GTPU)

Usage

Use this command to define the policy to detect gtp path failure.

Example

```
path-failure detection-policy gtp echo
```

pool

This command enables the default SGSN functionality for (flex) pooling and enables inclusion of the configured pool hop-counter count in new SGSN context/identify request messages.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
pool { default-sgsn | hop-counter count }
```

```
no pool { default-sgsn | hop-counter }
```

```
default pool hop-counter
```

no

Disables the default SGSN pooling functionality or removes the SGSN pool hop-counter IE from the GTP Identity/context requests.

default

Removes the SGSN pool hop-counter IE from the GTP Identity/context requests.

default-sgsn

Enables default SGSN pooling functionality.

hop-counter count

Enables and configures the SGSN pool hop-counter to set the number of hops and to include the configured count in the **new** SGSN Context Requests or the **new** SGSN Identify Requests.

If **default-sgsn** is enabled, then any messages relayed will have the default value of 4 for the counter if the message does not include this hop-counter ID.

count : Enter an integer from 1 to 255.

Default: 4

Usage

Use this command to enable the default flex functionality without exposing the pool (flex) structure. This functionality provides a means for SGSNs outside of the pool to reach a pooled SGSN on the basis of its NRI. Once the pooling has been enabled. Repeat the command using the **hop-counter** keyword to enable inclusion of the hop-counter IE in SGSN context/identify request messages and to configure the count for the pooling hop-counter. If the SGSN is behaving as the 'default SGSN', this SGSN will forward (relay) requests with the hop-count included to the target SGSN.

Example

Enable the default pooling functionality which allows an outside SGSN to reach a pooled SGSN:

■ pool

pool default-sgsn

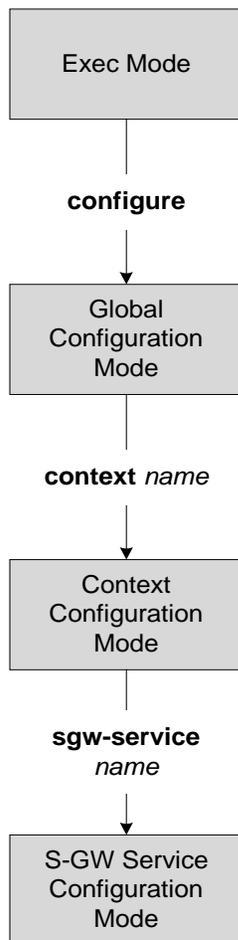

Set the hop-count to be included in messages to 25:

pool hop-count 25

Chapter 213

S-GW Service Configuration Mode Commands

The S-GW (Serving Gateway) Service Configuration Mode is used to create and manage the relationship between an eGTP service used for either ingress or egress control plane and user data plane network traffic.

accounting context

Configures the GTPP accounting context and group selection for S-GW service.

Product

S-GW

Privilege

Administrator

Syntax

```
accounting context name [ gtp group name ]
```

```
no accounting context
```

no

Removes the configured accounting context from this service.

context *name*

Specifies the context where GTPP accounting is performed. *name* must be an existing context configured on the system and be from 1 to 79 alpha and/or numeric characters.

If an accounting context name is not configured in the S-GW service, the context where the S-GW service resides is considered the accounting context and the default GTPP group is used.

gtp **group** *name*

Specifies a GTPP group used to perform GTPP accounting. *name* must be an existing GTPP group configured on the system and be from 1 to 79 alpha and/or numeric characters.

If a GTPP group is not configured, the system will use the default GTPP group in the specified accounting context. If the accounting context is not specified, the system will use default GTPP group in the context where the S-GW service resides.

Usage

Use this command to specify the accounting context and/or GTPP accounting group the S-GW service will use to perform GTPP accounting.

Example

The following command specifies a GTPP accounting context named *acct-2* and a GTPP accounting group named *gtp-grp-3* as the context and group the S-GW service will use:

```
accounting context acct-2 gtp group gtp-grp-3
```

associate

Associates the S-GW service with QoS and policy control and charging configurations.

Product

S-GW

Privilege

Administrator

Syntax

```
associate { accounting-policy name | egress-proto { gtp | gtp-pmip | pmip } [ egress-context name [ egtp-service name ] [ mag-service name ] ] | ims-auth-service name | ingress egtp-service name | qci-qos-mapping name }
```

```
no associate { accounting-policy name | egress-proto [ egress-context [ egtp-service ] [ mag-service ] ] | ims-auth-service name | ingress egtp-service | qci-qos-mapping name | }
```

no

Removes the specified association from the S-GW service.

accounting-policy *name*

Associates the S-GW service with an accounting policy configured in the same context. *name* must be an existing accounting policy and be from 1 to 63 alpha and/or numeric characters.

Accounting policies are configured through the **policy accounting** command in the Context Configuration Mode.

egress-proto { **gtp** | **gtp-pmip** | **pmip** } [**egress-context** *name* [**egtp-service** *name*] [**mag-service** *name*]]

Associates and configures the egress protocol for this S-GW service.

gtp: Specifies that GTP is to be used for the S-GW service egress.

gtp-pmip: Specifies that either GTP or PMIP is to be used for the S-GW service egress.

pmip: Specifies that PMIP is to be used for the S-GW service egress.

egress-context *name*: Specifies that the context in this keyword is to be used for the S-GW service egress. *name* must be an existing context on this system and be from 1 to 63 alpha and/or numeric characters.

egtp-service *name*: Specifies that the service in this keyword is to be used for the S-GW service egress. *name* must be an existing eGTP service on this system and be from 1 to 63 alpha and/or numeric characters.

mag-service *name*: Specifies that the service in this keyword is to be used for the S-GW service egress. *name* must be an existing MAG service on this system and be from 1 to 63 alpha and/or numeric characters.

ims-auth-service *name*

Associates the S-GW service with an IMS authorization service configured in the same context. *name* must be an existing IMS auth service and be from 1 to 63 alpha and/or numeric characters.

IMS authorization services are configured through the **ims-auth-service** command in the Context Configuration Mode.

ingress egtp-service *name*

Associates and configures the eGTP service ingress for this S-GW service. *name* must be an existing eGTP service on this system and be from 1 to 63 alpha and/or numeric characters.

qci-qos-mapping *name*

Associates the S-GW service with QCI to QoS mapping parameters. *name* must be an existing QCI-QoS mapping configuration and be from 1 to 63 alpha and/or numeric characters.

QCI-QoS mapping is configured through the **qci-qos-mapping** command in the Global Configuration Mode.

Usage

Use this command to select a pre-configured QoS mapping and/or policy control and charging configuration to be used by the S-GW service.

Example

The following command associates the S-GW service with an IMS authorization service named *ims-23*:

```
associate ims-auth-service ims-23
```

egtp-service

Configures an eGTP service to use as either an ingress (S1-U) or egress (S5/S8) service for the S-GW.

Product

S-GW

Privilege

Administrator

Syntax

```
egtp-service { egress { context name | service name } | ingress service name }  
no egtp-service { egress { context | service } | ingress service }
```

no

Removes the selected EGTP service from this service.

egress { context *name* | service *name* }

Specifies the egtp-service to be used as the egress eGTP service on a GTP based S5/S8 interface.

context *name*: Specifies the name of the context where the eGTP service resides. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing context name where an eGTP service resides.

Caution: **context *name*** is not supported in this release.

service *name*: Specifies the name of the egress eGTP service. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing eGTP service name.

ingress service *name*

Specifies the egtp-service to be used as the ingress eGTP service on the S11 interface. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing eGTP service name.

Usage

Use this command to configure the eGTP service to use with this S-GW service. The eGTP service must be existing and be configured with the appropriate parameters supporting the intended service type.

Example

The following command configures the S-GW service to use an eGTP service named *slu-egtp* as it's ingress service:

```
egtp-service ingress service slu-egtp
```

■ end

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous mode.

gtpu-error-ind

Configures the actions to be taken upon receiving a GTP-U error indication from an RNC, eNodeB, SGSN, or P-GW.

Product

S-GW

Privilege

Administrator

Syntax

```
gtpu-error-ind { { s12 | s1u } { local-purge | page-ue [ custom1-behavior ] } |
{ s4u | s5u } { local-purge | signal-peer } }
default gtpu-error-ind { s12 | s1u | s4u | s5u }
```

default

Resets the command to the default action for the specified interface. For S12 and S1-U, **page-ue** is the default action. For S4-U and S5-U, **local-purge** is the default action.

```
{ s12 | s1u } { local-purge | page-ue [ custom1-behavior ] }
```

Specifies the action to take when a GTP-U error indication is received from a Radio Network Controller (RNC) over an S12 interface or from an eNodeB over the S1-U interface.

local-purge: The S-GW clears the affected bearer (or PDN if error-ind is received on default bearer) locally without informing peer.

page-ue [custom1-behavior]: The S-GW moves the complete UE state to S1-Idle and starts paging for this UE. If the custom1-behavior option is specified, the S-GW will guard the paging attempt with a timer of 60 seconds. Within this time the bearer must have the eNodeB TEID refreshed by an MME.

Otherwise, the S-GW will clear the affected bearer with signaling. This is the default action for GTP-U error indication messages received on the S12 and S1-U interfaces.

```
{ s4u | s5u } { local-purge | signal-peer }
```

Specifies the action to take when a GTP-U error indication is received from an SGSN over an S4-U interface or from a P-GW over the S5-U interface.

local-purge: The S-GW clears the affected bearer (or PDN if error-ind is received on a default bearer) locally without informing the peer. This is the default action for GTP-U error indication messages received on the S4-U and S5-U interfaces.

signal-peer: The S-GW initiates control signalling towards the peer MME and P-GW. When signalling:

- For a bearer deletion, the S-GW sends a Delete-Bearer-Command message to the P-GW and a Delete-Bearer-Request (with EBI) message to the MME.
- For PDN deletion, the S-GW sends a Delete-Session-Request message to the P-GW and a Delete-Bearer-Request (with LBI) message to the MME.
- The S-GW will not wait for Delete replies from the peer. The request will be sent only once and local resources will be reset.

Usage

Use this command to specify the action to taken upon receiving a GTP-U error indication from an RNC over an S12 interface, an eNodeB across an S1-U interface, an SGSN over an S4-U interface, or from a P-GW across an S5-U interface.

Example

The following command sets the action to take upon receipt of a GTP-U error indication from the eNodeB to clear affected bearer:

```
gtpu-error-ind slu local-purge
```

mag-service

Identifies the Mobile Access Gateway (MAG) egress service through which calls are to be routed for this S-GW service.

Product

S-GW

Privilege

Administrator

Syntax

```
mag-service egress service name
```

```
no mag-service egress service
```

no

Removes the configured MAG egress service from this service.

egress service *name*

Specifies the MAG service name to be used as the egress MAG service on a PMIP based S5/S8 interface. *name* must be an existing MAG service and be from 1 to 63 alpha and/or numeric characters.

Usage

Use this command to specify the name of the MAG service where calls are to be routed.

Example

The following command specifies that an existing MAG service named *mag3* is to be used to route call through for this S-GW service:

```
mag-service egress service mag3
```

path-failure

Configures the action to take upon the occurrence of a path failure between the S-GW and the MME, P-GW, RNC, SGSN, or eNodeB.

Product

S-GW

Privilege

Administrator

Syntax

```
path-failure { s11 | s12 | s1u | s4 | s4u | s5 | s5u } ( local-purge | signal-peer )
```

```
default path-failure { s11 | s12 | s1u | s4 | s4u | s5 | s5u }
```

default

Returns the command to the default setting of “local purge” for the selected interface.

```
{ s11 | s12 | s1u | s4 | s4u | s5 | s5u }
```

Specifies the interface to which the action will be applied.

s11: Indicates that the path failure action is to be applied to the S11 interface between the S-GW and the MME.

s12: Indicates that the path failure action is to be applied to the S12 interface between the S-GW and the RNC.

s1u: Indicates that the path failure action is to be applied to the S1-U interface between the S-GW and the eNodeB.

s4: Indicates that the path failure action is to be applied to the S4 control plane interface between the S-GW and the SGSN.

s4u: Indicates that the path failure action is to be applied to the S4-U user plane interface between the S-GW and the SGSN.

s5: Indicates that the path failure action is to be applied to the S5 interface between the S-GW and the P-GW.

s5u: Indicates that the path failure action is to be applied to the S5-U user plane interface between the S-GW and the P-GW.

```
{ local-purge | signal-peer }
```

Specifies the action to apply to the selected interface.

local-purge: The S-GW clears the affected bearer (or PDN if path failure is received on a default bearer) locally without informing the peer. This is the default action for all interface.

signal-peer: The S-GW initiates control signalling towards the peer MME and P-GW. When signalling:

- For a bearer deletion, the S-GW sends a Delete-Bearer-Command message to the P-GW and a Delete-Bearer-Request (with EBI) message to the MME.
- For PDN deletion, the S-GW sends a Delete-Session-Request message to the P-GW and a Delete-Bearer-Request (with LBI) message to the MME.
- The S-GW will not wait for Delete replies from the peer. The request will be sent only once and local resources will be reset.

■ path-failure

Usage

Use this command to specify the type of action to take when a path failure occurs on one of the supported interfaces.

Example

The following command sets the path failure action for the S5 interface to “signal peer”:

```
path-failure s5 signal-peer
```

plmn

Configures the PLMN identifier for this S-GW service

Product

S-GW

Privilege

Administrator

Syntax

```
plmn id mcc number mnc number [ primary ]
```

```
no plmn id mcc number mnc number
```

no

Removes the configured PLMN ID for this S-GW service.

mcc *number*

Configures the Mobile Country Code for this PLMN ID. *number* must be an integer value from 100 to 999.

mnc *number*

Configures the Mobile Network Code for this PLMN ID. *number* must be an integer value from 00 to 999,

primary

Specifies that this is the primary PLMN ID for this S-GW service.

Usage

Use this command to configure PLMN IDs for this S-GW service

Example

The following command configures a “primary” PLMN ID for this S-GW service with an MCC of *123* and an MNC of *12*:

```
plmn id mcc 123 mnc 12 primary
```

Chapter 214

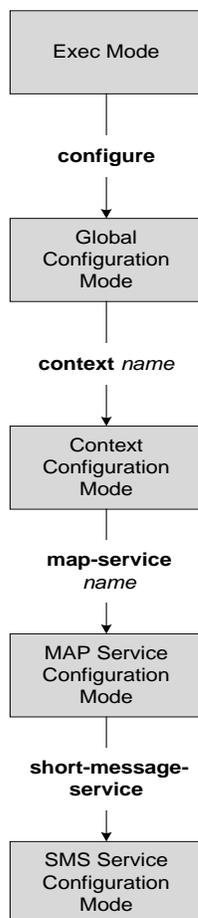

SMS Service Configuration Mode Commands

The SMS (short message service) Service configuration mode is used to create and manage properties of the SMS Service configuration.

The SGSN uses the SMS Service component to communicate via the Gd interface with a gateway message service controller (GMSC) to send short text messages (up to 140 octets in length) to a mobile (SMS-MT) and/or receive messages from a mobile (SMS-MO) .

When this mode is accessed, the command line will appear similar to

```
[<ctx_name>]asr5000(config-map-service-<map_service_name>-sms-service)#
```

■ plmn

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

cp-data

Enables the SGSN to send and/or receive cp-data (text messages).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
cp-data max-retransmission retries_num
```

```
default cp-data max-retransmissions
```

default

This keyword resets the SGSN's max-retransmission to the default number of retries.

```
max-retransmission retries_num
```

retries_num: enter an integer from 1 to 3.

Usage

Use this command to configure the number of times the SGSN will attempt to retransmit a message.

Example

```
cp-data max-retransmission 2
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Return to the Exec mode.

exit

Exits the current configuration mode and returns to the SMS configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Move to the previous configuration mode.

mo-message-forwarding-destination

This command defines the SGSN's handling policy for MO (mobile originating) message.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] mo-message-forwarding-destination { gsmc-selected-from-imsi | smsc-supplied-by-subscriber }
```

default

Resets the SMS service configuration to the default message forwarding technique.

gsmc-selected-from-imsi

Entering this keyword enables SMS-MO messages to be forwarded on the basis of their IMSI prefix.

smc-supplied-by-subscriber

Entering this keyword enables SMS-MO messages to be forwarded on the basis of the SMSC (SMS controller) address provided by the subscriber.

Usage

Use this command to define how the mobile originated SMS are to be routed.

Example

```
mo-message-forwarding-destination gsmc-selected-from-imsi
```

sm-sc-address-selection-prioritization

Define the routing selection priority for the SMSC (short message service center) address to be used for all MO-SMS.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sm-sc-address-selection-prioritization from-ms priority imsi-prefix priority  
msisdn-prefix priority
```

```
default sm-sc-address-selection-prioritization
```

from-ms *priority*

Configures a priority for the SMSC address send from the MS.

priority : Value must be a single digit, range 1-3.

imsi-prefix *priority*

Configures a priority for the SMSC address that is based on the IMSI-prefix.

priority : Value must be a single digit, range 1-3.

msisdn-prefix *priority*

Configures a priority for the SMSC address that is based on the MSISDN-prefix.

priority : Value must be a single digit, range 1-3.

default

By including the **default** keyword with the command, the SGSN knows to use the encoded default priorities for SMSC address selection for SMSC routing:

- *from-ms* priority 1,
- *imsi-prefix* priority 2,
- *msisdn-prefix* priority 3.

Usage

Use this command to define SMSC address routing priorities. Priorities must be defined for all parameters, all keywords, but they can be entered in any order. The addresses for the SMSCs are defined with the [sm-sc-routing](#) command.

An operator can use this configuration to prevent subscribers from using unauthorized SMSC addresses, for example, an unauthorized international SMSC.

Example

The keywords can be entered in any order but all keywords must be included in the command:

■ smsc-address-selection-prioritization

```
smsc-address-selection-prioritization msisdn-prefix 3 from-ms 1 imsi-  
prefix 2
```

smc-routing

This command configures the routing to the SMSC (short message service center).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] smc-routing { { any | imsi-starts-with | msisdn-starts-with } { isdn
isdn_number | mobile-global-title mgt_number [ max-gt-address-len max_gt_address
] | point-code pt_code } }
```

any

Configures routing according to any IMSI prefix.

imsi-starts-with *IMSI_prefix*

Defines the IMSI prefix. Enter a string of up to 15 digits.

msisdn-starts-with *msisdn_prefix*

Defines the MSISDN prefix. Enter a string of up to 15 digits.

isdn *isdn_number*

Defines the ISDN E.164 number (up to 15 digits) of the SMSC.

mobile-global-title *mgt_number* [**max-gt-address-len** *max_gt_address*]

Defines the mobile global title (MGT) E.214 address to be used for IMSI conversion.

Optionally, the maximum length of the GT address can be defined. If the length of the MGT string is greater than the defined max, then the least significant digits will be omitted.

mgt_number is a string of integers, up to 18.

max_gt_address is an integer from 1 to 32.

point-code *pt_code*

Defines the point code for the SMSC. Enter a string of up to 11 digits in SS7 dotted decimal or decimal format

Usage

This command defines the address format (IMSI, point code, mobile global title) and the address for SMSC routing.

Example

Use this command to define routing to the SMSC based on any point code.

```
smc-routing any point-code 1.222.1
```

■ smsc-routing

timeout

This command defines the SMS service timers.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
timeout { tc1n-timer time | tr1n-timer time | tr2n timer time }  
default timeout { tc1n-timer | tr1n-timer | tr2n timer }
```

default

Resets the configuration to the default value for the specified timer.

tc1n-timer *time*

Configures the TC1N timer in seconds.

time: Must an integer from 1 to 255. The default is 5 seconds.

tr1n-timer *time*

Configures the TR1N timer in seconds.

time: Must an integer from 1 to 255. The default is 30 seconds.

tr2n-timer *time*

Configures the TR2N timer in seconds.

time: Must an integer from 1 to 255. The default is 30 seconds.

Usage

Use this command to set SMS service timers. The command can be repeated to set all of the timers, one-at-a-time.

Example

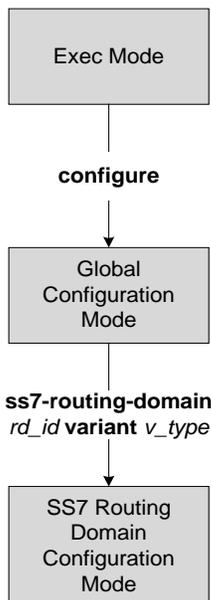

```
tr1n-timer 25
```

Chapter 215

SS7 Routing Domain Configuration Mode Commands

The SS7 Routing Domain configuration mode is used to configure Signaling System 7 (SS7) parameters. For convenience in configuration management, all SS7 parameters have been collected into a proprietary grouping called an *SS7 routing domains*.

```
[local]hostname(config-ss7-routing-domain-<ss7rd_id>)#
```

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

asp

This command creates or removes an M3UA Application Server Process (ASP) instance and enters the ASP configuration mode. See the *SGSN ASP Configuration Mode* chapter in the *Command Line Interface Reference* for command details.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
asp instance asp_inst
```

```
no asp instance asp_inst
```

```
default asp instance asp_inst end-point port
```

no

Deletes the ASP instance for the SS7 routing domain configuration.

default

Sets the ASP instance parameters to the end-point port value of 2905.

instance *asp_inst*

Identifies a specific ASP configuration. Up to four ASP instances can be configured for a single SS7 routing domain.

asp_inst : Must be an integer from 1 through 4.

Usage

Use this command to create an ASP instance or enter the ASP configuration mode.

Example

The following command enters the ASP configuration mode for a specific ASP.

```
asp instance 1
```

description

This command defines an alphanumeric string that describes the current SS7 routing domain. This is used for operator reference only.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

description *string*

no description

no

Removes the description string from the current SS7 routing domain configuration.

string

Specifies the alphanumeric string that is stored. Strings with spaces must be enclosed in double-quotes (see the example below).

string: Must be from 1 to 255 alphanumeric characters.

Usage

Use this command to set a description for reference by operators.

Example

The following command sets the description to identify a routing domain for messages transmitted within a national boundary.

```
description "National Service Routing Domain"
```

■ end

end

Exits the current configuration mode and returns to the Exec mode.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the Exec mode from any configuration mode.

exit

Exits the current configuration mode and returns to the context configuration mode.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the previous configuration mode.

inbound-asp-identifier validate

This command enables validation of ASP identifiers inbound to the SGSN via routes defined with this SS7 routing domain.

Important: This command is only available in releases 8.1 and higher.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
inbound-asp-identifier validate
```

```
[ default | no ] inbound-asp-identifier validate
```

default

Validates the inbound ASP Id.

no

Disables validation of the inbound ASP Id.

Usage

The standard is to validate the ASP Id. However, in some circumstances it is necessary to skip such validation. For example, if the same ASP Id is assigned to more than one RNC (peer-server).

Example

Use the following command to skip validation of inbound ASP Ids:

```
no inbound-asp-identifier validate
```

Use either of the following commands to enable validation if it has been disabled:

```
default inbound-asp-identifier validate
```

```
inbound-asp-identifier validate
```

linkset

This command creates an instance of an MTP3 linkset and enters the linkset configuration mode. See the *Linkset Configuration Mode* chapter in *Command Line Interface Reference* for the commands to configure the linkset.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] linkset id id
```

no

Removes the identified linkset definition from the system configuration.

id

This value uniquely identifies a linkset for the specific SS7 routing domain.

id : Must be an integer of 1 to 49.

Usage

This command creates instances of linkset configurations and provides access to the linkset configuration mode.

Example

Use the following command to create the 12th linkset:

```
linkset id 12
```

MTU-size

This command has been deprecated.

peer-server

This command creates a peer-server instance to setup a SIGTRAN peer for sending and receiving M3UA traffic. Completing the command automatically enters the peer- server configuration mode. To define 1 or more (up to 145) peer servers, use the commands documented in the *Peer-Server Configuration Mode* chapter in this reference.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
peer-server id svr_id
```

```
no peer-server id svr_id
```

no

Removes the identified peer-server definition from the system configuration.

svr_id

svr_id uniquely identifies a peer-server. The id must be an integer from 1 to 144.

Usage

Use the following command to create a definition for peer-server 2 and enter the configuration mode to configure the communication parameters for peer-server 12.

Example

```
peer-server id 12
```

route

This command configures SS7 routes for the current SS7 routing domain.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
route destination-point-code dp_code { linkset id id [ priority pri_value ] | peer-server-id srvr_id }
```

```
no route destination-point-code dp_code { linkset id id | peer-server-id srvr_id }
```

no

Removes the SS7 route from the current SS7 routing domain configuration.

destination-point-code *dp_code*

Specifies the SS7 destination point code for this route.

Reminder: the point-code structure must match the variant defined for the SS7 routing domain when the SS7RD was configured in the global configuration mode.

linkset id *id*

This keyword identifies a linkset instance, created and configured with the **linkset** command.

This keyword identifies a linkset instance, created and configured with the **linkset** command.

id : Must be an integer from 1 to 49.

peer-server-id *srvr_id*

This keyword identifies a peer-server configuration instance, created and configured with the **peer-server** command.

srvr_id must be an integer from 1 to 49.

Usage

This command associates the previously configured linksets and peer servers and the destination point codes with a specified SS7 route.

Example

Define a route setting an ITU-type destination point-code address for the linkset Id 12:

```
route destination-point-code 6.211.6 linkset id 12
```

routing-context

Identifies the routing context for this SS7 routing domain.

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
routing-context value
```

```
default routing-context
```

default

Resets the local routing context value to the index (instance ID) for this SS7 routing domain.

value

An integer that uniquely identifies the routing context for this SS7 routing domain.

value : Must be integers from 1 to 65535 (for releases 8.0) or 1 to 4294967295 (for releases 8.1 and higher)

.

Usage

Use this command to set the routing context IDs for a specific SS7 routing domain configuration.

Example

```
routing-context 2355
```

ssf

This command sets the network indicator in the subservice field for SS7 message signal units (MSUs).

Product

SGSN, HNB-GW

Privilege

Security Administrator, Administrator

Syntax

```
ssf ( international | national | reserved | spare )
```

international

The network indicator identifies the message as international with a point code structure that does not match the national point code structure.

national

The network indicator identifies the messages as having a national point code structure.

reserved

Provides an alternate network indicator for national messages.

spare

Provides an alternate network indicator for international messages.

Usage

In SS7 signaling, the Message Transfer Part (MTP) Level 2 message signal units (MSUs) contain a service information octet (SIO). The SIO field in an MSU contains a 4-bit subservice field (SSF) followed by a 4-bit service indicator. The indicator carried in the message's routing information typically identifies the structure of the point code as a message from within a nation or as a message coming from outside the nation - international. As well, the 4-bit SSF determines the point code structure of the messages transmitted from the SGSN.

Example

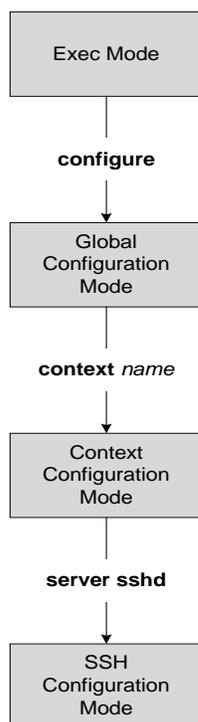

For messages being transmitted within a country, set the indicator to national with the following command.

```
ssf national
```

Chapter 216

SSH Configuration Mode Commands

The Secure Shell Configuration Mode is used to manage the SSH server options for the current context.

■ end

end

Exits the SSH server configuration mode and returns to the Exec mode.

Product

All

Privilege

Administrator, Config-administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the secure shell server configuration mode and returns to the context configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

listen

This command configures the SSH server in the current context to only listen for connections from the interface with the specified IP address. The default behavior is to listen on all interfaces.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
listen ip_address
```

```
no listen
```

```
no
```

Disable listening for a specific interface address and enable listening on all interfaces.

Usage

Use this command to configure the SSH server for the current context to only listen for connections from the interface with the specified IP address. Only one IP address may be set for listening.

Example

The following command specifies that the Server should only listen for connections in the interface with the IP address of 192.168.0.10:

```
listen 192.168.0.10
```

max servers

Configures the maximum number of SSH servers that can be started within any 60 second interval. If this limit is reached, the system waits two minutes before trying to start any more servers.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
max servers number
```

number

Default: 40

Specifies the maximum number of servers that can be spawned in any 60 second interval. *number* must be a value in the range from 1 to 100.

Usage

Set the number of servers to tune the system response as a heavily loaded system may need more servers to support the incoming requests.

The converse would be true as well in that a system can benefit by reducing the number of servers such that telnet services do not cause excessive system impact to other services.

Example

```
max servers 50
```

subsystem

Configures the system to perform file transfers using secure ftp (sftp) over ssh v2. Administrator users must be configured with the ftp attribute privilege to issue this command.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
subsystem { cli | sftp }
```

```
no subsystem { cli | sftp }
```

no

Disables either the sftp ssh file transfer method or disables access to the CLI over ssh.

cli

Default: Enabled

Configures the SSH system for the current context to allow access to the CLI.

sftp

Default: Disabled

Enables the SSH system for the current context to perform file transfers using secure ftp (sftp) over ssh v2.

Usage

Use this command to enable or disable file transfers using secure ftp over an ssh v2 tunnel. Also use this command to enable or disable access to the CLI over an SSH connection.

Example

The following command enables SFTP for the current context:

```
subsystem sftp
```

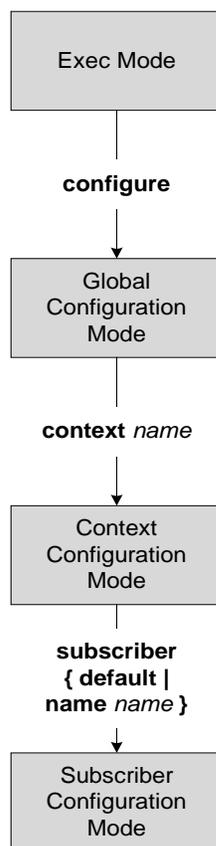

The following command disables access to the CLI through an SSH session for the current context:

```
no subsystem cli
```

Chapter 217

Subscriber Configuration Mode Commands

The Subscriber Configuration Mode is used to create local subscribers as well as to set default subscriber options for the current context.

aaa group

Configures a AAA server group for AAA functionality at the subscriber level.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] aaa group group_name
```

default aaa group

group_name

The AAA group to configure for authentication and/or accounting for the specific subscriber. *group_name* must be an alpha and/or numeric string of 1 through to 63 characters in length.

no

Disables the specified AAA group for the specific subscriber.

default

Sets/restores default AAA group specified at the context level or default subscriber profile.

Usage

Instead of having a single list of servers per context, this feature configures multiple server groups within a context and applies individual server group for subscribers in that context. Each server group consists of a list of AAA servers for each AAA function (accounting, authentication, charging, etc.).

Example

The following command applies the AAA server group *star1* to a subscriber within the specific context:

```
aaa group star1
```

The following command disables the AAA group for the specific subscriber:

```
no aaa group group_name
```

access-link ip-fragmentation

Configures IP fragmentation processing over the Access-link (\, GTP etc).

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
access-link ip-fragmentation { normal | df-ignore | df-fragment-and-icmp-notify }  
}
```

df-ignore

Default: Enabled

Ignore the DF bit setting. Fragment and forward the packet over the access link.

df-fragment-and-icmp-notify

Default: Disabled

Partially ignore the DF bit. Fragment and forward the packet, but also return an ICMP error message to the source of the packet. The number of ICMP errors sent like this is rate-limited to 1 ICMP error packet per second per session.

normal

Default: Disabled

Normal processing. Drop the packet and send an ICMP unreachable message to the source of packet. This is the default behavior.

Usage

If the IP packet to be forwarded is larger than the access-link MTU and if the DF (Don't Fragment) bit is set for the packet, then the fragmentation behavior configured by this command is applied. Use this command to fragment packets even if they are larger than the access-link MTU.

Example

Set fragmentation so that the DF bit is ignored and the packet is forwarded anyway by entering the following command:

```
access-link ip-fragmentation df-ignore
```

accounting-mode

This command sets the accounting mode for the current local subscriber configuration.

Product

PDSN, HA, ASN GW, S-GW

Privilege

Administrator

Syntax

```
accounting-mode { flow-based | gtp [ radius-diameter ] | none | radius-diameter
[ gtp ] | rf-style }
```

default accounting-mode

default

Sets the type of accounting to be performed for the current local subscriber to the default setting.

Default: **radius-diameter**

flow-based

Diameter flow-based accounting is enabled for the current local subscriber.

gtp [radius-diameter]

GTPP CDR RADIUS accounting is enabled for the current local subscriber. The **radius-diameter** keyword is available if both GTPP RADIUS and RADIUS-Diameter accounting are to be used.

none

Accounting is disabled for the current local subscriber and no charging records will be generated.

radius-diameter [gtp]

RADIUS-Diameter accounting is enabled for the current local subscriber. The **gtp** keyword is available if both GTPP RADIUS and RADIUS-Diameter accounting are to be used.

rf-style

Diameter Rf interface accounting is enabled for the current local subscriber.

Usage

This command specifies which protocol, if any, will be used to provide accounting for PDP contexts accessing the APN profile.

Use this command to enable or disable RADIUS/Diameter accounting for any subscribers that use the current local subscriber configuration.

If the **gtp** option is used, then GTPP RADIUS is used as configured in the Context Configuration mode or the AAA Server Group Configuration mode and GTPP charging records will be enabled.

If the **radius-diameter** option is used, either the RADIUS or the Diameter protocol is used as configured in the Context Configuration mode or the AAA Server Group Configuration mode.

RADIUS accounting can also be enabled and disabled at the context level with the **aaa accounting** command in the Context Configuration Mode. If RADIUS accounting is enabled at the context level, the **accounting-mode** command can be used to disable RADIUS accounting for individual local subscriber configurations.

If the accounting mode is set to **rf-style**, then BM will generate accounting records corresponding to AIMS RF.

Example

To disable accounting for the current subscriber, enter the following command:

```
accounting-mode none
```

active-charging bandwidth-policy

This command configures the bandwidth policy to be used for the subscriber.

Product

ACS

Privilege

Security Administrator, Administrator

Syntax

```
active-charging bandwidth-policy bandwidth_policy_name  
{ default | no } active-charging bandwidth-policy
```

default

Specifies that the default bandwidth policy configured in the rulebase be used for this subscriber.

no

Disables bandwidth control for this subscriber.

bandwidth_policy_name

Specifies name of the bandwidth policy.

bandwidth_policy_name must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage

Use this command to configure bandwidth policy to be used for subscribers.

Example

The following command configures a bandwidth policy named *standard* for the subscriber:

```
active-charging bandwidth-policy standard
```

active-charging rulebase

This command specifies the name of the rulebase to be used for this subscriber.

Product

ACS

Privilege

Security Administrator, Administrator

Syntax

```
active-charging rulebase rulebase_name
```

```
no active-charging rulebase
```

no

Removes the previously configured rulebase for the subscriber.

rulebase_name

Specifies name of the ACS rulebase.

rulebase_name must be the name of an ACS rulebase, and must be an alpha and/or numeric string of 1 through 63 characters in length.

Usage

This command specifies the name of the rulebase for specific subscriber (reals).
If the specified rulebase does not exist in the Active Charging service, the call will be rejected.

Example

The following command configures the ACS rulebase named *rule1* for the subscriber:

```
active-charging rulebase rule1
```

always-on

Once the idle timeout limit is reached, keep the current subscriber session connected as long as the subscriber is reachable.

Caution: When always-on is enabled, the subscriber must have an idle time-out period configured (default is 0, no time-out). Failure to configure an idle time-out results in a subscriber session that is indefinite in length.

Two timers and a counter are associated with this feature. Refer to the **timeout** command in this chapter and the **ppp echo-retransmit-timeout msec** and **ppp echo-max-retransmissions num_retries** commands.

Default: Disabled.

Product

PDSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

always-on

no always-on

no

Disables **always-on**. The user is disconnected after the idle time expires.

Usage

If this parameter is enabled for a subscriber, when the idle time-out limit is reached the subscribers IP/PPP session remains connected as long as the subscriber is reachable. This is true even if the airlink between the mobile device and the RN (Radio Node) is moved from active to dormant (inactive) status. When the idle timeout limit is reached, the PDSN determines availability using LCP keepalive messages. A response to these messages indicates that the “always-on” status should be maintained. Failure to respond to a predetermined number of LCP keepalive messages causes the PDSN to tear-down (disconnect) the subscriber session.

Example

Enable always on for the current subscriber by entering the following command:

```
always-on
```

asn nspid

This command specifies the network service provider (NSP) associated with a WIMAX subscriber in an ASN-GW service. When configured, the NSP ID is sent in the Access-Request and Accounting messages.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] asn nspid nsp_id
```

no

Removes/disables the configured identifiers for this network service provider in ASN-GW service.

asn nspid *nsp_id*

Specifies the network service provider for this subscriber. This enables the MS to discover all accessible NSPs, and to indicate the NSP selection during connectivity to the ASN.

Usage

Use this command to specify the NSP associated with a subscriber in an ASN-GW service. *nsp_id* is three bytes in HEX format. For example: FF-EE-01

Example

The following command specifies the NSP for a subscriber in an ASN service:

```
asn nspid 0F-01-FE
```

asn-header-compression-rohc

This command negotiates ROHC support for subscriber calls with AAA and WiMax. This configuration indicates the type of header compression supported and enabled on the ASN.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] asn-header-compression rohc
```

no

Removes/disables the configured identifiers for ROHC in ASN-GW service.

default

The default is *disabled*.

Usage

NAS uses this configuration to indicate and pack ROHC support the subscriber TLV in the WiMax-capability attribute in the Access Request. The ROHC header compression is applied only when the ROHC is supported on the ASNGW and ROHC support is indicated by the AAA.

asn-pdfid

This command configures the identifiers for packet data flow, service data flow, and service profile in an ASN-GW service.

Product

ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] asn-pdfid pdf_id asn-service-profile-id svc_profile_id asn-sdfid sdf_id
```

no

Removes/disables the configured identifiers for this subscriber in ASN-GW service.

asn-pdfid *pdf_id*

Specifies the an unique ASN Packet Data Flow identifier for this subscriber.
pdf_id must be an integer between 1 and 65535.

asn-service-profile-id *svc_profile_id*

Specifies an unique ASN Service Profile Identifier for this subscriber.
svc_profile_id is a preconfigured Service Profile Identifier configured in the Context Configuration Mode.

asn-sdfid *sdf_id*

Specifies the an unique ASN Service Data Flow identifier for this subscriber.
sdf_id must be an integer between 1 and 65535.

Usage

Use this command to configure subscriber profile for QoS parameters in an ASN-GW service. A maximum of 4 QoS profiles can be configured for a subscriber.

Example

The following command configures the QoS profile for a subscriber as PDF id 1, Service Profile id 3, and Service Data Flow id 2:

```
asn-pdfid 1 asn-service-profile-id 3 asn-sdfid 2
```

asn-policy

This command configures the identifiers for packet data flow, service data flow, and service profile in an ASN GW service.

Product

ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
asn-policy { classifiers downlink { strict | loose } | idle-mode { allow |
disallow } | auth-only {allow | disallow } }
```

```
[ no | default ] asn-policy idle-mode
```

```
[ default ] asn-policy classifiers downlink
```

no

Removes/disables the configured policy for this subscriber in ASN GW service.

default

Sets the ASN policy to default for this subscriber.

For downlink traffic classifier default policy is “loos” and for idle mode policy the default action is to allow idle mode operation in an ASN GW service.

idle-mode

Sets the idle mode policy for this subscriber in an ASN GW service.

allow

Default: enabled

Enables the policy for this subscriber to allow idle mode operation in an ASN GW service.

disallow

Default: disabled

Enable the policy for this subscriber to disallow idle mode operation in an ASN GW service.

classifiers downlink

Sets the classifier policy for all service flows coming from HA to FA for this subscriber’s matching classifier.

strict

Default: disabled

This option discards all the service flows coming from HA to FA and any other packets not matching to any of the classifiers set for this subscriber.

loose

Default: enabled

This option allows all the service flows coming from HA to FA and any other packet does not matching to any of the classifiers set for this subscriber and sent to the BS/MS over downlink flow

auth-only

Specifies whether the call is Auth only or not.

allow

Enables the policy for this subscriber to allow auth-only in an ASN GW service.

disallow

Default

Disables the policy for this subscriber to allow auth-only in an ASN GW service.

Usage

Use this command to configure subscriber policy to allow/disallow the idle mode operation or the downlink traffic flow for a subscriber in an ASN GW service.

For authentication configuration, the ASNGW supports the Initial Network Entry (INE) for Ethernet CS calls. The base station supports Ethernet CS traffic to the network. The INE procedure includes the Authentication of the service flows and IP-Address allocation through DHCP. Authentication is based on the Extensible Authentication Protocol (EAP).

This command allows MS to transition to idle mode with an ASN GW.

Example

The following command configures the policy to allow the idle mode for an MS with an ASN GW:

```
default asn-policy idle-mode
```

authorized-flow-profile-id

When a profile ID is requested by the Mobile Node (MN), this command sets the value that is authorized by the AGW.

Product

PDSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
authorized-flow-profile-id profile_id direction { bidirectional | forward | reverse }
```

```
no authorized-flow-profile-id profile_id
```

no

Remove the existing profile ID setting specified by *profile_id*. *profile_id* must be an integer from 0 through 65535.

profile_id

The profile ID number that is authorized for the current subscriber. *profile_id* must be an integer from 0 through 65535.

direction { **bidirectional** | **forward** | **reverse** }

This specifies in which data direction the profile ID should be applied.

- **bidirectional**: This profile ID pertains to both the forward and reverse directions.
- **forward**: This profile ID pertains to data going to the MN.
- **reverse**: This profile ID pertains to data coming from the MN.

Usage

Use this command to set the profile ID that the AGW will authorize for a subscriber.

Example

Set the profile ID for both directions to 3 for the current subscriber by entering the following command:

```
authorized-flow-profile-id 3 direction bidirectional
```

content-filtering category

This command enables/disables the specified preconfigured Category Policy Identifier for policy based Content Filtering support to the subscriber.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
content-filtering category policy-id cf_policy_id
```

```
no content-filtering category policy-id
```

no

Disables the configured category policy ID for content filtering support to the subscriber. This is the default setting.

```
category policy-id cf_policy_id
```

This command applies the content filtering category policy ID, configured in ACS Configuration Mode, to this subscriber.

cf_policy_id must be a category policy ID, and must be an integer from 1 through 4,294,967,295.

If the specified category policy ID is not configured in the ACS Configuration Mode, all packets will be passed regardless of the categories determined for such packets.

 **Important:** Category Policy ID configured through this mode overrides the Category Policy ID configured using the **content-filtering category policy-id** command in the ACS Rulebase Configuration Mode.

Usage

Use this command to enter the Content Filtering Policy Configuration Mode and to enable or disable the Content Filtering Category Policy ID for a subscriber.

 **Important:** If Content Filtering Category Policy ID is not specified here the similar command in the ACS Rulebase Configuration Mode determines the policy.

Up to 64 different policy identifier can be defined in a Content Filtering support service.

Example

The following command enters the Content filtering Policy Configuration Mode and enables the Category Policy ID 101 for Content Filtering support:

```
content-filtering category policy-id 101
```

■ content-filtering category

cscf core-service

CSCF/A-BG core service that maps to the current domain.

Product

SCM (CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

```
cscf core-service name name
```

```
no cscf core-service
```

```
cscf core-service name name
```

Specifies the name of the CSCF/A-BG core service.

name must be from 1 to 63 alpha and/or numeric characters.

```
no cscf core-service
```

Removes the CSCF/A-BG core service from the domain.

Usage

Use this command to map a CSCF/A-BG core service to the current domain.

Example

The following command creates a CSCF core service named *cs1*:

```
cscf core-service name cs1
```

The following command removes the CSCF core service from this domain:

```
no cscf core-service
```

cscf county-name

Assigns a Last Routing Option (LRO) profile county name to the subscriber for finding the correct Public Safety Answering Point (PSAP) during emergency calls.

Product

SCM (S-CSCF)

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] cscf county-name name
```

```
cscf county-name name
```

Specifies the LRO profile county name of the subscriber.

name must be an existing LRO profile county name and be from 1 to 127 alpha and/or numeric characters.

```
no
```

Removes the LRO profile county name from the subscriber.

Usage

Use this command to assign an LRO profile county name to the subscriber.

Example

The following command assigns county name *norfolk* to the subscriber:

```
cscf county-name norfolk
```

The following command removes county name *norfolk* from the subscriber:

```
no cscf county-name norfolk
```

cscf nat-applicable

Indicates if NAT (Network Address Translation) processing is required for this domain.

Product

SCM (CSCF/A-SBC)

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] cscf nat-applicable
```

no

Disables NAT processing for this domain.

Usage

Use this command to indicate whether NAT processing is required for this domain.

Example

The following command indicates NAT processing is required for this domain:

```
cscf nat-applicable
```

The following command disables NAT processing for this domain:

```
no cscf nat-applicable
```

cscf private-user-id

Assigns a private user identity to the subscriber.

Product

SCM (P-CSCF, S-CSCF, SIP Proxy)

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] cscf private-user-id user_id
```

no

Removed the private user identity of the subscriber.

```
cscf private-user-id user_id
```

Specifies the private user identity of the subscriber.

user_id must be from 1 to 127 alpha and/or numeric characters.

Usage

Use this command to assign a private user identity to the subscriber.

Example

The following command assigns a private user identity named *user007* to the subscriber:

```
cscf private-user-id user007
```

The following command removes private user identity named *user007* from the subscriber:

```
no cscf private-user-id user007
```

cscf session-template

Assigns a CSCF session template to the subscriber profile.

Product

SCM (P-CSCF, S-CSCF, SIP Proxy)

Privilege

Security Administrator, Administrator

Syntax

```
cscf session-template name name
```

```
no cscf session-template
```

```
cscf session-template name name
```

Specifies the name of the CSCF session template.

name must be an existing CSCF session template name and be from 1 to 79 alpha and/or numeric characters.

```
no cscf session-template
```

Removes the assignment of a session template to the subscriber profile.

Usage

Use this command to bind a CSCF session template to a subscriber profile.

Example

The following command assigns a CSCF session template named *template4* to the subscriber profile:

```
cscf session-template name template4
```

The following command removes the assignment of a session template to the subscriber profile:

```
no cscf session-template
```

data-tunneling ignore df-bit

This command controls the handling of the DF (Don't Fragment) bit present in the user IPv4/IPv6 packet for GRE, IP-in-IP tunneling used for the MIP data path. If this feature is enabled, and fragmentation is required for the tunneled user IPv4/IPv6 packet, then the DF bit is ignored and the packet is fragmented. Also the DF bit is not copied to the outer header. Default is enabled.

Product

PDSN, HA, FA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
data-tunneling ignore df-bit
```

```
no data-tunneling ignore df-bit
```

no

Disable this option. The DF bit in the tunneled IP packet header is not ignored during tunneling.

Usage

Use this command to configure a user so that during Mobile IP tunneling the DF bit is not ignored and packets are not fragmented.

Example

To disable fragmentation of a subscribers packets over a MIP tunnel even when the DF bit is present, enter the following command:

```
no data-tunneling ignore df-bit
```

dcca origin host

This command is obsolete. Refer to the **dcca origin endpoint** command.

dcca origin endpoint

This command is obsolete. To configure the Diameter Credit Control Origin Endpoint, in the Credit Control Configuration Mode, use the **diameter origin endpoint** command.

dcca peer-select

Specifies the Diameter credit control primary and secondary peer for credit control.

Product

ACS

Privilege

Security Administrator, Administrator

Syntax

```
dcca peer-select peer host_name [ realm realm_name ] [ secondary-peer host_name [ realm realm_name ] ]
```

```
no dcca peer-select
```

no

Removes the previously configured Diameter credit control peer selection.

peer *host_name*

A unique name that you specify for the peer.

peer_name must be an alpha and/or numeric string of from 1 through 127 characters. *peer_name* allows punctuation marks.

secondary-peer *host_name*

Specifies a back-up host that is used for fail-over processing. When the route-table does not find an AVAILABLE route the secondary host performs a fail-over processing.

realm *realm_name*

The *realm_name* must be an alpha and/or numeric string of 1 through 127 characters in length. The realm may typically be a company or service name. *realm_name* allows punctuation characters.

Usage

Use this command to select a Diameter credit control peer and realm.

WARNING: This configuration completely overrides all instances of **diameter peer-select** that have been configured with in the Credit Control Configuration Mode for an Active Charging service.

Example

The following command selects a Diameter credit control peer named *test* and a realm of *companyx*:

```
dcca peer-select peer test realm companyx
```

default

Restores the default value for the option specified for the current subscriber.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
default { access-link ip-fragmentation | accounting-mode | data-tunneling ignore
df-bit | idle-timeout-activity dormant-downlink-data | inter-pdsn-handoff | ip {
alloc-method | allowed-dscp | header-compression | hide-service-address |
multicast discard | qos-dscp | source-validation } | loadbalanace-tunnel-peers |
long-duration-action | mobile-ip { home-agent | mn-aaa-removal-indication | mn-
ha-hash-algorithm | reverse-tunnel | security-level | send { dns-address |
terminal-verification } } | permission | ppp { always-on-vse-packet | data-
compression { mode | protocols } | keepalive | min-compression-size | mtu } |
radius accounting interim interval-timeout | timeout { absolute | idle } }
```

access-link ip-fragmentation

Sets the method for fragmenting packets over the MN access link to its default of normal. Drop the packet and send ICMP unreachable to the source of packet.

accounting-mode

Enables Radius accounting for the current local subscriber configuration.

data-tunneling ignore df-bit

Sets this option to the default behavior, which is to send an *ICMP unreachable - need to frag* message back to the sender and drop the packet, in the case that fragmentation is required but the DF bit is set.

idle-timeout-activity dormant-downlink-data

Sets this option to the default behavior. When downlink data packets are transmitted to the Mobile node and the session is in dormant mode the session idle timer is reset.

inter-pdsn-handoff

During a handoff from one PDSN to another, if the Mobile requests an IP address of 0.0.0.0 or a mismatched IP address the PDSN will not disconnect the session immediately. The PDSN tries to assign the proposed address of the session in the IPCP configuration NAK.

```
ip { | allowed-dscp | header-compression | hide-service-address |
multicast discard | qos-dscp | source-validation | user-datagram-tos copy
}
```

allowed-dscp: resets the allowed DSCP parameters to the system defaults: class none, max-class be.

hide-service-address: specifies the default setting for hide the ip-address of the service from the subscriber. Default is Disabled
multicast discard: configures the default multicast settings which is to discard PDUs
qos-dscp: sets the quality of service setting to the system default.
source-validation: Specifies the default IP source validation. Default is Enabled.
user-datagram-tos copy: Disable copying of the IP TOS octet value to all tunnel encapsulation IP headers.

loadbalance-tunnel-peers

Sets the tunnel load balancing algorithm to the system default.

long-duration-action

Sets the action that is taken when the long duration timer expires to the default: detection.

```
mobile-ip { home-agent | mn-aaa-removal-indication | mn-ha-hash-algorithm
| reverse-tunnel | security-level | send { dns-address | terminal-
verification } }
```

allow-aaa-address-assignment: Disables the FA from accepting a home address assigned by an AAA server.

home-agent: Sets home agent IP address to its default of 0.0.0.0.

match-aaa-assigned-address: Disables the FA validating the home address in the RRQ against the one assigned by AAA server.

mn-aaa-removal-indication: Sets this parameter to its default of disabled.

mn-ha-hash-algorithm: Sets the encryption algorithm to the default of hmac-md5.

reverse-tunnel: Sets this parameter to its default of enabled.

security-level: Sets this parameter to its default of none.

send dns-address: Disables the HA from sending the DNS address NVSE in the RRP.

send terminal-verification: Disables the FA from sending the terminal verification NVSE in the RRQ.

permission

Restores the subscriber's service usage defaults.

```
ppp { always-on-vse-packet | data-compression { mode | protocols } | ip-
header-compression negotiation | keepalive | min-compression-size | mtu }
```

Sets the point-to-point protocol option defaults.

always-on-vse-packet: Re-enables the PDSN to send special 3GPP2 VSE PPP packets to the Mobile Node with a max inactivity timer value for always on sessions. This configuration is applicable only for PDSN sessions.

data-compression { mode | protocols }: restores the default value for either the data compression **mode** or compression **protocols** as follows:

- mode stateless
- all protocols enabled

ip-header-compression negotiation: sets the IP header compressions negotiation to the system default: force.

keepalive: sets the subscriber's PPP keep alive option to the system default: 30 seconds.

min-compression-size: restores the PPP minimum packet size for compression: 128 octets.

mtu: sets the maximum message transfer unit packet size to the system default: 1500 octets.

```
radius accounting interim interval-timeout
```

Disables the RADIUS accounting interim interval for the current subscriber.

```
timeout [ absolute | idle | long-duration ]
```

When a keyword is entered, this command resets the specified timeout to the system default: 0. When no keyword is specified, all timeouts are reset to the system defaults: 0.

Usage

Reset subscriber data to the system defaults. This is useful in setting the subscriber back to the basic values to possibly aid in trouble shooting or tuning a subscriber's access and options.

Example

```
default ip qos-dscp  
default permission  
default data-compression mode
```

dns

Configures the domain name servers for the current subscriber.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] dns { primary | secondary } ip_address
```

no

Indicates the IP address is to be removed as either a primary or secondary domain name server.

primary | secondary

primary: Indicates the primary domain name server for the subscriber is to be updated.

secondary: Indicates the secondary domain name server for the subscriber is to be updated.

ip_address

Specifies the IP address of the domain name server.

Usage

Set the subscriber DNS server lists as not all users will have the same set of servers.

Example

```
dns primary 1.2.3.4
```

```
no dns primary 1.2.3.4
```

```
dns secondary 1.2.5.6
```

```
no dns secondary 1.2.5.6
```

eap

This command specifies the lifetime for a master session key (MSK) for extensible authentication protocol (EAP) authentication.

Product

ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] eap msk-lifetime dur
```

default

Sets the lifetime duration to default value of 3600 seconds for master session key.

msk-lifetime *dur*

Specifies the lifetime duration on Master session key (MSK) in seconds for a WiMAX subscriber EAP authentication.

dur is the lifetime value in seconds and must be an integer from 60 through 65535.

Usage

This command is used to set the lifetime for MSK in EAP authentication for WiMAX subscriber.

Example

The following command sets the lifetime for MSK key to 4800 seconds for a WiMAX subscriber through EAP authentication:

```
eap msk-lifetime 4800
```

encrypted password

Designates use of password encryption.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
encrypted password password
```

password

password is the encrypted password and must be an alpha and/or numeric string of from 1 to 63 characters.

Usage

This command is normally used only inside configuration files.

Example

The following command sets an encrypted password of *qsdf12d4*:

```
encrypted password qsdf12d4
```

■ end

end

Exits the subscriber configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the subscriber configuration mode and returns to the context configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

■ external-inline-server

external-inline-server

This is a restricted command.

firewall policy

 **Important:** This command is only available in StarOS 8.0. In StarOS 8.1 and later, this configuration is available in the ACS Rulebase Configuration Mode.

This command enables/disables Stateful Firewall support for the subscriber.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
firewall policy firewall-required
```

```
{ default | no } firewall policy
```

no

Disables Stateful Firewall support for this subscriber.

default

Configures the default setting for Stateful Firewall support.
Default: Disabled

firewall-required

Enables Stateful Firewall support for this subscriber.

Usage

Use this command to enable or disable Stateful Firewall support for this subscriber.

 **Important:** Unless Stateful Firewall support for this subscriber is enabled using this command, firewall processing for this subscriber is disabled.

 **Important:** If firewall is enabled, and the rulebase has no firewall configuration, Stateful Firewall will cause all packets to be discarded.

Example

The following command enables Stateful Firewall support for this subscriber:

```
firewall policy firewall-required
```

The following command disables Stateful Firewall support for this subscriber:

■ firewall policy

```
no firewall policy
```

fw-and-nat policy

 **Important:** This command is customer-specific and is only available in StarOS 8.1. This command must be used to configure the Policy-based Firewall-and-NAT feature.

This command configures the Firewall-and-NAT policy for the subscriber.

Product

FW, NAT

Privilege

Security Administrator, Administrator

Syntax

```
fw-and-nat policy fw_nat_policy  
{ default | no } fw-and-nat policy
```

default

Specifies that the default Firewall-and-NAT policy configured in the rulebase be used for the subscriber.

no

Disables Firewall and NAT processing for the subscriber.

fw_nat_policy

Specifies the Firewall-and-NAT policy for the subscriber.

fw_nat_policy must be an alpha and/or numeric string of 1 through 63 characters in length. Note that this policy will override the **default Firewall-and-NAT policy** configured in the ACS rulebase.

Usage

Use this command to configure the Firewall-and-NAT policy for subscribers. Note that the policy configured in the subscriber mode will override the default policy configured in the ACS rulebase. If a policy is not configured in the subscriber mode, the default policy configured in the ACS rulebase will be applied.

Example

The following command configures a Firewall-and-NAT policy named *standard* for the subscriber:

```
fw-and-nat policy standard
```

idle-timeout-activity

Defines whether downlink (towards Mobile Node) data packets transmitted when the session is dormant is treated as activity for the idle-timer (inactivity timer).

By default, downlink data transmitted over a dormant session restarts the idle-timer for that session (it is treated as activity for the session).

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] idle-timeout-activity dormant-downlink-data
```

no

Dormant mode downlink data is not treated as activity for the session idle-timer. The session idle timer is not reset.

Usage

Use this command to disable or re-enable restarting the session idle timer when downlink data packets are transmitted to the Mobile Node when the session is in dormant mode.

Example

Use the following command to disable restarting the session idle timer when downlink data packets are transmitted to the Mobile Node when the session is in dormant mode:

```
idle-timeout-activity dormant-downlink-data
```

Use the following command to re-enable restarting the session idle timer when downlink data packets are transmitted to the Mobile Node when the session is in dormant mode:

```
no idle-timeout-activity dormant-downlink-data
```

ims application-manager

Specifies the application manager for the subscriber.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ims application-manager { domain-name domain-name | ipv4-address ipv4-address }
```

no

Disables the IMS application manager for this subscriber.

domain-name *domain-name*

Specifies the domain name of the application manager.

domain-name must be from 1 to 63 alpha and/or numeric characters.

ipv4-address *ipv4-address*

Specifies the IPv4/IPv6 address of the application manager.

Usage

The `ims application-manager` address is returned by HA to MN in DHCP Ack when it receives the DHCP inform from an AIMS subscriber.

Example

```
ims application-manager domain-name domain23ims application-manager ipv4-address 192.168.23.1
```

ims-auth-service

This command applies an IMS authorization service to a subscriber in a network access service (PDSN or GGSN service) for Gx/Ty interface support and functionality.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] ims-auth-service auth_svc_name
```

default

Sets / Restores default state of IMS authorization service, disabled or as specified at the context or network access service level or in subscriber template.

no

Disables the applied IMS authorization service for specific subscriber.

auth_svc_name

Specifies the name of IMS authorization service name that is used for Ty interface support for specific subscriber.

auth_svc_name must be from 1 to 63 alpha and/or numeric characters preconfigured within the same context of this subscriber.

Usage

This feature provides the IMS authorization service configuration for Gx/Ty interface in IMS service node.

Example

Following command applies a previously configured IMS authorization service named *ims_interface1* to a subscriber within the specific context.

```
ims-auth-service ims_interface1
```

inter-pdsn-handoff

Configure the system to enforce the MN's use of its assigned IP address during IPCP negotiations resulting from inter-PDSN handoffs.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] inter-pdsn-handoff require ip-address
```

no

Disables the rejecting of sessions when the MN uses a non-allocated IP address during IPCP re-negotiations.

Usage

This command is used to configure the system to reject sessions that are re-negotiating IPCP after an inter-PDSN handoff if the IP address they propose does not match the one initially provided by the PDSN. The session would be rejected even if the proposed address was 0.0.0.0.

If this parameter is disabled, the PDSN will attempt to re-assign the IP address initially provided.

Example

To set the PDSN to not allow a mismatched IP address during a PDSN to PDSN handoff of a MIP call, use the following command:

```
inter-pdsn-handoff require ip-address
```

To set the PDSN so that it will not disconnect the session immediately, if the Mobile requests an IP address of 0.0.0.0 or a mismatched IP address after inter-pdsn handoff, use the following command:

```
no inter-pdsn-handoff require ip-address
```

ip access-group

Configures IP access group for the current subscriber.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip access-group group_name [ in | out ]
```

no

Indicates the access group specified is to be cleared from the subscribers configuration.

group_name

Specifies the name of the IPv4/IPv6 access group. *acl_group_name* is a configured ACL group and must be an alpha and/or numeric string of 1 to 79 characters.

in | out

Default: both (in and out)

Specifies the access-group as either inbound or outbound by the keywords **in** and **out**, respectively. If neither of these key words is specified, the command associates the *group_name* access group with the current subscriber for both inbound and outbound access.

Usage

Set the subscriber access group to manage the access control for subscribers as a logical group.

Example

The following command associates the *sampleGroup* access group with the current subscriber for both inbound and outbound access:

```
ip access-group sampleGroup
```

The following removes the outbound access group flag for *sampleGroup*:

```
no ip access-group sampleGroup out
```

ip address

Configures a static IP address for use by the subscriber.

Product

PDSN, GGSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip address ip_address netmask
```

no

Removes a previously configured IP address assignment.

ip_address

The IP address assigned to the subscriber.

netmask

The subnet mask that corresponds to the assigned IP address.

Usage

Use this command to assign a static IP address to the subscriber. This address will be used each time the subscriber establishes data sessions.

Example

The following command configures a static IP address of *192.168.1.15* with a subnet mask of *255.255.255.0* to the subscriber:

```
ip address 192.168.1.15 255.255.255.0
```

ip address pool

Configures IP address pool properties for the subscriber.

Product

PDSN, GGSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip address pool name pool_name
```

no

Removes a previously configured static address.

name *pool_name*

Specifies the IP address pool or IP address pool group from which the subscribers IP address is assigned.

pool_name must be the name of an existing IP pool or IP pool group and from 1 to 31 alpha and/or numeric characters.

Usage

Use this command to specify the name of an IP address pool configured on the system from which IP addresses are to be dynamically assigned to sessions from this subscriber.

This command can be issued multiple times to specify multiple address pools for the subscriber. If multiple pools are specified, addresses are assigned for subscriber sessions from the pools based on the order in which the pools were configured.

If an address can not be provided from the first-specified pool for whatever reason, the system attempts to assign an address from the second-specified pool, and so on. This operation is independent of the priorities configured for the pools. For example, if pool1 was specified for the subscriber first, and pool2 second, the system always attempts to assign addresses from pool1. If an address can not be assigned from pool1 (i.e. all addresses are in use), the system then attempts to assign an address from pool2.

Example

The following command configures the subscriber to receive IP addresses from an IP address pool named *public1*:

```
ip address pool name public1
```

ip address secondary-pool

Configures secondary IP address pool properties for the subscriber to provide multiple IP host configuration behind one WiMAX CPE.

Product

ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip address secondary-pool name aux_pool_name
```

no

Removes a previously configured auxiliary pool named *aux_pool_name* for multiple host support in ASN GW service.

name *aux_pool_name*

Specifies the secondary/auxiliary IP address pool or IP address pool group from which the IP address is assigned to host behind a WiMAX CPE having primary IP address.

pool_name must be the name of an existing IP pool or IP pool group and from 1 to 31 alpha and/or numeric characters.

Usage

Use this command to specify the name of an IP address pool configured on the system from which IP addresses are to be dynamically assigned to host behind a WiMAX CPE for multiple host session support. This command designates the IP address to secondary hosts from locally configured secondary IP address pool. To enable multiple host support behind a WiMAX CPE and configure maximum number of supported hosts use **secondary-ip-host** command in ASN Gateway Service Configuration mode.

Example

The following command configures the subscriber to receive IP addresses from a secondary IP address pool named *auxiliary1* for secondary hosts behind the WiMAX CPE:

```
ip address secondary-pool name auxiliary
```

ip allowed-dscp

This command sets the Quality of Service (QoS) Differentiated Services (DiffServ) marking that a subscriber session is allowed. This is disabled by default.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip allowed-dscp class class max-class maxclass [ rt-marking marking ]
```

```
no ip allowed-dscp class
```

```
no ip allowed-dscp class
```

Resets the parameters to the defaults: class none, max-class **be**. This indicates that all packets are let through without any dscp checking

```
class class
```

This parameter specifies the Differentiated Services Codepoint (DSCP) class that the subscriber session may mark its packets with. If the subscriber sessions packets request a code point class higher than the code point class specified, the PDSN service re-marks the packets with the QOS-DSCP value specified by the **ip qos-dscp** command.

Default: none

class must be one of the following;

a: packets with AF DSCPs are allowed

e: packets with EF DSCP are allowed

o: packets for experimental or local use are allowed

ae: packets with AF and EF DSCPs are allowed

ao: packets with AF DSCPs or packets for experimental or local use are allowed

eo: packets with EF DSCPs or packets for experimental or local use are allowed

aeo: packets with AF or EF DSCPs or packets for experimental or local use are allowed

none: only the **be** and **sc1** through **sc7** code points are allowed

```
max-class maxclass
```

This parameter specifies the maximum code point that a subscriber session may mark its packets with. The subscriber sessions packets must be marked with a code point equal to or less than the code point specified. If the subscriber sessions packets request a code point higher than the code point specified, the PDSN service re-marks the packets with the QOS-DSCP value specified by the lower of the max-class and the **ip qos-dscp** command.

The list below lists the code points from lowest to highest precedence. For example, if the **maxclass** is set to af22, that becomes the maximum code point that the subscriber session may mark its packets with and only **be**, **af13**, **af12**, **af11**, **af23**, and **af22** are allowed. If a subscriber session marks its packets with anything after af22 in this list, the PDSN service re-marks the packets with the QOS-DSCP value specified by the lower of the maxclass and the **ip qos-dscp** command.

If class is set to none only the be and sc1 through sc7 codepoints are allowed. For example; if **class** is set to none and you set **max-class** to **sc1**, only the **sc1** and **be** codepoints are allowed.

Default: **be**

maxclass must be one of the following;

be: best effort forwarding
af13: assured Forwarding 13
af12: assured Forwarding 12
af11: assured Forwarding 11
af23: assured Forwarding 23
af22: assured Forwarding 22
af21: assured Forwarding 21
af31: assured Forwarding 31
af32: assured Forwarding 32
af33: assured Forwarding 33
af41: assured Forwarding 41
af42: assured Forwarding 42
af43: assured Forwarding 43
ef: expedited forwarding
sc1: selector class 1
sc2: selector class 2
sc3: selector class 3
sc4: selector class 4
sc5: selector class 5
sc6: selector class 6
sc7: selector class 7

rt-marking *marking*

This parameter is used for Mobile IP (MIP) reverse tunnels. When a MIP sessions packets do not have a DSCP marking, the Foreign Agent (FA) marks the packets with the value specified by **rt-marking** *marking*.

If the MIP sessions packets have a DSCP marking, the marking is subjected to the conformance rules for the values of class and max-class, then the final DSCP marking is copied from the inner IP header to the outer IP header.

Default: **be**

marking must be one of the following;

be: best effort forwarding
af11: assured Forwarding 11
af12: assured Forwarding 12
af13: assured Forwarding 13
af21: assured Forwarding 21
af22: assured Forwarding 22
af23: assured Forwarding 23
af31: assured Forwarding 31
af32: assured Forwarding 32
af33: assured Forwarding 33
af41: assured Forwarding 41
af42: assured Forwarding 42
af43: assured Forwarding 43
ef: expedited forwarding
sc1: selector class 1
sc2: selector class 2
sc3: selector class 3
sc4: selector class 4

■ ip allowed-dscp

sc5: selector class 5

sc6: selector class 6

sc7: selector class 7

Usage

Use this command to configure Quality of Service (QoS) for a subscriber session to allow a Differentiated Services (DiffServ) Code Point (DSCP) marker in the header of each IP packet that prompts network routers to apply differentiated grades of service to various packet streams.

This command uses **class** and type of marker (**rt-marking** for reverse tunnels) for configuration with **max-class** maximum code point that a subscriber session may mark its packets with.

Example

The following command will allow *o* packets for experimental or local use with best effort forwarding *be*:

```
ip allowed-dscp class o max-class be
```

ip context-name

Configures context to assign the subscriber to upon authentication. The context assigned to is considered the destination context which provides the configuration options for the services the subscriber is allowed to access.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip context-name name
```

no

Removes the current assigned context from the subscriber's data.

name

Specifies the name of the context to assign the subscriber to once authenticated. *name* must be from 1 to 79 alpha and/or numeric characters.

Usage

Set the subscriber IP context to a common context when all subscribers from one or more contexts will use the same egress context.

Example

```
ip context-name sampleName
```

```
no ip context-name sampleName
```

ip header-compression

Configures the IP packet header compression options for the current subscriber. Although this command configures IP header compression algorithms, the IPCP negotiations determine when the header compression algorithm is applied.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip header-compression { rohc [ any [ mode { optimistic | reliable |
unidirectional } ] | cid-mode { { large | small } [ marked-flows-only | max-cid
| max-hdr value | mrru value ] } | marked flows-only | max-hdr value | mrru
value | downlink | uplink ] | vj } +
```

```
[ default | no ] ip header-compression
```

default

Restores this command's default setting to the Van Jacobsen (VJ) header compression algorithm.

no

Disables all IP header compression.

```
rohc [ any [ mode { optimistic | reliable | unidirectional } ] | cid-mode
{ { large | small } [ marked-flows-only | max-cid | max-hdr value | mrru
value ] } } | marked flows-only | max-hdr value | mrru value | downlink |
uplink ]
```

Specifies that the Robust Header Compression (ROHC) algorithms is used for data.

 **Important:** ROHC is only supported for use with the PDSN.

any: Apply ROHC header compression in both the uplink and downlink directions.

mode { optimistic | reliable | unidirectional }:

- **optimistic:** Sets the ROHC mode to Bidirectional Optimistic mode (O-mode). In this mode packets are sent in both directions. A feedback channel is used to send error recovery requests and (optionally) acknowledgments of significant context updates from decompressor to compressor. Periodic refreshes are not used in the Bidirectional Optimistic mode.
- **reliable:** Sets the ROHC mode to Bidirectional Reliable mode (R-mode). This mode applies an intensive usage of a feedback channel and a strict logic at both the compressor and the decompressor that prevents loss of context synchronization between the compressor and the decompressor. Feedback is sent to acknowledge all context updates, including updates of the sequence number field.
- **unidirectional:** Sets the ROHC mode to Unidirectional mode (U-mode). With this mode packets are sent in one direction only, from the compressor to the decompressor. This mode therefore makes

ROHC usable over links where a return path from the decompressor to the compressor is unavailable or undesirable.

cid-mode { { **large** | **small** } [**marked-flows-only** | **dm** | **max-hdr value** | **mrru value**] }: Specifies the ROHC packet type to be used.

- **large** | **small** [**marked-flows-only** | **max-cid** | **max-hdr value** | **mrru value**]: Defines the ROHC packet type as large or small and optionally sets the following parameters for the packet type selected:
 - **marked-flows-only**: Specifies that ROHC is to be applied only to marked flows.
 - **max-cid integer**: Default: 0 The highest context ID number to be used by the compressor. *integer* must be an integer from 0 through 15 when small packet size is selected and must be an integer from 0 through 31 when large packet size is selected.
 - **max-hdr value**: Specifies the maximum header size to use. Default: 168. *value* must be an Integer from 0 through 65535.
 - **mrru value**: Specifies the maximum reconstructed reception unit to use. Default: 65535. *value* must be an Integer from 0 through 65535.

marked-flows-only: Specifies that ROHC is to be applied only to marked flows.

max-hdr value: Specifies the maximum header size to use. Default: 168. *value* must be an Integer from 0 through 65535.

mrru value: Specifies the maximum reconstructed reception unit to use. Default: 65535. *value* must be an Integer from 0 through 65535.

downlink: Apply the ROHC algorithm only in the downlink direction.

uplink: Apply the ROHC algorithm only in the uplink direction.

Important: When ROHC is enabled for downlink or uplink only the operational mode is Unidirectional.

vj

Specifies that the VJ algorithm is used for header compression.

+

Either one or both of the keywords may be entered in a single command.

If both **vj** and **rohc** are specified, **vj** must be specified first.

Important: If both VJ and ROHC header compression are specified, the optimum header compression algorithm for the type of data being transferred is used for data in the downlink direction.

Usage

Header compression can be used to provide a higher level of security in IP traffic enhance bandwidth usage and lower bit errors.

By default the header compression algorithm is set to **vj**.

Example

The following command disables all IP packet header compression:

```
no ip header-compression
```

The following command sets IP header compression to default vj algorithm:

```
default ip header-compression
```

The following command also sets the IP header compression to the vj algorithm:

```
ip header-compression vj
```

The following command enables the Internet Protocol Control Protocol (IPCP) to determine which protocol is the optimum algorithm for data in the downlink direction and use either VJ or ROHC as needed:

```
ip header-compression vj rohc
```

The following command enables ROHC for the downlink direction only:

```
ip header-compression rohc downlink
```

The following command enables ROHC in any direction using Bidirectional Optimistic mode:

```
ip header-compression rohc any mode Optimistic
```

ip hide-service-address

Hide the IP address of the service from the subscriber.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip hide-service-address
```

no

Disable this commands function. This is the default behavior.

Usage

Use this command to prevent subscribers from using traceroute to discover the network addresses that are in the public domain and configured on services. This prevent users from pinging such addresses.

ip local-address

Configures the local-side IP address of the subscriber's point-to-point connection.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip local-address ip_address
```

```
no ip local-address
```

no

Removes a previously configured IP local-address.

ip_address

Specifies an IP address configured in a destination context on the system through which a packet data network can be accessed.

Usage

This parameter specifies the IP address on the system that the MS uses as the remote-end of the PPP connection. If no local address is configured, the system uses an "unnumbered" scheme for local-side addresses.

Example

The following command configures a local address of 192.168.1.23 for the MS:

```
local-address 192.168.1.23
```

ip multicast discard

Configures the IP multicast discard packet behavior.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip multicast discard
```

no

Removes a previously configured IP multicast discard.

Usage

This command specifies if IP multicast discard is enabled or disabled.

ip qos-dscp

Configures quality of service options for the current subscriber using the differentiated services code point method. This is disabled by default.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip qos-dscp option
```

```
no ip qos-dscp
```

no

Sets the quality of service option to its default value.

option

Default: be

Specifies the subscriber's per hop quality of service setting as one of:

- af11 (assured Forwarding 11)
- af12 (assured Forwarding 12)
- af13 (assured Forwarding 13)
- af21 (assured Forwarding 21)
- af22 (assured Forwarding 22)
- af23 (assured Forwarding 23)
- af31 (assured Forwarding 31)
- af32 (assured Forwarding 32)
- af33 (assured Forwarding 33)
- af41 (assured Forwarding 41)
- af42 (assured Forwarding 42)
- af43 (assured Forwarding 43)
- be (best effort forwarding)
- ef (expedited forwarding)

Usage

Set the quality of service for a subscriber based upon the service level agreements.

Example

```
ip qos-dscp ef
```

```
no ip qos-dscp
```

ip route

Configures the static route to use to reach the subscriber's network.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip route ip_address ip_mask [ gateway_address ]
```

no

Removes the configured route information from the subscriber data.

ip_address

Specifies the target IP address for which the route information applies.

ip_mask

Specifies the networking mask for the route.

1 bits in the *ip_mask* indicate that bit position in the *ip_address* must also have a value of 1.

0 bits in the *ip_mask* indicate that bit position in the *ip_address* does not need to match, i.e., the bit can be either a 0 or a 1.

For example, if the IP address and mask were specified as 172.168.10.0 and 255.255.255.224, respectively, the network mask will be 172.168.0.0 (obtained by logically ANDing the IP address with the IP mask).

gateway_address

Default: assigned remote IP address will be used as the gateway address.

Specifies the IP address of the next hop gateway for the route.

Usage

The static routes are also known as framed IP routes for subscribers. Static routes are typically applicable for subscribers connecting via other networks or when the mobile device acts as a gateway to a network on the far side of the device.

For example, if the mobile device is assigned IP address 1.2.3.4 and it acts as a gateway for the network 10.2.3.0 (with a network mask of 255.255.255.0) a static route would be configured with the *ip_address* being 10.2.3.0, *ip_mask* being 255.255.255.0, and *gateway_address* being 1.2.3.4.

Example

```
no ip route 1.2.3.4 1.2.0.0
```

```
no ip route 1.2.3.4 1.2.0.0 1.2.255.254
```

ip source-validation

Enables/disables packet source validation for the current subscriber. Source validation requires the source address of received packets to match the IP address assigned to the subscriber (either statically or dynamically) during the session.

If an incorrect source address is received from the mobile node, the system attempts to renegotiate the PPP session. The parameters for IPsource validation can be set by the **ip source-violation** command.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip source-validation
```

no

Disables source validation.

Usage

Source validation is useful if packet spoofing is suspected or for verifying packet routing and labeling within the network.

Example

The following command enables IP source validation:

```
ip source-validation
```

The following command disables IP source validation:

```
no ip source-validation
```

ip user-datagram-tos copy

This CLI controls copying of IP TOS octet value from IPv4/IPv6 datagrams to the IP header in tunnel encapsulation. This is disabled by default.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
ip user-datagram-tos copy [ access-link-tunnel | both | data-tunnel ]
```

```
no ip user-datagram-tos copy
```

no

Disable copying of the IP TOS octet value to all tunnel encapsulation IP headers.

access-link-tunnel

Copy the IP TOS octet value to the tunnel encapsulation IP header on the access side (RP) tunnel.

both

Use both access-link-tunnel and data-tunnel.

data-tunnel

Copy the IP TOS octet value to the tunnel encapsulation IP header on the MIP data tunnel or L3 tunnel (IP-in-IP, GRE).

Usage

Use this command to enable the copying of the IP TOS octet value to the tunnel encapsulation IP header. This functionality will enable PCF to detect special TOS marking in the outer IP header of A11 packets and to identify certain packets as QChat control messages. The BSC/PCF must give higher priority to QChat control messages.

Example

Enable copying of the IP TOS octet value to the tunnel encapsulation IP header for the access side tunnel by entering the following command;

```
ip user-datagram-tos copy access-link-tunnel
```

Disable copying of the IP TOS octet value to all tunnel encapsulation IP headers by entering the following command;

```
no ip user-datagram-tos copy
```

ip vlan

Configures subscriber-to-Virtual LAN (VLAN) associations.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
ip vlan vlan-id
```

```
[ default | no ] ip vlan
```

default

Resets the vlan ID to the default setting.

no

Disables the vlan ID for the subscriber.

vlan-id

Is the vlan ID that is associated with the IP address for that session. *vlan-id* is an integer between 1 and 4094.

Usage

This command configures the subscriber vlan ID which is used with the assigned address for the subscriber session to receive packets. If the IP pool from which the address is assigned is configured with a vlan ID, then this subscriber configured vlan ID overrides it.

Subscriber traffic can be routed to specific VLANs based on the configuration of their user profile. Using this functionality provides a mechanism for routing all traffic from a subscriber over the specified VLAN. All packets destined for the subscriber must also be sent using only IP addresses valid on the VLAN or they will be dropped.

Example

Set the vlan ID to the default setting by entering the following command:

```
default ip vlan
```

ipv6 access-group

Configures the IPv6 access group for a subscriber.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
ipv6 access-group name [ in | out ]
```

in

Defines the access group as inbound.

out

Defines the access group as outbound.

Usage

Used to create an access group for a subscriber.

Example

The following command provides an example of an IPv6 access group with the name *list_1*:

```
ipv6 access-group list_1
```

ipv6 address

Configures a static IP address for use by the subscriber.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ipv6 address { prefix address | prefix-pool name }
```

no

Deletes a previously configured ipv6 address.

prefix

Specifies a static IPv6 address.

prefix-pool

Specifies an IPv6 prefix pool name.

Usage

Use this command to assign a static IPv6 address to the subscriber. This address will be used each time the subscriber establishes data sessions.

Example

The following command configures a static IP address of 1:1:1:1:1:1:1:1 with a length of 24 to the subscriber:

```
ipv6 address 1:1:1:1:1:1:1:1/24
```

ipv6 dns

Configures the IPv6 Domain Name Service (DNS) servers.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ipv6 dns { primary | secondary } { ipv6_dns_address }
```

no

Deletes a previously configured DNS server.

primary

Configures the primary DNS server for the subscriber.

secondary

Configures the secondary DNS server for the subscriber. Only one secondary DNS server can be configured.

ipv6_dns_address

Configures the IP address of the DNS server.

Usage

DNS servers are configured on a per subscriber basis. This allows each subscriber to use specific servers.

Example

The following command provides an example of setting the primary IPv6 DNS server:

```
ipv6 dns primary 1:1:1:1:1:1:1:1
```

ipv6 dns-proxy

Configures the domain name server proxy for the current subscriber.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] ipv6 dns-proxy
```

default

Disables the IPv6 DNS proxy functionality for a subscriber.

no

Removes the pre-enabled functionality of IPv6 DNS proxy for subscriber.

dns-proxy

Enables IPv6 DNS proxy functionality for a subscriber. If the functionality enabled, PDSN will act as a proxy DNS server.

Default: disabled.

Usage

Used to enable/disable IPv6 DNS proxy for the subscriber. When enabled, the PDSN acts as a proxy DNS server for DNS IPv6 queries coming from the mobile station to the PDSN's local PPP link address.

Example

The following command provides an example of disabling an IPv6 DNS proxy for the subscriber:

```
no ipv6 dns-proxy
```

ipv6 egress-address-filtering

Configures the egress address filtering for the subscriber.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ipv6 egress-address-filtering
```

no

Disables IPv6 egress address filtering.

ipv6 egress-address-filtering

Enables IPv6 egress address filtering.

Usage

Used to filter packets that arrive from the internet to a particular site.

Example

The following command provides an example disabling egress address filtering:

```
no ipv6 egress-address-filtering
```

ipv6 initial-router-advrt

Creates an IPv6 initial router advertisement interval for the subscriber.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
ipv6 initial-router-advrt { interval value | num-advrts value }
```

```
default ipv6 initial-router-advrt { interval | num-advrts }
```

default

Resets interval or num-advrts to their default setting.

interval *value*

Default: 3000ms

The time interval the initial IPv6 router advertisement is sent to the mobile node in milliseconds.
value is an integer between 100 and 16000 milliseconds.

num-advrts *value*

Default: 3

The number of initial IPv6 router advertisements sent to the mobile node.
value is an integer between 1 to 16.

Usage

This command is used to set the advertisement interval and the number of advertisements. Using a smaller advertisement interval increases the likelihood of router being discovered more quickly when it first becomes available.

Example

The following command specifies the initial ipv6 router interval to be 2000ms:

```
ipv6 initial-router-advrt interval 2000
```

ipv6 interface-id

Provides an IPv6 interface ID for the subscriber.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
ipv6 interface-id ifid
```

```
[ default | no ] ipv6 interface-id
```

default

No interface id set for IPv6CP negotiation to subscriber.

no

Deletes a previously configured ipv6 interface id.

interface-id *ifid*

It is a interface ID assigned to the Mobile during IPv6CP negotiation.
ifid is a 64 bit unsigned integer.

Usage

Used to provide a IPv6 ifid for the subscriber when using 6to4 routing.

Example

The following command provides an example of assigning an IPv6 interface ID of *00-00-00-05-47-00-37-44* to the subscriber:

```
ipv6 interface-id 00-00-00-05-47-00-37-44
```

ipv6 minimum-link-mtu

Configures the IPv6 minimum-link-MTU value.

Product

PDSN, GGSN, ASN GW

Privilege

.Security Administrator, Administrator

Syntax

```
ipv6 minimum-link-mtu value
```

```
default ipv6 minimum-link-mtu
```

default

Resets minimum link MTU to their default setting.
Default : 1280

value

Default: 1280
value is an integer between 100 and 2000 MTUs.

Usage

Used to override the IPv6 minimum link MTU values recommended by the standard.

Example

The following command provides an example of assigning an IPv6 minimum link MTU to *1580* to the subscriber:

```
ipv6 minimum-link-mtu 1580
```

ipv6 secondary-address

Configures additional IPv6 4-bit prefixes to the subscriber session.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ipv6 secondary-address { prefix ipv6_address_prefix | prefix-pool  
pool_name }
```

no

Deletes a previously configured ipv6 secondary address.

ipv6_address_prefix

The IPv6 secondary address and must be specified using colon notation.

pool_name

The name given to the secondary address prefix pool (a string size from 1 to 31 characters).

Usage

An IPv6 prefix pool name may be configured for a dynamic prefix, while the prefix is static. This command may be executed multiple times to configure multiple prefixes.

Example

The following command provides an example of assigning an IPv6 secondary address prefix-pool name of *eastcoast* to the subscriber:

```
ipv6 secondary-address prefix-pool eastcoast
```

l2tp send accounting-correlation-info

This command enables the L2TP LAC to send accounting correlation information (Correlation-Id, NAS-IP-Address and NAS-ID) in L2TP control message (ICRQ) during session setup to LNS.

Product

PDSN, LNS, LAC

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] l2tp send accounting-correlation-info
```

no

Disables the command and sets the setting to default mode for this subscriber.

default

Sets the setting to default mode of disable.

Usage

Use this command to enable the L2TP LAC to send accounting correlation information (Correlation-Id, NAS-IP-Address and NAS-ID) in L2TP control message (ICRQ) during session setup to LNS for this subscriber. LNS can be configured to include this information in ACS billing records, so that billing servers can easily correlate accounting records from PDSN/LAC and LNS. By default, this mode is disabled.

Example

Following command disables the inclusion of accounting correlation information in control messages during session setup to LNS for a subscriber:

```
default l2tp send accounting-correlation-info
```

l3-to-l2-tunnel address-policy

Configure the subscriber address allocation/validation policy, when subscriber L3 (IPV4) sessions are tunneled using an L2 tunneling protocol (e.g. L2TP).

Product

HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
l3-to-l2-tunnel address-policy { alloc-only | alloc-validate | no-alloc-validate }  
}
```

```
default l3-to-l2-tunnel address-policy
```

default

Restores the default value for l3-to-l2-tunnel address-policy.

alloc-only

Only allocate an address in the case of dynamic address assignment. Do not validate static addresses.

alloc-validate

Locally allocate and validate subscriber addresses.

no-alloc-validate

Do not allocate or validate subscriber addresses locally in the system for the current subscribers sessions. Pass the address between the remote tunnel terminator and the Mobile Node. This is the default behavior.

Usage

Use this command to configure the L3 to L2 tunnel address policy for MIP HA sessions tunneled from the system using L2TP tunnels or for GGSN IP Context sessions tunneled using L2TP to a remote LNS. Also refer to the *resource* keyword of the context configuration mode **ip pool** command.

Example

To set the L3 to L2 tunnel address policy so that the current subscriber must have IP addresses allocated and validated locally on the system, enter the following command:

```
l3-to-l2-tunnel address-policy alloc-validate
```

loadbalance-tunnel-peers

Configures the load balancing of traffic bound for L2TP tunnels configured on the system for the selected subscriber.

Product

L2TP

Privilege

Security Administrator, Administrator

Syntax

```
loadbalance-tunnel-peers { balanced | prioritized | random }
```

balanced

Enables the equal use of all configured tunnel peers (LNSs) for the selected subscriber.

prioritized

Enables the use of all configured tunnel peers (LNSs) for the selected subscriber based on the preference number assigned to the peer address.

random

Default: Enabled

Enables the random use of all configured tunnel peers (LNSs) for the selected subscriber.

Usage

Use to manage traffic loads on LAC ports and their respective L2TP Network Servers.

Example

Use the following command to randomly use all configured tunnel peers (LNSs):

```
loadbalance-tunnel peers random
```

long-duration-action

This command specifies what action is taken when the long duration timer expires.

Product

All

Privilege

Administrator

Syntax

```
long-duration-action { detection | disconnection [ dormant-only ] [ suppress-
notification ] }
```

detection

Default: Enabled

Detects long duration sessions and sends SNMP TRAP and CORBA notification. This is the default behavior. Use this command to detect a session exceeding the limit set by the long duration timer.

disconnection [dormant-only] [suppress-notification]

Default: Disabled

Detects a long duration session and disconnects the session after sending SNMP TRAP and CORBA notification.

suppress-notifiaction: Suppress the SNMP TRAP and CORBA notification after detecting and disconnecting a long duration session. Default: Disabled

dormant only: Disconnects the dormant sessions after long duration timer and inactivity time with idle time-out duration expires. If the long duration timeout is fired and the call is not dormant, the call is disconnected when the call later moves to dormancy.

Important: For HA calls, the inactivity-time is considered as gauge for dormancy.

It sends the SNMP TRAP and CORBA notification after disconnecting a long duration session. Default: Disabled

Usage

Use this command to determine what action is taken when a session exceeds the limit set by the long duration timer.

Example

Use the following command to enable disconnecting sessions that exceed the long duration timer:

```
long-duration-action disconnection
```

Use the following command to disconnect the session that exceed the long duration timer without sending SNMP TRAP and CORBA notification:

long-duration-action disconnection suppress-notification

Use the following command to disconnect the session that is in dormant and exceed the long duration timer and send SNMP TRAP and CORBA notification:

long-duration-action disconnection dormant-only

Note that in case of HA calls, the inactivity-time is considered as gauge for dormancy.

mediation-device

Enables the use of a mediation device for PDG-TTG subscriber and specifies the system context to use for communicating with the device.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
mediation-device context-name <context-name> [ no interims ]
```

```
[ no | default ] mediation-device
```

no

Deletes the mediation-device configuration.

default

Changes the mediation device to no context-name configured and restores the mediation device's default properties.

context-name *context-name*

Default: The subscriber's destination context.

Configures the mediation VPN context for the subscriber.

context-name can be from 1 to 79 alpha and/or numeric characters and is case sensitive.

If not specified, the mediation context is same as the destination context of the subscriber.

no-interims

Disables sending of interims to the mediation device.

Default: Disabled

Usage

This command is used to enable mediation device support for PDG-TTG subscriber. Mediation devices can be either deep-packet inspection servers or transaction control servers.

Keywords to this command can be used in combination to each other, depending on configuration requirements.

Example

The following command enables mediation device support for the subscriber and uses the protocol configuration located in an system context called *ggsn1*:

```
mediation-device context-name ggsn1
```

mobile-ip

Enables/disables the subscriber for mobile IP services and access.

Product

HA, FA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] mobile-ip { allow-aaa-address-assignment | dns-address source-priority {
aaa | home-agent } | gratuitous-arp aggressive | home-agent ip_address
[alternate] | match-aaa-assigned-address | mn-aaa-removal-indication | mn-ha-
hash-algorithm { hmac-md5 | md5 | rfc2002-md5 } | mn-ha-shared-key key | mn-ha-
spi spi_num | reverse-tunnel | security-level { ipsec | none } | send {
accounting-correlation-info | dns-address | imsi | terminal-verification } }
```

no

Disables the mobile IP option specified.

allow-aaa-address-assignment

Default: Disabled.

Enables the FA to accept a home address assigned by an AAA server. This should only be configured on the FA side.

dns-address source-priority { aaa | home-agent }

Sets the priority behavior on the FA to use either the DNS IP address information from the HA or the AAA server to include in the the RRP to the MN.

When the **no** keyword is used in conjunction with the **dns-address** keyword, information received from both the home-agent and the AAA server is sent if available.

DNS IP address information from the HA comes from the DNS NVSE in the RRP.

DNS IP address information from the AAA server is in the access accept message.

home-agent: If the DNS address is received from the home-agent only that information is sent to the MN. Otherwise the DNS address received from the AAA server is sent.

aaa: If the DNS address is received from the AAA server only that information is sent to MN. Otherwise the DNS address received from the home-agent is sent.

gratuitous-arp aggressive

Default: Disabled.

When enabled, this mode will cause the HA to send out gratuitous ARP messages for all Mobile IP (MIP) registration renewals and handoffs.

To disable this mode, use the **no** form of this command.

Important: This mode will only work for IP addresses that have been assigned from a static IP address pool.

home-agent *ip_address* [**alternate**]

Specifies the IP address of the mobile IP user's home agent. *ip_address* must be a an IPv4/IPv6 address. **alternate** - Specifies the secondary, or alternate, Home Agent to use when Proxy Mobile IP HA Failover is enabled.

match-aaa-assigned-address

Default: Disabled.

Enables the FA to validate the home address in the RRQ against the one assigned by AAA server. This should only be configured on the FA side.

mn-aaa-removal-indication

Default: Disabled.

When enabled, the MN-FA challenge and MN-AAA Authentication extensions are removed when relaying a Registration Request (RRQ) to the Home Agent (HA)

mn-ha-hash-algorithm { **hmac-md5** | **md5** | **rfc2002-md5** }

Speechifies the encryption algorithm to use.

Default: **hmac-md5**

hmac-md5: Use HMAC-MD5 hash algorithm, as defined in RFC-2002bis. This is the default algorithm.

md5: Use the MD-5 hash algorithm.

rfc2002-md5: Use the MD-5 hash algorithm variant as defined in RFC-2002.

mn-ha-shared-key *key*

This is the used to verify the MN-HA Authentication for a local subscriber in the current context. A string or a Hexadecimal number beginning with "0x" up to 127 bytes

mn-ha-spi *spi_num*

Specifies the SPI number. *spi_num* must be an integer from 256 through 4294967295.

reverse-tunnel

Default: enabled.

Enables the mobile IP user's for reverse IP tunnels. The **no** keyword is used to disable this option.

security-level { **ipsec** | **none** }

Default: none

The security-level option configures the security level needed for the subscriber's traffic.

ipsec: both MIP control and data traffic are secured with IPSEC

none: none of the traffic is secured

Important: This keyword corresponds to the 3GPP2-Security-Level RADIUS attribute. This attribute indicates the type of security that the home network mandates on the visited network.

Important: For this attribute, integer value: 3 : Enables IPsec for tunnels and registration messages 4 : Disables IPsec

```
send { accounting-correlation-info | dns-address | imsi | terminal-  
verification }
```

accounting-correlation-info: Configures whether the FA sends the correlation info to the NVSE in the RRQ. Default is disabled.

dns-address: Enables the HA to send the DNS address NVSE in the RRP. Default is disabled. This should only be enabled on the HA side.

imsi: Configures sending the IMSI NVSE in the RRQ. Default is sending IMSI in custom-1 format.

terminal-verification: Enables the FA to send the terminal verification NVSE in the RRQ. Default is disabled. This should only be enabled on the FA side.

Important: send dns-address is a proprietary feature developed for a specific purpose and requires the MN to be able to renegotiate IPCP for DNS addresses and reregister MIP if necessary. Since this feature needs the MN to support certain PPP/MIP behavior, and not all MNs may support that particular behavior, send dns-address should be enabled only after careful consideration.

Usage

Use as subscriber service contracts change.

Example

```
mobile-ip home-agent 1.2.3.4
```

```
no mobile-ip reverse-tunnel
```

mobile-ip ha

Accommodates two MIP HA options in subscriber mode.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] mobile-ip ha { assignment-table name | ignore-unknown-ha-addr-error }
```

no

Disables the mobile IP HA option specified.

assignment-table *name*

The name of an existing MIP HA Assignment table.

name must be a string of alphanumeric characters from 1 through 63 characters in length.

ignore-unknown-ha-addr-error

Default is disabled.

Enables or disables the HA to accept or reject the RRQ from a particular subscriber.

Usage

Use this command to assign a MIP HA Assignment table to the current subscriber.

Use this command to disable or enable the HA to accept or reject the RRQ from a particular subscriber when the HA address in the incoming MIP RRQ is not the same as the HA service address. The feature is off by default which causes the RRQ to be rejected with the error code UNKNOWN_HOME_AGENT.

Example

The following command assigns the MIP HA Assignment table named *Atable1* to the current subscriber:

```
mobile-ip ha assignment-table Atable1
```

The following command sets ignore-unknown-ha-addr-error to its default disabled state:

```
no mobile-ip ha ignore-unknown-ha-addr-error
```

mobile-ip reg-lifetime-override

This command overrides the mobile IP registration lifetime from HA with value configured for subscriber.

Product

PDSN, HA, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
mobile-ip reg-lifetime-override [ dur | infinite ]  
[ default | no ] mobile-ip reg-lifetime-override
```

dur

Default: 100 secs.

This the configurable value in seconds.

dur must be an integer from 1 through 65534.

infinite

Sets the mobile IP registration lifetime override value to infinite for a particular subscriber.

default

Sets the value of mobile IP registration lifetime override option to 100 seconds.

no

Disables the mobile IP registration lifetime override option specified.

Usage

Use this command to configure MIP registration-lifetime per realm/domain. This value overrides the default lifetime configured under HA service.

Example

The following command overrides the mobile IP registration lifetime value from HA service and assigns the MIP registration lifetime to 100 seconds for the current subscriber:

```
default mobile-ip reg-lifetime-override
```

mobile-ip send accounting-correlation-info

Enables the sending call correlation information NVSE's to the HA in MIP RRQ.

Product

PDSN, HA, ACS

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] mobile-ip send accounting-correlation-info
```

default

Disables the support for sending call correlation information NCSE's to the HA in MIP RRQ.
This is the default mode.

no

Removes the configured support for sending call correlation information.

Usage

Use this command to support PDSN-Correlation-ID VSE and send the call correlation information.

Example

The following command enables sending call correlation information NVSE's to the HA in MIP RRQ

```
mobile-ip send accounting-correlation-info
```

mobile-ipv6

Configures Mobile IPv6 related parameters for a subscriber.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] mobile-ipv6 { home-address ipv6_address | home-agent ipv6_address | home-link-prefix ipv6_address | tunnel mtu value }
```

default

Disables the support for sending call correlation information NCSE's to the HA in MIP RRQ. This is the default mode.

no

Removes the configured support for sending call correlation information.

home-address *ipv6_address*

Specifies the home address for the subscriber. *ipv6_address* must be a an IPv6 address in colon notation.

home-agent *ipv6_address*

Specifies the IPv6 address of the mobile IP user's home agent. *ipv6_address* must be a an IPv6 address in colon notation.

home-link-prefix *ipv6_address*

Specifies the IPv6 address of the mobile IP user's home link. *ipv6_address* must be a an IPv6 address in colon notation.

tunnel mtu *value*

Configures the tunnel MTU for the IPv6 tunnel between the HA and the mobile node. *value* must be an integer between 1024 and 2000. The default is 1500.

Usage

This command sets the mobile-ipv6 parameters for a subscriber. Use this command to set the home-address, home-agent, and home-link prefix

Example

Use the following command to set the tunnel value to 1800:

```
mobile-ipv6 tunnel mtu 1800
```

■ mobile-ipv6

nai-construction-domain

After authentication, the domain name set by this command replaces the NAI constructed domain for subscriber.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
nai-construction-domain domain_name
```

```
no nai-construction-domain
```

domain_name

Defines the domain name to use to replace the NAI constructed domain name. This must be a string of 1 to 79 characters.

no

Deletes the defined domain name.

Usage

Define or delete a domain name to use to replace the NAI constructed domain name after authentication.

Example

To set the domain name to *private1* use the following command:

```
nai-construction-domain private1
```

To delete the previously configured domain name, use the following command:

```
no nai-construction-domain
```

nbns

Configures and Enables use of NetBios Name Service for the subscriber.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
nbns { primary IPv4-address | secondary IPv4-address }
```

```
no nbns { primary [ IPv4-address ] | secondary [ IPv4-address ] }
```

primary

Designates primary NBNS server. Must be followed with IPv4 address in dotted-decimal notation.

secondary

Designates secondary/failover NBNS server. Must be followed with IPv4 address in dotted-decimal notation.

IPv4-address

Specifies the IPv4 address used for this service.

no

Removes/disables use of a previously configured NetBios Name Service.

Usage

This command specifies NBNS parameters. The NBNS option is present for both pdp type IP and pdp type PPP for GGSN.

The system can be configured to use of NetBios Name Service for the APN.

Example

The following command configures the subscriber's NetBios Name Service to primary IP *192.168.1.15*:

```
nbns primary 192.168.1.15
```

nexthop-forwarding-address

Configures the next hop forwarding address for the subscriber.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
nexthop-forwarding-address ip_address
```

```
no nexthop-forwarding-address
```

ip_address

Configures the IP address of the nexthop forwarding address.

no

Disables this function. This is the default setting.

Usage

Use this command to configure the next hop forwarding address for the subscriber.

Example

The following command configures the next hop forwarding address to *1 . 1 . 1 . 1* using IPv4:

```
nexthop-forwarding-address 1 . 1 . 1 . 1
```

npu qos

Configures an NPU QoS priority queue for packets from the subscriber.

Product

PDSN, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
npu qos traffic priority { best-effort | bronze | derive-from-packet-dscp | gold
| silver }
```

best-effort

Assigns the best-effort queue priority. This is the lowest priority.

bronze

Assigns the bronze queue priority. This is the third-highest priority.

derive-from-packet-dscp

Default: Enabled

Specifies that the priority is to be determined from the DS field in the packet's TOS octet.

gold

Assigns the gold queue priority. This is the highest priority.

silver

Assigns the silver queue priority. This is the second-highest priority.

Usage

This command is used in conjunction with the Network Processing Unit (NPU) Quality of Service (QoS) functionality.

The system can be configured to determine the priority of a subscriber packet either based on the configuration of the subscriber, or from the differentiated service (DS) field in the packet's TOS octet (representing the differentiated service code point (DSCP) value).

Refer to the System Administration and Configuration Guide for additional information on NPU QoS functionality.

Important: This functionality is not supported for use with the PDSN at this time.

Example

The following command configures the subscriber's priority queue to be gold:

```
npu qos traffic priority gold
```

nw-reachability-server

Bind the name of a configured network reachability server to the current subscriber and enable network reachability detection.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
nw-reachability server server_name
```

```
no nw-reachability server
```

server_name

The name of a network reachability server that has been defined in the current context. This is a string of from 1 through 16 characters.

```
no nw-reachability server
```

Delete the name of the network reachability server from the current subscribers configuration and disable network reachability failure detection for the current subscriber.

Usage

Use this command to define the network reachability server for the current subscriber and enable network reachability failure detection for the current subscriber. If a network reachability server is defined in an IP pool, that setting takes precedence over this command.

 **Important:** Refer to the HA configuration mode command `policy nw-reachability-fail` to configure the action that should be taken when network reachability fails.

 **Important:** Refer to the context configuration mode command `nw-reachability server` to configure network reachability servers.

 **Important:** Refer to the `nw-reachability server server_name` keyword of the `ip pool` command in the context configuration mode chapter to bind the network reachability server to an IP pool.

Example

To bind a network reachability server named *InternetDevice* to the current subscriber, enter the following command:

```
nw-reachability server InternetDevice
```

outbound

Configures the subscriber host password for use in authentication of PPP sessions.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
outbound [ encrypted ] password pwd
```

```
no outbound password
```

```
[ encrypted ] password pwd
```

Specifies the password to use for point-to-point protocol session host authentication. The **encrypted** keyword indicates the password specified uses encryption.

The password specified as *pwd* must be from 1 to 63 alpha and/or numeric characters without encryption and must be from 1 to 127 alpha and/or numeric characters when encryption has been indicated.

The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **password** keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

```
no outbound password
```

Used to clear the outbound password configuration from the subscriber data.

Usage

Set the outbound (egress) password for increased security.

Example

```
outbound password secretPwd  
outbound encrypted password scrambledPwd  
no outbound password
```

overload-disconnect

Sets the threshold parameter for overload disconnect.

Product

ASN GW, HA, PDIF, PDSN, PHS GWPDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
overload-disconnect [ threshold { inactivity-time inactivity_time_threshold |
connect-time connect_time_threshold } ]

[ default | no ] overload-disconnect [ threshold { inactivity-time | threshold
connect-time } ]
```

threshold inactivity-time *inactivity_time_threshold*

Sets the inactivity time threshold in seconds. This value must be from 0 to 4294967295. The default value of zero disables this feature. If *inactivity-time* for the subscriber's session is greater than *inactivity_time_threshold*, the session becomes a candidate for disconnection.

threshold connect-time *connect_time_threshold*

Sets the connection time threshold in seconds. This value must be from 0 to 4294967295. A value of zero disables this feature. If *connect-time* for the subscriber's session is greater than *connect_time_threshold*, the session becomes a candidate for disconnection.

default

This command enables the default condition for this subscriber.

no

Disables the overload disconnect feature for this subscriber. This is the default condition for PDIF.

Usage

Set a subscriber's overload disconnect threshold in seconds, based on either inactivity or connection time. When this threshold is exceeded during a session, the subscriber's session becomes a candidate for disconnection. To set overload-disconnect policies for the entire chassis, see **congestion-control overload-disconnect** in Global Configuration Mode Commands.

Example

```
overload-disconnect threshold inactivity-time inactivity_time_threshold
default overload disconnect threshold connect-time
no overload-disconnect threshold connect-time
```

■ overload-disconnect

`no overload disconnect`

password

Configures the subscribers password for the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ encrypted ] password pwd
```

```
no password
```

encrypted

Indicates the password provided is encrypted.

The **encrypted** keyword is intended only for use by the chassis while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **password** keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

pwd

Specifies the users password for authentication. *pwd* must be from 1 to 63 alpha and/or numeric characters or from 1 to 127 characters if the **encrypted** keyword was specified. A “null” password is allowed and is entered as consecutive quotes (“”). See Example(s) for correct syntax.

Important: Subscribers configured with a null password will be authenticated using PAP and CHAP (MD5) only. Subscribers configured without a password (**no password**) will only be able to access services if the service is configured to allow no authentication.

no

Used to clear the subscriber password configuration from the subscriber data.

Important: Subscribers with no password will only be able to access services if the service is configured to allow no authentication.

Usage

Password management is critical to system security and all precautions should be taken to ensure passwords are not shared or to easily deciphered.

Example

```
password secretPwd  
password ""
```

■ password

no password

pdif mobile-ip

Configures PDIF subscriber call setup parameters.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] pdif mobile-ip { release-tia | required | simple-ip-fallback }
```

[default | no]

Disables the option specified.

release-tia

Specifies that after subscriber call setup is complete, the tunnel inner address (TIA) is released. If Simple IP is enabled, the TIA becomes the principal communications tunnel and the restriction that it is only to be used to set up a Mobile-IP call is lifted. This parameter is disabled by default.

required

Specifies that Mobile IP is required for this subscriber whenever a call is set up. This parameter is disabled by default.

simple-ip-fallback

Specifies that Simple IP should be used when Mobile IP could not be established. This parameter is disabled by default.

Usage

Use this command to configure specific behavior for the PDIF subscriber during call setup.

Example

The following command enables the system to fall back to Simple IP when Mobile IP fails for this subscriber during call setup:

```
pdif mobile-ip simple-ip-fallback
```

permission

Enables/disables the ability to access wireless data services for the current subscriber.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] permission { ha-mobile-ip | pdsn-mobile-ip | pdsn-simple-ip }
```

no

Disables the usage of the specified service.

ha-mobile-ip | pdsn-mobile-ip | pdsn-simple-ip

ha-mobile-ip: enable/disable the home agent support for mobile IP service.

pdsn-mobile-ip: enable/disable the packet data and foreign agent support for mobile IP service.

pdsn-simple-ip: enable/disable the packet data support for simple IP service.

Usage

This is necessary per the services the subscriber is allowed to access in the current context.

Example

```
permission pdsn-mobile-ip
```

```
no permission ha-mobile-ip
```

policy ipv6 tunnel

Tunnel MTU for IPv6 Tunnel between HA and Mobile Node.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
policy ipv6 tunnel mtu exceed { fragment | notify-sender }
```

```
mtu exceed { fragment | notify-sender }
```

fragment: Adjust Tunnel MTU and Fragment Packets

notify-sender: Send a ICMPv6 Packet Too Big the original sender

Usage

Use this command to configure Tunnel MTU for IPv6 Tunnel between HA and Mobile Node.

Example

```
policy ipv6 tunnel mtu exceed fragment
```

policy-group

This command assigns/removes a flow-based traffic policy group to a subscriber.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] policy-group policy_group_name direction { in | out }
```

no

Removes assigned policy group from a subscriber configuration.

policy_group_name

Specifies the traffic policy group name for a subscriber session flow pre-configured within a destination context .

policy_group_name consist of from 1 to 15 alpha and/or numeric characters in length and is case sensitive.

direction { **in** | **out** }

Specifies the direction of flow in which the traffic policies need to be applied.

- **in**: specifies the incoming traffic
- **out**: specifies the outgoing traffic

Usage

Use this command to assign traffic policy group to a subscriber for traffic policing.

Example

```
policy-group traffic_policy_group1 direction in
```

ppp

Configures the point-to-point protocol options for the current subscriber.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
ppp { accept-peer-ipv6-ifid | always-on-vse-packet | data-compression { mode {
normal | stateless } | protocols { protocols [ protocols ] } | ip-header-
compression negotiation { detect | force | vj compress-slot-id { both | none |
receive | transmit } } | ipv4 { disable | enable | passive } | ipv6 { disable |
enable | passive } | keepalive seconds | min-compression-size min_octets | mtu
max_octets | remote-renegotiation disconnect { always | nai-prefix-msid-mismatch
} }
```

```
default ppp { accept-peer-ipv6-ifid | always-on-vse-packet | data-compression {
mode | protocols } | ip-header-compression negotiation [ vj compress-slot-id ] |
ipv4 | ipv6 | keepalive | min-compression-size | mtu | remote-renegotiation
disconnect }
```

```
no ppp { accept-peer-ipv6-ifid | always-on-vse-packet | data-compression
protocols | ipv4 | ipv6 | keepalive | mtu | remote-renegotiation disconnect }
```

default

Restores the default value for the option specified.

no

Resets the option specified to its default.

always-on-vse-packet

Default: Enabled

If the always-on feature is enabled for a session, this keyword enables the PDSN to send special 3GPP2 VSE PPP packets to the Mobile Node with a max inactivity timer value. This configuration is applicable only for PDSN sessions.

accept-ipv6-peer-ifield

Default: None

This is used to configure a 6to4 tunnel. It controls the behavior of IPv6CP negotiation for Interface ID. If enabled, PDSN will accept a valid interface-id proposed by the peer.

```
data-compression { mode { normal | stateless } | protocols { protocols [
protocols ] }
```

Default: all protocols enabled.

Specifies the subscribers mode of data compression or the compression protocol to use.

mode: sets the mode of compression where *modes* must be one of:

- normal (packets are compressed using the packet history for automatic adjustment for best compression)
- stateless (each packet compressed individually)

protocols protocols: sets the compression protocol where *protocols* must be one of:

- deflate (DEFLATE algorithm)
- mppc (Microsoft PPP algorithm)
- stac (STAC algorithm)

```
ip-header-compression negotiation { detect | force | vj compress-slot-id
{ both | none | receive | transmit } }
```

Default: **force**

PPP IP compression Van Jacobson (VJ) negotiation scheme. This command is applicable only if IP header compression is enabled for the subscriber.

detect: The local side does not include the VJ Compression option in its IPCP configuration request unless the peer sends an IPCP NAK including a VJ compression option. If the peer requests the VJ compression option in its IPCP request the local side will ACK/NAK.

force: The IP header compression negotiation in IPCP happens normally. The local side requests the VJ compression option in its IPCP configure request. If the peer side requests VJ compression in its IPCP request, the local side will ACK/NAK the option.

vj compress-slot-id [both | none | receive | transmit]: This keyword configures the direction in which VJ slotid compression should be negotiated.

- both** - If the client proposes VJ slotid compression, accept it and propose slotid compression for downlink and uplink.
- none** - If the client proposes VJ slotid compression, NAK the offer, do not propose slotid compression for downlink.
- receive** - (Default) If the client proposes VJ slotid compression in the uplink direction accept the configuration.
- transmit** - Propose VJ slotid compression for uplink.

```
ipv4 { disable | enable | passive }
```

Default: enable

Controls IPCP negotiation during PPP negotiation.

disable: The PDSN does not negotiate IPCP with the mobile.

enable: The PDSN negotiates IPCP with the mobile.

passive: The PDSN initiates IPCP only when the mobile sends an IPCP request.

```
ipv6 { disable | enable | passive }
```

Default: enable

Controls IPv6CP negotiation during PPP negotiation.

disable: The PDSN does not negotiate IPCP with the mobile.

enable: The PDSN negotiates IPCP with the mobile.

passive: The PDSN initiates IPCP only when the mobile sends an IPCP request.

```
keepalive seconds
```

Default: 30

Specifies the frequency of sending the Link Control Protocol keep alive messages. *seconds* must be either 0 or in the range from 5 to 14400.

The special value 0 disables the keep alive messages entirely.

min-compression-size *min_octets*

Default: 128

Specifies the smallest packet to which compression may be applied. *min_octets* must be a value in the range from 0 to 2000.

mtu *max_octets*

Default: 1500

Specifies the maximum size in octets the message transfer unit packets can reach. *max_octets* must be a value in the range from 100 to 2000.

remote-renegotiation disconnect { **always** | **nai-prefix-msid-mismatch** }

Default: Disabled

Terminates the already established PPP sessions if they are renegotiated by the remote side by sending LCP Conf-req/nak/ack. The following termination conditions are available:

- **always**: The session is automatically disconnected.
- **nai-prefix-msid-mismatch**: The session is disconnected only if the MSID of the session does not match NAI-Prefix (prefix before “@” for the NAI). The configuration of the renegotiated (new) NAI is used for the matching process.

Usage

Adjust packet sizes and compression to improve bandwidth utilization. Each network may have unique characteristics such that determining the best packet size and compression options may require system monitoring over an extended period of time.

Example

```
ppp data-compression protocols mode stateless

ppp mtu 500

no ppp data-compression protocols

no ppp keepalive
```

prepaid 3gpp2

Enables 3GPP2 compliant prepaid billing support for a subscriber to be configured by 3GPP2 attributes sent from a RADIUS server. If not enabled, prepaid attributes received from the RADIUS server are ignored.

Product

HA, PDSN

Privilege

Security Administrator, Administrator

Syntax

```
prepaid 3gpp2 { accounting [ no-final-access-request ] | duration-quota final-
duration-algorithm { current-time | last-airlink-activity-time | last-user-
layer3-activity-time } | preference { duration | volume } }
```

```
default prepaid 3gpp2 { duration-quota final-duration-algorithm | preference }
```

```
no prepaid 3gpp2 accounting
```

```
default prepaid 3gpp2 { duration-quota final-duration-algorithm |
preference }
```

Sets the 3GPP2 Pre-paid settings to the default values.

duration-quota final-duration-algorithm: Reset the end of billing duration quota algorithm to the default of current-time.

preference: Reset the preference to duration, If both duration and volume attributes are present.

```
no prepaid 3gpp2 accounting
```

Disables 3GPP2 prepaid accounting. All 3GPP2 Prepaid attributes received from a RADIUS server are ignored.

```
accounting [ no-final-access-request ]
```

Default: Disabled

Enabled 3GPP2 prepaid accounting behavior.

Sets the low-watermark for remaining byte credits. *percentage* is a percentage of the subscriber sessions total credits. When the low-watermark is reached a new RADIUS access-request is sent to the RADIUS server to retrieve more credits. *percentage* must be an integer from 1 to 99.

no-final-access-request: Stops sending final online access-request on termination of 3GPP2 prepaid sessions. By default, this option is disabled.

```
duration-quota final-duration-algorithm { current-time | last-airlink-
activity-time | last-user-layer3-activity-time }
```

Define what behavior specifies the end of the billing duration for duration-based quota usage accounting. The default behavior is the duration quota algorithm set to current-time.

Default: current-time

current-time: Selects the duration quota as the difference between the session termination timestamp and the session setup timestamp.

last-airlink-activity-time: Selects the duration quota as the difference between the last-user-activity timestamp (G17) and the session setup timestamp.

last-user-layer3-activity-time: Selects the duration quota as the difference between the timestamp of the last layer-3 packet sent to or received from the user and the session setup timestamp.

preference { duration | volume }

If both duration and volume RADIUS attributes are present this keyword specifies which attribute has precedence.

Default: duration

duration: The duration attribute takes precedence.

volume: The volume attribute takes precedence

Usage

Use this command to enable prepaid support for a default user or for the default user of a domain alias.

Example

The following command enables 3GPP2 prepaid support for the default user:

```
prepaid 3gpp2 accounting
```

prepaid custom

Enables custom prepaid billing support for a subscriber to be configured by attributes sent from a RADIUS server. If not enabled, prepaid attributes received from the RADIUS server are ignored. The keywords are to set prepaid values that are used if the corresponding RADIUS attribute is not present. If the RADIUS attribute is present it takes precedence over these values.

Product

HA, PDSN

Privilege

Security Administrator, Administrator

Syntax

```
prepaid custom { accounting | byte-count compressed | low-watermark percent
percentage | renewal interval seconds } | preference { duration | volume }
```

```
default prepaid custom { byte-count | low-watermark }
```

```
no prepaid custom { accounting | byte-count compressed | low-watermark | renewal
}
```

```
default prepaid custom { byte-count | low-watermark }
```

Resets custom prepaid settings to the default values.

byte-count: Reset to the default of basing the prepaid byte credits on the flow of uncompressed traffic.

low-watermark: Disable sending an access request to retrieve more credits when a low watermark is reached.

```
no prepaid custom { accounting | byte-count compressed | low-watermark |
renewal}
```

byte-count compressed: The prepaid byte credits are based on the flow of uncompressed traffic. This is the default.

low-watermark: Disables the low watermark feature. An access-request isn't sent to the RADIUS server until the credits granted for the subscriber session are depleted.

renewal: Disables time-based renewals for prepaid accounting.

accounting

Default: Disabled

Enabled custom prepaid accounting behavior.

byte-count compressed

Default: uncompressed.

When compression is used, the prepaid byte credits are based on the flow of compressed traffic. The default is to base the prepaid byte credits on the flow of uncompressed traffic.

low-watermark percent *percentage*

Default: Disabled.

Sets the low-watermark for remaining byte credits. *percentage* is a percentage of the subscriber sessions total credits. When the low-watermark is reached a new RADIUS access-request is sent to the RADIUS server to retrieve more credits. *percentage* must be an integer from 1 to 99.

renewal interval *seconds*

Default:

The time in seconds to wait before sending a new RADIUS access-request to the RADIUS server to retrieve more credits. *seconds* must be an integer from 60 through 65535.

preference { **duration** | **volume** }

If both duration and volume RADIUS attributes are present this keyword specifies which attribute has precedence.

Default: duration

duration: The duration attribute takes precedence.

volume: The volume attribute takes precedence

Usage

Use this command to enable prepaid support for a default user or for the default user of a domain alias.

Example

The following command enables custom prepaid support for the default user:

```
prepaid custom accounting
```

■ prepaid unclassify

prepaid unclassify

This command provides customer specific functionality.

prepaid voice-push

This command provides customer specific functionality.

prepaid wimax

Enables WiMAX prepaid accounting for this subscriber. This feature is disabled by default.

Product

ASN GW

Privilege

Administrator

Syntax

```
[ no ] prepaid wimax accounting
```

no

Disables WiMAX prepaid accounting for this subscriber.

Usage

Use this command to enable WiMAX prepaid accounting for this subscriber.

proxy-dns intercept list-name

Identifies a proxy DNS intercept rules list for the selected subscriber.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] proxy-dns intercept list-name name
```

no

Remove the intercept list from the subscribers profile.

proxy-dns intercept list-name name

Specifies a name of a proxy DNS intercept list used for the selected subscriber.

name is the name of the intercept list and must be a string from 1 to 63 characters in length.

Usage

Use this command to identify a proxy DNS rules list for the selected subscriber. For a more detailed explanation of the HA Proxy DNS Intercept feature, see the **proxy-dns intercept-list** command in the *Context Configuration Mode Commands* chapter.

proxy-mip

Configures support for Proxy Mobile IP for the subscriber.

Product

PDSN, GGSN, ASN GW, PDIF

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] proxy-mip required
```

no

Disables support for Proxy Mobile IP.

required

Enables support for Proxy Mobile IP.

Usage

When enabled through the session license and feature use key, the system supports Proxy Mobile IP to provide a mobility solution for subscribers with mobile nodes (MNs) capable of supporting only Simple IP. For subscriber sessions using Proxy Mobile IP, R-P and PPP sessions get established as they would for a Simple IP session. However, the AGW/FA performs Mobile IP operations with an HA (identified by information stored in the subscriber's profile) on behalf of the MN while the MN performs only Simple IP processes.

Example

The following command enables proxy mobile IP for the current subscriber:

```
proxy-mip required
```

qos rate-limit

Configure the action on subscriber traffic flow that violates or exceeds the peak/committed data rate under traffic policing functionality. When configured, the PDG/TTG performs traffic policing for the subscriber session. If the GGSN changes the QoS via an Update PDP Context Request, the PDG/TTG uses the new QoS values for traffic policing.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

```
qos rate-limit { downlink | uplink } [ qci qci_val ] [ burst-size { bytes |
auto-readjust [ duration dur ] } ] [ exceed-action { drop | lower-ip-precedence
| transmit } [ violate-action { drop | lower-ip-precedence | shape [ transmit-
when-buffer-full ] | transmit } ] ] | [ violate-action { drop | lower-ip-
precedence | shape [ transmit-when-buffer-full ] | transmit } [ exceed-action {
drop | lower-ip-precedence | transmit } ] ] +no qos rate-limit direction {
downlink | uplink } [ qci qci_val ]
```

no

Disables the QoS data rate limit configuration for the subscriber.

downlink

Apply the specified limits and actions to the downlink (to the data coming from the GGSN over the Gn' interface).

uplink

Apply the specified limits and actions to the uplink (to the data coming from the UE over the IPSec tunnel).

Important: If this keyword is omitted, the same values are used for all classes.

qci qci_val

qci_val is the QCI for which the negotiate limit is being set, it ranges from 1 to 9. If no *qci-val* is configured, it will be taken as undefined-qci (same as undefined-qos class).

burst-size { bytes | auto-readjust [duration dur] }

Default: See Usage section for this command

The burst size allowed, in bytes for peak data rate and committed data rate.

bytes must be an integer from 1 through 6000000.

Important: It is recommended that the minimum value of this parameter be configured to the greater of the following two values: 1) 3 times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the "bucket" for the configured peak-data-rate. In addition, if the committed-data-rate parameter is specified, the burst-size is applied to both the committed and peak rates.

auto-readjust [**duration** *dur*] keyword provides the option to calculate the Burst size dynamically while configuring rate-limit. Whenever this keyword is enabled to calculate burst size GGSN QoS negotiated rate to be enforced for this calculation. Every time there is a change in the rates (due to update QoS), the burst sizes will be updated accordingly. This keyword also provides two different burst sizes. One burst size for peak rate and another for committed rate.

By default this keyword is disabled.

duration *dur* describes the duration of burst in seconds. If duration is not specified this keyword will use 1 second as default value. *dur* must be an integer between 1 through 30.

exceed-action { **drop** | **lower-ip-precedence** | **transmit** }

Default: See Usage section for this command

The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate.

The following actions are supported:

- **drop**: Drop the packet.
- **lower-ip-precedence**: Transmit the packet after lowering the ip-precedence.
- **transmit**: Transmit the packet.

violate-action { **drop** | **lower-ip-precedence** | **transmit** }

Default: See Usage section for this command

The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:

- **drop**: Drop the packet.
- **lower-ip-precedence**: Transmit the packet after lowering the IP precedence.
- **transmit**: Transmit the packet after lowering the IP precedence.

shape [**transmit-when-buffer-full**]: Enables the traffic shaping and provides the buffering of user packets when subscriber traffic violates the allowed peak/committed data rate. The [**transmit-when-buffer-full**] keyword allows the packet to be transmitted when buffer memory is full.

transmit: Transmit the packet

Usage

This command configures the APN's quality of service (QoS) data rate shaping through traffic policing. This command enables the actions on subscriber flow exceeding or violating peak/committed data rate allowed. The shaping function also provides an enhanced function to buffer the exceeded user packets in a buffer memory and sends them to the subscriber when subscriber traffic goes below the committed or peak data rate limit.

Important: The user packet buffer function in traffic shaping is not applicable for real-time traffic.

Important: If the exceed/violate action is set to "lower-ip-precedence", this command may override the configuration of the **ip qos-dscp** command in the GGSN service configuration mode for packets from the GGSN to the PDG/TTG. In addition, the GGSN service **ip qos-dscp** command configuration can override the APN setting for packets from the GGSN to the Internet. Therefore, it is recommended that command not be used in conjunction with this action.

The command can be entered multiple times to specify different combinations of direction and class. If this command is not configured at all, the GGSN does not perform traffic policing or QoS negotiation with the PDG/TTG (i.e., it accepts all of the PDG/TTG-provided values for the PDP context).

Important: This command should be used in conjunction with the max-contexts command to limit the maximum possible bandwidth consumption by the APN.

Additional information on the QoS traffic shaping and policing functionality is located in the *System Enhanced Feature Configuration Guide*.

Default values:

The following table displays the default values for each of the traffic classes:

Class: Conversational	
Downlink Traffic: Disabled Peak Data Rate (in bps): 16000000 Committed Data Rate(in bps): 16000000 Exceed Action: lower-ip-precedence Violate Action: drop	Uplink Traffic: Disabled Peak Data Rate(in bps): 8640000 Committed Data Rate(in bps): 8640000 Exceed Action: lower-ip-precedence Violate Action: drop
Class: Streaming	
Downlink Traffic: Disabled Peak Data Rate(in bps): 16000000 Committed Data Rate(in bps): 16000000 Exceed Action: lower-ip-precedence Violate Action: drop	Uplink Traffic: Disabled Peak Data Rate(in bps): 8640000 Committed Data Rate(in bps): 8640000 Exceed Action: lower-ip-precedence Violate Action: drop
Class: Interactive, Traffic Handling Priority: 1	
Downlink Traffic: Disabled Peak Data Rate(in bps): 16000000 Committed Data Rate(in bps): n/a Exceed Action: n/a Violate Action: drop	Uplink Traffic: Disabled Peak Data Rate(in bps): 8640000 Committed Data Rate(in bps): n/a Exceed Action: n/a Violate Action: drop
Class: Interactive, Traffic Handling Priority: 2	
Downlink Traffic: Disabled Peak Data Rate(in bps): 16000000 Committed Data Rate(in bps): n/a Exceed Action: n/a Violate Action: drop	Uplink Traffic: Disabled Peak Data Rate(in bps): 8640000 Committed Data Rate(in bps): n/a Exceed Action: n/a Violate Action: drop
Class: Interactive, Traffic Handling Priority: 3	
Downlink Traffic: Disabled Peak Data Rate(in bps): 16000000 Committed Data Rate(in bps): n/a Exceed Action: n/a Violate Action: drop	Uplink Traffic: Disabled Peak Data Rate(in bps): 8640000 Committed Data Rate(in bps): n/a Exceed Action: n/a Violate Action: drop

--	---

Usage

This command configures the APN's quality of service (QoS) data rate shaping through traffic policing/shaping. This command enables the actions on subscriber flow exceeding or violating peak/committed data rate allowed. The shaping function also provides an enhanced function to buffer the exceeded user packets in a buffer memory and sends them to the subscriber when subscriber traffic goes below the committed or peak data rate limit.

 **Important:** The user packet buffer function in traffic shaping is not applicable for real-time traffic.

 **Important:** If the exceed/violate action is set to “lower-ip-precedence”, this command may override the configuration of the `ip qos-dscp` command in the GGSN service configuration mode for packets from the GGSN to the SGSN. In addition, the GGSN service `ip qos-dscp` command configuration can override the APN setting for packets from the GGSN to the Internet. Therefore, it is recommended that command not be used in conjunction with this action.

The command can be entered multiple times to specify different combinations of direction and class. If this command is not configured at all, the GGSN does not perform traffic policing or QoS negotiation with the SGSN (i.e. it accepts all of the SGSN-provided values for the PDP context).

 **Important:** This command should be used in conjunction with the `max-contexts` command to limit the maximum possible bandwidth consumption by the APN.

To calculate the burst size dynamically a new optional keyword `auto-readjust [duration dur]` is provided with `burst-size` keyword. By default the burst size is fixed if defined in bytes with this command. In other words irrespective of the rate being enforced, burst-size fixed as given in the `burst-size bytes` parameter.

For the need of variable burst size depending on the rate being enforced this new keyword `auto-readjust [duration dur]` is provided. Use of this keyword enables the calculation of burst size as per token bucket algorithm calculation as $T=B/R$, where T is the time interval, B is the burst size and R is the Rate being enforced.

It also provides different burst size for Peak and Committed data rate-limiting.

If `auto-readjust` keyword is not used a fixed burst size must be defined which will be applicable for peak data rate and committed data rate irrespective of rate being enforced.

If `auto-readjust` keyword is provided without specifying the duration a default duration of 1 second will be taken for burst size calculation.

Example

The following command lowers the IP precedence when the committed-data-rate and the peak-data-rate are violated in uplink direction:

```
qos rate-limit direction uplink violate-action lower-ip-precedence
```

The following command buffers the excess user packets when the subscriber traffic violates the configured peak or committed data-rate bps in uplink direction. Once the peak/committed data rate for that subscriber goes below the configured limit it transmits them. It also transmits them if buffer memory is full:

```
qos rate-limit direction uplink violate-action shape transmit-when-  
buffer-full
```

qos traffic-police

Enables and configures traffic policing through the bandwidth limits and action for the subscriber traffic if it exceeds/violates the peak or committed data rate. Uplink and downlink limits are configured separately.

Product

PDSN, HA, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
qos traffic-police direction { downlink | uplink } [ burst-size bytes ] [
committed-data-rate bps ] [ exceed-action { drop | lower-ip-precedence |
transmit } ] [ peak-data-rate bps ] [ violate-action { drop | lower-ip-
precedence | transmit } ]
```

```
no qos traffic-police direction { downlink | uplink }
```

downlink

Apply the specified limits and actions to the downlink (data to the subscriber).

uplink

Apply the specified limits and actions to the uplink (data from the subscriber).

burst-size *bytes*

Default: 3000

The peak burst size allowed, in bytes.

bytes must be an integer from 0 through 4294967295.

Important: It is recommended that this parameter be configured to at least the greater of the following two values: 1) 3 times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the “bucket” for the configured peak-data-rate.

committed-data-rate *bps*

Default: 144000

The committed data rate (guaranteed-data-rate) in bps (bits per second).

bps must be an integer from 0 through 4294967295).

exceed-action { drop | lower-ip-precedence | transmit }

Default: lower-ip-precedence

The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate.

The following actions are supported:

drop: Drop the packet

lower-ip-precedence: Transmit the packet after lowering the ip-precedence

transmit: Transmit the packet

peak-data-rate *bps*

Default: 256000

Specifies the peak data-rate for the subscriber, in bps (bits per second). *bps* must be an integer from 0 through 4294967295).

violate-action { **drop** | **lower-ip-precedence** | **transmit** }

Default: drop

The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:

drop: Drop the packet

lower-ip-precedence: Transmit the packet after lowering the IP precedence

transmit: Transmit the packet

no

Disable traffic policing for the specified direction for the current subscriber.

Usage

Use this command to limit the bandwidth a subscriber uses in the uplink and downlink directions.

Important: If the exceed/violate action is set to “lower-ip-precedence”, the TOS value for the outer packet becomes “best effort” for packets that exceed/violate the traffic limits regardless of what the **ip user-datagram-tos copy** command is configured to. In addition, the “lower-ip-precedence” option may also override the configuration of the **ip qos-dscp** command. Therefore, it is recommended that command not be used when specifying this option.

Details on the QoS traffic policing functionality is located in the System Enhanced Feature Configuration Guide.

Example

The following command sets an uplink peak data rate of *128000* bps and lowers the IP precedence when the committed-data-rate and the peak-data-rate are exceeded:

```
qos traffic-police direction uplink peak-data-rate 128000 violate-action
lower-ip-precedence
```

The following command sets a downlink peak data rate of *256000* bps and drops packets when the committed-data-rate and the peak-data-rate are exceeded:

```
qos traffic-police direction downlink peak-data-rate 256000 violate-
action drop
```

qos traffic-shape

Enables and configures traffic shaping functionality to provide the traffic shaping by means of buffering the data packets during congestion or when subscriber exceeds the configured peak or committed data rate limit. It buffers the data packets instead of discarding instantaneous burst and deliver it to subscriber when traffic flow is below the peak or committed data rate. Uplink and downlink traffic shaping are configured separately.

 **Important:** This feature is NOT supported for real-time traffic.

Product

PDSN, HA, GGSN, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
qos traffic-shape direction { downlink | uplink } [ burst-size bytes ] [
committed-data-rate bps ] [ exceed-action { drop | lower-ip-precedence |
transmit } ] [ peak-data-rate bps ] [ violate-action { drop | lower-ip-
precedence | buffer [ transmit-when-buffer-full ] | transmit } ] +
```

```
no qos traffic-shape direction { downlink | uplink }
```

downlink

Apply the specified limits and actions to the downlink (data to the subscriber).

uplink

Apply the specified limits and actions to the uplink (data from the subscriber).

burst-size bytes

Default: 3000

The peak burst size allowed, in bytes.

bytes must be an integer from 0 through 4294967295.

 **Important:** It is recommended that this parameter be configured to at least the greater of the following two values: 1) 3 times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the “bucket” for the configured peak-data-rate.

committed-data-rate bps

Default: 144000

The committed data rate (guaranteed-data-rate) in bps (bits per second).

bps must be an integer from 0 through 4294967295).

```
exceed-action { drop | lower-ip-precedence | transmit }
```

Default: lower-ip-precedence

The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate.

The following actions are supported:

drop: Drop the packet

lower-ip-precedence: Transmit the packet after lowering the ip-precedence

transmit: Transmit the packet

```
peak-data-rate bps
```

Default: 256000

Specifies the peak data-rate for the subscriber, in bps (bits per second).

bps must be an integer from 0 through 4294967295).

```
violate-action { drop | lower-ip-precedence | buffer [transmit-when-  
buffer-full] | transmit }
```

Default: See Usage section for this command

The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:

drop: Drop the packet

lower-ip-precedence: Transmit the packet after lowering the IP precedence

buffer [**transmit-when-buffer-full**]: Enables the traffic shaping and provides the buffering of user packets when subscriber traffic violates the allowed peak/committed data rate. The [**transmit-when-buffer-full**] keyword allows the packet to be transmitted when buffer memory is full.

transmit: Transmit the packet

+

More than one of the above keywords can be entered within a single command.

no

Disable traffic policing for the specified direction for the current subscriber.

Usage

Use this command to provide the traffic shaping function to a subscriber in the uplink and downlink directions. This feature is providing a traffic flow control different to QoS traffic policing. When a subscriber violates or exceeds the peak data rate instead of dropping the packets, as in QoS traffic policing, this feature provides the buffering facility of subscriber data packets and it sends the buffered data when the traffic flow is low or not in congestion state.

Important: If the exceed/violate action is set to “lower-ip-precedence”, the TOS value for the outer packet becomes “best effort” for packets that exceed/violate the traffic limits regardless of what the **ip user-datagram-tos copy** command is configured to. In addition, the “lower-ip-precedence” option may also override the configuration of the **ip qos-dscp** command. Therefore, it is recommended that command not be used when specifying this option.

Details on the QoS traffic policing functionality is located in the System Enhanced Feature Configuration Guide.

Example

The following command sets an uplink peak data rate of *128000* bps and lowers the IP precedence when the committed-data-rate and the peak-data-rate are exceeded:

```
qos traffic-shape direction uplink peak-data-rate 128000 violate-action  
lower-ip-precedence
```

The following command buffers the excess user packets when the subscriber traffic violates the configured peak-data-rate *256000* bps in downlink direction. Once the peak/committed data rate for that subscriber goes below the configured limit it transmits them. It also transmits them if buffer memory is full:

```
qos traffic-shape direction downlink peak-data-rate 256000 violate-action  
buffer transmit-when-buffer-full
```

radius accounting

Sets the RADIUS accounting parameters for the subscriber or domain. This command takes precedence over the similar context configuration command. This command is disabled by default.

Product

All

Privilege

Administrator

Syntax

```
radius accounting { interim { interval-timeout timeout | normal | suppress } |
ip remote-address list-id list_id | mode { session-based | access-flow-based {
none | auxillary-flows | all-flows | main-a10-only } } | start { normal |
suppress } | stop { normal | suppress } }
```

```
no radius accounting { ip remote-address list-id list_id | interim [ interval-
timeout ] }
```

```
interim { interval-timeout timeout | normal | suppress }
```

interval-timeout *timeout*: Indicates the time (in seconds) between updates to session counters (log file on RADIUS or AAA event log) during the session. *timeout* must be an integer from 50 to 40000000.

Caution: Interim interval settings received from the RADIUS server take precedence over this setting on the system. While the low limit of this setting on the system is a minimum of 50 seconds, the low limit setting on the RADIUS server can be as little as 1 second. To avoid increasing network traffic unnecessarily and potentially reducing network and system performance, do not set this parameter to a value less than 50 on the RADIUS server.

normal: If RADIUS accounting is enabled, send this Acct-Status-Type message when required by normal operation

suppress: If RADIUS accounting is enabled, suppress the sending of this Acct-Status-Type message.

```
ip remote-address list-id list_id
```

Specifies the identification number of the IP address list to use for the subscriber for remote address-based accounting.

list_id: Specifies the RADIUS accounting remote IP address list identifier for remote-address accounting for the subscriber. *list_id* must be an integer from 1 through 65535.

This command is used as part of the Remote Address-based accounting feature and associates the subscriber with a list of remote addresses. Remote address accounting data is collected each time the subscriber communicates with any of the addresses specified in the list.

Remote address lists are configured using the **list** keyword in the **radius accounting ip remote-address** command in the Context Configuration mode.

```
mode { session-based | access-flow-based { none | auxillary-flows | all-
flows | main-a10-only } }
```

Default: **session-based**

Specifies if the radius accounting mode is either session-based or access-flow-based.

session-based: configures session-based RADIUS accounting behavior for the subscriber - which means a single radius accounting message generated for the subscriber session not separate accounting messages for individual A10 connections or flows.

access-flow-based: configures access-flow-based RADIUS accounting behavior for the subscriber. This offers flexibility by generating separate accounting messages for flows and A10 sessions.

- **all-flows:** Generates separate RADIUS accounting messages per access flow. Separate accounting messages are not generated for data path connections. (For example, separate messages are not sent for the main A10 or auxiliary connections.)
- **auxiliary-flows:** Generates RADIUS accounting records for the main data path connection and for access-flows for all auxiliary data connections. (For example, separate RADIUS accounting messages are generated for the main A10 session and for access-flows within auxiliary A10 connections. The main A10 session accounting does not include octets or other accounting information from the auxiliary flows.)
- **main-a10-only:** Configures access-flow-based single accounting messages (for example only single start/interim/stop) are generated for the main A-10 flows only.
- **none:** Separate RADIUS accounting messages are generated for all data path connections (for example, PDSN main or auxiliary A10 connections) but not for individual access-flows. This is essentially A10 connection-based accounting.

```
start { normal | suppress }
```

normal: If RADIUS accounting is enabled, send this Acct-Status-Type message when required by normal operation

suppress: If RADIUS accounting is enabled, suppress the sending of this Acct-Status-Type message.

```
stop { normal | suppress }
```

normal: If RADIUS accounting is enabled, send this Acct-Status-Type message when required by normal operation

suppress: If RADIUS accounting is enabled, suppress the sending of this Acct-Status-Type message.

```
no
```

ip remote-address list-id list_id: Deletes the entry for the specified *list_id*.

interim [interval-timeout]: Disables the interim interval setting.

Usage

Use this command to allow a per-domain setting for the RADIUS accounting.

Example

Set the accounting interim interval to one minute (60 seconds) for all sessions that use the current subscriber configuration:

```
radius accounting interim interval-timeout 60
```

Do not send RADIUS interim accounting messages:

```
radius accounting interim suppress
```

Sets the accounting message start normal for main A-10 flows only.

```
radius accounting mode main-a10-only start normal
```

radius group

It applies a RADIUS server group at the subscriber level for AAA functionality.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
radius group group_name
```

```
{ default | no } radius group
```

group_name

Specifies the name of the server group that is used for authentication and/or accounting for the specific subscriber.

group_name must be an alpha and/or numeric string of 1 through 63 characters in length. It must be the same as configured earlier within the same context of subscriber.

default

Sets / Restores default RADIUS server group specified at the context level or default subscriber profile.

no

Disables the applied RADIUS group for specific subscriber.

Usage

This feature provides the RADIUS configurables under radius group node. Instead of having a single list of servers per context, this feature configures multiple server groups within a context and applies individual RADIUS server group for subscriber in that context. Each server group consists of a list of AAA servers. In case no RADIUS group is applied for the said subscriber or default subscriber profile, then the default server group available at context level is applicable for accounting and authentication of specific subscriber.

Example

Following command applies a previously configured RADIUS server group named *star1* to a subscriber within the specific context:

```
radius group star1
```

Following command disables the applied RADIUS server group for the specific subscriber.

```
no radius group
```

radius returned-framed-ip-address

Sets the policy whether or not to reject a call when the RADIUS server supplies 255.255.255.255 as the framed IP address and the MS does not supply an address.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
radius returned-framed-ip-address 255.255.255.255-policy { accept-call-when-ms-  
ip-not-supplied | reject-call-when-ms-ip-not-supplied }
```

```
default radius returned-framed-ip-address 255.255.255.255-policy
```

accept-call-when-ms-ip-not-supplied

Accept calls when the RADIUS server does not supply a framed IP address and the MS does not supply and address.

reject-call-when-ms-ip-not-supplied

Reject calls when the RADIUS server does not supply a framed IP address and the MS does not supply and address.

default

Set the policy to its default of rejecting calls when the RADIUS server does not supply a framed IP address and the MS does not supply and address.

Usage

Use this command to set the behavior for the current subscriber when the RADIUS server supplies 255.255.255.255 as the framed IP address and the MS does not supply an address.

Example

Use the following command to set the subscriber profile to reject calls when the RADIUS server does not supply a framed IP address and the MS does not supply and address:

```
radius returned-framed-ip-address 255.255.255.255-policy reject-call-  
when-ms-ip-not-supplied
```

rohc-profile-name

Identifies the RoHC profile configuration to be applied to bearer sessions belonging to this subscriber.

Product

HSGW,PDSN

Privilege

Administrator

Syntax

```
rohc-profile-name name
```

name

Specifies the name of the RoHC profile this subscriber will use to apply header compression and decompression parameters to bearer session data. *name* must be an existing RoHC profile and be from 1 to 63 alpha and/or numeric characters.

Usage

Use this command to specify a RoHC configuration profile to be applied to bearer sessions belonging to this subscriber. RoHC profiles are configured through the Global Configuration Mode using the **rohc-profile** command.

Example

The following command specifies that the RoHC profile named *rohc-cfg1* is to be applied to all bearer sessions belonging to this subscriber:

```
rohc-profile-name rohc-cfg1
```

secondary ip pool

This command specifies a secondary IP pool to be used as backup pool for NAT.

 **Important:** This command is license dependent, requiring the 600-00-7871 NAT Bypass license. Please contact your local sales representative for more information.

Product

NAT

Privilege

Security Administrator, Administrator

Syntax

```
secondary ip pool pool_name
```

```
no secondary ip pool
```

no

Removes the previous secondary IP pool configuration.

pool_name

Specifies the secondary IP pool name.

pool_name must be an alpha and/or numeric string of 1 through 31 characters in length.

Usage

Use this command to configure a secondary IP pool for NAT subscribers, which is not overwritten by the RADIUS supplied list. The secondary pool configured will be appended to the RADIUS supplied IP pool list / subscriber template provided IP pool list whichever is applicable during call setup.

Example

The following command configures a secondary IP pool named *test123*:

```
secondary ip pool test123
```

simultaneous

Enables/disables the simultaneous use of both Mobile and Simple IP services.

Product

PDSN, FA, HA, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] simultaneous simple-and-mobile-ip
```

no

Disables the simultaneous use.

Usage

Subscribers with mobile devices supporting mobile and simple IP services concurrently require this option to be set.

Example

```
no simultaneous simple-and-mobile-ip
```

```
simultaneous simple-and-mobile-ip
```

timeout

Configures the subscriber session timeouts.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
timeout { absolute | idle } seconds
```

```
no timeout [ absolute | idle ]
```

absolute

Default: 0

The absolute maximum time a session may exist in any state (active or dormant).

idle

Default: 0

The maximum duration of the session, in seconds, before the system automatically terminates the session due to inactivity.

seconds

Specifies the maximum amount of time, in seconds, before the specified timeout action is activated.

seconds must be a value in the range from 0 through 4294967295.

The special value 0 disables the timeout specified.

no

Indicates the timeout specified is to be returned to its default behavior. If no specific timeout is specified then all are set to their default behavior.

Usage

Reduce the idle timeout to free session resources faster for use by new requests.

Example

```
timeout absolute 1800
```

```
no timeout
```

timeout long-duration

Configures the long duration timeout and optionally the inactivity duration of HA subscriber session.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
timeout long-duration ldt_timeout [ inactivity-time inact_timeout ]
[ no | default ]timeout long-duration
```

no

Indicates the timeout specified is to be returned to its default behavior. If no specific timeout is specified then all are set to their default behavior.

long-duration *ldt_timeout*

Default: 0

Designates the maximum duration of the session, in seconds, before the system automatically reports/terminates the session.

ldt_timeout must be a value in the range from 0 through 4294967295.

The special value 0 disables the timer.

inactivity-time *inact_timeout*

Specifies the maximum amount of time, in seconds, before the specified session is marked as dormant.

inact_timeout must be a value in the range from 0 through 4294967295.

The special value 0 disables the inactivity time specified.

Usage

Use this command to set the long duration timeout period and inactivity timer for subscriber sessions. Reduce the idle timeout to free session resources faster for use by new requests.

Refer to the *long-duration-action detection* and *long-duration-action disconnection* section for more information.

Example

Following command sets the long duration timeout duration to 300 seconds and inactivity timer for subscriber session to 45 seconds:

```
timeout long-duration 300 inactivity-time 45
```

tpo policy

Specifies the Traffic Performance Optimization policy for subscriber(s).

Important: This is a restricted command. For more information contact your local sales representative.

Product

TPO

Privilege

Security Administrator, Administrator

Syntax

```
tpo policy tpo_policy_name
```

```
{ default | no } tpo policy
```

default

Configures the default setting.

Default: Use the default TPO policy configured in the rulebase.

no

Disables TPO in the subscriber configuration.

tpo_policy_name

Specifies the TPO policy for the subscriber(s), and must be an alpha and/or string of 1 through 63 characters in length.

Usage

Use this command to specify the TPO policy for the subscriber(s).

Example

The following command specifies to use the TPO policy named *tpo_policy_110*:

```
tpo policy tpo_policy_110
```

tunnel address-policy

This command specifies the policy for address allocation and validation for all tunneled calls (IP-IP, IP-GRE) except L2TP calls. This means that GGSN IP address validation could be disabled for specified incoming calls.

For GGSN systems, this command can also be specified in the APN Configuration mode (**tunnel address-policy**) which would mean the system defers to the old **l3-to-l2-tunnel address policy** command for calls coming through L2TP tunnels.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
tunnel address-policy { alloc-only | alloc-validate | no-alloc-validate }
default tunnel address-policy
```

alloc-only

IP addresses are allocated locally and no validation is done.

alloc-validate

Default.

The VPN Manager allocates and validates all incoming IP addresses from a static pool of IP addresses.

no-alloc-validate

No IP address assignment or validation is done for calls coming in via L3 tunnels. Incoming static IP addresses are passed. This allows for the greatest flexibility.

default

Resets the tunnel address-policy to alloc-validate.

Usage

This command supports scalable solutions for Corporate APN deployment as many corporations handle their own IP address assignment. In some cases this is done to relieve the customer or the mobile operators from the necessity of reconfiguring the range of IP addresses for the IP pools at the GGSN.

Example

Use the following command to reset the IP address validation policy to validate against a static pool of address:

```
default tunnel address-policy
```

Use the following command to disable all IP address validation for calls coming through tunnels:

```
tunnel address-policy no-alloc-validate
```

tunnel gre

Configures Generic Routing Encapsulation (GRE) tunnel parameters for the current subscriber.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
tunnel gre peer-address peer_address local-address local_addr
```

```
no tunnel gre peer-address peer_address
```

```
peer-address peer_address
```

Specifies the IP address of the external gateway terminating the GRE tunnel.

```
local-address local_addr
```

Specifies the IP address of the interface in the destination context originating the GRE tunnel.

```
no
```

Disables GRE tunneling for the current subscriber.

Usage

Subscriber IP payloads are encapsulated with IP/GRE headers and tunneled by the AGW to an external gateway.

Example

The following command configures the system to encapsulate subscriber traffic using GRE and tunnel it from a local address of `192.168.1.100` to a gateway with an IP address of `192.168.1.225`:

```
tunnel gre peer-address 192.168.1.225 local-address 192.168.1.100
```

tunnel ipip

Configures IP-in-IP tunnelling parameters for the current subscriber.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
tunnel ipip peer-address peer_address local-address local_addr ]
```

```
no tunnel ipip
```

```
peer-address peer_address
```

Specifies the IP address of the external gateway terminating the IP-in-IP tunnel.

```
local-address local_addr
```

Specifies the IP address of the interface in the destination context originating the IP-in-IP tunnel.

```
no
```

Disables IP-in-IP tunneling for the current subscriber.

Usage

Subscriber IP payloads are encapsulated with IP-in-IP headers and tunneled by the GGSN or PDSN to an external gateway.

Example

The following command configures the system to encapsulate subscriber traffic using IP-in-IP and tunnel it from a local address of *192.168.1.100* to a gateway with an IP address of *192.168.1.225*:

```
tunnel ipip peer-address 192.168.1.225
```

```
local-address 192.168.1.100
```

tunnel ipsec

This command configures sessions for the current subscriber to use an IPSEC tunnel based on the IP pool corresponding to the subscribers assigned ip address.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
tunnel ipsec use-policy-matching-ip-pooler-address  
no tunnel ipsec [ use-policy-matching-ip-pooler-address ]
```

no

Disables the use of the IPSEC policy that matches the IP pool that the assigned IP address relates to.

Usage

Use this command to set the current subscribers sessions to use an IPSEC policy that is assigned to the IP pool that the subscribers assigned IP address relates to.

Example

The following command enables the use of the policy that matches the IP pool address:

```
tunnel ipsec use-policy-matching-ip-pooler-address
```

tunnel l2tp

Configures the L2TP tunnel for the subscriber.

Product

L2TP

Privilege

Security Administrator, Administrator

Syntax

```
tunnel l2tp [ peer-address ip address [ [ encrypted ] [secret secret] ] [
preference number] [ tunnel-context context ] [ local-address ip_address ] [
crypto-map map_name { [ encrypted ] isakmp-secret secret } ] ]
```

```
no tunnel l2tp [ peer-address ip_address ]
```

peer-address *ip_address*

A peer L2TP Network Server (LNS) associated with this LAC (L2TP Access Concentrator). *ip_address* must be an IP address in IPv4/IPv6 format.

[**encrypted**] **secret** *secret*

The shared key (*secret*) between the L2TP Network Server (LNS) associated with this LAC (L2TP Access Concentrator). *secret* must be between 1 and 63 alpha and/or numeric characters and is case sensitive.

encrypted: The encrypted shared key between the L2TP Network Server (LNS) associated with this LAC (L2TP Access Concentrator). *secret* must be between 1 and 128 alpha and/or numeric characters and is case sensitive.

The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the **secret** keyword is the encrypted version of the plain text secret. Only the encrypted secret is saved as part of the configuration file.

preference *number*

Default: 1

The order in which a group of tunnels configured for this subscriber will be tried. *number* must be an integer between 1 and 65535.

tunnel-context *context*

The name of the context containing ports through which this subscriber's data traffic is to be communicated between this LAC and the LNS. *context* must be between 1 and 79 alpha and/or numeric characters.

local-address *ip_address*

A LAC service bind address which is given as a hint used to select a particular LAC service. *ip_address* must be an IP address in IPv4/IPv6 format.

```
crypto-map map_name { [encrypted] isakmp-secret secret }
```

map_name is the name of a crypto map that has been configured in the current context. *map_name* must be a string from 1 to 127 alphanumeric characters.

isakmp-secret *secret*: The pre-shared key for IKE. *secret* must be a string from 1 to 127 alphanumeric characters.

encrypted isakmp-secret *secret*: The pre-shared key for IKE. Encryption must be used when sending the key. *secret* must be a string from 1 to 127 alphanumeric characters.

no

Disables tunneling for the current subscriber. When *peer-address* is included, the tunneling for that specific L2TP Network Server (LNS) is disabled but tunneling to other configured LNSs is still enabled.

Usage

Use this command to configure specific L2TP tunneling parameters for the current subscriber.

Example

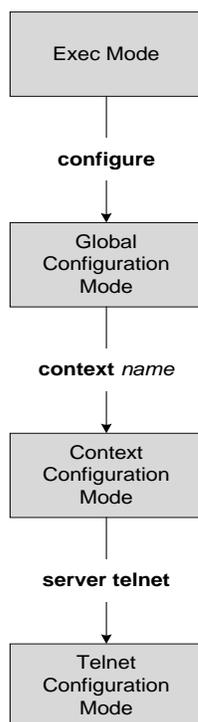

To specify L2tp tunneling to the LNS peer at the IP address *198.162.10.100* with a shared secret of *bigco* and preference of *1*, enter the following command:

```
tunnel l2tp peer-address 198.162.10.100 secret bigco preference 1
```

Chapter 218

Telnet Configuration Mode Commands

The Telnet Configuration Mode is used to manage the Telnet server options for the current context.

■ end

end

Exits the telnet server configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the telnet server configuration mode and returns to the context configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

max servers

Configures the maximum number of telnet servers that can be started within any 60 second interval. If this limit is reached, the system waits two minutes before trying to start any more servers.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
max servers count
```

count

Default: 40

Specifies the maximum number of servers that can be spawned in any 60 second interval. *count* must be a value in the range from 1 to 100.

Usage

Set the number of servers to tune the system response as a heavily loaded system may need more servers to support the incoming requests.

The converse would be true as well in that a system can benefit by reducing the number of servers such that telnet services do not cause excessive system impact to other services.

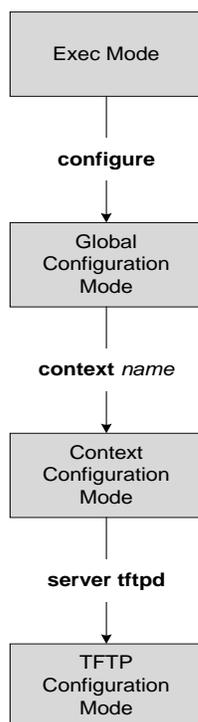

Example

```
max servers 50
```

Chapter 219

TFTP Configuration Mode Commands

The TFTP configuration mode is used to manage the TFTP servers for the current context.

■ end

end

Exits the TFTP server configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the TFTP server configuration mode and returns to the context configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

max servers

Configures the maximum number of TFTP servers that can be started within any 60 second interval. If this limit is reached, the system waits two minutes before trying to start any more servers.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
max servers count
```

count

Default: 40

Specifies the maximum number of servers that can be spawned in any 60 second interval. *count* must be a value in the range from 1 to 100.

Usage

Set the number of servers to tune the system response as a heavily loaded system may need more servers to support the incoming requests.

The converse would be true as well in that a system can benefit by reducing the number of servers such that TFTP services do not cause excessive system impact to other services.

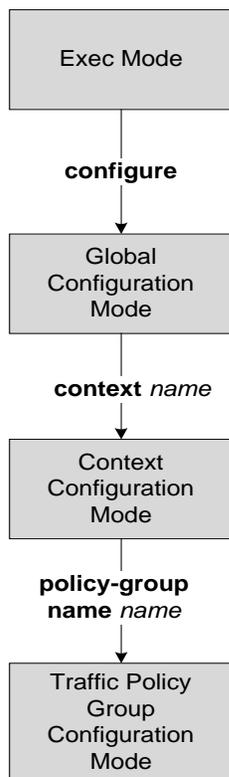

Example

```
max servers 50
```

Chapter 220

Traffic Policy Group Configuration Mode Commands

Policy-Group is used to form a set of configured Policy-Maps for Traffic Policy feature. It applies multiple policies for a subscriber session flow within a destination context.

■ end

end

Exits the context configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the context configuration mode and returns to the global configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the global configuration mode.

policy

This command assigns the traffic policies, pre-configured in Policy-Map configuration mode, to a Policy Group for flow-based traffic policing to a subscriber session flow.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] policy policy_map_name precedence value direction [ in | out ]
```

no

Disables/removes configured policy for traffic policing.

direction [in | out]

Specifies the direction in which the policies need to be applied.

policy_map_name

Specifies the policy string of size 1 to 15.

precedence *value*

Specifies the precedence of traffic policies to resolve.

value is an integer in the range from 1 through 16. If a session flow matches multiple policies this keyword resolves them.

Usage

Use this command to form a policy-group with a set of pre-configured Policy-Maps.

Example

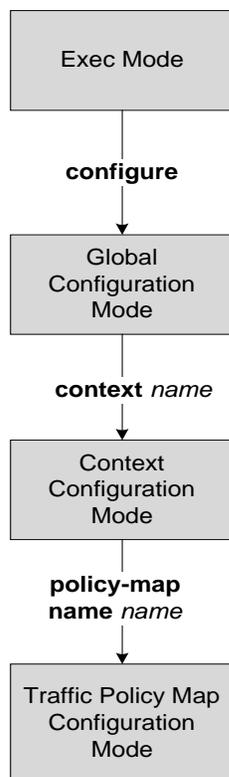

The following commands assigns the traffic policy policymap1 with precedence 2.

```
policy policymap1 precedence 2
```

Chapter 221

Traffic Policy-Map Configuration Mode Commands

Policy-Map is used to configure a flow-based traffic policy for Traffic Policy feature within a destination context. It designates the flow treatment based on the classification rules configured in Class-Map mode for a subscriber session flow.

3gpp2 data-over-signaling

This command configures 3GPP2 related flow treatment policy for the flow-based traffic policing to subscriber session.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
3gpp2 data-over-signaling marking [ class-map class_name ]
```

```
no 3gpp2 data-over-signaling marking
```

no

Disables configured 3GPP2 related flow treatment policy.

class_name

Disables configured 3GPP2 related flow treatment policy.

marking

Indicates 3GPP2 related traffic flow for data over signaling channel.

Usage

Use this command to mark traffic flows for 3GPP2 related policy.

Example

```
3gpp2 data-over-signaling marking
```

access-control

This command configures the access control action for traffic flow matching with Class-Map rules.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
access-control { allow | discard }
```

allow

This option allows the packets, if policy matches with the criteria defined in Class-Map assigned to the specific traffic policy.

discard

This option discards the packets, if policy matches with the criteria defined in Class-Map assigned to the specific traffic policy.

Usage

Configures the action or treatment for traffic flows matching with criteria specified in assigned Class-Map.

Example

The following command allows the packets or traffic flow on matching with criteria specified in assigned Class-Map for specific traffic policy.

```
access-control allow
```

accounting suppress

This command suppresses accounting action on traffic flow matching the policy map.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] accounting suppress
```

no

Removes the suppression of accounting for traffic flow matching this policy map.

Usage

Use this command to suppress accounting action on traffic flow matching this policy map.

Policy maps configured for accounting suppression are used to implement the QChat Billing Suppression feature to selectively start and terminate accounting sessions based on the categorization of traffic as being interesting or non-interesting. See the **accounting trigger** command.

Example

The following command configures suppression of accounting on traffic flows matching this policy map:

```
accounting suppress
```

accounting trigger

This command configures an accounting trigger policy map to selectively start and terminate accounting sessions based on the categorization of traffic as being interesting or non-interesting to support the QCHAT Billing Suppression feature.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] accounting trigger { inactivity-timeout | interesting-traffic |
intra-service-handoff }
```

default

Sets / Restores default value assigned for specified parameter.

no

Disables previously configured triggers.

inactivity-timeout

Generates an accounting stop message if there has been no data activity on the session for the interim accounting timeout interval.

Default: disabled

interesting-traffic

Generates an accounting start message upon arrival of interesting traffic.

Default: disabled

intra-service-handoff

Generates accounting start and stop messages during intra service handoffs within the same service.

Default: enabled

If this is disabled, the messages are suppressed during the handoffs. The current accounting session continues and no stop or start messages are generated during the intra service handoff.

Usage

Use this command to configure an accounting trigger policy map (ATPM) to selectively start and terminate accounting sessions based on the categorization of traffic as being interesting or non-interesting to support the QChat Billing Suppression feature.

Interesting traffic is identified as traffic that does not match any of the other Accounting Policy Maps (APMs) configured for accounting suppression. See the **accounting suppress** command.

An ATPM is similar to an APM, but without the class map rules. The ATPM is configured as of type accounting using the **type accounting** command.

In the ATPM, the trigger to start accounting for interesting traffic is configured using the **accounting trigger interesting-traffic** command. Accounting Start is triggered on arrival of interesting traffic, or change in airlink parameters conveyed through active-start airlink record. If an active-start record was included in the initial connection setup, Accounting Start is not triggered. But if the active-start comes separately and is the first one for the session, it is treated as airlink change and an Accounting Start is sent. Optionally, timeout can be triggered when there is no data traffic for the interim accounting timeout interval using the **accounting trigger inactivity-timeout stop** command. On timeout, the accounting session is terminated and an Accounting Stop message is sent. A new accounting session is created if interesting traffic resumes.

The ATPM should have the lowest precedence among the APMs.

As the airlink events are generated on the ingress side, the ATPM must be included in a policy group that is applied to the ingress direction in the subscriber profile. The configuration is applicable only for standard trigger policy and session based accounting mode.

Example

The following command sets the trigger to generate accounting start message upon arrival of interesting traffic:
accounting trigger interesting-traffic

class-map

This command assigns a traffic classification rule (Class-Map) to the policy map.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] class-map name
```

no

Enables/Disables **class-map**.

name

Specifies the name of the class map assigned for this policy map. The class map should be one that was configured in the Class Map Configuration Mode.

name must be the name of a class map, and must be a string of 1 through 15 characters in length.

Usage

Use this command to assigns a class map to the policy map for traffic policing. The class map is configured in the Class Map Configuration Mode.

Example

The following command assigns the class map classification1 to the current policy map:

```
class classification1
```

■ end

end

This command exits the current mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to change to the Exec mode.

exit

This command exits the current mode and returns to the parent mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent mode.

flow-tp-trigger

This command specifies that the traffic volume will be calculated based on the traffic on the flow.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
flow-tp-trigger volume traffic_volume_threshold
```

```
no flow-tp-trigger volume
```

traffic_volume_threshold

Specifies the volume threshold to trigger traffic policing.

volume is the value in bytes, and must be an integer from 1 through 4294967295.

Usage

This command is available if you have purchased and installed the Intelligent Traffic Control License on your system. Use this command to calculate the traffic volume based on the traffic on the flow.

Example

```
flow-tp-trigger volume500
```

ip header-compression

Enables the system to mark IP flows for RObust Header Compression.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip header-compression rohc flow-marking
```

no

Disables the setting.

rohc flow-marking

Marks the IP flow for SO67 and PPP ROHC.

Usage

Use this command to mark IP flows for SO67 and PPP ROHC.

Example

```
ip header-compression rohc flow-marking
```

qos encaps-header

Enables and configures Quality of Service (QoS) policy to use Differentiated Service Code Point (DSCP) marking in IP header field for the flow-based traffic policing to subscriber session flow.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
qos encaps-header dscp-marking { dscp_code | copy-from-user-datagram[ ignore-pcf-signaled-dscp ] }
no qos encaps-header dscp-marking { dscp_code | copy-from-user-datagram[ ignore-pcf-signaled-dscp ] }
```

no

Enables/Disables the **qos encaps-header**

The value must be expressed as a hexadecimal value from 0x00 through 0x3F.

dscp_code

Specifies the DSCP code value marked in IP header of packet/flow to determine the QoS for traffic policing. The value must be expressed as a hexadecimal value from 0x00 through 0x3F.

copy-from-user-datagram

Specifies to use DSCP code value from user datagram (UDP header) to determine the QoS for traffic policing.

ignore-pcf-signaled-dscp

Specifies to override the highest priority DSCP value signaled by the PCF.

user-datagram

Specifies to use the DSCP value copied from the user datagram.

Usage

Use this command to apply the QoS policy based on DSCP code value encapsulated in IP packet header or User datagram packet to subscriber session flow for flow-based traffic policing.

Important: Details on the QoS traffic policing functionality is located in the System Administration and Configuration Guide.

Example

The following command sets QoS policy with DSCP code value to 0x0C for Class 1, silver (AF12):

```
qos encaps-header dscp-marking 0x0c
```

qos traffic-police

Enables and configures Quality of Service (QoS) policy for the flow-based traffic policing to subscriber session flow on per-flow basis.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
qostraffic-policecommittedbpspeakbpsburst-sizebyteexceed-action { drop | lower-  
ip-precedence | allow } violate-action { drop | lower-ip-precedence | allow }  
  
no qostraffic-police
```

no

Enables/Disables the **qos traffic-police**

Important: It is recommended that this parameter be configured to at least the greater of the following two values: 1) 3 times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the “bucket” for the configured peak-data-rate.

burst-size *bytes*

Default: 3000

The peak burst size allowed, in bytes.

bytes must be an integer from 0 through 4294967295.

Important: It is recommended that this parameter be configured to at least the greater of the following two values: 1) 3 times greater than packet MTU for the subscriber connection, OR 2) 3 seconds worth of token accumulation within the “bucket” for the configured peak-data-rate.

committed *bps*

Default: 144000

The committed data rate (guaranteed-data-rate) in bps (bits per second).

bps must be an integer from 0 through 4294967295).

exceed-action { drop | lower-ip-precedence | allow }

Default: lower-ip-precedence

The action to take on the packets that exceed the committed-data-rate but do not violate the peak-data-rate.

The following actions are supported:

drop: Drop the packet

lower-ip-precedence: Transmit the packet after lowering the ip-precedence

allow: Transmit the packet

peak *bps*

Default: 256000

Specifies the peak data-rate for the subscriber, in bps (bits per second).

bps must be an integer from 0 through 4294967295.

violate-action { **drop** | **lower-ip-precedence** | **allow** }

Default: drop

The action to take on the packets that exceed both the committed-data-rate and the peak-data-rate. The following actions are supported:

drop: Drop the packet

lower-ip-precedence: Transmit the packet after lowering the IP precedence

allow: Transmit the packet

Usage

Use this command to apply the QoS policy to subscriber session flow for flow-based traffic policing.

Important: Details on the QoS traffic policing functionality are located in the System Administration.

Example

The following command sets committed data rate of 102400 bps with peak data rate of 128000 bps and burst size 2048 bytes. This lowers the IP precedence when the committed-data-rate exceeded and drops the packets when peak-data-rate are violated:

```
qos traffic-police committed 102400 peak 128000 burst-size 2048 exceed-action lower-  
ip-precedence violate-action drop
```

qos user-datagram dscp-marking

Enables and configures Quality of Service (QoS) policy related to differentiated service code point (DSCP) marking in user datagram of subscriber session flow on per-flow basis.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
qos user-datagram dscp-markingdscp_code
```

```
no qos user-datagram dscp-marking
```

dscp_code

Specifies the DSCP code value marked in IP header of packet/flow to determine the QoS for traffic policing. The value must be expressed as a hexadecimal value from 0x00 through 0x3F.

Usage

Use this command to apply the QoS policy to subscriber session flow by DSCP marking in user datagram.

Example

The following command sets DSCP marking for user datagram as 0x01 for QoS to subscriber session flow:

```
qos user-datagram dscp-marking 0x01
```

sess-tp-trigger

This command configures the trigger traffic control based on traffic volume on a session.

Product

PDSN, HA, ASN GW

Privilege

Security Administrator, Administrator

Syntax

```
sess-tp-trigger volume volume direction { both | downlink | uplink }  
no sess-tp-trigger
```

no

Enables/Disables the **sess-tp-trigger**

volume

Specifies the traffic volume threshold to trigger traffic control. *volume* is a value in bytes from 1 to 4294967295.

Usage

This command is available if you have purchased and installed the Intelligent Traffic Control License on your system. Use this command to configure the trigger traffic control based on traffic volume on a session.

Example

```
sess-tp-trigger 500
```

type

This command specifies the type of traffic policy within specific Policy-Map.

Product

PDSN, HA, ASN GW

Privilege

Administrator

Syntax

```
type { accounting | dynamic { three-gpp2 rev-A profile-id { any | id
profile_id | range low_value to high_value } flow-id { any | id flow_id |
range low_value to high_value } | pre-provisioned wimax asn-service-profile-
id { any | id service_id } asn-pdfid { any | id pdf_id } | static | template
}
```

accounting

Specifies the type of traffic policing as accounting for this specific policy map. This configuration is used for enabling/disabling the accounting of different flows matching with conditions within this Policy-Map.

dynamic

Identifies the type of policy map as dynamic.

three-gpp2 rev-A

Configures dynamic policy map type for CDMA2000-3GPP2 RevA service.

```
profile-id { any | id profile_id | range low_hex to high_hex }
```

Specifies the profile id matching in this policy map.

any allows any profile identifier matching with in this policy map.

id profile_id allows specific profile identifier matching with in this policy map. *profile_id* must be either a value in hexadecimal format from 0x0 to 0xFFFF.

range low_value to high_value: identifies a range in which a profile identifier must fall within to be considered a match. *low_value* and *high_value* must be either a value in hexadecimal format from 0x0 to 0xFFFF or 0 to 65535 - a string of size 1 to 6.

```
flow-id { any | id flow_id | range low_hex to high_hex }
```

Specifies the flow id matching in this policy map.

any allows any flow identifier matching with in this policy map.

id flow_id allows specific flow identifier matching with in this policy map. *flow_id* must be either a value in hexadecimal format from 0x0 to 0xFFFF or an integer from 0 to 65535.

range low_value to high_value: identifies a range in which a flow identifier must fall within to be considered a match. *low_value* and *high_value* must be either a value in hexadecimal format from 0x0 to 0xFFFF or 0 to 65535 - a string of size 1 to 6.

pre-provisioned

Identifies the type of policy map as pre-provisioned.

wimax

Configures WiMAX service policy map in an ASN-GW service.

asn-service-profile { any | id *service_id* }

Specifies the ASN Service profile identifier to match with in this policy map.

any: Allows any ASN Service Profile Identifier matching within this policy map.

id *service_id*: Allows specific Service Profile matching to a specified identifier. *service_id* must be an integer from 1 to 65535 and must match a service ID that was configured in the Subscriber Configuration Mode.

asn-pdfid { any | id *pdf_id* }

Specifies the ASN Packet Data Flow Identifier to match with in this policy map.

any: Allows any ASN Packet Data Flow Identifier matching within this policy map.

id *pdf_id*: Allows specific Packet Data Flow matching to a specified identifier. *pdf_id* must be an integer from 1 to 255 and must match a PDF ID that was configured in the Subscriber Configuration Mode.

static

Specifies the type of traffic policing as static for this specific Policy Map. In this type of policy, the traffic flow classification and flow treatment is pre-defined with classification rules through Class-Map configuration.

This is the detailed type of policy map.

template

Specifies the type of traffic policy to as a template to all subscribers associated with this policy map.

Usage

Specifies the type of traffic policy within the specific Policy-Map.

Example

The following commands configures the traffic policy for this Policy-Map as static:

```
type static
```

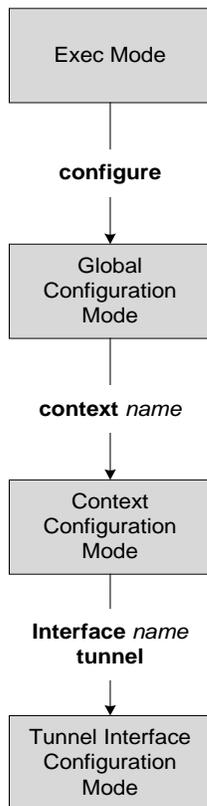

The following commands configures the traffic policy for this Policy-Map as pre-provisioned for WiMAX service requiring a match of any service profile and PDF id of 3:

```
type pre-provisioned wimax asn-service-profile any asn-pdfid id 3
```

Chapter 222

Tunnel Interface Configuration Mode Commands

The Tunnel Interface Configuration Mode is used to create and manage the IP interfaces for various type of tunnels and its parameters like addresses, address resolution options, etc.

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

description

Configures the description text for the current interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

description *text*

no description

no

Clears the description for the interface.

text

Specifies the descriptive text to use. *text* must be 0 to 79 alpha and/or numeric characters with no spaces or a quoted string of printable characters. The interface description is case sensitive.

Usage

Set the description to provide useful information on the interface's primary function, services, end users, etc. Any information useful may be provided.

Example

Following command sets the description about this interface:

```
description sampleInterfaceDescriptiveText
```

end

Exits the interface configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the Interface Configuration Mode and returns to the Context Configuration Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the context configuration mode.

ip address

This command configures the IPv4 address for the specific tunnel interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ip address [ip_address/ip_mask | ip_address ip_mask]
```

```
no ip address ip_address
```

no

Removes the configured IPv4 address bound to a tunnel interface.

```
ip_address/ip_mask | ip_address ip_mask
```

Specifies a destination IP address or group of addresses that will use this route.

ip_address/ip_mask: Specifies a combined IP address subnet mask bits to indicate what IP addresses to which the route applies. *ip_address/ip_mask* must be specified using the form 'IP Address/Mask Bits' where the IP address is specified using the standard IPv4 dotted decimal notation and the mask bits are a numeric value which is the number of bits in the subnet mask.

ip_address ip_mask: Specifies an IP address and the networking (subnet) mask pair which is used to identify the set of IP addresses to which the route applies. *ip_address* must be specified using the standard IPv4 dotted decimal notation. *ip_mask* must be specified using the standard IPv4 dotted decimal notation as network mask for subnets.

The mask as specified by *ip_mask* or resulting from *ip_address/ip_mask* is used to determine the network for packet routing.

0's in the resulting mask indicate the corresponding bit in the IP address is not significant in determining the network for packet routing.

1's in the resulting mask indicate the corresponding bit in the IP address is significant in determining the network.

Usage

Use this command to bind the IPv4 address to a tunnel interface. This address does not affect the encapsulation of packets going out on the tunnel interface.

Example

The following command will assign the 1.2.3.4 as IPv4 address to this tunnel interface:

```
ip address 1.2.3.4
```

ipv6 address

This command configures the IPv6 address for the specific tunnel interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
ipv6 address ipv6_address/ipv6_mask
```

```
no ipv6 address ipv6_address
```

no

Removes the configured IPv6 address bound to a tunnel interface.

ipv6_address/ipv6_mask

Specifies a destination IP address or group of addresses that will use this route.

ipv6_address/ipv6_mask: Specifies a combined IP address subnet mask bits to indicate what IP addresses to which the route applies. *ipv6_address/ipv6_mask* must be specified using the form 'IP Address/Mask Bits' where the IP address is specified using the standard IPv4 dotted decimal notation and the mask bits are a numeric value which is the number of bits in the subnet mask.

Usage

Use this command to bind the IPv6 address to a tunnel interface. This address does not affect the encapsulation of packets going out on the tunnel interface.

Example

The following command will assign the `1001::2:010:1234` as IPv4 address to this tunnel interface:

```
ipv6 address 1001::2:010:1234
```

tunnel-mode

This command configures the tunnel mode type for specific tunnel interface. It also creates the specific tunnel configuration mode if required.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
tunnel-mode {gre | ipv6ip}
```

```
default tunnel-mode
```

default

Sets the default tunnel mode for this interface. By default tunnel mode is set to IPv6-to-IPv4 type.

gre

Default: Disabled

This keyword sets the tunnel interface mode to GRE type and creates the GRE tunnel Configuration mode if required.

ipv6ip

Default: Enabled

This keyword sets the tunnel interface mode to IPv6-to-IPv4 type and creates the IPv6-to-IPv4 Tunnel Configuration mode, if required.

Usage

Use this command to set the tunnel mode type of GRE or IPv6-to-IPv4 for tunneling interface.

Example

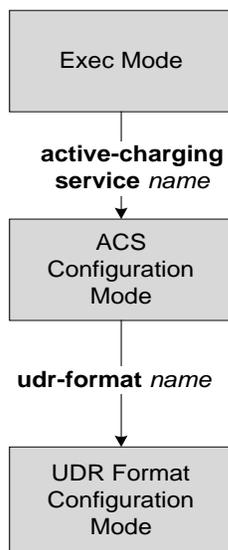

The following command sets the tunnel mode to GRE for specific interface:

```
tunnel-mode gre
```

Chapter 223

UDR Format Configuration Mode Commands

The UDR Format Configuration Mode enables configuring User Detail Record (UDR) formats. UDR file formats are represented in Comma Separated Value (CSV).

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

attribute

This command specifies the order of fields in the UDR.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
attribute attribute { [ format { MM/DD/YY-HH:MM:SS | MM/DD/YYYY-HH:MM:SS |
YYYY/MM/DD-HH:MM:SS | YYYYMMDDHHMMSS | seconds } [ localtime ] | [ { bytes |
pkts } { downlink | uplink } ] ] priority priority }
```

```
no attribute attribute [ priority priority ]
```

no

Removes the specified attribute configuration.

attribute

Specifies the attribute.

attribute must be one of the following:

Attribute	Description
diameter-session-id	Unique Diameter session identifier.  Important: This attribute is customer specific, and is only available in 8.3 and later releases.
radius-called-station-id	Called Station ID of the mobile handling the flow.
radius-calling-station-id	Calling Station ID of the mobile handling the flow.
radius-fa-nas-identifier	RADIUS NAS identifier of Foreign Agent (FA).
radius-fa-nas-ip-address	RADIUS IP address of Foreign Agent (FA).
radius-nas-identifier	RADIUS NAS identifier.

Attribute	Description
<code>radius-nas-ip-address</code>	<p>RADIUS NAS IP address.</p> <hr/> <p> Important: This attribute is interchangeable with <code>sn-st16-ip-addr</code> for the user.</p>
<code>radius-user-name</code>	User name associated with the flow.
<code>sn-3gpp2-bsid</code>	This option is obsolete. To configure this attribute see the rule-variable command.
<code>sn-3gpp2-carrier-id</code>	This option is obsolete. To configure this attribute see the rule-variable command.
<code>sn-3gpp2-esn</code>	This option is obsolete. To configure this attribute see the rule-variable command.
<code>sn-3gpp2-meid</code>	This option is obsolete. To configure this attribute see the rule-variable command.
<code>sn-3gpp2-service-option</code>	This option is obsolete. To configure this attribute see the rule-variable command.
<code>sn-acct-beginning-session</code>	<p>Session beginning information.</p> <hr/> <p> Important: This attribute is customer specific, and is only available in 8.3 and later releases.</p>
<code>sn-acct-session-continue</code>	<p>Session continue information.</p> <hr/> <p> Important: This attribute is customer specific, and is only available in 8.3 and later releases.</p>
<code>sn-acct-session-id</code>	Indicator for the Accounting Session Identifier.
<code>sn-acct-session-time</code>	<p>Duration from <code>acct-status-type:start</code> to <code>acct-status-type:stop</code>.</p> <hr/> <p> Important: This attribute is customer specific, and is only available in 8.3 and later releases.</p>

Attribute	Description
sn-acct-status-type	Accounting status identifier.  Important: This attribute is customer specific, and is only available in 8.3 and later releases.
sn-charging-type	Charging type: <ul style="list-style-type: none"> • offline • online  Important: This attribute is customer specific, and is only available in 8.3 and later releases.
sn-closure-reason	Includes reason for the termination of the flow/UDR: <ul style="list-style-type: none"> • 0 = CALL_TERMINATION — normal, i.e., subscriber session ended • 1 = PDSN_HO — handoff control processing specified • 2 = TIME_LIMIT • 3 = VOLUME_LIMIT • 4 = MGMT_INTERVENTION • 5 = ACCT_SESS_START • 6 = CCRU_RESPONSE • 7 = OFFLINE_CHARGING — for UDRs generated when offline charging trigger is received from DCCA
sn-content-id	Unique identifier for the content-id.
sn-content-label	Identifier for text label for content-id.
sn-content-vol	Identifier for content volume.
sn-correlation-id	RADIUS correlation identifier.
sn-duration	Time difference between the first and last packet of a single data flow accounted in the UDR record. I.e., the time difference between the first ICMP echo request and the last ICMP echo response before the record gets written for the content-id.
sn-end-time [format format]	Timestamp for last packet of flow in UTC.
sn-fa-correlation-id	RADIUS Correlation Identifier of the Foreign Agent (FA).
sn-fa-ip-address	FA IP address.
sn-filler-blank	Keeps attributes place blank and generates an empty UDR field.
sn-filler-zero	Fills '0' for this attribute place in the EDR/UDR.

Attribute	Description
sn-format-name	Indicates the name of the UDR/EDR format used.
sn-group-id	Indicates the sequence group identifier for the records.
sn-ha-ip-address	Home Agent IP address.  Important: This attribute is customer specific, and is only available in 8.3 and later releases.
sn-local-seq-no	Unique local sequence number of UDR identifier per ACSMgr/SessMgr and linearly increasing in UDR file.
sn-ocs-ip-address	Online Charging Server's IP address.  Important: This attribute is customer specific, and is only available in 8.3 and later releases.
sn-rulebase	Indicates the name of the ACS rulebase used.
sn-sequence-no	Unique sequence number (per sn-sequence-group and radius-nas-ip-address) of UDR identifier and linearly increasing in UDR file.
sn-served-bsa-addr	Indicator for address of Base Station Area being served.
sn-service-name	Indicator for ACS service name.
sn-st16-ip-addr	IP address of the chassis handling this flow.  Important: This attribute is interchangeable with radius-nas-ip-address for other systems.
sn-start-time [format format]	Timestamp for first packet of flow in UTC.
sn-stream-number	Unique UDR billing record identifier.  Important: This attribute is customer specific, and is only available in 8.3 and later releases.
sn-subscriber-id	Indicator for subscriber ID.
sn-subscriber-nat-flow-ip	NAT IP address(es) of NAT-enabled subscriber.

Attribute	Description
sn-timestamp	Timestamp when the UDR is actually generated.  Important: This attribute is customer specific, and is only available in 8.3 and later releases.

```
format { MM/DD/YY-HH:MM:SS | MM/DD/YYYY-HH:MM:SS | YYYY/MM/DD-HH:MM:SS | YYYYMMDDHHMMSS | seconds }
```

Specifies the timestamp format.

localtime

Specifies the local time. By default, timestamps are displayed in GMT.

```
{ bytes | pkts } { downlink | uplink }
```

Specifies bytes/packets sent/received from/by mobile.

priority *priority*

Specifies the position priority of the value within the UDR. Lower numbered priorities (across all attribute, event-label, and rule-variable) occur first.

priority must be an integer from 1 through 65535. Up to 50 position priorities (across all attribute, event-label, and rule-variable) can be configured.

Usage

Use this command to set the attributes and priority for UDR file format.

A particular field in UDR format can be entered multiple times at different priorities. While removing the UDR field using the **no attribute** command either you can remove all occurrences of a particular field by specifying the field name or a single occurrence by additionally specifying the optional **priority** keyword.

Consider the following scenario. If the volume/time threshold interval is large enough (or disabled). At time $t=0$, 10 ICMP packets are sent, which takes 9 seconds. There is nothing for the next 100 seconds, and then again 10 ICMP packets are sent which takes 10 seconds, and then again nothing for next the 60 seconds and then the session is terminated.

In this scenario:

- **sn-start-time** should be $t = 0$.
- **sn-end-time** should be $t = 0+9+100+10$ (**sn-end-time** would be the last ICMP packet sent).
- **sn-duration** should be **sn-end-time** minus **sn-start-time**, i.e. $0+9+100+10 - 0 = 119$ seconds (since the ICMP flow would exist between the two intervals of sending ICMP packets, the **sn-start-time** would be that of the first packet of the flow and **sn-end-time** of the last packet (20th packet). Hence, **sn-duration** would take into account all the seconds between the first and last packet of the flow).

Example

The following is an example of this command:

```
attribute radius-user-name priority 12
```

■ end

end

This command returns the CLI prompt to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to change to the Exec Mode.

event-label

This command configures an optional event ID to use in generated billing records.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
event-label label priority priority
```

```
no event-label
```

no

Removes the previously configured event label for UDR attribute.

label

Specifies event label for attribute to be used for UDR format.

label must be an alpha and/or numeric string of 1 through 63 characters in length.

priority *priority*

Specifies the CSV position of event ID in UDR.

priority must be an integer from 1 through 65535.

Usage

Use this command to set the event ID and its position in UDR file format.

Example

The following is an example of this command:

```
event-label radius_csv1 priority 23
```

exit

This command exits the UDR Format Configuration Mode and returns the CLI prompt to the ACS Configuration Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the ACS Configuration Mode.

rule-variable

This command specifies the order of fields in the UDR.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
rule-variable protocol rule priority priority
```

```
no rule-variable [ priority priority ] protocol rule
```

no

Removes the rule-variable protocol configuration.

protocol rule

Specifies the rule variable for UDR format.

protocol must be one of the following with specified rule:

- **bearer 3gpp2**: Bearer-related configuration:

- **always-on**
- **bsid**
- **carrier-id**
- **esn**
- **ip-qos**
- **ip-technology**
- **meid**
- **release-indicator**
- **serv-MDN**
- **service-option**
- **session-begin**
- **session-continue**

Important: For more information on protocol-based rules see the *ACS Ruledef Configuration Mode Commands* chapter.

priority *priority*

Specifies the CSV position of the value in the UDR.

priority must be an integer from 1 through 65535.

Usage

Use this command to set the rule variables priority for UDR file format.

A particular field in UDR format can be entered multiple times at different priorities. While removing the UDR field using the **no rule-variable** command either you can remove all occurrences of a particular field by specifying the field name or a single occurrence by additionally specifying the optional priority keyword.

Example

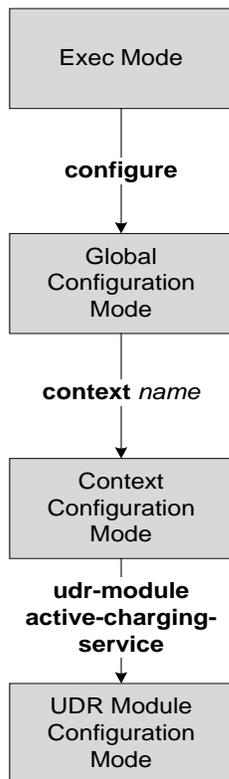

The following is an example of this command:

```
rule-variable bearer 3gpp2 bsid priority 36
```

Chapter 224

UDR Module Configuration Mode Commands

The UDR Module Configuration Mode is accessed from the Context Configuration Mode.

 **Important:** The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

cdr

This command configures the EDR/UDR file parameters.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
cdr [ push-interval value ] [ push-trigger space-usage-percent
trigger_percentage ] [ remove-file-after-transfer ] [ transfer-mode { pull |
push primary { encrypted-url encrypted_url | url url } [ via local-context ] [
secondary { encrypted-secondary-url enc_sec_url | url sec_url } ] } ] + | use-
harddisk ]
```

```
no cdr [ remove-file-after-transfer | use-harddisk ] +
```

```
default cdr [ push-interval | push-trigger space-usage-percent | remove-file-
after-transfer | transfer-mode [ push via ] | use-harddisk ] +
```

no

Disables the configured CDR storage and CDR file processing in this mode:

- **remove-file-after-transfer**: Retains a copy of the file even after it has been pushed or pulled to another server.
- **use-harddisk**: Disables data storage on the SMC hard disk.

Important: **use-harddisk** keyword is available only on the ASR 5000 chassis.

default

Configures the default setting for the specified keyword(s):

- **push-interval**: 300 seconds
- **push-trigger**: 80 percent
- **remove-file-after-transfer**: Disabled
- **transfer mode**: Pull
- **push via**: LC is used for push
- **use-harddisk**: Disabled

Important: **use-harddisk** keyword is only available on ASR 5000 chassis.

push-interval *value*

Specifies the transfer interval, in seconds, to push EDR and UDR files to an external file server. *value* must be an integer from 60 through 3600.

Default: 300

push-trigger space-usage-percent *trigger_percentage*

Specifies the EDR/UDR disk space utilization percentage, upon reaching which an automatic push is triggered and files are transferred to the configured external server.

trigger_percentage specifies the EDR/UDR disk utilization percentage for triggering push, and must be an integer from 10 through 80.

Default: 80%

remove-file-after-transfer

Specifies that the system must delete EDR/UDR files after they are transferred to the external file server.

Default: Disabled

transfer-mode { **pull** | **push primary** { **encrypted-url** *encrypted_url* | **url** *url* } [**via local-context**] [**secondary** { **encrypted-secondary-url** *enc_sec_url* | **secondary-url** *sec_url* }] }

Specifies the EDR/UDR file transfer mode.

- **pull**: Specifies that the L-ESS is to pull the CDR files.
- **push**: Specifies that the system is to push CDR files to the configured L-ESS.
- **primary encrypted-url** *encrypted_url*: Specifies the primary URL location in encrypted format to which the system pushes the CDR files.
encrypted_url must be the location name in an encrypted format, and must be an alpha and/or numeric string of 1 through 1024 characters in length.
- **primary url** *url*: Specifies the primary URL location to which the system pushes the CDR files.
url must be an alpha and/or numeric string of 1 through 1024 characters in the *//user:password@host:[port]/directory* format.
- **via local-context**: Configuration to select LC/SPIO for transfer of CDRs. The system pushes the UDR files via SPIO in the local context.
- **encrypted-secondary-url** *enc_sec_url*: Specifies the secondary URL location in encrypted format to which the system pushes the CDR files when the primary location is unreachable or fails.
enc_sec_url must be the location name in an encrypted format, and must be an alpha and/or numeric string of 1 through 1024 characters in length.
- **secondary-url** *sec_url*: Specifies the secondary URL location to which the system pushes the CDR files when the primary location is unreachable or fails.
sec_url must be an alpha and/or numeric string of 1 through 1024 characters in the *//user:password@host:[port]/directory* format.

use-harddisk

Specifies that on ASR 5000 chassis the hard disk on the SMC be used to store EDR/UDR files. On configuring to use the hard disk for EDR/UDR storage, EDR/UDR files are transferred from RAMFS on the PSC to the hard disk on the SMC.

Default: Disabled

Important: **use-harddisk** keyword is available only on the ASR 5000 chassis.

+

Indicates that more than one of the previous keywords can be entered within a single command.

Usage

Use this command to configure how charging data records (CDR) are moved and stored.

On the ASR 5000 chassis, run this command only from the local context. Running in any other context would fail and deliver an error message.

The **use-harddisk** keyword is only available on the ASR 5000 chassis. This command can be run only in a context where CDRMOD is running. Configuring in any other context will result in failure with the message “Failure: Please Check if CDRMOD is running in this context or not.”

This configuration can be applied either in the EDR/UDR module, but will be applicable both to the EDR and UDR modules. Configuring in one of the modules prevents the configuration to be done in the other module. If PUSH transfer mode is selected, the L-ESS server URL to which the CDR files need to be transferred to must be specified. The configuration allows a primary and a secondary server to be configured. Configuring the secondary server is optional. Whenever a file transfer to the primary server fails for four consecutive times, the files will be transferred to the secondary server. The transfer will switch back to the original primary server when:

- Four consecutive transfer failures to the secondary server occur
- After switching from the primary server, 30 minutes elapses

When changing **transfer-mode** from pull to push, disable the PULL from L-ESS and then change the transfer mode to push. Make sure that the push server URL configured is accessible from the local context. Also, make sure that the base directory that is mentioned contains udr directory created within it.

When changing **transfer-mode** from push to pull, after changing, enable PULL on the L-ESS. Any of the ongoing PUSH activity will continue till all the scheduled file transfers are completed. If there is no PUSH activity going on at the time of this configuration change, all the PUSH related configuration is nullified immediately.

Example

The following command configures the system to retain a copy of the data file after it has been transferred to the storage location:

```
no cdr remove-file-after-transfer
```

end

This command returns the CLI prompt to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to change to the Exec mode.

exit

This command exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

file

This command sets UDR file parameters.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
default file [ charging-service-name ] [ compression ] [ current-prefix ] [
delete-timeout ] [ directory ] [ field-separator ] [ file-sequence-number ] [
headers ] [ name ] [ reset-indicator ] [ rotation { num-records | time | volume
} ] [ sequence-number ] [ storage-limit ] [ time-stamp ] [ trailing-text ] [
udr-seq-num ]
```

default

Configures the default setting for the specified keyword(s). Using the **default file** command will reset some but not all keyword parameters to their default values. To ensure that the default is reset for a specific parameter, include the keyword in the command.

charging-service-name { include | omit }

Configures the inclusion and exclusion of charging service name in the file name.

- **include**: Sets this command to include the Charging service name in UDR file name.
- **omit**: Sets this command to exclude or omit the Charging service name from UDR file name.

Default: **include**

compression { gzip | none }

Configures the compression of the UDR file.

- **gzip**: Enables GNU zip compression of the UDR file at approximately 10:1 ratio.
- **none**: Disables Gzip compression.

Default: **none**

current-prefix *string*

Specifies a string to add to the beginning of the UDR file that is currently being used to store UDR records. *string* must be an alpha and/or numeric string of 1 through 31 characters in length.

Default: **curr**

delete-timeout *seconds*

Specifies a time period, in seconds, when completed UDR files are deleted. By default, files are never deleted.

seconds must be an integer from 3600 through 31536000.

Default: **Disabled**

directory *directory_name*

Specifies a subdirectory in the default directory in which to store UDR files.

directory_name must be an alpha and/or numeric string of 1 through 191 characters in length.

Default: /records/udr

exclude-checksum-record

When entered, this keyword excludes the final record containing #CHECKSUM followed by the 32-bit Cyclic redundancy check (CRC) of all preceding records from the UDR file.

Default: Disabled, inserts checksum record into the UDR file header.

field-separator { **hyphen** | **omit** | **underscore** }

Specifies the field separators between two fields of UDR file name.

- **hyphen**: Specifies the field separator as '-' (hyphen) symbol between two fields.
- **omit**: Removes or omits the field separator between two fields.
- **underscore**: Specifies the field separator as '_' (underscore) symbol between two fields.

Default: **underscore**

file-sequence-number **rulebase-seq-num**

Generates unique file sequence numbers for different rulebase-formatname combinations.

headers

Includes a file header summarizing the record layout.

name *file_name*

Default: udr

Specifies a string to use as the base file name for UDR files.

file_name must be an alpha and/or numeric string of 1 through 31 characters in length. The file name format is as follows:

base_rulebase_format_sequencenum_timestamp

- **base**: Specifies type of record in file or contains the operator-specified string.
Default: udr
- **rulebase**: Specifies the name of the ACS rulebase. UDRs from different rulebases go into different UDR files.
- **format**: Specifies the name of the UDR format if **single-udr-format** is specified, else the format field (and the trailing underscore) is omitted from the file name.
- **sequencenum**: This is a 5-digit sequence number to detect the missing file sequence. It is unique among all UDR files on the system.
- **timestamp**: Contains a timestamp based on file creation time in UTC time in MMDDYYYYHHMMSS format.

UDR files that have not been closed have a string added to the beginning of their file names.

File name for a UDR file in CSV format that contains information for rule base named *rulebase1* and a UDR schema named *udr_schema1* appears as follows:

udr_rulebase1_udr_schema1_00005_01302006143409

If file name is not configured it creates files for EDRs/UDRs/FDRs (xDRs) having following name template with limits to 256 characters:

basename_ChargSvcName_ timestamp_SeqNumResetIndicator_FileSeqNumber

- *basename*: A global-based configurable text string that is unique per system that uniquely identifies the global location of the system running ACS.
- *ChargSvcName*: A system context-based configurable text string that uniquely identifies a specific context-based charging service.
- *timestamp*: Date and time at the instance of file creation. Date and time in the form of “MMDDYYYYHHmmSS” where HH is a 24-hour value from 00-23.
- *SeqNumResetIndicator*: A one-byte counter used to discern the potential for duplicated FileSeqNumber with a range of 0 through 255, which is incremented by a value of 1 for the following conditions:
 - Failure of an ACS software process on an individual PSC
 - Failure of the system such that a second system takes over (for example, a standby or backup chassis put in place according to Inter-chassis Session Recovery)
 - File Sequence Number (FileSeqNumber) rollover from 999999999 to 0
- *FileSeqNumber*: unique file sequence number for the file with 9 digit integer having range from 000000000 to 999999999. It is unique on each chassis system.

File name for a closed xDR file in CSV format that contains information for ACS system *xyz_city1* and charging service name *preapaid2* with timestamp *12311969190000*, and file sequence number counter reset indicator to *002* for file sequence number *034939002* appears as follows:

xyz_city1_preapaid2_12311969190000_002_034939002

File name for a running xDR file in CSV format that contains information for the same parameters for file sequence number *034939003* prefixed with *curr_* and appears as follows:

curr_xyz_city1_preapaid2_12311969190000_002_034939002

reset-indicator

This option includes the reset indicator counter value from 0 to 255 in UDR file name and is incremented (by one) whenever any of the following conditions occur:

- An ACSMgr/SessMgr process fails
- A peer chassis has taken over in compliance with our Inter-chassis Session Recovery feature
- The sequence number in sequence-number keyword has rolled over to zero

rotation { num-records *records* | time *seconds* | volume *bytes* }

Specifies when to close a UDR file and create a new one.

- **num-records** *records*: Specifies the number of records that should be added to the file. When the number of records in the file reaches the specified value, the file is complete.

records must be an integer from 100 through 10240.

Default: 1024

- **time** *seconds*: Specifies the period of time to wait before closing the UDR file and creating a new one.

seconds must be an integer from 30 through 86400.

Default: 3600 seconds

- **volume** *bytes*: Specifies the maximum size of the UDR file before closing it and creating a new one.

bytes must be an integer from 51200 through 62914560.

Note that higher sets may provide the best compression ratio when the **compression** keyword is set to *gzip*.

Default: 102400 bytes

sequence-number { **length** *length* | **omit** | **padded** | **padded-six-length** | **unpadded** }

Specifies including/excluding sequence number in the file name.

- **length** *length*: Includes the sequence number with the specified length.

length must be the file sequence number length with preceding zeroes in the file name, and must be an integer from 1 through 9.

Important: The **length** configuration is applicable in both EDR and UDR modules. When applied in both modules without the **file udr-seq-num** configuration, the minimum among the two values will come into effect for both the modules. With the **file udr-seq-num** config, each module will use its own value of **length**.

- **omit**: Excludes the sequence number from the file name.
- **padded**: Includes the padded sequence number with preceding zeros in the file name. This is the default setting.
- **padded-six-length**: Includes the padded sequence number with six preceding zeros in the file name.
- **unpadded**: Includes the unpadded sequence number in the file name.

Default: **padded**

storage-limit *limit*

Default: 33554432

Specifies deleting files when the specified amount of space, in bytes, is used up for UDR/EDR file storage on the PSC RAM.

On an ASR 5000 chassis, *limit* must be an integer from 10485760 through 536870912.

Important: On an ASR 5000 chassis, the total storage limit is 536870912 bytes (512 MB). This limit is for both UDR and EDR files combined.

time-stamp { **expanded-format** | **rotated-format** | **unix-format** }

Specifies the timestamp of when the file was created be included in the file name.

- **expanded-format**: Specifies the UTC MMDDYYYYHHMMSS format.
- **rotated-format**: Specifies the YYYYMMDDHHMMSS format.
- **unix-format**: Specifies the UNIX format of *x.y*, where *x* is the number of seconds since 1/1/1970 and *y* is the fractional portion of the current second that has elapsed.

trailing-text *string*

Specifies the inclusion of arbitrary text string in the file name.

string must be an alpha and/or numeric string of 1 through 30 characters in length.

trap-on-file-delete

This keyword instructs the system to send an SNMP notification (trap) when an EDR/UDR file is deleted due to lack of space.

Default: Disabled

udr-seq-num

Specifies that the file sequence numbers that are part of the UDR file names be independently generated. If disabled, a single set of sequence numbers are shared by both EDR files and UDRs.

Default: Disabled

xor-final-record

Specifies inserting an xor checksum (in place of the CRC checksum) into the UDR file header if the **exclude-checksum-record** keyword is left at its default setting.

Default: Disabled

+

More than one of the previous keywords can be entered within a single command.

Usage

Use this command to configure UDR file characteristics.

Example

The following command sets the prefix of the current active UDR file to *current*:

```
file current-prefix current
```

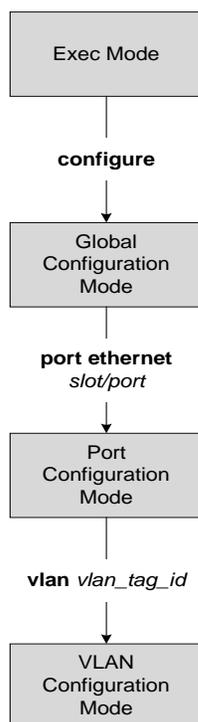

The following command sets the base file name to *UDRfile*:

```
file name UDRfile
```

Chapter 225

VLAN Configuration Mode Commands

The VLAN Configuration Mode is used to create and manage Virtual LANs and their bindings between contexts.

bind interface

Configures a virtual interface to context association for the current VLAN.

Product

PDSN, HA, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
bind interface interface_name context_name
```

```
no bind interface interface_name context_name
```

no

Indicates the binding between the virtual interface specified and the context specified is to be unbound for the current VLAN.

interface_name

Specifies the name of the virtual interface to be bound to the context. *interface_name* must be from 1 to 79 alpha and/or numeric characters.

context_name

Specifies the name of the context to be bound to the virtual interface. *context_name* must refer to a previously configured context.

Usage

Bind a virtual interface and context to allow the VLAN to provide service.

Example

```
bind interface sampleVirtual sampleContext
```

```
no bind interface sampleVirtual sampleContext
```

end

Exits the port configuration mode and returns to the Exec mode.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the VLAN configuration mode and returns to the port configuration mode.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Return to the port configuration mode.

ingress-mode

This command toggles between enabling and disabling the port ingress mode.

Product

PDSN, HA, SGSN

Privilege

Security Administrator, Administrator

Syntax

ingress-mode

Usage

Use this command to enable or disable the ingress mode for the port.

Example

ingress-mode

shutdown

Disables/enables traffic over the current VLAN.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

shutdown

no shutdown

no

Enables the VLAN. When omitted the VLAN is shutdown.

Usage

Shut down a VLAN.

This command is necessary to bring a VLAN into service by enabling it via the **no** keyword.

Example

To disable a VLAN from sending or receiving network traffic use the following command:

shutdown

To enable a VLAN use the following command:

no shutdown

vlan-map

This command sets a single next-hop IP address so that multiple vlans can use a single next-hop gateway. **vlan-map** is associated with a specific interface.

Product

PDSN, HA, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
vlan-map next-hop ip_address
```

```
next-hop ip_address
```

This keyword defines an IP address for the next-hop gateway.

ip_address: Can be either an IPv4 or IPv6 address in standard format.

Usage

Use vlan-map to combine multiple vlan links to go through a single IP address. This feature is used in conjunction with nexthop forwarding and overlapping IP pools.

After configuring the vlan-map, move to the Port Ethernet configuration mode to attach the vlan-map to a specific vlan.

Example

The following command sets an IPv4 for a next-hop gateway.

```
vlan-map next-hop 123.123.123.1
```
