Specifies an ID for the ISC template as an integer from 1 through 200.

Usage

Use this command to create an ISC template for the CSCF service and cause the system to enter the ISC Template Configuration Mode where parameters are configured for the new template.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-isc-tmpl)#
```

ISC Template Configuration Mode commands are defined in the *CSCF ISC Template Configuration Mode Commands* chapter.
Use this command when configuring the following SCM component: S-CSCF.

Example

The following command creates ISC template *10* and enters the ISC Template Configuration Mode:

```
cscf isc-template id 10
```

cscf last-route-profile

Creates a last route profile, which will be specified on peer server configuration to select the Last Routing Option (LRO) number while forwarding an emergency call packet to a particular peering server, and enters the Last Route Profile Criteria Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

cscf last-route-profile name *profile_name* **criteria { county-name | round-robin } [-noconfirm]**

no cscf last-route-profile name *profile_name*

---

cscf last-route-profile name *profile_name*

Specifies the name of the last route profile as an alphanumeric string of 1 through 79 characters.

---

criteria { county-name | round-robin }

county-name: Profile specific to the county-name criteria.
Entering this command results in the following prompt:

```
[context_name]hostname(config-county-name-lro-profile)#
```

Last Route Profile Criteria Configuration Mode commands are defined in the *CSCF Last Route Profile Criteria Configuration Mode Commands* chapter.
round-robin: Profile specific to the round-robin criteria.
Entering this command results in the following prompt:

```
[context_name]hostname(config-round-robin-lro-profile)#
```

Last Route Profile Criteria Configuration Mode commands are defined in the *CSCF Last Route Profile Criteria Configuration Mode Commands* chapter.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

---

no cscf last-route-profile name *profile*

Removes the specified CSCF last route profile from the context.

Usage

Use this command to create a last route profile and enter the Last Route Profile Criteria Configuration Mode.

Important: Last route profiles are associated with peer servers in the CSCF Peer Server Monitoring Configuration Mode.

Use this command when configuring the following SCM components: S-CSCF and SIP Proxy.

Example

The following command creates a last route profile named *lro1* and enters the CSCF Last Route Profile Criteria Configuration Mode to specify county name criteria:

```
cscf last-route-profile name lro1 criteria county-name
```

The following command creates a last route profile named *lro2* and enters the CSCF Last Route Profile Criteria Configuration Mode to specify round robin criteria:

```
cscf last-route-profile name lro2 criteria round-robin
```

cscf peer-servers

Creates a peer server type for next-hop session routing and enters the Peer Servers Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

cscf peer-servers *server_name* **type { type } [-noconfirm]**

no cscf peer-servers *server_name*

cscf peer-servers *server_name*

Specifies the name of the peer server as an alphanumeric string of 1 through 79 characters.

type { type }

Specifies the type of peer server to configure:

- **bgcf**: Border Gateway Control Function
- **ecscf**: Emergency Call/Session Control Function
- **ibcf**: Interconnect Border Control Function
- **icscf**: Interrogating Call/Session Control Function
- **mgcf**: Media Gateway Control Function
- **mrfc**: Media Resource Function Controller
- **other**: Other Function
- **pcscf**: Proxy Call/Session Control Function
- **scscf**: Serving Call/Session Control Function
- **sip-as**: Session Initiation Protocol-Application Server

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no cscf peer-servers *server_name*

Removes the specified CSCF peer server from the context.

Usage

Use this command to create a specific peer server and enter the Peer Servers Configuration Mode where connectivity parameters can be entered.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-peer-servers)#
```

Peer Servers Configuration Mode commands are defined in the *CSCF Peer Servers Configuration Mode Commands* chapter.
Use this command when configuring the following SCM components: E-CSCF, P-CSCF, S-CSCF, and SIP Proxy.

Example

The following command creates an I-CSCF server type called *icscf_peer1* and enters the Peer Servers Configuration Mode:

```
cscf peer-servers icscf_peer1 type icscf
```

cscf peer-servers-group

Creates a peer servers group and enters the Peer Servers Group Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

cscf peer-servers-group *group_name* **type sip-as [-noconfirm]**

no cscf peer-servers-group *group_name*

cscf peer-servers-group *group_name*

Specifies the name of the peer servers group as an alphanumeric string of 1 through 79 characters.

type sip-as

Specifies that the type of peer servers group to configure is **sip-as** (Session Initiation Protocol-Application Server).

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no cscf peer-servers-group *group_name*

Removes the specified CSCF peer servers group from the context.

Usage

Use this command to create a specific peer servers group and enter the Peer Servers Group Configuration Mode where peer servers lists can be managed.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-peer-servers-group)#
```

Peer Servers Group Configuration Mode commands are defined in the *CSCF Peer Servers Group Configuration Mode Commands* chapter.

Example

The following command creates a peer servers group called *group1* and enters the Peer Servers Group Configuration Mode:

```
cscf peer-servers-group group1 type sip-as
```

cscf policy

Creates a policy group for specific AoR profiles and enters the Policy Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

cscf policy { default | name *policy_name* **[-noconfirm] }**

no cscf policy name *policy_name*

---

default

Specifies that the system is to enter the AoR Policy Rules Configuration Mode for the default policy. The default policy uses AoR policy rules.
Entering this command results in the following prompt:
[*context_name*]*hostname*(config-aor-policy)#
Default (AoR) Policy Configuration Mode commands are defined in the *CSCF AoR Policy Rules Configuration Mode Commands* chapter.

---

cscf policy name *policy_name*

Specifies the name of the policy group as an alphanumeric string of 1 through 79 characters.
Entering this command results in the following prompt:
[*context_name*]*hostname*(config-cscf-policy)#
Policy Configuration Mode commands are defined in the *CSCF Policy Configuration Mode Commands* chapter.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

---

no cscf policy name *policy_name*

Removes the specified CSCF policy group from the context.

Usage

Use this command to create a policy group and enter either the AoR Policy Rules Configuration Mode (**default**) or Policy Configuration Mode (**name** *policy_name*).
Use this command when configuring the following SCM components: P-CSCF, S-CSCF, and SIP Proxy.

Example

The following command creates a policy group named *group2* and enters the CSCF Policy Configuration Mode:

```
cscf policy name group2
```

cscf prefix-table

Creates a CSCF prefix table and enters the CSCF Prefix Table Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

```
[ no ] cscf prefix-table
```

no

Removes the prefix table.

Usage

Use this command to create a CSCF prefix table and cause the system to enter the Prefix Table Configuration Mode. The prefix table is used to configure for each number (or number prefix) whether it is ported and the SIP routing domain.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-prefix-table)#
```

Prefix Table Configuration Mode commands are defined in the *CSCF Prefix Table Configuration Mode Commands* chapter.

Example

The following command creates a CSCF prefix table and enters the Prefix Table Configuration Mode:

```
cscf prefix-table
```

cscf routes

Creates a route group for specifying routing information and enters the Routes Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

cscf routes { default | name *route_name* **[-noconfirm] }**

no cscf routes name *route_name*

---

default

Specifies that the system is to enter the Routes Configuration Mode for the default route group.

---

cscf routes name *route_name*

Specifies the name of the route group as an alphanumeric string of 1 through 79 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

---

no cscf routes name *route_name*

Removes the specified CSCF route group from the context.

Usage

Use this command to create a route group and enter the Routes Configuration Mode.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-route)#
```

Routes Configuration Mode commands are defined in the *CSCF Routes Configuration Mode Commands* chapter.
Use this command when configuring the following SCM components: P-CSCF, S-CSCF, SIP Proxy.

Example

The following command creates a route group named *route_group5* and enters the Route Group Configuration Mode:

```
cscf routes name route_group5
```

cscf service

Creates a CSCF service or specifies an existing CSCF service and enters the CSCF Service Configuration Mode for the current context.

Product

SCM

Privilege

Administrator

Syntax

cscf service *service_name* **[-noconfirm]**

no cscf service *service_name*

cscf service *service_name*

Specifies the name of the CSCF service. If *service_name* does not refer to an existing service, the new service is created if resources allow.
service_name is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no cscf service *service_name*

Removes the specified CSCF service from the context.

Usage

Enter the CSCF Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-service)#
```

CSCF Service Configuration Mode commands are defined in the *CSCF Service Configuration Mode Commands* chapter.
Use this command when configuring the following SCM components: P-CSCF, S-CSCF, SIP Proxy.

Example

The following command enters the existing CSCF Service Configuration Mode (or creates it if it does not already exist) for the service named *cscf-service1*:

```
cscf service cscf-service1
```

The following command will remove *cscf-service1* from the system:

```
no cscf service cscf-service1
```

cscf session-template

Creates a session template and/or enters the Session Template Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

cscf session-template { default | name *template_name* **[-noconfirm] }**

no cscf session-template name *template_name*

default

Specifies that the system is to enter the Session Template Configuration Mode for the default session template.

cscf session-template name *template_name*

Specifies a name for the template as an alphanumeric string of 1 through 79 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no cscf session-template name *template_name*

Removes the specified CSCF session template from the context.

Usage

Use this command to create a new session template and enter the Session Template Configuration Mode or enter the mode for an existing template.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-session-template)#
```

Session Template Configuration Mode commands are defined in the *CSCF Session Template Configuration Mode Commands* chapter.
Use this command when configuring the following SCM components: P-CSCF, S-CSCF, SIP Proxy.

Example

The following command enters the Session Template Configuration Mode for a template named *sess_temp4*:

```
cscf session-template name sess_temp4
```

cscf subdomain-routes

Creates subdomain-route list and enters the Subdomain-route List Configuration Mode.

Product

SCM (I-CSCF)

Privilege

Administrator

Syntax

`[ no ] cscf subdomain-routes`

`no`

Removes the CSCF subdomain-route list from the context.

`cscf subdomain-routes`

Creates the CSCF subdomain-route list within the context.

Usage

Use this command to create a subdomain-route list and enter the Subdomain-route List Configuration Mode. I-CSCF, upon receiving the terminating request, checks the subdomain-route list for matches. If a match is found, the routing will happen based on it. Otherwise, I-CSCF performs a User Location Query (Location-Information-Request) before proceeding.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-subdomain-route)#
```

Subdomain-route List Configuration Mode commands are defined in the *CSCF Subdomain-route List Configuration Mode Commands* chapter.

Example

The following command enters the Subdomain-route List Configuration Mode:

```
cscf subdomain-routes
```

cscf translation

Creates a translation list and enters the Translation Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

cscf translation { default | name *list_name* **[-noconfirm] }**

no cscf translation name *list_name*

default

Specifies that the system is to enter the Translation Configuration Mode for the default translation list.

cscf translation name *list_name*

Specifies a name for the translation list as an alphanumeric string of 1 through 79 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no cscf translation name *list_name*

Removes the specified CSCF translation list from the context.

Usage

Use this command to create a new translation list and enter the Translation Configuration Mode or enter the mode for an existing list.
Translation lists are used to modify or replace a request-URI such as an E.164 number. For example, a translation list can be configured to append digits to the end of a number or replace a domain name with another.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-translation)#
```

Translation Configuration Mode commands are defined in the *CSCF Translation Configuration Mode Commands* chapter.
Use this command when configuring the following SCM components: P-CSCF, S-CSCF, SIP Proxy.

Example

The following command enters the Translation Configuration Mode for a translation list named *trans_list3*:

```
cscf translation name trans_list3
```

cscf urn-service-list

Creates a URN service list and enters the URN List Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

cscf urn-service-list { default | name *list_name* **[-noconfirm] }**

no cscf urn-service-list name *list_name*

default

Specifies that the system is to enter the URN List Configuration Mode for the default URN service list.

cscf urn-service-list name *list_name*

Specifies a name for the URN service list as an alphanumeric string of 1 through 79 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no cscf urn-service-list name *list_name*

Removes the specified CSCF URN service list from the context.

Usage

Use this command to create a URN service list name and enter the URN List Configuration Mode. URN lists contain URN to URI mappings used for emergency and location-based services. A URN service list is selected by a CSCF session template.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-service-urn)#
```

URN List Configuration Mode commands are defined in the *CSCF URN List Configuration Mode Commands* chapter.
Use this command when configuring the following SCM components: P-CSCF.

Example

The following command enters the URN List Configuration Mode for a URN list named *urn_list1*:

```
cscf urn-service-list name urn_list1
```

css server

This is a restricted command. In Release 9.0 and later, this command is obsolete.

dhcp-service

Adds a Dynamic Host Control Protocol (DHCP) service instance to the current context and enters the configuration mode for that service.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

dhcp-service *service_name* **[no] allow dhcp-relay-agent-auth-suboption[-noconfirm]**

no dhcp-service *service_name*

no

Removes a previously configured DHCP service from the current context.

dhcp-service *service_name*

Specifies the name of the DHCP service as an alphanumeric string of 1 through 63 characters that is case sensitive.

allow dhcp-relay-agent-auth-suboption

The DHCP Relay Agent Information Option conveys information between a DHCP Relay Agent and a DHCP server. This specification defines an authentication suboption for that option, containing a keyed hash in its payload. The suboption supports data integrity and replay protection for relayed DHCP messages.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

WARNING: If this keyword option is used with **no dhcp-service** *service_name* command the DHCP service named *service_name* is deleted with all active/inactive subscribers without prompting any warning or confirmation.

Usage

Use this command to add a DHCP service to a context configured on the system and enter the DHCP Service Configuration Mode. A DHCP service is a logical grouping of external DHCP servers.
The DHCP Configuration Mode provides parameters that dictate the system's communication with one or more of these DHCP servers.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (i.e. resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Refer to the *DHCP Service Configuration Mode* chapter of this reference for additional information.

Example

The following command creates a DHCP service called *dhcp1* and enter the DHCP Service Configuration Mode:

```
dhcp-service dhcp1
```

diameter accounting

This command configures Diameter accounting related settings.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter accounting { dictionary { aaa-custom1 | aaa-custom10 | aaa-custom2 | aaa-custom3 | aaa-custom4 | aaa-custom5 | aaa-custom6 | aaa-custom7 | aaa-custom8 | aaa-custom9 | nasreq | rf-plus } | endpoint *endpoint_name* **| hd-mode fall-back-to-local | hd-storage-policy** *hd_policy* **| max-retries** *max_retries* **| max-transmissions** *transmissions* **| request-timeout** *duration* **| server** *host_name* **priority** *priority* **}**

default diameter accounting { dictionary | hd-mode | max-retries | max-transmissions | request-timeout }

no diameter accounting { endpoint | hd-mode | hd-storage-policy | max-retries | max-transmissions | server *host_name* **}**

---

no diameter accounting { endpoint | hd-mode | hd-storage-policy | max-retries | max-transmissions | server *host_name* **}**

endpoint: Removes the currently configured accounting endpoint. The default accounting server configured in the default AAA group will be used.
hd-mode: Sends records to the Diameter server, if all Diameter servers are down or unreachable, then copies records to the local HDD and periodically retries the Diameter server.
hd-storage-policy: Disables use of the specified HD storage policy.
max-retries: Disables the retry attempts for Diameter accounting in this AAA group.
max-transmissions: Disables the maximum number of transmission attempts for Diameter accounting in this AAA group.
server *host_name*: Removes the Diameter host *host_name* from this AAA server group for Diameter accounting.

---

default diameter accounting { dictionary | hd-mode | max-retries | max-transmissions | request-timeout }

dictionary: Sets the context's dictionary to the default.
hd-mode: Sends records to the Diameter server, if all Diameter servers are down or unreachable, then copies records to the local HDD and periodically retries the Diameter server.
max-retries: 0 (disabled)
max-transmissions: 0 (disabled)
request-timeout: 20 seconds

---

dictionary { aaa-custom1 | aaa-custom10 | aaa-custom2 | aaa-custom3 | aaa-custom4 | aaa-custom5 | aaa-custom6 | aaa-custom7 | aaa-custom8 | aaa-custom9 | nasreq | rf-plus }

Specifies the Diameter accounting dictionary.

aaa-custom1 ... aaa-custom10: Configures the custom dictionaries. Even though the CLI syntax supports several custom dictionaries, not necessarily all of them have been defined. If a custom dictionary that has not been implemented is selected, the default dictionary will be used.
nasreq: nasreq dictionary—the dictionary defined by RFC 3588.
rf-plus: RF Plus dictionary.

---

endpoint *endpoint_name*

Enables Diameter to be used for accounting, and specifies which Diameter endpoint to use.
endpoint_name is an alphanumeric string of 1 through 63 characters.

---

hd-mode fall-back-to-local

Specifies that records be copied to the local HDD if the Diameter server is down or unreachable. CDF/CGF will pull the records through SFTP.

---

hd-storage-policy *hd_policy*

Specifies the HD Storage policy name.
hd_policy must be the name of a configured HD Storage policy, expressed as an alphanumeric string of 1 through 63 characters.
HD storage policies are configured through the Global Configuration Mode.
This and the **hd-mode** command are used to enable the storage of Rf Diameter Messages to HDD in case all Diameter Servers are down or unreachable.

---

max-retries *max_retries*

Specifies how many times a Diameter request should be retried with the same server, if the server fails to respond to a request.
max_retries specifies the maximum number of retry attempts. The value must be an integer from 1 through 1000.
Default: 0

---

max-transmissions *transmissions*

Specifies the maximum number of transmission attempts for a Diameter request. Use this in conjunction with the "**max-retries** *max_retries*" option to control how many servers will be attempted to communicate with.
transmissions specifies the maximum number of transmission attempts for a Diameter request. The value must be an integer from 1 through 1000. Default: 0

---

request-timeout *duration*

Specifies how long the system will wait for a response from a Diameter server before re-transmitting the request.
duration specifies the number of seconds the system will wait for a response from a Diameter server before re-transmitting the request. This value must be an integer from 1 through 3600. Default: 20

---

server *host_name* **priority** *priority*

Specifies the current context Diameter accounting server's host name and priority.
host_name specifies the Diameter host name, expressed as an alphanumeric string of 1 through 63 characters.
priority specifies the relative priority of this Diameter host. The priority is used in server selection. The priority must be an integer from 1 through 1000.

Usage

Use this command to manage the Diameter accounting options according to the Diameter server used for the context.

Example

The following command configures the Diameter accounting dictionary as **aaa-custom4**:

```
diameter accounting dictionary aaa-custom4
```

The following command configures the Diameter endpoint named *aaaa_test*:

```
diameter accounting endpoint aaaa_test
```

diameter authentication

This command configures Diameter authentication related settings.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter authentication { dictionary { aaa-custom1 | aaa-custom10 | aaa-custom11 | aaa-custom12 | aaa-custom13 | aaa-custom14 | aaa-custom15 | aaa-custom16 | aaa-custom17 | aaa-custom18 | aaa-custom19 | aaa-custom2 | aaa-custom20 | aaa-custom3 | aaa-custom4 | aaa-custom5 | aaa-custom6 | aaa-custom7 | aaa-custom8 | aaa-custom9 | nasreq } | endpoint *endpoint_name* **| max-retries** *max_retries* **| max-transmissions** *transmissions* **| redirect-host-avp { just-primary | primary-then-secondary } | request-timeout** *duration* **| server** *host_name* **priority** *priority* **}**

default diameter authentication { dictionary | max-retries | max-transmissions | redirect-host-avp | request-timeout }

no diameter authentication { endpoint | max-retries | max-transmissions | server *host_name* **}**

---

no diameter authentication { endpoint | max-retries | max-transmissions | server *host_name* **}**

- **endpoint**: Removes the authentication endpoint. The default server configured in default AAA group will be used.
- **max-retries**: Disables the retry attempts for Diameter authentication in this AAA group.
- **max-transmissions**: Disables the maximum transmission attempts for Diameter authentication in this AAA group.
- **server** *host_name*: Removes the Diameter host *host_name* from this AAA server group for Diameter authentication.

---

default diameter authentication { dictionary | max-retries | max-transmissions | redirect-host-avp | request-timeout }

Configures default setting for specified parameter.

- **dictionary**: Sets the context's dictionary to the default.
- **max-retries**: Sets the retry attempts for Diameter authentication requests in this AAA group to default 0 (disable).
- **max-transmissions**: Sets the configured maximum transmission attempts for Diameter authentication in this AAA group to default 0 (disable).
- **redirect-host-avp**: Sets the redirect choice to default (just-primary).
- **request-timeout**: Sets the timeout duration, in seconds, for Diameter authentication requests in this AAA group to default (20).

dictionary { aaa-custom1 | aaa-custom10 | aaa-custom11 | aaa-custom12 | aaa-custom13 | aaa-custom14 | aaa-custom15 | aaa-custom16 | aaa-custom17 | aaa-custom18 | aaa-custom19 | aaa-custom2 | aaa-custom20 | aaa-custom3 | aaa-custom4 | aaa-custom5 | aaa-custom6 | aaa-custom7 | aaa-custom8 | aaa-custom9 | nasreq }

Specifies the Diameter authentication dictionary.
aaa-custom1 ... aaa-custom8, aaa-custom10 ... aaa-custom20: Configures the custom dictionaries. Even though the CLI syntax supports several custom dictionaries, not necessarily all of them have been defined. If a custom dictionary that has not been implemented is selected, the default dictionary will be used.

Important: **aaa-custom11** dictionary is only available in Release 8.1 and later. **aaa-custom12** to **aaa-custom20** dictionaries are only available in Release 9.0 and later releases.

aaa-custom9: Configures the STa standard dictionary.
nasreq: nasreq dictionary—the dictionary defined by RFC 3588.

endpoint *endpoint_name*

Enables Diameter to be used for authentication, and specifies which Diameter endpoint to use.
endpoint_name is an alphanumeric string of 1 through 63 characters.

max-retries *max_retries*

Specifies how many times a Diameter authentication request should be retried with the same server, if the server fails to respond to a request.
max_retries specifies the maximum number of retry attempts, and must be an integer from 1 through 1000. Default: 0

max-transmissions *transmissions*

Specifies the maximum number of transmission attempts for a Diameter authentication request. Use this in conjunction with the "**max-retries** *max_retries*" option to control how many servers will be attempted to communicate with.
transmissions specifies the maximum number of transmission attempts, and must be an integer from 1 through 1000. Default: 0

diameter authentication redirect-host-avp { just-primary | primary-then-secondary }

Specifies whether to use just one returned AVP, or use the first returned AVP as selecting the primary host and the second returned AVP as selecting the secondary host.
just-primary: Redirect only to primary host.
primary-then-secondary: Redirect to primary host, if fails then redirect to the secondary host.
Default: **just-primary**

request-timeout *duration*

Specifies how long the system will wait for a response from a Diameter server before re-transmitting the request.
duration specifies the number of seconds the system will wait for a response from a Diameter server before re-transmitting the request, and must be an integer from 1 through 3600. Default: 20

server *host_name* **priority** *priority*

Specifies the current context Diameter authentication server's host name and priority.
host_name specifies the Diameter host name, expressed as an alphanumeric string of 1 through 63 characters.
priority specifies the relative priority of this Diameter host, and must be an integer from 1 through 1000. The priority is used in server selection.

Usage

Use this command to manage the Diameter authentication configurations according to the Diameter server used for the context.

Example

The following command configures the Diameter authentication dictionary *aaa-custom14*:

```
diameter authentication dictionary aaa-custom14
```

The following command configures the Diameter endpoint named *aaau1*:

```
diameter authentication endpoint aaau1
```

diameter authentication failure-handling

This command configures error handling for Diameter EAP requests.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter authentication failure-handling { authorization-request | eap-request | eap-termination-request } { request-timeout action { continue | retry-and-terminate | terminate } | result-code *result_code* **{ [to** *end_result_code* **] action { continue | retry-and-terminate | terminate } } }**

no diameter authentication failure-handling { authorization-request | eap-request | eap-termination-request } result-code *result_code* **[to** *end_result_code* **]**

default diameter authentication failure-handling { authorization-request | eap-request | eap-termination-request } request-timeout action

---

no

Disables Diameter authentication failure handling.

---

default

Configures the default Diameter authentication failure handling setting.

---

authorization-request

Specifies that failure handling is to be performed on Diameter authorization request messages (AAR/AAA).

---

eap-request

Specifies configuring failure handling for EAP requests.

---

eap-termination-request

Specifies configuring failure handling for EAP termination requests.

---

request-timeout action { continue | retry-and-terminate | terminate }

Specifies the action to be taken for failures:

- **continue**: Continues the session
- **retry-and-terminate**: First retries, if it fails then terminates the session
- **terminate**: Terminates the session

---

result-code *result_code* **{ [to** *end_result_code* **] action { continue | retry-and-terminate | terminate } }**

result_code: Specifies the result code, must be an integer from 1 through 65535.

to *end_result_code*: Specifies the upper limit of a range of result codes. *end_result_code* must be greater than *result_code*.
action { continue | retry-and-terminate | terminate }: Specifies action to be taken for failures:

- **continue**: Continues the session
- **retry-and-terminate**: First retries, if it fails then terminates the session
- **terminate**: Terminates the session

Usage

Use this command to configure error handling for Diameter EAP, EAP-termination, and authorization requests. Specific actions (continue, retry-and-terminate, or terminate) can be associated with each possible result-code. Ranges of result codes can be defined with the same action, or actions can be specific on a per-result code basis.

Example

The following commands configure result codes 5001, 5002, 5004, and 5005 to use **action continue** and result code 5003 to use a**ction terminate**:

```
diameter authentication failure-handling eap-request result-code 5002 to
5005 action continue

diameter authentication failure-handling eap-request result-code 5003
action terminate
```

diameter dictionary

This command is deprecated and is replaced by the **diameter accounting dictionary** and **diameter authentication dictionary** commands. See **diameter accounting** and **diameter authentication** commands respectively.

diameter endpoint

This command enables the creation, configuration or deletion of a Diameter endpoint.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter endpoint *endpoint_name* **[-noconfirm]**

no diameter endpoint *endpoint_name*

no

Removes the specified Diameter endpoint.

endpoint_name

Specifies name of the Diameter endpoint as an alphanumeric string of 1 through 63 characters that should be unique within the system.
If the named endpoint does not exist, it is created, and the CLI mode changes to the Diameter Endpoint Configuration Mode wherein the endpoint can be configured.
If the named endpoint already exists, the CLI mode changes to the Diameter Endpoint Configuration Mode wherein the endpoint can be reconfigured.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to create/configure/delete a Diameter origin endpoint.
Entering this command results in the following prompt:
`[context_name]hostname(config-ctx-diameter)`
Diameter origin endpoint configuration commands are described in the *Diameter Endpoint Configuration Mode Commands* chapter.

Example

The following command changes to the Diameter Endpoint Configuration CLI mode for Diameter origin endpoint named *test13*:

```
diameter endpoint test13
```

diameter sctp

This command configures Diameter SCTP parameters for all Diameter endpoints within the context. In 12.2 and later releases, this command is obsolete and replaced with **associate sctp-parameter-template**command in Diameter Endpoint Configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter sctp { hearbeat-interval *interval* **| path max-retransmissions** *retransmissions* **}**

default diameter sctp { heartbeat-interval | path max-retransmissions }

default

Configures this command with the default settings.

- **heartbeat-interval**: Sets the heartbeat interval to the default value.
- **path max-retransmissions**: Sets the SCTP path maximum retransmissions to the default value.

hearbeat-interval *interval*

Specifies the time interval between heartbeat chunks sent to a destination transport address in seconds.
interval must be an integer from 1 through 255.
Default: 30 seconds

path max-retransmissions *retransmissions*

Specifies the maximum number of consecutive retransmissions over a destination transport address of a peer endpoint before it is marked as inactive.
retransmissions must be an integer from 1 through 10.
Default: 10

Usage

Use this command to configure Diameter SCTP parameters for all diameter endpoints within the context.

Example

The following command configures the heartbeat interval to *60* seconds:

```
diameter sctp hearbeat-interval 60
```

The following command configures the maximum number of consecutive retransmissions to *6*, after which the endpoint is marked as inactive:

```
diameter sctp path max-retransmissions 6
```

diameter origin

This command is deprecated and is replaced by the **diameter endpoint** command.

dns-client

Creates a DNS client and/or enters the DNS Client Configuration Mode.

Product

SCM, SGSN, MME, P-GW

Privilege

Security Administrator, Administrator

Syntax

[no] dns-client *name* **[-noconfirm]**

no

Removes the specified DNS client from the context.

dns-client *name*

Specifies a name for the DNS client as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to create a new DNS client and enter the DNS Client Configuration Mode or enter the mode for an existing client.
Entering this command results in the following prompt:

```
[context_name]hostname(config-dns-client)#
```

DNS Client Configuration Mode commands are defined in the *DNS Client Configuration Mode Commands* chapter.

Example

The following command enters the DNS Client Configuration Mode for a DNS client named *dns1*:

```
dns-client dns1
```

domain

Configures a domain alias for the current context.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

domain [*] *domain_name* **[default subscriber** *subs_temp_name* **]**

no domain [*] *domain_name*

no domain [*] *domain_name*

Indicates the domain specified is to be removed as an alias to the current context.

domain [*] *domain_name*

domain_name specifies the domain alias to create/remove from the current context. If the domain portion of a subscribers user name matches this value, the current context is used for that subscriber.
domain_name is an alphanumeric string of 1 through 79 characters. The domain name can contain all special characters, however note that the character * (wildcard character) is only allowed at the beginning of the domain name.
If the domain name is prefixed with * (wildcard character), and an exact match is not found for the domain portion of a subscriber's user name, subdomains of the domain name are matched. For example, if the domain portion of a subscriber's user name is abc.xyz.com and you use the domain command **domain** **xyz.com* it matches. But if you do not use the wildcard (**domain** *xyz.com*) it does not match.

Important: The domain alias specified must not conflict with the name of any existing context or domain names.

default subscriber *subs_temp_name*

Specifies the name of the subscriber template to apply to subscribers using this domain alias.
subs_temp_name is an alphanumeric string of 1 through 127 characters. If this keyword is not specified the default subscriber configuration in the current context is used.

Usage

Set a domain alias when a single context may be used to support multiple domains via aliasing.

Example

```
domain sampleDomain.net

no domain sampleDomain.net
```

eap-profile

Creates a new, or specifies an existing, Extensible Authentication Protocol (EAP) profile and enters the EAP Configuration Mode.

Product

ASN-GW, PDIF

Privilege

Security Administrator, Administrator

Syntax

[no] eap-profile *name*

eap-profile *name*

Specifies the name of a new or existing EAP profile as an alphanumeric string of 1 through 256 characters.

Usage

Use this command to create a new or enter an existing EAP profile.
Entering this command results in the following prompt:

```
[context_name]hostname(config-ctx-eap-profile)#
```

EAP Configuration Mode commands are defined in the *EAP Configuration Mode Commands* chapter.

Example

The following command configures an EAP profile called *eap1* and enters the EAP Configuration Mode:

```
eap-profile eap1
```

edr-module active-charging-service

Enables the creation, configuration or deletion of the Event Data Record (EDR) module for this context.

Product

ACS, GGSN, HA, LNS, PDSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] edr-module active-charging-service [ charging | reporting ]
```

no

Removes the EDR module configuration for the current context.

edr-module active-charging-service

Enables the EDR data module for this context.

charging

Enables the EDR module for charging EDRs that are stored in the /records/edr directory.

reporting

Enables the EDR module for reporting EDRs that are stored in the /records/redr directory.

Usage

Use this command to create the EDR module for the context, and configure the EDR module for active charging service records. You must be in a non-local context when specifying this command, and you must use the same context when specifying the UDR module command.
If this CLI command is configured without the **charging** or **reporting** keywords, by default the EDR module is enabled for charging EDRs.

Example

The following command creates the EDR module for the context for charging EDRs, and enters the EDR Module Configuration Mode:

```
edr-module active-charging-service
```

egtp-service

Creates an eGTP service or specifies an existing eGTP service and enters the eGTP Service Configuration Mode for the current context.

Product

MME, P-GW, S-GW

Privilege

Administrator

Syntax

egtp-service *service_name* **[-noconfirm]**

no egtp-service *service_name*

egtp-service *service_name*

Specifies the name of the eGTP service as an alphanumeric string of 1 through 63 characters. If *service_name* does not refer to an existing service, the new service is created if resources allow.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no egtp-service *service_name*

Removes the specified eGTP service from the context.

Usage

Enter the eGTP Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-egtp-service)#
```

eGTP Service Configuration Mode commands are defined in the *eGTP Service Configuration Mode Commands* chapter.
Use this command when configuring the following GTP SAE components: MME, P-GW, and S-GW.

Example

The following command enters the existing eGTP Service Configuration Mode (or creates it if it does not already exist) for the service named *egtp-service1*:

```
egtp-service egtp-service1
```

The following command will remove *egtp-service1* from the system:

```
no egtp-service egtp-service1
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

event-notif-endpoint

Enables creation, configuration or deletion of an Event Notification collection server endpoint.

Product

IPCF

Privilege

Security Administrator, Administrator

Syntax

[no] event-notif-endpoint *en_node_name*

no

Removes the specified Event Notification collection server endpoint.

event-notif-endpoint *en_node_name*

Specifies name of the Event Notification collection server endpoint as an alphanumeric string of 1 through 31 characters.
If the named endpoint does not exist, it is created, and the CLI mode changes to the Event Notification Interface Endpoint Configuration Mode wherein the endpoint can be configured.
If the named endpoint already exists, the CLI mode changes to the Event Notification Interface Endpoint Configuration Mode wherein the endpoint can be reconfigured.

Usage

Use this command to create/configure/delete an Event Notification collection server endpoint.
Only 1 Event Notification interface across a chassis can be configured on a system.
Entering this command results in the following prompt:

```
[context_name]hostname(config-ntfyintf-endpoint)#
```

The commands configured in this mode are defined in the *Event Notification Interface Endpoint Configuration Mode Commands* chapter of *Command Line Interface Reference*.

Caution: This is a critical configuration. The PCC Event notification can not be collected on a server without this configuration. Any change to this configuration would lead to the loss of event notifications from PCC service on IPCF node.

Example

The following command creates an Event Notification Interface Endpoint named *event_intfc_3*:

```
event-notif-endpoint event_intfc_3
```

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

external-inline-server

This is a restricted command.

fa-service

Creates or deletes a foreign agent (FA) service or specifies an existing FA service for which to enter the FA Service Configuration Mode for the current context.

Product

PDSN, ASN-GW, FA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] fa-service name
```

no

Indicates the foreign agent service specified is to be removed.

fa-service *name*

Specifies the name of the FA service to configure as an alphanumeric string of 1 through 63 characters. If *name* does not refer to an existing service, the new service is created if resources allow.

Usage

Enter the FA Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (i.e. resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Example

The following command will enter the FA Service Configuration Mode creating the service *sampleService*, if necessary.

```
fa-service sampleService
```

The following command will remove *sampleService* as being a defined FA service.

```
no fa-service sampleService
```

firewall max-associations

This command is obsolete.

fng-service

Creates a new, or specifies an existing FNG service and enters the FNG Service Configuration Mode. A maximum of 16 FNG services can be created. This limit applies per ASR 5000 chassis and per context.

Product

FNG

Privilege

Security Administrator, Administrator

Syntax

fng-service *name* **[-noconfirm]**

no fng-service *name*

fng-service *name*

Specifies the name of a new or existing FNG service as an alphanumeric string of 1 through 63 characters that must be unique across all FNG services within the same context and across all contexts.

no fng-service *name*

Deletes the specified FNG service.

Usage

Use this command in Context Configuration Mode to create a new FNG service or modify an existing one. Executing this command enters the FNG Service Configuration Mode.

Example

The following command configures an FNG service named *fng1* and enters the FNG Service Configuration Mode:

```
fng-service fmg1
```

ggsn-service

Creates or deletes a Gateway GPRS Support Node (GGSN) service and enters the GGSN Service Configuration Mode within the current context to configure it.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

ggsn-service *svc_name* **[-noconfirm]**

no ggsn-service *svc_name*

no

Deletes a preciously configured GGSN service.

ggsn-service *svc_name*

Specifies the name of the GGSN service to create/configure as an alphanumeric string of 1 through 63 characters that is case sensitive.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Services are configured within a context and enable certain functionality. This command creates and allows the configuration of services enabling the system to function as a GGSN in a GPRS or UMTS network. This command is also used to remove previously configured GGSN services.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (i.e. resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Example

The following command creates a GGSN service named *ggsn1*:

```
ggsn-service ggsn1
```

gprs-service

Creates a GPRS service instance and enters the GPRS Service Configuration Mode. This mode configures all of the parameters specific to the operation of an SGSN in a GPRS network.

Important: For details about the commands and parameters for this mode, check the *GPRS Service Configuration Mode* chapter.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

gprs-service *srvc_name*

no gprs-service *srvc_name*

no

Removes the configuration for the specified IGPRS service from the configuration for the current context.

gprs-service *srvc_name*

Specifies the name of the GPRS service as a unique alphanumeric string of 1 through 63 characters.

Usage

Use this command to create or remove a GPRS service. Entering this command will move the system to the GPRS Service Configuration Mode and change the prompt to:

```
[context_name]hostname(config-gprs-service)#
```

Example

The following command creates an GPRS service named *gprs1*:

```
gprs-service gprs1
```

The following command removes the GPRS service named *gprs1*:

```
no gprs-service gprs1
```

gs-service

Creates a Gs service instance and enters the Gs Service Configuration Mode. This mode configures the parameters specific to the Gs interface between the SGSN and the MSC/VLR.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

gs-service *svc_name* **[-noconfirm]**

no gs-service *svc_name*

no

Remove the configured Gs service from the current context.

gs-service *svc_name*

Specifies the Gs service as a unique alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to create, edit, or remove a Gs service.
A maximum of 32 Gs service can be configured in one context/system. This limit is subject to maximum of 256 services (regardless of type) can be configured per system.

Important: For details about the commands and parameters for this mode, refer *Gs Service Configuration Mode* chapter.

Example

The following command creates an Gs service named *gs1*:

```
gs-service gs1
```

The following command removes the Gs service named *gs1*:

```
no gs-service gs1
```

gtpp algorithm

Configures GTPP routing algorithms for the current context.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

gtpp algorithm { first-server | round-robin | first-n *count* **}**

gtpp algorithm first-server

Specifies that accounting data is sent to the first available charging gateway function (CGF) based upon the relative priority of each configured CGF. Default: Enabled

gtpp algorithm round-robin

Specifies that accounting data is transmitted in a circular queue fashion such that data is sent to the highest priority CGF first, then to the next available CGF of the highest priority, and so on. Ultimately, the queue returns to the CGF with the highest configured priority. Default: Disabled

gtpp algorithm first-n *count*

Specifies that the AGW must send accounting data to *count* (more than one) CGFs based on their priority. Response from any one of the *count* CGFs would suffice to proceed with the call. The full set of accounting data is sent to each of the *count* CGFs.
count is the number of CGFs to which accounting data will be sent, and must be an integer from 2 through 65535. Default: 1 (Disabled)

Usage

Use this command to control how G-CDR/P-CDR accounting data is routed among the configured CGFs.

Example

The following command configures the system to use the round-robin algorithm when transmitting G-CDR/P-CDR accounting data:

```
gtpp algorithm round-robin
```

gtpp attribute

Allows the specification of the optional attributes to be present in the call detail records (CDRs) that the GPRS/PDN/UMTS access gateway generates. It also defines that how the information is presented in CDRs by encoding the attribute field values.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp attribute { apn-ni | apn-selection-mode | charging-characteristic-selection-mode | cell-plmn-id | diagnostics | duration-ms | dynamic flag | imei | local-record-sequence-number | losdv | ms-timezone | msisdn | |node-id | | node-id-suffix *suffix* **| pdn-connection-id | pdp-address | pdp-type | pgw-plm-id | plmn-id [unknown-use** *uncode_value* **] | rat | record-extensions rat | served-mnai | served-pdp-pdn-address-extension | sms { destination-number | recording-entity | service-centre } | start time | stop time | uli }**

default gtpp attribute { apn-ni | apn-selection-mode | charging-characteristic-selection-mode | cell-plmn-id | diagnostics | duration-ms | dynamic flag | imei | local-record-sequence-number | losdv | ms-timezone | msisdn | node-id | pdn-connection-id | pdp-address | pdp-type | pgw-plm-id | plmn-id | rat | record-extensions | served-mnai | served-pdp-pdn-address-extension | sms { destination-number | recording-entity | service-centre } | start time | stop time | uli }

no gtpp attribute { apn-ni | apn-selection-mode | charging-characteristic-selection-mode | cell-plmn-id | diagnostics | duration-ms | dynamic flag | imei | local-record-sequence-number | losdv | ms-timezone | msisdn | node-id | node-id-suffix | pdn-connection-id | pdp-address | pdp-type | pgw-plm-id | plmn-id | rat | record-extensions | served-mnai | served-pdp-pdn-address-extension | sms { destination-number | recording-entity | service-centre } | start time | stop time | uli }

default

Sets the default GTPP attributes in generated the CDRs. It also sets the default presentation of attribute values in generated CDRs.

no

Removes the configured GTPP attributes from the CDRs.

apn-ni

Default: Enabled
Includes the APN field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

apn-selection-mode

Default: Enabled

Includes the APN Selection Mode field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

charging-characteristics-selection-mode

Default: Enabled
Includes the Charging Characteristic Selection Mode field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

cell-plmn-id

Default: Disabled
This keyword configures the SGSN to include the cell's PLMN identifier (MCC and MNC) in generated CDRs (M-CDRs and/or the S-CDRs).
This keyword is applicable for SGSN only.

diagnostics

Default: Disabled
Includes the Diagnostic field in the CDR that is created when PDP contexts are released. The field will contain one of the following values:

- **36**: if the SGSN sends us "delete PDP context request".
- **38**: if the GGSN sends "delete PDP context request" due to GTP-C/GTP-U echo timeout with SGSN.
- **40**: if the GGSN sends "delete PDP context request" due to receiving a RADIUS Disconnect-Request message.
- **26**: if the GGSN sends "delete PDP context request" for any other reason (e.g., the operator types "clear subscribers" on the GGSN).

duration-ms

Default: Disabled
Specifies that the information contained in the mandatory Duration field be reported in milliseconds instead of seconds (as the standards require).

dynamic-flag

Default: Enabled
Includes the Dynamic Flag field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

imei

Default: Disabled
This keyword configures the SGSN to include the International Mobile Equipment Identifier (IM EI) in generated CDRs (M-CDRs and/or the S-CDRs).
This keyword is applicable for SGSN only.

local-record-sequence-number

Default: Disabled
Includes the Node ID field in the CDR that is created when PDP contexts are released. The field consists of a AAA Manager identifier automatically appended to the name of the GGSN or SGSN service.

The name of the GGSN/SGSN service may be truncated, because the maximum length of the Node ID field is 20 bytes. Since each AAA Manager generates CDRs independently, this allows the Local Record Sequence Number and Node ID fields to uniquely identify a CDR.

losdv

Default: Enabled
Includes the List of Service Data field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

ms-timezone

Default: Enabled
Includes the MS-Timezone field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

msisdn

Default: Disabled
This keyword configures the SGSN to include the Mobile Subscribers Integrated Services Digital Network identifier in generated CDRs (M-CDRs and/or the S-CDRs).
This keyword is applicable for SGSN only.

node-id

Default: Enabled
Includes the Node ID field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

node-id-suffix *string*

Default: Disabled
Specifies the string suffix to use in the NodeID field of GTPP CDRs. Each Session Manager task generates a unique NodeID string per GTPP context.
string: This is the configured Node-ID-Suffix having any string of 1 through 16 characters.

Important: The NodeID field is a printable string of the *ndddstring* format: *n*: The first digit is the SessMgr restart counter having a value between 0 and 7. *ddd*: The number of SessMgr instances. Uses the specified NodeID-suffix in all CDRs. The "Node-ID" field is consists of SessMgr Recovery counter (1 digit) *n* + AAA Manager identifier (3 digits) *ddd* + the configured Node-Id-suffix (1 to 16 characters) *string*.

Important: If the centralized LRSN feature is enabled, the "Node-ID" field consists of only the specified NodeID-suffix. Otherwise GTPP group name is used. For default GTPP groups, GTPP context-name (truncated to 16 characters) is used.

Important: SessMgr recovery counter gets updated in case of "session recovery not enabled" If session recovery is enabled, the counter never updates. The node-id is displayed in the G-CDR irrespective of gtpp dictionary. The G-CDR is not decoded in monitor protocol for custom1 / custom3 dictionaries.

pdn-connections-id

Default: Enabled

Includes the PDN Connection ID field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

pdp-address

Default: Enabled
Includes the PDP Address field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

pdp-type

Default: Enabled
Includes the PDP Type field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

pgw-plm-id

Default: Enabled
Includes the PGW PLMN-ID field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

plmn-id [unknown-use *uncode_value* **]**

Default: Enabled
Includes the SGSN PLMN Identifier value (the RAI) in generated CDR (M-CDRs and/or the S-CDRs), if it is provided by the SGSN in the GTP create PDP context request. It is omitted if the SGSN does not supply one.

Important: For the GGSN it provides radio access identifier as the SGSN PLMN Id and for SGSN it includes the PLMN-id of RNC.

unknown-use *uncode_value* encodes the specified value for "SGSN PLMN Identifier" in the CDR if SGSN PLMN-ID information is unavailable.
Must be followed by the *uncode_value* value to be encoded.
uncode_value must be an hexadecimal value between 0x0 and 0xFFFFFF.
This keyword is applicable for SGSN only.

rat

Default: Disabled
This keyword configures the SGSN to include the radio access technology attribute in generated CDRs (M-CDRs and/or the S-CDRs).
This keyword is applicable for SGSN only.

record-extensions rat

Default: Disabled
This keyword configures the SGSN to include the radio access technology attribute in record extension field of generated CDRs (M-CDRs and/or the S-CDRs).
This keyword is applicable for SGSN only.

served-mnai

Default: Enabled
Includes the Served MNAI field in the CDR that is created.

This keyword is applicable for P-GW and GGSN only.

served-pdp-pdn-address-extension

Default: Disabled
In support of IPv4v6 dual PDP address types, this keyword causes the SGSN to include IPv4v6 address information in the S-CDR. The IPv4 address goes in the a new PDP address extension field and the IPv6 address goes in the existing servedPDPAdress field.
This keyword is applicable for SGSN only.

sms { destination-number | recording-entity | service-centre }

Default: Disabled
This keyword configures the SGSN to include the SMS related attributes in generated S-SMO-CDRs or S-SMT-CDRs.
destination-number: This keyword includes the destination-number information of SMS in generated S-SMO-CDRs or S-SMT-CDRs.
Note: This is the destination number of the short message subscriber.
recording-entity: This keyword includes the recording entity information of SMS in generated S-SMO-CDRs or S-SMT-CDRs.
Note: The recording entity is the E.164 number of the SGSN.
service-centre: This keyword includes the service-centre information of SMS in generated S-SMO-CDRs or S-SMT-CDRs.
Note: This is the E.164 address of the SMS-service centre.
This keyword is applicable for SGSN only.

start-time

Default: Enabled
Includes the Start-Time field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

stop-time

Default: Enabled
Includes the Stop-Time field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

uli

Default: Enabled
Includes the User Location Information field in the CDR that is created.
This keyword is applicable for P-GW and GGSN only.

Usage

Use this command to configure the type of optional information fields to include in generated CDRs (M-CDRs, S-CDRs, S-SMO-CDR, S-SMT-CDR from SGSN and G-CDRs, eG-CDRs from GGSN) by the AGW (SGSN/GGSN/P-GW). In addition, it controls how the information for some of the mandatory fields are reported.
Fields described as optional by the standards but not listed above will always be present in the CDRs, except for Record Extensions (which will never be present).

Important: This command can be repeated multiple times with different keywords to configure multiple GTPP attributes.

Example

The following command configures the system to present the time provided in the Duration field of the CDR is reported in milliseconds:

```
gtpp attribute duration-ms
```

gtpp charging-agent

Configures the IP address and port of the system interface within the current context used to communicate with the Charging Gateway Function (CGF).

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp charging-agent address *ip_address* **[port** *port* **]**

no gtpp charging-agent

no

Removes a previously configured charging agent address.

gtpp charging-agent address *ip_address*

Specifies the IP address of the interface configured within the current context that is used to transmit CDR records (G-CDR/eGCRD/M-CDR/S-CDR) to the CGF. *ip_address* must be entered using IPV4 dotted-decimal notation.

port *port*

Specifies the Charging Agent UDP port. as an integer from 1 through 65535.
If *port* is not defined, IP will take the default port number 49999.

Important: Configuring gtpp charging-agent on port 3386 may interfere with a ggsn-service configured with the same ip address.

Usage

This command establishes a Ga interface for the system. For GTPP accounting, one or more Ga interfaces must be specified for communication with the CGF. These interfaces must exist in the same context in which GTPP functionality is configured (refer to the **gtpp** commands in this chapter).
This command instructs the system as to what interface to use. The IP address supplied is also the address by which the GSN is known to the CGF. Therefore, the IP address used for the Ga interface could be identical to one bound to a GSN service (a Gn interface).
If no GSN service is configured in the same context as the Ga interface, the address configured by this command is used to receive unsolicited GTPP packets.

Example

The following command configures the system to use the interface with an IP address of *192.168.13.10* as the accounting interface with port *20000* to the CGF:

```
gtpp charging-agent address 192.168.13.10 port 20000
```

gtpp data-request sequence-numbers

Configures the range of sequence numbers to be used in the GTPP data record transfer record (DRT). Use this command to set the start value for the sequence number.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpp data-request sequence-numbers start { 0 | 1 }

default gtpp data-request sequence-numbers start
```

default

Default is 0 (zero).

gtpp data-request sequence-numbers start { 0 | 1 }

Specifies the value of the start sequence number for the GTPP Data Record Transfer Request. Default: 0

- **0**: Designates the start sequence number as 0.
- **1**: Designates the start sequence number as 1.

Usage

When the GGSN/P-GW/SGSN is configured to send GTPP echo request packets, the SGSN always uses 0 as the sequence number in those packets. Re-using 0 as a sequence number in the DRT packets is allowed by the 3GPP standards; however, this CLI command ensures the possibility of inter-operating with CGFs that can not properly handle the re-use of sequence number 0 in the echo request packets.

Example

The following command sets the sequence to start at *1*.

```
gtpp data-request sequence-numbers start 1
```

gtpp dead-server suppress-cdrs

Enables or disables CDR archiving when a dead server is detected.

Important: This command is customer specific. For more information please contact your local Cisco service representative.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] gtpp dead-server suppress-cdrs
```

default

Configures the default setting.
Default: Disabled

no

Re-enables CDR archiving.

gtpp dead-server suppress-cdrs

Disables CDR archiving when a dead server is detected.

Usage

Use this command to enable/disable CDR archiving when a dead server is detected. With this CLI, once a server is detected as down, requests are purged. Also the requests generated for the period when the server is down are purged.

gtpp deadtime

Configures the amount of time to wait before attempting to communicate with a Charging Gateway Function (CGF) that was previously marked as unreachable.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

gtpp deadtime *time*

default gtpp deadtime

default

Configures this command with the default setting.
Default: 120 seconds

gtpp deadtime *time*

Specifies the amount of time (in seconds) that must elapse before the system attempts to communicate with a CGF that was previously unreachable. *time* is an integer from 1 through 65535.

Usage

If the system is unable to communicate with a configured CGF, after a pre-configured number of failures the system marks the CGF as being down.
This command specifies the amount of time that the system waits prior to attempting to communicate with the downed CGF.
Refer to the **gtpp detect-dead-server** and **gtpp max-retries** commands for additional information on the process the system uses to mark a CGF as down.

Example

The following command configures the system to wait *60* seconds before attempting to re-communicate with a CGF that was marked as down:

```
gtpp deadtime 60
```

gtpp detect-dead-server

Configures the number of consecutive communication failures that could occur before the system marks a Charging Gateway Function (CGF) as down.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

gtpp detect-dead-server consecutive-failures *max_number*

default gtpp detect-dead-server consecutive-failures

default

Configures this command with the default setting.
Default: 0

gtpp detect-dead-server consecutive-failures *max_number*

Specifies the number of failures that could occur before marking a CGF as down. *max_number* is an integer from 0 through 1000.

Usage

This command works in conjunction with the **gtpp max-retries** parameter to set a limit to the number of communication failures that can occur with a configured CGF.
The gtpp max-retries parameter limits the number of attempts to communicate with a CGF. Once that limit is reached, the system treats it as a single failure. The gtpp detect-dead-server parameter limits the number of consecutive failures that can occur before the system marks the CGF as down and communicate with the CGF of next highest priority.
If all of the configured CGFs are down, the system ignores the detect-dead-server configuration and attempt to communicate with highest priority CGF again.
If the system receives a GTPP Node Alive Request, Echo Request, or Echo Response message from a CGF that was previously marked as down, the system immediately treats it as being active.
Refer to the **gtpp max-retries** command for additional information.

Example

The following command configures the system to allow *8* consecutive communication failures with a CGF before it marks it as down:

```
gtpp detect-dead-server consecutive-failures 8
```

gtpp dictionary

Designates a dictionary used by GTPP for a specific context.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpp dictionary { custom1 | custom10 | custom11 | custom12 | custom13 | custom14 |
custom15 | custom16 | custom17 | custom18 | custom19 | custom2 | custom20 | custom21 |
custom22 | custom23 | custom24 | custom25 | custom26 | custom27 | custom28 | custom29 |
custom3 | custom30 | custom31 | custom32 | custom33 | custom34 | custom35 | custom36 |
custom37 | custom38 | custom39 | custom4 | custom40 | custom41 | custom42 | custom43 |
custom44 | custom45 | custom46 | custom47 | custom48 | custom49 | custom5 | custom50 |
custom51 | custom52 | custom53 | custom54 | custom55 | custom56 | custom57 | custom58 |
custom59 | custom6 |  custom60 | custom7 | custom8 | custom9 | standard }

default gtpp dictionary
```

default

Configures the default dictionary.

custom1

This is a custom-defined dictionary that conforms to TS 32.015 v 3.6.0 for R99. It supports the encoding of IP addresses in text format for G-CDRs.

custom2

Custom-defined dictionary.

custom3

This is a custom-defined dictionary that conforms to TS 32.015 v 3.6.0 for R99 except that it supports the encoding of IP addresses in binary format for G-CDRs.

custom4

This is a custom-defined dictionary that conforms to TS 32.015 v 3.6.0 for R99 except that:

- IP addresses are encoded in binary format.
- The Data Record Format Version information element contains 0x1307 instead of 0x1308.
- QoSRequested is not present in the LoTV containers.
- QoSnegotiated is added only for the first container and the container after a QoS change.

custom5

Custom-defined dictionary.

custom6

This is a custom-defined dictionary for eG-CDR encoding.

custom7 ... custom30

These custom-defined dictionary have default behavior or "standard" dictionary.

custom31

This is a custom-defined dictionary for S-CDR encoding that is based on 3GPP TS 32.298 v6.4.1 with a special field appended for the PLMN-ID.

custom33

This ia a custom-defined dictionary for S-CDR encoding that is based on the 3GPP TS 32.298 v6.4.1 with the following exceptions:

- Proprietary PLMN-ID field is present.
- It is a SEQUENCE and not a SET.
- Diagnostics and SGSN-Change fields are not supported.
- Indefinite length encoding is used.
- Booleans are encoded as 0x01(3GPP it is 0xff).
- IMEISV shall be sent if available else IMEI should be sent.
- Record Sequence Number is Mandatory.
- APN OI and NI part is length encoded.
- Cause for Record closure should be "RAT Change" instead of "intra-SGSN inter-system".

standard

Default: Enabled
This dictionary conforms to TS 32.215 v 4.6.0 for R4 (and also R5 - extended QoS format).

Usage

Use this command to designate specific dictionary used by GTPP for specific context.

Example

The following command configures the system to use *custom3* dictionary to encode IP address in Binary format in G-CDRs:

```
gtpp dictionary custom3
```

gtpp duplicate-hold-time

Configures the number of minutes to hold onto CDRs that are possibly duplicates while waiting for the primary Charging Gateway Function (CGF) to come back up.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp duplicate-hold-time *minutes*

default gtpp duplicate-hold-time

default

Configures this command with the default setting.
Default: 60 minutes

gtpp duplicate-hold-time *minutes*

Specifies the number of minutes to hold onto CDRs that may be duplicates whenever the primary CGF is down, *minutes* must be an integer from 1 through 10080.

Usage

Use this command to configure how long to hold onto CDRs that are possibly duplicates while waiting for the primary CGF to come back up. If the GGSN/P-GW determines that the primary CGF is down, CDRs that were sent to the primary CGF but not acknowledged are sent by the GSN to the secondary CGF as "possibly duplicates". When the primary CGF comes back up, the GSN uses GTPP to determine whether the possibly duplicate CDRs were received by the primary CGF. Then the secondary CGF is told whether to release or cancel those CDRs. This command configures how long the system should wait for the primary CGF to come back up. As soon as the configured time expires, the secondary CGF is told to release all of the possibly duplicate CDRs.

Example

Use the following command to set the amount of time to hold onto CDRs to 2 hours (120 minutes);

```
gtpp duplicate-hold-time 120
```

gtpp echo-interval

Configures the frequency at which the system sends GTPP echo packets to configured CGFs.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpp echo-interval time

{ default | no } gtpp echo-interval
```

default

Configures the default setting for this command,
Default: 60 seconds

no

Disables the use of the echo protocol except for the scenarios described in the *Usage* section for this command.

gtpp echo-interval *time*

Specifies the time interval (in seconds) for sending GTPP echo packets as an integer from 60 through 2147483647. Default: 60

Usage

The GTPP echo protocol is used by the system to ensure that it can communicate with configured CGFs. The system initiates this protocol for each of the following scenarios:

- Upon system boot
- Upon the configuration of a new CGF server on the system using the **gtpp server** command as described in this chapter
- Upon the execution of the **gtpp test accounting** command as described in the *Exec Mode Commands* chapter of this reference
- Upon the execution of the **gtpp sequence-numbers private-extensions** command as described in this chapter

The echo-interval command is used in conjunction with the gtpp max-retries and gtpp timeout commands as described in this chapter.
In addition to receiving an echo response for this echo protocol, if we receive a GTPP Node Alive Request message or a GTPP Echo Request message from a presumed dead CGF server, we will immediately assume the server is active again.
The alive/dead status of the CGFs is used by the AAA Managers to affect the sending of CDRs to the CGFs. If all CGFs are dead, the AAA Managers will still send CDRs, (refer to the **gtpp deadtime** command), albeit at a slower rate than if a CGF were alive. Also, AAA Managers independently determine if CGFs are alive/dead.

Example

The following command configures an echo interval of *120* seconds:

```
gtpp echo-interval 120
```

gtpp egcdr

Configures the eG-CDR and P-CDR (P-GW CDR) parameters and triggers.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
gtpp egcdr { final-record [ [ include-content-ids { all | only-with-traffic } ] [
closing-cause { same-in-all-partials | unique } ] ] | losdv-max-containers
max_losdv_containers | lotdv-max-containers max_lotdv_containers | rulebase-max-length
rulebase_name_max_length | service-data-flow threshold { interval interval | volume {
downlink bytes [ uplink bytes ] | total bytes | uplink bytes [ downlink bytes ] } } |
service-idle-timeout { 0 | service_idle_timeout } }

default gtpp egcdr { final-record include-content-ids only-with-traffic closing-cause
same-in-all-partials | losdv-max-containers | lotdv-max-containers | service-idle-timeout
0 }

no gtpp egcdr { rulebase-max-length | service-data-flow threshold { interval | volume {
downlink [ uplink ] | total | uplink [ downlink ] } } }
```

final-record [[include-content-ids { all | only-with-traffic }] [closing-cause { same-in-all-partials | unique }]]

Enables configuration of the final eG-CDR/P-CDR.
Default: Restores the GTPP eG-CDR/P-CDR final record to the default setting to include content IDs with some data to report are included. Also, sets the closing cause to the default of using the same closing cause for multiple final eG-CDR/P-CDRs.

- **include-content-ids**: Controls which content IDs are being included in the final eG-CDR/P-CDR.
  - **all**: Specifies that all content IDs be included in the final eG-CDR/P-CDR.
  - **only-with-traffic**: Specifies that only content-IDs with traffic be included in the final eG-CDR/P-CDRs.
- **closing-cause**: Configures closing cause for the final eG-CDR/P-CDR.
  - **same-in-all-partials**: Specifies that the same closing cause is to be included for multiple final eG-CDR/P-CDRs
  - **unique**: Specifies that the closing cause for final eG-CDR/P-CDRs is to be unique.

losdv-max-containers *max_losdv_containers*

The maximum number of List of Service Data Volume (LoSDV) containers in one eG-CDR/P-CDR.
max_losdv_containers must be an integer from 1 through 255.
Default: 10

lotdv-max-containers *max_lotdv_containers*

The maximum number of List of Traffic Data Volume (LoTDV) containers in one eG-CDR/P-CDR.
max_lotdv_containers must be an integer from 1 through 8.

Default: 8

rulebase-max-length *rulebase_name_max_length*

Specifies the maximum character length of charging rulebase name in LOSDVs of eG- CDR/P-CDR.
rulebase_name_max_length must be an integer from 0 through 63. Zero (0) means the rulebase name is added as-is.
Default: None. That is, full (un-truncated) charging rulebase name will go in LOSDVs of eG-CDR/P-CDR.

service-data-flow threshold { interval *interval* **| volume { downlink** *bytes* **[uplink** *bytes* **] | total** *bytes* **| uplink** *bytes* **[downlink** *bytes* **] } }**

Configures the thresholds for closing a service data flow container within an eG-CDR/P-CDR.

- **interval** *interval*: Specifies the time interval, in seconds, to close the eG-CDR/P-CDR if the minimum time duration thresholds for service data flow containers satisfied in flow-based charging.

  interval must be an integer from 60 through 40000000.

  Default: Disabled

- **volume { downlink** *bytes* **[uplink** *bytes* **] | total** *bytes* **| uplink** *bytes* **[downlink** *bytes* **] }**: Specifies the volume octet counts for the generation of the interim eG-CDR/P-CDRs to service data flow container in FBC.

  - **downlink** *bytes*: Specifies the limit for the number of downlink octets after which the eG-CDR/P-CDR is closed.
  - **total** *bytes*: Specifies the limit for the total number of octets (uplink+downlink) after which the eG-CDR/P-CDR is closed.
  - **uplink** *bytes*: Specifies the limit for the number of uplink octets after which the eG-CDR/P-CDR is closed.
  - *bytes* must be an integer from 10000 through 400000000.

A service data flow container has statistics for an individual content ID. When the threshold is reached, the service data flow container is closed.

service-idle-timeout { 0 | *service_idle_timeout* **}**

Specifies a time period where if no data is reported for a service flow, the service container is closed and added to eG-CDR/P-CDR (as part of LOSDV container list) with service condition change as ServiceIdleOut.
service_idle_timeout must be an integer from 10 through 86400.
0: Specifies no service-idle-timeout trigger.
Default: 0

Usage

Use this command to configure individual triggers for eG-CDR/P-CDR generation.
Use the **service-data-flow threshold** option to configure the thresholds for closing a service data flow container within an eG-CDR (eG-CDRs for GGSN and P-CDRs for PGW) during flow-based charging (FBC). A service data flow container has statistics regarding an individual content ID.
Thresholds can be specified for time interval and for data volume, by entering the command twice (once with interval and once with volume). When either configured threshold is reached, the service data flow container will be closed. The volume trigger can be specified for uplink or downlink or the combined total (uplink + downlink) byte thresholds.
When the PDP context is terminated, all service data flow containers will be closed regardless of whether the thresholds have been reached.

An eG-CDR/P-CDR will have at most ten service data flow containers. Multiple eG-CDR/P-CDRs will be created when there are more than ten.

Example

Use the following command to set the maximum number of LoSDV containers to *7*:

```
gtpp egcdr losdv-max-containers 7
```

The following command sets an eG-CDR threshold interval of *6000* seconds:

```
gtpp egcdr service-data-flow threshold interval 6000
```

gtpp error-response

Configures the response when the system receives an error response after transmitting a DRT (data record transfer) request.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpp error-response { discard-cdr | retry-request }

default gtpp error-response
```

default

Configures this command with the default setting.
Default: **retry-request**

gtpp error-response discard-cdr

Instructs the system to purge the request upon receipt of an error response and not to retry.

gtpp error-response retry-request

Instructs the system to retry sending a DRT after receiving an error response. This is the default behavior.

Usage

This command configures the system's response to receiving an error message after sending a DRT request.

Example

```
gtpp error-response discard-cdr
```

gtpp group

Configures GTPP server group in a context for the Charging Gateway Function (CGF) accounting server(s) that the system is to communicate with.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

[no] gtpp group *group_name* **[-noconfirm]**

gtpp group *group_name*

Specifies the name of GTPP server group that is used for charging and/or accounting in a specific context.
group_name must be an alphanumeric string of 1 through 63 character.
A maximum of eight GTPP server groups (excluding system created default GTPP server group "default") can be configured with this command in a context.

no

Removes the previously configured GTPP group within a context.
When a GTPP group is removed accounting information is not generated for all calls using that group and all calls associated with that group are dropped. A warning message displays indicating the number of calls that will be dropped.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

This feature provides the charging gateway function (CGF) accounting server configurable for a group of servers. Instead of having a single list of CGF accounting servers per context, this feature configures multiple GTPP accounting server groups in a context and each server group is consist of list of CGF accounting servers.
In case no GTPP server group is configured in a context, a server group named "default" is available and all the CGF servers configured in a specific context for CGF accounting functionality will be part of this "default" server group.

Example

The following command configures a GTPP server group named *star1* for CGF accounting functionality. This server group is available for all subscribers within that context.

```
gtpp group star1
```

gtpp max-cdrs

Configures the maximum number of charging data records (CDRs) included per packet.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp max-cdrs *max_cdrs* **[wait-time** *wait_time* **]**

default gtpp max-cdrs

default

Configures this command with the default setting.
Default: One CDR per packet; disables **wait-time**

gtpp max-cdrs *max_cdrs*

Specifies the maximum number of CDRs to be inserted in a single packet as an integer from 1 through 255.
Default: 1

wait-time *wait_time*

Specifies the number of seconds the system waits for CDRs to be inserted into the packet before sending it. *wait_time* must be an integer from 1 through 300. Default: Disabled

Important: If the **wait-time** expires, the packet is sent as this keyword over-rides *max_cdrs*.

Usage

CDRs are placed into a GTPP packet as the CDRs close. The system stops placing CDRs into a packet when either the maximum *max_cdrs* is met, or the **wait-time** expires, or the value for the **gtpp max-pdu-size** command is met.

Example

The following command configures the system to place a maximum of *10* CDRs in a single GTPP packet before transmitting the packet:

```
gtpp max-cdrs 10
```

gtpp max-pdu-size

Configures the maximum payload size of a single GTPP packet that could be sent by the system.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp max-pdu-size *pdu_size*

default gtpp max-pdu-size

default

Configures this command with the default setting.
Default: 65400 bytes

gtpp max-pdu-size *pdu_size*

Specifies the maximum payload size (in octets) of the GTPP packet as an integer from 1024 to 65400. The payload includes the CDR and the GTPP header.

Caution: This command is effective only when GTPP single-source is configured, otherwise this command has no effect.

Usage

The GTPP packet contains headers (layer 2, IP, UDP, and GTPP) followed by the CDR. Each CDR contains one or more volume containers. If a packet containing one CDR exceeds the configured maximum payload size, the system creates and send the packet containing the one CDR regardless.
The larger the packet data unit (PDU) size allowed, the more volume containers that can be fit into the CDR. The system performs standard IP fragmentation for packets that exceed the system's maximum transmission unit (MTU).

Important: The maximum size of an IPv4 PDU (including the IPv4 and subsequent headers) is 65,535. However, a slightly smaller limit is imposed by this command because the system's max-pdu-size doesn't include the IPv4 and UDP headers, and because the system may need to encapsulate GTPP packets in a different/larger IP packet (for sending to a backup device).

Example

The following command configures a maximum PDU size of *2048* octets:

```
gtpp max-pdu-size 2048
```

gtpp max-retries

Configures the maximum number of times the system attempts to communicate with an unresponsive Charging Gateway Function (CGF).

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp max-retries *max_attempts*

default gtpp max-retries

default

Configures this command with the default setting.
Default: 4

gtpp max-retries *max_attempts*

Specifies the number of times the system attempts to communicate with a CGF that is not responding. *max_attempts* is an integer from 1 through 15.

Usage

This command works in conjunction with the **gtpp detect-dead-server** and **gtpp timeout** parameters to set a limit to the number of communication failures that can occur with a configured CGF.
When the value specified by this parameter is met, a failure is logged. The gtpp detect-dead-server parameter specifies the number of consecutive failures that could occur before the server is marked as down.
In addition, the gtpp timeout command controls the amount of time between re-tries.
If the value for the max-retries is met, the system begins storing CDRs in Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context). Archived CDRs are re-transmitted to the CGF until they are acknowledged or the system's memory buffer is exceeded.
Refer to the **gtpp detect-dead-server** and **gtpp timeout** commands for additional information.

Example

The following command configures the maximum number of re-tries to be *8*:

```
gtpp max-retries 8
```

gtpp node-id

Configures the GTPP Node ID for all CDRs.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp node-id *node_id*

no gtpp node-id

no

Removes the previous gtpp node ID configuration.

gtpp node-id *node_id*

Specifies the node ID for all CDRs as an alphameric string of 1 through 16 characters.

Usage

Use this command to configure the GTPP Node ID for all CDRs.

Example

The following command configures the GTPP Node ID as *test123*:

```
gtpp node-id test123
```

gtpp redirection-allowed

Configures the system to allow or disallow the redirection of CDRs when the primary Charging Gateway Function (CGF) is unavailable.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpp redirection-allowed

{ default | no } gtpp redirection-allowed
```

default

Configures this command with the default setting. Default: Enabled

no

Deletes the command from the configuration.

gtpp redirection-allowed

Allows the redirection of CDRs when the primary Charging Gateway Function (CGF) is unavailable.

Usage

This command allows operators to better handle erratic network links, without having to remove the configuration of the backup server(s) via the **no gtpp server** command.
This functionality is enabled by default.
If the no gtpp redirection-allowed command is executed, the system only sends CDRs to the primary CGF. If that CGF goes down, we will buffer the CDRs in memory until the CGF comes back or until the system runs out of buffer memory. In addition, if the primary CGF announces its intent to go down (with a GTPP Redirection Request message), the system responds to that request with an error response.

gtpp redirection-disallowed

This command has been obsoleted and is replaced by the **gtpp redirection-allowed** command.

gtpp server

Configures the Charging Gateway Function (CGF) accounting server(s) with which the system will communicate.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp server *ip_address* [**max** *max_messages*] [**priority** *priority*] [**udp-portport** *port*] [**node-alive** { **enable** | **disable** }] [**-noconfirm]**

no gtpp server *ip_address*

---

no

Deletes a previously configured CGF.

---

gtpp server *ip_address*

Specifies the IP address of the CGF in IPv4 dotted-decimal or IPV6 colon-separated notation.

---

max *max_messages*

Default: 256
Specifies the maximum number of outstanding or unacknowledged GTPP packets (from any one AAA Manager task) allowed for this CGF before the system begins buffering the packets.
max_messages can be configured as an integer from 1 through 256.

---

priority *priority*

Default:1000
Specifies the relative priority of this CGF. When multiple CGFs are configured, the priority is used to determine which CGF server to send accounting data to.
priority can be configured as an integer from 1 through 1000. When configuring two or more servers with the same priority you will be asked to confirm that you want to do this. If you use the **-noconfirm** option, you are not asked for confirmation and multiple servers could be assigned the same priority.

---

udp-port *port*

Default: 3386
Specifies the UDP port the CGF is using. *port* can be configured as an integer from 1 through 65535.
Default value for port is 3286.

Important: The **udp-port** keyword option has been modified to **port** to make it a generic command. The **udp-port** keyword can still be used, however it will be in concealed mode and will not be shown in auto-complete or help for the command.

---

node-alive { enable | disable }

Default: Disable.

This optional keyword allows operator to enable/disable GSN to send Node Alive Request to GTPP Server (i.e. CGF). This configuration can be done per GTPP Server basis.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to configure the CGF(s) that the system sends CDR accounting data to. Multiple CGFs can be configured using multiple instances of this command. Up to 12 CGFs can be configured per system context. Each configured CGF can be assigned a priority. The priority is used to determine which server to use for any given subscriber based on the routing algorithm that has been implemented. A CGF with a priority of "1" has the highest priority.

Important: The configuration of multiple CGFs with the same IP address but different port numbers is not supported.

Each CGF can also be configured with the maximum allowable number of unacknowledged GTPP packets. Since multiple AAA Manager tasks could be communicating with the same CGF, the maximum is based on any one AAA Manager instance. If the maximum is reached, the system buffers the packets Random Access Memory (RAM). The system allocates memory as a buffer, enough to store one million CDRs for a fully loaded chassis (a maximum of one outstanding CDR per PDP context).

Example

The following command configures a CGF with an IP address of *192.168.2.2* and a priority of *5*.

```
gtpp server 192.168.2.2 priority 5
```

The following command deletes a previously configured CGF with an IP address of *100.10.35.7*:

```
no gtpp server 100.10.35.7
```

gtpp source-port-validation

Toggles port checking for node alive/echo/redirection requests from the CGF.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
gtpp source-port-validation

{ no | default } gtpp source-port-validation
```

no

Disables CGF port checking. Only the IP address will be used to verify CGF requests.

default

Configures this command with the default setting.
Default: Enabled

gtpp source-port-validation

Enables port checking for node alive/echo/redirection requests from the CGF.

Usage

This command is for enabling or disabling port checking on node alive/echo/redirection requests from the CGF. If the CGF sends messages on a non-standard port, it may be necessary to disable port checking in order to receive CGF requests. On the default setting, both IP and port are checked.

Example

The following command disables port checking for CGF requests:

```
no gtpp source-port-validation
```

gtpp storage-server

Configures information for the GTPP back-up storage server.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp storage-server *ip-address* **port** *port-num*

no gtpp storage-server *ip-address* **port** *port-num*

no

Removes a previously configured back-up storage server.

gtpp storage-server *ip-address*

Specifies the IP address of the back-up storage server expressed in IPv4 dotted-decimal notation.

port *port-num*

Specifies the UDP port number over which the GSN communicates with the back-up storage server. Default: 3386

Usage

This command configures the information for the server to which GTPP packets are to be backed-up to in the event that all CGFs are unreachable.
One backup storage server can be configured per system context.

Important: This command only takes affect if **gtpp single-source** in the Global Configuration Mode is also configured. Additionally, this command is customer specific. Please contact your local sales representative for additional information.

Example

The following command configures a back-up server with an IP address of *192.168.1.2*:

```
gtpp storage-server 192.168.1.2
```

gtpp storage-server local file

Configures the parameters for GTPP files stored locally on the GTPP storage server. This command is available for the ASR 5000 platform only.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

gtpp storage-server local file { **compression** { **gzip** | **none** } | **format** { **custom1** | **custom2** | **custom3** | **custom4** | **custom5** | **custom6** | **custom7** | **custom8** } | **name** { **format** *string* [**max-file-seq-num** *seq_number*] | **prefix** *prefix* } | **purge-processed-files** [**file-name-pattern** *file_pattern* | **purge-interval** *purge_dur*] | **rotation** { **cdr-count** *count* | **time-interval** *time* [**force-file-rotation**] | **volume mb** *size* } | **start-file-seq-num** *seq_num* [**recover-file-seq-num**] }

default gtpp storage-server local file { **compression** | **format** | **name** { **format** | **prefix** } | **purge-processed-files** | **rotation** { **cdr-count** | **time-interval** | **volume** } | **start-file-seq-num** }

no gtpp storage-server local file { **purge-processed-files** | **rotation** { **cdr-count** | **time-interval** } }

---

default

Configures default setting for the specified parameter.

---

no

Removes a previously configured parameters for local storage of CDR files on HDD on SMC card.

---

compression { gzip | none }

Configures the type of compression to be used on the files stored locally.

- **gzip**: Enables Gzip file compression.
- **none**: Disables Gzip file compression -this is the default value.

Default: Disabled

---

format { *custom-n* **}**

Configures the file format to be used to format files to be stored locally.
custom1: File format custom1—this is the default value.
custom2: File format custom2.
custom3: File format custom3.
custom4: File format custom4.
custom5: File format custom5.
custom6: File format custom6 with a block size of 8K for CDR files.
custom7: File format custom7 is a customer specific CDR file format.
custom8: File format custom8 is a customer specific CDR file format. It uses *node-id-suffix_date_time_fixed-length-seq-num*.u format for file naming.

Default: **custom1**

name { format | prefix *prefix* **}**

Allows the format of the CDR filenames to be configured independently from the file format.so that the name format contains the file name with conversion specifications.
prefix – Enter an alphanumeric string of 1 through 127 characters. The string **must begin** with the % (percent sign).

- **%y**: = year as a decimal number without century (range 00 to 99).
- **%Y**: year as a decimal number with century.
- **%m**: month as a decimal number (range 01 to 12).
- **%d**: day of the month as a decimal number (range 01 to 31).
- **%H**: hour as a decimal number 24-hour format (range 00 to 23).
- **%h**: hour as a decimal number 12-hour format (range 01 to 12).
- **%M**: minute as a decimal number (range 00 to 59).
- **%S**: second as a decimal number (range 00 to 60). (The range is up to 60 to allow occasional leap seconds.)
- **%Q**: File sequence number. Field width may be specified between the % and the Q. If the natural size of the field is smaller than this width, then the result string is padded (on the left) to the specified width with 0s
- **%N**: No of CDRs in the file. Field width may be specified between the % and the N. If the natural size of the field is smaller than this width, then the result string is padded (on the left) to the specified width with 0s
- **max-file-seq-no**: This can be configured optionally. It indicates the maximum value of sequence number in file name (starts from 1). Once the configured max-file-seq-no limit is reached, the sequence number will restart from 1. If no max-file-seq-no is specified then file sequence number ranges from 1 – 4294967295.

By default the above keyword is not configured (default gtpp storage-server local file name format). In which case the CDR filenames are generated based on the file format as before (maintains backward compatibility).

purge-processed-files [file-name-pattern *file_pattern* **| purge-interval** *purge_dur* **]**

Enables the GSN to periodically (every 4 minutes) delete locally processed (*.p) CDR files from the HDD on the SMC card. Default: Disabled

Important: This option is available only when GTPP server storage mode is configured for local storage of CDRs with the **gtpp storage-server mode local** command.

Optional keyword **file-name-pattern** *file_pattern* provides an option for user to control the pattern of files. *file_pattern* must be mentioned in *.p format in a string of size 1 through 127, which is also the default format. Wild cards * and : (synonymous to |) are allowed.
Optional keyword **purge-interval** *purge_dur* provides an option for user to control the purge interval duration (in minutes). *purge_dur* must be an integer from 1 through 259200. Default value 60.

rotation { cdr-count count | time-interval *time* **| volume mb** *size* **}**

Specifies rotation related configuration for GTPP files stored locally.

cdr-count *count*: Configures the CDR count for the file rotation as an integer from 1000 through 65000. Default value 10000.
time-interval *time*: Configures the time interval (in seconds) for file rotation as an integer from 30 through 86400. Default value 3600 (1 hour).
volume mb *size*: Configure the file volume (in MB) for file rotation. Enter an integer from 2 to 40. This trigger cannot be disabled. Default value is 4MB.

start-file-seq-num *seq_num* **[recover-file-seq-num]**

Specifies the start sequence number. The sequence number goes on incrementing until ULONG_MAX (or max-seq-num configured in file name format) and then it would rollover. If **recover-file-seq-num** is configured, every time the system is rebooted (or aaaproxy recovery/ planned/ unplanned packet service card migration), the file sequence number continues from the last sequence number and during rollover it starts from first-sequence number.
seq_num: Configures the sequence number. Enter an integer from 1 through 4294967295.
recover-file-seq-num: Configures the recovery of file sequence number. This is an optional field and if configured, every time the machine rebooted, the file sequence number continues from the last sequence number.

Usage

This command configures the parameters for storage of GTPP packets as files on the local server—meaning the hard disk.

Example

The following command configures rotation for every 1.5 hours (5400 seconds) for locally stored files.

```
gtpp storage-server local file rotation time-interval 5400 start-file-
seq-num 20 recover-file-seq-num
```

gtpp storage-server max-retries

Configures the maximum number of times the system attempts to communicate with an unresponsive GTPP back-up storage server.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

gtpp storage-server max-retries *max_attempts*

default gtpp storage-server max-retries

default

Configures this command with the default setting.
Default: 2

gtpp storage-server max-retries *max_attempts*

Specifies the number of times the system attempts to communicate with a GTPP back-up storage server that is not responding. *max_attempts* enter an integer from 1 through 15.

Usage

This command works in conjunction with the **gtpp storage-server timeout** parameters to set a limit to the number of communication failures that can occur with a configured GTPP back-up storage server.
The **gtpp storage-server timeout** command controls the amount of time between re-tries.

Example

The following command configures the maximum number of re-tries to be *8*:

```
gtpp storage-server max-retries 8
```

gtpp storage-server mode

Configures storage mode, local or remote, for CDRs. Local storage mode is available with ASR 5000 platforms only.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpp storage-server mode { local | remote | streaming }

default gtpp storage-server mode
```

default

Configures this command with the default setting.
Default: **remote**

gtpp storage-server mode local

Default: Disabled
Specifies the use of the hard disk on the SMC for storing CDRs

gtpp storage-server mode remote

Specifies the use of an external server for storing CDRs. This is the default value.

gtpp storage-server mode streaming

Default: Disabled
Allows the operator to configure "streaming" mode of operation for GTPP group. When this keyword is supplied the CDRs will be stored in following fashion:

- When GTPP link is active with CGF, CDRs are sent to a CGF via GTPP and local hard disk is NOT used as long as every record is acknowledged in time.
- If the GTPP connection is considered to be down, all streaming CDRs will be saved temporarily on the local hard disk and once the connection is restored, unacknowledged records will be retrieved from the hard disk and sent to the CGF.

Usage

This command configures whether the CDRs should be stored on the hard disk of the SMC or remotely, on an external server.

Example

The following command configures use of a hard disk for storing CDRs:

```
gtpp storage-server mode local
```

gtpp storage-server timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the GTPP back-up storage server.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

gtpp storage-server timeout *duration*

default gtpp storage-server timeout

default

Configures this command with the default setting.
Default: 30 seconds

gtpp storage-server timeout *duration*

Specifies the maximum amount of time (in seconds) the system waits for a response from the GTPP back-up storage server before assuming the packet is lost. *duration* is an integer from 30 through 120.

Usage

This command works in conjunction with the **gtpp storage-server max-retries** command to establish a limit on the number of times that communication with a GTPP back-up storage server is attempted before a failure is logged. This parameter specifies the time between retries.

Example

The following command configures a retry timeout of *60* seconds:

```
gtpp storage-server timeout 60
```

gtpp suppress-cdrs zero-volume-and-duration

Suppresses the CDRs created by sessions having zero duration and/or zero volume. By default this mode is disabled.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpp suppress-cdrs zero-volume-and-duration { gcdrs [ egcdrs ] | egcdrs [ gcdrs ] }

default gtpp suppress-cdrs zero-volume-and-duration
```

default

Configures this command with the default setting.
Default: Disabled.

gtpp suppress-cdrs zero-volume-and-duration gcdrs [egcdrs]

Suppresses G-CDRs before eG-CDRs.

gtpp suppress-cdrs zero-volume-and-duration egcdrs [gcdrs]

Suppresses eG-CDRs before G-CDRs.

Usage

Use this command to suppress the CDRs (G-CDRs and eG-CDRs) which were created when zero-duration sessions and zero-volume sessions are encountered due to any reason. By default this command is disabled and system will not suppress any CDR.

Example

The following command configures the system to suppress the eG-CDRs created for a zero duration session or zero volume session:

```
gtpp suppress-cdrs zero-volume-and-duration egcdrs gcdrs
```

gtpp timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the Charging Gateway Function (CGF).

Product

GGSN, SGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

gtpp timeout *time*

default gtpp timeout

default

Configures this command with the default setting. Default: 20 seconds

gtpp timeout *time*

Specifies the maximum amount of time (in seconds) the system waits for a response from the CGF before assuming the packet is lost. *time* is an integer from 1 through 60.

Usage

This command works in conjunction with the **gtpp max-retries** command to establish a limit on the number of times that communication with a CGF is attempted before a failure is logged.
This parameter specifies the time between retries.

Example

The following command configures a retry timeout of *30* seconds:

```
gtpp timeout 30
```

gtpp trigger

This command is left in place for backward compatibility. To disable and enable GTPP triggers you should use the **gtpp trigger** command in GTPP Server Group Configuration Mode.

gtpp transport-layer

Selects the transport layer protocol for the Ga interface for communication between the access gateways (GSNs) and GTPP servers.

Product

GGSN, P-GW, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
gtpp transport-layer { tcp | udp }

default gtpp transport-layer
```

default

Configures this command with the default setting.
Default: **udp**

gtpp transport-layer tcp

Default: Disabled
Enables the system to implement TCP as transport layer protocol for communication with GTPP server.

gtpp transport-layer udp

Default: Enabled
Enables the system to implement UDP as transport layer protocol for communication with GTPP server.

Usage

Use this command to select the TCP or UDP as the transport layer protocol for Ga interface communication between GTPP servers and AGWs (GSNs).

Example

The following command enables TCP as the transport layer protocol for the GSN's Ga interface.

```
gtpp transport-layer tcp
```

gtpu-service

Creates a GTP-U service or specifies an existing GTP-U service and enters the GTP-U Service Configuration Mode for the current context.

Product

GGSN, P-GW, S-GW

Privilege

Administrator

Syntax

gtpu-service *service_name* **[-noconfirm]**

no gtpu-service *service_name*

gtpu-service *service_name*

Specifies the name of the GTP-U service. If *service_name* does not refer to an existing service, a new service is created if resources allow. *service_name* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no gtpu-service *service_name*

Removes the specified GTP-U service from the context.

Usage

Enter the GTP-U Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-gtpu-service)#
```

GTP-U Service Configuration Mode commands are defined in the *GTP-U Service Configuration Mode Commands* chapter.

Example

The following command enters the existing GTP-U Service Configuration Mode (or creates it if it does not already exist) for the service named *gtpu-service1*:

```
gtpu-service gtpu-service1
```

The following command will remove *gtpu-service1* from the system:

```
no gtpu-service gtpu-service1
```

ha-service

Creates/deletes a home agent service or specifies an existing HA service for which to enter the Home Agent Service Configuration Mode for the current context.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

ha-service *name*

no ha-service *name*

no

Indicates the home agent service specified is to be removed.

ha-service *name*

Specifies the name of the HA service to configure. If *name* does not refer to an existing service, the new service is created if resources allow. *name* is an alphanumeric string of 1 through 63 characters.

Usage

Enter the HA Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (i.e. resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Example

The following command will enter, or create and enter, the HA service *sampleService*:

```
ha-service sampleService
```

The following command will remove *sampleService* as being a defined HA service:

```
no ha-service sampleService
```

hnbgw-service

Creates or removes an Home NodeB Gateway (HNB-GW) service or configures an existing HNB-GW service and enters the HNB-GW Service Configuration Mode for Femto UMTS access networks configuration in the current context.

Product

HNB-GW

Privilege

Administrator

Syntax

hnbgw-service *hnbgw_svc_name* **[-noconfirm]**

no hnbgw-service *hnbgw_svc_name*

no

Removes the specified HNB-GW service from the context.

hnbgw-service *hnbgw_svc_name*

Specifies the name of the HNB-GW service. If *service_name* does not refer to an existing service, the new service is created if resources allow. *hnbgw_svc_name* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to enter the HNB-GW Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of one HNB-GW service which is further limited to a maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-hnbgw-service)#
```

The commands available in this mode are defined in the *HNB-GW Service Configuration Mode Commands* chapter of *Command Line Interface Reference*.

Caution: This is a critical configuration. The HNB-GW service can not be configured without this configuration. Any change to this configuration would lead to restarting the HNB-GW service and removing or disabling this configuration will stop the HNB-GW service.

Example

The following command enters the existing HNB-GW Service Configuration Mode (or creates it if it does not already exist) for the service named *hnb-service1*:

```
hnbgw-service hnb-service1
```

The following command will remove *hnb-service1* from the system:

```
no hnbgw-service hnb-service1
```

hsgw-service

Creates an HSGW service or specifies an existing HSGW service and enters the HSGW Service Configuration Mode for the current context.

Product

HSGW

Privilege

Administrator

Syntax

hsgw-service *service_name* **[-noconfirm]**

no hsgw-service *service_name*

hsgw-service *service_name*

Specifies the name of the HSGW service. If *service_name* does not refer to an existing service, the new service is created if resources allow. *service_name* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no hsgw-service *service_name*

Removes the specified HSGW service from the context.

Usage

Enter the HSGW Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-hsgw-service)#
```

HSGW Service Configuration Mode commands are defined in the *HSGW Service Configuration Mode Commands* chapter.
Use this command when configuring the following eHRPD components: HSGW.

Example

The following command enters the existing HSGW Service Configuration Mode (or creates it if it does not already exist) for the service named *hsgw-service1*:

```
hsgw-service hsgw-service1
```

The following command will remove *hsgw-service1* from the system:

```
no hsgw-service hsgw-service1
```

hss-peer-service

Creates a Home Subscriber Service (HSS) peer service or configures an existing HSS peer service and enters the HSS Peer Service Configuration Mode.

Product

MME

Important: For an SGSN, this command is visible, but the feature is in development and not yet supported for configuration.

Privilege

Administrator

Syntax

hss-peer-service *service_name* **[-noconfirm]**

no hss-peer-service *service_name*

no mme-hss-service *service_name*

Removes the specified HSS peer service from the context.

hss-peer-service *service_name*

Specifies the name of the HSS peer service. If *service_name* does not refer to an existing service, a new service is created if resources allow. *service_name* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Enter the HSS Peer Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-hss-peer-service)#
```

HSS Peer Service Configuration Mode commands are defined in the *HSS Peer Service Configuration Mode Commands* chapter.

Example

The following command enters the existing HSS Peer Service Configuration Mode (or creates it if it does not already exist) for the service named *hss-peer1*:

```
hss-peer-service hss-peer1
```

The following command will remove *hss-peer1* from the system:

```
no hss-peer-service hss-peer1
```

ikev1 disable-initial-contact

Disables the sending of the INITIAL-CONTACT message in the IKEv1 protocol after the node creates a new Phase1 SA, caused either by Dead Peer Detection or by a rekey.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ikev1 disable-initial-contact
```

no

Disables this command, which re-enables the sending of the INITIAL-CONTACT message.

ikev1 disable-initial-contact

Enables the sending of the INITIAL-CONTACT message.

Usage

Use this command to disable the sending of the INITIAL-CONTACT message in the IKE v1 protocol.

Example

The following command disables the sending of the INITIAL-CONTACT message:

```
ikev1 disable-initial-contact
```

ikev1 disable-phase1-rekey

Configures the rekeying of Phase1 SA when the Internet Security Association and Key Management Protocol (ISAKMP) lifetime expires in Internet Key Exchange (IKE) v1 protocol.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ikev1 disable-phase1-rekey
```

no

Re-enables Phase 1 SAs when the ISAKMP lifetime expires.

ikev1 disable-phase1-rekey

Rekeys the Phase 1 SAs when the ISAKMP lifetime expires.

Usage

Use this command to disable the rekeying of Phase 1 SAs when the ISAKMP lifetime expires in IKE v1 protocol.

Example

The following command disables rekeying of Phase1 SAs when the lifetime expires:

```
ikev1 disable-phase1-rekey
```

ikev1 keepalive dpd

Configures the ISAKMP IPSec Dead Peer Detection (DPD) message parameters for IKE v1 protocol.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

`[ no ] ikev1 keepalive dpd interval` *`interval`* **`timeout`** *`time`* **`num-retry`** *`retries`*

`no`

Deletes previously configured IPSec DPD Protocol settings.

`ikev1 keepalive dpd interval` *`interval`*

Specifies the time interval (in seconds) at which IPSec DPD Protocol messages are sent. *`interval`* is an integer from 10 through 3600.

`timeout` *`time`*

Specifies the amount of time (in seconds) allowed for receiving a response from the peer security gateway prior to re-sending the message. *`time`* is an integer from 10 through 3600.

`num-retry` *`retries`*

Specifies the maximum number of times that the system should attempt to reach the peer security gateway prior to considering it unreachable. *`retries`* is an integer from 1 through 100.

Usage

Use this command to configure the ISAKMP dead peer detection parameters in IKE v1 protocol. Tunnels belonging to crypto groups are perpetually kept “up” through the use of the IPSec Dead Peer Detection (DPD) packets exchanged with the peer security gateway.

Important: The peer security gateway must support RFC 3706 in order for this functionality to function properly.

This functionality is for use with the Redundant IPSec Tunnel Fail-over feature and to prevent IPSec tunnel state mismatches between the FA and HA when used in conjunction with Mobile IP applications. Regardless of the application, DPD must be supported/configured on both security peers. If the system is configured with DPD but it is communicating with a peer that does not have DPD configured, IPSec tunnels still come up. However, the only indication that the remote peer does not support DPD exists in the output of the **`show crypto isakmp security associations summary dpd`** command.

Important: If DPD is enabled while IPSec tunnels are up, it will not take affect until all of the tunnels are cleared.

Example

The following command configures IPSec DPD Protocol parameters to have an interval of *15*, a timeout of *10*, to retry each attempt *5* times:

```
ikev1 keepalive dpd interval 15 timeout 10 num-retry 5
```

ikev1 policy

Configures or creates an ISAKMP policy with the specified priority and enters ISAKMP Configuration Mode for IKE v1 protocol.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] ikev1 policy *priority*

no

Removes a previously configured ISAKMP policy for IKE v1 protocol.

ikev1 policy *priority*

Specifies the priority of an ISAKMP policy as an integer from 0 through 100. ISAKMP policies for IKE v1 protocol with lower priority numbers take precedence over policies with higher priorities. “0” is the highest priority. Default: 0

Usage

Use this command to create ISAKMP policies to regulate how IPSec key negotiation is performed for IKE v1 protocol.
Internet Security Association Key Management Protocol (ISAKMP) policies are used to define Internet Key Exchange (IKE) SAs. The IKE SAs dictate the shared security parameters (i.e. which encryption parameters to use, how to authenticate the remote peer, etc.) between the system and a peer security gateway.
During Phase 1 of IPSec establishment, the system and a peer security gateway negotiate IKE SAs. These SAs are used to protect subsequent communications between the peers including the IPSec SA negotiation process.
Multiple ISAKMP policies can be configured in the same context and are used in an order determined by their priority number.

Example

Use the following command to create an ISAKMP policy with the priority *1* and enter the ISAKMP Configuration Mode:

```
ikev1 policy 1
```

ikev2-ikesa

Creates a new, or specifies an existing, IKEv2 security association transform set and enters the IKEv2 Security Association Configuration Mode.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

[no] ikev2-ikesa transform-set *name*

ikev2-ikesa transform-set *name*

Specifies the name of a new or existing security association transform set as an alphanumeric string of 1 through 127 characters.

Usage

Use this command to create a new or enter an existing IKEv2 security association transform-set. A list of up to four separate transform-sets can be created.
Entering this command results in the following prompt:

```
[context_name]hostname(cfg-ctx-ikev2ikesa-tran-set)#
```

IKEv2 Security Association Configuration Mode commands are defined in the *IKEv2 Security Association Configuration Mode Commands* chapter.

Example

The following command configures an IKEv2 security association transform set called *ikesa3* and enters the IKEv2 Security Association Configuration Mode:

```
ikev2-ikesa transform-set ikesa3
```

ims-auth-service

This command enables the creation, configuration or deletion of an IMS authorization service in the current context.

Product

GGSN, HA, IPSG, PDSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

ims-auth-service *auth_svc_name* **[-noconfirm]**

{ no | default } ims-auth-service *auth_svc_name*

no

Deletes the specified IMS authorization service within the current context.

default

Restores default state of IMS authorization service, disabled for a specific context.

auth_svc_name

Specifies name of the IMS authorization service as a unique alphanumeric string of 1 through 63 characters. A maximum of 16 authorization services can be configured globally in the system. There is also a system limit for the maximum number of total configured services.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to create/configure/delete an IMS authorization service for Gx interface support in the current context.
Entering this command results in the following prompt:
`[context_name]hostname(config-imsa-service)`
IMS authorization service configuration commands are described in the *IMS Authorization Service Configuration Mode Commands* chapter.

Example

The following command configures an IMS authorization service named *ims_interface1* within the current context:

```
ims-auth-service ims_interface1
```

ims-sh-service

Creates the specified IP Multimedia Subsystem (IMS) Sh service name to allow configuration of an Sh service.

Product

PDIF, SCM

Privilege

Administrator

Syntax

ims-sh-service *name*

no ims-sh-service *name*

no

Removes a previously configured IMS-Sh-service.

ims-sh-service *name*

Specifies the name of the IMS-Sh-service to be configured as an alphanumeric string of 1 through 63 characters.

Usage

The IMS-Sh-service is named in the pdif-service and/or cscf-service. Use this command to enter the IMS Sh Service Configuration Mode.
Entering this command results in the following prompt:
[*context_name*]*hostname*(config-ims-sh-service)#
IMS Sh Service Configuration Mode commands are defined in the *IMS Sh Service Configuration Mode Commands* chapter in this guide.

Example

The following example creates or enters an IMS Sh service named *ims-1*:

```
ims-sh-service ims-1
```

inspector

Configures a context-level inspector account within the current context.

Product

All

Privilege

Security Administrator

Syntax

inspector *user_name* **[encrypted] password** *password* **[ecs | noecs] [expiry-date** *date_time* **] [li-administration] [noecs] [timeout-absolute** *abs_seconds* **] [timeout-min-absolute** *abs_minutes* **] [timeout-idle** *timeout_duration* **] [timeout-min-idle** *idle_minutes* **]**

no inspector *user_name*

no

Removes a previously configured inspector account.

inspector *user_name*

Specifies a name for the context-level inspector account as an alphanumeric string of 1 through 32 characters.

[encrypted] password *password*

Specifies the password to use for the user which is being given context-level inspector privileges within the current context. The encrypted keyword indicates the password specified uses encryption.
password is an alphanumeric string of 1 through 63 characters without encryption, or 1 through 127 characters with encryption.
The encrypted keyword is intended only for use by the system while saving configuration scripts. The system displays the encrypted keyword in the configuration file as a flag that the variable following the password keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

ecs | noecs

Default: **noecs**
ecs: Permits the specific user to access ACS-specific configuration commands.
noecs: Prevents the specific user to access ACS-specific configuration commands.

expiry-date *date_time*

Specifies the date and time that this account expires. Enter the date and time in the format YYYY:MM:DD:HH:mm or YYYY:MM:DD:HH:mm:ss.
Where YYYY is the year, MM is the month, DD is the day of the month, HH is the hour, mm is minutes, and ss is seconds.

li-administration

Refer to the *Lawful Intercept Configuration Guide* for a description of this parameter.

timeout-absolute *abs_seconds*

This keyword is obsolete. It has been left in place for backward compatibility. If used a warning is issued and the value entered is rounded to the nearest whole minute.
Specifies the maximum amount of time (in seconds) the context-level inspector may have a session active before the session is forcibly terminated. *abs_seconds* must be an integer from 0 through 300000000. The value 0 disables the absolute timeout. Default: 0

timeout-min-absolute *abs_minutes*

Specifies the maximum amount of time (in minutes) the context-level inspector may have a session active before the session is forcibly terminated. *abs_minutes* must be an integer from 0 through 525600 (365 days). The value 0 disables the absolute timeout. Default: 0

timeout-idle *timeout_duration*

This keyword is obsolete. It has been left in place for backward compatibility. If used a warning is issued and the value entered is rounded to the nearest whole minute.
Specifies the maximum amount of idle time (in seconds) the context-level inspector may have a session active before the session is terminated. *timeout_duration* must be an integer from 0 through 300000000. The value 0 disables the idle timeout. Default: 0

timeout-min-idle *idle_minutes*

Specifies the maximum amount of idle time (in minutes) the context-level inspector may have a session active before the session is terminated. *idle_minutes* must be an integer from 0 through 525600 (365 days). The value 0 disables the idle timeout. Default: 0

Usage

Create new context-level inspector or modify existing inspector's options, in particular, the timeout values. Inspector users have minimal read-only privileges. Refer to the *Command Line Interface Overview* chapter for more information.

Important: A maximum of 128 administrative users and/or subscribers may be locally configured per context.

Example

The following command creates a context-level inspector account named *user1*:

```
inspector user1 password secretPassword
```

The following command removes a context-level inspector account named *user1*:

```
no inspector user1
```

interface

Creates or deletes an interface or specifies an existing interface. By identifying an interface, the mode changes to configure this interface in the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

interface *name* **[broadcast | loopback | point-to-point | tunnel]**

no interface *name*

no

Indicates the interface specified is to be removed.

interface *name*

Specifies the name of the interface to configure. If *name* does not refer to an existing interface, the new interface is created if resources allow. *name* is an alphanumeric string of 1 through 79 characters.

broadcast

Creates an Ethernet broadcast (IP) interface and enters the Ethernet Configuration Mode. Default: Enabled

Important: Refer to the *Ethernet Interface Configuration Mode Command* chapter for more information.

loopback

Creates an internal IP address that is always UP, is not bound to any physical card/port, and can be reached by any interface configured in the current context. As a loopback interface uses all available physical ports, this type of interface is particularly useful for load-balancing. The interface must be configured for loopback when configuring Interchassis Session Recovery (ICSR). A total of 256 loopback interfaces can be configured. Default: Disabled
This loopback option is not used to setup a diagnostic test port so it should not be confused with the loopback option used in the various card/port configuration modes.

Important: Refer to the *Loopback Interface Configuration Mode Command* chapter for more information.

point-to-point

Creates a permanent virtual connection (PVC) in the current context and enters the PVC Configuration Mode. Currently, this type of interface is only used with an optical (ATM) line card.

Important: Refer to the *PVC Interface Configuration Mode Command* chapter for more information.

tunnel

Creates a tunnel interface to support the various tunnel interfaces. Currently only IPv6-over-IPv4 and GRE tunnel interfaces are supported.

Important: Refer to the *Tunnel Interface Configuration Mode Commands* chapter for more information.

Usage

Use this command to enter or create the interface configuration mode for an existing interface or for a newly defined interface. This command is also used to remove an existing interface when it longer is needed.

Important: If no keyword is specified, broadcast is assumed and the interface is Ethernet by default.

For IPv6-over-IPv4 or GRE tunneling, you need to specify the interface type as **tunnel**.

Example

The following command enters the Ethernet Interface Configuration Mode creating the interface *sampleService*, if necessary:

```
interface sampleInterface
```

The following command removes *sampleService* as being a defined interface:

```
no interface sampleInterface
```

The following command enters the Tunnel Interface Configuration Mode creating the interface *GRE_tunnel1*, if necessary:

```
interface GRE_tunnel1 tunnel
```

ip access-group

Configures an access group with an Access Control List (ACL) for IP traffic for the current context. The Context-level ACL is applied only to outgoing packets.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip access-group *name* **[in | out] [** *priority_value* **]**

no ip access-group *name* **[in | out]**

no

Indicates the specified ACL rule is to be removed from the group.

ip access-group *name*

Specifies the ACL rule to be added/removed from the group.
In Release 8.1 and later, *name* is an alphanumeric string of 1 through 47 characters.
In Release 8.0, *name* is an alphanumeric string of 1 through 79 characters.

Important: Up to eight ACLs can be applied to a group provided that the number of rules configured within the ACL(s) does not exceed the 256-rule limit for the context.

in | out

The **in** and **out** keywords are deprecated and are only present for backward compatibility. The Context-level ACL are applied only to outgoing packets.

priority_value

Specifies the priority of the access group. 0 is the highest priority. If *priority_value* is not specified, the priority is set to 0. *priority_value* must be an integer from 0 through 4294967295. Default: 0
If access groups in the list have the same priority, the last one entered is used first.

Usage

Use this command to add IP access lists (refer to the **ip access-list** command) configured with in the same context to an ACL group.
Refer to the *Access Control Lists* appendix of the *System Administration Guide* for more information on ACLs.

Example

The following commands add *sampleGroup* to the context-level ACL with a priority of *0*:

```
ip access-group sampleGroup 0
```

ip access-list

Enables creation, configuration or deletion of an IP Access List in the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip access-list *name*

{ default | no } ip access-list *name*

default

Sets the context's default access control list to that specified by *name*.

no

Removes the specified access list.

ip access-list *name*

Specifies the access list name.
In Release 8.0, *name* is an alphanumeric string of 1 through 79 characters.
In Release 8.1 and later, *name* is an alphanumeric string of 1 through 47 characters.
If the named access list does not exist, it is created, and the CLI mode changes to the ACL Configuration Mode, wherein the access list can be configured.
If the named access list already exists, the CLI mode changes to the ACL Configuration Mode, wherein the access list can be reconfigured.

Usage

Executing this command enters the ACL Configuration Mode in which rules and criteria are defined for the ACL.

Important: A maximum of 64 rules can be configured per ACL. The maximum number of ACLs that can be configured per context is limited by the amount of available memory in the VPN Manager software task; it is typically less then 200.

The no version of this command deletes the ACL.
Refer to the *Access Control Lists* appendix of the *System Administration Guide* for more information on ACLs.

Example

The following command creates an access list named *sampleList*, and enters the ACL Configuration Mode:

```
ip access-list sampleList
```

ip arp

Configures the allocation retention priority (ARP) options for the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip arp *ip_address mac_address* **[vrf** *vrf_name* **]**

no ip arp *ip_address mac_address*

no

Removes the ARP configuration data for the specified IP address from the configuration.

ip_address

Specifies the IP address for which to configure the ARP options where *ip_address* is an IP address expressed in IPv4 dotted-decimal notation.

mac_address

Specifies the media-specific access control layer address for the IP address. *mac_address* must be specified as a an 6-byte hexadecimal number with each byte separated by a colon, for example., “AA:12:bb:34:f5:0E”.

vrf *vrf_name*

Associates a Virtual Routing and Forwarding (VRF) context with this static ARP entry.
vrf_name is name of a preconfigured virtual routing and forwarding (VRF) context configured in *Context Configuration Mode* via the **ip vrf** command.

Usage

Manage the IP address mapping which is a logical/virtual identifier to the more lower layer addressing used for address resolution in ICMP messages.
For tunnel-based interface, network IP pool can have overlapping ip-addresses across Verve. To manage it adding a preconfigured VRF context is required to associate with an static ARP entry. By default, the ARP is added in the given context. If the VRF name is specified, then the ARP is added to the VRF ARP table.

Example

The following commands set the IP and MAC address for the current context then remove it from the configuration:

```
ip arp 10.2.3.4 F1:E2:D4:C5:B6:A7

no ip arp 10.2.3.4
```

The following commands set the IP and MAC address for a VRF context *vrf1* in the configuration:

```
ip arp 10.2.3.4 F1:E2:D4:C5:B6:A7 vrf vrf1
```

ip as-path access-list

Defines Border Gateway Protocol (BGP) Autonomous System (AS) Path access lists.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

ip as-path access-list *list_name* **[{ deny | permit }** *reg_expr* **]**

no ip as-path access-list *list_name* **[{ deny | permit }** *reg_expr* **]**

no

Remove the specified regular expression from the AS path access list.

ip as-path access-list *list_name*

Specifies the name of an AS path list as an alphanumeric string of 1 through 79 characters.

{ deny | permit }

deny: Denies access to AS paths that match the regular expression.
permit: Allows access to AS paths that match the regular expression.

reg_expr

A regular expression to define the AS paths to match. *reg_expr* is an alphanumeric string of 1 through 254 characters.

Important: The **?** (question mark) character is not supported in regular expressions for this command.

Usage

Use this command to define AS path access lists for the BGP router in the current context. The chassis supports a maximum of 64 access lists per context.

Example

The following command creates an AS access list named *ASlist1* and permits access to AS paths:

```
ip as-path access-list ASlist1 permit
```

ip dns-proxy source-address

Enables the proxy DNS functionality and identifies this context as the destination context for all redirected DNS requests.

Important: This command must be entered in the destination context for the subscriber. If there are multiple destination contexts for different subscribers, the command must be entered in each context.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

`[ no ] ip dns-proxy source-address` *`ip_address`*

`no`

Removes the address in this context as a destination for redirected DNS packets.

`ip dns-proxy source-address` *`ip_address`*

Specifies an interface in this context used for redirected DNS packets. *`ip_address`* must be entered using IPv4 dotted-decimal notation.

Usage

Use this command to identify the interface in this context where redirected DNS packets are sent to the home DNS. The system uses this address as the source address of the DNS packets when forwarding the intercepted DNS request to the home DNS server. For a more detailed explanation of the proxy DNS intercept feature, see the **`proxy-dns intercept-list`** command.

Example

The following command identifies an interface with an address of *`10.23.255.255`* in a destination context where the system forwards all intercepted DNS requests:

```
ip dns-proxy source-address 10.23.255.255
```

ip domain-lookup

Enables or disables domain name lookup via domain name servers for the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip domain-lookup

no ip domain-lookup

no

Disables domain name lookup.

ip domain-lookup

Enables domain name lookup.

Usage

Domain name look up is necessary if the subscribers configured for the context are to be allowed to use logical host names for services which requires the host name resolution via DNS.

Example

```
ip domain-lookup

no ip domain-lookup
```

ip domain-name

Configures or removes a logical domain name for the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip domain-name *name*

no ip domain-name *name*

no

Indicates the logical domain name for the current context is to be removed.

ip domain-name *name*

Specifies the logical domain name to use for domain name server address resolution. *name* is an alphanumeric string of 1 through 1023 characters formatted to be a valid IP domain name.

Usage

Set a logical domain name if the context is to be accessed by logical domain name in addition to direct IP address.

Example

```
ip domain-name sampleName.org
```

ip forward

Configures an IP forwarding policy to forward outgoing pool packets whose flow lookup fails to the default-gateway.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip forward outbound unused-pool-dest-address default-gateway
```

no

Disables forwarding to the default gateway.

ip forward outbound unused-pool-dest-address default-gateway

Enables forwarding to the default gateway.

Usage

Use this command to set an IP forwarding policy that forwards outgoing pool packets whose flow lookup fails to the default gateway. By default, the behavior is to either send an ICMP Unreachable message or to discard the packet depending on the configuration of the IP pool.
Pool packets coming from the linecard whose flow lookup fails are discarded or ICMP unreachable is sent irrespective of whether this command is configured or not.

Example

To enable this functionality, enter the following command:

```
ip forward outbound unused-pool-dest-address default-gateway
```

To disable this functionality, enter the following command:

```
no ip forward outbound unused-pool-dest-address default-gateway
```

ip identification packet-size-threshold

Configures the packet size above which system will assign unique IP header identification.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

ip identification packet-size-threshold *size*

default ip identification packet-size-threshold

default

Restores default value of 576 bytes to IP packet size for fragmentation threshold.

ip identification packet-size-threshold *size*

Specifies the size of IP packet in bytes above which system will assign unique IP header identification for system generated IP encapsulation headers (such as MIP data tunnel). *size* is an integer from 0 through 2000. Default: 576

Usage

This configuration is used to set the upper limit of the IP packet size. All packets above that size limit will be considered “fragmentable”, and an unique non-zero identifier will be assigned.

Example

The following commands set the IP packet size to 1024 bytes as threshold. above this limit system will assign unique IP header identification for system generated IP encapsulation headers:

```
ip identification packet-size-threshold 1023
```

ip localhost

Configures or removes the static local host logical name to IP address mapping for the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip localhost *name ip_address*

no ip localhost *name ip_address*

no

Specifies that the static mapping must be removed.

ip localhost *name*

Specifies the logical host name (DNS) for the local machine on which the current context resides. *name* is an alphanumeric string of 1 through 1023 characters formatted to be a valid IP host name.

ip_address

Specifies the IP address for the static mapping. *ip_address* must be expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Avoid excessive DNS lookups across the network by statically mapping the logical host name to the local host's context.

Example

```
ip localhost localHostName 10.2.3.4

no ip localhost localHostName 10.2.3.4
```

ip name-servers

Modifies the list of domain name servers the current context may use for logical host name resolution.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip name-servers *ip_address secondary_ip_address*

no ip name-servers *ip_address*

no

Indicates the name server specified is to be removed from the list of name servers for the current context.

ip name-servers *ip_address*

Specifies the IP address of a domain name server using IPv4 dotted-decimal or IPv6 colon-separated notation.

secondary_ip_address

Specifies the IP address of a secondary domain name server using either IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Manage the list of name servers the current context may use in resolving logical host names.
The DNS can be specified at the Context level in Context configuration as well as at the APN level in APN Configuration Mode with **dns** and **ipv6 dns** commands, or it can be received from AAA server.
When DNS is requested in PCO configuration, the following preference will be followed for DNS value:

1. DNS Values received from LNS have the first preference.
2. DNS values received from RADIUS Server has the second preference.
3. DNS values locally configured with APN with **dns** and **ipv6 dns** commands has the third preference.
4. DNS values configured at context level has the last preference.

Important: The same preference would be applicable for the NBNS servers to be negotiated via ICPC with the LNS.

Example

```
ip name-servers 10.2.3.4
```

ip pool

Enables creation, configuration or deletion of IP address pools in the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip pool *pool_name* **{** *ip_address subnet_mask* **|** *ip_address_mask_combo* **| range** *start_ip_address end_ip_address* **} [address-hold-timer** *address_hold_timer* **] [advertise-if-used] [alert-threshold [group-available | pool-free | pool-hold | pool-release | pool-used]** *low_thresh* **[clear** *high_thresh* **]] [explicit-route-advertise] [group-name** *group_name* **] [include-nw-bcast] [napt-users-per-ip-address** *users_per_ip* **[alert-threshold { { pool-free | pool-hold | pool-release | pool-used }** *low_thresh* **[clear** *high_thresh* **] } +] [max-chunks-per-user** *max_chunks_per_user* **[nat-binding-timer** *nat_binding_timer* **] [nexthop-forwarding-address** *ip_address* **] [on-demand] [port-chunk-size** *port_chunk_size* **] [port-chunk-threshold** *port_chunk_threshold* **] [send-nat-binding-update] +] [nat** *priority* **] [nat-one-to-one [alert-threshold { { pool-free | pool-hold | pool-release | pool-used }** *low_thresh* **[clear** *high_thresh* **] } +] [nat-binding-timer** *nat_binding_timer* **] [nexthop-forwarding-address** *ip_address* **] [on-demand] [send-nat-binding-update] +] [nat-realm users-per-nat-ip-address** *users* **[on-demand [address-hold-timer** *address_hold_timer* **]]] [nexthop-forwarding-address** *ip_address* **[overlap vlanid** *vlan_id* **] [respond-icmp-echo** *ip_address* **]] [nw-reachability server** *server_name* **] [policy allow-static-allocation] [private** *priority* **] [public** *priority* **] [resource** *priority* **] [send-icmp-dest-unreachable] [srp-activate] [static] [suppress-switchover-arps] [tag { none | pdif-setup-addr }] [unicast-gratuitous-arp-address** *ip_address* **]** [**vrf** *vrf_name* {[**mpls-label input** *in_label_value* | **output** *out_label_value1* [*out_label_value2*] }] +

no ip pool *pool_name* **[address-hold-timer] [advertise-if-used] [alert-threshold [[group-available] [pool-free] [pool-hold] [pool-release] [pool-used] +] [explicit-route-advertise] [group-name] [include-nw-bcast] [nexthop-forwarding-address [respond-icmp-echo]] [nw-reachability server] [policy allow-static-allocation] [send-icmp-dest-unreachable] [srp-activate] [suppress-switchover-arps] [tag { none | pdif-setup-addr }] [unicast-gratuitous-arp-address] + [send-nat-binding-update]**

no

Removes the specified IP address pool from the current context's configuration, or disables the specified option(s) for the specified IP pool.

no alert-threshold

This command without any optional keywords disables all alert thresholds.

ip pool *name*

Specifies the logical name of the IP address pool. *name* must be an alphanumeric string of 1 through 31 characters.

Important: An error message displays if the **ip** *pool name* and the *group name* in the configuration are the same. An error message displays if the **ip** *pool name* or *group name* are already used in the context.

ip_address

Specifies the beginning IP address of the IP address pool using IPv4 dotted-decimal.

subnet_mask

Specifies the IP address mask bits to determine the number of IP addresses in the pool. *ip_mask* must be specified using IPv4 dotted-decimal notation.
1 bits in the *ip_mask* indicate that bit position in the *ip_address* must also have a value of 1.
0 bits in the *ip_mask* indicate that bit position in the *ip_address* does not need to match – the bit can be either a 0 or a 1.
For example, if the IP address and mask are specified as *172.168.10.0* and *255.255.255.224*, respectively, the pool will contain IP addresses in the range *172.168.10.0* through *172.168.10.31* for a total of 32 addresses.

ip_address_mask_combo

Specifies a combined IP address subnet mask bits to indicate what IP addresses the route applies to. *ip_address_mask_combo* must be specified using CIDR notation where the IP address is specified using IPv4 dotted-decimal notation and the mask bits are a numeric value which is the number of bits in the subnet mask.

range *start_ip_address end_ip_address*

Specifies the IP addresses for the IP pool as a range of addresses.
start_ip_address specifies the beginning of the range of addresses for the IP pool.
end_ip_address specifies the end of the range of addresses for the IP pool.
The IP address range must be specified using IPv4 dotted-decimal notation.
For example, if *start_ip_address* is specified as *172.168.10.0* and *end_ip_address* is specified as *172.168.10.31* the IP pool will contain addresses in the range *172.168.10.0* through *172.168.10.31* for a total of 32 addresses.

private [*priority* **]**

Address pool may only be used by mobile stations which have requested an IP address from a specified pool. When private pools are part of an IP pool group, they are used in a priority order according to the precedence setting. *priority* must be an integer from 0 through 10 with 0 being the highest priority. The default value is 0.

public [*priority* **]**

Address pool is used in priority order for assigning IP addresses to mobile stations which have not requested a specific address pool. *priority* must be an integer from 0 through 10 with 0 being the highest priority. The default value is 0.

static

Address pool is used for statically assigned mobile stations. Statically assigned mobile stations are those with a fixed IP address at all times.

tag { none | pdif-setup-addr }

Default: **none**
none: default tag for all IP address pools
pdif-setup-addr: pool with this tag should only be used for PDIF calls.

address-hold-timer *seconds*

When this is enabled, and an active subscriber is disconnected, the IP address is held or considered still in use, and is not returned to the free state until the address-hold-timer expires. This enables subscribers who reconnect within the length of time specified (in seconds) to obtain the same IP address from the IP pool. *seconds* is the time in seconds and must be an integer from 0 through 31556926.

alert-threshold { group-available | pool-free | pool-hold | pool-release | pool-used } *low_thresh* **[clear** *high_thresh* **]**

Default: All thresholds are disabled.
Configures IP address pool-level utilization thresholds. These thresholds take precedence over context-level IP pool thresholds.
group-available: Set an alert based on the available percentage of IP addresses for the entire IP pool group.
pool-free: Set an alert based on the percentage of IP addresses that are unassigned in this IP pool.
pool-hold: Set an alert based on the percentage of IP addresses from this IP pool that are on hold.
pool-release: Set an alert based on the percentage of IP addresses from this IP pool that are in the release state.
pool-used: This command sets an alert based on the percentage of IP addresses that have been assigned from this IP pool.

Important: Refer to the **threshold available-ip-pool-group** and **threshold monitoring** commands in this chapter for additional information on IP pool utilization thresholding.

low_thresh: The IP pool utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured as an integer between 0 and 100.
clear *high_thresh*: The IP pool utilization percentage that maintains a previously generated alarm condition. If the utilization percentage rises above the high threshold within the polling interval, a clear alarm is generated. It may be configured as an integer between 0 and 100.

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

group-name *group_name*

Assigns one or more preconfigured IP pools to the IP pool group. *group_name* is case sensitive and must be an alphanumeric string of 1 through 31 characters. One or more IP pool groups are assigned to a context and one IP pool group consists one or more IP pool(s).
IP pool group name is used in place of an IP pool name. When specifying a desired pool group in a configuration the IP pool with the highest precedence is used first. When that IP pool's addresses are exhausted the pool with the next highest precedence is used.

include-nw-bcast

Includes the network and broadcast addresses as part of the pool.

To remove the **include-nw-bcast** option from the ip pool, use the **no ip pool test include-nw-bcast** command.

napt-users-per-ip-address *users_per_ip* **[alert-threshold { { pool-free | pool-hold | pool-release | pool-used } *low_thresh* [clear *high_thresh*] } +] [max-chunks-per-user** *max_chunks_per_user* **[nat-binding-timer** *nat_binding_timer* **] [nexthop-forwarding-address** *ip_address* **] [on-demand] [port-chunk-size** *port_chunk_size* **] [port-chunk-threshold** *port_chunk_threshold* **] [send-nat-binding-update] +**

Important: In UMTS deployments this keyword is available in 9.0 and later releases. In CDMA deployments this keyword is available in 8.3 and later releases.

Important: In UMTS deployments, on upgrading from Release 8.1 to Release 9.0, and in CDMA deployments, on upgrading from Release 8.1 to 8.3, all NAT realms configured in Release 8.1 using the **nat-realm** keyword must be reconfigured using either the **nat-one-to-one** (for one-to-one NAT realms) or the **napt-users-per-ip-address** (for many-to-one NAT realms) keywords.

Configures many-to-one NAT realms.

- *users_per_ip*: Specifies how many users can share a single NAT IP address as an integer from 2 through 2016.
- **alert-threshold**: Specifies the alert threshold for the pool:

Important: Thresholds configured using the **alert-threshold** keyword are specific to the pool that they are configured in. Thresholds configured using the **threshold ip-pool-*** commands in the Context Configuration Mode apply to all IP pools in that context, and override the threshold configurations set within individual pools.

- **pool-free**: Percentage free alert threshold for this pool
- **pool-hold**: Percentage hold alert threshold for this pool
- **pool-release**: Percentage released alert threshold for this pool
- **pool-used**: Percentage used alert threshold for this pool
- *low_thresh*: The IP pool utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm. *low_thresh* must be an integer from 0 through 100.
- **clear** *high_thresh*: The IP pool utilization percentage that maintains a previously generated alarm condition. If the utilization percentage rises above the high threshold within the polling interval, a clear alarm is generated. *high_thresh* must be an integer from 0 through 100.

Important: The *high_thresh* value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

- **max-chunks-per-user** *max_chunks_per_user*: Specifies the maximum number of port chunks to be allocated per subscriber in the many-to-one NAT pool. *max_chunks_per_user* must be an integer from 1 through 2016. Default: 1
- **nat-binding-timer** *binding_timer*: Specifies NAT Binding Timer for the NAT pool. *timer* must be an integer from 0 through 31556926. If set to 0, is disabled. Default: 0

- **nexthop-forwarding-address** *address*: Specifies the nexthop forwarding address for this pool. *address* must be an IPv4 or IPv6 address. If configured for a NAT pool, packets that are NATed using that NAT pool will be routed based on the configured nexthop address.

Important: The **nexthop-forwarding-address** support for NAT IP pools is functional only in later releases of Release 9.0 and in 10.0 and later releases.

- **on-demand**: Specifies allocating IP when matching data traffic begins.
- **port-chunk-size** *size*: Specifies NAT port chunk size (number of NAT ports per chunk) for many-to-one NAT pool. *size* must be an integer from 32 through 32256.

Important: The **port-chunk-size** configuration is only available for many-to-one NAT pools.

- **port-chunk-threshold** *chunk_threshold*: Specifies NAT port chunk threshold in percentage of number of chunks for many-to-one NAT pool. *chunk_threshold* must be an integer from 1 through 100. Default: 100%

Important: The **port-chunk-threshold** configuration is only available for many-to-one NAT pools.

- **send-nat-binding-update**: Specifies sending NAT binding updates to AAA for this realm. Default: Disabled

Important: **send-nat-binding-update** is not supported for many-to-one realms.

The following IP pool configuration keywords can also be used in the many-to-one NAT pool configuration:

- **group-name** *group_name*: Specifies the pool group name. The grouping enables to bind discontiguous IP address blocks in individual NAT IP pools to a single pool group.

  This keyword is available for NAT pool configuration only in Release 10.0 and later.

  NAT pool and NAT pool group names must be unique.

  group_name is an alphanumeric string of 1 through 31 characters that is case sensitive.

- **srp-activate**

  Activates the IP pool for Interchassis Session Recovery (ICSR).

nat *priority*

Designates the IP address pool as a Network Address Translation (NAT) address pool.
priority specifies the priority of the NAT pool. 0 is the highest priority. If *priority* is not specified, the priority is set to 0.
Must be a value from 0 (default) to 10.

Important: This functionality is currently supported for use with systems configured as an A-BG or P-CSCF.

nat-one-to-one [alert-threshold { { pool-free | pool-hold | pool-release | pool-used } *low_thresh* [clear *high_thresh*] } +] [nat-binding-timer

nat_binding_timer **] [nexthop-forwarding-address** *ip_address* **] [on-demand] [send-nat-binding-update] +**

Important: In UMTS deployments this keyword is available in Release 9.0 and later releases. In CDMA deployments this keyword is available in Release 8.3 and later releases.

Important: In UMTS deployments, on upgrading from Release 8.1 to Release 9.0, and in CDMA deployments, on upgrading from Release 8.1 to Release 8.3, all NAT realms configured in Release 8.1 using the **nat-realm** keyword must be reconfigured using either the **nat-one-to-one** (for one-to-one NAT realms) or the **napt-users-per-ip-address** (for many-to-one NAT realms) keywords.

Configures one-to-one NAT realm.

- **alert-threshold**: Specifies alert threshold for this pool:

Important: Thresholds configured using the **alert-threshold** keyword are specific to the pool in which they are configured. Thresholds configured using the **threshold ip-pool *** commands in the Context Configuration Mode apply to all IP pools in the context, and override the threshold configurations set within individual pools.

- **pool-free**: Percentage free alert threshold for this pool
- **pool-hold**: Percentage hold alert threshold for this pool
- **pool-release**: Percentage released alert threshold for this pool
- **pool-used**: Percentage used alert threshold for this pool
- *low_thresh*: The IP pool utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm. *low_thresh* must be an integer from 0 through 100.
- **clear** *high_thresh*: The IP pool utilization percentage that maintains a previously generated alarm condition. If the utilization percentage rises above the high threshold within the polling interval, a clear alarm is generated. *high_thresh* must be an integer from 0 through 100.

Important: The *high_thresh* value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

- **nat-binding-timer** *nat_binding_timer*: Specifies NAT Binding Timer for the NAT pool. *binding_timer* must be an integer from 0 through 31556926. If set to 0, is disabled.

Important: For many-to-one NAT pools, the default NAT Binding Timer value is 60 seconds. For one-to-one NAT pools, it is 0. By default, the feature is disabled—the IP addresses/ port-chunks once allocated will never be freed.

- **nexthop-forwarding-address** *ip_address*: Specifies the nexthop forwarding address for this pool. *address* must be an IPv4 or IPv6 address. If configured for a NAT pool, packets that are NATed using that NAT pool will be routed based on the configured nexthop address.

Important: The **nexthop-forwarding-address** support for NAT IP pools is functional only in later releases of Release 9.0 and in Release 10.0 and later releases.

- **on-demand**: Specifies allocating IP address when matching data traffic begins.

- **send-nat-binding-update**: Specifies sending NAT binding updates to AAA for this realm. Default: Disabled

Important: **send-nat-binding-update** is not supported for many-to-one realms.

The following IP pool configuration keywords can also be used in the one-to-one NAT pool configurations:

- **address-hold-timer** *address_hold_timer*
- **group-name** *group_name*: Specifies the pool group name. The grouping enables to bind discontiguous IP address blocks in individual NAT IP pools to a single pool group. NAT pool and NAT pool group names must be unique. *group_name* is an alphanumeric string of 1 through 31 characters that is case sensitive. This keyword is available for NAT pool configuration only in StarOS 10.0 and later releases.
- **srp-activate**: Activates the IP pool for Interchassis Session Recovery (ICSR).

---

nat-realm users-per-nat-ip-address *users* **[on-demand [address-hold-timer** *address_hold_timer* **]]**

Important: The **nat-realm** keyword is only available in Release 8.1.

Important: In Release 8.1, the NAT On-demand feature is not supported.

Important: This functionality is currently supported for use with systems configured as an A-BG or P-CSCF.

Designates the IP address pool as a Network Address Translation (NAT) realm pool.
users-per-nat-ip-address *users*: Specifies the number of users sharing a single NAT IP address as an integer from 1 through 5000.
on-demand: Specifies to allocate IP when matching data traffic begins.
address-hold-timer *address_hold_timer*: Specifies the address hold timer (in seconds) for this pool as an integer from 0 through 31556926. If set to 0, the address hold timer is disabled.

---

nexthop-forwarding-address *ip_address*

A subscriber that is assigned an IP address from this pool is forwarded to the next hop gateway with the specified IP address.

---

overlap vlanid *vlan_id*

When a nexthop forwarding address is configured, this keyword can be configured to enable over-lapping IP address pool support and associates the pool with the specified virtual LAN (VLAN). *vlan_id* is the identification number of a VLAN assigned to a physical port and can be configured to any integer from 1 through 4095.
For more information on configuring VLANs, refer to the *System Administration Guide*.

Important: This functionality is currently supported for use with systems configured as an HA, or as a PDSN for Simple IP, or as a GGSN. This keyword can only be issued for pools of type private or static and must be associated with a different nexthop forwarding address and VLAN. A maximum of 256 over-lapping pools can be configured per context and a maximum of 256 over-lapping pools can be configured per HA or simple IP PDSN. For GGSNs, the total

number of pools is limited by the number of VLANs defined but the maximum number per context is 256. Additional network considerations and configuration outside of the system may be required.

nw-reachability server *server_name*

Binds the name of a configured network reachability server to the IP pool and enables network reachability detection for the IP pool. This takes precedence over any network reachability server settings in a subscriber configuration.
server_name: Specifies the name of a network reachable server that has been defined in the current context, expressed as an alphanumeric string of 1 through 16 characters.

Important: Also see the following commands for more information: Refer to the **policy nw-reachability-fail** command in the HA Configuration Mode to configure the action that should be taken when network reachability fails. Refer to the **nw-reachability server** command in this chapter to configure network reachability servers. Refer to the **nw-reachability-server** command in the Subscriber Configuration Mode to bind a network reachability server to a specific subscriber.

respond-icmp-echo *ip_address*

Pings the first IP address from overlapping IP address pools.

Important: In order for this functionality to work, all of the pools should contain an initial IP address that can be pinged.

resource

Specifies this IP pool as a resource pool. The IP addresses in resource pools may have IP addresses that also exist in other resource pools. IP addresses from a resource pool should not be used for IP connectivity within the system where the pool is defined. These IP addresses should be allocated for sessions which are L3 tunneled through the system (IP-in-IP or GRE). It is possible for resource pools in the same context to have overlapping addresses when the terminating network elements for the L3 tunnels are in different VPNs.
Default: Disabled
Also refer to the *Subscriber Configuration Mode Commands* chapter for a description of the **l3-to-l2-tunnel address-policy** command.

send-icmp-dest-unreachable

When enabled, this generates an ICMP destination unreachable PDU when the system receives a PDU destined for an unused address within the pool. Default: Disabled

explicit-route-advertise

When enabled, the output of **show ip pool verbose** includes the total number of explicit host routes.
Default: Enabled

srp-activate

Activates the IP pool for Interchassis Session Recovery (ICSR).

suppress-switchover-arp

Suppress corresponding gratuitous ARP generation when a line card switchover occurs. Default: Disabled

unicast-gratuitous-arp-address *ip_address*

Perform a unicast gratuitous ARP to the specified IP address rather than broadcast gratuitous ARP when gratuitous ARP generation is required. Default: Perform broadcast gratuitous ARP.

vrf *vrf_name* **{ [mpls-label input** *in_label_value* **\| output** *out_label_value1* **[** *out_label_value2* **] }**

Associates a preconfigured Virtual Routing and Forwarding (VRF) context instance with this IP pool and configures the other MPLS label parameters like values of In and Out labels.

Important: This command must be used with next-hop parameters.

vrf_name is name of a preconfigured virtual routing and forwarding (VRF) context configured in Context Configuration Mode through **ip vrf** command.

- *in_label_value* is the MPLS label that identifies the inbound traffic destined for this pool.
- The *out_label_value1* and *out_label_value2* identify the MPLS labels to be added to the outgoing packets sent for subscriber from this pool. Where *out_label_value1* is the inner output label and *out_label_value2* is the outer output label.

MPLS label values must be an integer from 16 through 1048575.
By default, the pools configured are bound to the default VRF unless specified with a VRF name.

Important: You cannot have overlapping pool addresses using the same VRF. Also you cannot have two pools using different VRFs but the same in-label irrespective of whether the pools are overlapping or not. The pool must be private or static pool in-order to be associated with a certain VRF. If the VRF with such a name is not configured, then the pool configuration would return an error prompting to add the VRF before configuring a pool.

policy allow-static-allocation

Configures static address allocation policy for dynamic IP pool. This keyword enables a dynamic IP pool to accept a static address for allocation.

Important: In static allocation scenario, the pool group name is returned by AAA in the attribute **SN1-IP-Pool-Name**, and the IP address to use will be returned in the **Framed-IP-Address** attribute.

+

Indicates that more than one of the previous keywords can be entered within a single command.

Usage

Define one or more pools of IP addresses for the context to use in assigning IPs to mobile stations. This command is also useful in resizing existing IP pools to expand or contract the number of addresses allocated. If you resize an IP pool, the change is effective immediately.
When using the **ip pool** command to resize an IP pool, the type must be specified since by default the command assumes the type as public. In other words, the CLI syntax to resize an IP pool is the same syntax used to create the pool. See examples below.

```
ip pool pool1 100.1.1.0/24 static
```

The syntax to resize that pool would be:

```
ip pool pool1 100.1.1.0/25 static
```

A pool which is deleted will be marked as such. No new IP addresses will be assigned from a deleted pool. Once all assigned IP addresses from a deleted pool have been released, the pool, and all associated resources, are freed.

Important: If an IP address pool is matched to a ISAKMP crypto map and is resized, removed, or added, the corresponding security association must be cleared in order for the change to take effect. Refer to the **clear crypto** command in the Exec mode for information on clearing security associations.

Over-lapping IP Pools: The system supports the configuration of over-lapping IP address pools within a particular context. Over-lapping pools are configured using either the resource or overlap keywords.
The **resource** keyword allows over-lapping addresses tunneled to different VPN end points.
The **overlap** keyword allows over-lapping addresses each associated with a specific virtual LAN (VLAN) configured for an egress port. It uses the VLAN ID and the nexthop address to determine how to forward subscriber traffic with addresses from the pool thus resolving any conflicts with overlapping addresses.
Note that if an overlapping IP Pool is bound to an IPSec Tunnel (refer to the **match ip pool** command in the *Crypto Group Configuration Mode* chapter), that tunnel carries the traffic ignoring the nexthop configuration. Therefore, the IPSec Tunnel takes precedence over the nexthop configuration. (Thus, one can configure the overlapping IP Pool with fake VLAN ID and nexthop and still be able to bind it to an IPSec Tunnel for successful operation.
The **overlap** keyword allows over-lapping addresses each associated with a specific VLAN can only be issued for pools of type private or static and must be associated with a different nexthop forwarding address and VLAN. A maximum of 128 over-lapping pools can be configured per context and a maximum of 256 over-lapping pools can be configured per system.

Important: Overlapping IP address functionality is currently supported for use with systems configured as an HA for Mobile IP, or as a PDSN for Simple IP, or as a GGSN. For deployments in which subscriber traffic is tunneled from the FA to the HA using IP-in-IP, a separate HA service must be configured for each over-lapping pool.

IP Pool Address Assignment Method: IP addresses can be dynamically assigned from a single pool or from a group of pools. The addresses are placed into a queue in each pool. An address is assigned from the head of the queue and, when released, returned to the end. This method is known as least recently used (LRU).
When a group of pools have the same priority, an algorithm is used to determine a probability for each pool based on the number of available addresses, then a pool is chosen based on the probability. This method, over time, allocates addresses evenly from the group of pools.

Important: Note that setting different priorities on each individual pool in a group can cause addresses in some pools to be used more frequently.

Important: In NAT IP pool configurations, the minimum number of public IP addresses that must be allocated to each NAT pool must be greater than or equal to the number of Session Managers (SessMgrs) available on the system. On the ASR 5000, it is >= 84 public IP addresses. This can be met by a range of 84 host addresses from a single Class C. The remaining space from the Class C can be used for other allocations.

Example

The following commands define a private IP address pool, a public IP address pool, and a static address pool, respectively.

```
ip pool samplePool1 1.2.3.0 255.255.255.0 private

ip pool samplePool2 1.3.0.0 255.255.0.0 public

ip pool samplePool3 1.4.5.0 255.255.255.0 static
```

The following command defines a private IP pool specified with a range of IP addresses. The pool has 101 addresses.

```
ip pool samplePool4 range 10.5.5.0 10.5.5.100 private
```

The following command sets the address hold timer on the pool to *60* minutes (*3600* seconds):

```
ip pool samplePool4 address-hold-timer 3600
```

The following command removes the IP address pool from the configuration:

```
no ip pool samplePool1
```

The following command creates a static IP pool:

```
ip pool pool1 100.1.1.0/24 static
```

The following command resizes the static IP pool created in the previous example:

```
ip pool pool1 100.1.1.0/25 static
```

ip prefix-list

Creates an IP prefix list for filtering routes.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

ip prefix-list name *list_name* **[seq** *seq_number* **] { deny | permit } { any |** *network_address*/*net_mask* **[ge** *ge_value* **] [le** *le_value* **]**

no ip prefix-list *list_name* **[seq** *seq_number* **] { deny | permit } { any |** *network_address*/*net_mask* **[ge** *ge_value* **] [le** *le_value* **]**

no

Delete the specified prefix-list entry.

name *list_name*

Specifies a name for the prefix list as an alphanumeric string of 1 through 79 characters.

seq *seq_number*

Assigns the specified sequence number to the prefix list entry as an integer from 1 through 4294967295.

deny

Specifies prefixes to deny.

permit

Specifies prefixes to permit.

any

Matches any prefix.

network_address/*net_mask* **[ge** *ge_value* **] [le** *le_value* **]**

Specifies the prefix to match.
network_address/*net_mask*: the IP address and the length, in bits, of the network mask that defines the prefix. The IP address and mask must be entered in IPv4 dotted-decimal notation. When neither **ge** (greater than or equal to) or **le** (less than or equal to) are specified an exact match is assumed.
ge *ge_value*: Specifies the minimum prefix length to match as an integer from 0 through 32. If only the ge value is specified, the range is from the ge value to 32. The ge value must be greater than *net_mask* and less than the le value.
le *le_value*: Specifies the maximum prefix length to match as an integer from 0 through 32. If only the le value is specified, the range is from the *net_mask* to the le value. The le value must be less than or equal to 32.
The following equation describes the conditions that ge and le values must satisfy:
net_mask **<** *ge_value* **<** *le_value* **<= 32**

Usage

Use this command to filter routes by their IP prefix.

Example

```
ip prefix-list name prelist10 seq 5 permit 192.168.100.0/8 ge 12 le 24
```

ip prefix-list sequence-number

Enables or disables the inclusion of IP prefix list sequence numbers in the configuration file. This option is enabled by default.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ip prefix-list sequence-number
```

no

Disables the listing of IP prefix list sequence numbers in the configuration file.

ip prefix-list sequence-number

Enables the listing IP of prefix list sequence numbers in the configuration file.

Usage

Use this command to enable and disable the inclusion of IP prefix list sequence numbers in the configuration file.

Example

To disable the inclusion of IP prefix list sequence numbers in the configuration file, enter the following command:

```
no ip prefix-list sequence-number
```

ip route

Adds or removes routing information from the current context's configuration.

Product

All

Privilege

Administrator

Syntax

[no] ip route (*ip_address* | static bfd }

[no] ip route { *ip_address*/*ip_mask* | *ip_address ip_mask* } { *gateway_ip_address* | next-hop *next_hop_ip_address* | point-to-point | tunnel } *egress_intrfc_name* [cost *cost*] [precedence *precedence*][vrf *vrf_name*] +

[no] ip route static bfd *if-name gateway_ip_address*

---

no

Indicates the route specified by this options is to be removed from the configuration.

---

ip route *ip_address*/*ip_mask* | *ip_address ip_mask*

Specifies a destination IP address or group of addresses that will use this route.
ip_address/*ip_mask*: Specifies a combined IP address subnet mask bits to indicate what IP addresses to which the route applies. *ip_address* must be entered using IPv4 dotted-decimal or IPv6 colon-separated notation. *ip_mask*/ is entered using CIDR notation; the mask bits are a numeric value which is the number of bits in the subnet mask.
ip_address ip_mask: Specifies an IP address and the networking (subnet) mask pair which is used to identify the set of IP addresses to which the route applies. *ip_address* must be specified using the standard IPv4 dotted decimal notation. *ip_mask* must be specified using the standard IPv4 dotted decimal notation as network mask for subnets.
The mask as specified by *ip_mask* or resulting from *ip_address*/*ip_mask* is used to determine the network for packet routing.
0's in the resulting mask indicate the corresponding bit in the IP address is not significant in determining the network for packet routing.
1's in the resulting mask indicate the corresponding bit in the IP address is significant in determining the network.

---

gateway_ip_address **| next-hop** *next_hop_ip_address* **| point-to-point | tunnel**

Specifies which device or network to use when forwarding packets.
gateway_ip_address: Specifies the IP address of the network gateway to which to forward packets. The address must be entered in IPv4 dotted-decimal notation (###.###.###.###).
next-hop *next_hop_ip_address*: Specifies the next-hop IP address to which packets are to be forwarded. The address must be entered in IPv4 dotted-decimal notation.
point-to-point: Specifies that the egress port is an ATM point-to-point interface.
tunnel: Sets the static route for this egress interface as tunnel type, such as IPv6-over-IPv4 or GRE.

egress_intrfc_name

Specifies the name of the egress (out-bound) interface name in the current context as an alphanumeric string of 1 through 79 characters.

cost *cost*

Specifies the relative cost of the route. *cost* must be an integer from 0 through 255 where 255 is the most expensive. Default: 0

precedence *precedence*

Specifies the selection order precedence for this routing information. *precedence* must be an integer from 1 through 254 where 1 is the highest precedence. Default: 1

vrf *vrf_name*

Associates a Virtual Routing and Forwarding (VRF) context with this static route configuration. *vrf_name* is the name of a preconfigured VRF context configured in *Context Configuration Mode* via the **ip vrf** command.

ip route static bfd*if-name gateway_ip_address*

Creates a static IP route that will be associated with Bidirectional Forwarding Detection (BFD). For additional information, see the *BFD Configuration Mode Commands* chapter.
if-name: Specifies the interface Name of the Interface to which the static BFD neighbor is bound as an alphanumeric string of 1 through 79 characters.
gateway_ip_address : Specifies the gateway address of the BFD neighbor in IPv4 dotted-decimal notation.

Usage

Use this command to configure IP route parameters. Precedence and cost options tailor the route selections such that routes of the same precedence are grouped together then lowest cost is selected first. This results in route's being selected first by lower precedence then the cost is used if multiple route's are defined with the same precedence.
This command also configures static IP routes when implementing Bidirectional Forwarding Detection (BFD).

Important: A maximum of 1,200 static routes may be configured per context.

Virtual Routing and Forwarding (VRF) context can be associated with static IP route for BGP/MPLS, GRE, or IPSec tunnel support.

Example

The following command adds a route using the combined IP address and subnet mask form:

```
ip route 10.2.3.0/32 192.168.1.2 egressSample1 precedence 160
```

The following configures route options for a route specified using the distinct IP address and subnet mask form:

```
ip route 10.2.3.4 255.224.0.0 10.1.2.3 egressSample2 cost 43
```

The following deletes the two routes configured above:

```
no ip route 10.2.3.0/32 192.168.1.2 egressSample1 precedence 160

no ip route 10.2.3.4 255.224.0.0 10.1.2.3 egressSample2 cost 43
```

The following command adds a route using the combined IP address and subnet mask form and specifies the egress interface as tunnel type:

```
ip route 10.2.3.0/32 tunnel egressSample1 precedence 160 vrf vrf1
```

ip routing maximum-paths

Enables Equal Cost Multiple Path (ECMP) routing support and specifies the maximum number of ECMP paths that can be submitted by a routing protocol in the current context.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

ip routing maximum-paths [*max_num*]

[default | no] ip routing maximum-paths

default

Resets the command to its default setting of 4.

no

Disables ECMP for the current context.

ip routing maximum-paths *max_num*

The maximum number of ECMP paths that can be submitted by a routing protocol. *max_num* must be an integer from 1 through 10. Default: 4

Usage

Use this command to enable ECMP for routing and set the maximum number of ECMP paths that can be submitted by a routing protocol.

Example

To enable ECMP and set the maximum number of paths that may be submitted by a routing protocol in the current context to *10*, enter the following command:

```
ip routing maximum-paths 10
```

To disable ECMP in the current context, enter the following command:

```
no ip routing maximum-paths
```

ip routing overlap-pool

Configures the routing behavior for overlap-pool addresses.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] ip routing overlap-pool
```

default

Resets the command to its default setting of disabled.

no

Disables the routing behavior for overlap-pool addresses for the current context.

ip routing overlap-pool

Advertises overlap-pool addresses in dynamic routing protocols when overlap pools are configured using vlan-ids. Default: disabled

Usage

Use this command configuration to advertise overlap-pool addresses in dynamic routing protocols when overlap pools are configured using vlan-ids. If the “ip routing overlap-pool” is configured, then the overlap-addresses are added as interface addresses and advertised.

ip vrf

Creates a Virtual Routing and Forwarding (VRF) context instance, assigns a VTF id, and configures the VRF parameters for BGP/MPLS VPN, GRE tunnel, and IPSec interface configuration.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip vrf *vrf_name*

no ip vrf

no

Disables IP Virtual Routing and Forwarding (VRF) parameters.

ip vrf *vrf_name*

Specifies the name of the virtual routing and forwarding interface as an alphanumeric string of 1 through 79 characters.

\

Usage

Use this command to create a VRF context and assigns a VRF id for BGP/MPLS VPN, IPSec, GRE tunnel configuration in this context instance. This command used when system works as a BGP router with MPLS VPN and binds a MPLS VPN to system or to facilitate GRE or IPSec tunnelling. The addresses that assigned to this interface are visible in the VRF routing table.
This command switches the command mode to IP VRF Context Configuration Mode and changes the CLI prompt to:

```
[context_name>]host_name(config-context-vrf)#
```

If required, this command creates IP VRF Context Configuration Mode instance.
While using this command user must take note of the following:

- A VRF context instance must be created and configured before referring, associating, or binding the same with any command or mode.
- If interface binding to a VRF context instance is changed or any IP address assigned to the interface is deleted a warning will be displayed.
- All interface bound with a VRF context instance will be deleted when that VRF is removed/deleted.
- An interface can be bound to only one VRF context instance.
- A maximum of 100 VRF context instances can be configured on a system.

Refer to the *IP VRF Context Configuration Mode Commands* chapter for parameter configuration.

Example

The following command configures the virtual routing and forwarding context instance *vrf1* in a context:

```
ip vrf vrf1
```

ipms

Enables/disables/manages an intelligent packet monitoring system (IPMS) client service and enters the IPMS Client Configuration Mode within the current context.

Product

IPMS

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ipms [ -noconfirm ]
```

no

Deletes a previously configured IPMS client service.

ipms

Configures IPMS client service.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

WARNING: If this keyword option is used with **no ipms** command the IPMS client service will be deleted with all active/inactive IPMS sessions without prompting any warning or confirmation.

Usage

Use this command to enable/disable/manage the IPMS client service within a context and configure certain functionality. This command enables and allows the configuration of service enabling the system to function as an IPMS-enabled Access Gateway in a network. This command is also used to remove previously configured IPMS client service.
A maximum of 1 IPMS client can be configured per system.

Important: The IPMS is a license enabled external application support. Refer to the *IPMS Installation and Administration Guide* for more information on this product.

Refer to the *IPMS Installation and Administration Guide* and *IPMS Configuration Mode* chapter of this reference for additional information.

Example

The following command creates an IPMS client service name within the context:

```
ipms
```

ipsec

Creates a new or specifies an existing IPSec transform set and enters the IPSec Transform Set Configuration Mode for the current context.

Product

PDIF, SCM

Privilege

Security Administrator, Administrator

Syntax

[no] ipsec transform-set *name*

ipsec transform-set *name*

Specifies the name of a new or existing transform set as an alphanumeric string of 1 through 127 characters.

Usage

Use this command to create an new or enter an existing IPSec transform-set. Up to four transform-sets can be created.
Entering this command results in the following prompt:
[*context_name*]*hostname*(cfg-ctx-ipsec-tran-set)#
IPSec Transform Set Configuration Mode commands are defined in the *IPSec Transform Set Configuration Mode Commands* chapter.

Example

The following command configures an IPSec transform set called *ipsec12* and enters the IPSec Transform Set Configuration Mode:

```
ipsec transfrom-set ipsec12
```

ipsg-service

Creates an IP Services Gateway service, or specifies an existing IPSG service, in the current context and enters the IPSG RADIUS Snoop or IPSG RADIUS Server Configuration Mode.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

ipsg-service *ipsg_service_name* **[mode { radius-server | radius-snoop }] [-noconfirm]**

no ipsg-service *ipsg_service_name* **[mode { radius-server | radius-snoop }]**

no

Deletes the named IPSG service.

ipsg-service *ipsg_service_name*

Specifies the name of the IPSG service to be configured. If *ipsg_service_name* does not refer to an existing service, the new service is created if resources allow.
ipsg_service_name is an alphanumeric string of 1 through 63 characters.

mode { radius-server | radius-snoop }

Configures the IPSG to perform as either a RADIUS server or as a device to extract user information from RADIUS accounting request messages (snoop). If the optional keyword **mode** is not entered, the system defaults to **radius-server**.

- **radius-server**: Creates an IP Services Gateway RADIUS Server service in the context and enters the IPSG RADIUS Server Configuration Mode.
- **radius-snoop**: Creates an IP Services Gateway RADIUS Snoop service in the context and enters the IPSG RADIUS Snoop Configuration Mode.

-noconfirm

Executes the command without an additional prompt and confirmation from the user.

Usage

Enter the IPSG RADIUS Snoop or IPSG RADIUS Server Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of one IPSG service can be configured per context.
Entering this command results in the following prompt (RADIUS Server shown):
[*context_name-service_name*]*hostname*(config-radius-server)#
IPSG service commands are defined in the *IPSG RADIUS Snoop Configuration Mode Commands* chapter or the *IPSG RADIUS Server Configuration Mode Commands* chapters.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: A large number of services greatly increases the complexity of system management and may impact overall system performance (i.e., resulting from system handoffs). Do not configure a large number of services unless your application requires it. Contact your Cisco service representative for more information.

Important: IP Services Gateway functionality is a license-controlled feature. A valid feature license must be installed prior to configuring an IPSG service. If you have not previously purchased this feature, contact your sales representative for more information.

For more information about the IP Services Gateway, refer to the *IP Services Gateway Administration Guide*.

Example

The following command configures an IPSG RADIUS Snoop service named *ipsg1* and enters the IPSG RADIUS Snoop Configuration Mode:

```
ipsg-service ipsg1 mode radius-snoop
```

ipv6 access-group

Configures the IPv6 Access group.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

ipv6 access-group *group name* **{** *priority_value* **}**

ipv6 access-group *group_name*

Specifies the name of the access group as an alphanumeric string of 1 through 79 characters.

priority_value

Specifies the priority of the access group. 0 is the highest priority. If *priority_value* is not specified the priority is set to 0. *priority_value* must be an integer from 0 through 4294967295. Default: 0
If access groups in the list have the same priority, the last one entered is used first.

Usage

Use this command to specify IPv6 access group name and priority. Use a lower value to indicate a higher priority for the group.

Example

```
ipv6 access-group group_1
```

ipv6 access-list

Configures access list (or packet filter) name and enters the IPv6 ACL Configuration Mode.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

[no] ipv6 access-list *name*

no

Indicates the access list specified is to be removed from the configuration.

ipv6 access-list *name*

Specifies the access list for which to enter the IPv6 ACL Configuration Mode or the list to remove. *name* is an alphanumeric string of1 through 79 characters.

Usage

Executing this command enters the IPv6 ACL Configuration Mode in which rules and criteria are defined for the ACL.

Example

```
ipv6 access-list samplelist

no ipv6 access-list samplelist
```

ipv6 dns-proxy

Configures the domain name server proxy for the context.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

ipv6 dns-proxy source-ipv4-address *ip_address*

no ipv6 dns-proxy source-ipv4-address *ip_address*

no

Removes the predefined IP address for local interface in the destination context.

ipv6 dns-proxy source-ipv4-address

Enables the IPv6 proxy DNS functionality for a context. PDSN will use this address as the source address of the IPv4 packets. Default: no address is configured.

ip_address

Specifies the IPv4 address of one of the local interface in the destination context to configure the IPv6 DNS proxy where *ip_address* must be specified using IPv4 dotted-decimal notation.

Usage

The IPv6 DNS proxy source IPv4 address is used as the source IP address for the DNS proxy transaction.

Example

The following command provides an example of configuring a IPv6 DNS proxy of *192.168.23.1*:

```
ipv6 dns-proxy source-ipv4-address 192.168.23.1
```

ipv6 neighbor

Adds a static IPv6 neighbor entry into the neighbor discovery table.

Product

PDIF

Privilege

Administrator, Security Administrator

Syntax

[no] ipv6 neighbor *ipv6_address hardware_address*

no

Removes the specified address.

ipv6 neighbor *ipv6_address hardware_address*

ipv6_address is the IP address of node to be added to the table.
hardware_address is the associated 48-bit MAC address.

Usage

Add a static IPv6 neighbor entry into the neighbor discovery table.

Example

Add the ipv6 address *fe80::210:83ff:fef7:7a9d::/24* and associated 48 bit MAC address *0:10:83:f7:7a:9d* to the table.

```
ipv6 neighbor fe80::210:83ff:fef7:7a9d::/24 0:10:83:f7:7a:9d
```

ipv6 pool

Modifies the current context's IP address pools by adding, updating or deleting a pool. This command also resizes an existing IP pool.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ipv6 pool *name* **{ 6to4 local-endpoint** *ipv4_address* **[default-relay-router** *router_address* **] | alert threshold | group-name** *name* **| policy { allow-static-allocation | dup-addr-detection} | prefix** *ip_address/len* **[6to4-tunnel local-endpoint** *ip_address* **| default-relay-router** *router_address* **] | range** *start_address end_address* **| suppress-switchover-arps } [private** *priority* **] [public** *priority* **] [shared** *priority* **] [static** *priority* **] [group-name** *name* **]**

no ipv6 pool *name*

---

no

Deletes the previously configured IPv6 pool.

---

ipv6 pool *name*

Specifies the logical name of the IP address pool as an alphanumeric string of 1 through 31 characters.

6to4-tunnel local-endpoint *ip_address*

Specifies the IPv4 address of the local interface to be used for IPv6-to-IPv4 compatible pool address construction.

---

alert threshold { 6to4 local-endpoint *ipv4_address* **| alert threshold | group-available | group-name** *name* **| policy { allow-static-allocation | dup-addr-detection } | pool-free | pool-used | prefix | range** *start_address end_address* **}**

Default: All thresholds are disabled.
Configures IP address pool-level utilization thresholds. These thresholds take precedence over context-level IPv6 pool thresholds.

- **6to4**: Sets an alert based on the IPv6 Pool for an IPv6-to-IPv4 compatible address type.
- **alert-threshold**: Sets an alert based on the percentage free alert threshold for this group.
- **group-available**: Sets an alert based on the percentage free alert threshold for this group.
- **group-name**: Sets an alert based on the IPv6 Pool Group.
- **policy allow-static-allocation**: Sets an alert based on the address allocation policy.
- **pool-free**: Sets an alert based on the percentage free alert threshold for this pool.
- **pool-used**: Sets an alert based on the percentage used alert threshold for this pool.
- **prefix**: Sets an alert based on the IPv6 Pool address prefix.
- **range**: Sets an alert based on the IPv6 address pool range of addresses.

- **suppress-switchover-arps**: Sets an alert based on the Suppress Gratuitous ARPs when performing a line card switchover.

---

group name *name*

IPv6 Pool Group.
The following options are available:

- **6to4**: IPv6 Pool for IPv6-to-IPv4 compatible address type
- **alert-threshold**: Percentage free alert threshold for this group
- **group-name**: IPv6 Pool Group
- **policy**: Configure an address allocation policy
- **prefix**: IPv6 Pool address prefix
- **range**: Configures IPv6 address pool to use a range of addresses
- **suppress-switchover-arps**: Suppress gratuitous ARPs when performing a line card switchover

---

ipv4_address

Specifies the beginning IPv4 address of the IPv4 address pool. *ipv4_address* must be specified using IPv4 dotted-decimal notation.

---

default-relay-router *router address*

Specifies the default relay router for the tunnel.

---

policy allow-static-allocation

Allows a dynamic pool to accept a static address allocation.
The following options are available:

- **6to4**: IPv6 Pool for IPv6- to-IPv4 compatible address type
- **alert-threshold**: Percentage free alert threshold for this group
- **group-name**: IPv6 Pool Group
- **policy**: Configure an address allocation policy
- **prefix**: IPv6 Pool address prefix
- **range**: Configures IPv6 address pool to use a range of addresses
- **suppress-switchover-arps**: Suppress gratuitous ARPs when performing a line card switchover

---

policy dup-addr-detection

This command is valid for IPv6 shared pools only (Sample syntax: **ipv6 pool** *name* **prefix** *ip_address/len* **shared policy dup-addr-detection**). When this policy is enabled, the IPv6 shared pool allows a prefix to be shared in different call sessions with different interface IDs for an IPv6 address. This allows the tracking of interface IDs per prefix and the detection of duplicated IDs.
With this policy disabled, the IPv6 shared pool will allow a prefix to be shared across different call sessions. The interface ID is not considered for any duplicate address detection. Default: Disabled
The following options are available:

- **6to4**: IPv6 pool for IPv6-to-IPv4 compatible address type
- **alert-threshold**: Percentage free alert threshold for this group
- **group-name**: IPv6 pool group

- **policy**: Configure an address allocation policy
- **prefix**: IPv6 pool address prefix
- **range**: Configures IPv6 address pool to use a range of addresses
- **suppress-switchover-arps**: Suppress gratuitous ARPs when performing a line card switchover

---

prefix *ip_address/len*

Specifies the beginning IPv6 address of the IPv6 address pool. *ip_address/len* must be specified using IPv6 colon-separated with CIDR notation.

---

range *start_address end_address*

Configures an IPv6 address pool to use a range of addresses.
start_address specifies the beginning of the range of addresses for the IPv6 pool. It must be specified using IPv6 colon-separated notation.
end_address specifies the end of the range of addresses for the IPv6 pool. It must be specified using IPv6 colon-separated notation.

---

suppress-switchover-arps

Suppresses gratuitous ARPs when performing a line card switchover.
The following options are available:

- **6to4**: IPv6 Pool for IPv6-to-IPv4 compatible address type
- **alert-threshold**: Percentage free alert threshold for this group
- **group-name**: IPv6 Pool Group
- **policy**: Configure an address allocation policy
- **prefix**: IPv6 Pool address prefix
- **range**: Configures IPv6 address pool to use a range of addresses
- **suppress-switchover-arps**: Suppress gratuitous ARPs when performing a line card switchover

---

private *priority* **| public** *priority* **| shared** *priority* **| static** *priority*

Default: **public**
private *priority*: Specifies that the address pool may only be used by mobile stations which have requested an IP address from a specified pool. When private pools are part of an IP pool group, they are used in a priority order according to the precedence setting. *priority* must be an integer from 0 through 10 with 0 being the highest. The default is 0.
public *priority*: Specifies that the address pool is used in priority order for assigning IP addresses to mobile stations which have not requested a specific address pool. *priority* must be n integer from 0 through 10 with 0 being the highest and with a default of 0.
shared *priority*: Specifies that the address pool that may be used by more than one session at any time. *priority* must be an integer from 0 through 10 with 0 being the highest and with a default of 0.
static *priority*: Specifies that the address pool is used for statically assigned mobile stations. Statically assigned mobile stations are those with a fixed IP address at all times. *priority* must be an integer from 0 through 10 with 0 being the highest and with a default of 0.

---

group-name *name*

Groups the IPv6 pools in to different groups. The subscribers/domain can be configured with the group-name instead of the prefix-pool names. *name* is the name of the group by which the IPv6 pool is to be configured expressed as an alphanumeric string of 1 through 79 characters.

Usage

Use this command to modify the current context's IP address pools by adding, updating, or deleting a pool. Also use this command to resize an existing IP pool.

Example

The following command adds an IPv6 pool named *ip6Star*:

```
ipv6 pool ip6Star
```

ipv6 route

Configures a static IPv6 route to the next-hop router.

Product

All

Privilege

Administrator

Syntax

[no] ipv6 route *ipv6_address/prefix_length* **{ interface** *name* **| next-hop** *ipv6_address* **interface** *name* **} [cost** *cost* **] [precedence** *precedence* **]**

no

Removes the specified static route.

ipv6 route *ipv6_address/prefix_length*

Specifies a destination IPv6 address or group of addresses that will use this route. *ipv6_address/prefix_length* must be specified using IPv6 colon-separated with CIDR notation.

interface *name*

Specifies the name of the interface on this system associated with the specified route or next-hop address. *name* must be an existing interface name on the system expressed as an alphanumeric string of 1 through 79 characters.

next-hop *ipv6_address*

The IPv6 address of the directly connected next hop device in IPv6 colon-separated notation.

cost *cost*

Defines the number of hops to the next gateway as an integer from 0 through 255. Default: 0

precedence *precedence*

Indicates the administrative preference of the route. A low precedence specifies that this route takes preference over the route with a higher precedence. *precedence* must be an integer from 1 through 254. Default: 1

Usage

Use this command to create a static route and send data traffic to a next-hop device.

Example

T the following example configures a static route with IPv6 prefix/length *2001:0db8:3c4d:0015:0000:0000:abcd:ef12/24* to the next hop interface *egress1*:

```
ipv6 route 2001:0db8:3c4d:0015:0000:0000:abcd:ef12/24 interface egress1
```

isakmp disable-phase1-rekey

This command is deprecated. Use **ikev1 disable-phase1-rekey** command to configure the parameters for Phase1 SA rekeying when ISAKMP lifetime expires for IKE v1 protocol.

isakmp keepalive

This command is deprecated. Use **ikev1 keepalive dpd** command to configure ISAKMP IPSec Dead Peer Detection (DPD) message parameters for IKE v1 protocol.

isakmp policy

This command is deprecated. Use **ikev1 policy** command to create/configure an ISAKMP policy with the specified priority for IKE v1 protocol.

iups-service

Creates an Iu-PS service instance and enters the Iu-PS Service Configuration Mode. This mode defines the configuration and usage of Iu-PS interfaces between the SGSN and the RNCs in the UMTS radio access network (UTRAN). It defines both the control plane (GTP-C) and the data plane (GTP-U) between these nodes.

Important: For details about the commands and parameters for this mode, check the *IuPS Service Configuration Mode Commands* chapter.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

iups-service *srvc_name*

no iups-service *srvc_name*

no

Remove the configuration for the specified Iu-PS service from the configuration for the current context.

iups-service *srvc_name*

Specifies the IuPS service name as a unique alphanumeric string of 1 through 63 characters.

Usage

Use this command to create, edit, or remove an Iu-PS service. Add up to eight definitions to be used with a single SGSN service so the SGSN can support multiple PLMNs.

Example

The following command creates an Iu-PS service named *iu-ps1*:

```
iups-service iu-ps1
```

The following command removes the Iu-PS service named *iu-ps1*:

```
no iups-service iu-ps1
```

l2tp peer-dead-time

Configures a delay when attempting to tunnel to a specific peer which is initially unreachable due to reasons such as a network issue or temporarily having reached its capacity.

Product

All

Privilege

Security Administrator, Administrator

Syntax

l2tp peer-dead-time *seconds*

default l2tp peer-dead-time

default

Rests the command to its default setting of 60.

peer-dead-time *seconds*

Specifies the interval (in seconds) to wait before attempting to tunnel to a specific peer which is initially unreachable as an integer from 5 through 64,000. Default: 60

Usage

The time to wait before trying to establish a tunnel to a known peer after the initial attempt was unsuccessful.

Example

The following example configures the delay in attempting to tunnel to a temporarily unreachable peer. The delay is set to *120* seconds in this example.

```
l2tp peer-dead-time 120
```

lac-service

Enters the LAC Service Configuration Mode, or is used to add or remove a specified L2TP Access Concentrator (LAC) service.

Product

All

Privilege

Security Administrator, Administrator

Syntax

[no] lac-service *name*

no

Removes the specified lac-service from the current context.

lac-service *name*

Specifies the name of a LAC service to configure, add, or remove as an alphanumeric string of 1 through 63 characters that is case-sensitive.

Usage

Enter the LAC Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (i.e. resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Example

To add a new LAC service named *LAC1* and enter the LAC Service Configuration Mode, enter the following command:

```
lac-service LAC1
```

To configure an existing LAC service named *LAC2*, enter the following command:

```
lac-service LAC2
```

To delete an existing LAC service named *LAC3*, enter the following command:

```
no lac-service LAC3
```

lawful-intercept

Refer to the *Lawful Intercept Configuration Guide* for a description of this command.

lawful-intercept dictionary

Refer to the *Lawful Intercept Configuration Guide* for a description of this command.

lma-service

Creates an Local Mobility Anchor (LMA) service or specifies an existing LMA service and enters the LMA Service Configuration Mode for the current context.

Product

P-GW

Privilege

Administrator

Syntax

lma-service *service_name* **[-noconfirm]**

no lma-service *service_name*

lma-service *service_name*

Specifies the name of the LMA service. If *service_name* does not refer to an existing service, the new service is created if resources allow.
service_name is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no lma-service *service_name*

Removes the specified LMA service from the context.

Usage

Enter the LMA Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-lma-service)#
```

LMA Service Configuration Mode commands are defined in the *LMA Service Configuration Mode Commands* chapter.
Use this command when configuring the following eHRPD and PMIP SAE components: P-GW.

Example

The following command enters the existing LMA Service Configuration Mode (or creates it if it does not already exist) for the service named *lma-service1*:

```
lma-service lma-service1
```

The following command will remove *lma-service1* from the system:

```
no lma-service lma-service1
```

Ins-service

Enters the LNS Service Configuration Mode, or is used to add or remove a specified L2TP Network Server (LNS) service.

Product

All

Privilege

Security Administrator, Administrator

Syntax

[no] lns-service *name*

no

Removes the specified lac-service from the current context.

lns-service *name*

Specifies the name of a LNS service to configure, add or remove as an alphanumeric string of 1 through 63 characters that is case-sensitive.

Usage

Enter the LNS Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (i.e. resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Example

To add a new LNS service named *LNS1* and enter the LNS Service Configuration Mode, enter the following commands:

```
lns-service LNS1
```

To configure an existing LNS service named *LNS2*, enter the following command:

```
lns-service LNS2
```

To delete an existing LNS service named *LNS3*, enter the following command:

```
no lns-service LNS3
```

logging

Modifies the logging options for a specified system log server for the current context.

Product

All

Privilege

Administrator

Syntax

[no] logging syslog *ip_address* **[event-verbosity { min | concise | full }] [facility** *facilities* **] [pdu-data { none | hex | hex-ascii }] [pdu-verbosity** *pdu_level* **] [rate** *value* **]**

---

no

Indicates that internal logging is to be disabled for the options specified.

---

logging syslog *ip_address*

Specifies the IP address of a system log server on the network in IPv4 dotted-decimal or IPv6 colon-separated notation.

---

event-verbosity { min | concise | full }

Specifies the level of detail to use in logging of events. Detail level must be one of the following:

- **min**: Displays minimal detail.
- **concise**: Displays summary detail.
- **full**: Displays full detail.

---

facility *facilities*

Default: **local7**

Specifies the local facility for which the system logging server's logging options shall be applied. Local facility must be one of the following:

- **local0**
- **local1**
- **local2**
- **local3**
- **local4**
- **local5**
- **local6**
- **local7**

Multiple system log servers can share the logging options of a given local facility. This allows for the logical grouping of system log servers and the options which affect all of those associated with the same local facility.

pdu-data { none | hex | hex-ascii }

Specifies output format for packet data units when logged. Format must be one of the following:

- **none**: Displays data in raw format.
- **hex**: Displays data in hexadecimal format.
- **hex-ascii**: Displays data in hexadecimal and ASCII format (similar to a main-frame dump).

pdu-verbosity *pdu_level*

Specifies the level of verboseness to use in logging of packet data units as a value from 1 through 5, where 5 is the most detailed.

rate *value*

Specifies the rate at which log entries are allowed to be sent to the system log server. No more than the number specified by *value* will be sent to a system log server within any given one-second interval. *value* must be an integer from 0 through 100000. Default: 1000

Usage

Set the log servers to enable remote review of log data.

Example

The following sets the logging for events to the maximum for the local7 facility:

```
logging syslog 10.2.3.4 event-verbosity full
```

The following command sets the logging for packet data units to level 3 and sets the output format to the main-frame style hex-ascii for the local3 facility:

```
logging syslog 10.2.3.4 facility local3 pdu-data hex-ascii pdu-verbosity
3
```

The following sets the rate of information for the local1 facility:

```
logging syslog 10.2.3.4 facility local1 rate 100
```

The following disables internal logging to the system log server specified:

```
no logging syslog 10.2.3.4
```

mag-service

Creates a Mobile Access Gateway (MAG) service or specifies an existing MAG service and enters the MAG Service Configuration Mode for the current context.

Product

HSGW, S-GW

Privilege

Administrator

Syntax

mag-service *service_name* **[-noconfirm]**

no mag-service *service_name*

mag-service *service_name*

Specifies the name of the MAG service. If *service_name* does not refer to an existing service, the new service is created if resources allow.
service_name is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no mag-service *service_name*

Removes the specified MAG service from the context.

Usage

Enter the MAG Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your Cisco service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-mag-service)#
```

MAG Service Configuration Mode commands are defined in the *MAG Service Configuration Mode Commands* chapter.
Use this command when configuring the following eHRPD and PMIP SAE components: HSGW and S-GW.

Example

The following command enters the existing MAG Service Configuration Mode (or creates it if it does not already exist) for the service named *mag-service1*:

```
mag-service mag-service1
```

The following command will remove *mag-service1* from the system:

```
no mag-service mag-service1
```

map-service

Creates a Mobile Application Part (MAP) Service instance and enters the MAP Service Configuration mode to define or edit the MAP service parameters.

MAP is the SS7 protocol that provides the application layer required by some of the nodes in GPRS/UMTS networks to communicate with each other in order to provide services to mobile phone users. MAP is used by the serving GPRS support node (SGSN) to access SS7 network nodes such as a home location register (HLR) or a radio access network (RAN).

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

map-service *srvc_name*

no map-service *srvc_name*

no

Remove the specified MAP service from the configuration for the current context.

map-service *srvc_name*

Specifies the name of the MAP service as a unique alphanumeric string of 1 through 63 characters.

Usage

Use this command to create, edit, or remove a MAP service configuration.

Important: For details about the commands and parameters, check the *MAP Service Configuration Mode Commands* chapter.

Example

The following command creates a MAP service named *map_1*:

```
map-service map_1
```

The following command removes the configuration for a MAP service named *map_1* from the configuration for the current context:

```
no map-service map_1
```

mme-service

Creates an Mobility Management Entity (MME) service or configures an existing MME service and enters the MME Service Configuration Mode for Evolved Packet Core (EPC) networks in the current context.

Product

MME

Privilege

Administrator

Syntax

mme-service *service_name* **[-noconfirm]**

no mme-service *service_name*

no

Removes the specified MME service from the context.

mme-service *service_name*

Specifies the name of the MME service. If *service_name* does not refer to an existing service, the new service is created if resources allow.
service_name is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Enter the MME Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 8 MME service can be configured on a system which is further limited to a maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-mme-service)#
```

MME Service Configuration Mode commands are defined in the *MME Service Configuration Mode Commands* chapter.

Caution: This is a critical configuration. The MME service cannot be configured without this configuration. Any change to this configuration would lead to restarting the MME service and removing or disabling this configuration will stop the MME service.

Example

The following command enters the existing MME Service Configuration Mode (or creates it if it does not already exist) for the service named *mme-service1*:

```
mme-service mme-service1
```

The following command will remove *mme-service1* from the system:

```
no mme-service mme-service1
```

mobile-ip fa newcall

Configures settings that effect all FA services in the current context.

Product

FA

Privilege

Security Administrator, Administrator

Syntax

mobile-ip fa { multiple-dynamic-reg-per-nai | newcall duplicate-home-address { accept | reject } }

{ default | no } mobile-ip fa { multiple-dynamic-reg-per-nai | newcall duplicate-home-address }

---

default

Configures the default setting for the specified parameter.

- **multiple-dynamic-reg-per-nai**: All FA services in the current context can not simultaneously setup multiple dynamic home address registrations that have the same NAI.
- **newcall duplicate-home-address**: **reject**

---

no

- **multiple-dynamic-reg-per-nai**: Disables all FA services in the current context from simultaneously setting up multiple dynamic home address registrations that have the same NAI.
- **newcall duplicate-home-address**: Resets this option to its default of reject.

---

mobile-ip fa multiple-dynamic-reg-per-nai

This keyword allows all FA services in the current context to simultaneously setup multiple dynamic home address registrations that have the same NAI.

---

mobile-ip fa newcall duplicate-home-address { accept | reject }

- **accept**: The new call is accepted and the existing call is dropped.
- **reject**: The new call is rejected with an Admin Prohibited code.

Usage

Use this command to set the behavior of all FA services in the current context.

Example

To configure all FA services to accept new calls and drop the existing call when the new call requests an IP address that is already in use by an existing call, enter the following command:

```
mobile-ip fa newcall duplicate-home-address accept
```

To enable all FA services in the current context to allow all FA services in the current context to simultaneously setup multiple dynamic home address registrations that have the same NAI, enter the following command:

```
mobile-ip fa multiple-dynamic-reg-per-nai
```

mobile-ip ha assignment-table

Creates a Mobile IP HA assignment table and enters Mobile IP HA Assignment Table Configuration Mode.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

mobile-ip ha assignment-table *atable_name* **[-noconfirm]**

no mobile-ip ha assignment-table *atable_name*

no

This keyword deletes the specified assignment table

mobile-ip ha assignment-table *atable_name*

Specifies the name of the MIP HA assignment table to create or edit as an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to create a new MIP HA assignment table or edit an existing MIP HA assignment table.

Important: A maximum of eight MIP HA assignment tables can be configured per context with a maximum of 8 MIP HA assignment tables across all contexts.

Important: A maximum of 256 non-overlapping hoa-ranges can be configured per MIP HA Assignment table with a maximum of 256 non-overlapping hoa-ranges across all MIP HA Assignment tables.

Example

The following command creates a new MIP HA assignment table name *MIPHAtable1* and enters MIP HA Assignment Table Configuration Mode without asking for confirmation from the user:

```
mobile-ip ha assignment-table MIPHAtable1
```

mobile-ip ha newcall

Configures the behavior of all HA services when duplicate home addresses and duplicate IMSI sessions occur for new calls.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
mobile-ip ha newcall { duplicate-home-address { accept | reject } | duplicate-imsi-
session { allow | disallow | global-disallow } | wimax-session-overwrite {allow |
disallow }

{ default | no } mobile-ip ha newcall { duplicate-home-address | duplicate-imsi-session |
wimax-session-overwrite }
```

---

default

Configures the default setting for the specified parameter.

- **duplicate-home-address**: **reject**—sets HA services to reject a new call that requests an IP address that is already assigned.
- **duplicate-imsi-session**: **allow**—sets HA services to accept new calls that have the same IMSI as a call that is already active.
- **wimax-session-overwrite:disallow**—disable session overwrite feature for WiMax mobile-ip calls on the HA.

---

no

Configures the default setting for the specified parameter.

---

mobile-ip ha newcall duplicate-home-address { accept | reject }

Configures the HA to either accept or reject new calls if the new call requests a static IP home address that is already assigned to an existing call from an IP address pool in the same destination context.

- **accept**: The new call is accepted and the existing call is dropped.
- **reject**: The new call is rejected with an Admin Prohibited code.

---

mobile-ip ha newcall duplicate-imsi-session { allow | disallow | global-disallow }

Configures the HA to either permit or not permit multiple sessions for the same IMSI.

- **allow**: Allows multiple sessions for the same IMSI.
- **disallow**: If a mobile node already has an active session and a new sessions is requested using the same IMSI, the currently active session is dropped and the new session is accepted.
- **global-disallow**: Enables HA services in this context to accept a new session and disconnect any other session(s) having the same IMSI being processed in this context. In addition, a request is sent to all other contexts containing HA services to do the same.

Important: In order to ensure a single session per IMSI across all contexts containing HA services, the global-disallow option must be configured in every context.

mobile-ip ha newcall wimax-session-overwrite { allow | disallow }

Use this command to enable or disable the overwrite feature for WiMAX mobile ip (MIPv4) calls on the HA.

Usage

Use this command to set the behavior of all HA services for new calls.

Example

To configure all HA services to accept new calls when the new call requests a static IP that is already assigned from an IP pool in the same destination context, enter the following command:

```
mobile-ip ha newcall duplicate-home-address accept
```

To configure all HA services to drop an active call and accept a new one that uses the same IMSI, enter the following command:

```
mobile-ip ha newcall duplicate-imsi-session disallow
```

mobile-ip ha reconnect

Sets the behavior of all HA services to reconnect dropped calls.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] mobile-ip ha reconnect [ static-homeaddr [ dynamic-pool-allocation ] ] }
```

mobile-ip ha reconnect

Reconnects dropped HA calls.

static-homeaddr

Specifies that the home address as a static IP address.

dynamic-pool-allocation

Allows a dynamic pool to accept a static address allocation.

Usage

Use this command to reset the HA behavior for new calls.

Example

```
mobile-ip ha reconnect

mobile-ip ha reconnect static-homeaddr

mobile-ip ha reconnect static-homeaddr dynamic-pool-allocation

no mobile-ip ha reconnect

no mobile-ip ha reconnect static-homeaddr
```

mpls bgp forwarding

Globally enables Multiprotocol Label Switching (MPLS) Border Gateway Protocol (BGP) forwarding.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] mpls bgp forwarding
```

no

Disables MPLS BGP forwarding.

mpls bgp

Enables MPLS BGP forwarding.

Usage

Use this command to globally enable the MPLS BGP forwarding. By enabling this command, the BGP VPNv4 routes need not have an underlying LSP to forward the IP packets. If this command is not enabled, then the nexthop for the BGP routes must be reachable via LDP.

Caution: This command should be enabled ONLY when all the BGP peering where VPNv4 routes are exchanged are one hop away.

Example

The following command enables the MPLS BGP forwarding on the system:

```
mpls bgp forwarding
```

mpls ip

Globally enables the Multiprotocol Label Switching (MPLS) forwarding of IPv4 packets along normally routed paths.

Product

GGSN, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] mpls ip
```

no

Disables MPLS forwarding of IPv4 packets configured on the system. **no mpls ip** stops dynamic label distribution on all the interfaces irrespective of interface configuration.

mpls ip

Enables MPLS forwarding of IPv4 packets configured on the system. It starts dynamic label distribution on all the interfaces irrespective of interface configuration.

Usage

Use this command to globally enable the MPLS forwarding of IPv4 packets along normally routed paths for the whole context. It still does not start label distribution over an interface until MPLS has been enabled for the interface as well. This command changes the context to MPLS IP configuration mode for MPLS protocols specific configuration.

Caution: This feature is not enabled by default.

Example

Following command enables MPLS forwarding of IPv4 packets along normally routed paths:

```
mpls ip
```

mseg-service

This command allows you to create/configure/delete a Mobile Services Edge Gateway (MSEG) service.

Important: This command is not supported in this release. For more information please contact your Cisco account representative.

Product

MSEG

Privilege

Security Administrator, Administrator

Syntax

mseg-service *mseg_service_name* **[-noconfirm]**

no mseg-service *mseg_service_name*

no

If previously configured, deletes the specified MSEG service from the current context.

mseg_service_name

Specifies the MSEG service to add/configure/delete.
mseg_service_name must be the name of an MSEG service, and must be an alphanumeric string of 1 through 63 characters.
If the named MSEG service does not exist, it is created and the CLI mode changes to the MSEG Service Configuration Mode wherein the MSEG service can be configured.
If the named MSEG service already exists, the CLI mode changes to the MSEG Service Configuration Mode for that MSEG service.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to create/configure/delete an MSEG service.
Entering this command results in the following prompt:
`[context_name]hostname(config-mseg-service)#`
MSEG service configuration commands are described in the *MSEG Service Configuration Mode Commands* chapter.

Example

The following command creates an MSEG service named *test*, and enters the MSEG Service Configuration Mode:

```
mseg-service test
```

nw-reachability server

Adds or deletes a reachability-detect server and configures parameters for retrying the failure-detection process. When network reachability is enabled, an ICMP ping request is sent to this device. If there is no response after a specified number of retries, the network is deemed failed. Execute this command multiple times to configure multiple network reachability servers.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

nw-reachability server *server_name* **[interval** *seconds* **] [local-addr** *ip_addr* **] [num-retry** *num* **] [remote-addr** *ip_addr* **] [timeout** *seconds***]**

no nw-reachability server *server_name*

no

Delete the reference to the specified network reachability server.

nw-reachability server *server_name*

Specifies the name for the network device that is sent ping packets to test for network reachability.

interval *seconds*

Specifies the frequency in seconds for sending ping requests. as an integer from 1 through 3600. Default: 60

local-addr *ip_addr*

Specifies the IP address to be used as the source address of the ping packets; If this is unspecified, an arbitrary IP address that is configured in the context is used. *ip_addr* must be entered using IPv4 dotted-decimal notation.

num-retry *num*

Specifies the number of retries before deciding that there is a network-failure. as an integer from 0 through 100. Default: 5

remote-addr *ip_addr*

Specifies the IP address of a network element to use as the destination to send the ping packets for detecting network failure or reachability. *ip_addr* must be entered using IPv4 dotted-decimal notation.

timeout *seconds*

Specifies how long to wait (in seconds) before retransmitting a ping request to the remote address as an integer from 1 through 1. Default: 3

Usage

Use this command to set up a network device on a destination network that is used ensure that Mobile IP sessions can reach the required network from the HA.

Important: Refer to the HA Configuration Mode command **`policy nw-reachability-fail`** to configure the action that should be taken when network reachability fails.

Important: Refer to the Subscriber Config Mode command **`nw-reachability-server`** to bind the network reachability to a specific subscriber.

Important: Refer to the **`nw-reachability server server_name`** keyword of the **`ip pool`** command in this chapter to bind the network reachability server to an IP pool.

Example

To set a network device called InternetDevice with the IP address of *`192.168.100.10`* as the remote address that is pinged to determine network reachability and use the address *`192.168.200.10`* as the origination address of the ping packets sent, enter the following command:

```
nw-reachability server InternetDevice local-addr 192.168.200.10 remote-
addr 192.168.100.10
```

network-requested-pdp-context activate

Configures the mobile station(s) (MSs) for which network initiated PDP contexts are supported.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

network-requested-pdp-context activate address *ip_address* **dst-context** *context_name* **imsi** *imsi* **apn** *apn_name*

no network-requested-pdp-context activate address *ip_address* **dst-context** *context_name*

no

Disables the system's ability to accept network-requested PDP contexts on the specified interface.

network-requested-pdp-context activate address *ip_address*

Specifies the static IP address of the MS n IPv4 dotted-decimal notation.

dst-context *context_name*

Specifies the name of the destination context configured on the system containing the static IP address pool in which the MS's IP address is configured. *context_name* is an alphanumeric string of 1 through 79 characters that is case sensitive.

imsi *imsi*

Specifies the International Mobile Subscriber Identity (IMSI) of the MS as a string of 1 through 15 numeric characters

apn *apn_name*

Specifies the Access Point Name (APN) that is passed to the SGSN by the system. *apn_name* is an alphanumeric string of 1 through 63 characters that is case sensitive.

Usage

Use this command to specify the MS(s) for which network initiated PDP contexts are supported.
When a packet is received for an MS that does not currently have a PDP context established, the system checks the configuration of this parameter to determine if the destination IP address specified in the packet is specified by this parameter. If the address is not specified, then the system discards the packet. If the address is specified, the system uses the configured IMSI and APN to determine the appropriate SGSN from the Home Location Register (HLR). The system communicates with the HLR through the interworking node configured using the network-requested-pdp-context gsn-map command.
Once the session is established, the destination context specified by this command is used in place of the one either configured within the specified APN template or returned by a RADIUS server during authentication.
This command can be issued multiple times supporting network initiated PDP contexts for up to 1,000 configured addresses per system context.

Example

The following command enables support for network initiated PDP contexts for an MS with a static IP address of *20.13.5.40* from a pool configured in the destination context pdn1 with an IMSI of *3319784450* that uses an APN template called *isp1*:

```
network-requested-pdp-context activate address 20.13.5.40 dst-context
pdn1 imsi 3319784450 apn isp1
```

network-requested-pdp-context gsn-map

Configures the IP address of the interworking node that is used by the system to communicate with the Home Location Register (HLR), and optionally sets the GTP version to use.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

network-requested-pdp-context gsn-map *ip_address* **[gtp-version { 0 | 1 }]**

no network-requested-pdp-context gsn-map

no

Deletes a previously configured gsn-map node.

network-requested-pdp-context gsn-map *ip_address*

Specifies the IP address of the gsn-map node in Pv4 dotted-decimal or IPv6 colon-separated notation.

gtp-version { 0 | 1 }

Specifies the gtp version used. Default: 1

Usage

Communications from the system to the HLR must go through a GSN-map interworking node that performs the protocol conversion from GTPC to SS7.
The UDP port for this communication is 2123.
Support for network requested PDP contexts must be configured within source contexts on the system. Only one gsn-map node can be configured per source context.
The source context also contains the GGSN service configuration that specifies the IP address of the Gn interface. If multiple GGSN services are configured in the source context, one is selected at random for initiating the Network Requested PDP Context Activation procedure.
Communication with the gsn-map node is done over the Gn interface configured for the GGSN service. The IP address of that interface is used as the system's source address.

Example

The following command configures the system to communicate with a gsn-map node having an IP address of *192.168.2.5*:

```
network-requested-pdp-context gsn-map 192.168.2.5
```

network-requested-pdp-context hold-down-time

Configures the time duration to that the system will wait after the SGSN rejects an attempt for a network-requested PDP context creation for the subscriber.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

network-requested-pdp-context hold-down-time *time*

default network-requested-pdp-context hold-down-time

default

Configures the default setting.
Default: 60 seconds

network-requested-pdp-context hold-down-time *time*

Specifies the time interval (in seconds) as an integer from 0 through 86400.

Usage

Packets received during this time period would be discarded, rather than being used to cause another network-requested PDP context creation attempt for the same subscriber. After the time period has expired, any subsequent packets received would cause another network-requested PDP context creation procedure to begin.

Example

The following command configures a hold-down-time of *120* seconds:

```
network-requested-pdp-context hold-down-time 120
```

network-requested-pdp-context interval

Configures the minimum amount of time that must elapse between the deletion of a network initiated PDP context and the creation of a new one for the same MS.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

network-requested-pdp-context interval *time*

default network-requested-pdp-context interval

default

Returns the command to its default setting of 60.

network-requested-pdp-context interval *time*

Specifies the minimum amount of time (in seconds) that must pass before the system allows another network-requested PDP context for a specific MS after the previous context was deleted. *time* is an integer from 0 through 86400. Default: 60

Usage

Once an MS deletes a PDP context that initiated from the network, the system automatically waits the amount of time configured by this parameter before allowing another network initiated PDP context for the same MS.

Example

The following command specifies that the system waits *120* seconds before allowing another network requested PDP context for an MS:

```
network-requested-pdp-context interval 120
```

network-requested-pdp-context sgsn-cache-time

Configures the time duration that the GGSN keeps the SGSN/subscriber pair cached in its local memory.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

network-requested-pdp-context sgsn-cache-time *time*

default network-requested-pdp-context sgsn-cache-time

default

Configures the default setting.
Default: 300 seconds

network-requested-pdp-context sgsn-cache-time *time*

Specifies the time interval (in seconds) as an integer from 0 through 86400.

Usage

For an initial network-requested PDP context creation, the system contacts the HLR (via the GSN-MAP interworking node) to learn which SGSN is currently servicing the subscriber. The system keeps that information in cache memory for the configured time, so that future network-requested PDP context creations for that subscriber can be initiated without having to contact the HLR again.

Example

The following command configures an sgsn-cache-time of *500* seconds:

```
network-requested-pdp-context sgsn-cache-time 500
```

operator

Configures a context-level operator account within the current context.

Product

All

Privilege

Security Administrator

Syntax

operator *user_name* **[encrypted] password** *password* **[ecs] [expiry-date** *date_time* **] [li-administration**] **[noecs] [timeout-absolute** *abs_seconds* **] [timeout-min-absolute** *abs_minutes* **] [timeout-idle** *timeout_duration* **] [timeout-min-idle** *idle_minutes* **]**

no operator *user_name*

no

Removes a previously configured context-level operator account.

operator *user_name*

Specifies a name for the account as an alphanumeric string of 1 through 32 characters.

[encrypted] password *password*

Specifies the password to use for the user which is being given context-level operator privileges within the current context. The **encrypted** keyword indicates the password specified uses encryption.
password is an alphanumeric string of 1 through 63 characters without encryption, or 1 through 127 with encryption.
The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **password** keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

ecs

Permits the specific user to access ACS-specific configuration commands from Exec Mode only. Default: ACS-specific configuration commands are not allowed.

expiry-date *date_time*

Specifies the date and time that this account expires. Enter the date and time in the format YYYY:MM:DD:HH:mm or YYYY:MM:DD:HH:mm:ss.
Where YYYY is the year, MM is the month, DD is the day of the month, HH is the hour, mm is minutes, and ss is seconds.

li-administration

Refer to the *Lawful Intercept Configuration Guide* for a description of this parameter.

noecs

Prevents the user from accessing ACS-specific configuration commands. Default: Enabled

timeout-absolute *abs_seconds*

This keyword is obsolete. It has been left in place for backward compatibility. If used a warning is issued and the value entered is rounded to the nearest whole minute.
Specifies the maximum amount of time (in seconds) the context-level operator may have a session active before the session is forcibly terminated. *abs_seconds* must be a value in the range from 0 through 300000000. The value 0 disables the absolute timeout. Default: 0

timeout-min-absolute *abs_minutes*

Specifies the maximum amount of time (in minutes) the context-level operator may have a session active before the session is forcibly terminated. *abs_minutes* must be an integer from 0 through 300000000. The value 0 disables the absolute timeout. Default: 0

timeout-idle *timeout_duration*

This keyword is obsolete. It has been left in place for backward compatibility. If used a warning is issued and the value entered is rounded to the nearest whole minute.
Specifies the maximum amount of idle time (in seconds) the context-level operator may have a session active before the session is terminated. *timeout_duration* must be an integer from 0 through 300000000. The value 0 disables the idle timeout. Default: 0

timeout-min-idle *idle_minutes*

Specifies the maximum amount of idle time (in minutes) the context-level operator may have a session active before the session is terminated. *idle_minutes* must be an integer from 0 through 300000000. The value 0 disables the idle timeout. Default: 0

Usage

Use this command to create new context-level operator or modify existing operator's options, in particular, the timeout values.
Operators have read-only privileges. They can maneuver across multiple contexts, but cannot perform configuration operations. Refer to the *Command Line Interface Overview* chapter for more information.

Important: A maximum of 128 administrative users and/or subscribers may be locally configured per context.

Example

The following command creates a context-level operator account named *user1* with ACS control:

```
operator user1 password secretPassword ecs
```

The following command removes a previously configured context-level operator account named *user1*:

```
no operator user1
```

optimize pdsn inter-service-handoff

Controls the optimization of the system's handling of inter-PDSN handoffs.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] optimize pdsn inter-service-handoff
```

default

Resets the command to its default setting of enabled.

no

Disables the feature.

optimize pdsn inter-service-handoff

Enables system optimization of the handling of inter-PDSN handoffs.

Usage

When more than one PDSN service is defined in a context, each PDSN-Service acts as an independent PDSN. When a Mobile Node (MN) moves from one PDSN service to another PDSN service, by rule, it is an inter-PDSN handoff. This command optimizes PDSN handoffs between PDSN Services that are defined in the same context in the system.

The default for this parameter is enabled. The no keyword disables this functionality.

When enabled, the system treats handoffs happening between two PDSN services in the same context as an inter-PDSN handoff. Existing PPP session states and connection information is reused. If the inter-PDSN handoff requires a PPP restart, then PPP is restarted. The optimized inter-service-handoff may not restart the PPP during handoffs allowing the MN to keep the same IP address for the Simple IP session.

Example

```
optimize pdsn inter-service-handoff
```

pcc-af-service

Creates or removes an IPCF Policy and Charging Control (PCC) Application Function (AF) service or configures an existing PCC-AF service. It enters the PCC-AF Service Configuration Mode to link, configure, and manage the Application Function endpoints and associated PCC services over the Rx interface for the IPCF services.

Product

IPCF

Privilege

Administrator

Syntax

pcc-af-service *service_name* [**-noconfirm**]

no pcc-af-service *service_name*

no

Removes the specified PCC-AF service from the context.

pcc-af-service *service_name*

Specifies the name of the PCC-AF service. If *service_name* does not refer to an existing service, the new service is created if resources allow. *service_name* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to enter the PCC-AF Service Configuration Mode for an existing service or for a newly defined PCC-AF service. This command is also used to remove an existing service.
The PCC-AF-Service consolidates the provisioning and management required for the PCC-AF services being supported by the network that fall under the PCC regime. The application service handles the **Rx** interface over which the IPCF may receive media information for the application usage from AF.

Important: In the absence of an Rx interface, the media information is available in the PCC-AF Service statically.

A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-imsapp-service)#
```

The commands available in this mode are defined in the *PCC -AF Service Configuration Mode Commands* chapter.

Caution: This is a critical configuration. The PCC-AF service cannot be configured without this configuration. Any change to this configuration would lead to restarting the PCC-AF service and removing or disabling this configuration will stop the PCC-AF service.

Example

The following command enters the existing PCC-AF Service Configuration Mode (or creates it if it does not already exist) for the service named *af-service1*:

```
pcc-af-service af-service1
```

The following command will remove *af-service1* from the system:

```
no pcc-af-service af-service1
```

pcc-policy-service

Creates or removes an IPCF PCC-Policy service or configures an existing PCC-Policy service. It enters the PCC-Policy Service Configuration Mode to link, configure, and manage the Gx interface endpoints for policy authorization where IPCF acts as a policy server.

Product

IPCF

Privilege

Administrator

Syntax

pcc-policy-service *service_name* [**-noconfirm**]

no pcc-policy-service *service_name*

no

Removes the specified PCC-Policy service from the context.

pcc-policy-service *service_name*

Specifies the name of the PCC-Policy service. If *service_name* does not refer to an existing service, the new service is created if resources allow. *service_name* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to enter the PCC-Policy Service Configuration Mode for an existing service or for a newly defined PCC-Policy service. This command is also used to remove an existing service.
The PCC-Policy-Service is mainly used to provide a mechanism to manage the external Gx or similar interfaces required for policy authorization purpose. It manages Gx and Gx-like interfaces such as Gxc/Gxa between IPCF/PCRF and PCEF or BBERF, which is based on the dictionary used for PCC.
Multiple instances of PCC-Policy-Service may exist in a system which could link with the same PCC-Service that controls the business logic. This service allows for management of configuration for peers as well self related to Gx like functions.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-pccpolicy-service)#
```

The commands available in this mode are defined in the *PCC-Policy Service Configuration Mode Commands* chapter.

Caution: This is a critical configuration. The PCC-Policy service cannot be configured without this configuration. Any change to this configuration would lead to restarting the PCC-Policy service and removing or disabling this configuration will stop the PCC-Policy service.

Example

The following command enters the existing PCC-Policy Service Configuration Mode (or creates it if it does not already exist) for the service named *gx-service1*:

```
pcc-policy-service gx-service1
```

The following command will remove *gx-service1* from the system:

```
no pcc-policy-service gx-service1
```

pcc-service

Creates or removes an IPCF Policy and Charging Control (PCC) service or configures an existing PCC service. It enters the PCC Service Configuration Mode for IPCF related configurations in the current context.

Product

IPCF

Privilege

Administrator

Syntax

pcc-service *service_name* [**-noconfirm**]

no pcc-service *service_name*

no

Removes the specified PCC service from the context.

pcc-service *service_name*

Specifies the name of the PCC service. If *service_name* does not refer to an existing service, the new service is created if resources allow. *service_name* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to enter the PCC Service Configuration Mode for an existing service or for a newly defined PCC service. This command is also used to remove an existing service.
The IPCF PCC Service Configuration Mode is used to link, consolidate and manage the policy logic for the networks. The authorization of resources for a subscriber's data usage under various conditions and policies are defined in the IPCF PCC service.
Only one PCC service can be configured on a system which is further limited to a maximum of 256 services (regardless of type) configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-pcc-service)#
```

The commands available in this mode are defined in the *PCC Service Configuration Mode Commands* chapter.

Caution: This is a critical configuration. The PCC service cannot be configured without this configuration. Any change to this configuration would lead to restarting the Policy and Charging Control service and removing or disabling this configuration will stop the PCC service.

Example

The following command enters the existing PCC Service Configuration Mode (or creates it if it does not already exist) for the service named *ipcf-service1*:

```
pcc-service ipcf-service1
```

The following command will remove *ipcf-service1* from the system:

```
no pcc-service ipcf-service1
```

pcc-sp-endpoint

Creates or removes an IPCF PCC Sp interface endpoint or configures an existing PCC Sp interface client endpoint. It enters the PCC Sp Endpoint Configuration Mode to link, configure, and manage the operational parameters related to its peer.

Product

IPCF

Privilege

Administrator

Syntax

pcc-sp-endpoint *sp_intfc1* **[-noconfirm]**

no pcc-sp-endpoint *sp_intfc1*

no

Removes the specified PCC Sp interface endpoint from the context.

pcc-sp-endpoint *sp_intfc1*

Specifies the name of the PCC Sp interface endpoint. If *sp_intfc_endpoint* does not refer to an existing endpoint, the new endpoint is created if resources allow. *sp_intfc_endpoint* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to enter the PCC-Sp-Endpoint Configuration Mode for an existing interface or for a newly defined PCC **Sp** interface endpoint. This command is also used to remove an existing endpoints.
An instance of PCC Sp endpoint represent a client end for SSC/SPR interactions. It is possible to support multiple Sp endpoints each supporting the same or different protocol. The PCC Sp endpoint facilitates the configuration of the treatment required of the Sp interface as well as manage the connection and operational parameters related to its peer.
Only one PCC Sp endpoint across a chassis can be configured on a system.
Entering this command results in the following prompt:

```
[context_name]hostname(config-spendpoint)#
```

The commands available in this mode are defined in the *PCC-Sp-Endpoint Configuration Mode Commands* chapter.

Caution: This is a critical configuration. The PCC Sp endpoint cannot be configured without this configuration. Any change to this configuration would lead to reset the PCC Sp interface and removing or disabling this configuration also disables the PCC Sp interface.

Example

The following command enters the existing PCC Sp Endpoint Configuration Mode (or creates it if it does not already exist) for the endpoint named *sp_intfc1*:

```
pcc-sp-endpoint sp_intfc1
```

The following command will remove *sp_intfc1* from the system:

```
pcc-sp-endpoint sp_intfc1
```

pdg-service

Creates a new PDG service or specifies an existing PDG service and enters the PDG Service Configuration Mode. A maximum of 16 PDG services can be created. This limit applies per ASR 5000 chassis and per context.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

no pdg-service *name*

pdg-service *name*

Specifies the name of a new or existing PDG service as an alphanumeric string 1 through 63 characters that must be unique across all FNG services within the same context and across all contexts.

no pdg-service *name*

Deletes the specified PDG service.

Usage

Use this command in Context Configuration Mode to create a new PDG service or modify an existing one. Executing this command enters the PDG Service Configuration Mode.

Example

The following command configures an PDG service named *pdg_service_1* and enters the PDG Service Configuration Mode:

```
pdg-service pdg_service_1
```

pdif-service

Creates a new, or specifies an existing, Packet Data Interworking Function (PDIF) service and enters the PDIF Service Configuration Mode.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

`[ no ] pdif-service` *`name`* **`[ -noconfirm ]`**

`pdif-service` *`name`*

Specifies the name of a new or existing PDIF service as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to create a new or enter an existing PDIF service.
Entering this command results in the following prompt:
[*`context_name`*]*`hostname`*(config-pdif-service)#
PDIF Service Configuration Mode commands are defined in the *PDIF Service Configuration Mode Commands* chapter.

Example

The following command configures a PDIF service called *`pdif2`* and enters the PDIF Service Configuration Mode:

```
pdif-service pdif2
```

pdsn-service

Creates or deletes a packet data service or specifies an existing PDSN service for which to enter the Packet Data Service Configuration Mode for the current context.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] pdsn-service name
```

no

Indicates the packet data service specified is to be removed.

pdsn-service *name*

Specifies the name of the PDSN service to configure. If *name* does not refer to an existing service, the new service is created if resources allow. *name* is an alphanumeric string of 1 through 63 characters.

Usage

Enter the PDSN Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your Cisco service representative for more information.

Example

The following command will enter the PDSN Service Configuration Mode creating the service *sampleService*, if necessary.

```
pdsn-service sampleService
```

The following command will remove *sampleService* as being a defined PDSN service.

```
no pdsn-service sampleService
```

pgw-service

Creates an PDN-Gateway (P-GW) service or specifies an existing P-GW service and enters the P-GW Service Configuration Mode for the current context.

Product

P-GW

Privilege

Administrator

Syntax

pgw-service *service_name* **[-noconfirm]**

no pgw-service *service_name*

pgw-service *service_name*

Specifies the name of the P-GW service. If *service_name* does not refer to an existing service, the new service is created if resources allow. *service_name* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no pgw-service *service_name*

Removes the specified P-GW service from the context.

Usage

Enter the P-GW Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-pgw-service)#
```

P-GW Service Configuration Mode commands are defined in the *P-GW Service Configuration Mode Commands* chapter.
Use this command when configuring the following eHRPD and SAE components: P-GW.

Example

The following command enters the existing P-GW Service Configuration Mode (or creates it if it does not already exist) for the service named *pgw-service1*:

```
pgw-service pgw-service1
```

The following command will remove *pgw-service1* from the system:

```
no pgw-service pgw-service1
```

pilot-packet

Configures pilot packets containing key pieces of information about a subscriber session to third party network elements.

Product

PDSN, HA

Privilege

Administrator

Syntax

```
pilot-packet source-ip-address source_ip_address destination-ip-address
destination_ip_address destination-udp-port udp_port_valueno pilot-packet
```

no

Disables Pilot packet option.

pilot-packet source-ip-address *source_ip_address*

Specifies the IP addresses for the sourcing and terminating Pilot Packets. The IP address must entered using IPv4 dotted-decimal or IPv6 colon-separated notation.

- *source_ip_address*: Specifies the IP address of the source for sending Pilot Packets.
- *destination_ip_address*: Specifies the IP address of the destination for the Pilot Packets.

destination-udp-port *udp_port_value*

Specifies the UDP port value as an integer from 1 through 65535.

Usage

Use this command to configure Pilot-Packet parameters.

Example

The following command configures pilot packets with source and destination IPv4/IPv6 addresses along with the destination port:

```
pilot-packet source-ip-address 10.2.3.4 destination-ip-address 10.3.4.5
destination-udp-port 221
```

policy

Enters an existing accounting policy or creates a new one where accounting parameters are configured.

Product

HSGW, P-GW, S-GW

Privilege

Administrator

Syntax

[no] policy accounting *name*

no

Removes the specified accounting policy from the context.

policy accounting *name*

Specifies the name of the existing or new accounting policy as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to enter the Accounting Policy Configuration mode to edit an existing accounting policy or configure an new policy.
Entering this command results in the following prompt:

```
[context_name]hostname(config-accounting-policy)#
```

Accounting Policy Configuration Mode commands are defined in the *Accounting Policy Configuration Mode Commands* chapter.

Example

The following command enters the Accounting Policy Configuration Mode for a policy named *acct5*:

```
policy accounting acct5
```

policy-group

Creates or deletes a policy group. It enters the Policy-Group Configuration Mode within the current destination context for flow-based traffic policing to a subscriber session flow.

Product

PDSN, HA, ASN-GW, HSGW

Privilege

Security Administrator, Administrator

Syntax

[no] policy-group name *policy_group*

no

Deletes configured policy group within the context.

policy-group name *policy_group*

Specifies the name of Policy-Group as an alphanumeric string of 1 through 15 characters that is case sensitive.

Usage

Use this command to form a policy group from a set of configured Policy-Maps. A policy group supports up to 16 policies for a subscriber session flow.

Example

The following command configures a policy group *policy_group1* for a subscriber session flow:

```
policy-group name policy_group1
```

policy-map

Creates or deletes a policy map. It enters the Traffic Policy-Map Configuration Mode within the current destination context to configure the flow-based traffic policing for a subscriber session flow.

Product

PDSN, HA, ASN-GW, HSGW

Privilege

Security Administrator, Administrator

Syntax

[no] policy-map name *policy_name*

no

Deletes configured Policy-Map within the context.

policy-map name *policy_name*

Specifies the name of Policy-Map as an alphanumeric string of 1 through 15 characters that is case sensitive.

Usage

Use this command to enter Traffic Policy-Map Configuration Mode and to set the Class-Map and corresponding traffic flow treatment to traffic policy for a subscriber session flow.

Example

Following command configures a policy map *policy1* where other flow treatments is configured.

```
policy-map name policy1
```

ppp

Configures point-to-point protocol parameters for the current context.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

ppp { acfc { receive { allow | deny } | transmit { apply | ignore | reject} } | auth-retry suppress-aaa-auth | chap fixed-challenge-length *length* **| dormant send-lcp-terminate | echo-max-retransmissions** *num_retries* **| echo-retransmit-timeout** *msec* **| first-lcp-retransmit-timeout** *milliseconds* **| lcp-authentication-discard retry-alternate** *num_discard* **| lcp-authentication-reject retry-alternate | lcp-start-delay** *delay* **| lcp-terminate connect-state | lcp-terminate mip-lifetime-expiry | lcp-terminate mip-revocation | max-authentication-attempts** *num* **| max-configuration-nak** *num* **| max-retransmissions** *number* **| max-terminate** *number* **| mru** *packet_size* **| negotiate default-value-options | peer-authentication** *user_name* **[encrypted] password** *password* **] | pfc { receive { allow | deny } | transmit { apply | ignore | reject} } | reject-peer-authentication | renegotiation retain-ip-address | retransmit-timeout** *milliseconds* **}**

no ppp { auth-retry suppress-aaa-auth | chap fixed-challenge-length | dormant send-lcp-terminate | lcp-authentication-descard retry-alternate *num_discard* **| lcp-authentication-reject retry-alternate | lcp-start-delay | lcp-terminate connect-state | reject-peer-authentication | renegotiation retain-ip-address }**

default lcp-authentication-descard retry-alternate *num_discard*

---

default

Restores the system defaults for the specific command/keyword.

---

no ppp { auth-retry suppress-aaa-auth | chap fixed-challenge-length | dormant send-lcp-terminate | lcp-authentication-discard retry-alternate *num_discard* **| lcp-authentication-reject retry-alternate | lcp-start-delay | lcp-terminate connect-state | lcp-terminate mip-lifetime-expiry | lcp-terminate mip-revocation | negotiate default-value-options | reject-peer-authentication | renegotiation retain-ip-address }**

Disables, deletes, or resets the specified option.
For **no ppp renegotiation retain-ip-address** the initially allocated IP address will be released and a new IP address will be allocated during PPP renegotiation.

---

ppp acfc { receive { allow | deny } | transmit { apply | ignore | reject} }

Configures PPP Address and Control Field Compression (ACFC) parameters.
receive { allow | deny }
This keyword specifies whether to allow Address and Control Field Compressed PPP packets received from the Peer. During LCP negotiation, the local PPP side indicates whether it can handle ACFC compressed PPP packets. Default: **allow**

When allow is specified, the local PPP side indicates that it can process ACFC compressed PPP packets and compressed packets are allowed. When deny is specified, the local PPP side indicates that it cannot handle ACFC compressed packets and compressed packets are not allowed.

transmit { apply | ignore | reject }

Specifies how Address and Control Field Compression should be applied for PPP packets transmitted to the Peer. During LCP negotiation, the Peer indicates whether it can handle ACFC compressed PPP packets.

Default: **ignore**

When apply is specified, if the peer requests ACFC, the request is accepted and ACFC is applied for transmitted PPP packets. When ignore is specified, if the peer requests ACFC, the request is accepted, but ACFC is not applied for transmitted PPP packets. When reject is specified, if the peer requests ACFC, the request is rejected and ACFC is not applied to transmitted packets.

---

auth-retry suppress-aaa-auth

This option does not allow PPP authentication retries to the AAA server after the AAA server has already authenticated a session. PPP locally stores the username and password, or challenge response, after a successful PPP authentication. If the Mobile Node retries the PAP request or CHAP-Response packet to the PDSN, PPP locally compares the incoming username, password or Challenge Response with the information stored from the previous successful authentication. If it matches, PAP ACK or CHAP Success is sent back to the Mobile Node, without performing AAA authentication. If the incoming information does not match with what is stored locally, then AAA authentication is attempted. The locally stored PPP authentication information is cleared once the session reaches a connected state.

Default: **no auth-retry suppress-aaa-auth**

Important: This option is not supported in conjunction with the GGSN product.

---

chap fixed-challenge-length *length*

Normally PPP CHAP uses a random challenge length from 17 to 32 bytes. This command allows you to configure a specific fixed challenge length of from 4 through 32 bytes. *length* must be an integer from 4 through 32.

Default: Disabled. PAP CHAP uses a random challenge length.

---

dormant send-lcp-terminate

Indicates a link control protocol (LCP) terminate message is enabled for dormant sessions.

Important: This option is not supported in conjunction with the GGSN product.

---

echo-max-retransmissions *num_retries*

Configures the maximum number of retransmissions of LCP ECHO_REQ before a session is terminated in an always-on session. *num_retries* must be an integer from 1 through 16. Default: 3

---

echo-retransmit-timeout *msec*

Configures the timeout (in milliseconds) before trying LCP ECHO_REQ for an always-on session. *msec* must be an integer from 100 through 5000. Default: 3000

first-lcp-retransmit-timeout *milliseconds*

Specifies the number of milliseconds to wait before attempting to retransmit control packets. This value configures the first retry. All subsequent retries are controlled by the value configured for the ppp **retransmit-timeout** keyword.
milliseconds must be an integer from 100 through 5000. Default: 3000

lcp-authentication-discard retry-alternate *num_discard*

Sets the number of discards up to which authentication option is discarded during LCP negotiation and retries starts to allow alternate authentication option. *num_discard* must be an integer from 0 through 5. Recommended value is 2. Default: Disabled.

lcp-authentication-reject retry-alternate

Specifies the action to be taken if the authentication option is rejected during LCP negotiation and retries the allowed alternate authentication option.
Default: Disabled. No alternate authentication option will be retried.

lcp-start-delay *delay*

Specifies the delay (in milliseconds) before link control protocol (LCP) is started. *delay* must be an integer from 0 through 5000. Default: 0

lcp-terminate connect-state

Enables sending an LCP terminate message to the Mobile Node when a PPP session is disconnected if the PPP session was already in a connected state.
Note that if the no keyword is used with this option, the PDSN must still send LCP Terminate in the event of an LCP/PCP negotiation failure or PPP authentication failure, which happens during connecting state.

Important: This option is not supported in conjunction with the GGSN product.

lcp-terminate mip-lifetime-expiry

Configures the PDSN to send an LCP Terminate Request when a MIP Session is terminated due to MIP Lifetime expiry (default).
Note that if the no keyword is used with this option, the PDSN does not send a LCP Terminate Request when a MIP session is terminated due to MIP Lifetime expiry.

lcp-terminate mip-revocation

Configures the PDSN to send a LCP Terminate Request when a MIP Session is terminated due to a Revocation being received from the HA (default).
Note that if the no keyword is used with this option, the PDSN does not send a LCP Terminate Request when a MIP session is terminated due to a Revocation being received from the HA.

max-authentication-attempts *num*

Configures the maximum number of time the PPP authentication attempt is allowed. *num* must be an integer from 1 through 10. Default: 1

max-configuration-nak *num*

This command configures the maximum number of consecutive configuration REJ/NAKs that can be sent during CP negotiations, before the CP is terminated. *num* must be an integer from 1 through 20. Default: 10

max-retransmission *number*

Specifies the maximum number of times control packets will be retransmitted. *number* must be an integer from 1 through 16. Default: 5

max-terminate *number*

Sets the maximum number of PPP LCP Terminate Requests transmitted to the Mobile Node. *number* must be an integer from 0 through 16. Default: 2

Important: This option is not supported in conjunction with the GGSN product.

mru *packet_size*

Specifies the maximum packet size that can be received in bytes. *packet_size* must be an integer from 128 through 1500. Default: 1500

negotiate default-value-options

Enables the inclusion of configuration options with default values in PPP configuration requests. Default: Disabled
The PPP standard states that configuration options with default values should not be included in Configuration Request (LCP, IPCP, etc.) packets. If the option is missing in the Configuration Request, the peer PPP assumes the default value for that configuration option.
When **negotiate default-value-options** is enabled, configuration options with default values are included in the PPP configuration Requests.

peer-authenticate *user_name* **[[encrypted] password** *password* **]**

Specifies the user name and an optional password required for point-to-point protocol peer connection authentications. *user_name* is an alphanumeric string of 1 through 63 characters. The keyword **password** is optional and if specified *password* is an alphanumeric string of 1 through 63 characters. The password specified must be in an encrypted format if the optional keyword **encrypted** was specified.
The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **password** keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.

pfc { receive { allow | deny } | transmit { apply | ignore | reject} }

Configures Protocol Field Compression (PFC) parameters.
receive { allow | deny } Default: **allow**
This keyword specifies whether to allow Protocol Field Compression (PFC) for PPP packets received from the peer. During LCP negotiation, the local PPP side indicates whether it can handle Protocol Field Compressed PPP packets.
When allow is specified, the peer is allowed to request PFC during LCP negotiation. When deny is specified, the Peer is not allowed to request PFC during LCP negotiation.
transmit { apply | ignore | reject } Default: **ignore**

This keyword specifies how Protocol field Compression should be applied for PPP packets transmitted to the Peer. During LCP negotiation, the Peer indicates whether it can handle PFC compressed PPP packets. When **apply** is specified, if the peer requests PFC, it is accepted and PFC is applied for transmitted PPP packets. When **ignore** is specified, If the peer requests PFC, it is accepted but PFC is not applied for transmitted packets. When **reject** is specified, all requests for PCF from the peer are rejected.

reject-peer-authentication

If disabled, re-enables the system to reject peer requests for authentication. Default: Enabled

renegotiation retain-ip-address

If enabled, retain the currently allocated IP address for the session during PPP renegotiation (Simple IP) between FA and Mobile node. Default: Enabled
If disabled, the initially allocated IP address will be released and a new IP address will be allocated during PPP renegotiation.

retransmit-timeout *milliseconds*

Specifies the number of milliseconds to wait before attempting to retransmit control packets. *milliseconds* must be an integer from 100 through 5000. Default: 3000

Usage

Modify the context PPP options to ensure authentication and communication for PPP sessions have fewer dropped sessions.

Example

The following commands set various PPP options:

```
ppp dormant send-lcp-terminate

ppp max-retransmission 3

ppp peer-authenticate user1 password secretPwd

ppp peer-authenticate user1

ppp retransmit-timeout 1000
```

The following command disables the sending of LCP terminate messages for dormant sessions.

```
no ppp dormant send-lcp-terminate
```

ppp magic-number

Manages magic number checking during LCP Echo message handling. The magic number is a random number chosen to distinguish a peer and detect looped back lines.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] ppp magic-number receive ignore
```

no

Disables the specified behavior.

default

Restores the system defaults for the specific command/keyword.

ppp magic-number receive ignore

Ignores the checking of magic number at the PDSN during LCP Echo message handling. Default: Disabled. If a valid magic numbers were negotiated for the PPP endpoints during LCP negotiation and LCP Echo Request/Response have invalid magic numbers, enabling this command will cause the system to ignore the checking of magic number during LCP Echo message handling.

Usage

Use this command to allow the system to ignore invalid magic number during LCP Echo Request/Response handling.

Example

The following command allows the invalid magic number during LCP Echo Request/Response negotiation:

```
ppp magic-number receive ignore
```

ppp statistics

Changes the manor in which some PPP statistics are calculated.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ppp statistics success-sessions { lcp-max-retry | misc-reasons | remote-terminated
}
```

no

Disable the specified behavior.

ppp statistics success-sessions lcp-max-retry

Alters statistical calculations so that: ppp successful session = successful sessions + lcp-max-retry.

ppp statistics success-sessions misc-reasons

Alters statistical calculations so that: ppp successful session = successful sessions + misc-reasons.

ppp statistics success-sessions remote-terminated

Alters statistical calculations so that: ppp successful session = successful sessions + remote-terminated.

Usage

Use this command to alter how certain PPP statistics are calculated.

Caution: This command alters the way that some PPP statistics are calculated. Please consult your designated service representative before using this command

Example

The following command alters the statistic “ppp successful session” so that it displays the sum of successful sessions and lcp-max-retry:

```
ppp statistics success-sessions lcp-max-retry
```

The following command disables the alteration of the statistic ppp successful session:

```
no ppp statistics success-sessions lcp-max-retry
```

proxy-dns intercept-list

Enters the HA Proxy DNS Configuration Mode and defines a name of a redirect rules list for the domain name servers associated with a particular FA (Foreign Agent) or group of FAs.

Important: HA Proxy DNS Intercept is a license-enabled feature.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

`[ no ] proxy-dns intercept-list` *`name`*

`no`

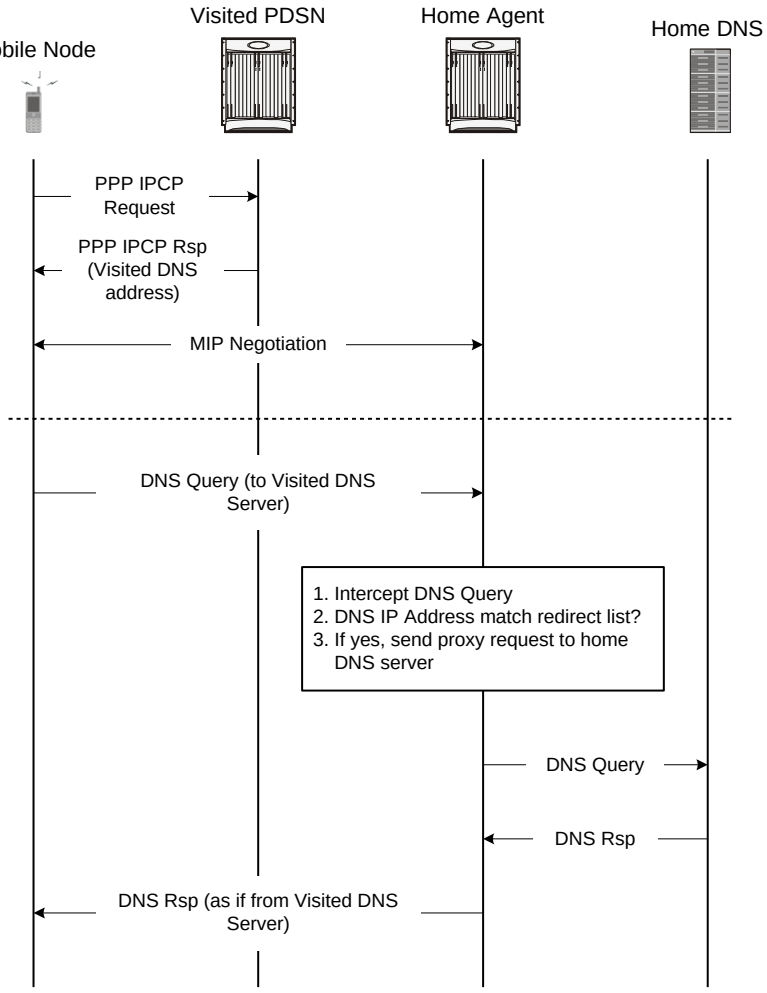
Removes the intercept list from the system.

`proxy-dns intercept-list` *`name`*

Defines the rules list and enters the Proxy DNS Configuration Mode. *`name`* must be an alphanumeric string of 1 through 63 characters.

Usage

Use this command to define a name for a list of rules pertaining to the IP addresses associated with the foreign network's DNS. Up to 128 rules of any type can be configured per rules list.
Upon entering the command, the system switches to the HA Proxy DNS Configuration Mode where the lists can be defines. Up to 64 separate rules lists can be configured in a single AAA context.
This command and the commands in the HA Proxy DNS Configuration Mode provide a solution to the Mobile IP problem that occurs when a MIP subscriber, with a legacy MN or MN that does not support IS-835D, receives a DNS server address from a foreign network that is unreachable from the home network. The following flow shows the steps that occur when this feature is enabled:



By configuring the Proxy DNS feature on the Home Agent, the foreign DNS address is intercepted and replaced with a home DNS address while the call is being handled by the home network.

Example

The following command creates a proxy DNS rules list named *list1* and places the CLI in the HA Proxy DNS Configuration Mode:

```
proxy-dns intercept-list list1
```

radius accounting

This command configures RADIUS accounting parameters for the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius accounting { archive [stop-only] | deadtime *dead_minutes* **| detect-dead-server { consecutive-failures** *consecutive_failures* **| keepalive | response-timeout** *timeout_duration* **} | interim interval** *seconds* **| max-outstanding** *max_messages* **| max-pdu-size** *octets* **| max-retries** *max_retries* **| max-transmissions** *max_transmissions* **| timeout** *timeout_duration* **| unestablished-sessions }**

no radius accounting { archive | detect-dead-server | interim interval | max-transmissions | unestablished-sessions }

default radius accounting { deadtime | detect-dead-server | interim interval *seconds* **| max-outstanding | max-pdu-size | max-retries | max-transmissions | timeout }**

---

no

Removes earlier configuration for the specified keyword.

---

default

Configures the default settings.

---

archive [stop-only]

Enables archiving of RADIUS Accounting messages in the system after the accounting message has exhausted retries to all available RADIUS Accounting servers. All RADIUS Accounting messages generated by a session are delivered to the RADIUS Accounting server in serial. That is, previous RADIUS Accounting messages from the same call must be delivered and acknowledged by the RADIUS Accounting server before the next RADIUS Accounting message is sent to the RADIUS Accounting server.
stop-only specifies archiving of STOP accounting messages only.
Default: Enabled

---

deadtime *dead_minutes*

Specifies the number of minutes to wait before attempting to communicate with a server which has been marked as unreachable.
dead_minutes must be an integer from 0 through 65535.
Default: 10

---

detect-dead-server { consecutive-failures *consecutive_failures* **| keepalive | response-timeout** *timeout_duration* **}**

- **consecutive-failures** *consecutive_failures*: Specifies the number of consecutive failures, for each AAA manager, before a server is marked as unreachable.

consecutive_failures must be an integer from 0 through 1000.

Default: 4

- **keepalive**: Enables the AAA server alive-dead detect mechanism based on sending keepalive authentication messages to all authentication servers.

  Default: Disabled

- **response-timeout** *timeout_duration*: Specifies the number of seconds for each AAA manager to wait for a response to any message before a server is detected as failed, or in a down state.

  timeout_duration must be an integer from 1 through 65535.

Important: If both **consecutive-failures** and **response-timeout** are configured, then both parameters have to be met before a server is considered unreachable, or dead.

interim interval *seconds*

Specifies the time interval (in seconds) for sending accounting INTERIM-UPDATE records. *seconds* must be an integer from 50 through 40000000.

Important: If RADIUS is used as the accounting protocol for the GGSN product, other commands are used to trigger periodic accounting updates. However, these commands would cause RADIUS STOP/START packets to be sent as opposed to INTERIM-UPDATE packets. Also note that accounting interim interval settings received from a RADIUS server take precedence over those configured on the system.

Default: Disabled

max-outstanding *max_messages*

Specifies the maximum number of outstanding messages a single AAA manager instance will queue. *max_messages* must be an integer from 1 through 4000. Default: 256

max-pdu-size *octets*

Specifies the maximum sized packet data unit which can be accepted/generated in bytes (octets). *octets* must be an integer from 512 through 4096. Default: 4096

max-retries *max_retries*

Specifies the maximum number of times communication with a AAA server will be attempted before it is marked as unreachable and the detect dead servers consecutive failures count is incremented. *max_retries* must be an integer from 0 through 65535. Default: 5
Once the maximum number of retries is reached this is considered a single failure for the consecutive failures count for detecting dead servers.

max-transmissions *max_transmissions*

Sets the maximum number of transmissions for a RADIUS accounting message before the message is declared as failed. *max_transmissions* must be an integer from 1 through 65535. Default: Disabled

timeout *seconds*

Specifies the amount of time to wait for a response from a RADIUS server before retransmitting a request. *seconds* must be an integer from 1 through 65535. Default: 3

unestablished-sessions

Indicates RADIUS STOP events are to be generated for sessions that were initiated but never fully established.

Usage

Manage the RADIUS accounting options according to the RADIUS server used for the context.

Example

The following commands configure accounting options.

```
radius accounting detect-dead-server consecutive-failures 5

radius accounting max-pdu-size 1024

radius accounting timeout 16
```

radius accounting algorithm

This command specifies the fail-over/load-balancing algorithm to select the RADIUS accounting server(s) to which accounting data must be sent.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
radius accounting algorithm { first-n n | first-server | round-robin }

default radius accounting algorithm
```

default

Configures the default setting.
Default: **first-server**

first-n *n*

Specifies that the AGW must send accounting data to *n* (more than one) AAA servers based on their priority. The full set of accounting data is sent to each of the *n* AAA servers. Response from any one of the servers would suffice to proceed with the call. On receiving an ACK from any one of the servers, all retries are stopped.
n is the number of AAA servers to which accounting data will be sent, and must be an integer from 2 through 128. Default: 1 (Disabled)

first-server

Specifies that the context must send accounting data to the RADIUS server with the highest configured priority. In the event that this server becomes unreachable, accounting data is sent to the server with the next-highest configured priority. This is the default algorithm.

round-robin

Specifies that the context must load balance sending accounting data among all of the defined RADIUS servers. Accounting data is sent in a circular queue fashion on a per Session Manager task basis, where data is sent to the next available server and restarts at the beginning of the list of configured servers. The order of the list is based upon the configured relative priority of the servers.

Usage

Use this command to specify the algorithm to select the RADIUS accounting server(s) to which accounting data must be sent.

Example

The following command specifies to use the round-robin algorithm to select the RADIUS server:

```
radius accounting algorithm round-robin
```

radius accounting apn-to-be-included

This command configures the Access Point Name (APN) to be included for RADIUS accounting.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
radius accounting apn-to-be-included { gi | gn }

default radius accounting apn-to-be-included
```

default

Configures the default setting.

gi

Specifies the usage of the Gi APN name in the RADIUS accounting request. The Gi APN represents the APN received in the Create PDP context request message from the SGSN.

gn

Specifies the usage of the Gn APN name in the RADIUS accounting request. The Gn APN represents the APN selected by the GGSN.

Usage

Use this command to configure the APN name for RADIUS Accounting. This can be set to either gi or gn.

Example

The following command specifies the usage of Gn APN name in the RADIUS accounting request:

```
radius accounting apn-to-be-included gn
```

radius accounting billing-version

This command configures the billing-system version of RADIUS accounting servers.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius accounting billing-version *version*

default radius accounting billing-version

default

Configures the default setting. Default: 0

version

Specifies the billing-system version of RADIUS accounting servers as an integer from 0 through 4294967295. Default: 0

Usage

Use this command to configure the billing-system version of RADIUS accounting servers.

Example

The following command configures the billing-system version of RADIUS accounting servers as *10*:

```
radius accounting billing-version 10
```

radius accounting gtp trigger-policy

This command configures the RADIUS accounting trigger policy for GTP messages.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
radius accounting gtp trigger-policy [ standard | ggsn-preservation-mode ]

default radius accounting gtp trigger-policy
```

default

Resets the RADIUS accounting trigger policy to standard behavior for GTP session.

standard

Sets the RADIUS accounting trigger policy to standard behavior which is configured for GTP session for GGSN service.

ggsn-preservation-mode

Sends RADIUS Accounting Start when the GTP message with private extension of preservation mode is received from SGSN.

Important: This is a customer-specific keyword and needs customer-specific license to use this feature. For more information on GGSN preservation mode, refer to *GGSN Service Configuration Mode Commands* chapter.

Usage

Use this command to set the trigger policy for the AAA accounting for a GTP session.

Example

The following command sets the RADIUS accounting trigger policy for GTP session to standard:

```
default radius accounting gtp trigger-policy
```

radius accounting ha policy

This command configures the RADIUS accounting policy for HA sessions.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

```
radius accounting ha policy { session-start-stop | custom1-aaa-res-mgmt }

default radius accounting ha policy
```

session-start-stop

Specifies to send Accounting Start when the session is connected, and send Accounting Stop when the session is disconnected. This is the default behavior.

custom1-aaa-res-mgmt

Accounting Start/Stop messages are generated to assist special resource management done by AAA servers. It is similar to the session-start-stop accounting policy, except for the following differences:

- Accounting Start is generated when a new call overwrites an existing session. Accounting Start is also generated during MIP session handoffs.
- No Accounting stop is generated when an existing session is overwritten and the new session continues to use the IP address assigned for the old session.

Usage

Use this command to set the behavior of the AAA accounting for an HA session.

Example

The following command sets the HA accounting policy to **custom1-aaa-res-mgmt**:

```
radius accounting ha policy custom1-aaa-res-mgmt
```

radius accounting interim volume

This command configures the volume of uplink and downlink volume octet counts that triggers RADIUS interim accounting.

Product

GGSN, PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

radius accounting interim volume { downlink *bytes* **uplink** *bytes* **| total** *bytes* **| uplink** *bytes* **downlink** *bytes* **}**

no radius accounting interim volume

no

Disables volume based RADIUS accounting.

downlink *bytes* **uplink** *bytes*

Specifies the downlink to uplink volume limit for RADIUS Interim accounting, in bytes. *bytes* must be an integer to 100000 through 4000000000.

total *bytes*

Specifies the total volume limit for RADIUS interim accounting in bytes. *bytes* must be an integer from 100000 through 4000000000.

uplink *bytes*

Specifies the uplink volume limit for RADIUS interim accounting in bytes. *bytes* must be an integer from 100000 through 4000000000.

downlink *bytes*

Specifies the downlink volume limit for RADIUS interim accounting in bytes. *bytes* must be an integer from 100000 through 4000000000.

Usage

Use this command to trigger RADIUS interim accounting based on the volume of uplink and downlink bytes.

Example

The following command triggers RADIUS interim accounting when the total volume of uplink and downlink bytes reaches *110000*:

```
radius accounting interim volume total 110000
```

radius accounting ip remote-address

This command configures IP remote address-based RADIUS accounting parameters.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

`[ no ] radius accounting ip remote-address { collection | list` *`list_id`* **`}`**

`no`

Removes earlier configuration for the specified keyword.

`collection`

Enables collecting and reporting Remote-Address-Based accounting in RADIUS Accounting. This should be enabled in the AAA Context. It is disabled by default.

`list` *`list_id`*

Enters the Remote Address List Configuration Mode. This mode configures a list of remote addresses that can be referenced by the subscriber's profile. *`list_id`* must be an integer from 1 through 65535.

Usage

This command is used as part of the Remote Address-based Accounting feature to both configure remote IP address lists and enable the collection of accounting data for the addresses in those lists on a per-subscriber basis.

Individual subscriber can be associated to remote IP address lists through the configuration/specification of an attribute in their local or RADIUS profile. (Refer to the **`radius accounting`** command in the Subscriber Configuration mode.) When configured/specified, accounting data is collected pertaining to the subscriber's communication with any of the remote addresses specified in the list.

Once this functionality is configured on the system and in the subscriber profiles, it must be enabled by executing this command with the collection keyword.

Example

The following command enables collecting and reporting Remote-Address-Based accounting in RADIUS Accounting:

```
radius accounting ip remote-address collection
```

radius accounting keepalive

This command configures the keepalive authentication parameters for the RADIUS accounting server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius accounting keepalive { calling-station-id *id* **| consecutive-response** *responses_no_of* **| framed-ip-address** *ip_address* **| interval** *interval_duration* **| retries** *retries_no_of* **| timeout** *timeout_duration* **| username** *user_name* **}**

no radius accounting keepalive framed-ip-address

default radius accounting keepalive { calling-station-id | consecutive-response | interval | retries | timeout | username }

no

Removes configuration for the specified keyword.

default

Configures the default settings.

calling-station-id *id*

Configures the Calling-Station ID to be used for the keepalive authentication as an alphanumeric string of size 1 to 15 characters. Default: 000000000000000

consecutive-response *responses_no_of*

Configures the number of consecutive authentication response after which the server is marked as reachable. *responses_no_of* must be an integer from 1 through 5. Default: 1

framed-ip-address *ip_address*

Specifies the framed ip-address to be used for the keepalive accounting in IPv4 dotted-decimal notation.

interval *interval_duration*

Configures the time interval (in seconds) between the two keepalive access requests. Default: 30

retries *retries_no_of*

Configures the number of times the keepalive access request to be sent before marking the server as unreachable. *retries_no_of* must be an integer from 3 through 10. Default: 3

timeout *timeout_duration*

Configures the time interval between each keepalive access request retries. *timeout_duration* must be an integer from 1 through 30. Default: 3

username *user_name*

Configures the user name to be used for the authentication as an alphanumeric string of 1 through 127 characters. Default: Test-Username

Usage

Configures the keepalive authentication parameters for the RADIUS accounting server.

Example

The following command sets the user name for the RADIUS keepalive access requests to *Test-Username2*:

```
radius accounting keepalive username Test-Username2
```

The following command sets the number of retries to *4*:

```
radius accounting keepalive retries 4
```

radius accounting rp

This command configures the current context's RADIUS accounting R-P originated call options.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
radius accounting rp { handoff-stop { immediate | wait-active-stop } | tod minute hour |
trigger-event { active-handoff | active-start-param-change | active-stop } | trigger-
policy { airlink-usage [ counter-rollover ] | custom [ active-handoff | active-start-
param-change | active-stop ] | standard } | trigger-stop-start }

no radius accounting rp { tod minute hour | trigger-event { active-handoff | active-
start-param-change | active-stop } | trigger-stop-start }

default radius accounting rp { handoff-stop | trigger-policy }
```

no

Removes earlier configuration for the specified keyword.

default

Configures this command with the default settings.

handoff-stop { immediate | wait-active-stop }

Specifies the behavior of generating accounting STOP when handoff occurs.

- **immediate**: Indicates that accounting STOP should be generated immediately on handoff, i.e. not to wait active-stop from the old PCF.
- **wait-active-stop**: Indicates that accounting STOP is generated only when active-stop received from the old PCF when handoff occurs.

Default: **wait-active-stop**

tod *minute hour*

Specifies the time of day a RADIUS event is to be generated for accounting. Up to four different times of the day may be specified through separate commands.
minute must be an integer from 0 through 59.
hour must be an integer from 0 through 23.

trigger-event { active-handoff | active-start-param-change | active-stop }

Configures the events for which a RADIUS event is generated for accounting as one of the following:

- **active-handoff**: Disables a single R-P event (and therefore a RADIUS accounting event) when an Active PCF-to-PFC Handoff occurs. Instead, two R-P events occur (one for the Connection Setup, and the second for the Active-Start). Default: Disabled

- **active-start-param-change**: Disables an R-P event (and therefore a RADIUS accounting event) when an Active-Start is received from the PCF and there has been a parameter change. Default: Enabled
- **active-stop**: Disables an R-P event (and therefore a RADIUS accounting event) when an Active-Stop is received from the PCF. Default: Disabled

Important: This keyword has been obsoleted by the **trigger-policy** keyword. Note that if this command is used, if the context configuration is displayed, RADIUS accounting RP configuration is represented in terms of the trigger-policy.

trigger-policy { airlink-usage [counter-rollover] | custom [active-handoff | active-start-param-change | active-stop] | standard }

Default:**airlink-usage**: Disabled
custom:

- **active-handoff**: Disabled
- **active-start-param-change**: Disabled
- **active-stop**: Disabled
- **standard**: Enabled

Configures the overall accounting policy for R-P sessions as one of the following:

- **airlink-usage [counter-rollover]**: Designates the use of Airlink-Usage RADIUS accounting policy for R-P, which generates a start on Active-Starts, and a stop on Active-Stops.

If the **counter-rollover** option is enabled, the system generates a STOP/START pair before input/output data octet counts (or input/output data packet counts) become larger than (2^32 - 1) in value. This setting is used to guarantee that a 32-bit octet count in any STOP message has not wrapped to larger than 2^32 thus ensuring the accuracy of the count. The system, may send the STOP/START pair at any time, so long as it does so before the 32-bit counter has wrapped. Note that a STOP/START pair is never generated unless the subscriber RP session is in the Active state, since octet/packet counts are not accumulated in the Dormant state.

- **custom**: Specifies the use of custom RADIUS accounting policy for R-P. The custom policy can consist of the following:
- **active-handoff**: Enables a single R-P event (and therefore a RADIUS accounting event) when an Active PCF-to-PFC Handoff occurs. Normally two R-P events will occur (one for the Connection Setup, and the second for the Active-Start).
- **active-start-param-change**: Enables an R-P event (and therefore a RADIUS accounting event) when an Active-Start is received from the PCF and there has been a parameter change.

Important: Note that a custom trigger policy with only **active-start-param-change** enabled is identical to the **standard** trigger-policy.

- **active-stop**: Enables an R-P event (and therefore a RADIUS accounting event) when an Active-Stop is received from the PCF.

Important: If the **radius accounting rp trigger-policy custom** command is executed without any of the optional keywords, all custom options are disabled.

- **standard**: Specifies the use of Standard RADIUS accounting policy for R-P in accordance with IS-835B.

trigger-stop-start

Specifies that a stop/start RADIUS accounting pair should be sent to the RADIUS server when an applicable R-P event occurs.

Usage

Use this command to configure the events for which a RADIUS event is sent to the server when the accounting procedures vary between servers.

Example

The following command enables an R-P event (and therefore a RADIUS accounting event) when an Active-Stop is received from the PCF:

```
radius accounting rp trigger-event active-stop
```

The following command generates the STOP only when active-stop received from the old PCF when handoff occurs:

```
default radius accounting rp handoff-stop
```

radius accounting server

This command configures RADIUS accounting server(s) in the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
radius [ mediation-device ] accounting server ip_address [ encrypted ] key value [ acct-
on { enable | disable } ] [ acct-off { enable | disable } ] [ max max_messages ] [
oldports ] [ port port_number ] [ priority priority ] [ type { mediation-device |
standard } ] [ admin-status { enable | disable } ] [ -noconfirm ]

no radius [ mediation-device ] accounting server ip_address [ oldports | port port_number
]
```

no

Removes the server or server port(s) specified from the list of configured servers.

mediation-device

Enables mediation-device specific AAA transactions use to communicate with this RADIUS server.

Important: If this option is not used, the system by default enables standard AAA transactions.

ip_address

Specifies the IP address of the accounting server.
ip_address must be specified in IPv4 dotted-decimal or IPv6 colon-separated notation. A maximum of 128 RADIUS servers can be configured per context. This limit includes accounting and authentication servers.

[encrypted] key *value*

Specifies the shared secret key used to authenticate the client to the servers. The **encrypted** keyword indicates the key specified is encrypted.
In 12.1 and earlier releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 256 characters with encryption.
In 12.2 and later releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 236 characters with encryption enabled.
The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **key** keyword is the encrypted version of the plaint text key. Only the encrypted key is saved as part of the configuration file.

acct-on { enable | disable }

Enables and disables sending of the Accounting-On message when a new RADIUS server is added to the configuration.

When enabled, the Accounting-On message is sent when a new RADIUS server is added in the configuration. However, if for some reason the Accounting-On message cannot be sent at the time of server configuration (for example, if the interface is down), then the message is sent as soon as possible. Once the Accounting-On message is sent, if it is not responded to after the configured RADIUS accounting timeout, the message is retried the configured number of RADIUS accounting retries. Once all retries have been exhausted, the system no longer attempts to send the Accounting-On message for this server.
Default: **disable**

---

acct-off { enable | disable }

Default: **enable**
Disables and enables the sending of the Accounting-Off message when a RADIUS server is removed from the configuration.
The Accounting-Off message is sent when a RADIUS server is removed from the configuration, or when there is an orderly shutdown. However, if for some reason the Accounting-On message cannot be sent at this time, it is never sent. The Accounting-Off message is sent only once, regardless of how many accounting retries are enabled.

---

max *max_messages*

Specifies the maximum number of outstanding messages that may be allowed to the server. *max_messages* must be an integer from 1 through 256. Default: 0

---

oldports

Sets the UDP communication port to the out of date standardized default for RADIUS communications to 1646.

---

port *port_number*

Specifies the port number to use for communications as an integer from 1 through 65535. Default: 1813

---

priority *priority*

Specifies the relative priority of this accounting server. The priority is used in server selection for determining which server to send accounting data to.
priority must be an integer from 1 through 1000, where 1 is the highest priority. When configuring two or more servers with the same priority you will be asked to confirm that you want to do this. If you use the **-noconfirm** option, you are not asked for confirmation and multiple servers could be assigned the same priority.
Default: 1000

---

type { mediation-device | standard }

Specifies the type of AAA transactions to use to communicate with this RADIUS server.

- **standard**: Use standard AAA transactions.
- **mediation-device**: This keyword is obsolete.

Default: **standard**

---

admin-status { enable | disable }

Enables or disables the RADIUS authentication/accounting/ charging server functionality, and saves the status setting in the configuration file to re-establish the set status at reboot.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

This command is used to configure the RADIUS accounting servers with which the system is to communicate for accounting.
Up to 128 RADIUS servers can be configured per context. The servers can be configured as Accounting, Authentication, charging servers, or any combination thereof.

Example

The following commands configure the RADIUS accounting server with the IP address set to 10.2.3.4, port to 1024, and priority to 10:

```
radius accounting server 10.2.3.4 key sharedKey port 1024 max 127

radius accounting server 10.2.3.4 encrypted key scrambledKey oldports
priority 10

no radius accounting server 10.2.5.6
```

The following command sets the accounting server with mediation device transaction for AAA server *10.2.3.4*:

```
radius mediation-device accounting server 10.2.3.4 key sharedKey port
1024 max 127
```

radius algorithm

This command configures the RADIUS authentication server selection algorithm for the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
radius algorithm { first-server | round-robin }

default radius algorithm
```

default

Configures this command with the default setting. Default: **first-server**

first-server

Sends authentication data to the first available server based upon the relative priority of each configured server.

round-robin

Sends authentication data in a circular queue fashion on a per Session Manager task basis where data is sent to the next available server and restarts at the beginning of the list of configured servers. The order of the list is based upon the configure relative priority of the servers.

Usage

Use this command to configure the context's RADIUS server selection algorithm to ensure proper load distribution through the available servers.

Example

The following command configures to use the round-robin algorithm for RADIUS server selection:

```
radius algorithm round-robin
```

radius allow

This command configures the system behavior to allow subscriber sessions when RADIUS accounting and/or authentication is unavailable.

Product

All products used in CDMA deployments

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] radius allow { accounting-down | authentication-down }
```

no

Removes earlier configuration for the specified keyword.

accounting-down

Allows sessions while accounting is unavailable (down). Default: Enabled

authentication-down

Allows sessions while authentication is not available (down). Default: Disabled

Usage

Allow sessions during system troubles when the risk of IP address and/or subscriber spoofing is minimal. The denial of sessions may cause dissatisfaction with subscribers at the cost/expense of verification and/or accounting data.

Important: Please note that this command is applicable ONLY to CDMA products. To configure this functionality in UMTS/LTE products (GGSN/P-GW), use the command **mediation-device delay-GTP-response** in APN Configuration mode.

Example

The following command configures the RADIUS server to allow the sessions while accounting is unavailable:

```
radius allow accounting-down
```

radius attribute

This command configures the system's RADIUS identification parameters.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius attribute { nas-identifier id | nas-ip-address address *primary_address* **[backup** *secondary_address* **] [nexthop-forwarding-address** *nexthop_ip_address* **] [vlan** *vlan_id* **] [mpls-label input** *in_label_value* **output** *out_label_value1 out_label_value1* **] }**

no radius attribute { nas-identifier | nas-ip-address }

default radius attribute nas-identifier

---

no

Removes earlier configuration for the specified keyword.

---

default

Configures the default setting.

---

nas-identifier *id*

Specifies the attribute name by which the system will be identified in Access-Request messages. *id* must be a alphanumeric string of 1 through 32 characters that is case sensitive.

---

nas-ip-address address *primary_address*

Specifies the AAA interface IP address(es) to used to identify the system. Up to two addresses can be configured. *primary_address* is the IP address of the primary interface to use in the current context in IPV4 dotted-decimal or IPv6 colon-separated notation.

---

backup *secondary_address*

Specifies the IP address of the secondary interface to use in the current context in IPV4 dotted-decimal or IPv6 colon-separated notation.

---

mpls-label input *in_label_value* **| output** *out_label_value1* **[** *out_label_value2* **]**

This command configures the traffic from the specified AAA client NAS IP address to use the specified MPLS labels.

- *in_label_value* is the MPLS label that identifies inbound traffic destined for the configured NAS IP address.
- *out_label_value1* and *out_label_value2* identify the MPLS labels to be added to the packets sent from the specified NAS IP address.
  - *out_label_value1* is the inner output label.
  - *out_label_value2* is the outer output label.

MPLS label values must be an integer from 16 through 1048575.

Important: This option is available only when nexthop-forwarding gateway is also configured with the **nexthop-forwarding-address** keyword.

nexthop-forwarding-address *nexthop_ip_address*

Configures the next hop IP address for this NAS IP address in IPV4 dotted-decimal or IPv6 colon-separated notation.

vlan *vlan_id*

Specifies the VLAN ID to be associated with the next-hop IP address as an integer from 1 through 4094.

Usage

This is necessary for NetWare Access Server usage such as the system must be identified to the NAS.
The system supports the concept of the active nas-ip-address. The active nas-ip-address is defined as the current source ip address for RADIUS messages being used by the system. This is the content of the nas-ip-address attribute in each RADIUS message.
The system will always have exactly one active nas-ip-address. The active nas-ip-address will start as the primary nas-ip-address. However, the active nas-ip-address may switch from the primary to the backup, or the backup to the primary. The following events will occur when the active nas-ip-address is switched:

- All current in-process RADIUS accounting messages from the entire system are cancelled. The accounting message is re-sent, with retries preserved, using the ne w active nas-ip-address. Acct-Delay-Time, however, is updated to reflect the time that has occurred since the accounting event. The value of Event-Timestamp is preserved.
- All current in-process RADIUS authentication messages from the entire system are cancelled. The authentication message is re-sent, with retries preserved, using the new active nas-ip-address. The value of Event-Timestamp is preserved.
- All subsequent in-process RADIUS requests uses the new active nas-ip-address.

The system uses a revertive algorithm when transitioning active NAS IP addresses as described below:

- If the configured primary nas-ip-address transitions from UP to DOWN, and the backup nas-ip-address is UP, then the active nas-ip-address switches from the primary to the backup nas-ip-address
- If the backup nas-ip-address is active, and the primary nas-ip-address transitions from DOWN to UP, then the active nas-ip-address switches from the backup to the primary nas-ip-address

Example

The following command configures the RADIUS attribute nas-ip-address as *10.2.3.4*:

```
radius attribute nas-ip-address 10.2.3.4
```

radius authenticate null-username

This command enables (allows) or disables (prevents) the authentication of user names that are blank or empty. This is enabled by default.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] radius authenticate null-username
```

default

Configures the default setting.
Default: Authenticate, send Access-Request messages to the AAA server, all user names, including NULL user names.

no

Disables sending an Access-Request message to the AAA server for user names (NAI) that are blank.

null-username

Enables sending an Access-Request message to the AAA server for user names (NAI) that are blank.

Usage

Use this command to disable, or re-enable, sending Access-Request messages to the AAA server for user names (NAI) that are blank (NULL).

Example

The following command disables sending of Access-Request messages for user names (NAI) that are blank:

```
no radius authenticate null-username
```

The following command re-enables sending of Access-Request messages for user names (NAI) that are blank:

```
radius authenticate null-username
```

radius authenticate apn-to-be-included

This command configures the Access Point Name (APN) to be included for RADIUS authentication.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] radius authenticate apn-to-be-included { gi | gn }
```

default

Configures the default setting.

gi

Specifies the use of the Gi APN name in the RADIUS authentication request. The Gi APN represents the APN received in the Create PDP Context Request message from the SGSN.

gn

Specifies the use of the Gn APN name in the RADIUS authentication request. The Gn APN represents the APN selected by the GGSN.

Usage

Use this command to configure the APN name for RADIUS authentication. This can be set to either gi or gn.

Example

The following command specifies the usage of Gn APN name in the RADIUS authentication request.

```
radius authenticate apn-to-be-included gn
```

radius authenticator-validation

This command enables (allows) or disables (prevents) the MD5 authentication of RADIUS users. By default this feature is enabled.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] radius authenticator-validation
```

no

Disables MD5 authentication validation for an Access-Request message to the AAA server.

default

Enables MD5 authentication validation for an Access-Request message to the AAA server.

Usage

Use this command to disable, or re-enable, sending Access-Request messages to the AAA server for MD5 validation.

Example

The following command disables MD5 authentication validation for Access-Request messages for user names (NAI):

```
no radius authenticator-validation
```

The following command enables MD5 authentication validation for Access-Request messages for user names (NAI):

```
radius radius authenticator-validation
```

radius change-authorize-nas-ip

This command configures the NAS IP address and UDP port on which the current context will listen for Change of Authorization (COA) messages and Disconnect Messages (DM). If the NAS IP address is not defined with this command, any COA or DM messages from the RADIUS server are returned with a Destination Unreachable error.

Product

PDSN, FA, HA, GGSN, LNS

Privilege

Security Administrator, Administrator

Syntax

radius change-authorize-nas-ip *ip_address* **[encrypted] key** *value* **[port** *port* **] [event-timestamp-window** *window* **] [no-nas-identification-check] [no-reverse-path-forward-check] [mpls-label input** *in_label_value* **| output** *out_label_value1* **[** *out_label_value2* **]**

no radius change-authorize-nas-ip

no

Deletes the NAS IP address information which disables the system from receiving and responding to COA and DM messages from the RADIUS server.

ip_address

Specifies the NAS IP address of the current context's AAA interface that was defined with the **radius attribute** command.
ip_address can be expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

[encrypted] key *value*

Specifies the shared secret key used to authenticate the client to the servers. The **encrypted** keyword indicates the key specified is encrypted.
In 12.1 and earlier releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 256 characters with encryption.
In 12.2 and later releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 236 characters with encryption enabled.
The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **key** keyword is the encrypted version of the plain text key. Only the encrypted key is saved as part of the configuration file.

port *port*

The UDP port on which to listen for CoA and DM messages. Default: 3799

event-timestamp-window *window*

When a COA or DM request is received with an event-time-stamp, if the current-time is greater than the received-pkt-event-time-stamp plus the event-time-stamp-window, the packet is silently discarded
When a COA or DM request is received without the event-timestamp attribute, the packet is silently discarded.

window must be an integer from 0 through 4294967295. If *window* is specified as 0 (zero), this feature is disabled; the event-time-stamp attribute in COA or DM messages is ignored and the event-time-stamp attribute is not included in NAK or ACK messages. Default: 300

no-nas-identification-check

Disables the context from checking the NAS Identifier/ NAS IP Address while receiving the CoA/DM requests. By default this check is enabled.

no-reverse-path-forward-check

Disables the context from checking whether received CoA or DM packets are from one of the AAA servers configured in the current context. Only the src-ip address in the received CoA or DM request is validated and the port and key are ignored. The reverse-path-forward-check is enabled by default.
When reverse-path-forward-check is disabled, CoA and DM messages are accepted from any AAA server.

mpls-label input *in_label_value* **| output** *out_label_value1* **[** *out_label_value2* **]**

This command configures COA traffic to use the specified MPLS labels.

- *in_label_value* is the MPLS label that identifies inbound COA traffic.
- *out_label_value1* and *out_label_value2* identify the MPLS labels to be added to COA response.
  - *out_label_value1* is the inner output label.
  - *out_label_value2* is the outer output label.

MPLS label values must be an integer from 16 through 1048575.

Usage

Use this command to enable the current context to listen for COA and DM messages.
Any one of the following RADIUS attributes may be used to identify the subscriber:

- **3GPP-IMSI**: The subscriber's IMSI. It may include the 3GPP-NSAPI attribute to delete a single PDP context rather than all of the PDP contexts of the subscriber when used with the GGSN product.
- **Framed-IP-address**: The subscriber's IP address.
- **Acct-Session-Id**: Identifies a subscriber session or PDP context.

Important: For the GGSN product, the value for Acct-Session-Id that is mandated by 3GPP is used instead of the special value for Acct-Session-Id that we use in the RADIUS messages we exchange with a RADIUS accounting server.

Important: When this command is used in conjunction with the GGSN, CoA functionality is not supported.

Example

The following command specifies the IP address *192.168.100.10* as the NAS IP address, a key value of *123456* and uses the default port of *3799*:

```
radius change-authorize-nas-ip 192.168.100.10 key 123456
```

The following command disables the nas-identification-check for the above parameters:

```
radius change-authorize-nas-ip 192.168.100.10 key 123456 no-nas-
identification-check
```

radius charging

This command configures basic RADIUS options for Active Charging Services.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius charging { deadtime *dead_minutes* **| detect-dead-server { consecutive-failures** *consecutive_failures* **| response-timeout** *timeout_duration* **} | max-outstanding** *max_messages* **| max-retries** *max_retries* **| max-transmissions** *transmissions* **| timeout** *timeout_duration* **}**

default radius charging { deadtime | detect-dead-server | max-outstanding | max-retries | max-transmissions | timeout }

no radius charging { detect-dead-server | max-transmissions | timeout }

no

Removes configuration for the specified keyword.

default

Configures the default settings.

deadtime *dead_minutes*

Specifies the number of minutes to wait before attempting to communicate with a server which has been marked as unreachable.
dead_minutes must be an integer from 0 through 65535.
Default: 10

detect-dead-server { consecutive-failures *consecutive_failures* **| response-timeout** *timeout_duration* **}**

consecutive-failures *consecutive_failures*: Default: 4. Specifies the number of consecutive failures, for each AAA manager, before a server is marked as unreachable. *consecutive_failures* must be an integer from 0 through 1000.
response-timeout *timeout_duration*: Specifies the number of seconds for each AAA manager to wait for a response to any message before a server is detected as failed, or in a down state. *timeout_duration* must be an integer from 1 through 65535.

max-outstanding *max_messages*

Specifies the maximum number of outstanding messages a single AAA manager instance will queue. *max_messages* must be an integer from 1 through 4000. Default: 256

max-retries *max_retries*

Specifies the maximum number of times communication with a AAA server will be attempted before it is marked as unreachable and the detect dead servers consecutive failures count is incremented. *max_retries* must be an integer from 0 through 65535. Default: 5

max-transmissions *transmissions*

Sets the maximum number of re-transmissions for RADIUS authentication requests. This limit is used in conjunction with the **max-retries** for each server. *transmissions* must be an integer from 1 through 65535. Default: Disabled
When failing to communicate with a RADIUS sever, the subscriber is failed once all of the configured RADIUS servers have been exhausted or once the configured number of maximum transmissions is reached. For example, if 3 servers are configured and if the configured max-retries is 3 and max-transmissions is 12, then the primary server is tried 4 times (once plus 3 retries), the secondary server is tried 4 times, and then a third server is tried 4 times. If there is a fourth server, it is not tried because the maximum number of transmissions (12) has been reached.

timeout *timeout_duration*

Specifies the number of seconds to wait for a response from the RADIUS server before re-sending the messages. *timeout_duration* must be an integer from 1 through 65535. Default: 3

Usage

Manage the basic Charging Service RADIUS options according to the RADIUS server used for the context.

Example

The following command configures the AAA server to be marked as unreachable when the consecutive failure count exceeds 6:

```
radius charging detect-dead-server consecutive-failures 6
```

The following command sets the timeout value to 300 seconds to wait for a response from RADIUS server before resending the messages:

```
radius charging timeout 300
```

radius charging accounting algorithm

This command specifies the fail-over/load-balancing algorithm to be used for selecting RADIUS servers for charging services.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
radius charging accounting algorithm { first-n n | first-server | round-robin }
```

first-n *n*

Specifies that the AGW must send accounting data to *n* (more than one) AAA servers based on their priority. Response from any one of the *n* AAA servers would suffice to proceed with the call. The full set of accounting data is sent to each of the *n* AAA servers.
n is the number of AAA servers to which accounting data will be sent, and must be an integer from 2 through 128. Default: 1 (Disabled)

first-server

Specifies that the context must send accounting data to the RADIUS server with the highest configured priority. In the event that this server becomes unreachable, accounting data is sent to the server with the next-highest configured priority. This is the default algorithm.

round-robin

Specifies that the context must load balance sending accounting data among all of the defined RADIUS servers. Accounting data is sent in a circular queue fashion on a per Session Manager task basis, where data is sent to the next available server and restarts at the beginning of the list of configured servers. The order of the list is based upon the configured relative priority of the servers.

Usage

Use this command to specify the accounting algorithm to use to select RADIUS servers for charging services configured in the current context.

Example

The following command specifies to use the round-robin algorithm to select the RADIUS server:

```
radius charging accounting algorithm round-robin
```

radius charging accounting server

This command configures RADIUS charging accounting servers in the current context for Active Charging Services prepaid accounting.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius charging accounting server *ip_address* **[encrypted] key** *key* **[max** *max_messages* **] [max-rate** *max_rate* **] [oldports] [port** *port_number* **] [priority** *priority* **] [admin-status { enable | disable }] [-noconfirm]**

no radius charging accounting server *ip_address* **[oldports | port** *port_number* **]**

---

no

Removes the server or server port(s) specified from the list of configured servers.

---

ip_address

Specifies IP address of the accounting server. in IPv4 dotted-decimal notation. A maximum of 128 RADIUS servers can be configured per context. This limit includes accounting and authentication servers.

[encrypted] key *key*

Specifies the shared secret key used to authenticate the client to the servers. The **encrypted** keyword indicates the key specified is encrypted.
In 12.1 and earlier releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 256 characters with encryption.
In 12.2 and later releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 236 characters with encryption enabled.
The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **key** keyword is the encrypted version of the plaint text key. Only the encrypted key is saved as part of the configuration file.

---

max *max_messages*

Specifies the maximum number of outstanding messages that may be allowed to the server. *max_messages* must be integer from 0 through 4000. Default: 0

---

max-rate *max_rate*

Specifies the rate (number of messages per second) at which the authentication messages should be sent to the RADIUS server. *max_rate* must be an integer from 0 through 1000. Default: 0 (Disabled)

---

oldports

Sets the UDP communication port to the out of date standardized default for RADIUS communications to 1646.

port *port_number*

Specifies the port number to use for communications as an integer from 1 through 65535. Default: 1813

priority *priority*

Specifies the relative priority of this accounting server. The priority is used in server selection for determining to which server to send accounting data. *priority* must be an integer 1 through 1000 where 1 is the highest priority. Default: 1000

admin-status { enable | disable }

Enables or disables the RADIUS authentication/ accounting/charging server functionality, and saves the status setting in the configuration file to re-establish the set status at reboot.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

This command is used to configure the RADIUS charging accounting server(s) with which the system is to communicate for Active Charging Services prepaid accounting requests.
Up to 128 AAA servers can be configured per context when the system is functioning as a PDSN and/or HA. Up to 16 servers are supported per context when the system is functioning as a GGSN.

Example

The following commands configure RADIUS charging accounting server with the IP address set to 10.2.3.4, port to 1024, and priority to 10:

```
radius charging accounting server 10.2.3.4 key sharedKey port 1024 max
127

radius charging accounting server 10.2.3.4 encrypted key scrambledKey
oldports priority 10
```

radius charging algorithm

This command configures the RADIUS authentication server selection algorithm for Active Charging Services for the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
radius charging algorithm { first-server | round-robin }

default radius charging algorithm
```

default

Configures the default setting. Default: **first-server**

first-server

Sends accounting data to the first available server based upon the relative priority of each configured server.

round-robin

Sends accounting data in a circular queue fashion on a per Session Manager task basis where data is sent to the next available server and restarts at the beginning of the list of configured servers. The order of the list is based upon the configured relative priority of the servers.

Usage

Set the context's RADIUS server selection algorithm for Active Charging Services to ensure proper load distribution through the servers available.

Example

The following command configures to use the round-robin algorithm for RADIUS server selection:

```
radius charging algorithm round-robin
```

radius charging server

This command configures the RADIUS charging server(s) in the current context for Active Charging Services prepaid authentication.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius charging server *ip_address* **[encrypted] key** *key* **[max** *max_messages* **] [max-rate** *max_rate* **] [oldports] [port** *port_number* **] [priority** *priority* **] [admin-status { enable | disable }] [-noconfirm]**

no radius charging server *ip_address* **[oldports | port** *port_number* **]**

---

no

Removes the server or server port(s) specified from the list of configured servers.

---

ip_address

Specifies the IP address of the server in IPv4 dotted-decimal notation. A maximum of 128 RADIUS servers can be configured per context. This limit includes accounting and authentication servers.

[encrypted] key *key*

Specifies the shared secret key used to authenticate the client to the servers. The **encrypted** keyword indicates the key specified is encrypted.
In 12.1 and earlier releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 256 characters with encryption.
In 12.2 and later releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 236 characters with encryption enabled.
The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **key** keyword is the encrypted version of the plain text key. Only the encrypted key is saved as part of the configuration file.

---

max *max_messages*

Specifies the maximum number of outstanding messages that may be allowed to the server. *max_messages* must be an integer from 0 through 4000. Default: 256

---

max-rate *max_rate*

Specifies the rate (number of messages per second), at which the authentication messages should be sent to the RADIUS server. *max_rate* must be an integer from 0 through 1000. Default: 0 (Disabled)

---

oldports

Sets the UDP communication port to the old default for RADIUS communications to 1645.

port *port_number*

Specifies the port number to use for communications as an integer from 1 through 65535. Default: 1812

priority *priority*

Specifies the relative priority of this accounting server. The priority is used in server selection for determining to which server to send accounting data. *priority* must be an integer from 1 through 1000 where 1 is the highest priority. Default: 1000

admin-status { enable | disable }

Enables or disables the RADIUS authentication/accounting/charging server functionality and saves the status setting in the configuration file to re-establish the set status at reboot.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

This command is used to configure the RADIUS charging server(s) with which the system is to communicate for Active Charging Services prepaid authentication requests.
Up to 128 AAA servers can be configured per context when the system is functioning as a PDSN and/or HA. Up to 16 servers are supported per context when the system is functioning as a GGSN.

Example

The following commands configure RADIUS charging server with the IP address set to 10.2.3.4, port to 1024, and priority to 10:

```
radius charging server 10.2.3.4 key sharedKey port 1024 max 127

radius charging server 10.2.3.4 encrypted key scrambledKey oldports
priority 10
```

radius deadtime

This command configures the maximum period of time (in minutes) that must elapse between when a context marks a RADIUS server as unreachable and when it can re-attempt to communicate with the server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius deadtime *minutes*

default radius deadtime

default

Configures the default setting.
Default: 10 minutes

minutes

Specifies the number of minutes to wait before changing the state of a RADIUS server from "Down" to "Active". *minutes* must be an integer from 0 through 65535.

Usage

Use this command to configure the basic RADIUS parameters according to the RADIUS server used for the context.

Important: This parameter should be set to allow enough time to remedy the issue that originally caused the server's state to be changed to "Down". After the deadtime timer expires, the system returns the server's state to "Active" regardless of whether or not the issue has been fixed.

Important: For a complete explanation of RADIUS server states, refer to the *RADIUS Server State Behavior* appendix in the *AAA and GTPP Interface Administration and Reference*.

Example

The following command configures the RADIUS deadtime to 100 minutes:

```
radius deadtime 100
```

radius detect-dead-server

This command configures how the system detects a dead RADIUS server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius detect-dead-server { consecutive-failures *consecutive_failures_count* **| keepalive | response-timeout** *timeout_duration* **}**

{ default | no } radius detect-dead-server

no

Removes the configuration.

default

Configures the default setting.

- **consecutive-failures**: Enabled; 4 consecutive failures
- **keepalive**: Disabled
- **response-timeout**: Disabled

consecutive-failures *consecutive_failures_count*

Specifies the consecutive number of times that the system must find the AAA server unreachable for the server to be marked unreachable, that is the server's state is changed from "Active" to "Down".
consecutive_failures_count must be an integer from 1 through 1000. Default: Enabled; 4 consecutive failures

keepalive

Enables the AAA server alive-dead detect mechanism based on sending keepalive authentication messages to all authentication servers. Default: Disabled

response-timeout *timeout_duration*

Specifies the time duration, in seconds, that the system must wait for a response from the AAA server to any message before the server is marked unreachable, that is the server's state is changed from "Active" to "Down".
timeout_duration must be an integer from 1 through 65535. Default: Disabled

Usage

Use this command to configure how the system detects a dead RADIUS server.

Important: If both **consecutive-failures** and **response-timeout** are configured, then both parameters must be met before a server's state is changed to "Down".

Important: The "Active" or "Down" state of a RADIUS server as defined by the system, is based on accessibility and connectivity. For example, if the server is functional but the system has placed it into a "Down" state, it could be the result of a connectivity problem. When a RADIUS server's state is changed to "Down", a trap is sent to the management station and the **deadtime** timer is started.

Example

The following command enables the detect-dead-server consecutive-failures mechanism and configures the consecutive number of failures to *10*:

```
radius detect-dead-server consecutive-failures 10
```

radius dictionary

Configures the RADIUS dictionary.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius dictionary *dictionary*

default radius dictionary

default

Configures the default setting.

dictionary

Specifies which dictionary to use.
dictionary must be one of the following values:

Table 15. RADIUS Dictionary Types

Dictionary	Description
3gpp	This dictionary consists of all the attributes in the standard dictionary, and all of the attributes specified in 3GPP 32.015.
3gpp2	This dictionary consists of all the attributes in the standard dictionary, and all of the attributes specified in IS-835-A.
3gpp2-835	This dictionary consists of all the attributes in the standard dictionary, and all of the attributes specified in IS-835.
custom*XX*	These are customized dictionaries. For information on custom dictionaries, please contact your local service representative. *XX* is the integer of the custom dictionary. NOTE: RADIUS dictionary *custom23* should be used in conjunction with Active Charging Service (ACS).
standard	This dictionary consists only of the attributes specified in RFC 2865, RFC 2866, and RFC 2869.
starent	This dictionary consists of all the attributes in the starent-vsa1 dictionary and incorporates additional VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the dictionaries supported by the system.
starent-835	This dictionary consists of all of the attributes in the starent-vsa1-835 dictionary and incorporates additional VSAs by using a two-byte VSA Type field. This dictionary is the master-set of all of the attributes in all of the -835 dictionaries supported by the system.

Dictionary	Description
starent-vsa1	This dictionary consists not only of the 3gpp2 dictionary, but also includes vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0–255). This is the default dictionary. ***Important:*** In 12.0 and later releases, no new attributes can be added to the **starent-vsa1** dictionary. If there are any new attributes to be added, these can only be added to the **starent** dictionary. For more information, please contact your Cisco account representative.
starent-vsa1-835	This dictionary consists not only of the 3gpp2-835 dictionary, but also includes vendor-specific attributes (VSAs) as well. The VSAs in this dictionary support a one-byte wide VSA Type field in order to support certain RADIUS applications. The one-byte limit allows support for only 256 VSAs (0–255). This is the default dictionary.

Usage

Use this command to configure the RADIUS dictionary.

Example

The following command configures the RADIUS dictionary standard.

```
radius dictionary standard
```

radius group

This command has been deprecated and is replaced by AAA Server Group configurations. See the *AAA Server Group Configuration Mode Commands* chapter.

radius ip vrf

This command associates the specific AAA group (NAS-IP) with a Virtual Routing and Forwarding (VRF) Context instance for BGP/MPLS, GRE, and IPSec tunnel functionality which needs VRF support for RADIUS communication.
By default the VRF is NULL, which means that AAA group is associated with global routing table.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius ip vrf *vrf_name*

no radius ip vrf

no

Disables the configured IP Virtual Routing and Forwarding (VRF) context instance and removes the association between the VRF context instance and the AAA group instance (NAS-IP).
By default this command is disabled, which means the NAS-IP being used is assumed a non-VRF IP and specific AAA group does not have any VRF association.

vrf_name

Specifies the name of a pre-configured VRF context instance. *vrf_name* is the alphanumeric string of a pre-configured VRF context configured in Context Configuration Mode via the **ip vrf** command.

Caution: Any incorrect configuration, such as associating AAA group with wrong VRF instance or removing a VRF instance, will fail the RADIUS communication.

Usage

Use this command to associate/disassociate a pre-configured VRF context for a feature such as BGP/MPLS VPN or GRE, and IPSec tunneling which needs VRF support for RADIUS communication.
By default the VRF is NULL, which means that AAA group (NAS-IP) is associated with global routing table and NAS-IP being used is assumed a non-VRF IP.
This IP VRF feature can be applied to RADIUS communication, which associates the VRF with the AAA group. This command must be configured whenever a VRF IP is used as a NAS-IP in the AAA group or at the Context level for 'default' AAA group.
This is a required configuration as VRF IPs may be overlapping hence AAA needs to know which VRF the configured NAS-IP belongs to. By this support different VRF-based subscribers can communicate with different RADIUS servers using the same, overlapping NAS-IP address, if required across different AAA groups.

Example

The following command associates VRF context instance *ip_vrf1* with specific AAA group (NAS-IP):

```
radius ip vrf ip_vrf1
```

radius keepalive

This command configures the keepalive authentication parameters for the RADIUS server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
radius keepalive [ calling-station-id id | consecutive-response responses_no_of |
encrypted | interval interval_duration | password | retries retries_no_of | timeout
timeout_duration | username user_name | valid-response access-accept [ access-reject ] ]

default radius keepalive { calling-station-id | consecutive-response | interval |
password | retries | timeout | username | valid-response }
```

default

Configures the default setting for the specified parameter.

calling-station-id *id*

Configures the Calling-Station ID to be used for the keepalive authentication. *id* must be an alphanumeric string of size 1 to 15 characters. Default: 000000000000000

consecutive-response *responses_no_of*

Configures the number of consecutive authentication responses after which the server is marked as reachable. *responses_no_of* must be an integer from 1 through 10. Default: 1

encrypted password

Designates use of encryption for the password.
In 12.1 and earlier releases, *password* must be an alphanumeric string of 1 through 63 characters.
In 12.2 and later releases, *password* must be an alphanumeric string of 1 through 132 characters.
Default: Test-Password

interval *interval_duration*

Configures the time interval (in seconds) between two keepalive access requests. *interval_duration* must be an integer from 30 through 65535. Default: 30

password

Configures the password to be used for the authentication as an alphanumeric string of 1 through 63 characters. Default: Test-Password

retries *retries_no_of*

Configures the number of times the keepalive access request are sent before marking the server as unreachable. *retries_no_of* must be an integer from 3 through 10. Default: 3

timeout *timeout_duration*

Configures the time interval (in seconds) between keepalive access request retries. *timeout_duration* must be an integer from 1 through 30. Default: 3

username *user_name*

Configures the user name to be used for authentication as an alphanumeric string of 1 through 127 characters. Default: Test-Username

valid-response access-accept [*access-reject* **]**

Configures the valid response for the authentication request.
If *access-reject* is configured, then both access-accept and access-reject are considered as success for the keepalive authentication request.
If *access-reject* is not configured, then only access-accept is considered as success for the keepalive access request.
Default: **keepalive valid-response access-accept**

Usage

Use this command to configure the Keepalive Authentication parameters for the RADIUS server.

Example

The following command sets the user name for the RADIUS keepalive access requests to *Test-Username2*:

```
radius keepalive username Test-Username2
```

The following command sets the number of retries to *4*:

```
radius keepalive retries 4
```

radius max-outstanding

This command configures the maximum number of outstanding messages a single AAA Manager instance will queue.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius max-outstanding *max_messages*

default radius max-outstanding

default

Configures the default setting.
Default: 256

max_messages

Specifies the maximum number of outstanding messages a single AAA Manager instance will queue. *max_messages* must be an integer from 1 through 4000. Default: 256

Usage

Use this command to configure the maximum number of outstanding messages a single AAA Manager instance will queue.

Example

The following command configures the maximum number of outstanding messages a single AAA Manager instance will queue to *100*:

```
radius max-outstanding 100
```

radius max-retries

This command configures the maximum number of times communication with a AAA server will be attempted before it is marked as “Not Responding”.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius max-retries *max_retries*

default radius max-retries

default

Configures the default setting.

max_retries

Specifies the maximum number of times communication with a AAA server will be attempted before it is marked as “Not Responding”, and the detect dead server’s consecutive failures count is incremented. *max_retries* must be an integer from 0 through 65535. Default: 5

Usage

Use this command to configure the maximum number of times communication with a AAA server will be attempted before it is marked as “Not Responding”.

Example

The following command configures the maximum number of times communication with a AAA server will be attempted before it is marked as “Not Responding” to *10*:

```
radius max-retries 10
```

radius max-transmissions

This command configures the maximum number of re-transmissions for RADIUS authentication requests.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius max-transmissions *max_transmissions*

{ default | no } radius max-transmissions

no

Deletes the RADIUS max-transmissions configuration.

default

Configures the default setting.
Default: Disabled

max_transmissions

Specifies the maximum number of re-transmissions for RADIUS authentication requests. This limit is used in conjunction with **radius max-retries** configuration for each server. *max_transmissions* must be an integer from 1 through 65535. Default: Disabled
When failing to communicate with a RADIUS sever, the subscriber is failed once all of the configured RADIUS servers have been exhausted, or once the configured number of maximum transmissions is reached. For example, if three servers are configured and if the configured max-retries is 3 and max-transmissions is 12, then the primary server is tried four times (once plus three retries), the secondary server is tried four times, and then a third server is tried four times. If there is a fourth server, it is not tried because the maximum number of transmissions (12) has been reached.

Usage

Use this command to configure the maximum number of re-transmissions for RADIUS authentication requests.

Example

The following command configures the maximum number of re-transmissions for RADIUS authentication requests to *10*:

```
radius max-transmissions 10
```

radius mediation-device

See the **radius accounting server** command.

radius probe-interval

This command configures the interval between two RADIUS authentication probes.

Product

All products supporting Interchassis Session Recovery (ICSR)

Privilege

Security Administrator, Administrator

Syntax

radius probe-interval *seconds*

default radius probe-interval

default

Configures the default setting of 3.

seconds

Specifies the time duration (in seconds) to wait before sending another probe authentication request to a RADIUS server. The value must be an integer from 1 through 65535. Default: 3

Usage

Use this command for ICSR support to set the duration between two authentication probes to the RADIUS server.

Example

The following command sets the authentication probe interval to 30 seconds.

```
radius probe-interval 30
```

radius probe-max-retries

This command configures the number of retries for RADIUS authentication probe response.

Product

All products supporting Interchassis Session Recovery (ICSR)

Privilege

Security Administrator, Administrator

Syntax

radius probe-max-retries *retries*

default radius probe-max-retries

default

Configures the default setting.
Default: 5

retries

Specifies the number of retries for RADIUS authentication probe response before the authentication is declared as failed. *retries* must be an integer from 1 through 65535. Default: 5

Usage

Use this command for ICSR support to set the number of attempts to send RADIUS authentication probe without a response before the authentication is declared as failed.

Example

The following command sets the maximum number of retries to *6*:

```
radius probe-max-retries 6
```

radius probe-message

This command configures the service ip-address to be sent as an AVP in RADIUS authentication probe messages.

Product

All products supporting Interchassis Session Recovery (ICSR)

Privilege

Security Administrator, Administrator

Syntax

radius probe-message local-service-address *ipv4/ipv6_address*

no radius probe-message local-service-address

---

no

Disables sending of AVPs configured under probe-message cli in RADIUS authentication probe messages.

---

radius probe-message local-service-address

radius probe-message
Configures AVPs to be sent in RADIUS authentication probe messages.
local-service-address
Configures the service ip-address to be sent as an AVP in RADIUS authentication probe messages.

---

ipv4/ipv6_address

Specifies the IPv4/IPv6 address of the server in IPv4 dotted-decimal or IPv6 colon-separated notation. A maximum of 128 RADIUS servers can be configured per context. This limit includes accounting and authentication servers.

Example

The following command configures the service ip-address *21.32.36.25* to be sent as an AVP in RADIUS authentication probe messages:

```
radius probe-message local-service-address 21.32.36.25
```

radius probe-timeout

This command configures the timeout duration to wait for a response for RADIUS authentication probes.

Product

All products supporting Interchassis Session Recovery (ICSR)

Privilege

Security Administrator, Administrator

Syntax

radius probe-timeout *timeout_duration*

default radius probe-timeout

default

Configures the default setting.
Default: 3

timeout_duration

Specifies the time duration (in seconds) to wait for a response from the RADIUS server before resending the authentication probe. *timeout_duration* must be an integer from 1 through 65535. Default: 3

Usage

Use this command for ICSR support to set the duration to wait for a response before re-sending the RADIUS authentication probe to the RADIUS server.

Example

The following command sets the authentication probe timeout to *120* seconds:

```
radius probe-timeout 120
```

radius server

This command configures RADIUS authentication server(s) in the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
radius server ip_address [ encrypted ] key value [ max max_messages ] [ max-rate max_rate
] [ oldports ] [ port port_number ] [ priority priority ] [ probe | no-probe ] [ probe-
username user_name ] [ probe-password [ encrypted ] password password ] [ type {
mediation-device | standard } ] [ admin-status { enable | disable } ] [ -noconfirm ]

no radius server ip_address [ oldports | port port_number ]
```

no

Removes the server or server port(s) specified from the list of configured servers.

ip_address

Specifies the IP address of the server in IPv4 dotted-decimal or IPv6 colon-separated notation. A maximum of 128 RADIUS servers can be configured per context. This limit includes accounting and authentication servers.

[encrypted] key *value*

Specifies the shared secret key used to authenticate the client to the servers. The **encrypted** keyword indicates the key specified is encrypted.
In 12.1 and earlier releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 256 characters with encryption.
In 12.2 and later releases, the key *value* must be an alphanumeric string of 1 through 127 characters without encryption, and 1 through 236 characters with encryption enabled.
The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **key** keyword is the encrypted version of the plain text key. Only the encrypted key is saved as part of the configuration file.

max *max_messages*

Specifies the maximum number of outstanding messages that may be allowed to the server. *max_messages* must be an integer from 0 through 4000. Default: 256

max-rate *max_rate*

Specifies the rate (number of messages per second), at which the authentication messages should be sent to the RADIUS server. *max_rate* must be an integer from 0 through 1000. Default: 0 (Disabled)

oldports

Sets the UDP communication port to the old default for RADIUS communications to 1645.

port *port_number*

Specifies the port number to use for communications as an integer from 1 through 65535. Default: 1812

priority *priority*

Specifies the relative priority of this accounting server. The priority is used in server selection for determining to which server is to send accounting data.
priority must be an integer from 1 through 1000 where 1 is the highest priority. When configuring two or more servers with the same priority you will be asked to confirm that you want to do this. If you use the **-noconfirm** option, you are not asked for confirmation and multiple servers could be assigned the same priority.
Default: 1000

probe

Enables probe messages to be sent to the specified RADIUS server.

no-probe

Disables probe messages from being sent to the specified RADIUS server. This is the default behavior.

probe-username *username*

Specifies the user name sent to the RADIUS server to authenticate probe messages. *username*must be an alphanumeric string of 1 through 127 characters.

probe-password [encrypted] password *password*

The password sent to the RADIUS server to authenticate probe messages.
encrypted: This keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **password** keyword is the encrypted version of the plain text password. Only the encrypted password is saved as part of the configuration file.
password *password*: Specifies the probe-user password for authentication. *password* must be an alphanumeric string of 1 through 63 characters.

type { mediation-device | standard }

Specifies the type of transactions the RADIUS server accepts.
mediation-device: Specifies mediation-device specific AAA transactions. This device is available if you purchased a transaction control services license. Contact your local sales representative for licensing information.
standard: Specifies standard AAA transactions. (Default)

admin-status { enable | disable }

Enables or disables the RADIUS authentication/accounting/charging server functionality, and saves the status setting in the configuration file to re-establish the set status at reboot.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

This command is used to configure the RADIUS authentication server(s) with which the system is to communicate for authentication.
Up to 128 RADIUS servers can be configured per context. The servers can be configured as Accounting, Authentication, charging servers, or any combination thereof.

Example

The following commands configure RADIUS server with the IP address set to 10.2.3.4, port to 1024, and priority to 10:

```
radius server 10.2.3.4 key sharedKey port 1024 max 127

radius server 10.2.3.4 encrypted key scrambledKey oldports priority 10
```

radius strip-domain

This command configures the stripping of the domain from the user name prior to authentication or accounting.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
radius strip-domain { authentication-only | accounting-only }

no radius strip-domain
```

no

Removes the RADIUS strip-domain configuration.

authentication-only

Specifies that the domain must be stripped from the user name prior to authentication.

accounting-only

Specifies that the domain must be stripped from the user name prior to accounting.

Usage

Use this command to configure the stripping of domain from the user name prior to authentication or accounting.
By default, strip-domain configuration will be applied to both authentication and accounting messages, if configured. When the argument **authentication-only** or **accounting-only** is present, **strip-domain** is applied only to the specified RADIUS message types.

Example

The following command configures the stripping of domain from the user name prior to authentication:

```
radius strip-domain authentication-only
```

radius timeout

This command configures the time duration to wait for a response from the RADIUS server before resending the messages.

Product

All

Privilege

Security Administrator, Administrator

Syntax

radius timeout *timeout_duration*

default radius timeout

default

Configures the default setting.

timeout_duration

Specifies the time duration (in seconds) to wait for a response from the RADIUS server before resending the messages. *timeout_duration* must be an integer from 1 through 65535. Default: 3

Usage

Use this command to configure the time duration to wait for a response from the RADIUS server before resending the messages.

Example

The following command configures the RADIUS timeout parameter to 300 seconds:

```
radius timeout 300
```

radius trigger

This command enables specific RADIUS triggers. The RADIUS Trigger configuration in the Context Configuration Mode is to enable backward compatibility. To configure RADIUS triggers for the default AAA group, you must configure them in the Context Configuration Mode.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] radius trigger { ms-timezone-change | qos-change | rai-change | rat-change |
serving-node-change | uli-change }

default radius trigger
```

no

Disables the specified RADIUS trigger.

default

Configures the default setting.
Default: All RADIUS triggers are enabled.

ms-timezone-change

Specifies to enable RADIUS trigger for MS time zone change.

qos-change

Specifies to enable RADIUS trigger for Quality of Service change.

rai-change

Specifies to enable RADIUS trigger for Routing Area Information change.

rat-change

Specifies to enable RADIUS trigger for Radio Access Technology change.

serving-node-change

Specifies to enable RADIUS trigger for Serving Node change.

uli-change

Specifies to enable RADIUS trigger for User Location Information change.

Usage

Use this command to enable RADIUS triggers.

Example

The following command enables RADIUS trigger for RAT change:

```
radius trigger rat-change
```

route-access-list extended

Configures an access list for filtering routes based on a specified range of IP addresses.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] route-access-list extended *identifier* **{ deny | permit } ip {** *network_parameter* **} {** *mask_parameter*

---

no

Deletes the specified route access list.

---

route-access-list extended *identifier*

Specifies a value to identify the route access list as an integer from 100 through 999.

---

deny

Deny routes that match the specified criteria.

---

permit

Permit routes that match the specified criteria.

---

ip *network_parameter ip_address wildcard_mask*

Specifies the network portion of the route to match. The network portion of the route is mandatory and must be expressed in one of the following ways:

- *ip_address wildcard_mask*: Matches a network address and wildcard mask expressed in IPv4 dotted-decimal notation.
- **any**: Matches any network address.
- **host** *network_address*: Match the specified network address exactly. *network_address* must be an IPv4 address specified in dotted-decimal notation.

---

mask_parameter

This specifies the mask portion of the route to match. The mask portion of the route is mandatory and must be expressed in one of the following ways:

- *mask_address wildcard_mask*: A mask address and wildcard mask expressed in IPv4 dotted-decimal notation.
- **any**: Match any network mask.
- **host** *mask_address*: Match the specified mask address exactly. *mask_address* must be an IPv4 address specified in dotted-decimal notation.

Usage

Use this command to create an extended route-access-list that matches routes based on network addresses and masks.

Example

Use the following command to create an extended route-access-list:

```
route-access-list extended 100 permit ip 192.168.100.0 0.0.0.255
```

route-access-list named

Configures an access list for filtering routes based on a network address and net mask.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] route-access-list named *list_name* **{ deny | permit } {** *ip_address*/*mask* **| any } [exact-match]**

no

Deletes the specified route access list.

route-access-list named *list_name*

Specifies name that identifies the route access list as an alphanumeric string of 1 through 79 characters.

deny

Denies routes that match the specified criteria.

permit

Permits routes that match the specified criteria.

ip_address/*mask*

Specifies the IP address (in IPv4 dotted-decimal notation) and the number of subnet bits, representing the subnet mask in CIDR notation (for example 10.1.1.1/24).

any

Matches any route.

exact-match

Matches the IP address prefix exactly.

Usage

Use this command to create route-access lists that specify routes that are accepted.

Example

Use the following command to create a route access list named *list27* that permits routes that match *192.168.1.0/24* exactly:

```
route-access-list named list 27 permit 192.168.1.0/24 exact-match
```

To delete the list, use the following command:

```
no route-access-list named list 27 permit 192.168.1.0/24 exact-match
```

route-access-list standard

Configures an access-list for filtering routes based on network addresses.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] route-access-list standard *identifier* **{ permit | deny } {** *ip_address wildcard_mask* **| any | host** *network_address* **}**

no

Deletes the specified route access list.

route-access-list standard *identifier*

Specifies a value that identifies the route-access-list as an integer from 1 through 99.

deny

Denies routes that match the specified criteria.

permit

Permits routes that match the specified criteria.

ip_address wildcard_mask

Specifies the IP address and subnet mask to match for routes. Both *ip_address* and *wildcard_mask* must be entered in IPv4 dotted-decimal notation. (For example, 192.168.100.0 255.255.255.0)

any

Matches any route.

host *network_address*

Matches only routes having the specified network address as if it had a 32-bit network mask. *network_address* must be an IPv4 address specified in dotted-decimal notation.

Usage

Use this command to create route-access-lists that specify routes that are accepted.

Example

Use the following command to create a route access list with an identifier of *10* that permits routes:

```
route-access-list standard 10 permit 192.168.1.0 255.255.255.0
```

To delete the list, use the following command:

```
no route-access-list standard 10 permit 192.168.1.0 255.255.255.0
```

route-map

Creates a route-map that is used by the routing features and enters Route-map Configuration mode. A route-map allows redistribution of routes and includes a list of match and set commands associated with it. The match commands specify the conditions under which redistribution is allowed; the set commands specify the particular redistribution actions to be performed if the criteria specified by match commands are met. Route-maps are used for detailed control over route distribution between routing processes. Up to eight route-maps can be created in each context. Refer to the *Route-map Configuration Mode Commands* chapter for more information.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

route-map *map_name* **{ deny | permit }** *seq_number*

no route-map *map_name*

no

Deletes the specified route map.

route-map *map_name*

Specifies the name of the route map to create or edit as an alphanumeric string of 1 through 69 characters.

deny

If the deny parameter is specified and the match command criteria are met, the route is not redistributed and any other route maps with the same map name are not examined. Set commands have no affect on deny route-maps.

permit

If the permit parameter is specified, and the match criteria are met, the route is redistributed as specified by set actions. If the match criteria are not met, the next route map with the same name is tested.

seq_number

Specifies the sequence number that indicates the position a new route map is to have in the list of route maps already configured with the same name. Route maps with the same name are tested in ascending order of their sequence numbers. This must be an integer from 1 through 65535.

Usage

Use this command to create route maps that allow redistribution of routes based on specified criteria and set parameters for the routes that get redistributed. The chassis supports a maximum of 64 route maps per context.

Example

To create a route map named map1 that permits routes that match the specified criteria, use the following command:

```
route-map map1 permit 10
```

To delete the route-map, enter the following command:

```
no route-map map1 permit 10
```

router

Enables BGP, Open Shortest Path First (OSPF) or OSPF version 3 (OSPFv3) routing functionality and enters the corresponding Configuration Mode. Refer to the *BGP Configuration Mode Commands*, *OSPF Configuration Mode Commands* or *OSPFv3 Configuration Mode Commands* chapter for details on associated Configuration mode commands.

Product

PDSN, HA, GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] router { bgp as_number | ospf | ospfv3  }
```

no

Disables the specified routing support in the current context.

bgp *as_number*

Enables a BGP routing service for this context and assigns it the specified Autonomous System (AS) number before entering the BGP Configuration mode. *as_number* must be an integer from 1 through 4294967295.

Important: BGP routing is supported only for use with the HA.

ospf

Enables OSPF routing in this context and enters OSPF Configuration mode.

ospfv3

Enables OSPFv3 routing in this context and enter OSPFv3 Configuration mode.

Usage

Use this command to enable and configure OSPF and BGP routing in the current context.

Important: You must obtain and install a valid license key to use these features. Refer to the *System Administration Guide* for details on obtaining and installing feature use license keys.

Example

The following command enables the OSPF routing functionality and enters the OSPF Configuration Mode:

```
router ospf
```

The following command enables the OSPFv3 routing functionality and enters the OSPFv3 Configuration Mode:

```
router ospfv3
```

The following command enables a BGP routing service with an AS number of *100*, and enters the BGP Configuration Mode:

```
router bgp 100
```

server

Configures remote server access protocols for the current context. This command is used to enter the specified protocols configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
server { ftpd | named | sshd | telnetd | tftpd }

no server { ftpd | named | sshd | telnetd | tftpd } [ kill ]
```

no

Disables the specified service.

server ftpd

Enters the FTP Server Configuration Mode.

Important: The FTPD server can only be configured in the local context.

server named

Starts the named server.

server sshd

Enters the SSH Server Configuration Mode.

Important: The SSHD server allows only three unsuccessful login attempts before closing a login session attempt.

server telnetd

Enters the Telnet Server Configuration Mode.

Important: The TELNET server allows only three unsuccessful login attempts before closing a login session attempt.

server tftpd

Enters the TFTP Server Configuration Mode.

Important: The TFTPD server can only be configured in the local context.

kill

Indicates all instances of the server are to be stopped.
This option only works with the **ftpd**, **sshd**, **telnetd**, and **tftpd** commands.

Usage

Enter the Context Configuration Mode for the appropriate, previously defined context, to set the server option(s). Repeat the command as needed to enable/disable more than one option server daemon.

Example

```
server ftpd

server named

no server tftpd

server sshd

server telnetd

no server telnetd kill
```

service-redundancy-protocol

Configures Interchassis Session Recovery (ICSR) services for the current context. This command is used to enter the Service Redundancy Protocol Configuration Mode.

Product

All products supporting ICSR

Privilege

Security Administrator, Administrator

Syntax

```
service-redundancy-protocol
```

Usage

Enter the configuration mode to set the service redundancy protocol options.

Example

The following command enters Service Redundancy Protocol Configuration Mode.

```
service-redundancy-protocol
```

session-event-module

Enables the event module, enters the Session Event Module Configuration Mode where the sending of Serving Gateway (S-GW) subscriber-specific event files to an external server can be configured.

Product

S-GW

Privilege

Administrator

Syntax

```
[ no ] session-event-module
```

no

Disables the event module configuration.

Usage

Enter the Session Event Module Configuration Mode where the sending of S-GW subscriber-specific event files to an external server can be configured.
Entering this command results in the following prompt:

```
[context_name]hostname(config-event)#
```

Session Event Module Configuration Mode commands are defined in the *Session Event Module Configuration Mode Commands* chapter.

sgsn-service

Creates an SGSN service instance and enters the SGSN Service Configuration mode. This mode configures or edits the configuration for an SGSN service which controls the SGSN functionality.

An SGSN mediates access to GPRS/UMTS network resources on behalf of user equipment (UE) and implements the packet scheduling policy between different QoS classes. It is responsible for establishing the packet data protocol (PDP) context with the GGSN.

Important: For details about the commands and parameters, check the *SGSN Service Configuration Mode* chapter.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

[no] sgsn-service *srvc_name*

no

Remove the configuration for the specified SGSN service from the configuration of the current context.

sgsn-service *srvc_name*

Specifies the name of the SGSN service as a unique alphanumeric string of 1 through 63 characters.

Usage

Use this command to create, edit, or remove an SGSN service

Example

The following command creates an SGSN service named *sgsn1* in the current context:

```
sgsn-service sgsn1
```

The following command removes the sgsn service named *sgsn1* from the configuration for the current context:

```
no sgsn-service sgsn1
```

sgs-service

Creates an SGs service instance and enters the SGS Service Configuration mode.

Product

MME

Privilege

Administrator

Syntax

[no] sgs-service *name*

no

Remove the configuration for the specified SGs service from the configuration of the current context.

sgs-service *name*

Specifies a name for an SGs service as a unique alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Enter the SGS Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following CLI prompt:

```
[context_name]hostname(config-sgs-service)#
```

SGS Service Configuration Mode commands are defined in the *SGS Service Configuration Mode Commands* chapter.

Example

The following command creates an SGS service named *sgs1* in the current context:

```
sgs-service sgs1
```

The following command removes the SGS service named *sgs1* from the configuration for the current context:

```
no sgs-service sgs1
```

sgtp-service

Creates an SGTP service instance and enters the SGTP Service Configuration mode. This mode configures the GPRS Tunneling Protocol (GTP) related settings required by the SGSN to support GTP-C (control plane) messaging and GTP-U (user data plane) messaging.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

[no] sgtp-service *svc_name*

no

Remove the configuration for the specified SGTP service from the configuration of the current context.

sgtp-service *svc_name*

Specifies a name for an SGTP service as a unique alphanumeric string of 1 through 63 characters.

Usage

Use this command to create, edit, or remove an SGTP service

Example

The following command creates an SGTP service named *sgtp1* in the current context:

```
sgtp-service sgtp1
```

The following command removes the sgsn service named *sgtp1* from the configuration for the current context:

```
no sgtp-service sgtp1
```

sgw-service

Creates an S-GW service or specifies an existing S-GW service and enters the S-GW Service Configuration Mode for the current context.

Product

S-GW

Privilege

Administrator

Syntax

sgw-service *service_name* **[-noconfirm]**

no sgw-service *service_name*

sgw-service *service_name*

Specifies the name of the S-GW service. If *service_name* does not refer to an existing service, the new service is created if resources allow. *service_name* is an alphanumeric string of 1 through 63 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

no sgw-service *service_name*

Removes the specified S-GW service from the context.

Usage

Enter the S-GW Service Configuration Mode for an existing service or for a newly defined service. This command is also used to remove an existing service.
A maximum of 256 services (regardless of type) can be configured per system.

Caution: Large numbers of services greatly increase the complexity of management and may impact overall system performance (for example, resulting from such things as system handoffs). Therefore, it is recommended that a large number of services only be configured if your application absolutely requires it. Please contact your local service representative for more information.

Entering this command results in the following prompt:

```
[context_name]hostname(config-sgw-service)#
```

S-GW Service Configuration Mode commands are defined in the *S-GW Service Configuration Mode Commands* chapter.
Use this command when configuring the following SAE components: S-GW.

Example

The following command enters the existing S-GW Service Configuration Mode (or creates it if it does not already exist) for the service named *sgw-service1*:

```
sgw-service sgw-service1
```

The following command will remove *spgw-service1* from the system:

```
no sgw-service sgw-service1
```

ssh

Generates public and private keys for use with the configured Secure Shell (SSH) server for the current context and sets the public/private key pair to specified values.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ssh { generate key | key *data* **length** *octets* **} [type { v1-rsa | v2-rsa | v2-dsa }]**

no ssh key [type { v1-rsa | v2-rsa | v2-dsa }]

no ssh key [type { v1-rsa | v2-rsa | v2-dsa }]

This command clears configured SSH keys. If type is not specified, all SSH keys are cleared.

ssh generate key

Generates a public/private key pair which is to be used by the SSH server. The generated key pair is in use until the command is issued again.

ssh key *data* **length** *octets*

Sets the public/private key pair to be used by the system where *data* is the encrypted key and *length* is the length of the encrypted key in octets. *data* must be an alphanumeric string of 1 through 1023 characters and *octets* must be a value in the range of 0 through 65535.

[type { v1-rsa | v2-rsa | v2-dsa }]

Specifies the type of SSH key to generate. If type is not specified, all three key types are generated.

- **v1-rsa**: SSH v1 RSA host key only
- **v2-rsa**: SSH v2 DSA host key only
- **v2-dsa**: SSH v2 RSA host key only

Important: For maximum security, it is recommended that only SSH v2 be used. **v2-rsa** is the recommended key type.

Usage

Generate secure shell keys for use in public key authentication.

Example

```
ssh generate key

ssh key g6j93fw59cx length 128
```

ssl

Creates a new Secure Sockets Layer (SSL) template or specifies an existing one and enters the SSL Template Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

[no] ssl template *name* **{ ssl-subscriber }**

no

Removes the specified SSL template from the context.

ssl template *name*

Specifies the name of a new or existing SSL template as an alphanumeric string of 1 through 127 alphanumeric characters.

ssl-subscriber

Specifies that the SSL template is an SSL subscriber template.

Usage

Use this command to create a new SSL template or modify an existing one.
Entering this command results in the following prompt:

```
[context_name]hostname(cfg-ctx-ssl-subscriber-template)#
```

SSL Template Configuration Mode commands are defined in the *SSL Template Configuration Mode Commands* chapter.

Example

The following command specifies the SSL template *ssl_template_1* and enters the SSL Template Configuration Mode:

```
ssl template ssl_template_1 ssl-subscriber
```

subscriber

Configures the specified subscriber for the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

subscriber { default | name *user_name* **} asn-service-info mobility [ipv4 | ipv6 | ipv6-ipv4]**

no subscriber { default | name *user_name* **}**

no

Indicates the subscriber specified is to be removed from the list of allowed users for the current context.

subscriber default | name *user_name*

default: Enters the Subscriber Configuration Mode for the context's default subscriber settings.
name *user_name*: Specifies the user which is to be allowed to use the services of the current context. *user_name* must be an alphanumeric string of 1 through 127 characters.
asn-service-info mobility: Indicates the type of mobility supported and enabled in the Autonomous System Number (ASN).

Usage

Enter the Subscriber Configuration Mode for actual users as well as for a default subscriber for the current context.
NAS uses the specified parameter for asn-service-info mobility to indicate and pack the mobility support field for IPv4, IPv6, or both, in the Service-Info attribute in the Access-request. RADIUS sends back this attribute in the Access-accept message by indicating respective bits to authorize the service indicated by NAS.

Important: A maximum of 128 subscribers and/or administrative users may be locally configured per context.

Example

Following command configures the default subscriber in a context:

```
subscriber default
```

Following command removes the default subscriber from a context:

```
no subscriber default
```

Following command configures a subscriber named *user1* in a context:

```
subscriber name user1
```

Following command removes a subscriber named *user1* from a context:

```
no subscriber name user1
```

threshold available-ip-pool-group

Configures context-level thresholds for IP pool utilization for the system.

Product

All

Privilege

Security Administrator, Administrator

Syntax

threshold available-ip-pool-group *low_thresh* **[clear** *high_thresh* **]**

default threshold available-ip-pool-group

default

Configures the default setting.

threshold available-ip-pool-group *low_thresh*

The low threshold IP pool utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm. *low_thresh* can be configured as an integer from 0 through 100. Default: 10

clear *high_thresh*

Specifies the high threshold IP pool utilization percentage that maintains a previously generated alarm condition. If the utilization percentage rises above the high threshold within the polling interval, a clear alarm will be generated. *high_thresh* can be configured as an integer from 0 through 100. Default: 10

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

When IP address pools are configured on the system, they can be assigned to a group. IP address pool utilization thresholds generate alerts or alarms based on the utilization percentage of all IP address contained in the pool group during the specified polling interval.

All configured public IP address pools that were not assigned to a group are treated as belonging to the same group. Individual configured static or private pools are each treated as their own group.

Alerts or alarms are triggered for IP address pool utilization based on the following rules:

- **Enter Condition**: Actual IP address utilization percentage per pool group ≤ Low Threshold
- **Clear Condition**: Actual IP address utilization percentage per pool group > High Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

The following table describes the possible methods for configuring IP pool utilization thresholds:

Table 16. IP Pool Utilization Thresholds - Configuration Methods

Method	Description
Context-level	A single IP pool utilization threshold can be configured for all IP pool groups within a given system context. If a single threshold is configured for all pool groups, separate alerts or alarms can be generated for each group. This command configures that threshold.
IP address pool-level	Each individual IP address pool can be configured with its own threshold. Thresholds configured for individual pools take precedence over the context-level threshold that would otherwise be applied (if configured). In the event that two IP address pools belonging to the same pool group are configured with different thresholds, the system uses the pool configuration that has the greatest low threshold for that group.

Example

The following command configures a context-level IP pool utilization low threshold percentage of *10* and a high threshold of *35* for an system using the Alarm thresholding model:

```
threshold available-ip-pool-group 10 clear 35
```

threshold ha-service init-rrq-rcvd-rate

Sets an alarm or alert based on the average number of calls setup per second for an HA service.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
threshold ha-service init-rrq-rcvd-rate high_thresh [ clear low_thresh ]

no threshold ha-service init-rrq-rcvd-rate
```

no

Deletes the alert or alarm.

threshold ha-service init-rrq-rcvd-rate *high_thresh*

Sets the high threshold average number of calls setup per second that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured as an integer from 0 through 1000000. Default: 0

clear *low_thresh*

Sets the low threshold average number of calls setup per second that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured as an integer from 0 through 1000000. Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the average number of calls setup per second is equal to or less than a specified number of calls per second.

Alerts or alarms are triggered for the number of calls setup per second based on the following rules:

- **Enter Condition**: Actual number of calls setup per second > High Threshold
- **Clear Condition**: Actual number of calls setup per second ≤ Low Threshold

Example

The following command configures a number of calls setup per second threshold of *1000* and a low threshold of *500* for a system using the Alarm thresholding model:

```
threshold ha-service init-rrq-rcvd-rate 1000 clear 500
```

threshold ip-pool-free

Sets an alarm or alert based on the percentage of IP addresses that are unassigned in an IP pool. This command affects all IP pools in the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

threshold ip-pool-free *low_thresh* **[clear** *high_thresh* **]**

default threshold ip-pool-free

default

Configures the default setting.

threshold ip-pool-free *low_thresh*

Sets the low threshold percentage of addresses available in an IP pool that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured as an integer between 0 and 100. Default: 0

clear *high_thresh*

Sets the high threshold percentage of addresses available in an IP pool that maintains a previously generated alarm condition. If the utilization percentage rises above the high threshold within the polling interval, a clear alarm will be generated. It may be configured as an integer between 0 and 100. Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

Use this command to set an alert or an alarm when the number of unassigned IP addresses in any pool is equal to or less than a specified percentage of the total number of addresses in the pool.
Alerts or alarms are triggered for percentage of IP address pool free based on the following rules:

- **Enter Condition**: Actual percentage of IP addresses free per pool ≤ Low Threshold
- **Clear Condition**: Actual percentage of IP addresses free per pool > High Threshold

Important: This command is overridden by the settings of the **alert-threshold** keyword of the **ip pool** command.

Example

The following command configures a context-level IP pool percentage of IP addresses that are unused low threshold percentage of *10* and a high threshold of *35* for an system using the Alarm thresholding model:

```
threshold ip-pool-free 10 clear 35
```

threshold ip-pool-hold

Sets an alert based on the percentage of IP addresses from an IP pool that are on hold. This command affects all IP pools in the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

threshold ip-pool-hold *high_thresh* **[clear** *low_thresh* **]**

default threshold ip-pool-hold

default

Configures the default setting.

threshold ip-pool-hold *high_thresh*

Sets the high threshold percentage of addresses on hold in an IP pool that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured as an integer from 0 through 100. Default: 0

clear *low_thresh*

Sets the low threshold percentage of addresses on hold in an IP pool that maintains a previously generated alarm condition. If the utilization percentage rises below the low threshold within the polling interval, a clear alarm will be generated. It may be configured as an integer from 0 through 100. Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the percentage of IP addresses on hold in any pool is equal to or greater than a specified percentage of the total number of addresses in the pool.
Alerts or alarms are triggered for percentage of IP address pool addresses on hold based on the following rules:

- **Enter Condition**: Actual percentage of IP addresses on hold per pool > High Threshold
- **Clear Condition**: Actual percentage of IP addresses on hold per pool ≤ Low Threshold

Important: This command is overridden by the settings of the **alert-threshold** keyword of the **ip pool** command.

Example

The following command configures a context-level IP pool percentage of IP addresses that are on high threshold percentage of *35* and a low threshold of *10* for an system using the Alarm thresholding model:

```
threshold ip-pool-hold 35 clear 10
```

threshold ip-pool-release

Sets an alert based on the percentage of IP addresses from an IP pool that are in the release state. This command affects all IP pools in the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

threshold ip-pool-release *high_thresh* **[clear** *low_thresh* **]**

default threshold ip-pool-release

default

Configures the default setting.

threshold ip-pool-release *high_thresh*

Sets the high threshold percentage of addresses in the release state in an IP pool that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured as an integer from 0 through 100. Default: 0

clear *low_thresh*

Sets the low threshold percentage of addresses in the release state in an IP pool that maintains a previously generated alarm condition. If the utilization percentage rises below the low threshold within the polling interval, a clear alarm will be generated. It may be configured as an integer from 0 through 100. Default:0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

Use this command to set an alert or an alarm when the number of IP addresses the release state in any pool is equal to or greater than a specified percentage of the total number of addresses in the pool.
Alerts or alarms are triggered for percentage of IP address pool addresses in the release state based on the following rules:

- **Enter Condition**: Actual percentage of IP addresses in the release state per pool > High Threshold
- **Clear Condition**: Actual percentage of IP addresses in the release state per pool ≤ Low Threshold

Important: This command is overridden by the settings of the **alert-threshold** keyword of the **ip pool** command.

Example

The following command configures a context-level IP pool percentage of IP addresses that are in the release state high threshold percentage of *35* and a low threshold of *10* for an system using the Alarm thresholding model:

```
threshold ip-pool-release 35 clear 10
```

threshold ip-pool-used

Sets an alert based on the percentage of IP addresses that have been assigned from an IP pool. This command affects all IP pools in the current context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

threshold ip-pool-used *high_thresh* **[clear** *low_thresh* **]**

default threshold ip-pool-used

default

Configures the default setting.

threshold ip-pool-used *high_thresh*

Sets the high threshold percentage of addresses assigned from an IP pool that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured as an integer from 0 through 100. Default: 0

clear *low_thresh*

Sets the low threshold percentage of addresses assigned from an IP pool that maintains a previously generated alarm condition. If the utilization percentage rises above the high threshold within the polling interval, a clear alarm will be generated. It may be configured to any integer between 0 and 100. Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the low threshold.

Usage

Use this command to set an alert or an alarm when the number of IP addresses assigned from any pool is equal to or greater than a specified percentage of the total number of addresses in the pool.
Alerts or alarms are triggered for percentage of IP address pool addresses used based on the following rules:

- **Enter Condition**: Actual percentage of IP addresses used per pool > High Threshold
- **Clear Condition**: Actual percentage of IP addresses used per pool ≤ Low Threshold

Important: This command is overridden by the settings of the **alert-threshold** keyword of the **ip pool** command.

Example

The following command configures a context-level IP pool percentage of IP addresses that are used high threshold percentage of *35* and a low threshold of *10* for an system using the Alarm thresholding model:

```
threshold ip-pool-used 35 clear 10
```

threshold monitoring

Enables or disables thresholds alerting for a group of thresholds.

Product

All

Privilege

Security Administrator, Administrator

Syntax

`[ default | no ] threshold monitoring available-ip-pool-group`

`default`

Configures the default setting.

`no`

Disables threshold monitoring for the specified value.

`threshold monitoring available-ip-pool-group`

Enables threshold monitoring for IP pool thresholds at the context level and the IP address pool-level. Refer to the **`threshold available-ip-pool-group`** command, the **`threshold ip-pool-x`** commands and the **`alert-threshold`** keyword of the **`ip pool`** command for additional information on these values.

Usage

Thresholding on the system is used to monitor the system for conditions that could potentially cause errors or outage. Typically, these conditions are temporary (i.e high CPU utilization, or packet collisions on a network) and are quickly resolved. However, continuous or large numbers of these error conditions within a specific time interval may be indicative of larger, more severe issues. The purpose of thresholding is to help identify potentially severe conditions so that immediate action can be taken to minimize and/or avoid system downtime.

Thresholding reports conditions using one of the following mechanisms:

- **SNMP traps:** SNMP traps have been created that indicate the condition (high threshold crossing and/or clear) of each of the monitored values. Complete descriptions and other information pertaining to these traps is located in the starentMIB(8164).starentTraps(2) section of the *SNMP MIB Reference*.

The generation of specific traps can be enabled or disabled on the system allowing you to view only those traps that are most important to you.

- **Logs:** The system provides a facility called threshold for which active and event logs can be generated. As with other system facilities, logs are generated Log messages pertaining to the condition of a monitored value are generated with a severity level of WARNING.
- **Alarm System:** High threshold alarms generated within the specified polling interval are considered "outstanding" until a the condition no longer exists and/or a condition clear alarm is generated.

"Outstanding" alarms are reported to through the system's alarm subsystem and are viewable through the CLI.

The following table indicates the reporting mechanisms supported by each of the above models.

Table 17. Thresholding Reporting Mechanisms by Model

Model	SNMP Traps	Logs	Alarm System
Alert	X	X	
Alarm	X	X	X

Refer to the **`threshold poll`** command in Global Configuration Mode Commands for information on configuring the polling interval over which IP address pool utilization is monitored.

Example

the following command enables threshold monitoring for IP pool thresholds at the context level and the IP address pool-level:

```
threshold monitoring available-ip-pool-group
```

threshold pdsn-service init-rrq-rcvd-rate

Sets an alarm or alert based on the average number of calls setup per second for a PDSN service.

Product

PDSN

Privilege

Security Administrator, Administrator

Syntax

threshold pdsn-service init-rrq-rcvd-rate *high_thresh* **[clear** *low_thresh* **]**

no threshold pdsn-service init-rrq-rcvd-rate

no

Deletes the alert or alarm.

threshold pdsn-service init-rrq-rcvd-rate *high_thresh*

Sets the high threshold average number of calls setup per second that must be met or exceeded within the polling interval to generate an alert or alarm. It can be configured as an integer between 0 and 1000000. Default: 0

clear *low_thresh*

Sets the low threshold average number of calls setup per second that must be met or exceeded within the polling interval to clear an alert or alarm. It can be configured as an integer between 0 and 1000000. Default: 0

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Use this command to set an alert or an alarm when the average number of calls setup per second is equal to or less than a specified number of calls per second.

Alerts or alarms are triggered for the number of calls setup per second based on the following rules:

- **Enter Condition**: Actual number of calls setup per second > High Threshold
- **Clear Condition**: Actual number of calls setup per second ≤ Low Threshold

Example

The following command configures a number of calls setup per second threshold of *1000* and a low threshold of *500* for a system using the Alarm thresholding model:

```
threshold pdsn-service init-rrq-rcvd-rate 1000 clear 500
```

udr-module active-charging-service

Enables creation, configuration and deletion of the User Data Record (UDR) module for the context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] udr-module active-charging-service
```

no

Deletes the UDR module configuration for the current context.

udr-module active-charging-service

Enables the UDR module configuration for the current context.

Usage

Use this command to create the UDR module for the context, and configure the UDR module for active charging service records. You must be in a non-local context when specifying this command, and you must use the same context when specifying the EDR module command.

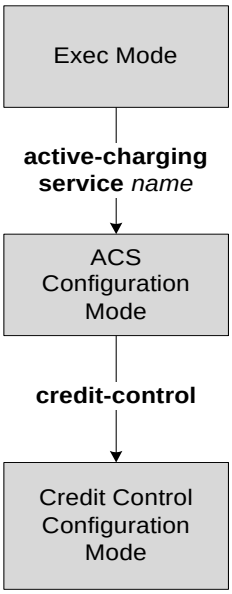
Example

The following command creates the UDR module for the context, and enters the UDR Module Configuration Mode:

```
udr-module active-charging-service
```

Chapter 54
Credit Control Configuration Mode Commands

The Credit Control Configuration Mode is used to configure prepaid services for Diameter/RADIUS applications.



apn-name-to-be-included

This command configures whether the virtual or real Access Point Name (APN) is sent in Credit Control Application (CCA) messaging.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
apn-name-to-be-included { gn | virtual }

default apn-name-to-be-included
```

default

Configures this command with the default setting.
Default: **gn**

gn

Sends the Gn APN name in the CCA messages.

virtual

Sends the virtual APN name, if configured in the APN Configuration Mode, in the CCA messages.

Usage

Use this command to configure the APN information in CCA messages. Virtual APN name can be set to be sent in CCA messages if it is configured in the APN Configuration Mode.

Example

The following command sets the virtual APN name to be sent in CCA message:

```
apn-name-to-be-included virtual
```

app-level-retransmission

This command enables/disables application-level retransmissions with the “T” bit set.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
app-level-retransmission { set-retransmission-bit | unset-retransmission-bit }

default app-level-retransmission
```

default

Configures this command with the default setting.
Default: **unset-retransmission-bit**

set-retransmission-bit

Sets the retransmission bit.

unset-retransmission-bit

Unsets the retransmission bit.

Usage

Use this command to enable application-level transmission with “T” bit set.
'T' bit setting is done only for DIABASE protocol-based rerouting and not for application-based retransmissions. In order to identify such retransmissions, the server expects the T bit to be set at all levels (both DIABASE and application) of retransmission, which can be achieved with this CLI command.

Example

The following command specifies to set retransmission bit:

```
app-level-retransmission set-retransmission-bit
```

diameter dictionary

This command configures the Diameter Credit Control dictionary for the Active Charging Service (ACS).

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter dictionary { dcca-custom1 | dcca-custom10 | dcca-custom11 | dcca-custom12 |
dcca-custom13 | dcca-custom14 | dcca-custom15 | dcca-custom16 | dcca-custom17 | dcca-
custom18 | dcca-custom19 | dcca-custom2 | dcca-custom20 | dcca-custom21 | dcca-custom22 |
dcca-custom23 | dcca-custom24 | dcca-custom25 | dcca-custom26 | dcca-custom27 | dcca-
custom28 | dcca-custom29 | dcca-custom3 |  dcca-custom30 | dcca-custom4 | dcca-custom5 |
dcca-custom6 | dcca-custom7 | dcca-custom8 | dcca-custom9 | standard }

default diameter dictionary
```

default

Configures this command with the default setting.
Default: standard dictionary

dcca-custom1 ... dcca-custom30

Specifies a custom Diameter dictionary.

standard

Specifies the standard Diameter dictionary.
Default: Enabled

Usage

Use this command to select the Diameter dictionary for ACS.

Example

The following command selects the standard Diameter dictionary:

```
diameter dictionary standard
```

diameter dynamic-rules request-quota

This command specifies to request quota immediately in the CCR sent to the Gy interface when the traffic matches the dynamic rules with Online AVP enabled and received over Gx interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter dynamic-rules request-quota { on-traffic-match | on-receiving-rule }

default diameter dynamic-rules request-quota
```

default

Configures this command with the default setting.
Default: **on-receiving-rule**

on-traffic-match

Requests quota only when there is traffic matching the dynamic rules with Online AVP enabled.

on-receiving-rule

Requests quota on receiving a dynamic rule with Online AVP enabled.

Usage

Use this command to request quota when the traffic matches the dynamic rules with Online AVP enabled.

Example

The following command specifies to request quota on receiving a dynamic rule with Online AVP enabled:

```
diameter dynamic-rules request-quota on-receiving-rule
```

diameter fui-redirected-flow

This command enables to control the behavior of marking redirected HTTP flow as free-of-charge.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] diameter fui-redirected-flow allow
```

no

Disables the behavior of marking redirected HTTP flow as free-of-charge.
Default: **diameter fui-redirected-flow allow**

Usage

Use this command to control the behavior of marking redirected HTTP flow as free-of-charge when the Final-Unit-Indication (FUI) Diameter AVP comes without Filter IDs.

Important: Note that the default value, when configured, does not appear in the output of the **show configuration** command output; instead appear only in the output of the **show configuration verbose** command. When the HTTP redirection feature is disabled using the **no diameter fui-redirected-flow allow** command, it will be appear in the output of the **show configuration** command.

Example

The following command specifies to allow the packets free of charge, when matching the redirected-flow:

```
diameter fui-redirected-flow allow
```

diameter gsu-with-only-infinite-quota

This command configures whether to accept/reject CCA messages that contain Granted-Service-Unit AVP with only infinite quota grants from the server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter gsu-with-only-infinite-quota { accept-credit-control-answer | reject-credit-control-answer }

default diameter gsu-with-only-infinite-quota
```

default

Configures this command with the default setting.
Default: **reject-credit-control-answer**

accept-credit-control-answer

Accepts the Credit-Control-Answer message.

reject-credit-control-answer

Rejects the Credit-Control-Answer message.

Usage

Use this command to accept/reject CCA messages that contain the Granted-Service-Unit AVP with only infinite quota grants from the server.

Example

The following command specifies to accept CCA with the Granted-Service-Unit AVP containing only Infinite quota:

```
diameter gsu-with-only-infinite-quota accept-credit-control-answer
```

diameter ignore-returned-rulebase-id

This command configures to accept/ignore the rulebase ID in the Rulebase-Id AVP returned by the Diameter server in CCA messages.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] diameter ignore-returned-rulebase-id
```

default

Configures this command with the default setting.
Default: Accept

no

Accepts the rulebase ID received from Diameter server in CCA.

Usage

Use this command to ignore/accept rulebase ID returned from the Diameter server in CCA.

Example

The following command ignores the rulebase ID returned from the Diameter server in CCA:

```
diameter ignore-returned-rulebase-id
```

diameter ignore-service-id

This command enables to accept/ignore service ID in the Service-Identifier AVP defined in the Diameter dictionaries. This command is applicable to all products that use the Gy interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] diameter ignore-service-id
```

default

Configures this command with the default setting.
Default: Accept

no

Specifies to accepts the service ID.

Usage

Use this command to ignore/accept service ID value in the Service-Identifier AVP in the Diameter dictionaries for Gy interface implementations.
This command can be used to disable the usage of the Service-Identifier AVP for Gy interface implementations even if any of the Diameter dictionaries support the Service-Identifier AVP, and if this AVP should not be used for Gy interactions but must be present in GCDRs/eGCDRs.

Example

The following command specifies to ignore service ID in the Diameter dictionaries:

```
diameter ignore-service-id
```

diameter mscc-final-unit-action terminate

This command enables either to terminate a PDP session immediately when the Final-Unit-Action (FUA) in a particular Multiple Service Credit Control (MSCC) is set as TERMINATE and the quota is exhausted for that service, or to terminate the session after all other MSCCs (categories) have used up their available quota.

Important: This command is available only in 10.2 and later releases.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
diameter mscc-final-unit-action terminate { category | session { on-per-mscc-exhaustion |
on-all-mscc-exhaustion } }

default diameter mscc-final-unit-action terminate
```

default

Configures this command with the default setting.
Default: Same as **diameter mscc-final-unit-action terminate category**

category

This is the standard behavior wherein the category is terminated if the Final-Unit-Indication AVP comes with TERMINATE for a given MSCC.

session { on-per-mscc-exhaustion | on-all-mscc-exhaustion }

Terminates the session depending on the quota usage of one MSCC or all the MSCCs.
on-per-mscc-exhaustion: When the FUA in a particular MSCC is set as TERMINATE and the quota is exhausted for that service, the session will be terminated immediately regardless of the state of the other MSCCs.
on-all-mscc-exhaustion: When the FUA in a particular MSCC is set as TERMINATE and the quota is exhausted for that service, the session termination will be initiated after all the other MSCCs (categories) have used up their available quota. There will no more CCR(U) messages sent requesting quota after receiving the FUA as TERMINATE in the MSCC level.

Usage

Use this command to terminate a PDP session immediately when the FUA in a particular MSCC is set as TERMINATE and the quota is exhausted for that service, or to terminate the session after all other MSCCs (categories) have used up their available quota.

Example

The following command terminates the PDP session after quota exhausts for all MSCCs when MSCC FUA is set to TERMINATE:

```
diameter mscc-final-unit-action terminate session on-all-mscc-exhaustion
```

diameter mscc-per-ccr-update

This command configures sending single/multiple Multiple-Services-Credit-Control (MSCC) AVP in CCR-U messages.

Important: This command is available only in 8.3 and later releases.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter mscc-per-ccr-update { multiple | single }

default diameter mscc-per-ccr-update
```

default

Configures this command with the default setting.
Default: **multiple**

multiple

Sends multiple Multiple-Services-Credit-Control AVP in a single CCR-U message.

single

Sends only one Multiple-Services-Credit-Control AVP in a CCR-U message.

Usage

Use this command to configure sending single/multiple Multiple-Services-Credit-Control AVP in CCR-U messages.

Example

The following command configures sending a single Multiple-Services-Credit-Control AVP in CCR-U messages:

```
diameter mscc-per-ccr-update single
```

diameter origin host

This command is obsolete. See the diameter origin endpoint command.

diameter origin endpoint

This command configures the Diameter Credit Control Origin Endpoint.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter origin endpoint *endpoint_name* **[realm** *realm_name* **]**

no diameter origin endpoint

no

Removes the Diameter Credit Control Origin Endpoint configuration.

endpoint *endpoint_name*

Specifies the Diameter Credit Control Origin Endpoint name as an alphanumeric string of 1 through 63 characters.

realm *realm_name*

Specifies the Diameter Credit Control Realm ID as an alphanumeric string of 1 through 127 characters.

Usage

Use this command to configure the Diameter Credit Control Origin Endpoint.
The endpoint to configure should be pre-configured. For information on creating and configuring a Diameter endpoint, see the **diameter endpoint** command in the Context Configuration mode.

Example

The following command configures a Diameter Credit Control Origin Endpoint named *test*:

```
diameter origin endpoint test
```

diameter peer-select

This command configures the Diameter credit control primary and secondary hosts for DCCA.

Product

All

Privilege

Security Administrator, Administrator

Syntax

In 8.x and earlier releases:

diameter peer-select peer *peer_name* **[realm** *realm_name* **] [secondary-peer** *secondary_peer_name* **[realm** *realm_name* **]] [imsi-based start-value** *imsi_start_value* **end-value** *imsi_end_value* **]**

no diameter peer-select [imsi-based start-value *imsi_start_value* **end-value** *imsi_end_value* **]**

In 9.0 and later releases, for UMTS deployments:

diameter peer-select peer *peer_name* **[realm** *realm_name* **] [secondary-peer** *secondary_peer_name* **[realm** *realm_name* **]] [imsi-based { { prefix | suffix }** *imsi/prefix/suffix_start_value* **} [to** *imsi/prefix/suffix_end_value* **]] [msisdn-based { { prefix | suffix }** *msisdn-based/prefix/suffix_start_value* **} [to** *msisdn-based/prefix/suffix_end_value* **]]**

no diameter peer-select [imsi-based { { prefix | suffix } *imsi/prefix/suffix_start_value* **} [to** *imsi/prefix/suffix_end_value* **]] | [msisdn-based { { prefix | suffix }** *msisdn-based/prefix/suffix_start_value* **} [to** *msisdn-based/prefix/suffix_end_value* **]]**

no

Removes previously configured Diameter credit control peer selection setting.

peer *peer_name*

Specifies the primary host name. as an alphanumeric string of 1 through 63 characters that can contain punctuation characters.

imsi-based start-value *imsi_start_value* **end-value** *imsi_end_value*

Important: This section applies only to 8.3 and earlier releases.

Specifies peer selection based on International Mobile Subscriber Identification (IMSI) range. **start-value** *imsi_start_value* specifies the start of range in integer value of IMSI, and **end-value** *imsi_end_value* specifies the end of range in integer value of IMSI.

imsi-based { { prefix | suffix } *imsi/prefix/suffix_start_value* } [to *imsi/prefix/suffix_end_value*]

Important: This section applies only to 9.0 and later releases for UMTS deployments.

Selects peer based on IMSI prefix or suffix or IMSI range.
prefix: Specifies the prefix range
suffix: Specifies the suffix range
imsi/prefix/suffix_start_value: Specifies the IMSI/prefix/suffix start value. *prefix/suffix* must be an IMSI prefix/suffix, and must be an integer from 1 through 15 characters.
imsi/prefix/suffix_end_value: Specifies the IMSI/prefix/suffix end value. *prefix/suffix* must be an IMSI prefix/suffix, and must be an integer from 1 through 15 characters that must be greater than the start value.

Important: If prefix/suffix is used, the lengths of both start and end prefix/suffix must be equal. If the **prefix** or **suffix** keyword is not specified, it will be considered as suffix.

msisdn-based { { prefix | suffix } *msisdn/prefix/suffix_start_value* } [to *msisdn/prefix/suffix_end_value*]

Specifies peer selection based on MSISDN prefix or suffix or MSISDN range.
prefix: Specifies the prefix range
suffix: Specifies the suffix range
msisdn/prefix/suffix_start_value: Specifies the MSISDN/prefix/suffix start value. *prefix/suffix* must be an MSISDN prefix/suffix, and must be an integer from 1 through 15 characters.
msisdn/prefix/suffix_end_value: Specifies the MSISDN/prefix/suffix end value. *prefix/suffix* must be an MSISDN prefix/suffix, and must be an integer from 1 through 15 characters that must be greater than the start value.

realm *realm_name*

The *realm_name* must be an alphanumeric string of 1 through 127 characters, and can contain punctuation characters. The realm may typically be a company or service name.

secondary-peer *secondary_peer_name*

Specifies a name for the secondary host to be used for failover processing. When the route-table does not find an AVAILABLE route, the secondary host performs a failover processing if the diameter session failover command is set.
secondary_peer_name must be an alphanumeric string of 1 through 63 characters, and can contain punctuation characters.

Usage

Use this command to configure Diameter credit control host selection.
If the **diameter peer-select** command is not configured, and if multiple peers are configured in the endpoint, the available peers configured in the endpoint are automatically chosen in a load-balanced round-robin manner.
StarOS 9.0 and later releases support peer selection using prefix or suffix of IMSI or IMSI range. Subscribers are now assigned to a primary OCS instance based on the value of the IMSI prefix or suffix of a length of 1 to 15 digits. If the prefix or suffix keyword is not specified, it will be considered as suffix. Up to 64 peer selects

can be configured. At a time either prefix or suffix mode can be used in one DCCA config. If prefix or suffix mode is used, the lengths of all prefix/suffix must be equal.
In 12.2 and later releases, Diameter peer selection can also be performed based on the configurable prefix or suffix of MSISDN or MSISDN range.
Each primary OCS may have a designated secondary OCS in case of failure of the primary. It will be the responsibility of the GGSN to use the appropriate secondary OCS in case of primary failure. The secondary OCS for each primary OCS will be one of the existing set of OCSs.

Example

The following command configures a Diameter credit control peer named *test* and the realm *companyx*:

```
diameter peer-select peer test realm companyx
```

The following command configures IMSI-based Diameter credit control peer selection in the IMSI range of *1234567890* to *1234567899*:

```
diameter peer-select peer star imsi-based start-value 1234567890 end-
value 1234567899
```

The following command configures IMSI-based DCCA peer selection with IMSI suffix of *100* through *200*:

```
diameter peer-select peer test_peer realm test_realm secondary-peer
test_sec_realm realm test_realm2 imsi-based suffix 100 to 200
```

diameter pending-timeout

This command configures the maximum time period to wait for response from a Diameter peer.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter pending-timeout *duration*

default diameter pending-timeout

default

Disables DCCA resending message at pending-timeout.

duration

Specifies the timeout duration (in seconds). The value must be an integer from 1 through 300.

after-expiry-try-secondary-host

This keyword is deprecated. This can now be managed using the **retry-after-tx-expiry** and **go-offline-after-tx-expiry** keywords in the failure-handling command.

Usage

Use this command to set the maximum time for Diameter credit control to receive a response from its peer. DCCA refers to this as the Tx Timer. Typically, this should be configured to a value smaller than the response-timeout value of Diameter Endpoint Configuration Mode. That value is typically too large for DCCA's purposes.

If DCCA gets a “no available routes” error before pending-timeout expires, then DCCA tries to send to the secondary host (if one has been configured). If DCCA gets no response and pending-timeout expires, then DCCA either tries the secondary host or gives up. This can now be managed using the failure-handling command.

If routing has failed, i.e., the attempt to the primary host, as well as, the attempt to the secondary host (if that has been configured), then the processing configured by the failure-handling command is performed.

The routing (i.e., returning a good response, no response or an error response such as "no available routes") is controlled by Diameter Endpoint Configuration Mode. That uses a watchdog timer (called Tw Timer) to attempt a different route to a host. Multiple routes could be attempted. If there's no response before the endpoint's configured response-timeout expires, then "no available routes" is the routing result. The routing logic remembers the status of routes, so it can return "no available routes" immediately, without using any timers.

The default case will disable DCCA resending message at Tx (pending-timeout). So messages are retried only at Tw (device watchdog timeout) by diabase or at response-timeout by DCCA.

Example

The following command configures a Diameter Credit Control Pending Timeout setting of *20* seconds:

```
diameter pending-timeout 20
```

diameter result-code

This command enables sending a GTP Create-PDP-Context-Rsp message with cause code based on the DCCA result code.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter result-code { authorization-rejected | credit-limit-reached | end-user-service-denied | user-unknown } use-gtp-cause-code { authentication-failure | no-resource-available | system-failure }

default diameter result-code { authorization-rejected | credit-limit-reached | end-user-service-denied | user-unknown } use-gtp-cause-code

default

Configures this command with the default setting.
In 12.1 and earlier releases: **no-resource-available**
In 12.2 and later releases: **system-failure**

authorization-rejected

Result code received as DIAMETER_AUTHORIZATION_REJECTED(5003).

credit-limit-reached

Result code received as DIAMETER_CREDIT_LIMIT_REACHED(4012).

end-user-service-denied

Result code received as DIAMETER_END_USER_DENIED(4010).

user-unknown

Result code received as DIAMETER_USER_UNKNOWN(5030).

use-gtp-cause-code

Cause code to be sent in GTP response.

authentication-failure

Sends the GTP cause code GTP_USER_AUTHENTICATION_FAILED in GTP response.

no-resource-available

Sends the GTP cause code GTP_NO_RESOURCES_AVAILABLE in GTP response.

system-failure

Sends the GTP cause code GTP_SYSTEM_FAILURE in GTP response.

Usage

On receiving result-code as AUTHORIZATION-REJECTED, CREDIT_LIMIT_REACHED, END_USER_DENIED or USER_UNKNOWN from DCCA server, based on this CLI configuration, in GTP Create-PDP-Context Response message the cause code can either be sent as GTP_NO_RESOURCE_AVAILABLE or GTP_AUTHENTICATION_FAILED or GTP_SYSTEM_FAILURE.

Example

The following command sets the deny cause as user authentication failure when the CCA-Initial has the result code DIAMETER_AUTHORIZATION_REJECTED(5003):

```
diameter result-code authorization-rejected use-gtp-cause-code
authentication-failure
```

diameter send-ccri

This command configures when to send an initial Credit Control Request (CCR-I) for the subscriber session.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter send-ccri { session-start | traffic-start }

default diameter send-ccri
```

default

Configures this command with the default setting.
Default: **session-start**

session-start

Sends CCR-I when the PDP context is being established (on receiving Create-PDP-Context-Request).

traffic-start

Delays sending CCR-I until the first data packet received from the subscriber.

Usage

Use this command to configure when to send CCR-Initial for the subscriber session.

Example

The following command configures to send CCR-I on traffic detection and not on context creation:

```
diameter send-ccri traffic-start
```

diameter service-context-id

This command configures the value to be sent in the Service-Context-Id AVP, which identifies the context in which DCCA is used.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter service-context-id *service_context_id*

default diameter service-context-id

default

Configures this command with the default setting. Currently, the default value is encoded based on the dictionary wherever applicable; when not applicable, it is not encoded.

service_context_id

Specifies the service context as an alphanumeric string of 1 through 63 characters that can contain punctuation characters.

Usage

If Service-Context-Id is applicable and configured using this command, it will be sent in the AVP Service-Context-Id in the Diameter CCR message.

Example

The following command specifies the value *version@customer.com* to be sent in the Service-Context-Id AVP in the Diameter CCR message:

```
diameter service-context-id version@customer.com
```

diameter session failover

This command enables/disables Diameter Credit Control Session Failover. When enabled, the secondary peer is used in the event the main peer is unreachable.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] diameter session failover
```

default

Configures this command with the default setting.
Default: Depends on the **failure-handling** configuration

no

If the primary server is not reachable, failover is not triggered and the session is torn down. No failover action is taken.

Usage

Use this command to enable/disable Diameter Credit Control Session Failover.
The failure-handling configuration comes into effect only if **diameter session failover** is present in the configuration. The failover can be overridden by the server in the response message, and it takes precedence.

Example

The following command enables Diameter Credit Control Session Failover:

```
diameter session failover
```

diameter update-dictionary-avps

This command enables dictionary control of the AVPs that need to be added based on the version of the specification with which the Online Charging System (OCS) is compliant. This command is applicable to all products that use the dcca-custom8 dictionary for Gy interface implementation.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter update-dictionary-avps { 3gpp-rel8 | 3gpp-rel9 }

[ default | no ] diameter update-dictionary-avps
```

default | no

Configures this command with the default setting.
Default: Compliant with the oldest release (Rel. 7) and send only Rel. 7 AVPs

3gpp-rel8

Select the 3GPP Rel. 8 AVPs for encoding.

3gpp-rel9

Selects the 3GPP Rel. 9 AVPs for encoding.

Usage

Important: This command is applicable ONLY to the dcca-custom8 dictionary. If, for any dictionary other than dcca-custom8, this command is configured with a value other than the default, configuration errors will be indicated in the output of the **show configuration errors section active-charging** command.

Use this command to encode the AVPs in the dictionary based on the release version of the specification to which the OCS is compliant with.

Example

The following command enables encoding of AVPs in the dictionary based on 3GPP Rel. 9:

```
diameter update-dictionary-avps 3gpp-rel9
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

failure-handling

This command configures Diameter Credit Control Failure Handling (CCFH) behavior in the event of communication failure with the prepaid server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
failure-handling { initial-request | terminate-request | update-request } { continue [
go-offline-after-tx-expiry | retry-after-tx-expiry ] | retry-and-terminate [ retry-after-
tx-expiry ] | terminate }

default failure-handling [ initial-request | terminate-request | update-request ]
```

---

default failure-handling [initial-request | terminate-request | update-request]

Configures the default CCFH setting.
initial-request: The default setting is **terminate**.
update-request: The default setting is **retry-and-terminate**.
terminate-request: The default setting is **retry-and-terminate**.

---

initial-request

Specifies the message type as CCR-Initial.

---

terminate-request

Specifies the message type as CCR-Terminate.

---

update-request

Specifies the message type as CCR-Update.

---

continue

Specifies the CCFH setting as continue. The online session is converted into an offline session. The associated PDP Context is established (new sessions) or not released (ongoing sessions).

---

retry-and-terminate

Specifies the CCFH setting as retry-and-terminate. The user session will continue for the duration of one retry attempt with the prepaid server. If there is no response from both primary and secondary servers, the session is torn down.

---

terminate

Specifies the CCFH setting as terminate. All type of sessions (initial or update) are terminated in case of failure.

go-offline-after-tx-expiry

Starts offline charging after Tx expiry.

retry-after-tx-expiry

Retries after Tx expiry. Enables secondary-host, if up, to take over after Tx expiry.

Usage

Use this command to select the CCFH behavior. The specified behavior is used for sessions when no behavior is specified by the prepaid server. By default, the CCFH is taken care at response-timeout except for terminate setting.
If the Credit-Control-Failure-Handling AVP is received from the server, the received setting will be applied to all the message types.
The following table indicates the CCFH behavior for the combination of different CCFH settings, and the corresponding CLI commands.

CCFH Setting	CLI Command	Behavior at Tx	Behavior at RT	Secondary is Up	Secondary is Down
Initial-request Message Type					
Continue	**initial-request continue**	N/A	Continue	Secondary takes over after RT	Offline after another RT. No more quota requests are performed for any rating group within the session after DCCA failure (even if connectivity to DCCA is restored)
	initial-request continue go-offline-after-tx-expiry	Offline	N/A	Offline at Tx	Offline at Tx
	initial-request continue retry-after-tx-expiry	Continue	N/A	Secondary takes over after Tx	Offline after another Tx
Retry-and-terminate	**initial-request retry-and-terminate**	N/A	Retry	Secondary takes over after RT	Terminate after another RT
	initial-request retry-and-terminate retry-after-tx-expiry	Retry	N/A	Secondary takes over after Tx	Terminate after another Tx
Terminate	**initial-request terminate**	Terminate	N/A	Terminate after Tx	Terminate after Tx
Update-request Message Type					
Continue	**update-request continue**	N/A	Continue	Secondary takes over after RT	Offline after another RT
	update-request continue go-offline-after-tx-expiry	Offline	N/A	Offline at Tx	Offline at Tx

CCFH Setting	CLI Command	Behavior at Tx	Behavior at RT	Secondary is Up	Secondary is Down
	update-request continue retry-after-tx-expiry	Continue	N/A	Secondary takes over after Tx	Offline after another Tx
Retry-and-terminate	**update-request retry-and-terminate**	N/A	Retry	Secondary takes over after RT	Sends CCR-T after another RT
	update-request retry-and-terminate retry-after-tx-expiry	Retry	N/A	Secondary takes over after Tx	Sends CCR-T after another Tx
Terminate	**update-request terminate**	Terminate	N/A	Sends CCR-T after Tx	Sends CCR-T after Tx
Terminate-request Message Type					
Continue	**terminate-request continue**	N/A	Retry	CCR-T is sent to secondary after RT	Terminate after another RT
	terminate-request continue go-offline-after-tx-expiry	Retry	N/A	CCR-T is sent to secondary after Tx	Terminate after another Tx
	terminate-request continue retry-after-tx-expiry	Retry	N/A	CCR-T is sent to secondary after Tx	Terminate after another Tx
Retry-and-terminate	**terminate-request retry-and-terminate**	N/A	Retry	CCR-T is sent to secondary after RT	Terminate after another RT
	terminate-request retry-and-terminate retry-after-tx-expiry	Retry	N/A	CCR-T is sent to secondary after Tx	Terminate after another Tx
Terminate	**terminate-request terminate**	Terminate	N/A	Terminate after Tx	Terminate after Tx

Example

The following command sets the Credit Control Failure Handling behavior for initial request message type to **retry-and-terminate**:

```
failure-handling initial-request retry-and-terminate
```

mode

This command configures the Prepaid Credit Control mode to RADIUS or Diameter.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
mode { diameter | radius }

default mode
```

default

Configures the default prepaid credit control mode.
Default: **diameter**

diameter

Enables Diameter Credit Control Application (DCCA) for prepaid charging.

radius

Enables RADIUS Credit Control for prepaid charging.

Usage

Use this command to configure the prepaid charging application mode to Diameter or RADIUS credit control.

Example

The following command specifies to use RADIUS prepaid credit control application:

```
mode radius
```

pending-traffic-treatment

This command controls the pass/drop treatment of traffic while waiting for definitive credit information from the server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
pending-traffic-treatment { { { forced-reauth | trigger | validity-expired } drop | pass
} | { { noquota | quota-exhausted } buffer | drop | limited-pass volume | pass } }

default pending-traffic-treatment { forced-reauth | noquota | quota-exhausted | trigger |
validity-expired }
```

default

Configures this command with the default setting.
Default: **drop**

forced-reauth

Sets the Diameter credit control pending traffic treatment to forced reauthorization.

trigger

Sets the Diameter credit control pending traffic treatment to trigger.

validity-expired

Sets the Diameter credit control pending traffic treatment to validity expired.

noquota

Sets the Diameter credit control pending traffic treatment to no quota.

quota-exhausted

Sets the Diameter credit control pending traffic treatment to quota exhausted.

buffer

Specifies to tentatively count/time traffic, and then buffer traffic pending arrival of quota. Buffered traffic will be forwarded and fully charged against the quota when the quota is eventually obtained and the traffic is passed.

drop

Drops any traffic when there is no quota present.

limited-pass *volume*

Enables limited access for subscribers when the OCS is unreachable.
volume specifies the Default Quota size (in bytes) and must be an integer from 1 through 4294967295.

This feature allows the subscriber to use the network when the OCS response is slow. This configuration enables to set a Default Quota size from which the subscriber can consume quota until response from the OCS arrives. The traffic consumed by the subscriber from the Default Quota at the beginning of the session is reported and counted against the quota assigned from the OCS.
Default Quota is not used for subsequent credit requests.
If the Default Quota is NOT exhausted before the OCS responds with quota, traffic is allowed to pass. Initial Default Quota usage is counted against initial quota allocated. If quota allocated is less than the actual usage, the actual usage and request additional quota are reported. If no additional quota is available, the traffic is denied.
If the Default Quota is NOT exhausted before the OCS responds with denial of quota, traffic is blocked after the OCS response. The gateway will report usage on Default Quota even in for CCR-U (FINAL) or CCR-T until the OCS responds.
If the Default Quota is exhausted before the OCS responds, the session is dropped.
The default pending-traffic-treatment for **noquota** is drop. The **default pending-traffic-treatment noquota** command removes any Default Quota limit configured.

pass

Passes all traffic more or less regardless of quota state.

Usage

Use this command to set the Diameter credit control pending traffic treatment while waiting for definitive credit information from the server.
This CLI command is different than the **failure-handling** command, which specifies behavior in the case of an actual timeout or error, as opposed to the behavior while waiting. See also the **buffering-limit** command in the Active Charging Service Configuration Mode.

Example

The following command sets the Diameter credit control pending traffic treatment to drop any traffic when there is no quota present:

```
pending-traffic-treatment noquota drop
```

quota

This command sets various time-based quotas in the prepaid credit control service.

Product

All

Privilege

Security Administrator, Administrator

Syntax

quota *holding_time* **| validity-time** *validity_time* **}**

{ default | no } quota { holding-time | validity-time }

holding-time *holding_time*

Specifies the Quota Holding Time (QHT) in seconds. The value must be an integer from 1 through 4000000000.

validity-time *validity_time*

Specifies the validity lifetime of the quota, in seconds. The value must be an integer from 1 through 65535.

Usage

Use this command to set the prepaid credit control quotas.

Example

The following command sets the prepaid credit control request holding time to *30000* seconds:

```
quota holding-time 30000
```

quota request-trigger

This command configures the action on the packet that triggers the credit control application to request quota.

Product

All

Privilege

Security Administrator, Administrator

Syntax

quota request-trigger { exclude-packet-causing-trigger | include-packet-causing-trigger }

{ default | no } quota request-trigger

default quota request-trigger

Configures this command with the default setting. Default: **include-packet-causing-trigger**

no

Same as the **default quota request-trigger** command.

Important: In 10.0 and later releases, this keyword is deprecated.

exclude-packet-causing-trigger

Excludes the packet causing threshold limit violation trigger.

include-packet-causing-trigger

Includes the packet causing the threshold limit violation trigger.

Usage

Use this command to configure action on the packet that triggers the credit control application to request quota, whether the packet should be excluded/included in the utilization information within the quota request.

Example

The following command sets the system to exclude the packets causing threshold limit triggers from accounting of prepaid credit of a subscriber:

```
quota request-trigger exclude-packet-causing-trigger
```

quota time-threshold

This command configures the time threshold limit for subscriber quota in the prepaid credit control service.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
quota time-threshold { abs_time_value | percent percent_value }

{ default | no } quota time-threshold
```

default

Configures this command with the default setting.
Default: Disabled

no

Disables time threshold for prepaid credit control quota.

abs_time_value

Specifies the absolute threshold time (in seconds) for configured time quota in prepaid credit control charging. *abs_time_value* must be an integer from 1 through 86400. To disable this assign 0. Default: 0 (Disabled)

percent_value

Specifies the time threshold value as a percentage of the configured time quota in DCCA. *percent_value* must be an integer from 1 through 100.

Usage

Use this command to set the time threshold for prepaid credit control quotas.

Example

The following command sets the prepaid credit control time threshold to *400* seconds:

```
quota time-threshold 400
```

quota units-threshold

This command sets the unit threshold limit for subscriber quota in the prepaid credit control service.

Product

All

Privilege

Security Administrator, Administrator

Syntax

quota unit-threshold { *abs_unit_value* **| percent** *percent_value* **}**

{ default | no } quota units-threshold

default

Configures this command with the default setting.
Default: Disabled

no

Disables unit threshold for DCCA quota.

abs_unit_value

Specifies the absolute threshold value (in units) for the configured units quota in prepaid credit control application. *abs_unit_value* must be an integer from 1 through 4000000000. To disable this assign 0.
Default: 0 (Disabled)

percent_value

Specifies the time threshold value as a percentage of the configured units quota in DCCA. *percent_value* must be an integer from 1 through 100.

Usage

Use this command to set the units threshold for prepaid credit control quotas.

Example

The following command sets the prepaid credit control time threshold to *160400* units:

```
quota units-threshold 160400
```

quota volume-threshold

This command sets the volume threshold limit for subscriber quota in the prepaid credit control service.

Product

All

Privilege

Security Administrator, Administrator

Syntax

quota volume-threshold { *abs_vol_value* | percent *percent_value* }

{ default | no } quota volume-threshold

default

Configures this command with the default setting.
Default: Disabled

no

Disables volume threshold for prepaid credit control quota.

abs_vol_value

Specifies the absolute threshold volume (in bytes) to the configured volume quota in prepaid credit control. *abs_vol_value* must be an integer from 1 through 4000000000. To disable this assign 0. Default: 0 (Disabled)

percent *percent_value*

Specifies the volume threshold value as a percentage of the configured volume quota in prepaid credit control. *percent_value* must be an integer from 1 through 100.

Usage

Use this command to set the volume threshold for prepaid credit control quotas.

Example

The following command sets the prepaid credit control volume threshold to *160400* bytes:

```
quota volume-threshold 160400
```

radius usage-reporting-algorithm

This command configures the usage reporting algorithm for RADIUS prepaid using the Diameter Credit-Control Application (DCCA).

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
radius usage-reporting-algorithm { cumulative | relative }

default radius usage-reporting-algorithm
```

default

Configures this command with the default setting.
Default: **cumulative**

cumulative

Reports the total accumulated usage of quota in every accounting interim.

relative

Reports the quota usage per accounting interim (since the previous usage report).

Usage

Use this command to configure the usage reporting algorithm for RADIUS prepaid using DCCA.

Example

The following command configures the usage reporting algorithm for RADIUS prepaid using DCCA to *relative*:

```
radius usage-reporting-algorithm relative
```

redirect-indicator-received

This command configures the action on buffered packets when a redirect-indicator is received from the RADIUS server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
redirect-indicator-received { discard-buffered-packet | reprocess-buffered-packet }

{ default | no } redirect-indicator-received
```

default

Configures this command with the default setting. Default: **discard-buffered-packet**

no

Disables the redirect-indicator-received configuration.

discard-buffered-packet

Discards the buffered packet.

reprocess-buffered-packet

Redirects the buffered packet on receiving a redirect-indicator from the RADIUS server.

Usage

Use this command to configure the action taken on buffered packet when redirect-indicator is received. Diameter can return a redirect URL but not a redirect indicator, however RADIUS can return a redirect indicator. In this situation, any subsequent subscriber traffic would match ruledefs configured with cca redirect-indicator, and charging actions that have flow action redirect-url should be configured. However, some handsets do not retransmit, so there will be no subsequent packets. On configuring reprocess-buffered-packet, the ruledefs are reexamined to find a new charging action, which may have flow action redirect-url configured.

Example

The following command configures the action taken on buffered packet when redirect-indicator is received to reprocess-buffered-packet:

```
redirect-indicator-received reprocess-buffered-packet
```

servers-unreachable

This command configures whether to continue or terminate calls when Diameter server(s) or the OCS become unreachable.

Product

All

Privilege

Security Administrator, Administrator

Syntax

In 12.1 and earlier releases:

```
servers-unreachable { initial-request { continue | terminate [ after-timer-expiry timeout_period ] } | update-request { continue | terminate [ after-quota-expiry | after-timer-expiry timeout_period ] } }

no servers-unreachable { initial-request | update-request }
```

In 12.2 and later releases:

```
servers-unreachable { behavior-triggers { initial-request | update-request } transport-failure [ response-timeout | tx-expiry ] | initial-request { continue [ { [ after-interim-timetimeout_period ] [ after-interim-volume quota_value ] } server-retries retry_count ] | terminate [ { [ after-interim-time timeout_period ] [ after-interim-volume quota_value ] } server-retries retry_count | after-timer-expiry timeout_period ] } | update-request { continue [ { [ after-interim-time timeout_period ] [ after-interim-volume quota_value ] } server-retries retry_count ] | terminate [ { [ after-interim-time timeout_period ] [ after-interim-volume quota_value ] } server-retries retry_count ] | after-quota-expiry | after-timer-expiry timeout_period ] } }

no servers-unreachable { initial-request | update-request }

default servers-unreachable behavior-triggers { initial-request | update-request }
```

no

Deletes the current servers-unreachable configuration.

behavior-triggers { initial-request | update-request } transport-failure [response-timeout | tx-expiry]

This keyword is used to determine when to apply server-unreachable action. This supports three configurable options to apply server-unreachable action either at transport failure, Tx expiry or at response timeout. Out of these three options, the transport failure is the default option.

- **initial-request**: Specifies the behavior when Diameter server(s)/OCS become unreachable during initial session establishment.
- **update-request**: Specifies the behavior when Diameter server(s)/OCS become unreachable during mid-session.
- **transport-failure [response-timeout | tx-expiry]**: Specifies to trigger the behavior either at transport failure, response timeout or at Tx expiry.

initial-request { continue | terminate [after-timer-expiry *timeout_period* **] }**

Important: This section applies only to 12.1 and earlier releases.

Specifies behavior when Diameter server(s)/OCS become unreachable during initial session establishment.

- **continue**: Specifies to continue call if Diameter server(s) becomes unreachable.
- **terminate [after-timer-expiry** *timeout_period* **]**: Specifies to terminate call if Diameter server(s) becomes unreachable.

  after-timer-expiry *timeout_period*: Specifies to terminate call after timeout period expires.

  timeout_period specifies the timeout period, in seconds, and must be an integer from 1 through 4294967295.

initial-request { continue [{ [after-interim-time *timeout_period* **] [after-interim-volume** *quota_value* **] } server-retries** *retry_count* **] | terminate [{ [after-interim-time** *timeout_period* **] [after-interim-volume** *quota_value* **] } server-retries** *retry_count* **] | after-timer-expiry** *timeout_period* **}**

Important: This section applies only to 12.2 and later releases.

Specifies behavior when Diameter server(s)/OCS become unreachable during initial session establishment.

- **continue**: Specifies to continue call if Diameter server(s) becomes unreachable.
- **terminate**: Specifies to terminate call if Diameter server(s) becomes unreachable.
  - **after-interim-time** *timeout_period*: Specifies to continue or terminate call after the interim timeout period expires.

    timeout_period specifies the timeout period, in seconds, and must be an integer from 1 through 4294967295.
  - **after-interim-volume** *quota_value*: Specifies to continue or terminate call on exhaustion of the assigned quota.

    quota_value specifies the volume-based quota value, in bytes, and must be an integer from 1 through 4294967295.

    The **after-interim-volume** and **after-interim-time** can be configured in one of the following ways:
    - **after-interim-volume** *quota_value* **server-retries** *retry_count*
    - **after-interim-time** *timeout_period* **server-retries** *retry_count*
    - **after-interim-volume** *quota_value* **after-interim-time** *timeout_period* **server-retries** *retry_count*
  - **after-timer-expiry** *timeout_period*: Specifies to terminate call after timeout period expires.

    timeout_period specifies the timeout period, in seconds, and must be an integer from 1 through 4294967295.
  - **server-retries** *retry_count*: Specifies the number of retries that should happen to OCS before allowing the session to terminate/offline.

retry_count specifies the retries to OCS, and must be an integer from 0 through 65535. If the value 0 is defined for this keyword, the retry to OCS will not happen instead the configured action will be immediately applied.

update-request { continue | terminate [after-quota-expiry | after-timer-expiry *timeout_period* **] }**

Important: This section applies only to 12.1 and earlier releases.

Specifies behavior when Diameter server(s)/OCS become unreachable during mid session.

- **continue**: Specifies to continue call if Diameter server(s) becomes unreachable.
- **terminate [after-quota-expiry | after-timer-expiry** *timeout_period* **]**: Specifies to terminate call if Diameter server(s) becomes unreachable.
  - **after-quota-expiry**: Specifies to terminate call on exhaustion of all available quota.
  - **after-timer-expiry** *timeout_period*: Specifies to terminate call after timeout period expires.

    timeout_period specifies the timeout period, in seconds, and must be an integer from 1 through 4294967295.

update-request { continue [{ [after-interim-time *timeout_period* **] [after-interim-volume** *quota_value* **] } server-retries** *retry_count* **] | terminate [{ [after-interim-time** *timeout_period* **] [after-interim-volume** *quota_value* **] } server-retries** *retry_count* **] | after-quota-expiry | after-timer-expiry** *timeout_period* **] }**

Important: This section applies only to 12.2 and later releases.

Specifies behavior when Diameter server(s)/OCS become unreachable during mid session.

- **continue**: Specifies to continue call if Diameter server(s) becomes unreachable.
- **terminate**: Specifies to terminate call if Diameter server(s) becomes unreachable.
  - **after-interim-time** *timeout_period*: Specifies to continue or terminate call after the interim timeout period expires.

    timeout_period specifies the timeout period, in seconds, and must be an integer from 1 through 4294967295.
  - **after-interim-volume** *quota_value*: Specifies to continue or terminate call on exhaustion of the assigned quota.

    quota_value specifies the volume-based quota value, in bytes, and must be an integer from 1 through 4294967295.

    The **after-interim-volume** and **after-interim-time** can be configured in one of the following ways:

    - **after-interim-volume** *quota_value* **server-retries** *retry_count*
    - **after-interim-time** *timeout_period* **server-retries** *retry_count*
    - **after-interim-volume** *quota_value* **after-interim-time** *timeout_period* **server-retries** *retry_count*

- **after-quota-expiry**: Specifies to terminate call on exhaustion of all available quota.
- **after-timer-expiry** *timeout_period*: Specifies to terminate call after timeout period expires.

  timeout_period specifies the timeout period, in seconds, and must be an integer from 1 through 4294967295.
- **server-retries** *retry_count*: Specifies the number of retries that should happen to OCS before allowing the session to terminate/offline.

  retry_count specifies the retries to OCS, and must be an integer from 0 through 65535. If the value 0 is defined for this keyword, the retry to OCS will not happen instead the configured action will be immediately applied.

Usage

Use this command to configure whether to continue/terminate calls when Diameter server(s)/OCS are unreachable. This command can be used to verify the functionality of the configurable action if the OCS becomes unreachable.
In 12.1 and earlier releases, the OCS is considered down/unreachable when all transport/TCP connections are down for that OCS.
In 12.2 and later releases, the OCS is declared unreachable when all transport connections are down OR message timeouts happen (for example, a Tx expiry or response timeout, for all available OCS servers) owing to slow response from the OCS (may be due to network congestion or other network related issues).
The following set of actions are performed if the servers become unreachable:

- During initial session establishment:
  - Block traffic: Terminate the session.
  - Continue call: Continue by making the session offline.
  - Pass traffic until timer expiration post which terminates the call: Session would be offline while the timer is running.
  - Pass traffic until interim time expiration post which continues or terminates the call: Session would be offline while the timer is running.
  - Pass traffic until interim volume expiration post which continues or terminates the call: Session would be offline while the timer is running.
- During mid session:
  - Block traffic: Terminate the session.
  - Continue call: Continue by making the session offline.
  - Run out of session quota post which terminates the call.
  - Pass traffic until timer expiration post which terminates the call: Session would be offline while the timer is running.
  - Pass traffic until interim time expiration post which continues or terminates the call: Session would be offline while the timer is running.
  - Pass traffic until interim volume expiration post which continues or terminates the call: Session would be offline while the timer is running.

This command works on the same lines as the **failure-handling** command, which is very generic for each of the xxx-request and applies for Credit-Control-Failure-Handling (CCFH) during:

1. Application-level (Tx) timeout: Here message is sent out but server does not respond for the configured “pending-timeout” so application does CCFH actions.

2. Diabase-level request timeout: Here message is sent out but server does not respond and Diabase detects timeout of the application message and application does CCFH actions.
3. TCP connection error: Here message is NOT sent out due to no TCP connection and application does CCFH actions.

This CLI command is specifically for TCP connection error. The administrator can configure both of the following commands:

failure-handling initial-request continue

servers-unreachable initial-request terminate after-timer-expiry *30*

For conditions 1 and 2 described above, the **failure-handling** command will be applied, whereas for condition 3 both **failure-handling** and/or **servers-unreachable** commands can be used. This way, the operator has the flexibility to configure CCFH independent of OCS-unreachable feature, that is have two different failure handlings for same request types (as illustrated in the example above.)

Important: Please note that the flexibility to configure CCFH independent of OCS-unreachable feature is applicable only to 12.1 and earlier releases. In 12.2 and later releases, if configured, the **servers-unreachable** takes precedence over the **failure-handling** command.

If server returns the CC-Failure-Handling AVP, it would apply for conditions 1 and 2 described above. It would also apply for condition 3 if the **servers-unreachable** command is not configured. But, if configured it would take the highest precedence for all Diabase errors scenarios.

This command can also be used to control the triggering of behavior based on either due to transport failure, response message timeouts or Tx expiry when OCS becomes unreachable. The transport failure could be due to no TCP connection and the message timeout could be due to network congestion or any other network related issues.

The following are the possible and permissible configurations with respect to behavior triggering:

- **servers-unreachable behavior-triggers { initial-request | update-request } transport-failure**
- **servers-unreachable behavior-triggers { initial-request | update-request } transport-failure response-timeout**
- **servers-unreachable behavior-triggers { initial-request | update-request } transport-failure tx-expiry**

Of these configurations, the first one is considered to be the default configuration and it will take care of backward compatibility.

Example

The following command configures to terminate initial request calls if Diameter servers/OCS becomes unreachable after a timeout period of *1111* seconds:

```
servers-unreachable initial-request terminate after-timer-expiry 1111
```

timestamp-rounding

This command configures how to convert exact time into the units that are used in quotas.

Product

ACS

Privilege

Security Administrator, Administrator

Syntax

```
timestamp-rounding { ceiling | floor | roundoff }

default timestamp-rounding
```

default

Configures the default timestamp-rounding setting.
Default: **roundoff**

timestamp-rounding ceiling

Round off to the smallest integer greater than the fraction.
If the fractional part of the seconds is greater than 0, add 1 to the number of seconds and discard the fraction.

timestamp-rounding floor

Discard the fractional part of the second.

timestamp-rounding roundoff

Set the fractional part of the seconds to the nearest integer value. If the fractional value is greater than or equal to 0.5, add 1 to the number of seconds and discard the fractional part of second.

Usage

Use this command to configure how to convert exact time into the units that are used in quotas for CCA charging.
The specified rounding will be performed before system attempts any calculation. For example using round-off, if the start time is 1.4, and the end time is 1.6, then the calculated duration will be 1 (i.e., 2 – 1 = 1).

Example

The following command sets the CCA timestamp to nearest integer value second (for example, 34:12.23 to 34:12.00):

```
timestamp-rounding roundoff
```

trigger type

This command enables/disables triggering a credit reauthorization when the named values in the subscriber session changes.

Product

All

Privilege

Security Administrator, Administrator

Syntax

[no] trigger type { cellid | lac | | mcc | mnc | qos | rat | serving-node | sgsn } +

default trigger type

default

Configures this command with the default setting.
Default: No triggers.

no

Removes the previously configured trigger type.

cellid

Sets the trigger based on change in cell identity or Service Area Code (SAC).

lac

Sets the trigger based on change in Location Area Code.

mcc

Sets the trigger based on change in Mobile Country Code (MCC).

mnc

Sets the trigger based on change in Mobile Network Code (MNC).

qos

Sets the trigger based on change in the Quality of Service (QoS).

rat

Sets the trigger based on change in the Radio Access Technology (RAT).

serving-node

Sets the trigger based on change in serving node. The serving node change causes the credit control client to ask for a re-authorization of the associated quota.
Typically used as an extension to sgsn trigger in P-GW, however, may also be used alone.

sgsn

Sets the trigger based on change in the IP address of SGSN.

+

Indicates that more than one of the previous keywords can be entered within a single command.

Usage

Use this command to set the credit control reauthorization trigger.

Example

The following command selects a credit control trigger as **lac**:

```
trigger type lac
```

usage-reporting

This command configures the ACS Credit Control usage reporting type.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
usage-reporting quotas-to-report based-on-grant { report-only-granted-volume }

default usage-reporting quotas-to-report
```

default

Configures this command with the default setting.
Default: Disabled

report-only-granted-volume

Suppresses the input and output octets. If the Granted-Service-Unit (GSU) AVP comes with CC-Total-Octets, then the device will send total, input and output octets in Used-Service-Unit (USU) AVP. If it comes with Total-Octets, the device will send only Total-Octets in USU.

Usage

Use this command to configure reporting usage only for granted quota. On issuing this command, the Used-Service-Unit AVP will report quotas based on grant i.e, only the quotas present in the Granted-Service-Unit AVP.
With this command only the units for which the quota was granted by the DCCA server will be reported irrespective of the reporting reason.

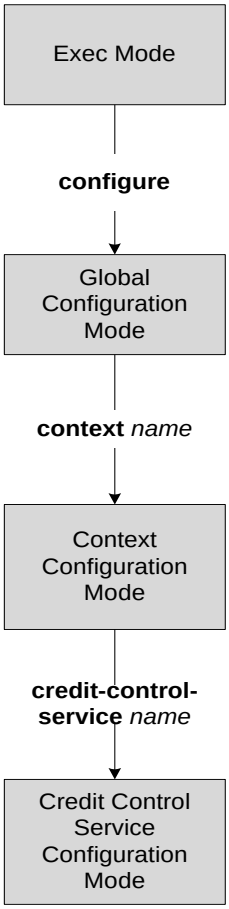
Example

The following command configures to report usage based only on granted quota:

```
usage-reporting quotas-to-report based-on-grant
```

Chapter 55
Credit Control Service Configuration Mode Commands

The Credit Control Service Configuration Mode is used to create and manage Credit Control Service.



diameter dictionary

This command configures the Diameter dictionary to be used for this Credit Control Service instance.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
diameter dictionary { custom1 | standard }

default diameter dictionary
```

default

Configures the default setting.

dictionary { custom1 | standard }

Specifies the Diameter dictionary to be used.
custom1: Specifies the custom dictionary **custom1**.
standard: Specifies the standard dictionary.

Usage

Use this command to configure the Diameter dictionary to be used for this Credit Control Service instance.

Example

The following command configures the standard Diameter dictionary:

```
diameter dictionary standard
```

diameter endpoint

This command configures the Diameter Credit Control Interface Endpoint.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter endpoint *endpoint_name*

{ default | no } diameter endpoint

default

Configures the default setting.

no

Removes the previous Diameter endpoint configuration.

endpoint_name

Specifies the Diameter endpoint name as an alpha and/or numeric string of 1 through 63 characters.

Usage

Use this command to configure the Diameter Credit Control Interface Endpoint.

Example

The following command configures the Diameter Credit Control Interface Endpoint named *test135*:

```
diameter endpoint test135
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

failure-handling

This command configures the Diameter failure handling behavior.

Product

All

Privilege

Security Administrator, Administrator

Syntax

failure-handling { initial-request | terminate-request | update-request } { diameter-result-code *result_code* **[to** *result_code* **] | peer-unavailable | request-timeout } action { continue | retry-and-continue | retry-and-terminate | terminate }**

{ default | no } failure-handling { initial-request | terminate-request | update-request } { diameter-result-code *result_code* **[to** *result_code* **] | peer-unavailable | request-timeout }**

default

Configures the default setting.

no

Removes the previous failure handling configuration.

initial-request | terminate-request | update-request

initial-request: Specifies failure handling for Initial Request.
terminate-request: Specifies failure handling for Terminate Request.
update-request: Specifies failure handling for Update Request.

diameter-result-code | peer-unavailable | request-timeout

diameter-result-code *result_code* **[to** *result_code* **]**: Specifies Diameter result code(s) for failure handling.
result_code must be an integer from 3000 through 9999.
to *result_code*: Specifies the range of Diameter result codes.
peer-unavailable: Specifies failure handling for peer being unavailable.
request-timeout: Specifies failure handling for request timeouts.

action { continue | retry-and-continue | retry-and-terminate | terminate }

Specifies the failure handling action.
continue: Continue the session without credit control.
retry-and-continue: Retry and, even if credit control is not available, continue.
retry-and-terminate: Retry and then terminate.
terminate: Terminate the session.

Usage

Use this command to configure the Diameter failure handling behavior.

Example

The following command configures initial request failure handling behavior for Diameter result codes *3001* to *4001* with terminate action:

```
failure-handling initial-request diameter-result-code 3001 to 4001 action
terminate
```

request timeout

This command configures the timeout period for Diameter requests.

Product

All

Privilege

Security Administrator, Administrator

Syntax

request timeout *timeout*

{ default | no } request timeout

default

Configures the default setting.

no

Removes the previous request timeout configuration.

timeout

Specifies the timeout period in seconds. The value must be an integer from 1 through 300.

Usage

Use this command to configure the Diameter request timeout value, after which the request is deemed to have failed. This timeout is an overall timeout, and encompasses all retries with the server(s).

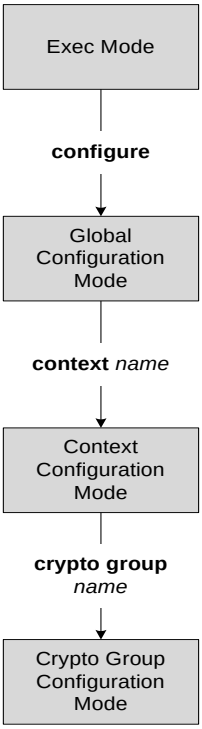
Example

The following command configures the timeout period to *150* seconds:

```
request timeout 150
```

Chapter 56
Crypto Group Configuration Mode Commands

The Crypto Group Configuration Mode is used to configure crypto (tunnel) groups that provide fail-over redundancy for IPSec tunnels to packet data networks (PDNs).



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

match address

Associates an access control list (ACL) with the crypto group.

Product

PDSN, HA, GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

[no] match address *acl_name* **[** *preference* **]**

no

Deletes a previously configured ACL association.

match address *acl_name*

Specifies the name of the ACL being matched to the crypto group entered as an alphanumeric string of 1 through 47 characters.

preference

The priority of the ACL.
The ACL preference is factored when a single packet matches the criteria of more than one ACL.
preference is an integer from 0 through 4294967295; 0 is the highest priority.
If multiple ACLs are assigned the same priority, the last one entered will be used first.

Important: The priorities are only compared for ACLs matched to other groups or to policy ACLs (those applied to the entire context).

Usage

IP ACLs are associated with crypto groups using this command. Both the crypto group and the ACLs must be configured in the same context.
ISAKMP crypto maps can then be associated with the crypto group. This allows user traffic matching the rules of the ACL to be handled according to the policies configured as part of the crypto map.

Example

The following command associates an ACL called *corporate_acl* to the crypto group:

```
match address corporate_acl
```

match ip pool

Matches the specified IP pool to the current crypto group. This command can be used multiple times to match more than one IP pool.

Product

PDSN, HA, GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

[no] match ip pool pool-name *pool_name*

no

Deletes the matching statement for the specified IP pool from the crypto group.

match ip pool pool-name *pool_name*

Specifies the name of an existing IP pool that should be matched entered as an alphanumeric string of 1 through 31 characters.

Usage

Use this command to set the names of IP pools that should be matched in the current crypto group.

Example

The following command sets a rule for the current crypto group that will match an IP pool named *ippool1*:

```
match ip pool pool-name ippool1
```

switchover

Configures the fail-over properties for the crypto group as part of the Redundant IPSec Fail-Over feature.

Product

PDSN, HA, GGSN, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] switchover auto [ do-not-revert ]
```

no

Disables the automatic switchover of tunnels. This applies to switching primary-to-secondary and secondary-to-primary.

switchover auto

Allows the automatic switchover of tunnels. Default: Enabled

do-not-revert

Disables the automatic switchover of secondary tunnels to primary tunnels. Default: Disabled

Usage

This command configures the fail-over options for the Redundant IPSec Fail-over feature.
If the automatic fail-over options are disabled, tunneled traffic must be manually switched to the alternate tunnel (or manually activated if no alternate tunnel is configured and available) using the following command in the Exec Mode:

```
crypto-group group_name activate { primary | secondary }
```

For a definition of this command, see the **crypto-group** section of the Exec Mode Commands chapter of this guide.

Example

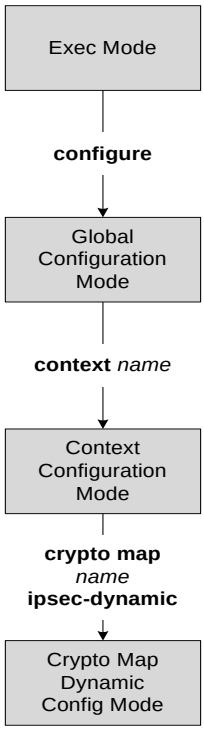
The following command disables the automatic secondary-to-primary switchover:

```
switchover auto do-not-revert
```

Chapter 57
Crypto Map Dynamic Configuration Mode Commands

The Crypto Map Dynamic Configuration Mode is used to configure IPSec tunnels that are created as needed to facilitate subscriber sessions using Mobile IP or L2TP.

Modification(s) to an existing dynamic crypto map configuration will not take effect until the related security association has been cleared. Refer to the description of the **`clear crypto security-association`** command in the *Exec Mode Commands* chapter for more information.



end

Exits the current configuration mode and returns to the Exec mode.

Security Administrator, Administrator

Syntax

set { control-dont-fragment { clear-bit | copy-bit | set-bit } | isakmp natt [keepalive *time* **] | pfs { group1 | group2 | group5} | phase1-idtype { id-key-id | ipv4-address } [mode { aggressive | main }] | phase2-idtype { ipv4-address | ipv4-address-subnet} | security-association lifetime { keepalive | kilo-bytes** *kbytes* **| seconds** *secs* **} | transform-set** *transform_name* **[transform-set** *transform_name2 ...* **transform-set** *transform_name6* **] }**
no set { pfs | security-association lifetime {keepalive | kilo-bytes | seconds } | phase1-idtype | phase2-idtype | transform-set *transform_name* **[transform-set** *transform_name2 ...* **transform-set** *transform_name6* **] }**

---

no

Deletes the specified parameter or resets the specified parameter to the default value.

---

control-dont-fragment { clear-bit | copy-bit | set-bit }

Controls the don't fragment (DF) bit in the outer IP header of the IPSec tunnel data packet. Options are:

- **clear-bit**: Clears the DF bit from the outer IP header (sets it to 0).
- **copy-bit**: Copies the DF bit from the inner IP header to the outer IP header. This is the default action.
- **set-bit**: Sets the DF bit in the outer IP header (sets it to 1).

---

isakmp natt [keepalive *time* **]**

Enable IPSec NAT Traversal.
keepalive *time*: The time to keep the NAT connection alive in seconds. *time* must be an integer of from 1 through 3600.

---

pfs { group1 | group2 | group5 }

Specifies the modp Oakley group (also known as the Diffie-Hellman [D-H] group) that is used to determine the length of the base prime numbers that are used for Perfect Forward Secrecy (PFS).

- **group1**: Diffie-Hellman Group1 (768-bit modp)
- **group2**:- Diffie-Hellman Group2 (1024-bit modp)
- **group5**:- Diffie-Hellman Group5 (1536-bit modp)

---

phase1-idtype { id-key-id | ipv4-address } [mode { aggressive | main }]

Sets the IKE negotiations Phase 1 payload identifier.
Default: ipv4-address

id-key-id: Use ID_KEY_ID as the Phase 1 payload identifier.
ipv4-address: Use IPV4_ADDR as the Phase 1 payload identifier.
mode { aggressive | main }: Specify the IKE mode.

---

phase2-idtype { ipv4-address | ipv4-address-subnet }

Sets the IKE negotiations Phase 2 payload identifier.
Default: ipv4-address-subnet
ipv4-address: Use IPV4_ADDR as the Phase 2 payload identifier.
ipv4-address-subnet: Use IPV4_ADDR_SUBNET as the Phase 2 payload identifier.

---

security-association lifetime { keepalive | kilo-bytes *kbytes* **| seconds** *secs* **}**

Defaults:

- **keepalive**: Disabled
- **kilo-bytes**: 4608000 kbytes
- **seconds**: 28800 seconds

This keyword specifies the parameters that determine the length of time an IKE Security Association (SA) is active when no data is passing through a tunnel. When the lifetime expires, the tunnel is torn down. Whichever parameter is reached first expires the SA lifetime.

- **keepalive**: The SA lifetime expires only when a keepalive message is not responded to by the far end.
- **kilo-bytes**: This specifies the amount of data in kilobytes to allow through the tunnel before the SA lifetime expires; entered as an integer from 2560 through 4294967294.
- **seconds**: The number of seconds to wait before the SA lifetime expires; entered as an integer from 1200 through 86400.

Important: If the dynamic crypto map is being used in conjunction with Mobile IP and the Mobile IP renewal timer is less than the crypto map's SA lifetime (either in terms of kilobytes or seconds), then the **keepalive** parameter **must** be configured.

---

transform-set *transform_name* **[transform-set** *transform_name2 ...* **transform-set** *transform_name6* **]**

Specifies the name of a transform set configured in the same context that will be associated with the crypto map. Refer to the command **crypto ipsec transform-set** for information on creating transform sets. You can repeat this keyword up to 6 times on the command line to specify multiple transform sets. *trasnform_name* is the name of the transform set entered as an alphanumeric string from 1 through 127 characters that is case sensitive.

Usage

Use this command to set parameters for a dynamic crypto map.

Example

The following command sets the PFS group to Group1:

```
set pfs group1
```

The following command sets the SA lifetime to *50000* KB:

```
set security-association lifetime kilo-bytes 50000
```

The following command sets the SA lifetime to *10000* seconds:

```
set security-association lifetime seconds 10000
```

The following command enables the SA to re-key when the tunnel lifetime expires:

```
set security-association lifetime keepalive
```

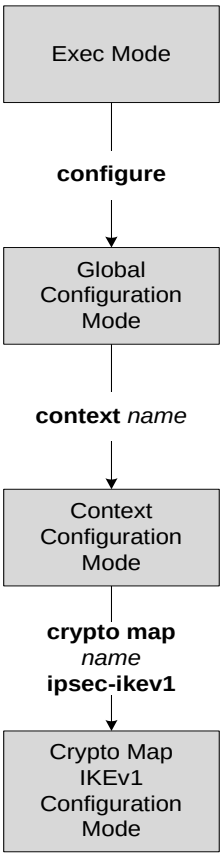
The following command defines transform sets *tset1* and *tset2*:

```
set transform-set tset1 transform-set tset2
```

Chapter 58
Crypto Map IKEv1 Configuration Mode Commands

The Crypto Map IKEv1 Configuration Mode is used to configure properties for IPSec tunnels that will be created using the Internet Key Exchange (IKE) that operates within the framework of the Internet Key Exchange version 1 (IKEv1).

Modification(s) to an existing IKEv1 crypto map configuration will not take effect until the related security association has been cleared. Refer to the description of the **`clear crypto security-association`** command in the *Exec Mode Commands* chapter for more information.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

match address

Matches or associates the crypto map to an access control list (ACL) configured in the same context.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] match address *acl_name priority*

no

Removes a previously matched ACL.

match address *acl_name*

Specifies the name of the ACL with which the crypto map is to be matched as an alphanumeric string of 1 through 79 characters that is case sensitive.

priority

Specifies the preference of the ACL. The ACL preference is factored when a single packet matches the criteria of more than one ACL.
The preference is an integer value from 0 to 4294967295; 0 is the highest priority. Default: 0

Important: The priorities are only compared for ACLs matched to other crypto maps or to policy ACLs (those applied to the entire context).

Usage

ACLs matched to crypto maps are referred to as crypto ACLs. Crypto ACLs define the criteria that must be met in order for a subscriber data packet to routed over an IPSec tunnel.
Prior to routing, the system examines the properties of each subscriber data packet. If the packet properties match the criteria specified in the crypto ACL, the system will initiate the IPSec policy dictated by the crypto map.

Example

The following command sets the crypto map ACL to the ACL named *ACLlist1* and sets the crypto maps priority to the highest level.

```
match address ACLlist1 0
```

match crypto group

Matches or associates the crypto map a crypto group configured in the same context.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] match crypto group *group_name* **{ primary | secondary }**

no

Deletes a previously configured crypto group association.

match crypto group *group_name*

Specifies the name of the crypto group entered as an alphanumeric string of 1 through 127 characters that is case sensitive.

primary

Specifies that the policies configured as part of this crypto map will be used for the primary tunnel in the Redundant IPSec Tunnel Failover feature.

secondary

Specifies that the policies configured as part of this crypto map will be used for the secondary tunnel in the Redundant IPSec Tunnel Failover feature.

Usage

Use this command to dictate the primary and secondary tunnel policies used for the Redundant IPSec Tunnel Failover feature.
At least two policies must be configured to use this feature. One policy must be configured as the primary, the other as the secondary.

Example

The following command associates the crypto map to a crypto group called *group1* and dictates that it will serve as the primary tunnel policy:

```
match crypto group group1 primary
```

match ip pool

Matches the specified IP pool to the current IKEv1 crypto map. This command can be used multiple times to change more than one IP pool.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] match ip pool pool-name *pool_name*[**destination-network** *ip_address* **{ /** *mask* **| mask** *ip_mask* **}]**

no

Delete the matching statement for the specified IP pool from the crypto map.

match ip pool pool-name *pool_name*

Specifies the name of an existing IP pool that should be matched as an alphanumeric string of 1 through 31 characters.

destination-network *ip_address* **{ /** *mask* **| mask** *ip_mask* **}**

Specifies the IP address of the destination network in IPv4 dotted-decimal notation.
/mask specifies the subnet mask bits (representing the subnet mask) and must be an integer from 1 to 32 (CIDR notation). This variable must be entered in theIPv4 dotted-decimal notation/subnet bits format (for example, 10.1.1.1/24).
mask *ip_mask* specifies the subnet mask in dotted decimal notation.
An IP pool attached to the crypto map can have multiple IPSec tunnels according to the destination of the packet being forwarded to internet.

Important: Each invocation of this command will add another destination network to the IP pool, with a maximum of eight destination networks per crypto map.

Usage

Use this command to set the names of IP pools that should be matched in the current crypto map.

Important: If an IP address pool that is matched to a IKEv1 crypto map is resized, removed, or added, the corresponding security association must be cleared in order for the change to take effect. Refer to the **clear crypto** command in the Exec mode for information on clearing security associations.

Example

The following command sets a rule for the current crypto map that will match an IP pool named *ippool1*:

```
match ip pool pool-name ippool1
```

set

Configures parameters for the dynamic crypto map.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

set { control-dont-fragment { clear-bit | copy-bit | set-bit } | ikev1 natt [keepalive *time* **] | pfs { group1 | group2 | group5 } | phase1-idtype { id-key-id | ipv4-address [mode { aggressive | main }] | phase2-idtype { ipv4-address | ipv4-address-subnet } | security-association lifetime { disable-phase2-rekey | keepalive | kilo-bytes** *kbytes* **| seconds** *secs* **} transform-set** *transform_name* **[transform-set** *transform_name2 ...* **transform-set** *transform_name6* **]**
no set { ikev1 natt | pfs | phase1-idtype | phase2-idtype | security-association lifetime { disable-phase2-rekey | keepalive | kilo-bytes | seconds } | transform-set *transform_name* **[transform-set** *transform_name2 ...* **transform-set** *transform_name6* **]**

---

set control-dont-fragment { clear-bit | copy-bit | set-bit }

Controls the don't fragment (DF) bit in the outer IP header of the IPsec tunnel data packet. Options are:

- **clear-bit**: Clears the DF bit from the outer IP header (sets it to 0).
- **copy-bit**: Copies the DF bit from the inner IP header to the outer IP header. This is the default action.
- **set-bit**: Sets the DF bit in the outer IP header (sets it to 1).

---

set ikev1 natt [keepalive *time* **]**

Specifies IKE parameters.
natt: Enables IPSec NAT Traversal.
keepalive *time*: The time to keep the NAT connection alive in seconds. *time* must be an integer of from 1 through 3600.

---

set pfs { group1 | group2 | group5 }

Specifies the modp Oakley group (also known as the Diffie-Hellman [D-H] group) that is used to determine the length of the base prime numbers that are used for Perfect Forward Secrecy (PFS).

- **group1**: Diffie-Hellman Group1 (768-bit modp)
- **group2**: Diffie-Hellman Group2 (1024-bit modp)
- **group5**: Diffie-Hellman Group5 (1536-bit modp)

---

set phase1-idtype { id-key-id | ipv4-address [mode { aggressive | main }]

Sets the IKE negotiations Phase 1 payload identifier. Default: id-key-id
id-key-id: ID KEY ID
ipv4-address: ID IPV4 Address

- **mode**: Configures IKE mode
- **aggressive**: IKE negotiation mode: AGGRESSIVE

- **main**: IKE negotiation mode: MAIN

set phase2-idtype { ipv4-address | ipv4-address-subnet }

Sets the IKE negotiations Phase 2 payload identifier.
Default: ipv4-address-subnet

- **ipv4-address**: Use IPV4_ADDR as the Phase 2 payload identifier.
- **ipv4-address-subnet**: Use IPV4_ADDR_SUBNET as the Phase 2 payload identifier.

set security-association lifetime { disable-phase2-rekey | keepalive | kilo-bytes *kbytes* **| seconds** *secs* **}**

Defaults:

- **disable-phase2-rekey**: Rekeying is enabled by default
- **keepalive**: Disabled
- **kilo-bytes:** 4608000 kbytes
- **seconds:** 28800 seconds

Specifies the parameters that determine the length of time an IKE Security Association (SA) is active when no data is passing through a tunnel. When the lifetime expires, the tunnel is torn down. Whichever parameter is reached first expires the SA lifetime.

- **disable-phase2-rekey**: If this keyword is specified, the Phase2 SA is not rekeyed when the lifetime expires.
- **keepalive**: The SA lifetime expires only when a keepalive message is not responded to by the far end.
- **kilo-bytes**: This specifies the amount of data (n kilobytes) to allow through the tunnel before the SA lifetime expires. *kbytes* must be an integer from 2560 through 4294967294.
- **set seconds**: The number of seconds to wait before the SA lifetime expires. *secs* must be an integer from 1200 through 86400.

Important: If the dynamic crypto map is being used in conjunction with Mobile IP and the Mobile IP renewal timer is less than the crypto map's SA lifetime (either in terms of kilobytes or seconds), then the keepalive parameter must be configured.

transform-set *transform_name* **[transform-set** *transform_name2* **... transform-set** *transform_name6* **]**

Specifies the name of a transform set configured in the same context that will be associated with the crypto map. Refer to the command **crypto ipsec transform-set** for information on creating transform sets. You can repeat this keyword up to 6 times on the command line to specify multiple transform sets. *transform_name* is the name of the transform set entered as an alphanumeric string of 1 through 127 characters that is case sensitive.

no

Deletes the specified parameter or resets the specified parameter to the default value.

Usage

Use this command to set parameters for a dynamic crypto map.

Example

The following command sets the PFS group to Group1:

```
set pfs group1
```

The following command sets the SA lifetime to *50000* KB:

```
set security-association lifetime kilo-bytes 50000
```

The following command sets the SA lifetime to *10000* seconds:

```
set security-association lifetime seconds 10000
```

The following command enables the SA to re-key when the tunnel lifetime expires:

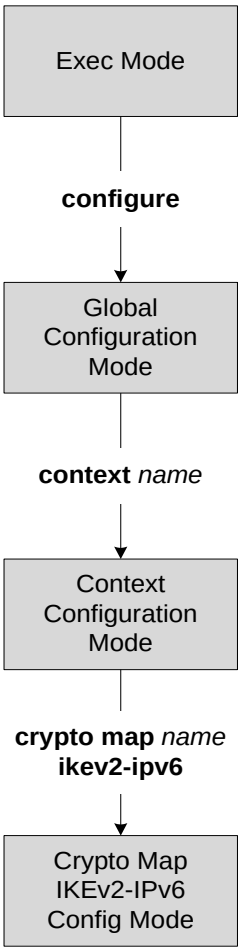
```
set security-association lifetime keepalive
```

The following command defines transform sets *tset1* and *tset2*.

```
set transform-set tset1 transform-set tset2
```

Chapter 59
Crypto Map IKEv2-IPv6 Configuration Mode Commands

The Crypto Map IKEv2-IPv6 Configuration Mode is used to configure an IKEv2 IPsec policy for secure X3 interface tunneling between a P-GW and a lawful intercept server.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

authentication

Configures the subscriber authentication method used for the P-GW lawful intercept service.

Product

P-GW

Privilege

Administrator

Syntax

authentication pre-shared-key { encrypted key *value* **| key** *value* **}**

---

authentication pre-shared-key { encrypted key *value* **| key** *value* **}**

Specifies that a pre-shared key is to be used for authenticating a subscriber in the PDIF service.
encrypted key *value*: Specifies that the pre-shared key used for authentication is encrypted and expressed as an alphanumeric string of 1 through 255 characters.
key *value*: Specifies that the pre-shared key used for authentication is clear text and expressed as an alphanumeric string of 1 through 255 characters.

Usage

Use this command to specify the type of authentication performed for subscribers attempting to access the P-GW service using this crypto map.

Example

The following command sets the authentication method to an open key value of *6d79706173737 6f7264*:

```
authentication pre-shared-key key 6d79706173737 6f7264
```

control-dont-fragment

Controls the Don't Fragment (DF) bit in the outer IP header of the IPSec tunnel data packet.

Product

P-GW

Privilege

Administrator

Syntax

```
control-dont-fragment { clear-bit | copy-bit | set-bit }
```

{ clear-bit | copy-bit | set-bit }

clear-bit: Clears the DF bit from the outer IP header (sets it to 0).
copy-bit: Copies the DF bit from the inner IP header to the outer IP header. This is the default action.
set-bit: Sets the DF bit in the outer IP header (sets it to 1).

Usage

A packet is encapsulated in IPsec headers at both ends. The new packet can copy the DF bit from the original unencapsulated packet into the outer IP header, or it can set the DF bit if there is not one in the original packet. It can also clear a DF bit that it does not need.

Example

The following command sets the DF bit in the outer IP header:

```
control-dont-fragment set-bit
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

ikev2-ikesa

Configures parameters for the IKEv2 IKE Security Associations within this crypto template.

Product

P-GW

Privilege

Administrator

Syntax

ikev2-ikesa { max-retransmissions *number* **| rekey | setup-timer** *sec* **}**

default ikev2-ikesa { max-retransmissions | rekey | setup-timer }

no ikev2-ikesa rekey

default

Restores the selected keyword to its default value.

no ikev2-ikesa

Disables a previously enabled parameter.

ikev2-ikesa max-retransmissions *number*

Specifies the maximum number of retransmissions of an IKEv2 IKE exchange request if a response has not been received. *number* must be an integer from 1 to 8. Default: 5

ikev2-ikesa rekey

Specifies if IKESA rekeying should occur before the configured lifetime expires (at approximately 90% of the lifetime interval). Default is not to re-key.

ikev2-ikesa setup-timer *sec*

Specifies the number of seconds before an IKEv2 IKE Security Association that is not fully established is terminated. *sec* must be an integer from 1 to 3600. Default: 60

Usage

Use this command to configure parameters for the IKEv2 IKE Security Associations within this crypto template.

Example

The following command configures the maximum number of IKEv2 IKESA request retransmissions to 7:

```
ikev2-ikesa max-retransmissions 7
```

match

Matches or associates the crypto map to an access control list (ACL) configured in the same context.

Product

P-GW

Privilege

Administrator

Syntax

match address *acl_name* **[** *priority* **]**

no match address

no

Removes a previously matched ACL.

match address *acl_name*

Specifies The name of the ACL with which the crypto map is to be matched. *acl_name* is an alphanumeric string of 1 through 79 characters that is case sensitive.

priority

Specifies the preference of the ACL as integer from 0 through 4294967295. 0 is the highest priority. Default: 0
The ACL preference is factored when a single packet matches the criteria of more than one ACL.

Important: The priorities are only compared for ACLs matched to other crypto maps or to policy ACLs (those applied to the entire context).

Usage

ACLs matched to crypto maps are referred to as crypto ACLs. Crypto ACLs define the criteria that must be met in order for a subscriber data packet to routed over an IPSec tunnel.
Prior to routing, the system examines the properties of each subscriber data packet. If the packet properties match the criteria specified in the crypto ACL, the system will initiate the IPSec policy dictated by the crypto map.

Example

The following command sets the crypto map ACL to the ACL named *acl-list1* and sets the crypto maps priority to the highest level.

```
match address acl-list1 0
```

payload

Creates a new, or specifies an existing, crypto template payload and enters the Crypto Template Payload Configuration Mode.

Product

P-GW

Privilege

Administrator

Syntax

payload *name* **match ipv6**

no payload *name*

payload *name*

Specifies the name of a new or existing crypto template payload as an alphanumeric string of 1 through 127 characters.

match ipv6

Filters IPSec IPv6 Child Security Association creation requests for subscriber calls using this payload. Further filtering can be performed by applying the following:

Usage

Use this command to create a new or enter an existing crypto template payload. The payload mechanism is a means of associating parameters for the Security Association (SA) being negotiated.
Two payloads are required: one each for MIP and IKEv2. The first payload is used for establishing the initial Child SA Tunnel Inner Address (TIA) which will be torn down. The second payload is used for establishing the remaining Child SAs. Note that if there is no second payload defined with home-address as the *ip-address-allocation* then no MIP call can be established, just a Simple IP call.
Currently, the only available match is for ChildSA, although other matches are planned for future releases.
Entering this command results in the following prompt:
[*ctxt_name*]*hostname*(cfg-crypto-<*name*>-ikev2-tunnel-payload)#
Crypto Template IKEv2-IPv6 Payload Configuration Mode commands are defined in the Crypto Template IKEv2-IPv6 Payload Configuration Mode Commands chapter.

Example

The following command configures a crypto template payload called *payload5* and enters the Crypto Template IKEv2-IPv6 Payload Configuration Mode:

```
payload payload5 match ipv6
```

peer

Configures the IP address of a peer IPSec server.

Product

P-GW

Privilege

Administrator

Syntax

peer *ip_address*

no peer

no

Removes the configured peer server IP address.

peer *ip_address*

Specifies the IP address of a peer IPSec server in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Use this command to specify a peer IPsec peer server. The IPsec peer server can also be the Lawful Intercept server.

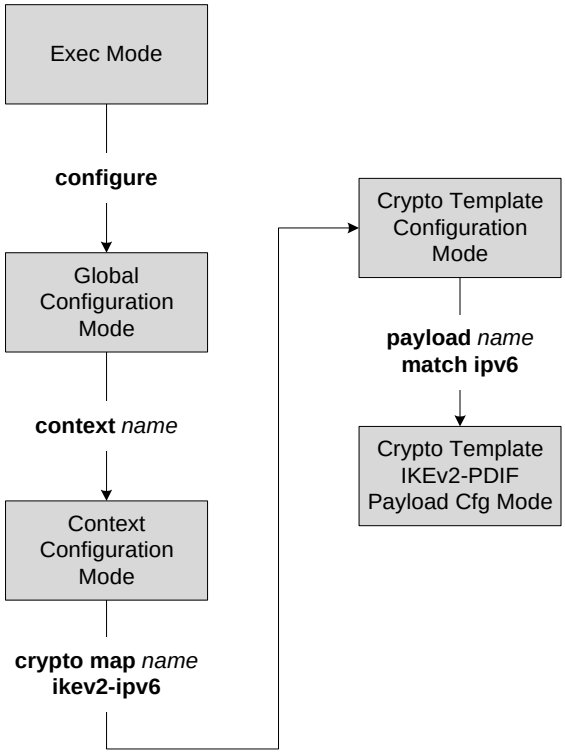
Example

The following command configures the system to recognize an IPsec peer server with an IPv6 address of *fe80::200:f8ff:fe21:67cf*:

```
peer fe80::200:f8ff:fe21:67cf
```

Chapter 60
Crypto Map IKEv2-IPv6 Payload Configuration Mode Commands

The Crypto Map IKEv2-IPv6 Payload Configuration Mode is used to assign the correct IPSec transform-set from a list of up to four different transform-sets, and to assign Mobile IP addresses.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

ipsec

Configures the IPSec transform set to be used for this crypto template payload.

Product

P-GW

Privilege

Administrator

Syntax

ipsec transform-set list *name*

no ipsec transform-set list

ipsec transform-set list *name*

Specifies the context configured IPSec transform set name to be used in the crypto template payload. This is a space-separated list. From 1 to 4 transform sets can be entered. *name* is an alphanumeric string of 1 through 127 characters.

Usage

Use this command to list the IPSec transform set(s) to use in this crypto template payload.

Example

The following command configures IPSec transform sets named *ipset1* and *ipset2* to be used in this crypto template payload:

```
ipsec transform-set list ipset1 ipset2
```

lifetime

Configures the number of seconds for IPSec Child SAs derived from this crypto template payload to exist.

Product

P-GW

Privilege

Administrator

Syntax

lifetime *sec* **[kilo-bytes** *kbytes* **]**

default lifetime

default

Returns the lifetime value to the default setting of 86400.

lifetime *sec*

Specifies the number of seconds for IPSec Child Security Associations derived from this crypto template payload to exist. *sec* must be an integer from 60 through 604800. Default: 86400

kilo-bytes *kbytes*

Specifies lifetime in kilo-bytes for IPSec Child Security Associations derived from this Crypto Map. *kbytes* must be an integer from 1 through 2147483648.

Usage

Use this command to configure the number of seconds for IPSec Child Security Associations derived from this crypto template payload to exist.

Example

The following command configures the IPSec child SA lifetime to be 120 seconds:

```
lifetime 120
```

rekey

Configures child security association rekeying.

Product

P-GW

Privilege

Administrator

Syntax

```
rekey [ keepalive ]

[ default | no ] rekey
```

default

Returns the feature to the default setting of disabled.

no

Disables this feature.

keepalive

If specified, a session will be rekeyed even if there has been no data exchanged since the last rekeying operation. By default rekeying is only performed if there has been data exchanged since the previous rekey.

Usage

Use this command to enable or disable the ability to rekey IPSec Child SAs after approximately 90% of the Child SA lifetime has expired. The default, and recommended setting, is not to perform rekeying. No rekeying means the PDIF will not originate rekeying operations and will not process CHILD SA rekeying requests from the MS.

Example

The following command disables rekeying:

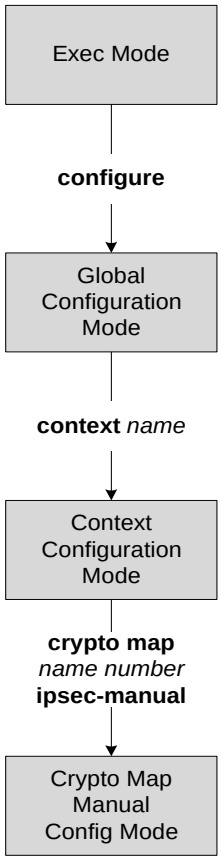
```
no rekey
```

Chapter 61
Crypto Map Manual Configuration Mode Commands

The Crypto Map Manual Configuration Mode is used to configure static IPSec tunnel properties.

Modification(s) to an existing crypto map manual configuration will not take effect until the related security association has been cleared. Refer to the description of the **`clear crypto security-association`** command in the *Exec Mode Commands* chapter for more information.

Important: Because manual crypto map configurations require the use of static security keys (associations), they are not as secure as crypto maps that rely on dynamically configured keys. Therefore, they only be used for testing purposes.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

match address

Matches or associates the crypto map to an access control list (ACL) configured in the same context.

Product

PDSN, HA, GGSN, PDIF

Privilege

Security Administrator, Administrator

Syntax

[no] match address *acl_name* **[** *priority* **]**

no

Removes a previously matched ACL.

match address *acl_name*

Specifies the name of the ACL with which the crypto map is to be matched. *acl_name* is an alphanumeric string of 1 through 47 characters that is case sensitive.

priority

Specifies the preference of the ACL. The ACL preference is factored when a single packet matches the criteria of more than one ACL. *priority* is an integer from 0 through 4294967295. 0 is the highest priority. Default: 0

Important: The priorities are only compared for ACLs matched to other crypto maps or to policy ACLs (those applied to the entire context).

Usage

ACLs matched to crypto maps are referred to as crypto ACLs. Crypto ACLs define the criteria that must be met in order for a subscriber data packet to routed over an IPSec tunnel.
Prior to routing, the system examines the properties of each subscriber data packet. If the packet properties match the criteria specified in the crypto ACL, the system will initiate the IPSec policy dictated by the crypto map.

Example

The following command sets the crypto map ACL to the ACL named *ACLlist1* and sets the crypto maps priority to the highest level.

```
match address ACLlist1 0
```

set control-dont-fragment

Controls the Don't Fragment (DF) bit in the outer IP header of the IPSec tunnel data packet.

Product

PDSN, HA, GGSN, PDIF

Privilege

Security Administrator, Administrator

Syntax

```
set control-dont-fragment { clear-bit | copy-bit | set-bit }

default set control-dont-fragment { clear-bit | copy-bit | set-bit }
```

default

Sets or restores default value assigned to a specified parameter.

set control-dont-fragmentclear-bit

Clears the DF bit from the outer IP header (sets it to 0).

set control-dont-fragmentcopy-bit

Copies the DF bit from the inner IP header to the outer IP header. This is the default action.

set control-dont-fragmentset-bit

Sets the DF bit in the outer IP header (sets it to 1).

Usage

Use this command to clear, copy, or set the don't fragment (DF) bit in the outer IP header of the IPSec tunnel data packet.

Example

The following command sets the DF bit in the outer IP header.

```
set control-dont-fragment set-bit
```

set peer

Configures the IP address of the peer security gateway that the system will establish the IPSec tunnel with.

Product

PDSN, HA, GGSN, PDIF

Privilege

Security Administrator, Administrator

Syntax

[no] set peer *gw_address*

no

Removes a previously configured peer address.

set peer *gw_address*

Specifies the IP address of the peer security gateway with which the IPSec tunnel will be established.

Usage

Once the manual crypto map is fully configured and applied to an interface, the system will establish an IPSec tunnel with the security gateway specified by this command.
Because the tunnel relies on statically configured parameters, once created, it never expires; it exists until its configuration is deleted.

Example

The following command configures a security gateway address of *192.168.1.100* for the crypto map with which to establish a tunnel.

```
set peer 192.168.1.100
```

set session-key

Configures session key parameters for the manual crypto map.

Product

PDSN, HA, GGSN, PDIF

Privilege

Security Administrator, Administrator

Syntax

set session-key { inbound | outbound } { ah *ah_spi* **[encrypted] key** *ah_key* **| esp** *esp_spi* **[encrypted] cipher** *encryption_key* **[encrypted] authenticator** *auth_key* **}**
no set session-key { inbound | outbound }

---

no

Removes previously configured session key information.

---

inbound

Specifies that the key(s) will be used for tunnels carrying data sent by the security gateway.

---

outbound

Specifies that the key(s) will be used for tunnels carrying data sent by the system.

---

ah *ah_spi*

Configures the Security Parameter Index (SPI) for the Authentication Header (AH) protocol. The SPI is used to identify the AH security association (SA) between the system and the security gateway. *ah_spi* is an integer from 256 through 4294967295.

---

encrypted

Indicates the key provided is encrypted.
The **encrypted** keyword is intended only for use by the system while saving configuration scripts. The system displays the **encrypted** keyword in the configuration file as a flag that the variable following the **key**, **cipher**, and/or **authenticator** keyword is the encrypted version of the plain text key. Only the encrypted key is saved as part of the configuration file.

---

key *ah_key*

Configures the key used by the system to de/encapsulate IP packets using Authentication Header (AH) protocol. *ah_key* must be entered as either an alphanumeric string or a hexadecimal number beginning with "0x".
The length of the configured key must match the configured algorithm.

---

esp *esp_spi*

Configures SPI for the Encapsulating Security Payload (ESP) protocol. The SPI is used to identify the ESP security association (SA) between the system and the security gateway. *esp_spi* is an integer from 256 through 4294967295.
The length of the configured key must match the configured algorithm.

cipher *encryption_key*

Specifies the key used by the system to de/encrypt the payloads of IP packets using the ESP protocol. *encryption_key* must be entered as either an alphanumeric string or a hexadecimal number beginning with "0x".
The length of the configured key must match the configured algorithm.

authenticator *auth_key*

Specifies the key used by the system to authenticate the IP packets once encryption has been performed. *auth_key* must be entered as either an alphanumeric string or a hexadecimal number beginning with "0x".
The length of the configured key must match the configured algorithm.

Usage

Manual crypto maps rely on the use of statically configured keys to establish IPSec tunnels. This command allows the configuration of the static keys.
Identical keys must be configured on both the system and the security gateway in order for the tunnel to be established.
The length of the configured key must match the configured algorithm.
This command can be entered up to two time for the same crypto map: once to configure inbound key properties, and once to configure outbound key properties.

Example

The following command configures a manual crypto map with the following session key properties:

- Keys are for tunnels initiated by the system to the security gateway.
- ESP will be used with an SPI of *310*.
- Encryption key is *sd23r9skd0fi3as*.
- Authentication key is *sfd23408imi9yn*.

```
set session-key outbound esp 310 cipher sd23r9skd0fi3as authenticator
sfd23408imi9yn
```

set transform-set

Configures the name of a transform set that the crypto map is associated with.

Product

PDSN, HA, GGSN, PDIF

Privilege

Security Administrator, Administrator

Syntax

[no] set transform-set *transform_name*

no

Removes a previously configured transform set association.

set transform-set *transform_name*

Specifies the name of the transform set expressed as an alphanumeric string of 1 through 127 characters that is case sensitive.

Usage

System transform sets contain the IPSec policy definitions for crypto maps. Refer to the **crypto ipsec transform-set** command for information on creating transform sets.

Important: Transform sets must be configured prior to configuring session key information for the crypto map.

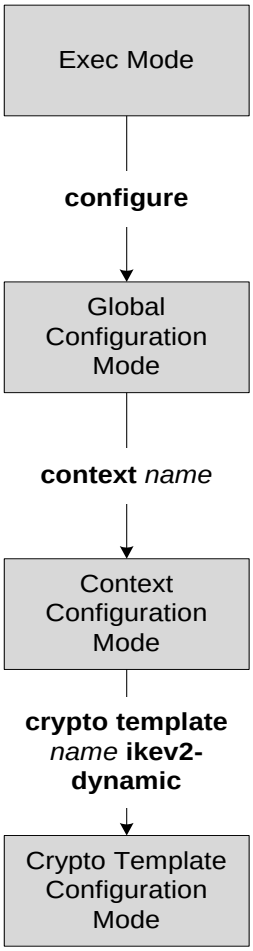
Example

The following command associates a transform set named *esp_tset* with the crypto map:

```
set transform-set esp_tset
```

Chapter 62
Crypto Template Configuration Mode Commands

The Crypto Template Configuration Mode is used to configure an IKEv2 IPSec policy. It includes most of the IPSec parameters and IKEv2 parameters for cryptographic and authentication algorithms. A security gateway service will not function without a configured crypto template. Only one crypto template can be configured per service.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

authentication

Configures the authentication method used for services using the crypto template.

Product

All IPSec-related services

Privilege

Security Administrator, Administrator

Syntax

authentication { eap-profile *name* **[second-phase eap-profile** *name* **] | gateway { encrypted key** *value* **| key** *clear_text* **} | local { certificate | pre-shared-key { encrypted key** *value* **| key** *clear_text* **} | pre-shared-key { encrypted key** *value* **| key** *clear_text* **} | remote { certificate | eap-profile** *name* **[second-phase eap-profile** *name* **] | pre-shared-key { encrypted key** *value* **| key** *clear_text* **} }**

[default | no] authentication gateway

default

Returns the command to its default setting.

no

Removes the authentication gateway form the configuration.

no authentication [local | remote] pre-shared-key

Disables authentication for the local/remote pre-shared-key.

---

eap-profile *name* **[second-phase eap-profile** *name* **]**

Specifies that authentication is to be performed using a named Extensible Authentication Protocol (EAP) profile. *name* is an alphanumeric string of 1 through 127 characters. Entering this keyword places the CLI in the EAP Authentication Configuration Mode.
The **second-phase eap-profile** *name* is only required for installations using multiple authentications. *name* must be an alphanumeric string of 1 through 127 characters.

---

gateway { encrypted key *value* **| key** *clear_text* **}**

Specifies the pre-shared gateway key used for gateway authentication.
encrypted key *value*: Specifies that the pre-shared key used for authentication is encrypted. *value* must be an alphanumeric string of 1 through 255 characters.
key *clear_text*: Specifies that the pre-shared key used for authentication is clear text. *clear_text* must be an alphanumeric string of 1 through 255characters.

---

local { certificate | pre-shared-key { encrypted key *value* **| key** *clear_text* **}**

Specifies the local authentication method required for services using the crypto template.
certificate: Specifies that the certificate method of authentication must be used for services using the crypto template.
pre-shared-key { encrypted key *value* **| key** *clear_text* **}**: Specifies that a pre-shared key is to be used for services using the crypto template. **encrypted key** *value* configures an encrypted pre-shared key used for authentication. *value* must be an alphanumeric string of 1 through 255characters. **key**

clear_text configures a clear text pre-shared key used for authentication. *clear_text* must be an alphanumeric string of 1 through 255characters.

---

pre-shared-key { encrypted key *value* **| key** *clear_text* **}**

Specifies that a pre-shared key is to be used for services using the crypto template.
encrypted key *value*: Specifies that the pre-shared key used for authentication is encrypted. *value* must be an alphanumeric string of 1 through 255 characters.
key *clear_text*: Specifies that the pre-shared key used for authentication is clear text. *clear_text* must be an alphanumeric string of 1 through 255 characters.

---

remote { certificate | eap-profile *name* **[second-phase eap-profile** *name* **] | pre-shared-key { encrypted key** *value* **| key** *clear_text* **}**

Specifies the remote authentication method required for services using the crypto template.
certificate: Specifies that the certificate method of remote authentication must be used for services using the crypto template.
eap-profile *name* **[second-phase eap-profile** *name* **]**: Specifies that remote authentication is to be performed using a named EAP profile. *name* must be an alphanumeric string of 1 through 127 characters. Entering this keyword places the CLI in the EAP Authentication Configuration Mode.
The **second-phase eap-profile** *name* is only required for installations using multiple authentications. *name* must be an alphanumeric string of 1 through 127 characters.
pre-shared-key { encrypted key *value* **| key** *clear_text* **}**: Specifies that a pre-shared key is to be used for services using the crypto template. **encrypted key** *value* configures an encrypted pre-shared key used for authentication. *value* must be an alphanumeric string of 1 through 255 characters. **key** *value* configures a clear text pre-shared key used for authentication. *clear_text* must be an alphanumeric string of 1 through 255 characters.

Usage

Use this command to specify the type of authentication performed for subscribers or gateways attempting to access the service using this crypto template.
Entering the **authentication eap-profile** command results in the following prompt:
[*context_name*]*hostname*(cfg-crypto-tmpl-eap-key)#
EAP Authentication Configuration Mode commands are defined in the *EAP Authentication Configuration Mode Commands* chapter.

Example

The following command enables authentication via an EAP profile named *eap23* for subscribers using the service with this crypto template:

```
authentication eap-profile eap23
```

ca-certificate list

Used to bind an X.509 Certificate Authority (CA) root certificate to a crypto template.

Product

All

Privilege

Administrator

Syntax

ca-certificate list ca-cert-name *name***[ca-cert-name** *name* **]**

no ca-certificate

no

Removes a CA root certificate from the list.

ca-certificate list ca-cert-name *name*

Binds the named X.509 Certificate Authority (CA) root certificate to a crypto template. *name* is an alphanumeric string of 1 through 127 characters.

Usage

Used to bind an X.509 CA root certificate to a template.

Example

Use the following example to add a CA root certificate to a list:

```
ca-certificate list CA_list1
```

ca-crl list

Binds one or more Certificate Authority-Certificate Revocation Lists (CA-CRLs) to this crypto template.

Product

All

Privilege

Administrator

Syntax

ca-crl list ca-crl-name *name* **[ca-crl-name** *name* **] +**

no ca-crl

no

Removes the CA-CRL configuration from this template.

ca-crl list ca-crl-name *name*

Specifies the CA-CRL to associate with this crypto template. *name* must be the name of an existing CA-CRL expressed as an alphanumeric string of 1 through 129 characters. Multiple lists can be configured for a crypto template.

Usage

Use this command to associate a CA-CRL name with this crypto template.
CA-CRLs are configured in the Global Configuration Mode. For more information about configuring CA-CRLs, refer to the **ca-crl name** command in the *Global Configuration Mode Commands* chapter.

Example

The following example binds CA-CRLs named *CRL-5* and *CRL-7* to this crypto template:

```
ca-crl list ca-crl-name CRL-5 ca-crl-name CRL-7
```

certificate

Used to bind an X.509 trusted certificate to a crypto template.

Product

All

Privilege

Administrator

Syntax

[no] certificate name *name*

no

Removes any applied certificate or prevents the certificate from being included in the Auth Exchange response payload.

name *name*

Binds the named X.509 trusted certificate to a crypto template. *name* is an alphanumeric string of 1 through 127 characters.

Usage

Can be used to bind an X.509 certificate to a template, or include or exclude it from the Auth Exchange response payload.

Example

Use the following example to prevent a certificate from being included in the Auth Exchange payload:

```
no certificate
```

control-dont-fragment

Controls the Don't Fragment (DF) bit in the outer IP header of the IPSec tunnel data packet.

Product

All

Privilege

Administrator

Syntax

```
control-dont-fragment { clear-bit | copy-bit | set-bit }
```

{ clear-bit | copy-bit | set-bit }

Configures the option to perform on the DF bit.

- **clear-bit**: Clears the DF bit from the outer IP header (sets it to 0).
- **copy-bit**: Copies the DF bit from the inner IP header to the outer IP header. This is the default action.
- **set-bit**: Sets the DF bit in the outer IP header (sets it to 1).

Usage

A packet is encapsulated in IPSec headers at both ends. The new packet can copy the DF bit from the original unencapsulated packet into the outer IP header, or it can set the DF bit if there is not one in the original packet. It can also clear a DF bit that it does not need.

Example

The following command sets the DF bit in the outer IP header:

```
control-dont-fragment set-bit
```

default

Restores the default values for the selected parameter.

Product

All

Privilege

Security Administrator, Administrator

Syntax

default { authentication gateway | certificate | dns-handling | dos cookie-challenge detect-dos-attack | ikev2-ikesa { ignore-rekeying-requests | keepalive-user-activity | max-retransmission | mobike | policy error-notification | rekey | retransmission-timeout | setup-timer } | keepalive | nai | natt }

---

authentication gateway

Configures the default pre-shared gateway key used for authentication.

---

certificate

Configures the system to remove the certificate for a given crypto template.

---

dns-handling

Configures the system to use normal DNS handling.

---

dos cookie-challenge detect-dos-attack

Configures the system to disable any Denial of Service attacks.

---

ikev2-ikesa { ignore-rekeying-requests | keepalive | max-retransmission | mobike | policy error-notification | rekey | retransmission-timeout | setup-timer }

Configures the system to use the following ikev2-ikesa defaults:

- **ignore-rekeying-requests**: Ignore any IKE_SA rekeying requests received.
- **keepalive-user-activity**: Keepalive messages received from peer will not reset the user inactivity timer.
- **max-retransmission**: Set the number of IKEv2 IKE exchange request retransmissions if the corresponding response has not been received. Default is 5.
- **mobike:** Set MOBIKE to disable.
- **policy error-notification**: Set the default policy error notification method to send error notify messages to the MS.
- **rekey**: Set the default rekeying of IKE_SA to disabled.
- **retransmission-timeout**: Set the maximum number of milliseconds to elapse before an IKEv2 IKE exchange request is retransmitted if the corresponding IKEv2 IKE exchange response has not been received to 500.

- **setup timer**: Set the number of seconds to elapse before a non-fully-established IKEv2 IKE SA is terminated to 60.

keepalive

Enables Dead Peer Detection for all SAs derived from this crypto template.

nai

Sets the default NAI parameters to be used for the crypto template (IDr) to none

natt

Enables NAT-T initiation for all SAs derived from this crypto template.

Usage

Use these commands to restore default parameters.

Example

Use the following command to disable MOBIKE by default:

```
default mobike
```

dns-handling

Adds a custom option to define the ways a DNS address is returned based on proscribed circumstances described below.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
[ default ] dns-handling { normal | custom }
```

default

Configures the default condition as **normal**. By default, PDIF always returns the DNS address in the config payload in the second authentication phase if one is received from either the configuration or the HA.

dns-handling normal

This is the default action. PDIF always returns the DNS address in the config payload in the second authentication phase if one is received from either the configuration or the HA.

dns-handling custom

Configures the PDIF to behave as described in the Usage section below.

Usage

During IKEv2 session setup, MS may or may not include INTERNAL_IP4_DNS in the Config Payload (CP). PDIF may obtain one or more DNS addresses for the subscriber in DNS NVSE from a proxy-MIP Registration Reply message. If Multiple Authentication is used, these DNS addresses may be also received in Diameter AVPs during the first authentication phase, or in RADIUS attributes in the Access Accept messages during the second authentication phase.
In **normal** mode, by default PDIF always returns the DNS address in the config payload in the second authentication phase if one is received from either the configuration or the HA.
In **custom** mode, depending on the number of INTERNAL_IP4_DNS, PDIF supports the following behaviors:

- If MS includes no INTERNAL_IP4_DNS in Config Payload: PDIF doesn't return any INTERNAL_IP4_DNS option to MS, whether or not PDIF has received one(s) in DNS NVSE from HA or from local configurations.
- If MS requests one or more INTERNAL_IP4_DNS(s) in Config Payload, and if P-MIP NVSE doesn't contain any DNS address or DNS address not present in any config, PDIF omits INTERNAL_IP4_DNS option to MS in the Config Payload.
- And if P-MIP NVSE includes one DNS address (a.a.a.a / 0.0.0.0), then PDIF sends one INTERNAL_IP4_DNS option in Config Payload back to the MS.
- If the Primary DNS is a.a.a.a and the Secondary DNS is 0.0.0.0, then a.a.a.a is returned (only one instance of DNS attribute present in the config payload).
- If the Primary DNS is 0.0.0.0 and the Secondary DNS is a.a.a.a, then a.a.a.a is returned (only one instance of DNS attribute present in the config payload). PDIF does not take 0.0.0.0 as a valid DNS address that can be assigned to the MS.

- And if P-MIP NVSE includes two DNS addresses (a.a.a.a and b.b.b.b) or configurations exists for these two addresses, then PDIF sends two INTERNAL_IP4_DNSs in the CP for the MS (typically known as primary and secondary DNS addresses).

Example

The following configuration applies the **custom** dns-handling mode:

```
dns-handling custom
```

dos cookie-challenge notify-payload

Configure the cookie challenge parameters for IKEv2 INFO Exchange notify payloads for the given crypto template.

Product

All

Privilege

Administrator

Syntax

```
dos cookie-challenge notify-payload [ half-open-sess-count { start integer | stop integer } ]

[ default | no ] cookie-challenge detect-dos-attack
```

default

Default is to disabled condition.

no

Prevents Denial of Service cookie transmission. This is the default condition.

half-open-sess-count *start* **|** *stop*

The **half-open-sess-count** is the number of half-open sessions per IPSec manager.
A session is considered half-open if a PDIF has responded to an IKEv2 INIT Request with an IKEv2 INIT Response, but no further message was received on that particular IKE SA.

- *start*: Starts when the current half-open-sess-count exceeds the start count. The start count is an integer from 0 to 100000.
- *stop*: Stops when the current half-open-sess-count drops below the stop count. The stop count number is an integer from 0 to 100000. It is always less than or equal to the start count number

Important: The start count value 0 is a special case whereby this feature is always enabled. In this event, both **Start** and **Stop** must be 0.

Usage

This feature (which is disabled by default) helps prevent malicious Denial of Service attacks against the server by sending a challenge cookie. If the response from the sender does not incorporate the expected cookie data, the packets are dropped.

Example

The following example configures the cookie challenge to begin when the half-open-sess-count reaches *50000* and stops when it drops below *20000*:

```
dos cookie-challenge notify-payload half-open-sess-count start 50000 stop 20000
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

ikev2-ikesa

Configures parameters for the IKEv2 IKE Security Associations within this crypto template.

Product

All

Privilege

Administrator

Syntax

ikev2-ikesa { allow-empty-ikesa | keepalive-user-activity | max-retransmissions *number* **| retransmission-timeout** *msec* **| policy error-notification [invalid-message-id | invalid-syntax] rekey | setup-timer** *sec* **| transform-set list** *name* **}**

default ikev2-ikesa { allow-empty-ikesa | max-retransmissions | policy error-notification [invalid-message-id | invalid-syntax] rekey | retransmission-timeout | setup-timer }

no ikev2-ikesa { allow-empty-ikesa | keepalive-user-activity | list *name* **| policy error-notification [invalid-message-id | invalid-syntax] | rekey }**

no ikev2-ikesa

Disables a previously enabled parameter.

allow-empty-ikesa

Default is not to allow-empty-ikesa. Activate to have the IKEv2 stack keep the IKE SA when all the Child SAs have been deleted.

keepalive-user-activity

Default is no keepalive-user-activity. Activate to reset the user inactivity timer when keepalive messages are received from peer.

max-retransmissions *number*

Specifies the maximum number of retransmissions of an IKEv2 IKE exchange request if a response has not been received. *number* must be an integer from 1 through 8. Default: 5

policy error-notification

Default policy is to generate an IKEv2 Invalid Message ID error when PDIF receives an out-of-sequence packet. Default is to enable.

retransmission-timeout *msec*

Specifies the timeout period in milliseconds before a retransmission of an IKEv2 IKE exchange request is sent (if the corresponding response has not been received). *msec* must be an integer from 300 to 15000. Default: 500

rekey

Specifies if IKESA rekeying should occur before the configured lifetime expires (at approximately 90% of the lifetime interval). Default is not to re-key.

setup-timer *sec*

Specifies the number of seconds before a IKEv2 IKE Security Association that is not fully established is terminated. *sec* must be an integer from 1 through 3600. Default: 16

transform-set list *name*

Specifies the name of context-level configured IKEv2 IKE Security Association transform set. *name* must be an existing IKEv2 IKESA Transform Set expressed as an alphanumeric string of 1 through 127 characters.

list

A space-separated list of IKEv2-IKESA SA transform sets to be used for deriving IKEv2 IKE Security Associations from this crypto template. A minimum of one transform-set is required; maximum configurable is six.

Usage

Use this command to configure parameters for the IKEv2 IKE Security Associations within this crypto template.

Example

The following command configures the maximum number of IKEv2 IKESA request retransmissions to *7*:

```
ikev2-ikesa max-retransmissions 7
```

The following command configures the IKEv2 IKESA request retransmission timeout to *400*:

```
ikev2-ikesa retransmission-timeout 400
```

The following command configures the IKEv2 IKESA transform set list name to *ikesa43*:

```
ikev2-ikesa transform-set list ikesa43
```

keepalive

Configures keepalive or dead peer detection for security associations used within this crypto template.

Product

All

Privilege

Security Administrator, Administrator

Syntax

keepalive [interval *sec* **] [timeout** *sec* **] [num-retry** *num* **]**

default keepalive [interval] [timeout] [num-retry]

no keepalive

no

Disables keepalive messaging.

interval *sec*

Specifies the amount of time (in seconds) that must elapse before the next keepalive request is sent. *sec* must be an integer from 10 through 3600. Default: 10

timeout *sec*

Specifies the amount of time (in seconds) that the system will wait without receiving a reply before retrying the keepalive request. *sec* must be an integer from 10 through 3600. Default: 10

num-retry *num*

Specifies the number of times the system will retry a non-responsive peer before defining the peer as off-line or out-of-service. *num* must be an integer from 1 through 100. Default: 2

Usage

Use this command to set parameters associated with determining the availability of peer servers.

Example

The following command sets a keepalive interval to three minutes (*180* seconds), the timeout to *30* seconds, and the retry attempts number to *5*:

```
keepalive interval 180 timeout 30 num-retry 5
```

max-childsa

Defines a soft limit for the number of Child SAs Child SAs per IKEv2 policy.

Product

FNG

Privilege

Security Administrator, Administrator

Syntax

```
max-childsa <1 . . 4> [ overload action < ignore | terminate > ]
```

max-childsa < 1 . . 4 >

Specifies a soft limit for the maximum number of Child SAs per IKEv2 policy, which can be from 1 to 4.

overload-action

The action taken when the specified soft limit for the maximum number of Child SAs is reached, as follows:

- **ignore**: The IKEv2 stack ignores the specified soft limit for Child SAs.
- **terminate**: The IKEv2 stack rejects any new Child SAs if the specified soft limit is reached.

Usage

The FNG maintains two maximum Child SA values per IKEv2 policy. The first is a system-enforced maximum value, which is four Child SAs per IKEv2 policy. The second is a configurable soft maximum value, which can be a value between one and four. This command defines the soft limit for the maximum number of Child SAs per IKEv2 policy.

Example

The following command specifies a soft limit of 2 Child SAs with the overload action of terminate.

```
max-childsa 2 overload action terminate
```

nai

Configures the Network Access Identifier (NAI) parameters to be used for the crypto template IDr.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

[default | no] nai idr *name* **id-type {rfc822-addr | fqdn | ip-addr | key-id }**

default

Configures the default command **no nai idr**. As a result, the default behavior is for the PDIF-service IP address to be sent as the IDr value of type ID_IP_ADDR.

no

no nai idr configures the value whereby the PDIF service IP address is sent as the IDr value with the type ID_IP_ADDR. This is the default condition.

nai idr *name*

Specifies the name of the IDr crypto template as an alphanumeric string of 1 through 79 characters.

id-type { rfc822-addr | fqdn | ip-addr | key-id }

Configures the NAI IDr type parameter. If no id-type is specified, then **rfc822-addr** is assumed.

- **rfc822-addr**: configures NAI Type ID_RFC822_ADDR.
- **fqdn**: configures NAI Type ID_FQDN.
- **ip-addr**: configures NAI Type ID_IP_ADDR.
- **key-id**: configures NAI Type ID_KEY_ID.

Usage

The configured IDr is sent from the PDIF to the MS in the first IKEv2 AUTH response.

Example

The following command configures the NAI IDr to the default condition.

```
no naiidr
```

natt

Configures Network Address Translation - Traversal (NAT-T) for all security associations associated with this crypto template. This feature is disabled by default.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] natt [ send-keepalive ]
```

default

Disables NAT-T for all security associations associated with this crypto template.

no

Disables NAT-T for all security associations associated with this crypto template.

send-keepalive

Sends NAT-Traversal keepalive messages.

Usage

Use this command to configure NAT-T for security associations within this crypto template.

Example

The following command disables NAT-T for this crypto template:

```
no natt
```

payload

Creates a new, or specifies an existing, crypto template payload and enters the Crypto Template Payload Configuration Mode.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

`[ no ] payload` *`name`* **`match childsa [ match { ipv4 | ipv6 } ]`**

`no`

Removes a currently configured crypto template payload.

`payload` *`name`*

Specifies the name of a new or existing crypto template payload as an alphanumeric string of 1 through 127 characters.

`match childsa [ match { ipv4 | ipv6 }`

Filters IPSec Child Security Association creation requests for subscriber calls using this payload. Further filtering can be performed by applying the following:

- **`match ipv4`**: Configures this payload to be applicable to IPSec Child Security Association requests for IPv4.
- **`match ipv6`**: Configures this payload to be applicable to IPSec Child Security Association requests for IPv6.

Usage

Use this command to create a new or enter an existing crypto template payload. The payload mechanism is a means of associating parameters for the Security Association (SA) being negotiated.
Two payloads are required: one each for MIP and IKEv2. The first payload is used for establishing the initial Child SA Tunnel Inner Address (TIA) which will be torn down. The second payload is used for establishing the remaining Child SAs. Note that if there is no second payload defined with home-address as the *`ip-address-allocation`* then no MIP call can be established, just a Simple IP call.
Currently, the only available match is for ChildSA, although other matches are planned for future releases. Omitting the second match parameter for either IPv4 or IPv6 will make the payload applicable to all IP address pools.
Crypto Template Payload Configuration Mode commands are defined in the *Crypto Template IKEv2-Dynamic Payload Configuration Mode Commands* chapter.

Example

The following command configures a crypto template payload called *`payload5`* and enters the Crypto Template Payload Configuration Mode:

```
payload payload5 match childsa
```

peer network

Configures a list of allowed peer addresses on this crypto template.

Product

All

Privilege

Administrator

Syntax

peer network *ip_address* **{/***mask* **| mask** *ip_mask* **} [encrypted pre-shared-key** *key* **| pre-shared-key** *key* **]**

no peer network *ip_address* **mask** *ip_mask*

no

Removes the specified peer network IP address from this crypto template.

peer network *ip_address* **{/***mask* **| mask** *ip_mask* **}**

Specifies the IP address of the peer network in IPv4 dotted-decimal or IPv6 colon-separated notation.
/*mask* specifies the subnet mask bits. *mask* must be and integer value from 1 to 32 for IPv4 addresses and 1 to 128 for IPv6 addresses (CIDR notation).
mask *ip_mask* specifies the subnet mask in IPv4 dotted-decimal or IPv6 colon-separated notations.

[encrypted pre-shared-key *key* **| pre-shared-key** *key* **]**

encrypted preshared key *key*: Specifies that an encrypted pre-shared key is to be used for IPSec authentication for the address range. *key* must be an alphanumeric string or hexadecimal sequence from 16 to 64.
preshared key *key*: Specifies that a pre-shared key is to be used for IPSec authentication for the address range. *key* must be an alphanumeric string or hexadecimal sequence from 1 to 32.

Usage

Use this command to configure a list or range of allowed peer network IP addresses for this template.

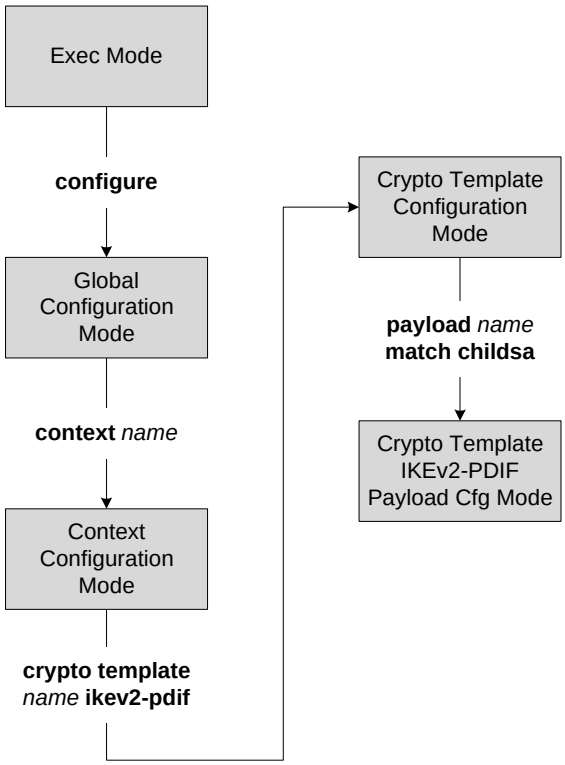
Example

The following command configures a set of IP addresses with starting address of *10.2.3.4* and a bit mask of *8*:

```
peer network 10.2.3.4/8
```

Chapter 63
Crypto Template IKEv2-Dynamic Payload Configuration Mode Commands

The Crypto Template IKEv2-Dynamic Payload Configuration Mode is used to assign the correct IPSec transform-set from a list of up to four different transform-sets, and to assign Mobile IP addresses. There should be two payloads configured. The first must have a dynamic addressing scheme from which the ChildSA gets a TIA address. The second payload supplies the ChildSA with a HoA, which is the default setting for `ip-address-allocation`.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

default

Sets or restores the default value for the specified parameter.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
default { ignore-rekeying-requests | ip-address-allocation lifetime | maximum-child-sa |
rekey | tsi | tsr }
```

ignore-rekeying-requests

Configures the system to ignore IPSec SA rekey requests.

ip-address-allocation

Configures the crypto map payload IP address allocation scheme to be the home address.

lifetime

Configures the default lifetime for IPSec Child SAs derived from this crypto template. **lifetime:** 86400 seconds.

maximum-child-sa

Configures the maximum number of IPSec Child SAs to be derived from an IKEv2 IKE SA by default.

rekey

Configures the system to disable Child SA rekeying.

tsi

Configures the default TSi payload to be that of the mobile endpoint.

tsr

Configures the default TSr payload option.

Usage

Configures system defaults.

Example

Use the following configuration to set the TSi payload start-address to be that of the mobile endpoint:

```
default tsi
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

ignore-rekeying-requests

Ignores CHILD SA rekey requests from the Packet Data Interworking Function (PDIF).

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
ignore-rekeying-requests
```

Usage

Prevents creation of a CHILD SA based on this crypto template.

Example

The following command prevents creation of a CHILD SA based on this crypto template:

```
ignore-rekeying-requests
```

ip-address-allocation

Configures IP address allocation for subscribers using this crypto template payload. Configure two payloads per crypto template. The first must have a dynamic address to assign a tunnel inner address (TIA) to the ChildSA. The second payload is configured after a successful MAnaged IP (MIP) initiation and can use the default Home Address (HoA) option.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
ip-address-allocation { dynamic | home-address | static }

default ip-address-allocation
```

ip-address-allocation dynamic

Specifies that the IP address for the subscriber is allocated from a dynamic IP pool.

ip-address-allocation home-address

The IP address for the subscriber is allocated by the Home Agent. This is the default setting for this command.

ip-address-allocation static

The IP address for the subscriber is a static simple IP address.

Usage

Use this command to configure how ChildSA payloads are allocated IP addresses for this crypto template.

Example

The following command is for the first ChildSA and will ensure that it gets a TIA address from an IP address pool:

```
ip-address-allocation dynamic
```

The following command is for the second ChildSA and will ensure that it gets a HoA address from the HA:

```
default ip-address-allocation
```

ipsec

Configures the IPSec transform set to be used for this crypto template payload.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

[no] ipsec transform-set list *name*

no

Specifies the IPSec transform set to be deleted. This is a space-separated list. From 1 to 4 transform sets can be entered. *name* must be an alphanumeric string of 1 through 127 characters.

ipsec transform-set list *name*

Specifies the context configured IPSec transform set name to be used in the crypto template payload. This is a space-separated list. From 1 to 4 transform sets can be entered. *name* must be an alphanumeric string of 1 through 127 characters.

Usage

Use this command to list the IPSec transform set(s) to use in this crypto template payload.

Example

The following command configures IPSec transform sets named *ipset1* and *ipset2* to be used in this crypto template payload:

```
ipsec transform-set list ipset1 ipset2
```

lifetime

Configures the number of seconds for IPSec Child SAs derived from this crypto template payload to exist.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

lifetime *sec*

default lifetime

lifetime *sec*

Specifies the number of seconds for IPSec Child Security Associations derived from this crypto template payload to exist. *sec* is an integer from 60 through 86400. Default: 86400

default lifetime

Sets the lifetime to its default value of 86400 seconds.

Usage

Use this command to configure the number of seconds for IPSec Child Security Associations derived from this crypto template payload to exist.

Example

The following command configures the IPSec child SA lifetime to be *120* seconds:

```
lifetime 120
```

maximum-child-sa

Configures the maximum number of IPSec child security associations that can be derived from a single IKEv2 IKE security association.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

maximum-child-sa *num*

default maximum-child-sa

maximum-child-sa *num*

Specifies the maximum number of IPSec child security associations that can be derived from a single IKEv2 IKE security association. *num* must be 1. Default: 1

default maximum-child-sa

Sets the maximum number of Child SAs to its default value of 1.

Usage

Use this command to configure the maximum number of IPSec child security associations that can be derived from a single IKEv2 IKE security association.

Example

The following command configures the maximum number of child SAs to 1:

```
maximum-child-sa 1
```

rekey

Configures IPSec Child Security Association rekeying.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] rekey [ keepalive ]
```

no

Disables this feature.

keepalive

If specified, a session will be rekeyed even if there has been no data exchanged since the last rekeying operation. By default, rekeying is only performed if there has been data exchanged since the previous rekey.

Usage

Use this command to enable or disable the ability to rekey IPSec Child SAs after approximately 90% of the Child SA lifetime has expired. The default, and recommended setting, is not to perform rekeying. No rekeying means the PDIF will not originate rekeying operations and will not process CHILD SA rekeying requests from the UE.

Example

The following command disables rekeying:

```
no rekey
```

tsi

Configures the IKEv2 Traffic Selector-Initiator (TSi) payload address options.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

tsi start-address { any { end-address any } | endpoint { end-address *endpoint* **} }**

any { end-address any }

Configures the TSi payload to allow all IP addresses.

endpoint { end-address *endpoint* **}**

Configures the TSi payload start-address to be that of the Mobile endpoint. This is the default value. *endpoint* is the mobile endpoint netmask.

Usage

On receiving a successful IKE_SA_INIT Response from PDIF, the MS sends an IKE_ AUTH Request for the first EAP-AKA authentication. If the MS is capable of doing multiple-authentication, it includes the MULTI_AUTH_SUPPORTED Notify payload in the IKE_AUTH Request. MS also includes an IDi payload containing the NAI, SA, TSi, TSr, and CP (requesting IP address and DNS address) payloads.

Example

Use the following example to configure a TSi payload that allows all addresses:

```
tsi start-address any end-address any
```

tsr

Configures the IKEv2 Traffic Selector-Responder (TSr) payload address options.

Product

PDG/TTG

Privilege

Security Administrator, Administrator

Syntax

tsr start-address *ipv4 address* **end-address** *ipv4 address*

start-address *ipv4 address*

Configures the TSr payload to include the TSr start IPv4 address of an address range for the Phase 1 multiple traffic selector feature.

end-address *ipv4 address*

Configures the TSr payload start-address to include the IPv4 address of the TSr end of an address range for the Phase 1 multiple traffic selector feature.

Usage

As part of Phase 1 of the Multiple Traffic Selector feature, this command is used to specify an IPv4 address range in the single TSr payload that the PDG/TTG returns in the last IKE_AUTH message. This TSr is Child SA-specific.

Example

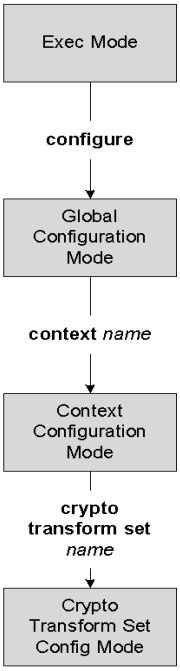
Use the following example to configure a TSr payload that specifies an IPv4 address range for the payload:

```
tsr start-address ipv4 10.2.3.4 end-address 10.2.3.155
```

Chapter 64
Crypto Transform Set Configuration Mode Commands

The Crypto Transform Set Configuration Mode is used to configure properties for system transform sets.

Transform Sets are used to define IPSec security associations (SAs). IPSec SAs specify the IPSec protocols to use to protect packets.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

mode

Configures the IPSec encapsulation mode.

Product

PDSN, HA, GGSN, PDIF

Privilege

Security Administrator, Administrator

Syntax

```
mode { transport | tunnel }
```

mode transport

Specifies that the transform set only protects the upper layer protocol data portions of an IP datagram, leaving the IP header information unprotected. Default: Disabled

Important: This mode should only be used if the communications end-point is also the cryptographic end-point.

mode tunnel

Specifies that the transform set protects the entire IP datagram.
This mode should be used if the communications end-point is different from the cryptographic end-point as in a VPN. Default: Enabled

Usage

This command specifies the encapsulation mode for the transform set.

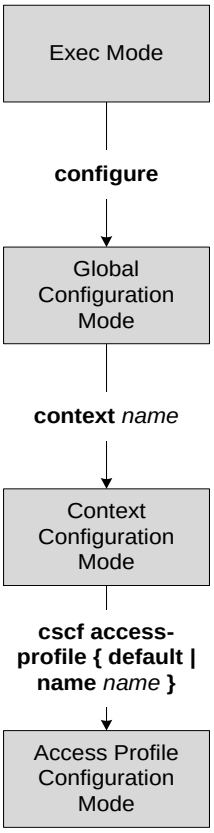
Example

The following command configures the transforms set's encapsulation mode to transport:

```
mode transport
```

Chapter 65
CSCF Access Profile Configuration Mode Commands

The Access Profile Configuration Mode is used to set commands supporting the use of signaling compression, authentication, and SIP timers for subscribers accessing the system from varying network types.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

access-security-type

Sets the type of access security for a P-CSCF/A-BG.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] access-security-type ipsec-3gpp-cscf
```

no

Disables the selected access security type.

ipsec-3gpp-cscf

Security mechanism 3GPP/3GPP2 IPSec.

Usage

Use this command to enable or disable an access security type for a P-CSCF or A-BG.

Example

Enables 3GPP/3GPP2 IPSec access security on P-CSCF or A-BG:

```
access-security-type ipsec-3gpp-cscf
```

Disables 3GPP/3GPP2 IPSec access security on P-CSCF or A-BG:

```
no access-security-type ipsec-3gpp-cscf
```

authentication

Sets the authentication method to use for subscribers using this access profile.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] authentication { aka-v1 | custom-md5 | md5 }
```

no

Disables the selected authentication type.

aka-v1 | custom-md5 | md5

aka-v1: Specifies that the AKA-v1 algorithm will be used for subscribers using this access profile.
custom-md5: Specifies that custom algorithm HTTP-Digest-MD5 will be used for subscribers using this access profile.
md5: Specifies that the MD5 algorithm will be used for subscribers using this access profile. This is the default setting for this command.

Usage

Use this command to set the authentication method used for subscribers using this access profile.

Example

The following command sets the authentication type for subscribers using this access profile to **md5**:

```
authentication md5
```

diameter-selection

Enables or disables prefix and capability-based CDF server selection for this access profile. By default, this command is disabled.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ no ] diameter-selection cdf
```

no

Disables prefix and capability-based CDF server selection.

Usage

Use this command to enable or disable prefix and capability-based CDF server selection per access-type.

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

pcrf-policy-control

Enables PCRF policy control for this access profile.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ default | no ] pcrf-policy-control
```

default | no

PCRF policy control is disabled.

Usage

Use this command to enable or disable PCRF policy control for this access profile.

sigcomp

Enables signalling compression for the Access Profile.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] sigcomp [ force ]
```

no

Disables signalling compression for the Access Profile.

force

Specifies that signaling compression is to be forced for the access type. When this feature is enabled, messages received by the P-CSCF/A-BG that are not compressed are rejected.

Usage

Use this command to enable signalling compression for the specific Access Profile.

timeout

Sets timeout values for CSCF and SIP transactions for subscribers using this Access Profile.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
timeout sip { 3gpp-d sec | 3gpp-t1 msec | 3gpp-t2 sec | 3gpp-t4 sec | c sec | d sec |
invite-expiry sec | t1 msec | t2 sec | t4 sec }

default timeout sip { 3gpp-d | 3gpp-t1 | 3gpp-t2 | 3gpp-t4 | c | d | invite-expiry | t1 |
t2 | t4 }
```

---

sip { 3gpp-d *sec* **| 3gpp-t1** *msec* **| 3gpp-t2** *sec* **| 3gpp-t4** *sec* **| c** *sec* **| d** *sec* **| invite-expiry** *sec* **| t1** *msec* **| t2** *sec* **| t4** *sec* **}**

Sets transaction and expiry timers for SIP.
3gpp-d *sec*: This time is used to control the retransmission of 200OK messages to INVITEs after an ACK is sent. The ACK transaction is cleared after this period. This timer is applicable only for unreliable transport.
sec must be an integer from 0 to 2147483646.
Default: 64*T1 (128 seconds, recommended minimum)
3gpp-t1 *msec*: This timer is used to control the time interval between each retransmission. The interval doubles after each retransmission. This is used by P-CSCF/A-BG only when it sending message toward the UE. Example: T1, 2T1, 4T2, etc. This timer is applicable only for unreliable transport.
msec must be an integer from 0 to 2147483646.
Default: 2000 ms (2 secs, recommended minimum).
3gpp-t2 *sec*: This timer is used to control the period for which the request continues to get retransmitted. This is used by P-CSCF/A-BG only when it sending message toward the UE. This timer is applicable both for reliable and unreliable transport.
sec must be an integer from 0 to 2147483646.
Default: 16 seconds (recommended minimum).
3gpp-t4 *sec*: This timer is used to control the period for which the final response to non-invite transaction should be buffered. The buffered response for the retransmitted non-invite request should be sent within that interval. This timer is applicable only for unreliable transport.
sec must be an integer from 0 to 2147483646.
Default: 17 seconds (recommended minimum).
c *sec*: This timer is used for an INVITE transaction; if the response is a provisional response with status codes 101 to 199 inclusive (anything but 100), the proxy must reset timer C for that client transaction. The timer may be reset to a different value, but this value must be greater than 3 minutes (180 seconds). When timer C in S-CSCF fires first, S-CSCF will send CANCEL request to Terminating P-CSCF and Terminating P-CSCF will send CANCEL request to UAS .
sec must be an integer from 180 to 2147483646.
Default: 180 seconds
d *sec*: This time is used to control the retransmission of 200 OK to INVITE after ACK is sent. The ACK transaction will be cleared after this interval. This timer is applicable only for unreliable transport.
sec must be an integer from 0 to 2147483646.
Default: 64*T1 (32 seconds, recommended minimum)

invite-expiry *sec*: This timer is used by SIP while acting as UA Role and no final response is received for the INVITE request sent. This timer is applicable for both reliable and unreliable transport.
sec must be an integer from 0 to 2147483646.
Default: 100 seconds (recommended minimum).
t1 *msec*: Specifies the time interval (in milliseconds) between each retransmission. The interval doubles after each retransmission, for example: T1, 2T1, 4T2, etc. This timer is applicable only for unreliable transport.
msec must be an integer from 0 to 2147483646.
Default: 500 milliseconds (recommended minimum).
t2 *sec*: This timer is used to control the period for which the request keeps getting retransmitted. This timer is applicable both for reliable and unreliable transport.
sec must be an integer from 0 to 2147483646. The recommended minimum value for this parameter is 4 seconds.
Default: 64*T1 (32 seconds)
t4 *sec*: This timer is used to control the period for which the final response to non-invite transaction should be buffered so as to send the buffered response for the retransmitted non-invite request within that interval. This timer is applicable only for unreliable transport.
sec must be an integer from 0 to 2147483646.
Default: 5 seconds (recommended minimum).

default

Sets/restores default value assigned for specified parameter.

Usage

Use this command to configure SIP Stack timers and CSCF service specific timers for subscriber traffic using this Access Profile.

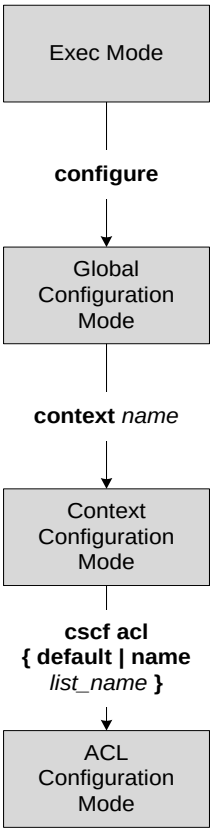
Example

The following command sets the SIP d timer to *64* seconds:

```
timeout sip d 64
```

Chapter 66
CSCF ACL Configuration Mode Commands

The CSCF ACL (Access Control List) Configuration Mode is used to configure session permissions (permit/deny access) within the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

after

Places the CSCF ACL entry at the bottom or end of the ACL. Use this command in conjunction with the **permit** and/or **deny** commands.

Product

SCM

Privilege

Administrator

Syntax

after

Usage

Add this command before the **permit** and/or **deny** commands to place the entry at the end of the ACL.

before

Places the CSCF ACL entry at the beginning or top of the ACL. Use this command in conjunction with the **permit** and/or **deny** commands.

Product

SCM

Privilege

Administrator

Syntax

before

Usage

Add this command before the **permit** and/or **deny** commands to place the entry at the beginning of the ACL.

deny

Configures the system to deny subscriber sessions based on criteria matching the received packet.

Product

SCM

Privilege

Administrator

Syntax

deny { any | destination aor *aor* **| log { any | destination aor** *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability** *capability_type* **| user-agent device-type** *device_type* **} | source { address** *ip_address* **| aor** *aor* **} | subscriber-capability** *capability_type* **| user-agent device-type** *device_type* **} +**

no deny { any | destination aor *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability** *capability_type* **}**

any

Filters all CSCF sessions.

destination aor *aor*

Filters sessions based on the destination AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

log { any | destination aor *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability {** *capability_type* **} | user-agent device-type** *device_type* **}**

Enables logging for CSCF sessions meeting the criteria specified in the ACL. The logs can be viewed by executing the **logging filter active facility acl-log** command in the Exec mode.
Specifies the criteria that packets will be compared against. The following criteria are supported:

- **any**
- **destination aor** *aor*
- **source address** *ip_address*
- **source aor** *aor*
- **subscriber-capability** *capability_type*
- **user-agent device-type** *device_type*

source { address *ip_address* **| aor** *aor* **}**

Filters session based on the source IP address or AoR.

- *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
- *aor* must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the *SCM Engineering Rules* Appendix in the *Cisco ASR 5000 Series Session Control Manager Administration Guide* for more information about regular expressions.

subscriber-capability { *capability_type* }

Filters session based on one of the following subscriber capability types:

- **at** - Custom AT Type
- **audio** - Audio Capability Type
- **chat** - Custom CHAT Type
- **cs** - Custom CS Type
- **ft** - Custom FT Type
- **im** - Custom IM Type
- **mms** - Custom MMS Type
- **msg** - Custom MSG Type
- **oma-sip-im** - Custom OMA SIP-IM Type
- **rcs-dp** - Custom RCS-DP Type
- **rcs-e** - Custom RCS-E Type
- **rcs-ft** - Custom RCS-FT Type
- **rcs-im** - Custom RCS-IM Type
- **rcs-is** - Custom RCS-IS Type
- **rcs-sp** - Custom RCS-SP Type
- **rcs-vs** - Custom RCS-VS Type
- **text** - Text Capability Type
- **video** - Video Capability Type
- **vt** - Custom VT Type
- **vt-ft** - Custom VT-FT Type
- **vt-is** - Custom VT -IS Type
- **vt-loc** - Custom VT-LOC Type
- **vt-memo** - Custom VT-MEMO Type

user-agent device-type *device_type*

Filters session based on device-type in user-agent header.
device_type must be from 1 to 15 characters in length. The following user agent device types are supported.

- feature_phone
- smart_phone
- pad
- tablet_pc
- pc

- soft_phone
- modem

+

This symbol indicates that the keywords can be entered multiple times within a single command.

no deny { any | destination aor *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability {** *capability_type* **} }**

Removes specified filter criteria.

Usage

Specifies the subscriber sessions to deny based on the criteria specified.

Example

The following command denies access to subscribers with a source address of *1.2.3.4*:

```
deny source address 1.2.3.4
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

```
exit
```

Usage

Return to the previous mode.

permit

Configures the system to allow subscriber sessions based on criteria matching the received packet.

Product

SCM

Privilege

Administrator

Syntax

permit { any | destination aor *aor* **| log { any | destination aor** *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability** *capability_type* **| user-agent device-type** *device_type* **} | source { address** *ip_address* **| aor** *aor* **} | subscriber-capability** *capability_type* **| user-agent device-type** *device_type* **} +**

no permit { any | destination aor *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability** *capability_type* **}**

any

Filters all CSCF sessions.

destination aor *aor*

Filters sessions based on the destination AoR.
aor must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the *SCM Engineering Rules* Appendix in the *Cisco ASR 5000 Series Session Control Manager Administration Guide* for more information about regular expressions.

log { any | destination aor *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability { ***capability_type* **} | user-agent device-type** *device_type* **}**

Enables logging for CSCF sessions meeting the criteria specified in the ACL. The logs can be viewed by executing the **logging filter active facility acl-log** command in the Exec mode.
Specifies the criteria that packets will be compared against. The following criteria are supported:

- **any**
- **destination aor** *aor*
- **source address** *ip_address*
- **source aor** *aor*
- **subscriber-capability** *capability_type*
- **user-agent device-type** *device_type*

source { address *ip_address* **| aor** *aor* **}**

Filters session based on the source IP address or AoR.

- *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
- *aor* must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

subscriber-capability { *capability_type* **}**

Filters session based on one of the following subscriber capability types:

- **at** - Custom AT Type
- **audio** - Audio Capability Type
- **chat** - Custom CHAT Type
- **cs** - Custom CS Type
- **ft** - Custom FT Type
- **im** - Custom IM Type
- **mms** - Custom MMS Type
- **msg** - Custom MSG Type
- **oma-sip-im** - Custom OMA SIP-IM Type
- **rcs-dp** - Custom RCS-DP Type
- **rcs-e** - Custom RCS-E Type
- **rcs-ft** - Custom RCS-FT Type
- **rcs-im** - Custom RCS-IM Type
- **rcs-is** - Custom RCS-IS Type
- **rcs-sp** - Custom RCS-SP Type
- **rcs-vs** - Custom RCS-VS Type
- **text** - Text Capability Type
- **video** - Video Capability Type
- **vt** - Custom VT Type
- **vt-ft** - Custom VT-FT Type
- **vt-is** - Custom VT -IS Type
- **vt-loc** - Custom VT-LOC Type
- **vt-memo** - Custom VT-MEMO Type

user-agent device-type *device_type*

Filters session based on device-type in user-agent header.
device_type must be from 1 to 15 characters in length. The following user agent device types are supported.

- feature_phone
- smart_phone
- pad
- tablet_pc
- pc

- soft_phone
- modem

+

This symbol indicates that the keywords can be entered multiple times within a single command.

no permit { any | destination aor *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability {** *capability_type* **} }**

Removes specified filter criteria.

Usage

Specifies the subscriber sessions to permit based on the criteria specified.

Example

The following command permits access to subscribers with a destination AoR of *$.@abc123.com*:

```
permit destination aor $.@abc123.com
```

redirect

Configures the system to redirect subscriber sessions to another CSCF based on criteria matching the received packet.

Product

SCM

Privilege

Administrator

Syntax

redirect { address *ip_address* **| host** *host_name* **} [port** *port_number* **] { any | destination aor** *aor* **| log { any | destination aor** *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability** *capability_type* **| user-agent device-type** *device_type* **} | source { address** *ip_address* **| aor** *aor* **} | subscriber-capability** *capability_type* **| user-agent device-type** *device_type* **} +**

no redirect { address *ip_address* **| host** *host_name* **} [port** *port_number* **] { any | destination aor** *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability** *capability_type* **}**

address *ip_address*

The address to which UE should be redirected.
ip_address must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.

host *host_name*

The host to which UE should be redirected.
host_name must be an existing name from 1 to 79 characters in length.

port *port_number*

The port at which request should be redirected.
port_number must be an integer from 1 to 65535.

any

Redirect UE to address/host.

destination aor *aor*

Redirect UE to address/host if destination AoR matches.
aor must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

log { any | destination aor *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability { ** *capability_type* **} | user-agent device-type** *device_type* **}**

Enables logging for redirect ed UE meeting the criteria specified in the ACL. The logs can be viewed by executing the **logging filter active facility acl-log** command in the Exec mode.

Specifies the criteria that packets will be compared against. The following criteria are supported:

- **any**
- **destination aor** *aor*
- **source address** *ip_address*
- **source aor** *aor*
- **subscriber-capability** *capability_type*
- **user-agent device-type** *device_type*

---

source { address *ip_address* **| aor** *aor* **}**

Redirect UE to address/host if source IP address or AoR matches.

- *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
- *aor* must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

---

subscriber-capability { *capability_type* **}**

Redirect UE to address/host if contact has one of the following subscriber capability types:

- **at** - custom AT type
- **audio** - audio capability type
- **chat** - custom CHAT type
- **cs** - custom CS type
- **ft** - custom FT type
- **im** - custom IM type
- **mms** - custom MMS type
- **msg** - Custom MSG Type
- **oma-sip-im** - Custom OMA SIP-IM Type
- **rcs-dp** - Custom RCS-DP Type
- **rcs-e** - Custom RCS-E Type
- **rcs-ft** - Custom RCS-FT Type
- **rcs-im** - Custom RCS-IM Type
- **rcs-is** - Custom RCS-IS Type
- **rcs-sp** - Custom RCS-SP Type
- **rcs-vs** - Custom RCS-VS Type
- **text** - Text Capability Type
- **video** - Video Capability Type
- **vt** - Custom VT Type
- **vt-ft** - Custom VT-FT Type
- **vt-is** - Custom VT -IS Type

- **vt-loc** - Custom VT-LOC Type
- **vt-memo** - Custom VT-MEMO Type

---

user-agent device-type *device_type*

Redirect UE to address/host according to device-type in user-agent header.
device_type must be from 1 to 15 characters in length. The following user agent device types are supported.

- feature_phone
- smart_phone
- pad
- tablet_pc
- pc
- soft_phone
- modem

+

This symbol indicates that the keywords can be entered multiple times within a single command.

---

no redirect { address *ip_address* **| host** *host_name* **} [port** *port_number* **] { any | destination aor** *aor* **| source { address** *ip_address* **| aor** *aor* **} | subscriber-capability {** *capability_type* **} }**

Removes specified redirect location and filter criteria.

Usage

Specifies the subscriber sessions to redirect based on the criteria specified.

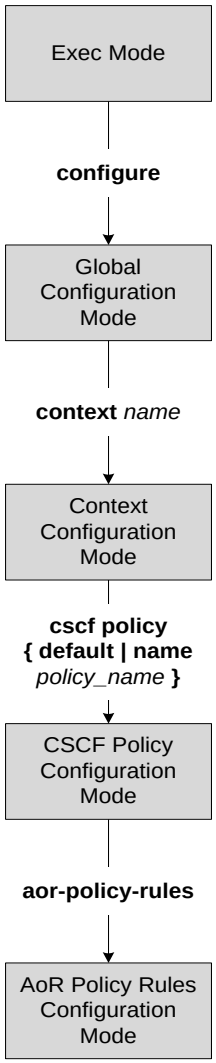
Example

The following command redirects subscribers with a destination AoR of *$.@abc123.com* to host *scscf.com*:

```
redirect host scscf.com destination aor $.@abc123.com
```

Chapter 67
CSCF AoR Policy Rules Configuration Mode Commands

The CSCF AoR Policy Rules Configuration Mode is used to manage AoR policy profiles within the system. Both default and user-defined profiles can be managed in this mode.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

after

Places the CSCF policy entry at the bottom or end of the policy list. Use this command in conjunction with the **aor** command.

Product

SCM

Privilege

Administrator

Syntax

after

Usage

Add this command before the **aor** command to place the entry at the end of the policy list.

aor

Configures an AoR profile and enters the AoR Profile Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

[no] aor *aor_name*

no

Removes the AoR profile from the system.

aor_name

Specifies a name for the AoR profile.
aor_name must be from 1 to 79 alpha and/or numeric characters in length.

Usage

Use this command to create or modify an AoR profile and enter the CSCF Policy Rules Configuration Mode. Entering this command results in the following prompt:
[*context_name*]*hostname*(config-*aor_name*-aor)#
CSCF Policy Rules Configuration Mode commands are defined in the CSCFPolicy Rules Configuration Mode Commands chapter of this guide.

Example

The following command creates an AoR profile named *aor5* and enters the AoR Profile Configuration Mode:

```
aor aor5
```

before

Places the CSCF policy entry at the top or beginning of the policy list. Use this command in conjunction with the **aor** command.

Product

SCM

Privilege

Administrator

Syntax

before

Usage

Add this command before the **aor** command to place the entry at the beginning of the policy list.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

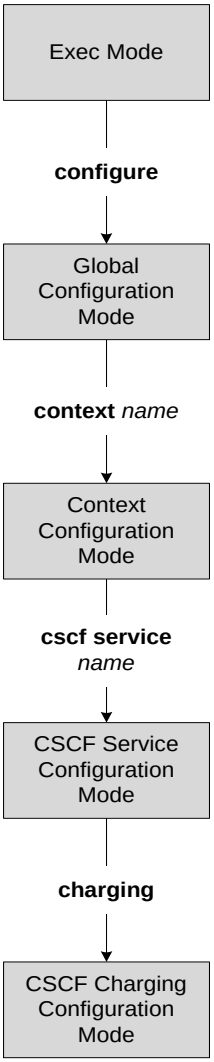
```
exit
```

Usage

Return to the previous mode.

Chapter 68
CSCF Charging Configuration Mode Commands

The CSCF Charging Configuration Mode is used to manage CSCF service policy profiles within the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exclude

Configures the service to exclude SIP requests from the Rf charging configuration.

Product

SCM

Privilege

Administrator

Syntax

[no] exclude { custom *sip_method* **| invite | message | notify | register | subscribe | update }**

no

Removes the exclusion of the specified SIP request message type.

custom *sip_method*

Specifies CUSTOM SIP requests that are to be excluded from Rf charging.
sip_method can be a name of any SIP method and be from 1 to 31 alpha and/or numeric characters.

invite

Specifies that INVITE SIP requests are to be excluded from Rf charging.

message

Specifies that MESSAGE SIP requests are to be excluded from Rf charging.

notify

Specifies that NOTIFY SIP requests are to be excluded from Rf charging.

register

Specifies that REGISTER SIP requests are to be excluded from Rf charging.

subscribe

Specifies that SUBSCRIBE SIP requests are to be excluded from Rf charging.

update

Specifies that UPDATE SIP requests are to be excluded from Rf charging.

Usage

Use this command to exclude specific SIP requests from Rf charging.

Example

The following command configures the service to exclude SIP REGISTER requests from Rf charging:

```
exclude register
```

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

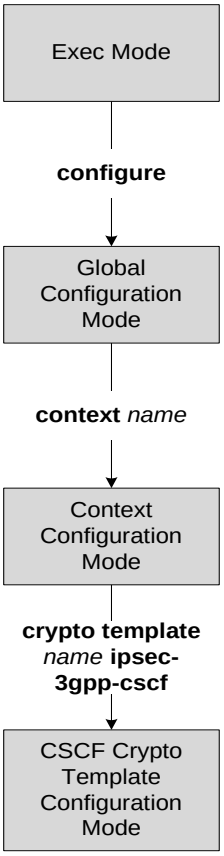
```
exit
```

Usage

Return to the previous mode.

Chapter 69
CSCF Crypto Template Configuration Mode Commands

The CSCF Crypto Template Configuration Mode is used to configure a P-CSCF IPsec policy. It includes most of the IPsec parameters and Internet Key Exchange version 1 (IKEv1) parameters for cryptographic and authentication algorithms etc. A P-CSCF service will not support IPSec without a configured crypto template. Only one crypto template can be configured per P-CSCF service.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec Mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Returns to the previous mode.

ipsec

Configures parameters for the 3GPP/3GPP2 P-CSCF security associations within this crypto template.

Product

SCM

Privilege

Security Administrator, Administrator

Syntax

ipsec transform-set list *list_name*

transform-set list *name*

transform-set: Specifies a context-level IPSec security association transform set to be used for deriving 3GPP/3GPP2 P-CSCF security associations from this crypto template.
list *list_name:* A space separated list of 3GPP/3GPP2 P-CSCF security association transform sets. *list_name* must be an existing 3GPP/3GPP2 P-CSCF transform set and be from 1 to 127 alpha and/or numeric characters.

Important: A minimum of one transform set is required. A maximum of four transform sets may be specified.

Usage

Use this command to configure parameters for the 3GPP/3GPP2 P-CSCF security associations within this crypto template.

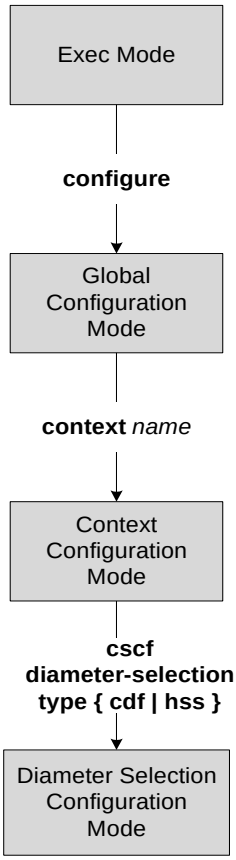
Example

The following command configures the 3GPP/3GPP2 P-CSCF transform set list name to *ikev1list1*:

```
ipsec transform-set list ikev1list1
```

Chapter 70
CSCF Diameter Selection Configuration Mode Commands

The Diameter Selection Configuration Mode is used to configure AAA group selection criteria that will be used for all CDF (enabled for a given access type) or HSS interactions for a subscriber.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

aaa-group

Configures diameter selection entries.

Product

SCM

Privilege

Administrator

Syntax

aaa-group *name* **{ [preference** *value* **] criteria { aor** *aor_prefix* **| subscriber-capability** *capability_type* **| subscriber-ip-type { v4 | v6 } } +**

no aaa-group *name* **preference** *value*

name

Specifies a name for the diameter selection entry.
name must be from 1 to 63 alpha and/or numeric characters.

preference *value*

Configures preference that will be associated with each diameter selection entry. If preference is specified, the entry matching the preference is updated and a new entry is created in the prefix table. If preference is not specified, it is assigned a preference one greater than the last entry's preference in the diameter selection table.
value must be an integer from 1 to 65535.

criteria

Specifies AAA group selection criteria.

aor *aor_prefix*

Filters based on the source or destination AoR.
aor_prefix must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the *SCM Engineering Rules* Appendix in the *Cisco ASR 5000 Series Session Control Manager Administration Guide* for more information about regular expressions.

subscriber-capability *capability_type*

Filters based on the capability of the subscriber.

- **at** - Custom AT Type
- **audio** - Audio Capability Type
- **chat** - Custom CHAT Type
- **cs** - Custom CS Type
- **ft** - Custom FT Type
- **im** - Custom IM Type

- **mms** - Custom MMS Type
- **msg** - Custom MSG Type
- **oma-sip-im** - Custom OMA SIP-IM Type
- **rcs-dp** - Custom RCS-DP Type
- **rcs-e** - Custom RCS-E Type
- **rcs-ft** - Custom RCS-FT Type
- **rcs-im** - Custom RCS-IM Type
- **rcs-is** - Custom RCS-IS Type
- **rcs-sp** - Custom RCS-SP Type
- **rcs-vs** - Custom RCS-VS Type
- **text** - Text Capability Type
- **video** - Video Capability Type
- **vt** - Custom VT Type
- **vt-ft** - Custom VT-FT Type
- **vt-is** - Custom VT -IS Type
- **vt-loc** - Custom VT-LOC Type
- **vt-memo** - Custom VT-MEMO Type

---

subscriber-ip-type { v4 | v6 }

Filters based on the IP type of the subscriber.
v4 - IPv4 type
v6 - IPv6 type

+

This symbol indicates that the keywords can be entered multiple times within a single command.

---

no aaa-group *name* **preference** *value*

Removes configured diameter selection entry.

Usage

This command configures matching criteria for selecting a AAA group name. When a subscriber registers, the selection criteria are compared and the AAA group name from the matching entry will be picked up. The selected aaa-group will be used for all CDF (enabled for a given access type) or HSS interactions for that subscriber.

Example

The following command creates a diameter selection entry named *aaa1*, with a destination AoR criteria of *$.@abc123.com* and preference 125 associated with it:

```
aaa-group aaa1 preference 125 criteria aor $.@abc123.com
```

The following command (immediately following in the configuration file) creates a diameter selection entry named *aaa2*, with a destination AoR criteria of *user@cisco.com* and preference 126 automatically associated with it:

```
aaa-group aaa2 criteria aor user@cisco.com
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

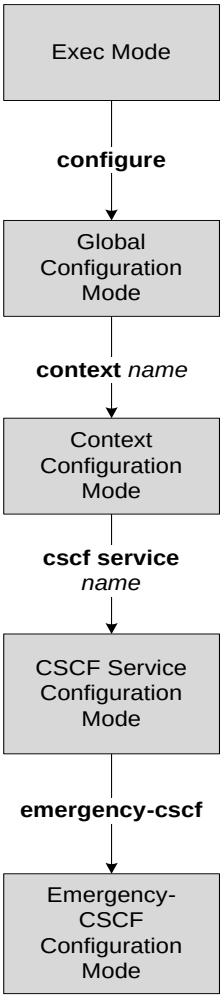
```
exit
```

Usage

Use this command to return to the parent configuration mode.

Chapter 71
CSCF Emergency-CSCF Configuration Mode Commands

The Emergency-CSCF Configuration Mode is used to set commands supporting the role of the CSCF service as an Emergency CSCF.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

privacy

Enables privacy support on the E-CSCF.

Product

SCM

Privilege

Administrator

Syntax

```
[ no | default ] privacy
```

no | default

Removes privacy support from the E-CSCF.

Usage

Use this command to enable privacy support for Emergency CSCF service.

psap-file

Sets the location of the PSAP-Database file to maintain and access the ESRK-Ranges provided by the operator for the E-CSCF.

Product

SCM

Privilege

Administrator

Syntax

psap-file *file_name*

no psap-file

no

Removes the PSAP-Database file from the E-CSCF.

file_name

Specifies the PSAP-Database file in one of the following formats:

- ftp://[username]:[password]@host[/directory]/<filename>
- file:/flash[/directory]/<filename> - URL

Usage

This command is used by the SRDB proclet for ESRK-PSAP database management for the E-CSCF.

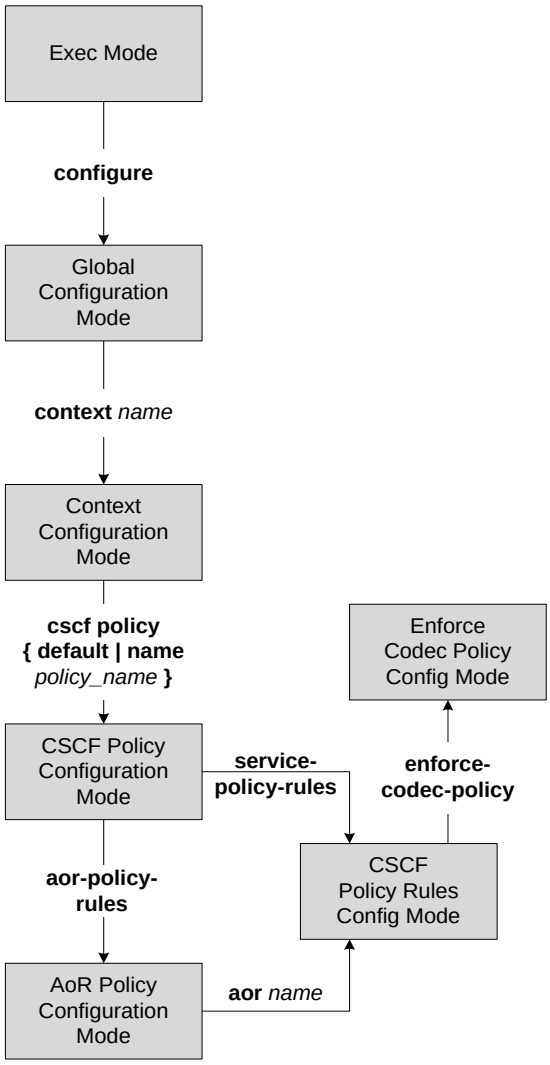
Example

The following command specifies a PSAP-Database file for the E-CSCF:

```
psap-file
ftp://[username]:[password]@10.6.2.246/home/nthattil/psap_profile_CSV_new1.csv
```

Chapter 72
CSCF Enforce Codec Policy Configuration Mode Commands

The CSCF Enforce Codec Policy Configuration Mode is used to manage audio and video codec policies within the system. The parameters defined in this chapter are derived from IETF RFC 3551: “RTP Profile for Audio and Video Conferences with Minimal Control”.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

dynamic-codec

Creates a list of dynamic codecs supported by the system.

Product

SCM

Privilege

Administrator

Syntax

dynamic-codec { audio *encoding_name* **| video** *encoding_name* **} [** *clock_rate* **] [** *channels* **]**

default dynamic-codec

no dynamic-codec [*encoding_name* **] [** *clock_rate* **] [** *channels* **]**

---

audio *encoding_name* **| video** *encoding_name*

audio *encoding_name:* Specifies the encoding name of the dynamic audio codec added to the allowed codec list. *encoding_name* must be from 1 to 49 alpha and/or numeric characters.
video *encoding_name:* Specifies the encoding name of the dynamic video or audio-video codec added to the allowed codec list. *encoding_name* must be from 1 to 49 alpha and/or numeric characters.

[*clock_rate* **] [** *channels* **]**

clock_rate: Specifies the sampling rate of the codec. *clock_rate* must be an integer from 0 to 1000000.
channels: Specifies the number of channels required by the codec. *channels* must be an integer from 1 to 1000000.
Valid dynamic audio codecs:

Encoding Name	Clock Rate (Hz)	Channels
G726-40	8,000	1
G726-32	8,000	1
G726-24	8,000	1
G726-16	8,000	1
G729D	8,000	1
G729E	8,000	1
GSM-EFR	8,000	1
L8	Variable	Variable
RED	See RFC3551	
VDVI	Variable	1

Valid dynamic video codecs:

Encoding Name	Clock Rate (Hz)
H263-1998	90,000

default

Specifies that the default list of dynamic codecs is added to the allowed codecs list. Default dynamic codecs: H263 and AMR.

no dynamic-codec [*encoding_name* **] [** *clock_rate* **] [** *channels* **]**

Specifies that all dynamic codecs are removed from the allowed codecs list. If an *encoding_name* is specified, then only the codec specified by the *encoding_name* is removed. Furthermore, if a supporting *clock_rate* and/or *channels* are specified, then only the *encoding_name* with the specified *clock_rate* and/or *channels* is removed.

Usage

Use this commands to create a list of supported dynamic audio and video codecs in the system. When a request is received by the CSCF, the SDP fields in the message are checked to determine the codec being used. The codec in the SDP fields must match a codec in the allowed codec list or the CSCF rejects the request.

Example

The following command adds the GSM-EFR codec to the allowed dynamic codec list:

```
dynamic-codec GSM-EFR
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

static-codec

Creates a list of static codecs supported by the system.

Product

SCM

Privilege

Administrator

Syntax

```
static-codec { audio payload_type | video payload_type }

default static-codec

no static-codec [ payload_type ]
```

---

audio *payload_type* **| video** *payload_type*

audio *payload_type:* Specifies the audio codec added to the allowed codecs list. *payload_type* must be an integer from 0 to 95. Default value is 5.

Valid static audio codecs:

0: PCMU	7: LPC	14: MPA	21: unassigned
1: reserved	8: PCMA	15: G728	22: unassigned
2: reserved	9: G722	16: DVI4	23: unassigned
3: GSM	10: L16	17: DVI4	
4: G723	11: L16	18: G729	
5: DVI4	12: QCELP	19: reserved	
6: DVI4	13: CN	20: unassigned	

video *payload_type:* Specifies the video or audio-video codec added to the allowed codecs list. *payload_type* must be an integer from 0 to 95. Default value is 5.

Valid static video codecs:

24: unassigned	28: nv	32: MPV	72-76: reserved
25: CelB	29: unassigned	33: MP2T	77-95: unassigned
26: JPEG	30: unassigned	34: H263	
27: unassigned	31: H261	35-71: unassigned	

---

default

Specifies that the default list of static codecs is added to the allowed codecs list.
The default static codec is 5: DVI4.

no static-codec [*payload_type* **]**

Specifies that all static codecs are removed from the allowed codecs list. If a *payload_type* is specified, then only the codec specified by the *payload_type* is removed.

Usage

Use this commands to create a list of supported static audio and video codecs in the system. When a request is received by the CSCF, the SDP fields in the message are checked to determine the codec being used. The codec in the SDP fields must match a codec in the allowed codec list or the CSCF rejects the request.

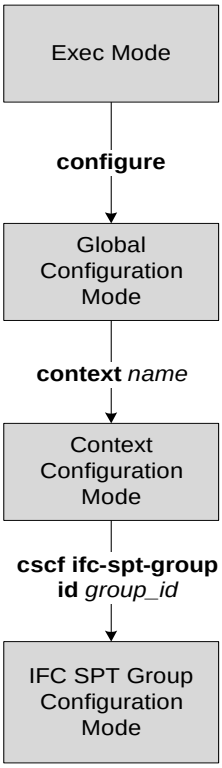
Example

The following command adds the G729 audio codec to the allowed codecs list:

```
static-codec 18
```

Chapter 73
CSCF IFC SPT Group Mode Commands

The CSCF iFC SPT Group Configuration Mode is used to associate individual SPT conditions with an Initial Filter Criteria (iFC) Service Point Trigger (SPT) group.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

spt-condition

Assigns iFC SPT conditions to an existing iFC SPT group.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

`[ no ] spt-condition id` *`cond_id`*

`no`

Removes the specified CSCF iFC SPT condition from the iFC SPT group.

`spt-condition id` *`cond_id`*

Specifies the name of an existing iFC SPT condition.
`cond_name` must be an integer from 1 to 200.

Usage

Use this command to associate individual SPT conditions with an iFC SPT group.

Important: An iFC SPT group may be associated with multiple SPT conditions.

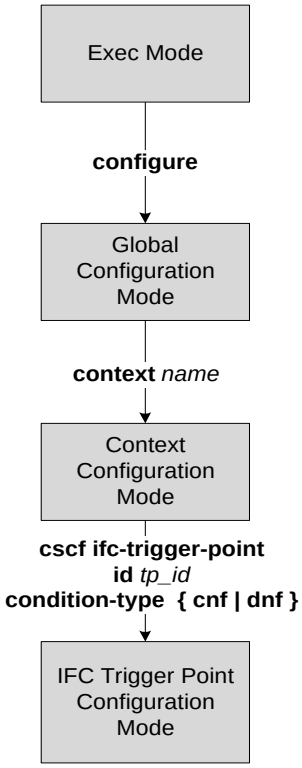
Example

The following command assigns 2 to an iFC SPT group:

```
spt-condition id 2
```

Chapter 74
CSCF IFC Trigger Point Mode Commands

The CSCF iFC Trigger Point Configuration Mode is used to associate an Initial Filter Criteria (iFC) Service Point Trigger (SPT) group with an iFC trigger point.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

spt-group

Assigns an existing iFC SPT group to an iFC trigger point.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

[no] spt-group id *group_id*

no

Removes the specified CSCF iFC SPT group from the iFC trigger point.

spt-group id *group_id*

Specifies the ID of an existing iFC SPT group.
group_id must be an integer from 1 to 200.

Important: An iFC SPT group can be assigned to more than one iFC trigger point.

Usage

Use this command to associate an iFC SPT group with an iFC trigger point.

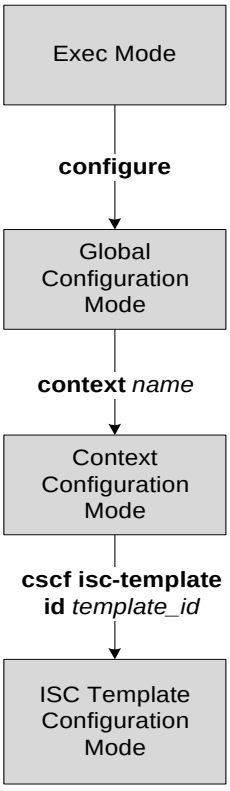
Example

The following command assigns iFC SPT group *2* to an iFC trigger point:

```
spt-group id 2
```

Chapter 75
CSCF ISC Template Configuration Mode Commands

The CSCF ISC Template Configuration Mode is used to configure the IMS Service Control (ISC) interface within the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

cnsa

Core Network Service Authorization (CNSA) related commands used to create media profile and service ids.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

cnsa { media-profile-id *profile_id* **| service-id** *service_id* **[** *service_id* **]...[** *service_id* **] }**

no cnsa { media-profile-id | service-id [*service_id* **] [** *service_id* **]...[** *service_id* **] }**

media-profile *profile_id*

Specifies the cnsa media profile id.
profile_id must be an integer from 0 to 10.
The media profile id is assigned to a service policy using the **cnsa-media-profile** command under CSCF Service configuration.

Important: You can only create one media profile id per ISC template.

service-id *service_id*

Specifies the cnsa service id(s). These ids represent URN parameters which are ICSI (IMS Communication Service Identifier) values that are mapped to a service profile through a media profile id.
service_id must be from 1 to 79 alpha and/or numeric characters.

no cnsa { media-profile-id | service-id [*service_id* **] [** *service_id* **]... [** *service_id* **] }**

Removes a media profile or service id(s).

Usage

Use this command to configure cnsa media profile ids and service ids. Information for core network authorization is received from HSS. It contains a list of service ids and a media profile id. Since the media profile id is an integer value, the S-CSCF needs to have a static database that contains the mapping between the integer value and the subscribed media profile. The media profile id is assigned to this service policy using the **cnsa-media-profile** command under CSCF Service configuration.
The S-CSCF selects the service profile based on the media profile id set and the policies, such as enforce-codec-policy and video-sessions, will be matched with the incoming request. Other policies, if configured, will be ignored in this scenario.

Example

The following command defines the media profile id as 2:

```
cnsa media-profile-id 2
```

The following command defines several service ids:

```
cnsa service-id xxx:exampletelephony.version1 xxx:abc.com
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

filter-criteria

Configure the filter criteria to be used by this template.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

[no] filter-criteria id *criteria_id*

no

Removes the specified filter criteria.

id *criteria_id*

Specifies the ID of existing filter criteria to be used by this template. The particular criteria applied to a subscriber will be based on the priority parameter.
criteria_id must be an integer from 1 to 200.

Important: Filter criteria can be assigned to more than one ISC template.

Usage

Use this command to configure the filter criteria to be used by this template.

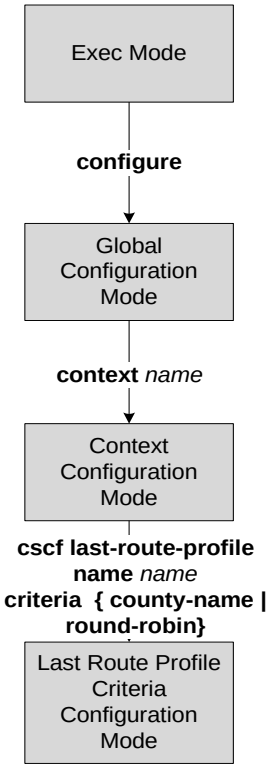
Example

The following command identifies the filter criteria *1*:

```
filter-criteria id 1
```

Chapter 76
CSCF Last Route Profile Criteria Configuration Mode Commands

The CSCF Last Route Profile Criteria Configuration Mode is used to configure county names and assign them Last Routing Option (LRO) numbers to be used by the CSCF last route profile. The S-CSCF forwards emergency call packets to the correct Public Safety Answering Point (PSAP) based on this criteria, which it receives from a peer server.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

county-name

Configure county names and assign them Last Routing Option (LRO) numbers to be used by the CSCF last route profile.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

county-name *county_name* **lro-number** *value*

[no] county-name *county_name*

county_name

Specifies the county name.
county_name must be from 1 to 79 alpha and/or numeric characters in length.

lro-number *value*

Specifies an existing LRO number.
value can be a maximum of ten digits in length.

no county-name *county_name*

Removes the specified county name.

Usage

Use this command to configure county names and assign them LRO numbers.

Important: You may configure up to 100 county names.

Example

The following command creates a county name called *norfolk* and assigns it an LRO number of *8884384357*:

```
county-name norfolk lro-number 8884384357
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

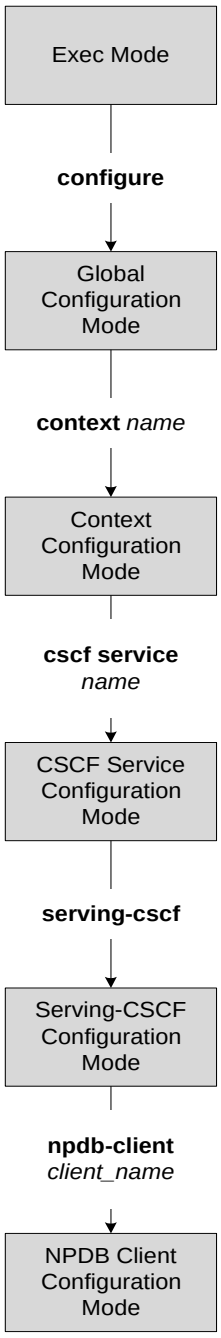
```
exit
```

Usage

Return to the previous mode.

Chapter 77
CSCF NPDB Client Configuration Mode Commands

The NPDB Client Configuration Mode is used to set various commands supporting the role of the NPDB (Number Portability Data Base) client. The NPDB client in a CSCF service performs query for called subscriber number on NPDB server, which returns the Routing Number for the query.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

bind

Binds the NPDB client to an IP address.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

bind address *IPv4_address* **system-id** *system_id* **id** *client_id* **[encrypted] password** *password*

no bind

address *IPv4_address*

Specifies the NPDB client IP address to establish the TCP connection with NPDB server.
IPv4_address must be expressed in dotted decimal notation for IPv4.

system-id *system_id*

Specifies the identifier of the system performing query to NPDB server.
system_id must be an unsigned integer from 0 to 4294962295.

id *client_id*

Specifies the ID of the NPDB client.
client_id must be from 1 to 15 alpha and/or numeric characters.

[encrypted] password *password*

Specifies the password of the NPDB client and whether it is encrypted.
password *password* must be from 1 to 15 alpha and/or numeric characters.
encrypted password *password* must be from 1 to 132 alpha and/or numeric characters.

Important: Normally, encrypted passwords are only used inside configuration files

no bind

Removes the binding of the NPDB client.

Usage

Use this command to establish the NPDB client parameters for TCP connection with NPDB server.

Important: This command can be entered multiple times to identify multiple IP addresses.

In connected state, only NPDB client will able to send query messages to get routing number from NPDB server. When query message is received in non-connected state from core, the NPDB client sends an error message to CSCF core.

Example

The following command binds the NPDB client to an IP address of *1.2.3.4*, system ID of *4294*, client ID of *asdds*, and encrypted password *A01h4b5t5rojj205dhrete*:

```
bind address 1.2.3.4 system-id 4294 id asdds encrypted password
A01h4b5t5rojj205dhrete
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

npdb-primary-server

Configure the NPDB primary server.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

npdb-primary-server { address *IPv4_address* **| domain** *domain* **} port** *port_number*

no npdb-primary-server

---

address *IPv4_address* **| domain** *domain*

Specifies the NPDB primary server.
address *IPv4_address*: IP addresses must be expressed in dotted decimal notation for IPv4.
domain *domain*: Domain name must be entered using from 1 to 255 alpha and/or numeric characters.

---

port *port_number*

Specifies the port at which NPDB primary server listens.
port_number may be an integer from 1024 to 65534.

---

no

Removes the NPDB primary server.

Usage

Use this command to configure the NPDB primary server.

Example

The following command adds an NPDB primary server with an IP address of *1.2.3.4* and a port number of *3878*:

```
npdb-primary-server address 1.2.3.4 port 3878
```

npdb-secondary-server

Configure the NPDB secondary server.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

npdb-secondary-server { address *IPv4_address* **| domain** *domain* **} port** *port_number*

no npdb-secondary-server

---

address *IPv4_address* **| domain** *domain*

Specifies the NPDB secondary server.
address *IPv4_address*: IP addresses must be expressed in dotted decimal notation for IPv4.
domain *domain*: Domain name must be entered using from 1 to 255 alpha and/or numeric characters.

---

port *port_number*

Specifies the port at which NPDB secondary server listens.
port_number may be an integer from 1024 to 65534.

---

no

Removes the NPDB secondary server.

Usage

Use this command to configure the NPDB secondary server.

Example

The following command adds an NPDB secondary server with an IP address of *1.2.3.5* and a port number of *3878*:

```
npdb-secondary-server address 1.2.3.5 port 3878
```

timeout

Sets timeout values for NPDB client.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

timeout { bind-response *sec* **| error-response** *sec* **| idle** *sec* **| ping** *sec* **| ping-response** *sec* **| query-response** *sec* **| release-response** *sec* **| tcp-retry** *sec* **}**

[default | no] timeout { bind-response | error-response | idle | ping | ping-response | query-response | release-response | tcp-retry }

bind-response *sec*

Default: 30
This timer is used to specify the timeout for connection path creation in seconds.
sec must be an integer from 1 to 5000.

error-response *sec*

Default: 30
This timer is used to specify the timeout for error response in seconds.
sec must be an integer from 1 to 5000.

idle *sec*

Default: 30
This timer is used to specify the timeout interval for retrying failed NPDB BIND in seconds.
sec must be an integer from 1 to 5000.

ping *sec*

Default: 20
This timer is used to specify the timeout to send ping message to make the connection alive in seconds.
sec must be an integer from 1 to 5000.

ping-response *sec*

Default: 30
This timer is used to specify the timeout for ping response in seconds.
sec must be an integer from 1 to 5000.

query-response *sec*

Default: 6
This timer is used to specify the timeout for query response in seconds.
sec must be an integer from 1 to 5000.

release-response *sec*

Default: 30
This timer is used to specify the timeout for release response in seconds.
sec must be an integer from 1 to 5000.

tcp-retry *sec*

Default: 15
This timer is used to specify the timeout interval for retrying failed TCP connection in seconds.
sec must be an integer from 1 to 5000.

default

Returns the command to the default settings. See keywords above for specific defaults.

no

Deletes the value configured for the specified timer.

Usage

Use this command to configure timeout values for NPDB client.
When CSCF service is started, NPDB client establishes TCP connections with NPDB primary and secondary servers (if configured) and sets the connection path by sending Bind message to server. If NPDB client fails to establish TCP connection to either of the servers, it will retry the connection every TCPRetryTimer interval until it is successful. When the connection is successful, NPDB client will go to the connected state and will start PingTimer. Whenever NPDB client receives service request from CSCF core, it sends the request based on the connected state of the server(s); it should always give higher preference to the primary server. When it fails to send a query message to server, NPDB client returns failure to the core. If both servers are not in connected state, NPDB client will send failure message to CSCF core.

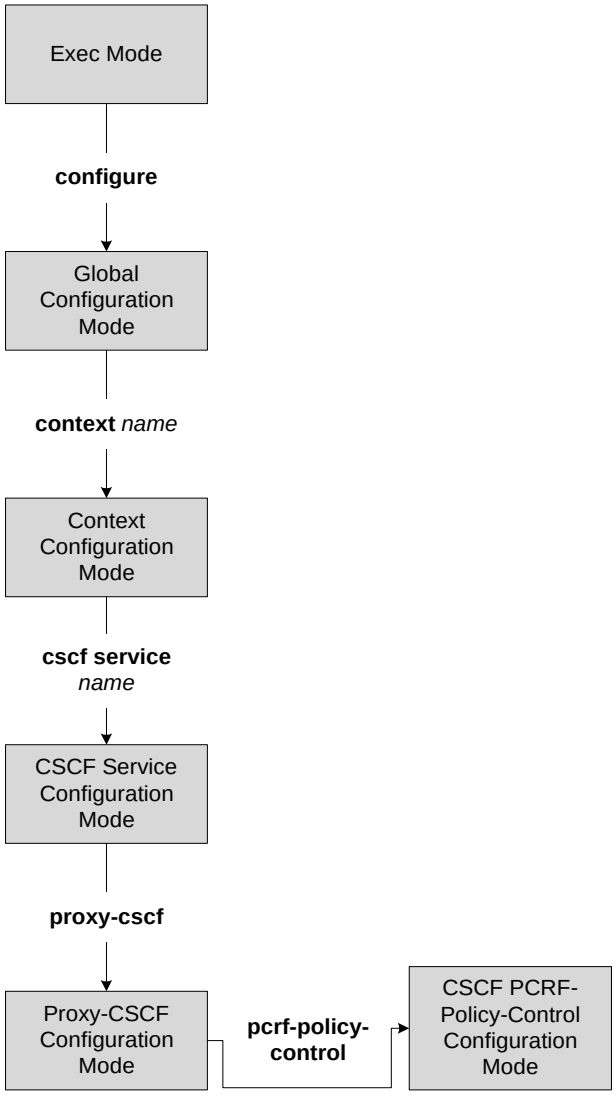
Example

The following command sets the release response timeout to *64* seconds:

```
timeout release-response 64
```

Chapter 78
CSCF PCRF-Policy-Control Configuration Mode Commands

The PCRF-Policy-Control Configuration Mode is used to enable PCRF policy control within the service.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

authorization mediatype

Enables media authorization, using external PCRF via Rx, of specific media types (present in the SDP of a SIP message) only.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] authorization mediatype { application | audio | control | data | message | others
| text | video }
```

mediatype { application | audio | control | data | message | others | text | video }

Enables the external authorization of calls for the following SDP media types:

- **application**
- **audio**
- **control**
- **data**
- **message**
- **others**
- **text**
- **video**

no

Disables external authorization for the specified media type.

Usage

As Per 3GPP 29.214V8.5, P-CSCF/A-BG will authorize VOIP calls only for the media types enabled via this command. The P-CSCF/A-BG sends all media information for all supported media types present in SDP in AAR message to PCRF via Rx. For the other (unsupported) media types, P-CSCF will not send media information in AAR.
Be default, media authorization for all the media types is enabled.

Example

Enables the P-CSCF to authorize calls for audio media types:

```
authorization mediatype audio
```

Disables the authorization of calls for audio media types:

```
no authorization mediatype audio
```

authorization policy-interworking-failure

Allows/rejects a session based on configuration in case of failure from PCRF.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

authorization policy-interworking-failure { session-continue | session-reject [response-code *code* **])**

default authorization policy-interworking-failure

session-continue

P-CSCF continues session in case of failure from PCRF.

session-reject

P-CSCF rejects session in case of failure from PCRF.

response-code *code*

Specifies SIP response code for rejected session.
number must be an integer from 400 to 699. Default is 500.

default

By default, **session-reject** is activated to reject session with default response code 500.

Usage

Use this command to configure for policy interworking failure. Allow or reject a session based on configuration in case of failure from PCRF.

Example

The following command rejects session in case of failure from PCRF with SIP response code *450*:

```
authorization policy-interworking-failure session-reject response-code
450
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

signaling-bearer-loss

Enables subscription to Notification of Signaling Transmission Path Status, as well as IPCAN Change type notification. This command is enabled by default.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] signaling-bearer-loss subscription
```

no

Disables subscription to Notification of Signaling Transmission Path Status, as well as IPCAN Change type notification.

subscription

Enables subscription to Notification of Signaling Transmission Path Status, as well as IPCAN Change type notification.

Usage

Use this command to enable or disable subscription to Notification of Signaling Transmission Path Status, as well as IPCAN Change type notification.
When enabled, the P-CSCF/A-BG sends AAR to the external PCRF via the Rx interface after UE registration. When disabled, the P-CSCF/A-BG will not subscribe to any event during Registration with PCRF and no diameter session will be established.

Example

Enables subscription to Notification of Signaling Transmission Path Status, as well as IPCAN Change type notification:

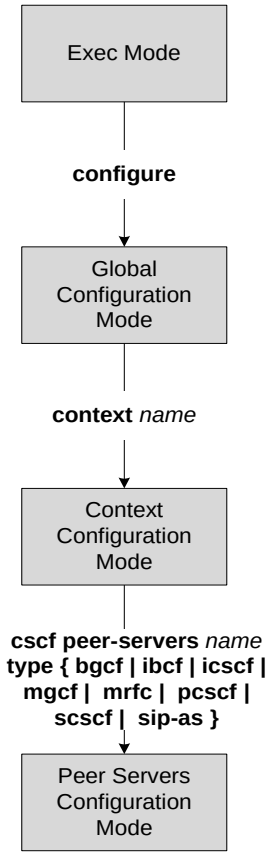
```
signaling-bearer-loss subscription
```

Disables subscription to Notification of Signaling Transmission Path Status, as well as IPCAN Change type notification:

```
no signaling-bearer-loss subscription
```

Chapter 79
CSCF Peer Servers Configuration Mode Commands

The CSCF Peer Servers Configuration Mode is used to configure peer servers (for next-hop session routes) within the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

hunting-method

Configures the method by which server is contacted.

Product

SCM

Privilege

Administrator

Syntax

```
hunting-method { round-robin | sequence-on-failure | weighed }

default hunting-method
```

round-robin | sequence-on-failure | weighed

Specifies the hunting method for the server.
round-robin: Specifies that the server will be used in round-robin fashion. This is the default setting.
sequence-on-failure: Specifies that the server will be used sequentially if a failure occurs on a server (i.e., first peer server is always used, except on failure, during which next peer server in the list will be used).
weighed: Specifies that the peer server has a set "weight" that determines use as compared to the other like-configured peer servers. The actual weight of the peer server is configured in the **server** command in this mode.

default

Specifies that the server will be used in round-robin fashion.

Usage

Use this command to configure the method that is used by the system to connect to the peer server.

Example

The following command sets the hunting method for a server to contact sequentially only when a server fails:

```
hunting-method sequence-on-failure
```

server

Configures the name, IP address, and port of servers belonging to this peer server and enters the Server Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

server *name* **{ address** *ip_address* **| domain** *domain_name* **} [port** *number* **] [transport { tcp | udp }] [weight** *number* **]**

no server *name*

name

Specifies a name for the server. *name* must be from 1 to 79 alpha and/or numeric characters in length.

address *ip_address*

Specifies the IP address of the server. *ip_address* is expressed in dotted decimal notation for IPv4 or colon notation for IPv6.

domain *domain_name*

Specifies the domain name of the peer server. *domain_name* must be from 1 to 255 alpha and/or numeric characters in length.

port *number*

Specifies the port number of the server.
number must be an integer value from 1 to 65535.

transport { tcp | udp }

Specifies the transport type (TCP or UDP).

weight *number*

Default: 5
Specifies a weighted number for the specific peer server for load balancing purposes. *number* must be an integer value from 1 to 10. Higher weight implies larger server capability (and more routed requests).

Important: This keyword is only valid if the **weighed** keyword is applied to the **hunting-method** command in this mode.

no server *name*

Removes the specified server from the group.

Usage

Use this command to configure servers and enter the Server Configuration Mode.
Entering this command results in the following prompt:

```
[context_name]hostname(config-server_name-peer-server)#
```

Server Configuration Mode commands are defined in the *CSCF Peer Server Monitoring Configuration Mode Commands* chapter.

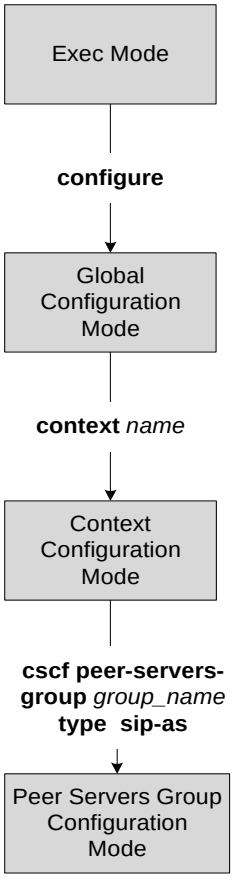
Example

The following command configures a server named *scscf5* with an IP address of *1.2.3.4* and a port number of *5060*:

```
server scscf5 address 1.2.3.4 port 5060
```

Chapter 80
CSCF Peer Servers Group Configuration Mode Commands

The CSCF Peer Servers Group Configuration Mode is used to configure peer servers lists within a peer servers group.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

peer-servers

Configures peer servers lists in the peer servers group.

Product

SCM

Privilege

Administrator

Syntax

peer-servers *list_name* **{ default | mode { active | standby } }**

no peer-servers *list_name*

list_name

Specifies a name for the peer servers list. *list_name* must be from 1 to 79 alpha and/or numeric characters in length.

default

Specifies that the peer servers list is default.

mode { active | standby }

Specifies whether the peer servers list is active or standby.

no peer-servers *list_name*

Removes the specified peer servers list from the group.

Usage

Use this command to manage peer servers lists in a peer servers group.

Important: There can be one active, one standby, and one default peer servers list in a peer servers group.

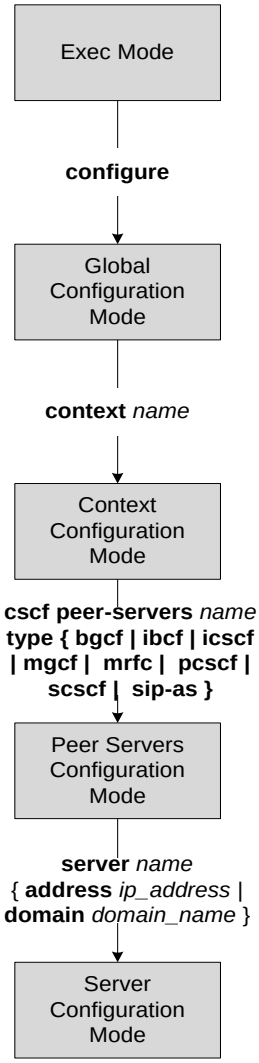
Example

The following command configures an active peer servers list named *active_as_list*:

```
peer-servers active_as_list mode active
```

Chapter 81
CSCF Peer Server Monitoring Configuration Mode Commands

The CSCF Peer Server Monitoring Configuration Mode is used to configure an individual peer server's monitoring parameters and operational mode. It also associates a network session template with the server.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

dummy-as

Sets a response code for Dummy-AS peer server.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

dummy-as custom-response-code *SIP_response_code*

default dummy-as custom-response-code

custom-response-code *SIP_response_code*

If the peer server is configured as dummy-as and it is chosen as per routing table configured, a UMM response message will be formed with the response code configured and sent as reply to incoming MESSAGE/PUBLISH requests.
SIP_response_code must be an integer from 200 to 699.

Important: The response code can be 2xx/4xx/5xx/6xx; 3xx,401,and 407 are not allowed.

default dummy-as custom-response-code

Sets the response code to 200.

Usage

Use this command to configure a response code for Dummy-AS. If this mode is selected, then MESSAGE/PUBLISH requests will be responded to by S-CSCF with configured response code.

Example

The following command configures AS as Dummy-AS with a corresponding response code of *425*:

```
dummy-as custom-response-code 425
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

```
exit
```

Usage

Return to the previous mode.

ims-capable

Indicates whether the peer server belongs to a 3GPP/IMS network or a non-IMS network such as the Internet. This command is used to determine at the S-CSCF whether SIP signaling inter-working is needed when the calls are forwarded to external networks.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ no ] ims-capable
```

no

Removes the identification of "IMS capable" from the selected peer server.

Usage

Use this command to identify a peer server as IMS capable allowing the S-CSCF to use SIP signalling inter-working when forwarding calls to non-IMS capable networks.

lro-selection-profile

Binds a CSCF last route profile with the peer server.

Product

SCM

Privilege

Administrator

Syntax

lro-selection-profile name *profile_name*

no lro-selection-profile

lro-selection-profile name *profile_name*

profile_name must be an existing CSCF last route profile and be from 1 to 79 alpha and/or numeric characters.

no lro-selection-profile

Removes CSCF last route profile from the peer server group.

Usage

Use this command to identify a CSCF last route profile to use for finding the correct Public Safety Answering Point (PSAP) during emergency calls.

Example

The following command assigns a CSCF last route profile named *lro1* to the peer server group:

```
lro-selection-profile name lro1
```

The following command removes a CSCF last route profile from the peer server group:

```
no lro-selection-profile
```

mode

Sets the peer server mode to either active or standby. By default, peer servers are in active mode.

Product

SCM

Privilege

Administrator

Syntax

```
mode { active | standby }
```

active

Defines the mode of the CSCF peer server as active.

standby

Defines the mode of the CSCF peer server as standby.

Usage

Use this command to set the peer server mode to either active or standby.

Example

The following command sets the peer server's mode to standby:

```
mode standby
```

monitor-status

Sets parameters for monitoring the status of peer servers.

Product

SCM

Privilege

Administrator

Syntax

```
monitor-status { max-response-codes negative max | [ monitor-interval seconds ] [
monitor-message options [ max-forwards max | response-timer seconds ] ] [ monitor-
response-timer seconds ] | response-code { positive SIP_response_code | negative
SIP_response_code } | timer [ mark-out-of-service seconds ] [ unavailable-monitor-
interval seconds ] [ unavailable-notification seconds ] }

no monitor-status { monitor | response-code [ negative | positive ] [ SIP_response_code ]
}
```

max-response-codes negative *max*

Default: 1
Specifies the maximum number of negative response codes to receive to mark server unavailable.
max must be an integer from 1 to 10.

monitor-interval *seconds*

Default: 30
Specifies the interval that peer server monitoring will occur.
seconds must be an integer from 1 to 65535.

monitor-message options [max-forwards *max* **| response-timer** *seconds* **]**

Specifies that SIP message (OPTIONS) are to be sent periodically after each monitoring interval.
max-forwards *max*: Max-forwards in number of hops. *max* must be an integer from 0 to 70.
response-timer *seconds*: Response wait timer in seconds. *seconds* must be an integer from 1 to 65535.

monitor-response-timer *seconds*

Default: 180
Specifies the interval that the CSCF will wait for responses from the peer server.
seconds must be an integer from 1 to 65535.

response-code { positive *SIP_response_code* **| negative** *SIP_response_code* **}**

Specifies the Options Message response codes.
negative: Negative response codes. *SIP_response_code* must be an integer from 300 to 699.
positive: Positive response codes. *SIP_response_code* must be an integer from 200 to 299.

timer mark-out-of-service *seconds*

Default: 864000
Timer to mark server out-of-service from unavailable state.

seconds must be an integer from 0 to 2147483646.

timer unavailable-monitor-interval *seconds*

Periodic monitor interval to be used when server is marked as unavailable.
seconds must be an integer from 0 to 2147483646.

timer unavailable-notification *seconds*

Default: 180
Time after which to send notification to operations administrator.
seconds must be an integer from 0 to 2147483646.

no monitor-status { monitor | response-code [negative | positive] [*SIP_response_code* **] }**

Disables peering server status monitoring.

Usage

Use this command to set parameters for monitoring the status of a peer server.

Example

The following command sets the monitoring interval to three minutes (*180* seconds) and the response timer to six minutes (*360* seconds):

```
monitor-status monitor-interval 180 monitor-response-timer 360
```

nw-session-template

Specifies a session template for sessions terminating from the peer server group.

Product

SCM

Privilege

Administrator

Syntax

nw-session-template name *template_name*

no nw-session-template

name *template_name*

template_name must be an existing session template created in the Session Template Configuration Mode.

no

Removes session template from the peer server group.

Usage

Use this command to identify a session template to use for sessions terminating from the peer server group.

Example

The following command identifies a session template named *template-25* to use for sessions terminating from the peer server group:

```
nw-session-template template-25
```

registration

This command specifies whether the S-CSCF skips third party registration to the Application Server (AS) by a configured time after initial registration.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

registration skip-count *count*

no registration skip-count

skip-count *count*

Number of times to skip third party registration.
count must be an integer from 0 (default) to 60.

no registration skip-count

The S-CSCF does not skip third party registration to the AS by a configured time after initial registration.

Usage

Use this command to specify whether the S-CSCF skips third party registration to the Application Server (AS) by a configured time after initial registration. After skipping the configured number of times, the third party register should be sent again to AS to reduce overload on AS.

Example

The following command sets the number of times to skip third party registration to *25*:

```
registration skip-count 25
```

tps-rate

Controls the rate of messages based on Transactions Per Second (TPS) from S-CSCF towards the peer server application server (AS).

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
tps-rate rate [ exclude Register ]

no tps-rate
```

rate

TPS from S-CSCF towards the peer server AS.
rate must be an integer from 1 to 1000.

exclude Register

Specifies that for Register method, TPS rate need not be applied.

no

TPS rate not applied from S-CSCF towards the peer server AS.

Usage

Use this command to control the TPS towards the peer server AS. If TPS rate is exceeded, the incoming requests will be rejected with 500 error response; Retry-After Header specifies the number of seconds before UE should retry.

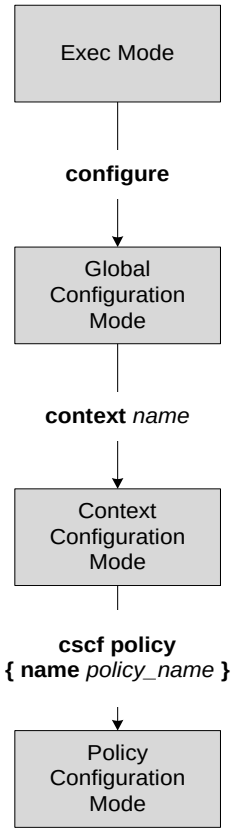
Example

The following command sets the TPS rate towards the AS to *25*:

```
tps-rate 25
```

Chapter 82
CSCF Policy Configuration Mode Commands

The CSCF Policy Configuration Mode is used to manage AoR policy profiles within the system. User-defined profiles can be managed in this mode.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

aor-policy-rules

Specifies that the newly created policy is an AoR policy and enters the AoR Policy Rules Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

```
aor-policy-rules
```

Usage

Use this command to create an AoR policy group and enter the AoR Policy Rules Configuration Mode. Entering this command results in the following prompt:

```
[context_name]hostname(config-aor-policy)#
```

AoR Policy Configuration Mode commands are defined in the *CSCF AoR Policy Rules Configuration Mode Commands* chapter.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

```
exit
```

Usage

Return to the previous mode.

service-policy-rules

Specifies that the newly created policy is a service policy and enters the Service Policy Rules Configuration Mode.

Product

SCM

Privilege

Administrator

Syntax

```
service-policy-rules
```

Usage

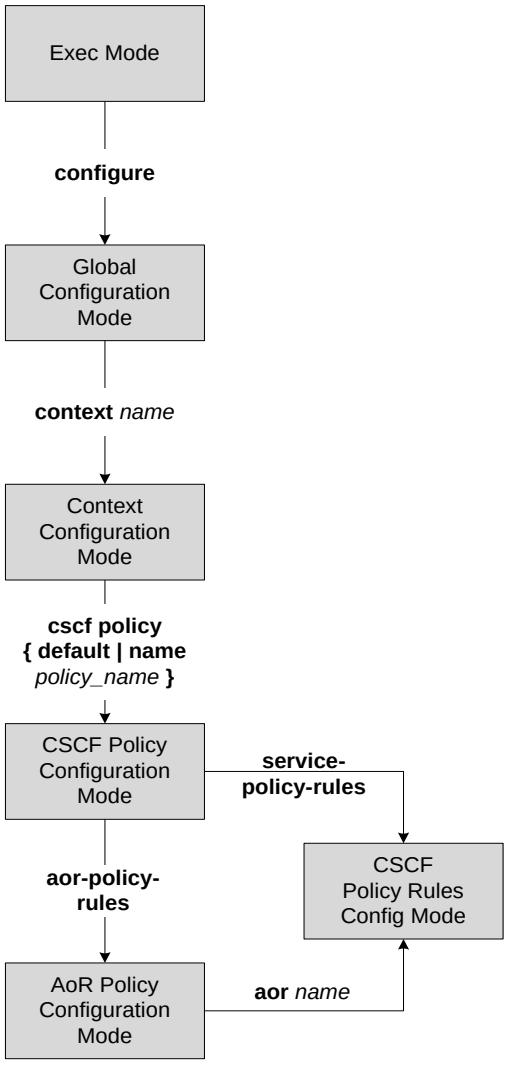
Use this command to create a service policy group and enter the CSCF Policy Rules Configuration Mode. Entering this command results in the following prompt:

```
[context_name]hostname(config-service-policy)#
```

Service Policy Rule Configuration Mode commands are defined in the *CSCF Policy Rules Configuration Mode Commands* chapter.

Chapter 83
CSCF Policy Rules Configuration Mode Commands

The CSCF Policy Rules Configuration Mode is used to manage CSCF AoR and service policy profiles within the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

allow-noauth

Configures the policy to allow unauthenticated access. Default is disabled.

Product

SCM

Privilege

Administrator

Syntax

```
[ default | no ] allow-noauth
```

default | no

Disables the allow-noauth functionality for this policy.

Usage

Use this command to allow access to subscribers without authenticating them.

allow-unsecure

Configures the policy to allow access to the system without a security association. Default is disabled.

Product

SCM

Privilege

Administrator

Syntax

```
[ default | no ] allow-unsecure
```

default | no

Disables the allow-unsecure functionality for this policy.

Usage

Use this command to enable the policy to provide subscriber access to system without a security association.

authorization

Configures the policy to allow early bandwidth or provisional response authorization. Default is disabled.

Product

SCM

Privilege

Administrator

Syntax

```
[ default | no ] authorization { early-bandwidth | prov-response }
```

early-bandwidth

Enables early bandwidth policy.

prov-response

Enables AAR for provisional responses like 18X.

default | no

Disables the early bandwidth or provisional response authorization functionality for this policy.

Usage

Use this command to enable the policy to provide early bandwidth or provisional response authorization.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

enforce-codec-policy

Enters the Enforce Codec Policy Command Mode where allowed static and dynamic codec lists are managed.

Product

SCM

Privilege

Administrator

Syntax

```
[ default | no ] enforce-codec-policy
```

default | no

Disables the codec policy.

Usage

Use this command to enter the Enforce Codec Policy Configuration Mode.
Entering this command results in the following prompt:

```
[context_name]hostname(config-policy-enforce-codec)#
```

CSCF Enforce Codec Policy Mode commands are defined in the *Enforce Codec Policy Configuration Mode Commands* chapter in this guide.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

max-cscf-concurrent-sessions

Configures the maximum number of concurrent sessions allowed per subscriber.

Product

SCM

Privilege

Administrator

Syntax

max-cscf-concurrent-sessions *number*

default max-cscf-concurrent-sessions

number

Default: 5
Specifies the number of concurrent sessions allowed per subscriber for this policy. *number* must be an integer from 1 to 100.

default

Resets defaults for this command.

Usage

Use this command to set the maximum number of allowed sessions per subscriber for this policy.
If enabled, the **subscriber-policy-override** command in the CSCF Service Configuration Mode overrides the service-level policy.

Example

The following command sets the maximum number of concurrent sessions for a subscriber using this policy to 7:

```
max-cscf-concurrent-sessions 7
```

policy

Configures the overload response for this policy. When the P-CSCF/A-BG becomes congested, this overload policy is used to reject subsequent sessions or redirect them to another server.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
policy overload { redirect address1 [ weight weight1 ] [ address2 [ weight weight2 ] ]
... | reject [ use-reject-code { admin-prohibited | insufficient-resources } ] }

default policy overload

no policy overload redirect address1[address2] ...
```

redirect *address1* **[weight** *weight1* **] [** *address2* **[weight** *weight2* **]] ...**

Specifies that upon policy overload, the system will redirect the session to another CSCF.
address1 must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
weight *weight1*: Defines the priority of the redirect address.
weight1 must be an integer from 1 to 10. Default is 1.

reject [use-reject-code { admin-prohibited | insufficient-resources }]

Specifies that upon policy overload, the system will reject the session. This is the default setting.
use-reject-code: Specifies that a reject code will be returned upon policy overload.

- **admin-prohibited**: Specifies that the "admin-prohibited" reject code will be returned upon policy overload.
- **insufficient-resources**: Specifies that the "insufficient resources" reject code will be returned upon policy overload. This is the default reject code.

default policy overload

Resets defaults for this command.

no policy overload redirect *address1* **[** *address2* **] ...**

Removes configured policy overload redirect address(es).

Usage

Use this command to define the response to an overload condition on the P-CSCF/A-BG using this AoR policy.

Example

The following command configures the policy overload response to redirect to a series of CSCFs with IP address of *1.2.3.4*, *1.2.3.5*, and *1.2.3.6* with respective priorities (weights) of *1*, *3*, and *2*:

```
policy overload redirect 1.2.3.4 weight 1 1.2.3.5 weight 3 1.2.3.6 weight
2
```

qos

Configures QoS bandwidth settings for uplink and downlink.

Product

SCM

Privilege

Administrator

Syntax

qos bandwidth { downlink| uplink } [peak *value* **]**

bandwidth { downlink| uplink }

downlink: Configures the downlink bandwidth.
uplink: Configures the uplink bandwidth.

peak *value*

Peak value of bandwidth in kilobits per second (kbit/s).
value must be an integer from 1 to 99999999.

Usage

The P-CSCF/A-BG fills the required bandwidth for downlink and uplink from the Session Description Protocol (SDP) in the message when communicating with an external policy server via Rx/Tx/Gq. Use this command to configure the peak uplink and downlink bandwidth to be used when the SDP does not contain bandwidth.

Example

Set the peak uplink bandwidth to *256* kbit/s:

```
qos bandwidth uplink peak 256
```

video-sessions

Configures the policy to allow video bearers. Default is disabled.

Product

SCM

Privilege

Administrator

Syntax

```
[ default | no ] video-sessions
```

default | no

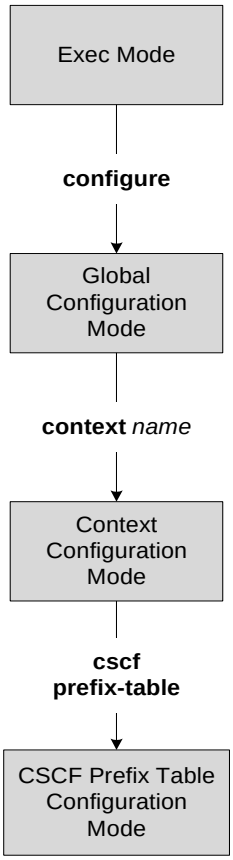
Disables the “allow video sessions” feature.

Usage

Use this command to allow video session via this policy.

Chapter 84
CSCF Prefix Table Configuration Mode Commands

The CSCF prefix table is used to configure for each number (or number prefix) whether it is ported and the SIP routing domain. Only one CSCF prefix table can be configured per context.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

number

Determines for each number (or number prefix) in a prefix table whether it is ported and the SIP routing domain.

Product

SCM

Privilege

Administrator

Syntax

number *number* **[ported] [routing-domain** *domain_name* **]**

no number *number*

number

Specifies number or number prefix. *number* must be a string of digits from 1 to 31 and/or special character "$."

Important: If the number is a prefix, it should end with "$."

ported

The number (or number prefix) is in ported range and NPDB (Number Portability Data Base) has to be contacted.

routing-domain *domain*

Specifies the SIP routing domain for this number (or number prefix). *domain_name* must be from 1 to 79 alpha and/or numeric characters in length.

no number *number*

Removes the specified number or number prefix from the prefix table.

Usage

Use this command to determine whether each number (or number prefix) in a prefix table is ported and the SIP routing domain. The S-CSCF service will use the prefix table configured in its source context for the lookup.

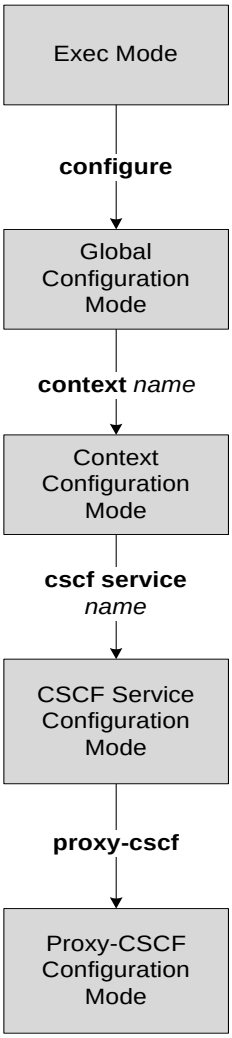
Example

The following command specifies a ported number prefix named *821057$.* with SIP routing domain *cisco.com*:

```
number 821057$ ported routing-domain cisco.com
```

Chapter 85
CSCF Proxy-CSCF Configuration Mode Commands

The Proxy-CSCF Configuration Mode is used to enable Diameter policy control within the service.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

allow rfc3261-ua-interworking

Enables the function to allow IMS interworking with RFC3261 SIP User Agents.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] allow rfc3261-ua-interworking
```

no

Disables the interworking capability.

Usage

Use this command to enable the P-CSCF/A-BG to allow IMS interworking with RFC3261 SIP User Agents.

core-reg-expiry-time

Configures Registration Expiry Timer Handling in P-CSCF/A-BG to keep pin holes open in B2BUA mode.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

core-reg-expiry-time *sec*

[default | no] core-reg-expiry-time

sec

Expiry age should be less than or equal to the maximum in seconds. Must be an integer from 300 to 86400.

default

Sets the core-reg-expiry-time to 3600 seconds.

no

Disables the timer.

Usage

Use this command to configure Registration Expiry Timer Handling in P-CSCF/A-BG to keep pin holes open in B2BUA mode.

Example

The following sets the core-reg-expiry-time to *4000* seconds:

```
core-reg-expiry-time 4000
```

diameter

This command:

- configures the Diameter dictionary used in this function.
- configures the policy control origin endpoint used in this function.
- enables the selection of a Diameter policy control peer server providing Rx/Tx/Gq applications for this service.
- configures the Diameter requested timeout value used in this function.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

diameter location-info { dictionary { e2custom01 | e2custom02 | e2custom03 | e2custom04 | e2custom05 | e2custom06 | e2custom07 | e2custom08 | e2custom09 | e2standard } | origin endpoint endpoint_name | peer-select peer *peer_name* **[peer-realm** *realm_name* **] [secondary-peer** *peer_name* **[sec-peer-realm** *realm_name* **]] | request-timeout** *sec* **}**

diameter policy-control { dictionary { Gq-custom | Gq-standard | Rq-custom| Rx-rel8 | Rx-standard | Tx-standard | custom01 | custom02 | custom03 | custom04 | custom05 | custom06 | custom07 | custom08 | custom09 } | origin endpoint endpoint_name | peer-select peer *peer_name* **[peer-realm** *realm_name* **] [secondary-peer** *peer_name* **[sec-peer-realm** *realm_name* **]] | request-timeout** *sec* **}**

In StarOS v12.2 and later:

diameter policy-control { dictionary { gq-custom | gq-standard | rq-custom | rx-custom01 | rx-custom02 | rx-custom03 | rx-custom04 | rx-custom05 | rx-rel8 | rx-standard | tx-standard } | origin endpoint endpoint_name | peer-select peer *peer_name* **[peer-realm** *realm_name* **] [secondary-peer** *peer_name* **[sec-peer-realm** *realm_name* **]] | request-timeout** *sec* **}**

default diameter { location-info | policy-control } { **dictionary | request-timeout }**

no diameter { location-info | policy-control } [origin endpoint | peer-select]

---

location-info

Defines the E2 interface for location information.

---

dictionary { e2custom01...e2custom09 | e2standard }

custom01...custom09: Specifies that a customer-specific (custom) dictionary is to be used for expansion and behaviors.
e2standard: Specifies that the E2-Standard-Dictionary is to be used.

Important: If this keyword is not configured, the system defaults to the default dictionary (e2standard). In the Proxy-CSCF configuration, at any time, the location-info dictionary can either be an explicitly configured dictionary or the default dictionary. Hence, there is no corresponding "no" CLI to disable the location-info dictionary setting.

policy-control

Defines external policy control.

dictionary { Gq-custom | Gq-standard | Rq-custom | Rx-rel8 | Rx-standard | Tx-standard | custom01...custom09 }

Gq-custom: Specifies that the Gq Operax dictionary is to be used for Operax-specific behavior.
Gq-standard: Specifies that the Gq standard dictionary is to be used.
Rq-custom: Specifies that the Rq custom dictionary is to be used.
Rx-rel8: Specifies that the Rx Release 8 dictionary is to be used.
Rx-standard: Specifies that the Rx standard dictionary is to be used.
Tx-standard: Specifies that the Tx standard dictionary is to be used.
custom01...custom09: Specifies that a customer-specific (custom) dictionary, for customer-specific expansion and behaviors, is to be used.

dictionary { gq-custom | gq-standard | rq-custom | rx-custom01 | rx-custom02 | rx-custom03 | rx-custom04 | rx-custom05 | rx-rel8 | rx-standard | tx-standard }

gq-custom : Specifies that the Gq Operax dictionary is to be used for Operax-specific behavior.
gq-standardd: Specifies that the Gq standard dictionary is to be used.
rq-custom: Specifies that the Rq custom dictionary is to be used.
rx-custom01...rx-custom05: Specifies that a customer-specific (custom) dictionary, for customer-specific expansion and behaviors, is to be used.
rx-rel8: Specifies that the Rx Release 8 dictionary is to be used.
rx-standard: Specifies that the Rx standard dictionary is to be used.
tx-standard: Specifies that the Tx standard dictionary is to be used.

origin endpoint *endpoint_name*

Specifies the Diameter location-info or policy control endpoint name.
endpoint_name must be the endpoint's name and an alpha and/or numeric string of 1 through 63 characters in length.

peer-select peer *peer_name*

Specifies the name of the Diameter location-info or policy control peer server.
peer_name must be from 1 to 63 alpha and/or numeric characters in length.
Diameter peer servers are configured through the **diameter endpoint** command in the Context Configuration Mode. The **diameter endpoint** command is a generic command and can be found in the Cisco ASR 5000 Series Command Line Interface Reference.

peer-realm *realm_name*

Specifies the realm name for which the Diameter location-info or policy control peer server has responsibility.
realm_name must be from 1 to 63 alpha and/or numeric characters in length.

Important: If this keyword is not configured, the system defaults to the realm name configured for the selected peer server.

`secondary-peer` *`peer_name`*

Specifies the name of the secondary Diameter location-info or policy control peer server.
`peer_name` must be from 1 to 63 alpha and/or numeric characters in length.

`sec-peer-realm` *`realm_name`*

Specifies the realm name for which the secondary Diameter location-info or policy control peer server has responsibility.
`realm_name` must be from 1 to 63 alpha and/or numeric characters in length.

Important: If this keyword is not configured, the system defaults to the realm name configured for the selected peer server.

Important: The "**`diameter location-info peer-select peer`** *`<primary_peer>`* **`peer-realm`** *`<primary_peer_realm>`* **`secondary-peer`** *`<secondary_peer>`* **`sec-peer-realm`** *`<secondary_peer_realm>`*" CLI configures Peer Switching—selecting which peers the Diameter messages are routed to. When the secondary peer is configured, in case the primary fails, request messages are rerouted to the secondary. Note that the "**`no diameter location-info peer-select`**" CLI command will remove the entire Peer Switching CLI from the configuration.

`request-timeout` *`sec`*

Specifies the Diameter location-info or policy control requested timeout value in seconds.
`sec` must be an integer from 1 to 300.
Default: 10

Important: If this keyword is not configured, the system defaults to the default setting (10 seconds). In the Proxy-CSCF configuration, at any time, the request-timeout setting can either be an explicitly configured value or the default value. Hence, there is no corresponding "no" CLI to disable the request-timeout setting.

`default`

Sets the Diameter's location-info or policy control dictionary or requested timeout value as the default.

`no`

Removes the Diameter location-info or policy control origin endpoint or Diameter peer from the service.

Usage

Use this command to:

- define the Diameter dictionary to use for the service.
- specify the Diameter origin endpoint.
- specify a Diameter location-info or policy control peer server to support Rx/Tx/Gq applications.
- specify the Diameter requested timeout value for this service.

Example

The following command configures the system to use the Tx standard Diameter dictionary for this service:

```
diameter policy-control dictionary Tx-standard
```

The following command sets the Diameter location-info origin endpoint to *test*:

```
diameter location-info origin endpoint test
```

The following command selects a Diameter policy control peer server with a name of *diam-2* and a realm name of *realm-6*:

```
diameter policy-control peer-select peer diam-2 peer-realm realm-6
```

emergency

Configures the function to allow or disallow the emergency-session or emergency-registration of a particular type.

Product

SCM (P-CSCF, A-BG, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] emergency { registration [ visited-ue ] | session [ 3gpp-ims-xml-body |
anonymous | non-emergency-registered | sdp-cs-media | visited-ue ] }
```

default

Specifies that the emergency-session or emergency-registration of a particular type can be allowed.

no

Disallows the emergency-session or emergency-registration of a particular type.

registration [visited-ue]

Allow emergency-registration. By default, it's allowed.
visited-ue: Allow emergency-registration from a visited UE. By default, it's allowed.

session [3gpp-ims-xml-body | anonymous | non-emergency-registered | sdp-cs-media | visited-ue]

Specifies the type of emergency-session to be allowed or disallowed. By default, all are allowed.
3gpp-ims-xml-body: Allow 3GPP IM CN XML body to be added in 380 response messages.
anonymous: Allow anonymous subscribers (unregistered UEs) to initiate emergency sessions.
non-emergency-registered: Allow non-emergency registered subscribers to initiate emergency sessions.
sdp-cs-media: Allow emergency calls with SDP CS Media.
visited-ue: Allow emergency calls from visited UE.

Usage

Use this command to configure the function to allow or disallow the emergency-session or emergency-registration of a particular type.

Example

The following command configures the function to allow non-emergency registered subscribers to initiate emergency sessions:

```
emergency session non-emergency-registered
```

emergency-call-mode

Enables the P-CSCF/A-BG service to add “P-Emergency-Call-Mode-Preference” header in 200OK to REGISTER message. By default, this command is disabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
emergency-call-mode { 3gpp-cs | 3gpp-ims }

[ default | no ] emergency-call-mode
```

3gpp-cs | 3gpp-ims

3gpp-cs: Specifies 3GPP CS access preference in header.
3gpp-ims (default): Specifies 3GPP IMS access preference in header.

default

Specifies 3GPP IMS access preference in header.

no

Disables “P-Emergency-Call-Mode-Preference” header insertion for the P-CSCF/A-BG service.

Usage

Enabling this command allows the P-CSCF or A-BG to add a “P-Emergency-Call-Mode-Preference” header in 200OK to REGISTER message.

Example

The following command enables “P-Emergency-Call-Mode-Preference” header insertion with a 3GPP CS access preference defined:

```
emergency-call-mode 3gpp-cs
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

interrogating-cscf-role

Enables the function to also perform as an Interrogating-CSCF.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] interrogating-cscf-role
```

no

Disables the Interrogating-CSCF role in this function.

Usage

Use this command to enable the P-CSCF/A-BG to also perform as an Interrogating-CSCF.

Important: All Interrogating-CSCF functions have been moved to the Serving-CSCF exclusively in v10.0 and beyond.

message-max-size

Configures the maximum message body size in MESSAGE method.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

message-max-size *limit*

[default | no] message-max-size

limit

Default: 1024
Configures the maximum SIP message size limit in bytes for any SIP message buffer.
limit must be an integer from 512 to 65535.

Important: Message body size should be less than the max-sipmsg-size set in the CSCF Service Configuration Mode.

default | no

Returns/sets the maximum SIP message size to 1024 bytes.

Usage

Use this command to configure the maximum SIP message size for any SIP message buffer.

Example

The following command limits the SIP message size to *4000* bytes:

```
message-max-size 4000
```

network-id

Configures the Network Identifier.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

[no] network-id *id*

no

Removes the configured Network Identifier of the entity.

id

The Network Identifier of the entity.
id must be from 1 to 79 alpha and/or numeric characters in length.

Usage

The Network Identifier is used by the P-CSCF or A-BG to fill the P-Visited-Network-ID header.

Example

Sets the Network Identifier to *pcscf01.company.com:*

```
network-id pcscf01.company.com
```

pcrf-policy-control

Enables enables external policy control via PCRF through the Rx Diameter interface and enters the PCRF-Policy-Control Configuration Mode. Default is disabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] pcrf-policy-control
```

no

Disables external policy control via PCRF for this service. P-CSCF/A-BG will not establish any Diameter session with PCRF, even though the PCRF is configured. This option disables both authorization and subscription to PCRF during Registration and VOIP call.

Usage

Use this command to enable PCRF policy control and enter the PCRF-Policy-Control Configuration Mode. It enables authorization and subscription to PCRF during Registration and VOIP calls. If the P-CSCF cannot connect to the PCRF server (due to wrong configuration in CSCF or PCRF unavailability), then P-CSCF/A-BG does not authorize media and VOIP calls will be rejected due to auth failure. Registrations will be handled normally.
Entering this command results in the following prompt:

```
[context_name]hostname(config-pcrf-policy-control)#
```

PCRF-Policy-Control Configuration Mode commands are defined in the *CSCF PCRF-Policy-Control Configuration Mode Commands* chapter in this guide.

peer-sbc

Configures peer Session Border Controller (SBC) addresses from where the P-CSCF/A-BG service can receive requests.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

[no] peer-sbc *ip_address*

no

Removes the IP address of a peer SBC from this P-CSCF/A-BG service.

ip_address

Specifies the IP address of a peer SBC for this P-CSCF/A-BG service.
ip_address is expressed in standard dotted decimal notation for IPv4 or colon notation for IPv6.

Usage

Use this command to specify peer Session Border Controller (SBC) addresses from where the P-CSCF/A-BG service can receive requests.

Important: This command must be entered multiple times if more than one SBC is present.

Example

The following commands identify three peer SBCs for a single P-CSCF/A-BG service:

```
peer-sbc 200.6.2.3

peer-sbc 200.6.2.10

peer-sbc 200.6.2.11
```

The following command removes the peer SBC with IP address *200.6.2.10* from the P-CSCF/A-BG service:

```
no peer-sbc 200.6.2.10
```

plmn-id

Configures location specific mobile network identifiers used to help translate local emergency and service-related numbers. Default is disabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

plmn-id mcc *code* **mnc** *code*

no plmn-id

mcc *code*

Specifies the Mobile Country Code for the mobile access network. *code* must be a three-digit integer from 200 to 999.

mnc *code*

Specifies the Mobile Network Code for the mobile access network. *code* must be a two or three-digit integer from 00 to 999.

no

Removes the access network configuration for this P-CSCF/A-BG service.

Usage

Use this command to help match location specific emergency/service numbers when configuring translations. The **mcc** and **mnc** values are compared against those received in p-access-network-info headers as per 3GPP TS 24.229. If **mnc** is not provided in the criteria only **mcc** is compared.

Example

The following command identifies the mobile network with a MCC of *123* and a MNC of *12*:

```
plmn-id mcc 123 mnc 12
```

reg-preloaded-route

Enables the function to use the preloaded-route-headers received in REGISTER for routing at P-CSCF.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ default | no ] reg-preloaded-route
```

default | no

Disables the ability to use preloaded-route-headers for routing REGISTER.

Usage

Use this command to enable or disable usage of preloaded-route-headers for routing REGISTER.

reg-service-route

Enables the function to use service routes when routing re-registrations.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] reg-service-route
```

no

Disables the ability to use service routes for re-registration.

Usage

Use this command to enable the P-CSCF/A-BG service to use service routes when routing re-registrations.

reliable-prov-resp

Enables/disables the reliability of provisional responses feature.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
reliable-prov-resp { mandatory | optional }

[ no ] reliable-prov-resp
```

mandatory | optional

mandatory: Both inbound and outbound will request reliability.
optional(default): Reliability is imposed by inbound side. Only if inbound call requests reliability will outbound also request reliability.

no

Disables the reliability of provisional responses feature.

Usage

Use this command to enable/disable the reliability of provisional responses feature.

Example

The following command sets the reliability of provisional responses feature to mandatory:

```
reliable-prov-resp mandatory
```

The following command disables the reliability of provisional responses feature:

```
no reliable-prov-resp
```

restoration-procedure

Enables the P-CSCF/A-BG service to reject with a 504 response when it receives 3xx, 480, or “no response” to service request. This feature is disabled by default.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] restoration-procedure
```

no

Disables restoration procedure on the P-CSCF/A-BG service.

Usage

Restoration procedure is intended to handle unreachability of service-route header content. Enabling this command allows the P-CSCF/A-BG service to reject with a 504 response when it receives 3xx, 480, or “no response” to service request.

Example

Enables restoration procedure on the P-CSCF/A-BG service:

```
restoration-procedure
```

Disables restoration procedure on the P-CSCF/A-BG service:

```
no restoration-procedure
```

security-parameters

Enters the Security Configuration Mode in which Denial of Service (DOS) prevention commands can be configured.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
security-parameters
```

Usage

Use this command to enter the Security Configuration Mode.
Entering this command results in the following prompt:

```
[context_name]hostname(config-security-parameters)#
```

Security Configuration Mode commands are defined in the *CSCF Security Configuration Mode Commands* chapter in this guide.

sigcomp

Enables signaling compression for the P-CSCF/A-BG service and enters the Signaling Compression Configuration Mode.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] sigcomp
```

no

Disables signaling compression for the P-CSCF/A-BG service.

Usage

Use this command to enable signaling compression for the P-CSCF/A-BG service and enter the CSCF Signaling Compression Configuration Mode.
Entering this command results in the following prompt:

```
[context_name]hostname(config-sigcomp)#
```

Signaling Compression Configuration Mode commands are defined in the *CSCF Signaling Compression Configuration Mode Commands* chapter in this guide.

sip-header

Enable SIP header insertion for the P-CSCF/A-BG service. SIP header insertion is disabled by default.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] sip-header insert { p-access-network-info | p-cust1-prid-info | p-user-database }
```

no

Disables SIP header insertion for the P-CSCF/A-BG service.

insert { p-access-network-info | p-cust1-prid-info | p-user-database }

p-access-network-info: Inserts P-Access-Network-Info (PANI) header in received request/response.
p-cust1-prid-info: Inserts a custom header, P-LGUPlus-PRID-Info, which contains the private user id of the user sending any dialogue creating request or any standalone requests, to be added in the message toward nexthop. Addition of the header will be done when P-CSCF forwards this message.
p-user-database: Inserts P-User-Database (PUD) header in SIP (REGISTER) message and Invite from I-CSCF to S-CSCF.

Usage

Enabling this command allows SIP header insertion on the P-CSCF or A-BG.

Important: Use the **access-type** command to configure a ue-ip-address-range per access type. CSCF Service Configuration Mode commands are defined in the *CSCF Service Configuration Mode Commands* chapter in this guide.

Example

Enables SIP PANI header insertion for the P-CSCF/A-BG service:

```
sip-header insert p-access-network-info
```

sip-param

Enable the addition of "integrity-protected" parameter in the authorization header of a SIP (REGISTER) message for the P-CSCF/A-BG service.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] sip-param insert integrity-protected [ transparent ]
```

no

Disables the addition of "integrity-protected" parameter in the authorization header of a SIP (REGISTER) message for the P-CSCF/A-BG service.

insert integrity-protected

Inserts "integrity-protected" parameter in the authorization header of a SIP (REGISTER) message for the P-CSCF/A-BG service.

transparent

Pass the "integrity-protected" parameter received from the previous node unmodified.

Usage

Enabling this command allows the P-CSCF or A-BG to add the "integrity-protected" parameter in the authorization header of a SIP (REGISTER) message. The parameter will be used by the S-CSCF to decide which authentication mode to use to authenticate the user.

Example

Enables the addition of **integrity-protected** parameter:

```
sip-param insert integrity-protected
```

Disables the addition of **integrity-protected** parameter:

```
no sip-param insert integrity-protected
```

store-session-path

Enables the P-CSCF or A-BG to store and process the session path information, which includes the Route list, Record-Route list, Service-Route list, and ViaList.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
[ no ] store-session-path
```

no

Disables the storing of session path information by the P-CSCF or A-BG. In addition, the P-CSCF/A-BG will not overwrite the Route list, Record-Route list, Service-Route list, or ViaList in the in-dialog request and responses.

Usage

Enabling this command allows the P-CSCF or A-BG to store and process the session path information.

Example

Enables the storage and processing of session path information:

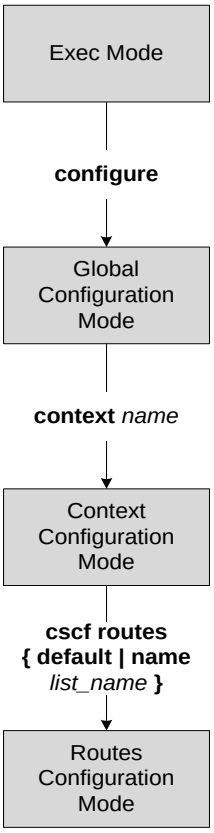
```
store-session-path
```

Disables the storage and processing of session path information:

```
no store-session-path
```

Chapter 86
CSCF Routes Configuration Mode Commands

The CSCF Routes Configuration Mode is used to configure session forwarding within the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

after

Places the CSCF route entry at the bottom or end of the route list. Use this command in conjunction with the **route** command.

Product

SCM (P-CSCF, S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

after

Usage

Add this command before the **route** command to place the entry at the end of the route list.

before

Places the CSCF route entry at the top or beginning of the route list. Use this command in conjunction with the **route** command.

Product

SCM (P-CSCF, S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

before

Usage

Add this command before the **route** command to place the entry at the beginning of the route list.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

route

Configure the routing parameters for the context.

Product

SCM (P-CSCF, S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

route { domain *name* **| local { icscf | pcscf | scscf } | nexthop-address** *address* **| peer-servers** *server_name* **| peer-servers-group** *group_name* **| route-list** *group_name* **| vpn** *name* **} [[mod-req-uri] base-criteria** *criteria* **[filter-criteria1** *criteria* **] [filter-criteria2** *criteria* **]] [log]**

no route { domain *name* **| local { icscf | pcscf | scscf } | nexthop-address** *address* **| peer-servers** *server_name* **| peer-servers-group** *group_name* **| route-list** *group_name* **| vpn** *name* **} base-criteria** *criteria* **[filter-criteria1** *criteria* **] [filter-criteria2** *criteria* **]**

domain *name*

Specifies a valid next-hop domain name. *name* must be from 1 to 79 alpha and/or numeric characters in length.

local { icscf | pcscf | scscf }

Specifies a local interrogating, serving, or proxy call/session control function to which all calls processed by the context will be routed.

nexthop-address *ip_address*

Specifies a next-hop address.
ip_address must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.

peer-servers *server_name*

Specifies a configured peer server.
server_name must be the name of a configured peer server on this system.

peer-servers-group *group_name*

Specifies a configured peer servers group.
group_name must be the name of a configured peer servers group on this system.

route-list *group_name*

Specifies a configured route list group.
group_name must be the name of a configured route list group on this system.

vpn *name*

Specifies a configured VPN context on the system.
name must be a configured context name.

mod-req-uri

Specifies that a route lookup should be performed and the request URI modified.

base-criteria *criteria*

Specifies the base criteria that packets will be compared against. The following criteria is supported:

- **access-type** *type*: Filters sessions based on a specific access-type used by the subscriber. Possible access types are:
  - **3gpp-geran**: 3GPP Access Type
  - **3gpp-utran-fdd**: 3GPP Access Type
  - **3gpp-utran-tdd**: 3GPP Access type
  - **3gpp2-1x**: 3GPP2 Access Type
  - **3gpp2-1x-hrpd**: 3GPP2 Access Type
  - **3gpp2-umb**: 3GPP2-UMB
  - **adsl**: FixedLine Access Type
  - **adsl2**: FixedLine Access Type
  - **adsl2p**: FixedLine Access Type ADSL2+
  - **docsis**: DOCSIS
  - **gshdsl**: Fixed Line Access Type G.SHDSL
  - **hdsl**: Fixed Line Access Type
  - **hdsl2**: Fixed Line Access Type
  - **idsl**: Fixed Line Access Type
  - **ieee-80211**: WLAN Access Type
  - **ieee-80211a**: WLAN Access Type
  - **ieee-80211b**: WLAN Access Type
  - **ieee-80211g**: WLAN Access Type
  - **ieee-80216e**: Wireless MAN Access Type
  - **radsl**: Fixed Line Access Type
  - **sdsl**: Fixed Line Access Type
  - **vdsl**: Fixed Line Access Type
- **any**: Filters all CSCF sessions.
- **carrier-id** *name*: Filters sessions based on the carrier's ID. *name* must be from 1 to 79 alpha and/or numeric characters in length.
- **destination aor** *aor*: Filters sessions based on the destination AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

  Important: The destination aor and carried-id criteria cannot occur in the same route rule.

- **nexthop-uri** *name*: Filters sessions based on Address of Record. *name* must be from 1 to 79 alpha and/or numeric characters in length.

- **plmn-id mcc** *mcc_code* **mnc** *mnc_code*: Filters sessions based on the mobile country and network codes. *mcc_code* must be a three-digit integer from 200 to 999. *mnc_code* must be a two or three-digit integer from 00 to 999.
- **source address** *ip_address*: Filters sessions based on source IP address. *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
- **source aor** *aor*: Filters sessions based on the source AoR. *aor* must be an existing AoR from 1 to 79 characters in length.
- **subscriber-capability** *capability_type*: Filters sessions based on capability of the subscriber. Possible capability types are:
  - **at** - Custom AT Type
  - **audio** - Audio Capability Type
  - **chat** - Custom CHAT Type
  - **cs** - Custom CS Type
  - **ft** - Custom FT Type
  - **im** - Custom IM Type
  - **mms** - Custom MMS Type
  - **msg** - Custom MSG Type
  - **oma-sip-im** - Custom OMA SIP-IM Type
  - **rcs-dp** - Custom RCS-DP Type
  - **rcs-e** - Custom RCS-E Type
  - **rcs-ft** - Custom RCS-FT Type
  - **rcs-im** - Custom RCS-IM Type
  - **rcs-is** - Custom RCS-IS Type
  - **rcs-sp** - Custom RCS-SP Type
  - **rcs-vs** - Custom RCS-VS Type
  - **text** - Text Capability Type
  - **video** - Video Capability Type
  - **vt** - Custom VT Type
  - **vt-ft** - Custom VT-FT Type
  - **vt-is** - Custom VT -IS Type
  - **vt-loc** - Custom VT-LOC Type
  - **vt-memo** - Custom VT-MEMO Type
- **subscriber-ip-type { v4 | v6 }**: Filters sessions based on IP type of the subscriber. Possible IP types are:
  - **v4** - IPV4 Type
  - **v6** - IPV6 Type
- **time-of-day**: Filters sessions based on the time of the day. Additional filter criteria for **time-of-day** is as follows:

- **day-of-month** *day*: Filters session based on the day of the month. *day* must be an integer from 1 to 31.
- **day-of-week** *day*: Filters session based on the day of the week. *day* must be an integer from 1 to 7 with 1 signifying Sunday and 7 signifying Saturday.
- **start** *date/time* **[end** *date/time* **]**: Filters sessions based on a start time to, optionally, an end time during the day. *date/time* must be integers in either of the following formats: YYYY:MM:DD:HH:mm or YYYY:MM:DD:mm:ss. YYYY: year range 2005 to 2099 MM: months (integer range 1 to 12) DD: days (integer range 1 to 31) HH: hours (integer range 0 to 23) mm: minutes (integer range 0 to 59) ss: seconds (integer range 0 to 59)
- **week-of-month** *week*: Filters sessions based on the week of the month. *week* must be an integer from 1 to 5.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

filter-criteria1 *criteria*

Specifies the filter criteria that packets that have passed the base criteria will be compared against. The following criteria is supported:

- **access-type** *type*: Filters sessions based on a specific access-type used by the subscriber. Possible access types are:
  - **3gpp-geran**: 3GPP Access Type
  - **3gpp-utran-fdd**: 3GPP Access Type
  - **3gpp-utran-tdd**: 3GPP Access type
  - **3gpp2-1x**: 3GPP2 Access Type
  - **3gpp2-1x-hrpd**: 3GPP2 Access Type
  - **3gpp2-umb**: 3GPP2-UMB
  - **adsl**: FixedLine Access Type
  - **adsl2**: FixedLine Access Type
  - **adsl2p**: FixedLine Access Type ADSL2+
  - **docsis**: DOCSIS
  - **gshdsl**: Fixed Line Access Type G.SHDSL
  - **hdsl**: Fixed Line Access Type
  - **hdsl2**: Fixed Line Access Type
  - **idsl**: Fixed Line Access Type
  - **ieee-80211**: WLAN Access Type
  - **ieee-80211a**: WLAN Access Type
  - **ieee-80211b**: WLAN Access Type
  - **ieee-80211g**: WLAN Access Type
  - **ieee-80216e**: Wireless MAN Access Type
  - **radsl**: Fixed Line Access Type

- **sdsl**: Fixed Line Access Type
- **vdsl**: Fixed Line Access Type

- **any**: Filters all CSCF sessions.
- **carrier-id** *name*: Filters sessions based on the carrier's ID. *name* must be from 1 to 79 alpha and/or numeric characters in length.
- **destination aor** *aor*: Filters sessions based on the destination AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

> ***Important:*** The destination aor and carried-id criteria cannot occur in the same route rule.

- **nexthop-uri** *name*: Filters sessions based on Address of Record. *name* must be from 1 to 79 alpha and/or numeric characters in length.
- **plmn-id mcc** *mcc_code* **mnc** *mnc_code*: Filters sessions based on the mobile country and network codes. *mcc_code* must be a three-digit integer from 200 to 999. *mnc_code* must be a two or three-digit integer from 00 to 999.
- **source address** *ip_address*: Filters sessions based on source IP address. *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
- **source aor** *aor*: Filters sessions based on the source AoR. *aor* must be an existing AoR from 1 to 79 characters in length.
- **subscriber-capability** *capability_type*: Filters sessions based on capability of the subscriber. Possible capability types are:
  - **at** - Custom AT Type
  - **audio** - Audio Capability Type
  - **chat** - Custom CHAT Type
  - **cs** - Custom CS Type
  - **ft** - Custom FT Type
  - **im** - Custom IM Type
  - **mms** - Custom MMS Type
  - **msg** - Custom MSG Type
  - **oma-sip-im** - Custom OMA SIP-IM Type
  - **rcs-dp** - Custom RCS-DP Type
  - **rcs-e** - Custom RCS-E Type
  - **rcs-ft** - Custom RCS-FT Type
  - **rcs-im** - Custom RCS-IM Type
  - **rcs-is** - Custom RCS-IS Type
  - **rcs-sp** - Custom RCS-SP Type
  - **rcs-vs** - Custom RCS-VS Type
  - **text** - Text Capability Type
  - **video** - Video Capability Type

- **vt** - Custom VT Type
- **vt-ft** - Custom VT-FT Type
- **vt-is** - Custom VT -IS Type
- **vt-loc** - Custom VT-LOC Type
- **vt-memo** - Custom VT-MEMO Type

- **subscriber-ip-type { v4 | v6 }**: Filters sessions based on IP type of the subscriber. Possible IP types are:
  - **v4** - IPV4 Type
  - **v6** - IPV6 Type
- **time-of-day**: Filters sessions based on the time of the day. Additional filter criteria for **time-of-day** is as follows:
  - **day-of-month** *day*: Filters session based on the day of the month. *day* must be an integer from 1 to 31.
  - **day-of-week** *day*: Filters session based on the day of the week. *day* must be an integer from 1 to 7 with 1 signifying Sunday and 7 signifying Saturday.
  - **start** *date/time* **[end** *date/time* **]**: Filters sessions based on a start time to, optionally, an end time during the day. *date/time* must be integers in either of the following formats: YYYY:MM:DD:HH:mm or YYYY:MM:DD:mm:ss. YYYY: year range 2005 to 2099 MM: months (integer range 1 to 12) DD: days (integer range 1 to 31) HH: hours (integer range 0 to 23) mm: minutes (integer range 0 to 59) ss: seconds (integer range 0 to 59)
  - **week-of-month** *week*: Filters sessions based on the week of the month. *week* must be an integer from 1 to 5.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

filter-criteria2 *criteria*

Specifies the filter criteria that packets that have passed the base criteria and filter-criteria1 will be compared against. The following criteria is supported:

- **access-type** *type*: Filters sessions based on a specific access-type used by the subscriber. Possible access types are:
  - **3gpp-geran**: 3GPP Access Type
  - **3gpp-utran-fdd**: 3GPP Access Type
  - **3gpp-utran-tdd**: 3GPP Access type
  - **3gpp2-1x**: 3GPP2 Access Type
  - **3gpp2-1x-hrpd**: 3GPP2 Access Type
  - **3gpp2-umb**: 3GPP2-UMB
  - **adsl**: FixedLine Access Type
  - **adsl2**: FixedLine Access Type
  - **adsl2p**: FixedLine Access Type ADSL2+
  - **docsis**: DOCSIS

- **gshdsl**: Fixed Line Access Type G.SHDSL
- **hdsl**: Fixed Line Access Type
- **hdsl2**: Fixed Line Access Type
- **idsl**: Fixed Line Access Type
- **ieee-80211**: WLAN Access Type
- **ieee-80211a**: WLAN Access Type
- **ieee-80211b**: WLAN Access Type
- **ieee-80211g**: WLAN Access Type
- **ieee-80216e**: Wireless MAN Access Type
- **radsl**: Fixed Line Access Type
- **sdsl**: Fixed Line Access Type
- **vdsl**: Fixed Line Access Type

- **any**: Filters all CSCF sessions.
- **carrier-id** *name*: Filters sessions based on the carrier's ID. *name* must be from 1 to 79 alpha and/or numeric characters in length.
- **destination aor** *aor*: Filters sessions based on the destination AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

> ***Important:*** The destination aor and carried-id criteria cannot occur in the same route rule.

- **nexthop-uri** *name*: Filters sessions based on Address of Record. *name* must be from 1 to 79 alpha and/or numeric characters in length.
- **plmn-id mcc** *mcc_code* **mnc** *mnc_code*: Filters sessions based on the mobile country and network codes. *mcc_code* must be a three-digit integer from 200 to 999. *mnc_code* must be a two or three-digit integer from 00 to 999.
- **source address** *ip_address*: Filters sessions based on source IP address. *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
- **source aor** *aor*: Filters sessions based on the source AoR. *aor* must be an existing AoR from 1 to 79 characters in length.
- **subscriber-capability** *capability_type*: Filters sessions based on capability of the subscriber. Possible capability types are:
  - **at** - Custom AT Type
  - **audio** - Audio Capability Type
  - **chat** - Custom CHAT Type
  - **cs** - Custom CS Type
  - **ft** - Custom FT Type
  - **im** - Custom IM Type
  - **mms** - Custom MMS Type
  - **msg** - Custom MSG Type

- **oma-sip-im** - Custom OMA SIP-IM Type
- **rcs-dp** - Custom RCS-DP Type
- **rcs-e** - Custom RCS-E Type
- **rcs-ft** - Custom RCS-FT Type
- **rcs-im** - Custom RCS-IM Type
- **rcs-is** - Custom RCS-IS Type
- **rcs-sp** - Custom RCS-SP Type
- **rcs-vs** - Custom RCS-VS Type
- **text** - Text Capability Type
- **video** - Video Capability Type
- **vt** - Custom VT Type
- **vt-ft** - Custom VT-FT Type
- **vt-is** - Custom VT -IS Type
- **vt-loc** - Custom VT-LOC Type
- **vt-memo** - Custom VT-MEMO Type

- **subscriber-ip-type { v4 | v6 }**: Filters sessions based on IP type of the subscriber. Possible IP types are:
  - **v4** - IPV4 Type
  - **v6** - IPV6 Type
- **time-of-day**: Filters sessions based on the time of the day. Additional filter criteria for **time-of-day** is as follows:
  - **day-of-month** *day*: Filters session based on the day of the month. *day* must be an integer from 1 to 31.
  - **day-of-week** *day*: Filters session based on the day of the week. *day* must be an integer from 1 to 7 with 1 signifying Sunday and 7 signifying Saturday.
  - **start** *date/time* **[end** *date/time* **]**: Filters sessions based on a start time to, optionally, an end time during the day. *date/time* must be integers in either of the following formats: YYYY:MM:DD:HH:mm or YYYY:MM:DD:mm:ss. YYYY: year range 2005 to 2099 MM: months (integer range 1 to 12) DD: days (integer range 1 to 31) HH: hours (integer range 0 to 23) mm: minutes (integer range 0 to 59) ss: seconds (integer range 0 to 59)
  - **week-of-month** *week*: Filters sessions based on the week of the month. *week* must be an integer from 1 to 5.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

log

Enables logging for CSCF sessions meeting the criteria specified in the ACL. The logs can be viewed by executing the **logging filter active facility cscf-acl-log** command in the Exec mode.

no route { domain *name* **| local { icscf | pcscf | scscf } | nexthop-address** *address* **| peer-servers** *group_name* **| route-list** *group_name* **| vpn** *name* **} base-criteria** *criteria* **[filter-criteria1** *criteria* **] [filter-criteria2** *criteria* **]**

Removes the specified routing parameters for the CSCF service.

Usage

Use this command to configure routing parameters for the service.

Important: Use the **before** or **after** command to place the route entry in the route list.

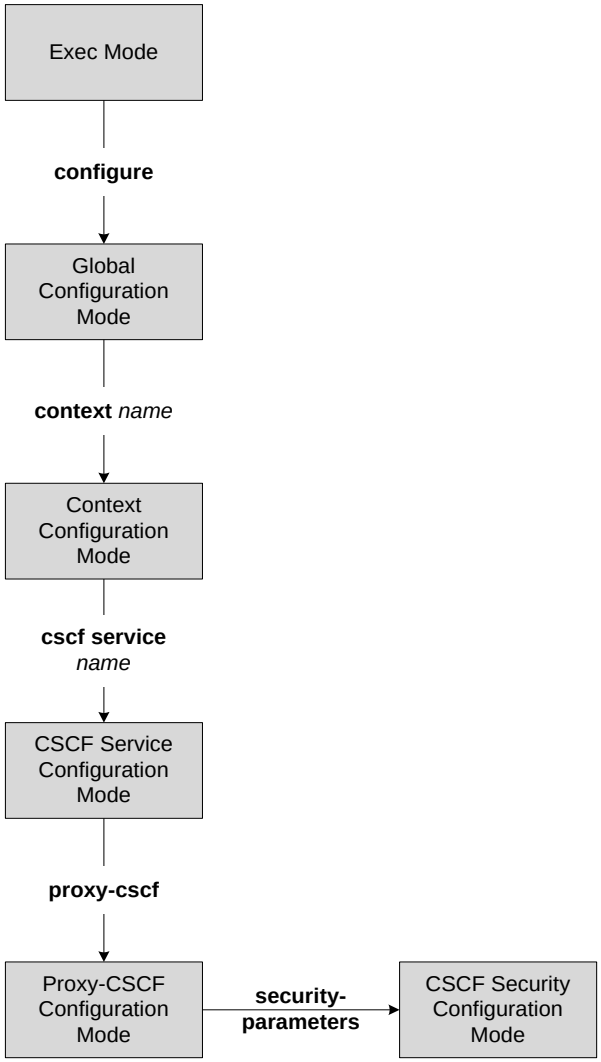
Example

The following command is placed at the end of the route list and routes sessions to a peer server group named *icscf_peer5*, filters sessions with a base criteria of the source address (*1.2.3.4*) and a filter criteria of the destination AoR (*$.@test.com*):

```
after route peer-servers icscf_peer5 base-criteria source address 1.2.3.4
filter-criteria1 destination aor $.@test.com
```

Chapter 87
CSCF Security Configuration Mode Commands

The CSCF Security Configuration Mode is used to configure Denial of Service (DOS) prevention commands.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

auth-failure-weight

Sets a severity number for authorization failures used in calculating a value for determining when to suspend registration attempts.

Important: The system will ignore the configuration of this command unless the **dos-prevention** command has been enabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

auth-failure-weight *weight*

default auth-failure-weight

weight

Default: 1
Assigns a weight to an authorization failure. Defines the severity of a single authorization failure.
weight must be an integer from 1 to 5.

default

Sets /restores the default value assigned to the specified command.

Usage

Use this command to define the severity of an authorization failure. This parameter is used in calculating the current number of authorization failures to compare to the **per-aor-failure-limit** and the **per-ip-failure-limit**. Configuring this command with a lower number causes the system to suspend registration attempts with repeated authorization failures much sooner than when configured with a higher number.

Example

The following command assigns a weight of *3* to an authorization failure:

```
auth-failure-weight 3
```

bad-request-weight

Sets a severity number for bad registration requests used in calculating a value for determining when to suspend registration attempts.

Important: The system will ignore the configuration of this command unless the **dos-prevention** command has been enabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

bad-request-weight *weight*

default bad-request-weight

weight

Default: 2
Assigns a weight to a bad registration request. Defines the severity of a single bad request.
weight must be an integer from 1 to 5.

default

Sets /restores the default value assigned to the specified command.

Usage

Use this command to define the severity of bad registration request. This parameter is used in calculating the current number of request failures to compare to the **per-aor-failure-limit** and the **per-ip-failure-limit**. Configuring this command with a lower number causes the system to suspend registration attempts with repeated request failures much sooner than when configured with a higher number.

Example

The following command assigns a weight of *3* to a bad registration request:

```
bad-request-weight 3
```

dos-prevention

Enables the denial of service prevention feature.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] dos-prevention
```

[default | no]

Disables the denial of service prevention feature.

Usage

Use this command to enable the denial of service prevention feature. The default value for this command is disabled. When this command is enabled, the commands in this mode are enabled with default values configured.

Important: This command must be enabled before configuring other commands in this mode.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Return to the previous mode.

forking-contact-limit

Sets a limit on the number of contacts a user ID can register with the system.

Important: The system will ignore the configuration of this command unless the **dos-prevention** command has been enabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

forking-contact-limit *limit*

default forking-contact-limit

limit

Default: 0
Sets the maximum number of contacts a user ID can register with the system. 0 specifies that unlimited contacts can be registered per user ID.
limit must be an integer from 0 to 10.

default

Sets /restores the default value assigned to the specified command.

Usage

Use this command to limit the number of contacts a user ID can register with the system.

Example

The following command limits all users to *2* registered contacts on the system:

```
forking-contact-limit 2
```

greylist-duration

Configures the amount of time an AoR or IP address remains on a “grey list” after having crossed the registration authorization limit or the bad registration request limit.

Important: The system will ignore the configuration of this command unless the **dos-prevention** command has been enabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

greylist-duration *time*

default greylist-duration

time

Default: 10
Defines the time, in minutes, that an AoR or IP address remains on a “grey list”.
time must be an integer from 5 to 1,440.

default

Sets /restores the default value assigned to the specified command.

Usage

Use this command to specify the amount of time AoRs or IP addresses remain on a “grey list” after having crossed the registration authorization limit or the bad registration request limit. Limits are described in the **per-aor-failure-limit** command and the **per-ip-failure-limit** command.

Example

The following command sets the duration AoRs or IP addresses remain on a “grey list” to *30* minutes:

```
greylist-duration 30
```

per-aor-failure-limit

Sets a failure limit that, when exceeded, causes the suspension of registration attempts for the offending AoR.

Important: The system will ignore the configuration of this command unless the **dos-prevention** command has been enabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

per-aor-failure-limit *limit*

default per-aor-failure-limit

limit

Default: 200
Defines the threshold for registration failures based on a calculation using weighted multipliers defined in **auth-failure-weight** and **bad-request-weight**.
limit must be an integer from 5 to 10,000.

default

Sets /restores the default value assigned to the specified command.

Usage

Use this command to set a failure limit for registration attempts from an identified AoR. The following calculation determines when this threshold is reached for a specific AoR:
Current authorization failures ÷ **auth-failure-weight** = current failures per AoR
or
Total bad registration requests ÷ **bad-request-weight** = current failures per AoR
If **auth-failure-weight** = *2* and **bad-request-weight** = *1*, and the **per-aor-failure-limit** = *100*, then the tolerance for registration authentication failures = 50 per AoR and the tolerance for bad registration requests = 100 per AoR.
When an AoR reaches the failure limit, it is added to a "grey list" for a period of time as defined by the **greylist-duration** command.

Example

The following command sets the AoR failure limit to *300*:

```
per-aor-failure-limit 300
```

per-ip-failure-limit

Sets a failure limit that, when exceeded, causes the suspension of registration attempts for the offending IP address.

Important: The system will ignore the configuration of this command unless the **dos-prevention** command has been enabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

per-ip-failure-limit *limit*

default per-ip-failure-limit

limit

Default: 100
Defines the threshold for registration failures based on a calculation using weighted multipliers defined in **auth-failure-weight** and **bad-request-weight**.
limit must be an integer from 5 to 10,000.

default

Sets /restores the default value assigned to the specified command.

Usage

Use this command to set a failure limit for registration attempts from an identified IP address. The following calculation determines when this threshold is reached for any IP address:
Current authorization failures ÷ **auth-failure-weight** = current failures per AoR
or
Total bad registration requests ÷ **bad-request-weight** = current failures per AoR
If **auth-failure-weight** = *2* and **bad-request-weight** = *1*, and the **per-ip-failure-limit** = *200*, then the tolerance for registration authentication failures = 100 per each IP address and the tolerance for bad registration requests = 200 per each IP address.
When an IP address reaches the failure limit, it is added to a "grey list" for a period of time as defined by the **greylist-duration** command.

Example

The following command sets the IP address registration failure limit to *200*:

```
per-ip-failure-limit 200
```

threshold-rate

Configures the rate per second at which the system must receive bad requests before it considers the requests a DoS attack.

Important: The system will ignore the configuration of this command unless the **dos-prevention** command has been enabled.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

threshold-rate *rate*

default threshold-rate

rate

Default: 1
Specifies the rate per second that the system must receive bad requests to determine that it is under a DoS attack.
rate must be an integer from 1 to 1,000.

default

Sets /restores the default value assigned to the specified command.

Usage

Use this command to specify the threshold rate for bad requests. For example, if a malicious user sends bad requests at a rate of 5 per second and this parameter is set to 10, the system will not consider itself under a DoS attack.

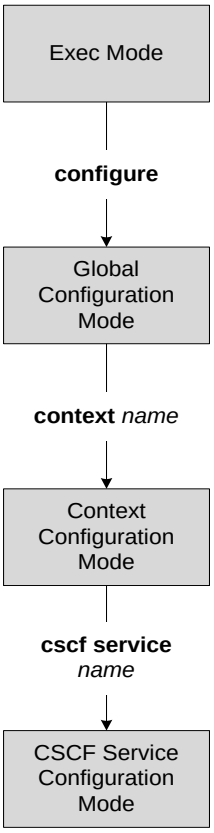
Example

The following command sets the threshold rate to *5* bad requests per second:

```
threshold-rate 5
```

Chapter 88
CSCF Service Configuration Mode Commands

The CSCF Service Configuration Mode is used to create and manage CSCF services within the current context.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

RetryAfter-header-value

Sets the minimum and maximum value in seconds for Retry-After Header.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

RetryAfter-header-value min-value *sec* **max-value** *sec*

default RetryAfter-header-value

min-value *sec* **max-value** *sec*

min-value *sec*: Specifies the minimum amount of time for Retry-After Header. *sec* must be an integer from 2 to 3600. Default is 2 seconds.
max-value *sec*: Specifies the maximum amount of time for Retry-After Header. *sec* must be an integer from 3 to 3601. Default is 10 seconds.

Important: Maximum value should be greater than minimum value.

default

Returns the command to the default settings.

Usage

Use this command to set the minimum and maximum value in seconds for Retry-After Header. If Transactions Per Second (TPS) rate towards the peer-server application server (AS) is exceeded, the incoming requests will be rejected with 500 error response; Retry-After Header specifies the number of seconds before UE should retry.

Example

The following command configures the minimum value to *3*and maximum value to *12* for Retry-After Header:

```
RetryAfter-header-value min-value 3 max-value 12
```

access-service

Configures the name of the P-CSCF/A-BG access service from which the system receives requests and sends responses. The access service lets the core service know where a packet needs to be routed.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

```
access-service name name
no access-service [ name name ]
```

name *name*

Specifies the name of the P-CSCF/A-BG access service from which the system receives requests and sends responses.
name must be from 1 to 63 alpha and/or numeric characters.

Important: This command should only be issued in the core service configuration, however, multiple access services may be configured per core service.

no

Removes the access service.

Usage

Use this command to identify the name of the P-CSCF/A-BG access service from which the system receives requests and sends responses from/to the UEs. This command is used in systems that deploy two P-CSCF/A-BG services in bridging (Back-to-Back User Agent) mode configurations where an access service P-CSCF/A-BG faces the UE network and a core P-CSCF/A-BG faces the public network.

Example

The following command identifies the P-CSCF/A-BG access service named to the CSCF/A-BG core service:

```
access-service name HA3
```

access-type

Specifies the access types for IMS core.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

access-type { type } access-profile { default | name *access_profile_name* **} | ue-ip-address-range name** *ue_ip_name* **{ address** *ip_address_mask* **| range** *start_ip_address end_ip_address* **}**

vdsl: FixedLine Access Type

---

access-profile { default | name *access_profile_name* **}**

Associates an access type with a CSCF access profile. Different access types can refer to the same access profile.

---

ue-ip-address-range name *ue_ip_name* **{ address** *ip_address_mask* **| range** *start_ip_address end_ip_address* **}**

Configures UE IP address/range for a specific access type.
ue_ip_name must be from 1 to 79 alpha and/or numeric characters.
address *ip_address_mask*: Specifies a combined IP address subnet mask bits to indicate what IP addresses the specific access-type applies to. *ip_address_mask* must be specified using the form "IP Address/Mask Bits" where the IP address must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6, and the mask bits are a numeric value, which is the number of bits in the subnet mask.
range *start_ip_address end_ip_address*: Configure UE IP range for specific access-type.

- *start_ip_address* specifies the beginning of the range of addresses.
- *end_ip_address* specifies the end of the range of addresses.
- *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.

---

no

Removes the specified access type from a CSCF access profile or UE IP address/range.

Usage

Use this command to associated the access types for a specified CSCF access profile or UE IP address/range name.

Important: Use the **sip-header** command to enable SIP P-Access-Network-Info (PANI) header insertion. CSCF Proxy-CSCF Configuration Mode commands are defined in the *CSCF Proxy-CSCF Configuration Mode Commands* chapter in this guide.

Example

The following command identifies the access type adsl and assigns it to access profile *ap1*:

```
access-type adsl access-profile name ap1
```

allow-dereg

Allows the CSCF to send de-registration requests. Feature is disabled by default.

Product

SCM

Privilege

Administrator

Syntax

```
[ no ] allow-dereg
```

no

Disables the feature.

Usage

Use this command to allow the CSCF service to send de-registration requests.
If the UE stops sending keepalive packets, which ends the connection between the UE and the proxy, UE information is cleared from the Proxy-CSCF (P-CSCF) or Access Border Gateway (A-BG). If de-registration requests are enabled, any UE-related information that is shared with the Serving-CSCF (S-CSCF) will also be cleared.

bind

Binds the CSCF service to a logical IP interface and specifies the maximum number of sessions that can access this service over the specified interface.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

bind address *ip_address* **[cscf-hostname** *host_name* **] [ipsec-crypto-template** *template* **] [max-sessions** *max#* **] [port** *number* **] [reserved-call-capacity** *percentage* **] [tls-crypto-template** *template* **[tls-port** *number* **]] [transport tcp] [use-serviceport-towards-network]**

no bind address

---

address *ip_address*

Specifies the IP address of the interface to which the service is being bound.
ip_address must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.

---

cscf-hostname *host_name*

Specifies the local host name of the CSCF service.
host_name must be an existing CSCF service name and be from 1 to 127 alpha and/or numeric characters.
Configuring this keyword associates the CSCF service with the AOR domain configured in the **default-aor-domain** command and uses the domain name in SIP headers.

Important: If this keyword is not configured, SIP headers will contain the IP address of the CSCF service instead of the domain name.

---

ipsec-crypto-template *template*

Specifies the name of an existing IPSec CSCF crypto template to be used for accessing CSCF service by user equipment. Valid only for P-CSCF or A-BG.
template must be an existing IPSec CSCF crypto template and be from 1 to 127 alpha and/or numeric characters.

Important: The IPSec CSCF crypto template should be configured in the same context in which the P-CSCF is configured.

---

max-sessions *max#*

Default: 500,000
Specifies the maximum number of sessions managed by this service on this interface.
max# must be configured to any integer value from 0 to 500,000.

Important: The total session capacity of the system is 500,000. **max-sessions** is also limited by the capacity in the license generated for the service. If licenses for PDSN/GGSN/HA are generated for *x* number of sessions, then the license for the CSCF service will be generated at 500,000-*x*. Hardware configuration and installed features can also affect the maximum number of sessions that can be supported.

port *number*

Default: 5060
Specifies the UDP port number.
number must be an integer value from 1 to 65534.

reserved-call-capacity *percentage*

Default: 10
Specifies the call capacity percentage per session manager (sessmgr).
percentage must be an integer value from 1 to 50.

tls-crypto-template *template* **[tls-port** *number* **]**

Specifies the name of an existing Transport Layer Security (TLS) crypto template to enable TLS functionality. Valid only for P-CSCF or A-BG.
template must be an existing TLS crypto template and be from 1 to 127 alpha and/or numeric characters.
Default: 5061
Specifies the TLS port number.
number must be an integer value from 1 to 65534.

Important: When the **tls-crypto-template** is configured, TCP transport must be enabled, otherwise this command will throw an error. The configured **tls-crypto-template** should be should be configured in the same context in which the P-CSCF service is configured and must be complete with all certificate and cipher suite configuration. If the **tls-crypto-template** is not present or not completely configured, the P-CSCF service will not be started.

transport tcp

Enables TCP transport for the address.

use-serviceport-towards-network

Enables use of service port for sending and receiving UDP messages from network elements.

no

Removes the binding of the service to a specified interface.

Usage

Use this command to associated the service with a specific logical IP address. This command also configures the identity of the CSCF in SIP headers as either the domain name of the CSCF service or the IP address.

Important: Multiple keywords can be used per bind command.

Example

The following command binds the CSCF service to a logical interface with an IP address of *1.2.3.4* and sets the maximum number of supported sessions for this interface at *250000*:

```
bind address 1.2.3.4 max-sessions 250000
```

caller-preference

Enables custom SIP caller preferences; standards-based caller preference will not be applied.

Product

SCM

Privilege

Administrator

Syntax

```
caller-preference custom

[ default | no ] caller-preference
```

default

Enables standards-based caller preference.

no

Disables custom caller preference processing; contact will be selected without considering caller preference.

Usage

Use this command to enable or disable custom SIP caller preferences.

charging

Enables Rf charging in this CSCF service for SIP messages.

Product

SCM

Privilege

Administrator

Syntax

`[ default | no ] charging`

`default | no`

Disables Rf charging in this CSCF service for SIP messages.

Usage

Use this command to enable the RF charging feature in this service and enter the CSCF Charging Configuration Mode.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-charging)#
```

CSCF Charging Configuration Mode commands are defined in the *CSCF Charging Configuration Mode Commands* chapter in this guide.

cnsa-media-profile

Configures the media profile id to be set for a previously created service policy.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ no ] cnsa-media-profile profile_id cscf-service-policy policy_name content-type {
application-3gpp-ims-xml | application-pidf-diff-xml | application-pidf-partial-xml |
application-pidf-xml | application-reginfo-xml | application-sdp | application-xml |
message-sipfrag | multipart-mixed | multipart-related | text-plain }
```

---

no

Removes the media profile from the service policy.

---

cnsa-media-profile *profile_id*

Specifies the media profile id.
profile_id must be an integer from 0 to 10 and be an existing media profile id in the system. CNSA media profile ids are created and maintained in the CSCF ISC Template Configuration Mode.

---

cscf-service-policy *policy_name*

Assigns the media profile id to a service policy.
policy_name must be from 1 to 63 alpha and/or numeric characters and be an existing policy name in the system. Service policies are created and maintained in the CSCF Policy Configuration Mode.

---

content-type { application-3gpp-ims-xml | application-pidf-diff-xml | application-pidf-partial-xml | application-pidf-xml | application-reginfo-xml | application-sdp | application-xml | message-sipfrag | multipart-mixed | multipart-related | text-plain }

Specifies the content type(s).
application-3gpp-ims-xml - format for exchanging information in SIP Requests and Responses as used within the 3GPP IM CN Subsystem
application-pidf-diff-xml - contains changed presence elements. Contains full presence document when there are many changes
application-pidf-partial-xml - contains only changed parts of PIDF-based presence information
application-pidf-xml - XML MIME entity that contains presence information
application-reginfo-xml - used in Notifications to SIP user agents about registration expiry
application-sdp - SDP session description
application-xml - content type for generic xml documents
message-sipfrag - contains subsets of well formed SIP messages
multipart-mixed - intended for use when the body parts are independent and need to be bundled in a particular order
multipart-related - intended for compound objects consisting of several inter-related body parts
text-plain - plain text

Important: You may specify multiple types of content.

Usage

Use this command to assign a media profile id to a service policy. The policies defined in the service policy apply to all subscribers using this service.
CNSA media profile ids are created and maintained in the CSCF ISC Template Configuration Mode. Service policies are created and maintained in the CSCF Policy Configuration Mode.

Example

The following command defines the media profile id as *2* and assigns it to *serv_policy3* with plain text content type.

```
cnsa-media-profile 2 cscf-service-policy serv_policy3 content-type text-
plain
```

core-service

Configures a core service if:

- CSCF services are run in bridging (Back-to-Back User Agent) mode
- A-BG is an Application-level Gateway (ALG) for Network Address Translation (NAT)

By default, no core-service name will be present.

Product

SCM (CSCF, A-BG)

Privilege

Administrator

Syntax

[no] core-service name *service_name*

no

Removes the core service.

name *service_name*

Specifies the name of the core service.
service_name must be from 1 to 80 alpha and/or numeric characters.

Usage

Use this command to assign a core service to the CSCF/A-BG service.

Example

The following command identifies the core service:

```
core-service name service1
```

custom reg-binding

Enables the S-CSCF to return only one binding (latest contact) for each registration without including other bindings, if any. Default is disabled.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ no ] custom reg-binding
```

no

S-CSCF returns all the bindings for AOR in 200 OK REGISTER response.

Usage

Use this command to control whether the S-CSCF returns only one or all bindings for AOR in 200 OK REGISTER response.

custom response

Configures reject with specific response code for UE capability failure or UE status. Feature is disabled by default.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

custom response { ue-capability-failure *capability_type* **| ue-status** *status* **} reject response-code** *response_code*

no custom response { ue-capability-failure *capability_type* **| ue-status** *status* **}**

ue-capability-failure *capability_type*

Specifies UE capability failure type:

- **all** - UE capability all
- **at** - UE capability AT
- **audio** - UE capability audio
- **chat** - UE capability CHAT
- **cs** - UE capability CS
- **ft** - UE capability FT
- **im** - UE capability IM
- **mms** - UE capability MMS
- **msg** - UE capability MSG
- **oma-sip-im** - UE capability OMA SIP-IM
- **rcs-dp** - UE capability RCS-e DP
- **rcs-e** - UE capability RCS-E
- **rcs-ft** - UE capability RCS-e FT
- **rcs-im** - UE capability RCS-e IM
- **rcs-is** - UE capability RCS-e IS
- **rcs-sp** - UE capability RCS-e SP
- **rcs-vs** - UE capability RCS-e VS
- **text** - UE capability text
- **video** - UE capability video
- **vt** - UE capability VT
- **vt-ft** - UE capability VT-FT
- **vt-is** - UE capability VT-IS
- **vt-loc** - UE capability VT-LOC

- **vt-memo** - UE capability VT-MEMO

ue-status *status*

Specifies UE status:

- **1x-busy** - UE status 1x-busy
- **all** - UE status all
- **idle** - UE status idle
- **power-off** - UE status power-off
- **unreg** - UE status unreg
- **vt-busy** - UE status vt-busy

reject response-code *response_code*

Specifies reject for UE capability failure with specific response code.
response_code must be an integer from 400 to 699.

no

Removes customer-specific UE capability failure or UE status configuration, if present, and uses default RFC/3GPP specification behavior.

Usage

As per RFC/3GPP specifications, S-CSCF rejects with 480 response code for UE capability failure (caller preference) or UE status. Use this command to configure the S-CSCF to reject with specific response code based on UE capability failure or UE status.

Example

The following command configures S-CSCF reject with response code *455* for a UE capability audio failure.

```
custom-response ue-capability-failure audio reject response-code 455
```

custom volte

Enables custom Voice over LTE (VoLTE) features.

Product

SCM

Privilege

Administrator

Syntax

```
[ default | no ] custom volte
```

default | no

Disables custom features.

Usage

Use this command to enable or disable custom VoLTE features.

default-aor-domain

Configures the domain name of the service.

Product

SCM

Privilege

Administrator

Syntax

[no] default-aor-domain *alias*

no

Removes the domain name from the service.

alias

Specifies the domain name for the service.
alias is the name of the domain for this service and must be from 1 to 79 alpha and/or numeric characters in length.

Usage

Use this command to define the domain name of the service.

Example

The following command defines the domain name of the CSCF service as *business.com*:

```
default-aor-domain business.com
```

emergency-cscf

Enables the Emergency-CSCF for the service and enters the Emergency-CSCF Configuration Mode. Default is disabled.

Product

SCM

Privilege

Administrator

Syntax

```
[ no ] emergency-cscf
```

no

Disables the E-CSCF for the service.

Usage

Use this command to enable the Emergency-CSCF feature and enter the Emergency-CSCF Configuration Mode.
Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-service-emergency-cscf)#
```

Emergency-CSCF Configuration Mode commands are defined in the *CSCF Emergency-CSCF Configuration Mode Commands* chapter in this guide.

Important: Only one function (P-CSCF, S-CSCF, E-CSCF, SIP Proxy, or A-BG) can be enabled per service.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

```
exit
```

Usage

Return to the previous mode.

history-info

Enables the addition of the history-info header to SIP requests in order to capture request URI information. By default, this command is disabled.

Product

SCM

Privilege

Administrator

Syntax

```
[ default | no ] history-info
```

default | no

Disables the inclusion of the history-info header.

Usage

Use this command to include the history-info header in SIP requests to capture the request URI information for routing or translation.

interface statistics sip

Enables interface SIP statistic collection in this CSCF service.

Product

SCM

Privilege

Administrator

Syntax

```
[ default | no ] interface statistics sip
```

default | no

Disables interface SIP statistic collection for this service.

Usage

Use this command to enable or disable the collection of interface SIP statistics in this service.

interrogating-cscf

This command is not supported in this release.

ipv4-ipv6-interworking

Allows the P-CSCF to provide IPv4-IPv6 interworking when UEs are IPv6-only and the IMS core network is IPv4-only. Feature is disabled by default.

Product

SCM (P-CSCF)

Privilege

Administrator

Syntax

```
[ no ] ipv4-ipv6-interworking
```

no

Disables the feature.

Usage

Use this command to allow IPv4-IPv6 interworking functionality.

keepalive

Configures the CSCF to receive and respond to different types of keep-alive requests.

Product

SCM

Privilege

Administrator

Syntax

```
keepalive [ expire-timer sec [ max-retry num ] | max-retry num [ expire-timer sec ] |
method { crlf | stun } [ expire-timer sec [ max-retry num ] | max-retry num [ expire-
timer sec ] ] ]

default keepalive [ expire-timer | max-retry [ expire-timer ] | method [ expire-timer |
max-retry ] ]

no keepalive [ method { crlf | stun } ]
```

expire-timer *sec*

Default: 29
This value is used according to timed-keepalives parameter present in Path header. UEs are expected to send keepalive messages according to this time interval.
sec must be an integer from 24 to 150.

max-retry *num*

Default: 3
Specifies the maximum number of times the CSCF waits for the UE to send a keepalive request before it deletes the user information.
num must be an integer from 1 to 10.

method { crlf | stun }

Default: both methods enabled.
Specifies the method of keepalive messages supported by the CSCF.
crlf: "\r\n" string (CRLF packets) sent by UE
stun: STUN protocol messages (rfc3489-bis)

default

Returns the command to the default settings. All methods are enabled by default. See keywords above for specific defaults.

no

Disables the specified method of keepalive messages.

Usage

Use this command to configure how the CSCF manages keepalive requests.

Example

The following example sets the expire timer to *40* and the maximum retry parameter to *5*:

```
keepalive expire-timer 40 max-retry 5
```

lawful-intercept

Enables Lawful Intercept (LI) in this CSCF service. Feature is disabled by default.

Product

SCM

Privilege

Administrator

Syntax

```
[ no ] lawful-intercept
```

no

Disables the feature.

Usage

Refer to the *Lawful Intercept Configuration Guide* for more information on LI.

li-packet-cable

Refer to the *Lawful Intercept Configuration Guide* for a description of this command.

max-sipmsg-size

Configures the maximum SIP message size.

Product

SCM

Privilege

Administrator

Syntax

max-sipmsg-size *limit*

[default | no] max-sipmsg-size

limit

Default: 4096
Configures the SIP message size limit in bytes.
limit must be an integer from 1024 to 65535.

Important: Maximum SIP message size should be more than the message-max-size set in the CSCF Proxy-CSCF Configuration Mode.

default | no

Returns/sets the maximum SIP message size to 4096 bytes.

Usage

Use this command to configure the maximum SIP message size.

Example

The following command limits the SIP message size to *4500* bytes:

```
max-sipmsg-size 4500
```

media-bridging

Enables SDP modification that terminate media on CSCF. Feature is disabled by default.

Product

SCM (P-CSCF)

Privilege

Administrator

Syntax

media-bridging [v6port-range *start_port end_port* **]**

no media-bridging

v6port-range *start_port end_port*

Specifies port ranges to be used with IPv6 addresses. Only selected ports from the range specified should be used for media bridging.
start_port: Start of port range; must be an integer from 1024 to 65535.
end_port: End of port range; must be an integer from 1025 to 65535.

no

Disables the feature.

Usage

Use this command to allow termination of media on CSCF.

Example

The following command allows media bridging on ports *2000* to *4000* for IPv6 addresses:

```
media-bridging v6port-range 2000 4000
```

monitoring

Enables thresholds alerting for this CSCF service.

Product

SCM

Privilege

Administrator

Syntax

```
monitoring
```

Usage

Use this command to enable thresholds alerting for this CSCF service.

multiple-reg same-private-id

This command allows multiple registrations for the same private user-id from different devices.

Product

SCM (P-CSCF, A-BG, S-CSCF)

Privilege

Administrator

Syntax

```
[ default | no ] multiple-reg same-private-id
```

default | no

Multiple registrations are not allowed for the same private user-id.

Usage

Use this command to allow or disallow multiple registrations for the same private user-id from different devices.

Example

The following command allows multiple registrations for the same private user-id from different devices:

```
multiple-reg same-private-id
```

nat-policy

Configures a NAT (Network Address Translation) policy for the service if the CSCF service is performing one of the following functions:

- CSCF services are run in bridging (Back-to-Back User Agent) mode
- A-BG is an Application-level Gateway (ALG) for NAT

Product

SCM(CSCF, A-BG)

Privilege

Administrator

Syntax

nat-policy *policy_name* { **private-address** { **address** *ip_address_mask* | **default | range** *start_ip_address end_ip_address* } | **bridge-network** { **address** *ip_address_mask* | **range** *start_ip_address end_ip_address* }

no nat-policy *policy_name*

---

policy_name

Specifies a name for the NAT policy.
policy_name must be from 1 to 79 alpha and/or numeric characters.

---

private-address { address *ip_address_mask* **| default|range** *start_ip_address end_ip_address* **}**

Specifies the private-address policy type for nat-pool.
address *ip_address_mask*: Address for nat-policy policy type for nat-pool. Specifies a combined IP address subnet mask bits to indicate what IP addresses the specific policy type applies to. *ip_address_mask* must be specified using the form "IP Address/Mask Bits" where the IP address must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6, and the mask bits are a numeric value, which is the number of bits in the subnet mask.
default: Default for nat-policy policy type for nat-pool. Default is defined as the address range specified by rfc1918.

- 10.0.0.0 - 10.255.255.255 (10/8 prefix)
- 172.16.0.0 - 172.31.255.255 (172.16/12 prefix)
- 192.168.0.0 - 192.168.255.255 (192.168/16 prefix)

range *start_ip_address end_ip_address*: Range for nat-policy policy type for nat-pool.

- *start_ip_address* specifies the beginning of the range of addresses.
- *end_ip_address* specifies the end of the range of addresses .
- *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.

---

bridge-network { address *ip_address_mask* **| range** *start_ip_address end_ip_address* **}**

Specifies the bridge-network policy type for S-CSCF bridging.
address *ip_address_mask*: Address for bridge-network policy type for S-CSCF bridging. Specifies a combined IP address subnet mask bits to indicate what IP addresses the specific policy type applies to.

ip_address_mask must be specified using the form "IP Address/Mask Bits" here the IP address must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6, and the mask bits are a numeric value, which is the number of bits in the subnet mask.

range *start_ip_address end_ip_address*: Range for bridge-network policy type for S-CSCF bridging.

- *start_ip_address* specifies the beginning of the range of addresses.
- *end_ip_address* specifies the end of the range of addresses.
- *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.

no

Removes the specified NAT policy from the service.

Usage

Generally, if a SIP packet has a VIA address (physical address that identifies where the service is located) different from the Source address, ALG functionality is invoked. Even if the VIA and Source addresses are the same, however, this command allows the ALG functionality to be started. For ALG to start, the VIA address should belong to one of the nat-policy address ranges.

Example

The following command identifies the NAT policy named *policy1* with a private-address policy type of *10.10.10.10 255.255.255.0*:

```
nat-policy policy1 private-address address 10.10.10.10 255.255.255.0
```

The following command identifies the NAT policy named *policy2* with a private-address range policy type of *172.162.23.23 172.162.23.230*:

```
nat-policy policy2 private-address address 172.162.23.23 172.162.23.230
```

The following command identifies the NAT policy named *policy3* with a default policy type:

```
nat-policy policy3 private-address default
```

nat-pool

Configures a NAT (Network Address Translation) pool for the service if the CSCF service is performing one of the following functions:

- P-CSCF services are run in bridging (Back-to-Back User Agent) mode
- A-BG is an Application-level Gateway (ALG) for NAT

By default, no nat-pool name will be present.

Product

SCM(P-CSCF, A-BG)

Privilege

Administrator

Syntax

nat-pool name *pool_name* **[signalling-pool** *signalling_pool_name* **]**

no nat-pool name *pool_name*

name *pool_name*

Specifies the name of an existing NAT pool.
pool_name must be from 1 to 32 alpha and/or numeric characters.

Important: NAT pools are created in *Context Configuration Mode* with the **ip pool** command.

signalling-pool *signalling_pool_name*

Specifies the name of an existing IP pool from where IP addresses will be used to fill in signalling headers only.
signalling_pool_name must be from 1 to 32 alpha and/or numeric characters.

Important: If **signalling-pool** is not specified, service IP:port will be filled in signalling headers.

no

Removes the NAT pool from the service.

Usage

Use this command to assign a NAT pool to the P-CSCF/A-BG service.

Example

The following command identifies the NAT pool:

```
nat-pool name pool2
```

policy

Enables or disables early media support and IBCF capability in P-CSCF/A-BG. In addition, configures Interim-Interval value for CSCF accounting sessions, overload response, and the congestion control threshold and tolerance values that are to be monitored on this CSCF service.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

policy { accounting interim-interval *value* **| allow-early-media | ibcf-capability domain** *domain/name* **| overload [drop | redirect** *IPv4_address1* **[weight** *weight1* **] [** *IPv4_address2* **[weight** *weight2* **]] ... | reject] | threshold congestion-control { system-cpu-utilization** *percent* **| tolerance** *percent* **} }**

default policy { allow-early-media | overload | threshold congestion-control { system-cpu-utilization | tolerance } }

no policy { accounting interim-interval | allow-early-media | ibcf-capability domain *domain/name* **| overload [redirect** *IPv4_address1* **] [** *IPv4_address2* **] ... | threshold congestion-control { system-cpu-utilization | tolerance } }**

accounting interim-interval *value*

Default: Disabled
Used to configure Interim-Interval value for CSCF accounting sessions.
value can be configured to any integer value from 50 to 7200. This value is sent in the "Acct-Interim-Interval" AVP of the accounting message. Based on the response message from accounting server, Interim-Interval timer is started.

allow-early-media

Default: Enabled
Allows early media by doing QoS commit during QoS Authorization (with PCRF) in P-CSCF.

ibcf-capability domain *domain/name*

Enables IBCF capability to support Mx reference point in CSCF.
IBCF capability domain name must be entered using from 1 to 80 alpha and/or numeric characters.

Important: This CLI can be repeated to add/delete multiple entities to/from the ibcf-capability domain table. An ibcf-capability domain can be removed by using the **no** keyword; using the **no** keyword without giving any domain name will delete all entries from the list.

overload [drop | redirect *IPv4_address1* **[weight** *weight1* **] [** *IPv4_address2* **[weight** *weight2* **]] ... | reject]**

Configures the overload response for this policy. When the P-CSCF/A-BG becomes congested, this overload policy is used to drop/reject subsequent sessions or redirect them to another server.

drop: Specifies that upon policy overload, the system will drop the session.
redirect: Specifies that upon policy overload, the system will redirect the session to another CSCF.

- *IPv4_address1* must be expressed in dotted decimal notation.
- **weight** *weight1*: Defines the priority of the redirect address.

  weight1 must be an integer from 1 to 10. Default is 1.

reject: Specifies that upon policy overload, the system will reject the session with 503 (Service Unavailable) SIP error response. This is the default setting.

---

threshold congestion-control { system-cpu-utilization *percent* **| tolerance** *percent***}**

Enables congestion control. CSCF performs congestion control based on the memory usage inside every sessmgr at two levels.

- **Level 1**: For every new call/event received, the system checks if sessmgr memory-usage is above a threshold value (such as 95 percent). If it is, memory-congestion is triggered and new call messages are rejected with 500 SIP response. Memory congestion is disabled when memory usage drops by a tolerance value (default is 10 percent).
- **Level 2**: If the sessmgr usage reaches 100 percent, all newly received SIP messages are dropped at the socket layer in that sessmgr except for the BYE message. The new SIP messages are not processed until the memory reaches the threshold value (95 percent).

A trap is also generated whenever sessmgr is in congestion state
system-cpu-utilization *percent*: The average percent utilization of a CPU in a PSC/PSC2/PSC3 running the CSCF service as measured in 10 second intervals.
percent can be configured to any integer value from 0 to 100. This value becomes the upper threshold for triggering the CPU-based congestion for CSCF services. Default is 80
tolerance *percent*: The percentage under a configured threshold that dictates the point at which the condition is cleared.
percent is an integer value from 1 to 25. Default is 5

---

default

Returns the command to the default settings. See keywords above for specific defaults.

---

no

Disables the specified functionality.

Usage

Use this command to set the following policy for this CSCF service:

- Configure Interim-Interval value for CSCF accounting sessions.
- Set QoS support during either the initial SDP response or the 200OK response to the INVITE. When **allow-early-media** is enabled, QoS commit is done during initial SDP answer. When disabled, QoS commit is done during 200OK INVITE. By default, this command is enabled.
- Enable or disable IBCF capability.
- Define the response to an overload condition.
- Set thresholds to dictate the conditions for which congestion control is to be enabled and establish limits for defining the state of the CSCF service (congested or clear). The tolerance parameter establishes the threshold at which the condition is cleared.

Important: When congestion is triggered, new CSCF calls are not rejected.

Example

The following command sets the upper threshold for CPU utilization for triggering congestion control at *90%*.

```
policy threshold congestion-control system-cpu-utilization 90
```

The following command sets the tolerance to its default value of *5*.

```
default policy threshold congestion-control tolerance
```

policy-name

Assigns a previously created service policy to this service.

Product

SCM

Privilege

Administrator

Syntax

policy-name *name*

no policy-name

name

Specifies the name of the service policy being assigned to this service.
name must be from 1 to 79 alpha and/or numeric characters and be an existing policy name in the system.
Service policies are created and maintained in the CSCF Policy Configuration Mode.

no

Remove the assigned service policy from this service.

Usage

Use this command to assign a service policy to this service. The policies defined in the service policy apply to all subscribers using this service. Service policies are created and maintained in the CSCF Policy Configuration Mode.

Example

The following command assigns a service policy named *serv_policy3* to this service:

```
policy-name serv_policy3
```

proxy-cscf

Enables the Proxy-CSCF for the service and enters the Proxy-CSCF Configuration Mode. Default is disabled.

Product

SCM (P-CSCF)

Privilege

Administrator

Syntax

```
[ no ] proxy-cscf
```

no

Disables the P-CSCF for the service.

Usage

Use this command to enable the Proxy-CSCF feature and enter the Proxy-CSCF Configuration Mode. Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-service-proxy-cscf)#
```

Proxy-CSCF Configuration Mode commands are defined in the *CSCF Proxy-CSCF Configuration Mode Commands* chapter in this guide.

Important: The Proxy-CSCF is a license-enabled function of the Session Control Manager. Only one function (P-CSCF, S-CSCF, E-CSCF, SIP Proxy, or A-BG) can be enabled per service.

proxy-serving-cscf

This command is not supported in this release.

recurse-on-redirect-resp

Enables the 3xx recursion feature. If enabled, the service will send further invites to the contacts specified upon receiving a 3xx redirect response. Default is disabled.

Product

SCM

Privilege

Administrator

Syntax

```
[ no ] recurse-on-redirect-resp
```

no

Disables the 3xx recursion feature.

Usage

When enabled and on receipt of a 3xx response, the service will collect the SIP URIs present in the Contact header(s) of 3xx and recursively contact each one of them until the call succeeds. The contacts are tried serially. There is a maximum implementation limit of 50 URIs. Each contact, in turn, can send a 3xx response. The service will honor them and append the new contacts. When disabled, the service treats a 3xx response as the final failure response and declares the call attempt “failed”. By default, this feature is disabled.

Example

Enable recursion on 3xx:

```
recurse-on-redirect-resp
```

Disable recursion on 3xx:

```
no recurse-on-redirect-resp
```

reject-on-cnsa-failure

Enables rejection of messages on Core Network Service Authorization failure. Default is disabled.

Product

SCM

Privilege

Administrator

Syntax

```
[ no ] reject-on-cnsa-failure
```

no

Disables the rejection of messages on Core Network Service Authorization failure.

Usage

Enables rejection of messages on Core Network Service Authorization failure. By default, this feature is disabled.
In a mobile originating case, S-CSCF checks for the presence of P-Preferred-Service (PPS) header. If the header is present, media profile authentication is successful and if the incoming ICSI (IMS Communication Service Identifier) value also matches with one of the values in the service_id list, then the request will be forwarded after replacing the PPS header with PAS (P-Asserted-Service). If media profile authentication fails, S-CSCF will check reject-on-cnsa-failure. If enabled, then call is rejected with 403 message. If disabled, a default ICSI is selected from the service_id list and will be put into PAS while forwarding the request by the S-CSCF on service authentication failure.
In PPS is not received by the S-CSCF and media profile authentication is successful, an ICSI from the service_id list, if present, is selected and will be added in PAS header. If media profile authentication fails, reject-on-cnsa-failure is checked. If enabled, call is rejected with 403 message. If disabled, PAS header is added if service_id list is present with an ICSI value.

Example

Enable rejection of messages on Core Network Service Authorization failure:

```
reject-on-cnsa-failure
```

Disable rejection of messages on Core Network Service Authorization failure:

```
no reject-on-cnsa-failure
```

release-call-on-media-loss

Release call on detection of media loss.

Product

SCM (P-CSCF, A-BG)

Privilege

Administrator

Syntax

release-call-on-media-loss media-type audio [timeout *seconds* **]**

no release-call-on-media-loss

media-type audio

Enables the release of SIP calls upon the detection of media loss on media-type audio.

timeout *seconds*

Specifies the media loss timeout value; media loss after timeout value results in call release.
seconds must be an integer from 5 to 3600.
If timeout value is not configured, media loss after 5 seconds results in call release.

no

Disables the release of SIP calls upon the detection of media loss.

Usage

Use this command to enable the release of SIP calls upon the detection of media loss.

Example

Enables the release of SIP calls upon the detection of media loss:

```
release-call-on-media-loss media-type audio
```

Enables the release of SIP calls upon the detection of media loss:

```
no release-call-on-media-loss
```

rfc3261-proxy

Enables RFC3261 proxy (SIP Proxy) for this service and enters the SIP Proxy Configuration Mode. Default is disabled.

Product

SCM (SIP Proxy)

Privilege

Administrator

Syntax

`[ default | no ] rfc3261-proxy`

`default | no`

Disables RFC3261 proxy in this service.

Usage

Use this command to enable the Sip Proxy feature and enter the SIP Proxy Configuration Mode. Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-service-rfc3261-proxy)#
```

SIP Proxy Configuration Mode commands are defined in the *CSCF SIP Proxy Configuration Mode Commands* chapter in this guide.

Important: The SIP Proxy is a license-enabled function of the Session Control Manager. Only one function (P-CSCF, S-CSCF, E-CSCF, SIP Proxy, or A-BG) can be enabled per service.

serving-cscf

Enables Serving-CSCF for the service and enters the Serving-CSCF Command Mode. Default is disabled.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ no ] serving-cscf
```

no

Disables S-CSCF for the service.

Usage

Use this command to enable the Serving-CSCF feature and enter the Serving-CSCF Configuration Mode. Entering this command results in the following prompt:

```
[context_name]hostname(config-cscf-service-serving-cscf)#
```

Serving-CSCF Configuration Mode commands are defined in the *CSCF Serving-CSCF Configuration Mode Commands* chapter in this guide.

Important: The Serving-CSCF is a license-enabled function of the Session Control Manager. Only one function (P-CSCF, S-CSCF, E-CSCF, SIP Proxy, or A-BG) can be enabled per service.

serving-cscf-list

Configure a list of Serving CSCFs and their capabilities.

Product

SCM

Privilege

Administrator

Syntax

```
[ no ] serving-cscf-list server { address address | domain domain } { capability value |
port num { capability value } }
```

no

Removes an entry from this list.

server { address *address* **| domain** *domain* **}**

Specifies the S-CSCF server.
address *address*: IP addresses must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
domain *domain*: Domain names must be entered using from 1 to 80 alpha and/or numeric characters.

capability *value*

Specifies the capability of the S-CSCF server. *value* is assigned by the Service Provider and may be an integer from 1 to 999999.

port *num*

Specifies the port at which service is provided by the S-CSCF server. *num* may be an integer from 1 to 65535.

Usage

Use this command to configure a list of Serving CSCFs and their capabilities.

Important: This command can be entered multiple times to identify multiple Serving CSCFs.

Example

The following command adds a S-CSCF with an IP address of *1.2.3.4* and a capability value of *75* to this service's list:

```
serving-cscf-list server address 1.2.3.4 capability 75
```

session-timer

Configures the session expiry for sessions (Session will expire at the configured value unless refreshed.) and the minimum number of seconds in a session timer (session-expires) value the system will allow.

Product

SCM

Privilege

Administrator

Syntax

session-timer { min-se *sec* **[session-expires** *sec* **] | session-expires** *sec* **[min-se** *sec* **] }**

default session-timer [min-se] [session-expires]

no session-timer

min-se *sec*

Default: 90
Specifies the minimum number of seconds the system will allow a session-expires value in a session request.
sec must be an integer value between 90 and the value of the **session-expires** command.

session-expires *sec*

Default: 1800 (30 minutes)
Specifies the number of seconds a session is allowed exist before it expires.
sec must be an integer value between 90 and 18000.

default

Returns the command to the default settings.

no

Disables the session timer.

Usage

Use this command to set a session expiry value for all invites generated by the SCM and a minimum value for a session request session timer the system will allow. If a session is requested with a timer of less than this command's value, the system will reject the request with a "422 Session Interval Too Small" response code.

Example

The following command sets the session expiry for all sessions generated by the SCM to 60 minutes:

```
session-timer session-expires 3600
```

strict-check configured-aor-domain

Enables strict checking on default-aor-domain so S-CSCF will reject registration and invite if there is a mismatch between AoR in To/From and the configured default-aor-domain.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ default | no ] strict-check configured-aor-domain
```

default | no

Disables strict checking on default-aor-domain. This is the default behavior.

Usage

Use this command to enable or disable strict checking on default-aor-domain. This allows support for registration of subscribers from multiple domains.

strict-outbound

When enabled, the CSCF rejects registration without outbound parameters from an already registered AoR (the AoR would have included outbound parameters in a previous registration). When disabled, the CSCF allows registration without outbound parameters from the previously registered AoR.

Product

SCM

Privilege

Administrator

Syntax

```
[ no ] strict-outbound
```

no

Disables the feature. This is the default behavior.

Usage

Use this command to reject registration from a previously registered AoR if the AoR fails to register with outbound parameters but included them in the previous registration.

subscriber-policy-override

Configures the system to allow the subscriber-based policy to override the service-based policy. Default is disabled.

Product

SCM

Privilege

Administrator

Syntax

```
[ default | no ] subscriber-policy-override
```

default | no

Removes the subscriber policy override from the service.

Usage

By default, if a conflict occurs between the subscriber-based policy and the service-based policy, the service policy takes precedence. Use this command to override the default behavior of the system and allow the subscriber-based policy to overrule the service policy.

subscription

Enables the registration event package for the service and configures a system-wide subscription lifetime for all subscribers to the service.

Product

SCM

Privilege

Administrator

Syntax

subscription package reg [lifetime { default *sec* **| max** *sec* **[default** *sec* **] | min** *sec* **[max** *sec* **] [default** *sec* **] }]**

[default | no] subscription package reg

package reg [lifetime { default *sec* **| max** *sec* **] | min** *sec* **}**

default *sec*: Specifies the default amount of time that a subscription can exist on the system. *sec* must be an integer from 60 to max sec -1.
Default: 3761

Important: **default** *sec* must be < or = to max sec and > or = to min sec.

The following keywords are specific to the S-CSCF functionality:
max *sec*: Specifies the maximum amount of time that a subscription can exist on the system.
sec must be an integer from 60 to 2147483646.
Default: 86400

Important: **max** *sec* must be > or = to min sec.

min *sec*: Specifies the minimum amount of time that a subscription can exist on the system.
sec must be an integer from 60 to max sec -1.
Default: 60

Important: **min** *sec* must be < or = to max sec.

default

Returns the command to the default settings.

no

Disables the registration event package for the service.

Usage

Use this command to enable the registration event package for the service and control the amount of time subscriptions are allowed to exist on this service.
The system responds to subscriptions in the following manner:
Using default values:

- If a subscription with an expiration value lower than the service's minimum (60) is received, the service will respond with a 423 Interval Too Small message.
- If a subscription with an expiration value higher than the service's maximum (2147483646) is received, the service will automatically reduce the expiration value to the default value.

If a subscription is received missing the "Expires" value, or the value is malformed, the service will automatically respond with 3761 in the 200OK message.

Example

The following command configures the maximum subscription lifetime to *43200* (12 hours):

```
subscription package reg lifetime max 43200
```

support-content-type any

Validates Content-Type in this CSCF service.

Product

SCM

Privilege

Administrator

Syntax

```
[ no ] support-content-type any
```

no

Disables the feature. If disabled, CSCF service rejects unsupported Content-Type with “415 Unsupported Media Type”.

Usage

Use this command to either allow any type of Content-Type or reject unsupported Content-Type.

Example

Allows any type of Content-Type for the CSCF service:

```
support-content-type any
```

Rejects unsupported Content-Type for the CSCF service:

```
no support-content-type any
```

tcp-proxy

Enables SIP TCP proxy for the CSCF service.

Product

SCM

Privilege

Administrator

Syntax

tcp-proxy [port *port_number* **]**

no tcp-proxy

port *port_number*

Default: 5062
Specifies the port used for SIP TCP proxy connections.
port_number must be an integer from 1 to 65534.

no

Disables SIP TCP proxy for the CSCF service

Usage

Use this command to enable SIP TCP proxy for the CSCF service.

Example

Enables SIP TCP proxy for the CSCF service on port *5062*:

```
tcp-proxy port5062
```

Disables SIP TCP proxy for the CSCF service:

```
no tcp-proxy
```

threshold

Enables thresholds alerting and configuration of thresholds for CSCF Service.

Product

SCM

Privilege

Administrator

Syntax

```
threshold { { call-setup-failures | call-total-active | error-no-resource | error-
presence | error-reg-auth | error-tcp | invite-rcvd-rate | monitoring | reg-rcvd-rate |
reg-total-active | route-failures } high_thresh [ clear low_thresh ] | monitoring }

[ default | no ] threshold monitoring
```

{ call-setup-failures | call-total-active | error-no-resource | error-presence | error-reg-auth | error-tcp | invite-rcvd-rate | reg-rcvd-rate | reg-total-active | route-failures } *high_thresh* **clear** *low_thresh*

call-setup-failures: Number of CSCF call setup failures.
Default: 0
call-total-active: Number of total active CSCF calls.
Default: 0
error-no-resource: Number of CSCF call setup failures due to no-resource.
Default: 0
error-presence: Number of CSCF Presence errors.
Default: 0
error-reg-auth: Number of CSCF Registration Authentication failures.
Default: 0
error-tcp: Number of CSCF call setup failures due to TCP error.
Default: 0
invite-rcvd-rate: Number of CSCF calls per polling interval.
Default: 0
reg-rcvd-rate: Number of CSCF registrations per polling interval.
Default: 0
reg-total-active: Number of total CSCF active registrations.
Default: 0
route-failures: Maximum number of route-failures, after which the alarm/alert will be raised. Default: 5
high_thresh: The high threshold number that must be met or exceeded within the polling interval to generate an alert or alarm. Can be configured to any integer value between 0 and 2000000 (0 and 60000 for route-failures).
clear *low_thresh*: The low threshold number that must be met or exceeded within the polling interval to clear an alert or alarm. Can be configured to any integer value between 0 and 2000000 (0 and 60000 for route-failures).

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

monitoring

Enables thresholds alerting for CSCF Service.

default

Returns the command to the default settings.

no

Disables thresholds alerting for CSCF Service.

Usage

Use this command to:

- enable/disable thresholds alerting for CSCF Service
- set an alert or an alarm when a threshold exceeds the configured level

Alerts or alarms are triggered for the number of registration reply errors on the following rules:

- Enter condition: Actual number > High Threshold
- Clear condition: Actual number < Low Threshold

Example

The following command configures a route failures threshold of *1000* and a low threshold of *500* for a system using the Alarm thresholding model:

```
threshold route-failures 1000 clear 500
```

timeout

Sets timeout values for CSCF and SIP transactions.

Product

SCM

Privilege

Administrator

Syntax

```
timeout { hss-wait sec | map-slr-response sec | no-answer sec | policy-interface sec |
sip { 3gpp-d sec | 3gpp-t1 msec | 3gpp-t2 sec | 3gpp-t4 sec | c sec | d sec | idle-tcp-
connection msec  [ cleanup-timer msec ] | invite-expiry sec | t1 msec | t2 sec | t4 sec }
}

default timeout { hss-wait | map-slr-response | no-answer | policy-interface | sip {
3gpp-d | 3gpp-t1 | 3gpp-t2 | 3gpp-t4 | c | d | idle-tcp-connection | invite-expiry | t1 |
t2 | t4 } }
```

hss-wait *sec*

Default: 5
This timer is used by S-CSCF with HSS interface for timeout.
sec must be an integer from 0 to 2147483646.

map-slr-response *sec*

Default: 15
This timer is used by the E-CSCF for MAP SLR response timeout.
sec must be an integer from 15 to 30.

no-answer *sec*

Default: 100
This timer is specially used for No-Answer Call Feature executed by S-CSCF. The timer will be started as soon as 180 Ringing response is received and No-Answer call feature is enabled. The value of this timer should be always less than INVITE Timeout used by DC-SIP.
sec must be an integer from 0 to 2147483646.

policy-interface *sec*

Default: 5
This timer is used by the P-CSCF/A-BG with Policy interface for timeout.
sec must be an integer from 0 to 2147483646.

sip { 3gpp-d *sec* **| 3gpp-t1** *msec* **| 3gpp-t2** *sec* **| 3gpp-t4** *sec* **| c** *sec* **| d** *sec* **| idle-tcp-connection** *msec* **[cleanup-timer** *msec* **] | invite-expiry** *sec* **| t1** *msec* **| t2** *sec* **| t4** *sec* **}**

Sets transaction and expiry timers for SIP.

- **3gpp-d** *sec*: This timer is used to control the retransmission of 200OK messages to INVITEs after an ACK is sent. The ACK transaction is cleared after this period. This timer is applicable only for unreliable transport. *sec* must be an integer from 0 to 2147483646.

Default: 64*T1 (128 seconds, recommended minimum)

- **3gpp-t1** *msec*: This timer is used to control the time interval between each retransmission. The interval doubles after each retransmission. This is used by P-CSCF/A-BG only when it sending message toward the UE. Example: T1, 2T1, 4T2, etc. This timer is applicable only for unreliable transport. *msec* must be an integer from 0 to 4294967294.

  Default: 2000 ms (2 secs, recommended minimum).

- **3gpp-t2** *sec*: This timer is used to control the period for which the request continues to get retransmitted. This is used by P-CSCF/A-BG only when it sending message toward the UE. This timer is applicable both for reliable and unreliable transport. *sec* must be an integer from 0 to 2147483646.

  Default: 16 seconds (recommended minimum).

- **3gpp-t4** *sec*: This timer is used to control the period for which the final response to non-invite transaction should be buffered. The buffered response for the retransmitted non-invite request should be sent within that interval. This timer is applicable only for unreliable transport. *sec* must be an integer from 0 to 2147483646.

  Default: 17 seconds (recommended minimum).

- **c** *sec*: This timer is used for an INVITE transaction; if the response is a provisional response with status codes 101 to 199 inclusive (anything but 100), the proxy must reset timer C for that client transaction. The timer may be reset to a different value, but this value must be greater than 3 minutes (180 seconds). When timer C in S-CSCF fires first, S-CSCF will send CANCEL request to Terminating P-CSCF and Terminating P-CSCF will send CANCEL request to UAS . *sec* must be an integer from 180 to 2147483646.

  Default: 180 seconds

- **d** *sec*: This timer is used to control the retransmission of 200OK to INVITE after ACK is sent. The ACK transaction will be cleared after this interval. This timer is applicable only for unreliable transport. *sec* must be an integer from 0 to 2147483646.

  Default: 64*T1 (32 seconds, recommended minimum)

- **idle-tcp-connection** *msec*: This timer is used for closing idle TCP connections. If there is not activity in the TCP connection for the configuration duration, then the connection will be closed. *msec* must be an integer from 1000 (recommended minimum) to 4294967294.

  Default: 42000 milliseconds.

- **cleanup-timer** *msec*: This timer is used to control how often to check for idle TCP connections. *msec* must be an integer from 2000 to 2147483646.

  Default: 2000 milliseconds.

- **invite-expiry** *sec*: This timer is used by SIP while acting as UA Role and no final response is received for the INVITE request sent. This timer is applicable for both reliable and unreliable transport. *sec* must be an integer from 0 to 2147483646.

  Default: 100 seconds (recommended minimum).

- **t1** *msec*: Specifies the time interval (in microseconds) between each retransmission. The interval doubles after each retransmission, for example: T1, 2T1, 4T2, etc. This timer is applicable only for unreliable transport. *msec* must be an integer from 0 to 2147483646.

  Default: 500 milliseconds (recommended minimum).

- **t2** *sec*: This timer is used to control the period for which the request keeps getting retransmitted. This timer is applicable both for reliable and unreliable transport. *sec* must be an integer from 0 to 2147483646. The recommended minimum value for this parameter is 4 seconds.

  Default: 64*T1 (32 seconds)

- **t4** *sec*: This timer is used to control the period for which the final response to non-invite transaction should be buffered so as to send the buffered response for the retransmitted non-invite request within that interval. This timer is applicable only for unreliable transport. *sec* must be an integer from 0 to 2147483646.

  Default: 5 seconds (recommended minimum).

default

Returns the command to the default settings. See keywords above for specific defaults.

Usage

Use this command to configure SIP Stack timers and CSCF service specific timers.

Example

The following command sets the SIP d timer to *64* seconds:

```
timeout sip d 64
```

transport-switching

Sets the message size that triggers a transport protocol switch.

Product

SCM

Privilege

Administrator

Syntax

transport-switching policy protocol tcp trigger msg-size *size*

default transport-switching policy protocol tcp trigger msg-size

policy protocol tcp trigger msg-size *size*

Default: 1300
Specifies the size of the SIP message beyond which transport changes to TCP.
size can be configured to any integer value between 1300 and 65535.

default

Returns the size of the SIP message beyond which transport changes to TCP to 1300 bytes.

Usage

Use this command to configure the size of the SIP message beyond which transport changes to TCP.

Example

Switch to TCP transport protocol when the SIP message size is *4000* bytes or more:

```
transport-switching policy protocol tcp trigger msg-size 4000
```

trusted-domain-entity

Adds trusted network nodes (or entities) to a table used by this service to identify those nodes that can be trusted with subscriber information.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

trusted-domain-entity *address* **[foreign-network] [private-network]**

no trusted-domain-entity *address*

trusted-domain-entity *address*

Specifies the IP address of the network node identified as a trusted entity by this service. *address* must be either an IP address or a domain name. IP addresses must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6. Domain names must be entered using from 1 to 80 alpha and/or numeric characters.

foreign-network

Entity belongs to Foreign Network.

private-network

Entity belongs to Private Network.

no

Removes an entry from this service's trusted domain table.

Usage

Use this command to identify to the service the network entities that can be trusted with subscriber information by this service.

Important: This command can be entered multiple times to identify multiple trusted network entities.

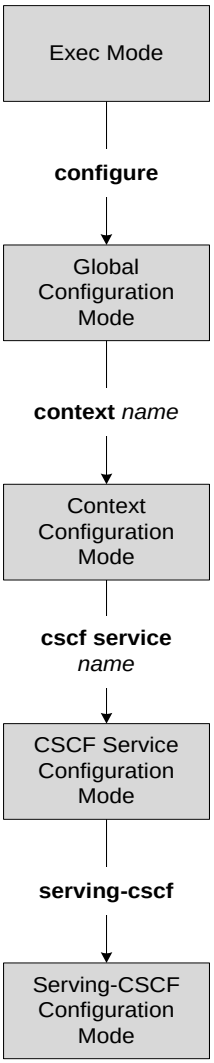
Example

The following command adds a network node with an IP address of *1.2.3.4* to this service's trusted domain table:

```
trusted-domain-entity 1.2.3.4
```

Chapter 89
CSCF Serving-CSCF Configuration Mode Commands

The Serving-CSCF Configuration Mode is used to set various commands supporting the role of the CSCF service as a Serving CSCF.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

3gpp

Enables/disables functionality related to 3GPP Release 8 support. This command is disabled by default.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

3gpp Rel8 Cx { alias-indication | dynamic-password-change | ims-restoration | num-auth-vectors *value* **}**

[default | no] 3gpp Rel8 Cx { alias-indication | dynamic-password-change | ims-restoration | num-auth-vectors }

Rel8 Cx

Specifies functionality related to 3GPP Release 8 support.

alias-indication

Enables alias indication functionality, a collaborative information exchange between the S-CSCF and HSS. Use this command to display alias information from the HSS.
If both the HSS and the S-CSCF support this feature, Alias Group IDs will be displayed in the output of the **show subscribers cscf-only full** command.

dynamic-password-change

Enables dynamic password change support on the S-CSCF service, as per 3GPP 33.203 release 8 version 8.8.0.

ims-restoration

Enables IMS restoration procedures on the S-CSCF service. Use this command to enable IMS REGISTER and INVITE restoration procedures defined in 3GPP TS 23.820.

num-auth-vectors *value*

Enables configurable value for SIP-Number-Auth-Items in MAR.
value must be an integer from 1 to 3. Default is 1.
SCSCF can retrieve multiple authentication vectors from HSS by setting SIP-Number-Auth-Items to an appropriate value. Previously, S-CSCF always set this value to “1”. Using higher values helps to reduce MAR-MAA transactions.

default | no

Disables specified 3GPP Release 8 support feature.

Usage

Use this command to configure the S-CSCF to support 3GPP Release 8 functionality.

Example

The following command enables 3GPP Release 8 alias indication functionality on this service:

```
3gpp Rel8 Cx alias-indication
```

The following command disables 3GPP Release 8 dynamic password change support on this service:

```
no 3gpp Rel8 Cx dynamic-password-change
```

allow rfc3261-ua-interworking

Enables the function to allow IMS interworking with RFC3261 SIP User Agents.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ no ] allow rfc3261-ua-interworking
```

no

Disables the interworking capability.

Usage

Use this command to enable the S-CSCF to allow IMS interworking with RFC3261 SIP User Agents.

as-call invite-request-uri update

Enabling this command causes request-URIs in INVITE messages to be updated with the result of the translation before being passed to an Application Server (AS). This command is disabled by default.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] as-call invite-request-uri update
```

default | no

The translation result is ignored.

Usage

Use this command to update the request-URI in INVITE messages with the result of the translation before passing it to an AS.

authentication

Configures the authentication method used by the S-CSCF service.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
authentication { aka-v1 value | allow-auth-rsp-failure re-register | allow-hss-failure
re-register | allow-noauth [ invite | re-register| register ] | allow-noipauth [ invite |
re-register| register ] | allow-skip-sar re-register | allow-unsecure | aor-auth |
custom-md5 value | md5 value }

no authentication { aka-v1 | allow-auth-rsp-failure re-register | allow-hss-failure re-
register | allow-noauth [ invite | re-register| register ] | allow-noipauth [ invite |
re-register| register ] | allow-skip-sar re-register | allow-unsecure | aor-auth |
custom-md5 | md5 }
```

aka-v1 *value*

Specifies that AKA-v1 algorithm is used as the authentication type when accessing the CSCF service. *value* specifies a preference - the lower the value, the higher the preference. *value* must be an integer from 1 to 1000.

Important: In order to change a priority level, you must remove the original value and configure a new one.

allow-auth-rsp-failure re-register

Specifies that S-CSCF will not validate authorization received from UE for challenge re-register. If enabled, S-CSCF will send SAR without validating authentication; after receiving SAA, it will send 200 OK for register.

allow-hss-failure re-register

Specifies that S-CSCF should send 200 OK for re-register in case of HSS failure.
When S-CSCF receives register, it sends MAR/SAR to HSS to authenticate the user when authentication is enabled and to get the subscriber profile. When S-CSCF fails to receive response MAA/SAA from HSS, it sends 500 error response to UE. When **allow-hss-failure** is enabled, S-CSCF sends 200 OK for register instead of 500 response.

allow-noauth [invite | re-register| register]

Specifies that access to the S-CSCF service is allowed if authentication fails.
invite: Specifies that access to the S-CSCF service is allowed if authentication fails on INVITE requests only.
re-register: Specifies that access to the S-CSCF service is allowed if authentication fails on RE-REGISTER requests when the request is integrity-protected only.

registration: Specifies that access to the S-CSCF service is allowed if authentication fails on REGISTER requests only.

---

allow-noipauth [invite | re-register| register]

Specifies that access to the S-CSCF service is allowed if early IMS-based IP authentication fails.
invite: Specifies that access to the S-CSCF service is allowed if early IMS-based IP authentication fails on INVITE requests only.
re-register: Specifies that access to the S-CSCF service is allowed if authentication fails on RE-REGISTER requests when the request is integrity-protected only.
registration: Specifies that access to the S-CSCF service is allowed if early IMS-based IP authentication fails on REGISTER requests only.

---

allow-skip-sar re-register

Specifies that S-CSCF should skip SAR to HSS for re-register.
When S-CSCF receives re-register/challenge for re-register, it sends SAR to HSS to get subscriber profile. To avoid overloading HSS, enabling **allow-skip-sar** allows S-CSCF to skip SAR for re-register.

---

allow-unsecure

Specifies that un-secure access is allowed to the S-CSCF service.

---

aor-auth

Specifies that authentication is based on the AoR when accessing the S-CSCF service.

---

custom-md5 *value*

Specifies that custom algorithm HTTP-Digest-MD5 is used as the authentication type for accessing the S-CSCF service. *value* specifies a preference - the lower the value, the higher the preference. *value* must be an integer from 1 to 1000.

Important: In order to change a priority level, you must remove the original value and configure a new one.

---

md5 *value*

Specifies that the MD5 algorithm is used as the authentication type for accessing the S-CSCF service. *value* specifies a preference - the lower the value, the higher the preference. *value* must be an integer from 1 to 1000.

Important: In order to change a priority level, you must remove the original value and configure a new one.

---

no authentication { aka-v1 | allow-auth-rsp-failure re-register | allow-hss-failure re-register | allow-noauth [invite | re-register| register] | allow-noipauth [invite | re-register| register] | allow-skip-sar re-register | allow-unsecure | aor-auth | custom-md5 | md5 }

Disables the specified authentication method for the S-CSCF service.

Usage

Use this command to configure the authentication method used by the S-CSCF service.

Important: The S-CSCF supports multiple authorization schemes, but this requires disabling all authorization configured in the S-CSCF service so that it will send "Unknown" in the Sip-Authorization-Scheme AVP. This allows the HSS to dictate authorization. The following commands disable all authorization configured in the S-CSCF service to allow HSS to control authorization:

```
authentication allow-noipauth

allow rfc3261-ua-interworking

no authentication aka-v1

no authentication md5
```

Example

The following command configures the authentication method used by the S-CSCF service to MD5 with a preference of *3*:

```
authentication md5 3
```

bgcf-proxy

Enables SIP BGCF proxy for the service.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
bgcf-proxy [ port value | transport { tcp | udp } port value ] ]

[ default | no ] bgcf-proxy
```

port *value*

Configures port value for SIP BGCF proxy.
value must be an integer from 1 to 65534.

transport

Enables the specific transport protocol for BGCF proxy.

- **tcp**: Enables TCP transport protocol for BGCF proxy.
- **udp**: Enables UDP transport protocol for BGCF proxy.

default | no

Disables SIP BGCF proxy for the service.

Usage

Use this command to enable or disable SIP BGCF proxy for the service.

Example

The following command enables a SIP BGCF proxy on port *561* for this service:

```
bgcf-proxy port 561
```

The following command disables SIP BGCF proxy for this service:

```
no bgcf-proxy
```

diversion-info

Enabling this command prompts the service to add a diversion header (draft-levy-sip-diversion-08) when the call is diverted to a different endpoint due to a call feature. By default, diversion-info is disabled.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] diversion-info
```

default | no

The service will not add a diversion header.

Usage

Use this command to enable the service to add a diversion header to call setup packets when calls are diverted due to the application of call features.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

```
exit
```

Usage

Return to the previous mode.

forking

Controls the default-request forking-type in S-CSCF.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
forking { parallel | serial }

[ default | no ] forking
```

parallel | serial

Defines the fork type for request forking.

- **parallel**: Perform parallel forking of request.
- **serial**: Perform serial forking of request.

default

Perform parallel forking of request.

no

Do not perform any forking of request.

Usage

Use this command to control the default-request forking-type in S-CSCF. This configuration will be effective in the absence of "Request-Disposition" header in the message.

Example

The following command enables serial forking of request:

```
forking serial
```

The following command disables any forking of request:

```
no forking
```

interrogating-cscf-role

Enables the function to also perform as an Interrogating-CSCF.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ no ] interrogating-cscf-role
```

no

Disables the Interrogating-CSCF role in this function.

Usage

Use this command to enable the S-CSCF to also perform as an Interrogating-CSCF.

local-call-features

Enables/disables local call features. This command is disabled by default.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ default | no ] local-call-features
```

default | no

Disables local call features for this S-CSCF.

Usage

Use this command to enable local call features.

network-id

Configures the Network Identifier.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

network-id *id*

no network-id

id

The Network Identifier of the entity.
id must be from 1 to 79 alpha and/or numeric characters in length.

no

Removes the configured Network Identifier of the entity.

Usage

The Network Identifier is used to compare with the P-Visited-Network-ID header received from P-CSCF to decide home or roaming subscriber at S-CSCF service.

Example

Sets the Network Identifier to *pcscf01.company.com:*

```
network-id pcscf01.company.com
```

npdb-client

Creates an NPDB (Number Portability Data Base) client under CSCF and enters the CSCF NPDB Client Configuration Mode.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

npdb-client *client_name* **[-noconfirm]**

no npdb-client

client_name

Specifies the name of the NPDB client.
client_name must be from 1 to 79 alpha and/or numeric characters.

-noconfirm

Indicates that the command is to execute without any additional prompt and confirmation from the user.

no

Deletes NPDB client under CSCF.

Usage

Use this command to enable the NPDB client feature and enter the NPDB Client Configuration Mode. Entering this command results in the following prompt:

```
[context_name]hostname(config-npdb-client)#
```

NPDB Client Configuration Mode commands are defined in the *CSCF NPDB Client Configuration Mode Commands* chapter in this guide.

Example

The following command creates an NPDB client named *npdb1* and enters NPDB Client Configuration Mode:

```
npdb-client npdb1
```

policy

Configures the policy for Served User Routing in this S-CSCF service.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ default | no ] policy allow p-served-user-routing
```

default | no

Disables Served User Routing functionality for this S-CSCF.

allow p-served-user-routing

Enables Served User Routing functionality for this S-CSCF.

Usage

Use this command to enable/disable the policy for Served User Routing.

Example

The following command enables Served User Routing on this service:

```
policy allow p-served-user-routing
```

The following command disables Served User Routing on this service:

```
no policy allow p-served-user-routing
```

registration lifetime

Configures a registration lifetime for all subscribers to the service.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

registration lifetime { default *sec* **| implicit** *sec* **| max** *sec* **| min** *sec* **}**

default registration lifetime

{ default *sec* **| implicit** *sec* **| max** *sec* **| min** *sec* **}**

default *sec*: Specifies the default amount of time that a registration can exist on the system.
sec must be an integer from 60 to **max** *sec* -1.
Default: 3600

Important: **default** *sec* must be < or = to max *sec* and > or = to min *sec*.

implicit *sec*: Specifies the implicit amount of time that a registration can exist on the system. *sec* must be an integer from 60 to 1209600.
Default: 0
max *sec*: Specifies the maximum amount of time that a registration can exist on the system.
sec must be an integer from 60 to 1209600.
Default: 86400

Important: **max** *sec* must be > or = to min *sec*.

min *sec*: Specifies the minimum amount of time that a registration can exist on the system.
sec must be an integer from 60 to **max** *sec* -1.
Default: 60

Important: **min** *sec* must be < or = to max *sec*.

default

Returns the command to the default settings.

Usage

Use this command to control the amount of time registrations are allowed to exist on this service.
The system responds to registrations in the following manner:
If implicit-timer is configured (>0), and if UE expires time < min expires time, respond with 200 OK with Expires-header set to configured implicit-expires time.
If implicit timer is not configured (=0), the service will respond with a 423 Interval Too Small message.

Using default values:

- If a registration with an expiration value lower than the service's minimum (60) is received, the service will respond with a 423 Interval Too Small message.
- If a registration with an expiration value higher than the service's maximum (2147483646) is received, the service will automatically reduce the expiration value to the default value.
- If a registration is received missing the "Expires" value, or the value is malformed, the service will automatically respond with 3761 in the 200 OK message.

Example

The following command configures the maximum registration lifetime to *43200* (12 hours):

```
registration lifetime max 43200
```

reliable-prov-resp

Enables/disables the reliability of provisional responses feature.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
reliable-prov-resp { mandatory | optional }

no reliable-prov-resp
```

mandatory | optional

mandatory: Both inbound and outbound will request reliability.
optional (default): Reliability is imposed by inbound side. Only if inbound call requests reliability will outbound also request reliability.

no

Disables the reliability of provisional responses feature.

Usage

Use this command to enable/disable the reliability of provisional responses feature.

Example

The following command sets the reliability of provisional responses feature to mandatory:

```
reliable-prov-resp mandatory
```

server-name

Enables/disables filling the server name AVP in MAR and SAR for Cx interface with configured server name. This command is disabled by default.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

server-name *server_name*

no server-name

server_name

Configures the name that will be used to fill the server name AVP in MAR and SAR for Cx interface. *name* must be from 1 to 63 alpha and/or numeric characters.

no

S-CSCF uses configured cscf-hostname or bind IP address to fill the server name AVP in MAR and SAR for Cx interface. This is the default CSCF behavior.

Usage

Use this command to enable/disable filling the server name AVP in MAR and SAR for Cx interface with configured server name.

Example

The following command configures the CSCF server name as *stp-c-scscf1.cisco.co.kr*:

```
server-name stp-c-scscf1.cisco.co.kr
```

sifc

Enables Shared Initial Filter Criteria (SiFC) functionality. This command is disabled by default.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] sifc
```

default | no

Disables shared iFC functionality for this S-CSCF.

Usage

Use this command to configure the S-CSCF to share iFC functionality.

Important: 48 SiFC IDs are supported per subscriber.

If both the HSS and the S-CSCF support this feature, subsets of iFC may be shared by several service profiles. The HSS downloads the unique identifiers of the shared iFC sets to the S-CSCF. The S-CSCF uses a locally administered database to map the downloaded identifiers onto the shared iFC sets.
If the S-CSCF does not support this feature, the HSS will not download identifiers of shared iFC sets.

Important: When using this feature option, the network operator is responsible for keeping the local databases in the S-CSCFs and HSSs consistent.

sip-header insert

Enable SIP header insertion for the S-CSCF service. SIP header insertion is disabled by default.

Product

SCM (S-CSCF)

Privilege

Administrator

Syntax

```
[ no ] sip-header insert { p-cust1-prid-info | p-user-database }
```

no

Disables specific SIP header insertion for the S-CSCF service.

p-cust1-prid-info

Inserts a custom header, P-LGUPlus-PRID-Info, which contains the private user id of the user sending the REGISTER request, to be added in the REGISTER message toward AS during third party registration.

p-user-database

Inserts PUD header in SIP (REGISTER) message and Invite from I-CSCF to S-CSCF.

Usage

Enabling this command allows header insertion in SIP (REGISTER) message.

Example

The following command disables insertion of custom header, P-LGUPlus-PRID-Info, in SIP (REGISTER) message:

```
no sip-header insert p-cust1-prid-info 5
```

The following command enables insertion of PUD header in SIP (REGISTER) message and Invite from I-CSCF to S-CSCF:

```
sip-header insert p-user-database 5
```

sip-request

Configures SIP Request-related configuration in this S-CSCF service.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
sip-request re-route { max-attempts attempts | response-code code }

default sip-request re-route max-attempts

no sip-request re-route response-code code
```

re-route

Specify SIP Request re-route related configuration.

max-attempts *attempts*

Specifies the maximum number of re-route attempts that a S-CSCF should allow for a given call before passing the negative response upstream.
attempts must be an integer from 1 to 10.
Default: 2

response-code *code*

Specifies the list of Response codes that will be considered as re-routable responses to a call attempt.
code must be a three-digit integer from 400 to 699.

Important: You may configure a maximum of five response code values per S-CSCF service.

default

Specifies a maximum number of two re-route attempts that a S-CSCF should allow for a given call before passing the negative response upstream.

no

Disables the specified Response code.

Usage

Use this command to configure:

- list of Response codes that will be considered as re-routable responses to a call attempt.
- the maximum number of re-route attempts that a S-CSCF should allow for a given call before passing the negative response upstream.

Example

The following command configures the maximum number of re-route attempts to *5*:

```
sip-request re-route max-attempts 5
```

tas

Configures the S-CSCF to perform Telephony Application Server (TAS) functions.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] tas
```

default | no

Disables the TAS feature for this S-CSCF.

Usage

Use this command to configure the S-CSCF to perform TAS functions.

tas-service

Identifies the name of the service configured on the system performing Telephony Application Server (TAS) functions.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

tas-service *name*

no tas-service

name

Specifies the name of the service configured on the system performing TAS functions.
name must be from 1 to 63 alpha and/or numeric characters and be an existing service.

no

Removes the TAS name from the S-CSCF configuration.

Usage

Use this command to identify the name of the service configured on the system performing TAS functions

Example

The following command identifies the TAS service name as *scscf3*:

```
tas-service scscf3
```

user-authorization

Enables sending user-authorization to HSS. User-authorization is disabled by default.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] user-authorization
```

default | no

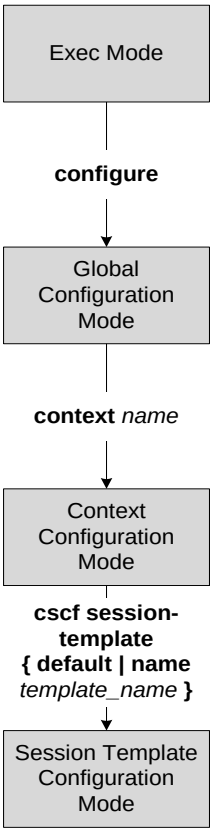
Disables sending user-authorization to HSS.

Usage

If this command is enabled, and I-CSCF role is enabled in S-CSCF, I-CSCF will send UAR/UAA diameter message to HSS.

Chapter 90
CSCF Session Template Configuration Mode Commands

The CSCF Session Template Configuration Mode is used to classify users and/or domains (AoRs) within the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

inbound-cscf-acl

Configures the ACL to use for inbound sessions using this template.

Product

SCM

Privilege

Administrator

Syntax

inbound-cscf-acl { default | name *acl_name* **}**

no inbound-cscf-acl name *acl_name*

default | name *acl_name*

default: Specifies that the default ACL should be used for inbound sessions using this template.
name *acl_name*: Specifies an existing ACL to use for inbound sessions using this template. *acl_name* must be the name of an existing ACL.

no inbound-cscf-acl name *acl_name*

Removes the ACL from this template.

Usage

Use this command to identify an ACL to use on inbound sessions using this template.

Example

The following command sets the inbound ACL for this template to an ACL named *acl_in22*:

```
inbound-cscf-acl name acl_in22
```

outbound-cscf-acl

Configures the ACL to use for outbound sessions using this template.

Product

SCM

Privilege

Administrator

Syntax

outbound-cscf-acl { default | name *acl_name* **}**

no outbound-cscf-acl name *acl_name*

default | name *acl_name*

default: Specifies that the default ACL should be used for outbound sessions using this template.
name *acl_name*: Specifies an existing ACL to use for outbound sessions using this template. *acl_name* must be the name of an existing ACL.

no outbound-cscf-acl name *acl_name*

Removes the ACL from this template.

Usage

Use this command to identify an ACL to use on outbound sessions using this template.

Example

The following command sets the outbound ACL for this template to an ACL named *acl_out22*:

```
outbound-cscf-acl name acl_out22
```

policy-profile

Configures an AoR policy group to be used for sessions using this template.

Product

SCM

Privilege

Administrator

Syntax

policy-profile { default | name *profile_name* **}**

no policy-profile name *profile_name*

default | name *profile_name*

default: Specifies that the default policy group will be used for sessions using this template.
name *profile_name*: Specifies an existing policy group. *profile_name* must be an existing CSCF policy group.

no policy-profile name *profile_name*

Removes the policy group from the template.

Usage

Use this command to specify a policy group for the template.

Example

The following command specifies that a policy group called *aor_grp1* will be used for sessions using this template:

```
policy-profile name aor_grp1
```

route-list

Configures a route group to be used for sessions using this template.

Product

SCM

Privilege

Administrator

Syntax

route-list { default | name *group_name* **}**

no route-list name *group_name*

default | name *group_name*

default: Specifies that the default route group will be used for sessions using this template.
name *group_name*: Specifies an existing route group. *group_name* must be an existing peer server group.

no route-list name *group_name*

Removes the route group from this template.

Usage

Use this command to specify a route group for the template.

Example

The following command specifies an accounting server group called *route_grp2* that will be used for sessions using this template:

```
route-list name route_grp2
```

translation-list

Configures a translation list to be used for sessions using this template.

Product

SCM

Privilege

Administrator

Syntax

translation-list { default | name *list_name* **}**

no translation-list name *list_name*

default | name *list_name*

default: Specifies that the default translation list will be used for sessions using this template.
name *list_name*: Specifies an existing translation list. *list_name* must be an existing translation list.

no translation-list name *list_name*

Removes the translation list from this template.

Usage

Use this command to specify a translation list for the template.

Example

The following command specifies a translation list called *trans_list6*:

```
translation-list name trans_list6
```

urn-service-list

Configures an URN service list to be used for sessions using this template.

Product

SCM

Privilege

Administrator

Syntax

urn-service-list { default | name *list_name* **}**

no urn-service-list name *list_name*

default | name *list_name*

default: Specifies that the default URN service list will be used for sessions using this template.
name *list_name*: Specifies an existing URN service list name. *list_name* must be from 1 to 79 alpha and/or numeric characters and be an existing URN service list.

no urn-service-list name *list_name*

Removes the service list from this template.

Usage

Use this command to specify a URN service list for this template. URN service lists are configured in the URN Service List Configuration Mode.

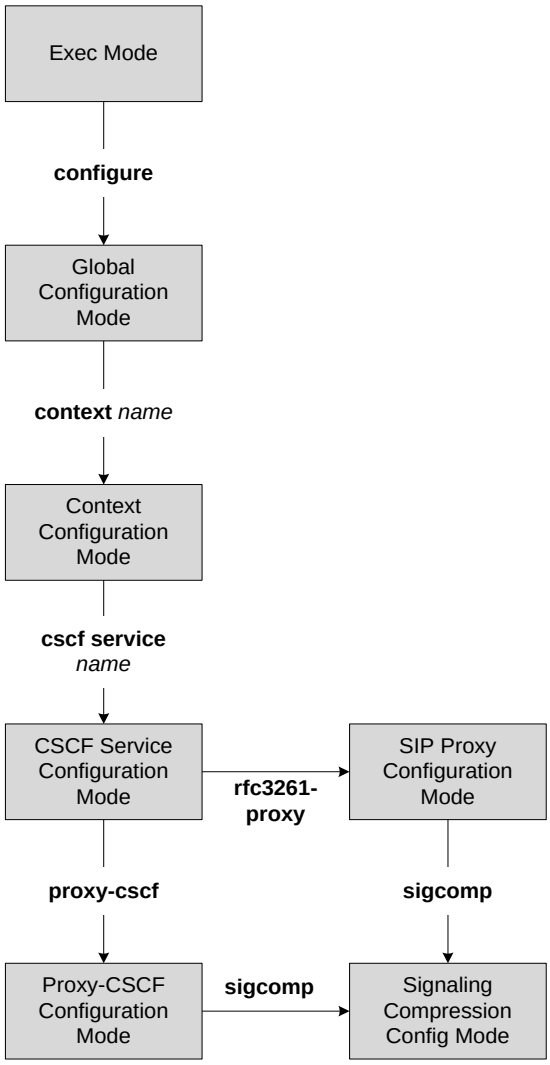
Example

The following command specifies that a URN service list named *urn_list5* will be used for sessions using this template:

```
urn-service-list name urn_list5
```

Chapter 91
CSCF Signalling Compression Configuration Mode Commands

The CSCF Signalling Compression Configuration Mode is used to set memory allocation parameters in support of SIP signalling compression. More information regarding signalling compression refer to the IETF RFC 3320 “Signaling Compression (SigComp)”.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

compression-mode

Configures the dynamic compression mode to be used while sending a SigComp message. Simple dynamic mode is the default.

Product

SCM

Privilege

Administrator

Syntax

```
compression-mode { multiple-dynamic | simple-dynamic | static | update-dynamic }

default compression-mode
```

multiple-dynamic | simple-dynamic | static | update-dynamic

Default: **simple-dynamic**
multiple-dynamic: A maximum of four dynamic states will be created per compartment. The dynamic states are updated for each message by deleting the oldest dynamic state and creating the new one. The dynamic states will be updated in FIFO (First In, First Out) order.
simple-dynamic: Only one dynamic state will be created per compartment. The same state will be used for compression.
static: No dynamic states will be created. Only static dictionary will be used for compression.
update-dynamic: Only one dynamic state will be created per compartment, but the dynamic state will be updated for every new message.

default compression-mode

Returns the dynamic compression mode to simple dynamic.

Usage

Use this command to configure the dynamic compression mode to be used.

Example

The following command sets the compression mode to multiple dynamic:

```
compression-mode multiple-dynamic
```

The following command completely disables the creation of dynamic states for compression:

```
compression-mode static
```

decompression-memory-size

Sets the amount of memory available for decompressing one SigComp message. A portion of the allocated memory is used to buffer the message before it is decompressed. The memory is allocated for each SigComp message and is reclaimed once decompression is completed.

Product

SCM

Privilege

Administrator

Syntax

```
decompression-memory-size { 128k | 16k | 32k | 64k | 8k }

default decompression-memory-size
```

128k | 16k | 32k | 64k | 8k

Default: **8k**
Specifies the amount of memory (in kilobytes) to allocate for decompressing one SigComp message.

default

Returns the command to the default settings.

Usage

Use this command to set the memory size used to decompress a single SigComp message.

Example

The following command sets the memory size for decompressing SigComp messages to 16k:

```
decompression-memory-size 16k
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

state-memory-size

Sets the memory allocated to a compartment for the creation of state. Compartments are application-specific groupings of messages that relate to a peer endpoint. The system allocates memory per compartment. The memory is reclaimed when the system determines that the compartment is no longer required.

Product

SCM

Privilege

Administrator

Syntax

```
state-memory-size { 4k | 8k }

default state-memory-size
```

4k | 8k

Default: **4k**
Specifies the amount of memory to allocate to a compartment for the creation of state.

default

Returns the command to the default settings.

Usage

Use this command to specify a memory size allocated to message groupings for the creation of state.

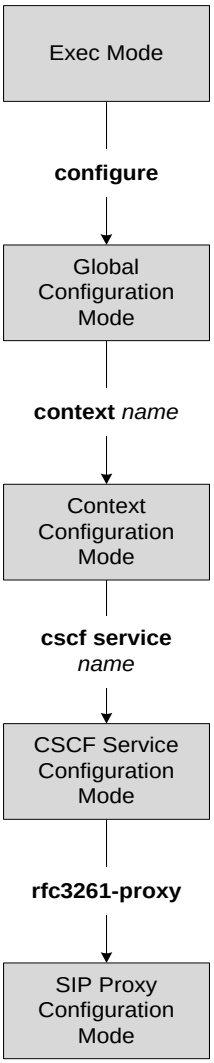
Example

The following command sets the state memory size to **8k**:

```
state-memory-size 8k
```

Chapter 92
CSCF SIP Proxy Configuration Mode Commands

The SIP Proxy Configuration Mode is used to set various commands supporting the role of the CSCF service as a RFC3261-compliant SIP proxy server.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

as-call

Enabling this command causes request-URIs in INVITE messages to be updated with the result of the translation before being passed to an Application Server. This command is disabled by default.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] as-call invite-request-uri update
```

default | no

The translation result is ignored.

Usage

Use this command to update the request-URI in INVITE messages with the result of the translation before passing it to an AS.

authentication

Configures the authentication method used by the CSCF service.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

authentication { aka-v1 *value* **| allow-noauth [invite | re-register| register] | allow-noipauth [invite | re-register| register] | allow-unsecure | aor-auth | md5** *value* **}**

no authentication { aka-v1 | allow-noauth [invite | re-register| register] | allow-noipauth [invite | re-register| register] | allow-unsecure | aor-auth | md5 }

aka-v1 *value*

Specifies that AKA-v1 algorithm is used as the authentication type when accessing the CSCF service. *value* specifies a preference - the lower the value, the higher the preference. *value* must be an integer from 1 to 1000.

Important: In order to change a priority level, you must remove the original value and configure a new one.

allow-noauth [invite | re-register| register]

Specifies that access to the CSCF service is allowed if authentication fails.
invite: Specifies that access to the CSCF service is allowed if authentication fails on INVITE requests only.
re-register: Specifies that access to the CSCF service is allowed if authentication fails on RE-REGISTER requests when the request is integrity-protected only.
registration: Specifies that access to the CSCF service is allowed if authentication fails on REGISTER requests only.

allow-noipauth [invite | re-register| register]

Specifies that access to the CSCF service is allowed if early IMS-based IP authentication fails.
invite: Specifies that access to the CSCF service is allowed if early IMS-based IP authentication fails on INVITE requests only.
re-register: Specifies that access to the CSCF service is allowed if authentication fails on RE-REGISTER requests when the request is integrity-protected only.
registration: Specifies that access to the CSCF service is allowed if early IMS-based IP authentication fails on REGISTER requests only.

allow-unsecure

Specifies that un-secure access is allowed to the CSCF service.

aor-auth

Specifies that authentication is based on the AoR when accessing the CSCF service.

md5 *value*

Specifies that the MD5 algorithm is used as the authentication type for accessing the CSCF service. *value* specifies a preference - the lower the value, the higher the preference. *value* must be an integer from 1 to 1000.

Important: In order to change a priority level, you must remove the original value and configure a new one.

no authentication { aka-v1 | allow-noauth [invite | re-register| register] | allow-noipauth [invite | re-register| register] | allow-unsecure | aor-auth | md5 }

Disables the specified authentication method for the CSCF service.

Usage

Use this command to configure the authentication method used by the CSCF service.

Important: The S-CSCF supports multiple authorization schemes, but this requires disabling all authorization configured in the S-CSCF service so that it will send "Unknown" in the Sip-Authorization-Scheme AVP. This allows the HSS to dictate authorization. The following commands disable all authorization configured in the S-CSCF service to allow HSS to control authorization:

```
authentication allow-noipauth

allow rfc3261-ua-interworking

no authentication aka-v1

no authentication md5
```

Example

The following command configures the authentication method used by the CSCF service to MD5 with a preference of *3*:

```
authentication md5 3
```

diversion-info

Enabling this command prompts the service to add a diversion header (draft-levy-sip-diversion-08) when the call is diverted to a different endpoint due to a call feature. By default diversion-info is disabled.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] diversion-info
```

default | no

The service will not add a diversion header.

Usage

Use this command to enable the service to add a diversion header to call setup packets when calls are diverted due to the application of call features.

emergency

Configures the function to allow or disallow the emergency-session or emergency-registration of a particular type.

Product

SCM (P-CSCF, A-BG, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] emergency { registration [ visited-ue ] | session [ 3gpp-ims-xml-body |
anonymous | non-emergency-registered | sdp-cs-media | visited-ue ] }
```

default

Specifies that the emergency-session or emergency-registration of a particular type can be allowed.

no

Disallows the emergency-session or emergency-registration of a particular type.

registration

Allow emergency-registration. By default, it's allowed.
visited-ue: Allow emergency-registration from a visited UE. By default, it's allowed.

session

Specifies the type of emergency-session to be allowed or disallowed. By default, all are allowed.
3gpp-ims-xml-body: Allow 3GPP IM CN XML body to be added in 380 response messages.
anonymous: Allow anonymous subscribers (unregistered UEs) to initiate emergency sessions.
non-emergency-registered: Allow non-emergency registered subscribers to initiate emergency sessions.
sdp-cs-media: Allow emergency calls with SDP CS Media.
visited-ue: Allow emergency calls from visited UE.

Usage

Use this command to configure the function to allow or disallow the emergency-session or emergency-registration of a particular type.

Example

The following command configures the function to allow non-emergency registered subscribers to initiate emergency sessions:

```
emergency session non-emergency-registered
```

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

```
end
```

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

```
exit
```

Usage

Return to the previous mode.

registration

Configures a registration lifetime for all subscribers to the service.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

registration lifetime { default *sec* **| max** *sec* **| min** *sec* **}**

default registration lifetime

{ default *sec* **| max** *sec* **| min** *sec* **}**

default *sec*: Specifies the default amount of time that a registration can exist on the system. *sec* must be an integer from 60 to **max** *sec* -1. Default is 3600. default *sec* must be < or = to max *sec* and > or = to min *sec*.
max *sec*: Specifies the maximum amount of time that a registration can exist on the system. *sec* must be an integer from 60 to 1209600. Default is 86400. max *sec* must be > or = to min *sec*.
min *sec*: Specifies the minimum amount of time that a registration can exist on the system. *sec* must be an integer from 60 to **max** *sec* -1. Default is 60. min *sec* must be < or = to max *sec*.

---

default registration lifetime

Returns the command to the default settings.

Usage

Use this command to control the amount of time registrations are allowed to exist on this service.
The system responds to registrations in the following manner:
Using default values:

- If a registration with an expiration value lower than the service's minimum (60) is received, the service will respond with a 423 Interval Too Small message.
- If a registration with an expiration value higher than the service's maximum (2147483646) is received, the service will automatically reduce the expiration value to the default value.
- If a registration is received missing the "Expires" value, or the value is malformed, the service will automatically respond with 3761 in the 200OK message.

Example

The following command configures the maximum registration lifetime to *43200* (12 hours):

```
registration lifetime max 43200
```

reliable-prov-resp

Enables/disables the reliability of provisional responses feature.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
reliable-prov-resp { mandatory | optional }

no reliable-prov-resp
```

mandatory | optional

mandatory: Both inbound and outbound will request reliability.
optional (default): Reliability is imposed by inbound side. Only if inbound call requests reliability will outbound also request reliability.

no

Disables the reliability of provisional responses feature.

Usage

Use this command to enable/disable the reliability of provisional responses feature.

Example

The following command sets the reliability of provisional responses feature to mandatory:

```
reliable-prov-resp mandatory
```

The following command disables the reliability of provisional responses feature:

```
no reliable-prov-resp
```

sifc

Enables Shared Initial Filter Criteria (SiFC) functionality. This command is disabled by default.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] sifc
```

default | no

Disables shared iFC functionality for this SIP Proxy.

Usage

Use this command to configure the SIP Proxy to share iFC functionality.
If both the HSS and the SIP Proxy support this feature, subsets of iFC may be shared by several service profiles. The HSS downloads the unique identifiers of the shared iFC sets to the SIP Proxy. The SIP Proxy uses a locally administered database to map the downloaded identifiers onto the shared iFC sets.
If the SIP Proxy does not support this feature, the HSS will not download identifiers of shared iFC sets.

Important: When using this feature option, the network operator is responsible for keeping the local databases in the S-CSCFs and HSSs consistent.

sigcomp

Enables signaling compression for the SIP Proxy service and enters the Signaling Compression Configuration Mode.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ no ] sigcomp
```

no

Disables signaling compression for the CSCF service.

Usage

Use this command to enable signaling compression for the SIP Proxy service and enter the CSCF Signaling Compression Configuration Mode.
Entering this command results in the following prompt:

```
[context_name]hostname(config-sigcomp)#
```

Signaling Compression Configuration Mode commands are defined in the *CSCF Signaling Compression Configuration Mode Commands* chapter in this guide.

tas

Configures the SIP Proxy to perform Telephony Application Server (TAS) functions.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

```
[ default | no ] tas
```

default | no

Disables the TAS feature for this SIP Proxy.

Usage

Use this command to configure the SIP Proxy to perform TAS functions.

tas-service

Identifies the name of the service configured on the system performing Telephony Application Server (TAS) functions.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Administrator

Syntax

tas-service *name*

[default | no] tas-service

name

Specifies the name of the service configured on the system performing TAS functions. *name* must be from 1 to 63 alpha and/or numeric characters and be an existing service.

default | no

Removes the TAS name from the SIP Proxy configuration.

Usage

Use this command to identify the name of the service configured on the system performing TAS functions. The ims-sh-service commands are defined in the Context Configuration Mode Commands chapter in this guide.

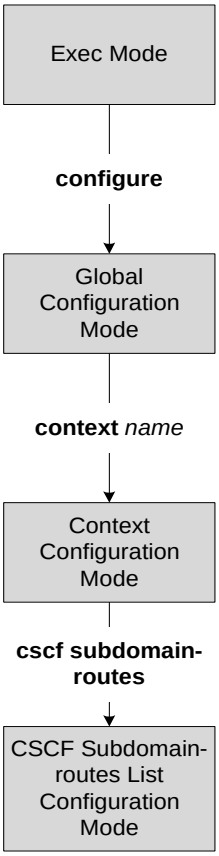
Example

The following command identifies the TAS service name as *scscf3*:

```
tas-service scscf3
```

Chapter 93
CSCF Subdomain-route List Configuration Mode Commands

The CSCF Subdomain-route List Configuration Mode is used to configure the subdomain-routes for the I-CSCF. These subdomain-routes are used to send messages over the Ma-interface (I-CSCF interface toward AS).



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

after

Places the subdomain-route at the bottom or end of the subdomain-routes list. Use this command in conjunction with the **route** command.

Product

SCM (I-CSCF)

Privilege

Administrator

Syntax

after

Usage

Add this command before the **route** command to place the route at the end of the subdomain-routes list.

before

Places the subdomain-route at the beginning or top of the subdomain-routes list. Use this command in conjunction with the **route** command.

Product

SCM (I-CSCF)

Privilege

Administrator

Syntax

before

Usage

Add this command before the **route** command to place the route at the beginning of the subdomain-routes list.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

route

Creates a route entry to be used in the subdomain-routes list for the I-CSCF.

Product

SCM (I-CSCF)

Privilege

Administrator

Syntax

`[ no ] route peer-servers` *`name`* **`[ log ] base-criteria destination aor`** *`aor`*

`no`

Removes specified route entry.

`peer-servers` *`name`*

Specifies the name of a peer server group.
`name` must be an existing peer server group from 1 to 79 alpha and/or numeric characters in length.

`log`

Enables logging for CSCF sessions meeting the criteria specified. The logs can be viewed by executing the **`logging filter active facility cscf`** command in the Exec mode.

`base-criteria destination aor` *`aor`*

Filters routes based on the destination AoR.
`aor` must be an existing AoR from 1 to 79 alpha and/or numeric characters in length.

Important: AoR regular expressions are supported. Refer to the *SCM Engineering Rules* Appendix in the *Session Control Manager Administration Guide* for more information about regular expressions.

Usage

Use this command to create and order routes in the subdomain-routes list for the I-CSCF. I-CSCF, upon receiving the terminating request, checks the subdomain-route list for matches. If a match is found, the routing will happen based on it. Otherwise, I-CSCF performs a User Location Query (Location-Information-Request) before proceeding.

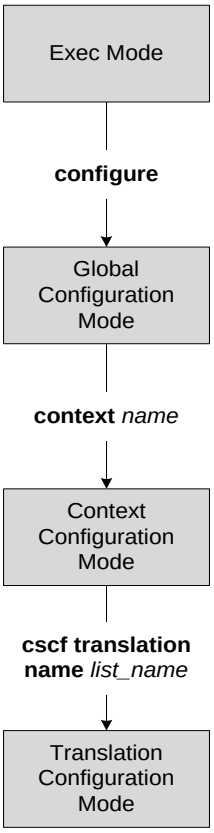
Example

The following command creates a route for the subdomain-routes list to peer server group *`ps5`* with a destination AoR of *`$.@abc123.com`*:

```
route peer-servers ps5 base-criteria destination aor $.@abc123.com
```

Chapter 94
CSCF Translation Configuration Mode Commands

The CSCF Translation Configuration Mode is used to configure session re-addressing within the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

after

Places the CSCF translation entry at the bottom or end of the translation list. Use this command in conjunction with the **uri-readdress** command.

Product

SCM

Privilege

Administrator

Syntax

after

Usage

Add this command before the **uri-readdress** command to place the entry at the end of the translation list.

before

Places the CSCF translation entry at the top or beginning of the translation list. Use this command in conjunction with the **uri-readdress** command.

Product

SCM

Privilege

Administrator

Syntax

before

Usage

Add this command before the **uri-readdress** command to place the entry at the beginning of the translation list.

end

Exits the current mode and returns to the Exec Mode.

Product

All

Privilege

Administrator

Syntax

end

Usage

Change the mode back to the Exec mode.

exit

Exits the current mode and returns to the previous mode.

Product

All

Privilege

Administrator

Syntax

exit

Usage

Return to the previous mode.

uri-readdress

Configures readdress criteria for URI translations.

Product

SCM

Privilege

Administrator

Syntax

uri-readdress type *trans_type* **[log] { base-criteria** *criteria* **} [filter-criteria1** *criteria* **] [filter-criteria2** *criteria* **]**

no uri-readdress type *trans_type* **{ base-criteria** *criteria* **} [filter-criteria1** *criteria* **] [filter-criteria2** *criteria* **]**

---

type *trans_type*

Specifies that the translation list (*trans_type*) entry is to be identified as one of the following:
blocking-cid: Identifies the translation list entry type as “call ID blocking”.
cancel-blocking-cid: Identifies the translation list entry type as “cancel call ID blocking”.
cancel-cid: Identifies the translation list entry type as “cancel call ID display”.
cancel-cw: Identifies the translation list entry type as “cancel call-waiting”.
cfbl-off: Identifies the translation list entry type as “call forward busy line off”.
cfbl-on: Identifies the translation list entry type as “call forward busy line on”.
cfna-off: Identifies the translation list entry type as “call forward no answer off”.
cfna-on: Identifies the translation list entry type as “call forward no answer on”.
cfu-off: Identifies the translation list entry type as “call forward unconditional off”.
cfu-on: Identifies the translation list entry type as “call forward unconditional on”.
cid: Identifies the translation list entry type as “call ID display”.
cw-off: Identifies the translation list entry type as “call-waiting off”.
cw-on: Identifies the translation list entry type as “call-waiting on”.
directory-assistance: Identifies the translation list entry type as “directory assistance”.
emergency: Identifies the translation list entry type as “emergency”.
international: Identifies the translation list entry type as “international”.
local: Identifies the translation list entry type as “local”.
long-distance: Identifies the translation list entry type as “long-distance”.
none: Identifies the translation list entry type as “any”.
operator-assistance: Identifies the translation list entry type as “operator assistance”.
premium-service: Identifies the translation list entry type as “premium service”.
service: Identifies the translation list entry type as “special service”.
tollfree: Identifies the translation list entry type as “toll free”.

---

log

Enables logging for CSCF sessions meeting the readdress criteria for URI translations.

---

base-criteria *criteria*

Specifies the base criteria that packets will be compared against. The following criteria is supported:

- **any**: Filters all CSCF sessions.

- **destination aor** *aor*: Filters sessions based on the destination AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

- **plmn-id mcc** *mcc_code* **mnc** *mnc_code*: Filters sessions based on the mobile country and network codes. *mcc_code* must be a three-digit integer from 200 to 999. *mnc_code* must be either a two or three-digit integer from 00 to 999 or **any** (any MNC code).
- **source address** *ip_address*: Filters sessions based on source IP address. *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
- **source aor** *aor*: Filters sessions based on the source AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

filter-criteria1 *criteria*

Specifies the filter criteria that packets that have passed the base criteria will be compared against. The following criteria is supported:

- **any**: Filters all CSCF sessions.
- **destination aor** *aor*: Filters sessions based on the destination AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

- **plmn-id mcc** *mcc_code* **mnc** *mnc_code*: Filters sessions based on the mobile country and network codes. *mcc_code* must be a three-digit integer from 200 to 999. *mnc_code* must be either a two or three-digit integer from 00 to 999 or **any** (any MNC code).
- **source address** *ip_address*: Filters sessions based on source IP address. *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
- **source aor** *aor*: Filters sessions based on the source AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

filter-criteria2 *criteria*

Specifies the filter criteria that packets that have passed the base criteria and filter criteria1 will be compared against. The following criteria is supported:

- **any**: Filters all CSCF sessions.
- **destination aor** *aor*: Filters sessions based on the destination AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

Important: AoR regular expressions are supported. Refer to the SCM Engineering Rules Appendix in the Session Control Manager Administration Guide for more information about regular expressions.

- **plmn-id mcc** *mcc_code* **mnc** *mnc_code*: Filters sessions based on the mobile country and network codes. *mcc_code* must be a three-digit integer from 200 to 999. *mnc_code* must be either a two or three-digit integer from 00 to 999 or **any** (any MNC code).

- **source address** *ip_address*: Filters sessions based on source IP address. *ip_address* must be expressed in dotted decimal notation for IPv4 or colon notation for IPv6.
- **source aor** *aor*: Filters sessions based on the source AoR. *aor* must be an existing AoR from 1 to 79 characters in length.

no uri-readdress type *trans_type* **{ base-criteria** *criteria* **} [filter-criteria1** *criteria* **] [filter-criteria2** *criteria* **]**

Remove the readdress configuration.

Usage

Use this command to readdress URIs based on specified criteria and enters the URI Readdress Configuration Mode. Readdressing can be used for:

- **Mobility**: When roaming in a visited domain.
- **Service Aliases**: Resolving well-known addresses via SIP-AS.
- **Number Translation**: Adding or deleting prefixes such as +1 to/from PSTN numbers.
- **Voice VPNs**: Using inter-office extensions to dial remote offices.

Entering this command results in the following prompt:

```
[context_name]hostname(config-uri-readdress)#
```

URI readdress commands are defined in the *CSCF URI Readdress Configuration Mode Commands* chapter of this reference.

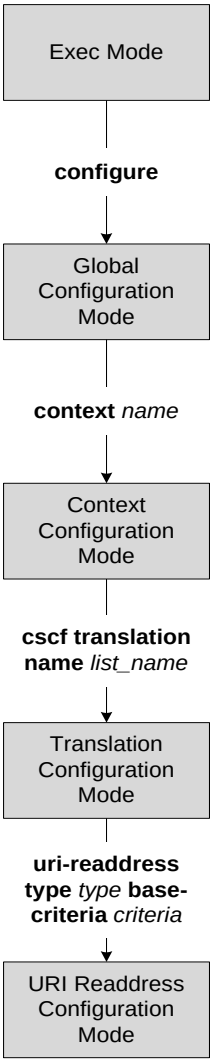
Example

The following command readdresses sessions to a domain named *service.com*, filters sessions with a base criteria of the source address (*1.2.3.4*) and a filter criteria of the destination AoR (*$.@test.com*):

```
uri-readdress type service base-criteria source address 1.2.3.4 filter-
criteria1 destination aor $.@test.com
```

Chapter 95
CSCF URI Readdress Configuration Mode Commands

The URI Readdress Configuration Mode is used to set URI translations.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

action

Adjusts a target address to route sessions to appropriate locations.

Product

SCM

Privilege

Administrator, Config-administrator

Syntax

```
action { add string | delete num_chars | modify string } position num length length
target { destination | source } { aor | domain | user }

no action
```

add *string* **| delete** *num_chars* **| modify** *string*

add *string*: Adds a specified string to a location indicated by the **position** keyword for the targeted source or destination address component (aor, domain, or user). *string* must be from 1 to 79 alpha and/or numeric characters.
delete *num_chars*: Deletes a number of characters starting from a location specified by the **position** keyword for the targeted source or destination address component (aor, domain, or user). *num_chars* must be an integer from 1 to 79.
modify *string*: Modifies a specified string in a location starting with the **position** keyword for the targeted source or destination address component (aor, domain, or user). The number of characters in the *string* variable will replace the same number in the address. *string* must be from 1 to 79 alpha and/or numeric characters.

position *num*

Specifies the position in the target string where the action is to occur. *num* must be an integer from 1 to 79.

length *length*

Specifies the length of the target string where the action is to occur. *length* must be an integer from 1 to 79.

Important: The **length** keyword is only supported in **modify** actions.

target { destination | source }

Species that the action is to occur within the source or destination address.

aor | domain | user

aor: Specifies that the action is applied to AoRs in the targeted source or destination address.
domain: Specifies that the action is applied to domains in the targeted source or destination address.
user: Specifies that the action is applied to users in the targeted source or destination address.

no

Disables target address to route sessions.

Usage

Use this command to manipulate SIP packets matching the criteria in the uri-readdress command.

Example

The following command prepends a “+1” to a destination AoR:

```
action add +1 position 1 target destination aor
```

The following command removes the first two characters from the destination AoR:

```
action delete 2 position 1 target destination aor
```

The following command replaces characters 2 through 4 with the characters “abc” in the destination AoR:

```
action modify abc position 2 target destination aor
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

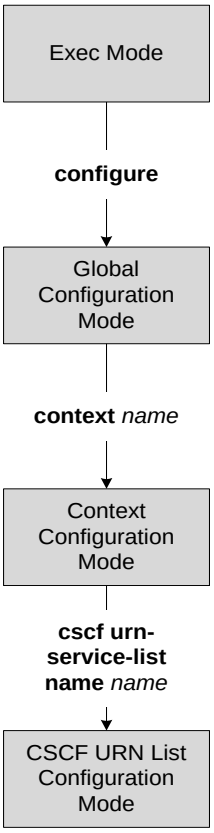
```
exit
```

Usage

Use this command to return to the parent configuration mode.

Chapter 96
CSCF URN List Configuration Mode Commands

The CSCF URN List Configuration Mode is used to map URNs to URIs for emergency and local call services.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

cscf-urn-service-mapping

Adds an entry to the service URN mapping table that maps uniform resource names (URNs) to URIs in order to direct specific service-oriented identifiers to the proper location in a network. The table is used after CSCF translation if the result is a local service.

Product

SCM

Privilege

Administrator

Syntax

`[ no ] cscf-urn-service-mapping urn` *`urn`* **`uri`** *`uri`*

`no`

Removes an entry from the service URN mapping table.

`urn` *`urn`*

Specifies the URN to be routed via a URL to the appropriate destination. *`urn`* must be from 1 to 79 alpha and/or numeric characters.

`uri` *`uri`*

Specifies the URI used to route the URN to the appropriate location. *`uri`* must be from 1 to 79 alpha and/or numeric characters.

Usage

Use this command to add an entry to the service URN mapping table that routes a translated URN to a URI for local services.

Important: Service URN mapping tables are limited to 30 URN to URI mapping entries.

Example

The following command map URN *`business`* to URI *`corp@123.45.678.9:5020`* and adds it to the service URN mapping table:

```
cscf-urn-service-mapping urn business uri corp@123.45.678.9:5020
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

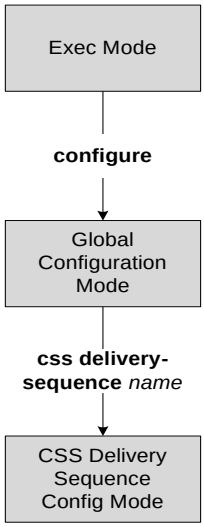
Usage

Use this command to return to the parent configuration mode.

Chapter 97
CSS Delivery Sequence Configuration Mode Commands

The CSS Delivery Sequence Configuration Mode is used to configure the order in which traffic is delivered to Content Service Steering (CSS) services and their associated content servers.

Important: This is a restricted configuration mode. In 9.0 and later releases, this configuration mode is deprecated.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

This is a restricted command. In 9.0 and later releases, this command is deprecated.

exit

This is a restricted command. In 9.0 and later releases, this command is deprecated.

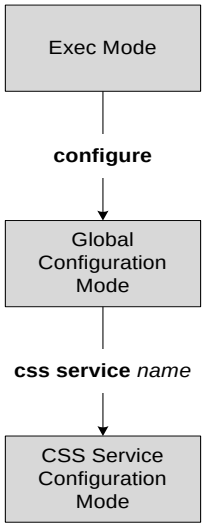
redirect service (any)

This is a restricted command. In 9.0 and later releases, this command is deprecated.

Chapter 98
CSS Service Configuration Mode Commands

The CSS Service Configuration Mode is used to configure properties for Content Service Steering (CSS) services. A CSS service binds a set of delivery interfaces to a service name and specifies a recovery mechanism.

Important: This is a restricted configuration mode. In 9.0 and later releases, this configuration mode is deprecated.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

This is a restricted command. In 9.0 and later releases, this command is deprecated.

exit

This is a restricted command. In 9.0 and later releases, this command is deprecated.

recovery

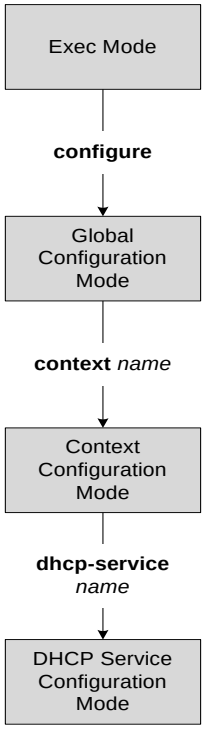
This is a restricted command. In 9.0 and later releases, this command is deprecated.

server-interface

This is a restricted command. In 9.0 and later releases, this command is deprecated.

Chapter 99
DHCP Service Configuration Mode Commands

The Dynamic Host Control Protocol (DHCP) Configuration Mode is used to create and manage DHCP service instances for the current context.



allow

Allows the specified options on the DHCP service.

Product

P-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] allow { dhcp-inform | dhcp-relay-agent-auth-suboption | dhcp-relay-agent-option |
dhcp-server rapid-commit }
```

no

Disables an option on the DHCP service.

dhcp-inform

Enables the sending of DHCP inform after configuration for address recovery.

dhcp-relay-agent-auth-suboption

Enables the sending of DHCP relay agent authentication suboption in all outgoing messages.

dhcp-relay-agent-option

Enables the sending of DHCP relay agent option in all outgoing messages.

dhcp-server rapid-commit

Enables support of the rapid commit feature for DHCP server functionality, as defined in RFC 4039.

Usage

Use this command to enable/disable options on the DHCP service.

Example

The following command enables support of the rapid commit feature for DHCP server functionality:

```
allow dhcp-server rapid-commit
```

bind

Binds the DHCP service to a logical IP interface facilitating the system's connection to the DHCP server. This command also configures traffic from the specified DHCP service bind address to use the specified Multiple Protocol Label Switching (MPLS) labels.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
bind address ip_address [ nexthop-forwarding-address nexthop_ip_address [ mpls-label
input in_mpls_label_value output out_mpls_label_value1 [ out_mpls_label_value2 ] ] ]

no bind address ip_address
```

no

Removes a previously configured binding.

address *ip_address*

Specifies the IP address of an interface in the current context through which the communication with the DHCP server occurs. *ip_address* must be expressed in IPv4 dotted-decimal notation.

nexthop-forwarding-address *nexthop_ip_address*

Specifies the next hop gateway address for in MPLS network to which the packets with MPLS labels will be forwarded. *nexthop_ip_address* must be expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

mpls-label input *in_mpls_label_value*

Specifies the MPLS label to identify inbound traffic destined for the configured DHCP service bind address *ip_address*.
in_mpls_label_value is the MPLS label that will identify inbound traffic destined for the configured DHCP service and must be an integer from 16 through 1048575.

Important: This keyword is license-enabled and available with valid MPLS feature license only.

Caution: For DHCP over MPLS feature to work in StarOS 9.0 onward the **dhcp ip vrf** command must be configured in DHCP service. Without **dhcp ip vrf** command the DHCP service using MPLS labels will not be started as a part of a DHCP over MPLS configuration. In StarOS 9.0 onward this keyword is a critical parameter for the DHCP-Service. Any change in its value will result in DHCP-service restart and clearing of the existing calls.

output *out_mpls_label_value1* **[** *out_mpls_label_value2* **]**

Adds the MPLS label to the outbound traffic sent from the configured DHCP service bind address *ip_address*. The labels *out_mpls_label_value1* and *out_mpls_label_value2* identify the MPLS labels to be added to packets sent from the specified dhcp service bind address.

out_mpls_label_value1 is the inner output label and must be an integer from 16 through 1048575.
out_mpls_label_value2 is the outer output label and must be an integer from 16 through 1048575.

Important: This keyword is license-enabled and available with valid MPLS feature license only.

Usage

Use this command to associate or tie the DHCP service to a specific logical IP address previously configured in the current context and bound to a port. Once bound, the logical IP address or interface is used in the giaddr field of the DHCP packets.
When this command is executed, the DHCP service is started and begins the process of requesting addresses from the DHCP server and storing them in cache memory for allocation to PDP contexts.
This command can also be used to configure MPLS labels for inbound and outbound traffic through this DHCP address.
Only one interface can be bound to a service.
For DHCP over MPLS feature to work in StarOS 9.0 onward **dhcp ip vrf** command must be configured in DHCP service. Without **dhcp ip vrf** command the DHCP service using MPLS labels will not be started.

Caution: As a part of DHCP over MPLS configuration, the **mpls-label input** keyword in the **bind address** command is also a critical parameter for the DHCP-Service. Any change in its value will result in DHCP-service restart and clearing of the existing calls.

Example

The following command binds the DHCP service to the interface with an IP address of 1*92.168.1.210*:

```
bind address 192.168.1.210
```

default

Restores DHCP service parameters to their factory default settings.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

default { T1-threshold | T2-threshold | dhcp { chaddr-validate | client-identifier | deadtime | detect-dead-server { consecutive-failures } | server selection-algorithm } | lease-duration | max-retransmissions | retransmission-timeout }

---

dhcp { deadtime | detect-dead-server { consecutive-failures } | server-selection-algorithm }

Restores the following DHCP parameters to their respective default settings:

- **deadtime**: Default 10 minutes
- **detect-dead-server** { **consecutive-failures** }: Default 5
- **server-selection-algorithm**: Default First-server

---

lease-duration

Restores the lease-duration parameter to its default setting of 86400 seconds.

---

max-retransmissions

Restores the max-retransmissions parameter to its default setting of 5.

---

retransmission-timeout

Restores the retransmission-timeout parameter to its default setting of 3000 milli-seconds.

T1-threshold

Restores the T1-threshold parameter to its default setting of 50%.

T2-threshold

Restores the T2-threshold parameter to its default setting of 88%.

Usage

After system parameters have been modified, this command is used to set/restore specific parameters to their default values.

Example

The following command restores the DHCP deadtime parameter to its default setting of 10 minutes:

```
default dhcp deadtime
```

dhcp chaddr-validate

Configures the behavior of the client hardware address (chaddr) validation in DHCP messages.

Product

GGSN, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
[ default | no ] dhcp chaddr-validate
```

default

Validates the chaddr value received in a DHCPACK message with the chaddr value sent in a DHCPREQUEST message.

no

Disables validation of the chaddr value received in DHCPACK message with the chaddr value sent in a DHCPREQUEST message.

Important: The chaddr information value in the DHCPACK message will be parsed but not be validated against the value maintained with client. The chaddr information value in DHCPACK will be ignored and not be stored internally.

Usage

Use this command to configure behavior relating to the validation of chaddr information validation in the DHCPACK messages.

Example

The following command specifies that the chaddr will not be validated in the DHCP messages:

```
no dhcp chaddr-validate
```

dhcp client-identifier

Configures the behavior relating to inclusion of a client identifier DHCP option in DHCP messages.

Product

GGSN, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
dhcp client-identifier { mac-address | msisdn | none }

default dhcp client-identifier
```

default

Sets the behavior of DHCP client identifier to default – do not to include client identifier option in any DHCP message.

mac-address

Specifies the subscribers mac-address as the DHCP client-identifier option in any DHCP message.

msisdn

Specifies that the subscriber's MSISDN be included in the client-identifier option of the relevant DHCP messages. Default: disabled

Important: This keyword is GGSN license controlled.

none

Specifies that DHCP client-identifier option would not be included in any DHCP messages. This is the default behavior. Default: enabled

Usage

Use this command to configure behavior relating to inclusion or exclusion of DHCP client identifier option from DHCP messages.

Example

The following command specifies that DHCP client-identifier option be excluded from DHCP messages:

```
dhcp client-identifier none
```

dhcp deadtime

Configures the amount of time that the system waits prior to re-communicating with a DHCP server that was previously marked as down.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

dhcp deadtime *max_time*

max_time

Specifies the maximum amount of time (in minutes) to wait before communicating with a DHCP server that was previously unreachable. *max_time* is an integer value from 1 through 65535. Default: 10

Usage

If the system is unable to communicate with a configured DHCP server, after a pre-configured number of failures the system marks the server as being down.
This command specifies the amount of time that the system waits prior to attempting to communicate with the downed server.

Important: If all DHCP servers are down, the system will immediately treat all DHCP servers as active, regardless of the deadtime that is specified.

Refer to the **dhcp detect-dead-server** and **max-retransmissions** commands for additional information on the process the system uses to mark a server as down.

Example

The following command configures the system to wait *20* minutes before attempting to re-communicate with a dhcp server that was marked as down:

```
dhcp deadtime 20
```

dhcp detect-dead-server

Configures the number of consecutive communication failures that could occur before the system marks a DHCP server as down.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

dhcp detect-dead-server consecutive-failures *max_number*

consecutive-failures *max_number*

Specifies the number of failures that could occur before marking a DHCP server as down as an integer from 1 through 1000. Default: 5

Usage

This command works in conjunction with the *max-retransmissions* parameter to set a limit to the number of communication failures that can occur with a configured DHCP server.
The *max-retransmissions* parameter limits the number of attempts to communicate with a server. Once that limit is reached, the system treats it as a single failure. This parameter limits the number of consecutive failures that can occur before the system marks the server as down and communicate with the server of next highest priority.
If all of the configured servers are down, the system ignores the detect-dead-server configuration and attempt to communicate with highest priority server again.
If the system receives a message from a DHCP server that was previously marked as down, the system immediately treats it as being active.

Example

The following command configures the system to allow *8* consecutive communication failures with a DHCP server before it marks it as down:

```
dhcp detect-dead-server consecutive-failures 8
```

dhcp ip vrf

Enables DHCP-over-MPLS support and associates the specific DHCP service with a pre-configured Virtual Routing and Forwarding (VRF) Context instance for virtual routing and forwarding.

Product

All

Privilege

Security Administrator, Administrator

Syntax

dhcp ip vrf *vrf_name*

no dhc ip vrf

no

Removes/disassociates configured IP Virtual Routing and Forwarding (VRF) context instance.

vrf_name

Specifies the name of a pre-configured VRF context instance to be associated with a DHCP service. *vrf_name* is the name of a pre-configured VRF context configured in Context Configuration mode and associated with the IP Pool used by the DHCP service.

Usage

Use this command to enable the DHCP-over-MPLS support and to associate/disassociate a pre-configured VRF context to a DHCP service for this feature.
By default the VRF is NULL, which means that DHCP service is bound with binding address given by **bind address** command only.
VRF is not a critical parameter for the DHCP Service but bind address is a critical parameter for DHCP Service, and while starting DHCP Service, if this command is configured, then the bind address should be present in that VRF, and If this command is not configured, bind address should be present in the context where DHCP Service is configured.
For the DHCP over MPLS feature to work in StarOS 9.0 onward this command must be configured in the DHCP service. Without this command the DHCP service using MPLS labels will not be started.

Caution: As a part of this configuration the **mpls-label input** keyword in the **bind address** command is also a critical parameter for the DHCP-Service. Any change in its value will result in DHCP-service restart and clearing of the existing calls.

Example

Following command associates VRF context instance *dhcp_vrf1* with this DHCP service:

```
dhcp ip vrf dhcp_vrf1
```

dhcp server

Configures DHCP servers with which the DHCP service is to communicate.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

dhcp server *ip_address* **[priority** *priority* **]**

no dhcp server *ip_address*

no

Deletes a previously configured DHCP server.

ip_address

Specifies the IP address of the DHCP server expressed in IPv4 dotted-decimal notation.

priority *priority*

Specifies the priority of the server if multiple servers are configured. *priority* is an integer from 1 through 1000. 1 is the highest priority.

Usage

Use this command to configure the DHCP server(s) that the system is to communicate with. Multiple servers can be configured each with their own priority. Up to 20 DHCP servers can be configured.
All DHCP messages are sent/received on UDP port 67.

Important: If a server is removed, all calls having an IP address allocated from the server will be released.

Example

The following command configures a DHCP server with an IP address of *192.168.1.200* and a priority of *1*:

```
dhcp server 192.168.1.200 priority 1
```

dhcp server selection-algorithm

Specifies the algorithm used to select DHCP servers with which to communicate when multiple servers are configured.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

```
dhcp server selection-algorithm { first-server | round-robin }
```

first-server

Uses the first-server algorithm. This algorithm dictates that the system select the DHCP servers according to their priority starting with the highest priority server. The system communicates with the server of the next highest priority only when the previous server is unreachable. Default: Enabled

round-robin

Uses the round-robin algorithm. This algorithm dictates that the system communicates with the servers in a circular queue according to the server's configured priority starting with the highest priority server. The next request is communicated with the next highest priority server, and so on until all of the servers have been used. At this point, the system starts from the highest priority server. Default: Disabled

Usage

Use this command to determine how configured DHCP servers are utilized by the system.

Example

The following command configures the DHCP service to use the round-robin selection algorithm:

```
dhcp server selection-algorithm round-robin
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

lease-duration

Configures the minimum and maximum allowable lease times that are accepted in responses from DHCP servers.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

lease-duration min *min_time* **max** *max_time*

min *min_time*

Specifies the minimum acceptable lease time (in seconds) as an integer from 600 trough 3600. Default: 600

max *max_time*

Specifies the maximum acceptable lease time (in seconds) as an integer from 10800 through 4294967295. Default: 86400

Usage

To reduce the call setup time, the system requests IP addresses from the DHCP server in blocks rather than on a call-by-call basis. Each address received has a corresponding lease time, or time that it is valid. The values configured by command represent the minimum and maximum times that the system allows and negotiates for the lease(s).

If the DHCP server responds with values that are out of the range specified by the min and max values, the system accumulates warning statistics. Responses that fall below the minimum value are rejected by the system and the system contacts the DHCP server with the next highest priority. Responses that are greater than the maximum value are accepted.

When half of the lease time has expired, the system automatically requests a lease renewal from the DHCP server. This is configured using the **T1-threshold** command.

Example

The following command configures the minimum allowable lease time for the system to be *1000* and the maximum to be *36000*:

```
lease-duration min 1000 max 36000
```

max-retransmissions

Configures the maximum number of times that the system attempts to communicate with an unresponsive DHCP server before it is considered a failure.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

max-retransmissions *max_number*

max_number

Specifies the maximum number of re-attempts the system tries when no response is received from a DHCP server. *max_number* is an integer from 1 through 20. Default: 5

Usage

This command works in conjunction with the *dhcp detect-dead-server* parameter to set a limit to the number of communication failures that can occur with a configured DHCP server.
When the value specified by this parameter is met, a failure is logged. The *dhcp detect-dead-server* parameter specifies the number of consecutive failures that could occur before the server is marked as down.
In addition, the **retransmission-timeout** command controls the amount of time between re-tries.

Example

The following command configures the maximum number of times the system re-attempts communication with a DHCP server that is unresponsive to *5*:

```
max-retransmissions 5
```

retransmission-timeout

Configures the amount of time that must pass with no response before the system re-attempts to communicate with the DHCP server.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

retransmission-timeout *time*

time

Specifies the time that the system waits (in milliseconds) before reattempting communication with the DHCP server. *time* is an integer from 100 through 20000. Default: 10000

Usage

This command works in conjunction with the **max-retransmissions** command to establish a limit on the number of times that communication with a DHCP server is attempted before a failure is logged. This parameter specifies the time between retries.

Example

The following command configures a retry timeout of *1000* milliseconds:

```
retransmission-timeout 1000
```

T1-threshold

Configures the DHCP T1 timer as a percentage of the allocated IP address lease.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

T1-threshold *percentage*

percentage

Specifies the percentage of the allocated IP address lease time at which the DHCP call-line state is changed to "RENEWING". *percentage* is an integer from 40 through 66. Default: 50

Usage

This command is used to identify the time at which a subscriber must renew their DHCP lease as a percentage of the overall lease time. (Refer to the **lease-duration** command in this chapter for information on configuring the IP address lease period.)
For example, if the lease-duration was configured to have a maximum value of 12000 seconds, and this command is configured to 40%, then the subscriber would enter the RENEWING state after 4800 seconds.

Example

The following command configures the T1 threshold to *40*%:

```
T1-threshold 40
```

T2-threshold

Configures the DHCP T2 timer as a percentage of the allocated IP address lease.

Product

GGSN, ASN-GW, HA, P-GW

Privilege

Security Administrator, Administrator

Syntax

T2-threshold *percentage*

percentage

Specifies the percentage of the allocated IP address lease time at which the DHCP call-line state is changed to "REBINDING". *percentage* is an integer from 67 through 99. Default: 88

Usage

This command is used to identify the time at which a subscriber re-binds their DHCP leased IP address as a percentage of the overall lease time. (Refer to the **lease-duration** command in this chapter for information on configuring the IP address lease period.)
For example, if the lease-duration was configured to have a maximum value of 12000 seconds, and this command is configured to 70%, then the subscriber would enter the REBINDING state after 8400 seconds.

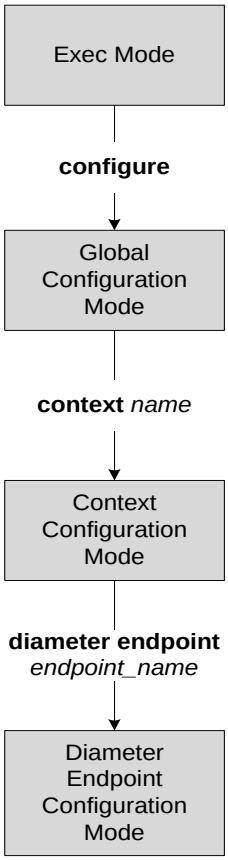
Example

The following command configures the T2 threshold to *70*%:

T2-threshold 70 *70*

Chapter 100
Diameter Endpoint Configuration Mode Commands

Diameter Endpoint Configuration Mode is accessed from the Context Configuration Mode. The base Diameter protocol operation is configured in this mode.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

associate

This command associates/disassociates a Stream Control Transmission Protocol (SCTP) parameter template with the Diameter endpoint.

Product

MME

Privilege

Administrator

Syntax

associate sctp-parameters-template *template_name*

no associate sctp-parameters-template

no

Disassociates an SCTP parameter template with the Diameter endpoint.

sctp-parameters-template *template_name*

Associates a previously created SCTP parameter template with the Diameter endpoint. *template_name* specifies the name for a pre-configured SCTP parameter template. For more information on SCTP parameter templates, refer to the **sctp-param-template** command in the *Global Configuration Mode Commands* chapter.

Usage

Use this command to associate a configured SCTP parameter template with the Diameter endpoint. The SCTP parameter template allows for SCTP timer values to be configured for the interface using the Diameter endpoint configuration. For more information on SCTP parameters, refer to the *SCTP Parameter Template Configuration Mode Commands* chapter.

Important: Only one SCTP parameter template can be associated with the Diameter endpoint configuration. The SCTP parameter template should be configured prior to issuing this command.

Only the following parameters from the template will be associated with the endpoint. When no SCTP parameter template is associated with the endpoint, the following default values are used:
sctp-cookie-life *60000* (default for the parameter template as well)
sctp-max-init-retx *5* (default for the parameter template as well)
sctp-max-path-retx *10* (default in the parameter template is 5)
sctp-rto-initial *3000* (default for the parameter template as well)
sctp-rto-max *60000* (default for the parameter template as well)
sctp-rto-min *1000* (default for the parameter template as well)
sctp-sack-period *200* (default for the parameter template as well)
timeout sctp-heart-beat *30* (default for the parameter template as well)

Example

The following command associates a pre-configured SCTP parameter template called *sctp1* to the Diameter endpoint:

```
associate sctp-parameters-template sctp1
```

cea-timeout

This command configures the Capabilities-Exchange-Answer (CEA) message timeout duration for Diameter sessions.

Product

All

Privilege

Security Administrator, Administrator

Syntax

cea-timeout *timeout*

default cea-timeout

default

Configures this command with the default setting.
Default: 30 seconds

timeout

Specifies the timeout duration (in seconds) to make the system wait for this duration for a CEA message. *timeout* must be an integer from 1 through 120.

Usage

Use this command to configure the CEA timer, i.e., how long to wait for the Capabilities-Exchange-Answer message.

Example

The following command sets the Diameter CEA timeout to *16* seconds:

```
cea-timeout 16
```

connection retry-timeout

This command configures the Diameter Connection Retry Timeout parameter.

Product

All

Privilege

Security Administrator, Administrator

Syntax

connection retry-timeout *timeout*

default connection retry-timeout

default

Configures this command with the default setting.
Default: 30 seconds

timeout

Specifies the connection retry timeout duration in seconds, and must be an integer from 1 through 3600.

Usage

Use this command to configure the Diameter Connection Retry Timeout parameter.

Example

The following command sets the Diameter Connection Retry Timer to *120* seconds:

```
connection retry-timeout 120
```

connection timeout

This command configures the Diameter Connection Timeout parameter.

Product

All

Privilege

Security Administrator, Administrator

Syntax

connection timeout *timeout*

default connection timeout

default

Configures this command with the default setting.
Default: 30 seconds

timeout

Specifies the connection timeout duration (in seconds) as an integer from 1 through 30.

Usage

Use this command to configure the Diameter Connection Timeout parameter.

Example

The following command sets Diameter connection timeout to *16* seconds:

```
connection timeout 16
```

destination-host-avp

This command controls encoding of the Destination-Host AVP in initial/retried requests.

Product

All

Privilege

Security Administrator, Administrator

Syntax

destination-host-avp { session-binding | always | initial-request | retried-request }

default destination-host-avp

default

Configures this command with the default setting. Default: session-binding

session-binding

Includes the Destination-Host AVP when the Diameter session is bound with a host.

always

Includes the Destination-Host AVP in all types of request messages.

initial-request

Includes the Destination-Host AVP in an initial request but not in a retried request.

retried-request

Includes the Destination-Host AVP in a retried request but not in an initial request.

Usage

Use this command to control encoding of the Destination-Host AVP in initial/retried requests.
This command has been introduced in release 12.0, in earlier releases, the Destination-Host AVP is not sent in session-setup/initial request (first message sent on that interface for that subscriber. The message will vary with different interfaces. For example, CCR-Initial for Gy, ACR-start for Rf, and so on). Also, Destination-Host AVP was not sent in retried requests. For example, CCR-Update failed to be responded by server. The message was retransmitted to alternate server.
In both these scenarios, it is not known which server will respond to the initial/retried message, so the Destination-Realm is encoded but not the Destination-Host. Only after a response for this message is received from one of the hosts present in that realm, the session is considered to be BOUND with that server. Any message sent after this binding will have the Destination-Host AVP encoded.
In this release, with this CLI command, if the application has selected one of the servers using application-level commands like the **peer-select** command for credit-control or the **diameter authentication** or **accounting server** command in a AAA group, encoding of this AVP in initial/retried request is configurable.

Example

The following command specifies to include the Destination-Host AVP in initial request but not in retried request:

```
destination-host-avp initial-request
```

device-watchdog-request

This command manages the transport failure algorithm and configures the number of Device Watchdog Requests (DWRs) that will be sent before a connection is closed.

Product

All

Privilege

Security Administrator, Administrator

Syntax

device-watchdog-request max-retries *retry_count*

default device-watchdog-request max-retries

default

Configures this command with the default setting. Default: 1

retry_count

Specifies the maximum number of DWRs, and must be an integer from 1 through 10.

Usage

Use this command to configure the number of DWRs to be sent before closing the connection from a Diameter endpoint.

Example

The following command sets the DWRs to *3*:

```
device-watchdog-request max-retries 3
```

dpa-timeout

This command configures the Disconnect-Peer-Answer (DPA) message timeout duration for Diameter sessions.

Product

All

Privilege

Security Administrator, Administrator

Syntax

dpa-timeout *timeout*

default dpa-timeout

default

Configures this command with the default setting.
Default: 30 seconds

timeout

Specifies the DPA message timeout duration (in seconds) as an integer from 1 through 60.

Usage

Use this command to set the timer for DPA message timeout during Diameter connection session. This makes the system wait for this duration for DPA message.

Example

The following command sets the Diameter DPA timeout to *16* seconds:

```
dpa-timeout 16
```

dscp

This command sets the Differential Services Code Point (DSCP) value in the IP header of the Diameter messages sent from the Diameter endpoint.

Product

All

Privilege

Security Administrator, Administrator

Syntax

dscp { *value* **| af11 | af12 | af13 | af21 | af22 | af23 | af31 | af32 | af33 | af41 | af42 | af43 | be | cs1 | cs2 | cs3 | cs4 | cs5 | cs6 | cs7 | ef }**

default dscp

value

Specifies to configure a unique DSCP as an integer in the range of 0 through 63.

af *xx*

Specifies the use of an assured forwarding *xx* per hop behavior (PHB).

be

Specifies the use of best effort forwarding PHB. This is the default.

cs*x*

Specifies the use of class selector *x* per PHB.

ef

Specifies the use of expedited forwarding PHB.

Usage

Use this command to set the DSCP in the IP header of the diameter messages sent from the diameter endpoint. In addition to the recommended PHBs the user may configure their own DSCP as an integer in the range of 0 through 63.

Example

The following command sets the DSCP to *be*:

```
dscp be
```

dynamic-peer-discovery

This command configures the system to dynamically locate peer Diameter servers by means of DNS.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
dynamic-peer-discovery [ protocol { sctp | tcp } ]

{ default | no } dynamic-peer-discovery
```

default

Configures this command with the default setting.
Default: disabled

no

Removes the configuration.

protocol { sctp | tcp }

Configures peer discovery to use a specific protocol. Default: TCP
sctp: Uses Streaming Control Transmission Protocol (SCTP) for peer discovery.
tcp: Uses Transmission Control Protocol (TCP) for peer discovery.

Usage

Use this command to configure the system to dynamically locate peer Diameter servers by means of DNS. Configure the **dynamic-peer-realm** command to locate Diameter servers using Naming Authority Pointer (NAPTR) queries. If the peer realm command is not configured, configuring this command will still allow applications to trigger an NAPTR query on their chosen realms.
The preferred transport protocol is TCP to resolve instances were multiple NAPTR responses with the same priority are received. The one using the TCP transport protocol will be chosen. If the transport protocol is configured through the CLI, then the configured protocol is given preference.
The IP address version will be the same as that of the origin host address configured for the endpoint. For IPv4 endpoints, A-type DNS queries will be sent to resolve Fully Qualified Domain Names (FQDNs). For IPv6 endpoints, AAAA-type queries are sent.

Example

The following command configures the system to dynamically locate peer Diameter servers using SCTP:

```
dynamic-peer-discovery protocol sctp
```

dynamic-peer-failure-retry-count

This command configures the number of times the system will attempt to connect to a dynamically discovered Diameter peer.

Product

All

Privilege

Security Administrator, Administrator

Syntax

dynamic-peer-failure-retry-count *no_of_retries*

default dynamic-peer-failure-retry-count

default

Configures this command with the default setting.
Default: 8

no_of_retries

Specifies the number of retry attempts to connect to a dynamically discovered Diameter peer. The value must be an integer from 0 through 255.

Usage

Use this command to configure the number of times the system attempts to connect to a dynamically discovered Diameter peer.
After the specified number of attempts if the peer is still not open, the peer is moved into blacklist and other peers are tried. The blacklisted peer will be retried after a time period of one hour.

Example

The following command sets the retry attempts to *10*:

```
dynamic-peer-failure-retry 10
```

dynamic-peer-realm

This command configures the name of the realm where peer Diameter servers can be dynamically discovered.

Product

All

Privilege

Security Administrator, Administrator

Syntax

[no] dynamic-peer-realm *realm_name*

no

Removes the specified dynamic peer realm name from this endpoint configuration.

realm_name

Specifies the name of the peer realm where peer Diameter server are to be dynamically discovered. *realm_name* must be an existing realm, and must be an alphanumeric string of 1 through 127 characters.

Usage

Use this command to locate Diameter servers using Naming Authority Pointer (NAPTR) queries. Multiple realms can be configured. Even if the **dynamic-peer-discovery** command is not enabled, the realm configuration(s) will trigger dynamic peer discovery on all diabase instances.

Example

The following command configures a peer realm, used for dynamic peer discovery, with a name of *service-provider.com*:

```
dynamic-peer-realm service-provider.com
```

dynamic-route

This command configures the expiration time for dynamic routes created after a Diameter destination host is reached.

Product

All

Privilege

Security Administrator, Administrator

Syntax

dynamic-route expiry-timeout *value*

default dynamic-route expiry-timeout

default

Configures this command with the default setting. Default: 86400 seconds (1 day)

value

Specifies the time (in seconds) that a dynamic route to a Diameter host will expire. The value must be an integer from 1 through 86400000.

Usage

Use this command to set expiration times for dynamic routes that are set up after a Diameter host has been reached.

Example

The following command sets the dynamic route expiration to *43200* seconds:

```
dynamic-route expiry-timeout 43200
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

load-balancing-algorithm

This command configures the behavior for load balancing Diameters peers in the event of a failure of an active server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

load-balancing-algorithm { highest-weight | lowest-weight-borrowing min-active-servers *number* **}**

default load-balancing-algorithm

default

Configures this command with the default setting.
Default: **highest-weight**

highest-weight

Selects an idle server with the highest weight in failure scenarios. If multiple servers have the same high weight, load balancing is performed among those servers.

lowest-weight-borrowing min-active-servers *number*

Borrows an idle server with the lowest weight and adds it to the group of servers where load balancing is performed. *number* specifies the number of servers that must always be available as active for load balancing. *number* must be an integer from 2 through 4000.

Usage

Use this command to configure the behavior for load balancing Diameter peers in the event of a failure of an active server.

Example

The following command configures the load balancing behavior for Diameter peers to borrowing minimally active servers (lower weight) and maintaining an active server group of *30* servers:

```
load-balancing-algorithm lowest-weight-borrowing min-active-servers 30
```

max-outstanding

This command configures the maximum number of Diameter messages that any application can send to any one peer, while awaiting responses.

Product

All

Privilege

Security Administrator, Administrator

Syntax

max-outstanding *messages*

{ default | no } max-outstanding

no

Disables the maximum outstanding messages configuration.

default

Configures this command with the default setting.
Default: 256

messages

Specifies the maximum outstanding peer transmit window size setting. The input must be an integer from 1 through 4096.

Usage

Use this command to set the unanswered Diameter messages that any application may send to any one peer, while awaiting responses. An application will not send any more Diameter messages to that peer until it has disposed of at least one of those queued messages. It disposes a message by either receiving a valid response or by discarding the message due to no response.

Example

The following command sets the Diameter maximum outstanding messages setting to *1024*:

```
max-outstanding 1024
```

origin address

This command has been deprecated. See the origin host and origin realm commands.

origin host

This command sets the origin host for the Diameter endpoint.

Product

All

Privilege

Security Administrator, Administrator

Syntax

origin host *host_name* **address** *ipv4/ipv6_address* **[port** *port_number* **] [accept-incoming-connections] [address** *ipv4/ipv6_address_secondary* **]**

no origin host *host_name* **address** *ipv4/ipv6_address* **[port** *port_number* **]**

no

Removes the origin host configuration.

origin host *host_name*

Specifies the host name to bind the Diameter endpoint. *host_name* must be the local Diameter host name, and must be an alphanumeric string of 1 through 255 characters.

address *ipv4/ipv6_address*

Specifies the IP address to bind the Diameter endpoint using IPv4 dotted-decimal or IPv6 colon-separated notation. This address must be one of the addresses of a chassis interface configured within the context in which Diameter is configured.

port *port_number*

Specifies the port number for the Diameter endpoint (on inbound connections). The port number must be an integer from 1 through 65535. Default: 3868
Port number in the origin host should be configured only when the chassis is running in server mode, i.e. when **accept-incoming-connections** is configured.
In this case it will open a listening socket on the specified port. For configurations where chassis is operating as a client, port number should not be included. In this case, a random source port will be chosen for outgoing connections. This is applicable for both with or without multi-homing.

Important: Currently if multi-homing is configured, then the specified port is used instead of randomly chosen port. This is done so that application knows which port is used by the kernel as it will have to use the same port while adding/removing IP address from the association. Nevertheless, configuring port number in origin host for client mode is not supported.

accept-incoming-connections

Accepts inbound connection requests for the specified host.

address *ipv4/ipv6_address_secondary*

Specifies the secondary bind address for the Diameter endpoint in IPv4 dotted-decimal or IPv6 colon-separated notation. This address must be one of the addresses of a chassis interface configured within the context in which Diameter is configured.

Usage

Use this command to set the bind address for the Diameter endpoint.
Diameter agent on the chassis listens to standard TCP port 3868 and also supports the acceptance of any incoming TCP connection from external server.
The command **origin host** *host-name* must be entered exactly once. Alternatively, the **origin host** *host-name* **address** *ipv4/ipv6_address* **[port** *port_number* **]** command may be entered one or more times. The host names should be unique across all endpoints within the system. The host names and address values or address/port combinations should be unique across all endpoints within the system.

Example

The following command sets the origin host name to *test* and the IP address to *10.1.1.1*:

```
origin host test address 10.1.1.1
```

origin realm

This command configures the realm to use in conjunction with the origin host.

Product

All

Privilege

Security Administrator, Administrator

Syntax

[no] origin realm *realm_name*

no

Removes the origin realm configuration.

realm_name

Specifies the realm to bind the Diameter endpoint. The *realm_name* must be an alphanumeric string of 1 through 127 characters. The realm is the Diameter identity. The originator's realm must be present in all Diameter messages. The origin realm can typically be a company or service name.

Usage

Use this command to set the realm for the Diameter endpoint.
Diameter agent on the chassis listens to standard TCP port 3868 and also supports the acceptance of any incoming TCP connection from external server.

Example

The following command sets the origin realm to *companyx*:

```
origin realm companyx
```

peer

This command specifies a peer address for the Diameter endpoint.

Product

All

Privilege

Security Administrator, Administrator

Syntax

peer [*] *peer_name* **[*] [realm** *realm_name* **] { address** *ipv4/ipv6_address* **[[port** *port_number* **] [connect-on-application-access] [send-dpr-before-disconnect disconnect-cause** *disconnect_cause* **] [sctp]] + | fqdn** *fqdn* **[[port** *port_number* **] [send-dpr-before-disconnect disconnect-cause** *disconnect_cause* **]] }**

no peer *peer_name* **[realm** *realm_name* **]**

no

Removes the specified peer configuration.

[*] *peer_name* **[*]**

Specifies the peer's name as an alphanumeric string of 1 through 63 characters that allows punctuation characters.
The Diameter server endpoint can now be a wildcarded peer name (with * as a valid wildcard character). Client peers which satisfy the wild-carded pattern are treated as valid peers and the connection will be accepted. The wildcarded token indicates that the peer name is wildcarded and any '*' in the preceding string is treated as a wildcard.

realm *realm_name*

Specifies the realm of this peer as an alphanumeric string of 1 through 127 characters. The realm name can be a company or service name.

address *ipv4/ipv6_address*

Specifies the Diameter peer IP address in IPv4 dotted-decimal or IPv6 colon-separated notation. This address must be the IP address of the device with which the chassis is communicating.

fqdn *fqdn*

Specifies the Diameter peer FQDN as an alphanumeric string of 1 through 127 characters.

port *port_number*

Specifies the port number for this Diameter peer. The port number must be an integer from 1 through 65535.

connect-on-application-access

Activates peer on first application access.

send-dpr-before-disconnect

Sends Disconnect-Peer-Request (DPR).

disconnect-cause

Sends Disconnect-Peer-Request to the specified peer with the specified disconnect reason. The disconnect cause must be an integer from 0 through 2, for one of the following:

- REBOOTING(0)
- BUSY(1)
- DO_NOT_WANT_TO_TALK_TO_YOU(2)

sctp

Uses Stream Control Transmission Protocol (SCTP) for this peer.

+

Indicates that more than one of the previous keywords can be entered within a single command.

Usage

Use this command to add a peer to the Diameter endpoint.
If the Diameter server side endpoint is catering to multiple peers, there has to be an entry for each peer in the peer list for that endpoint.
In cases where the client like GGSN does not use a diameter proxy, the peer list can be as large as the number of session managers on a GGSN. This might lead to a very complex configuration at the Diameter server endpoint.
To simplify the configurations, the Diameter server endpoint accepts a wildcarded peer name (with * as a valid wildcard character).
The client peers which satisfy the wild-carded pattern are treated as valid peers and the connection will be accepted. The new token ‘wildcarded*’ indicates that the peer name is wildcarded and any ‘*’ in the preceding string should be treated as a wildcard.
For example, if the peer name is prefixed and suffixed with *ggsn* (* wildcard character) and an exact match is not found for the peer name portions peers like *0001-sessmgr.ggsn-gx*, *0002-sessmgr.ggsn-gx*, will be treated as valid peers at the Diameter server endpoint.

Example

The following command adds the peer named *test* with IP address *10.1.1.1* using port *126*:

```
peer test address 10.1.1.1 port 126
```

response-timeout

This command configures the Response Timeout parameter. Response timeout specifies the maximum allowed response time for request messages sent from Diameter applications to Diameter server. On failure of reception of response for those request message within this specified time, this will be handled as failure by the corresponding applications and appropriate failure action will be initiated.

Product

All

Privilege

Security Administrator, Administrator

Syntax

response-timeout *timeout*

default response-timeout

default

Configures this command with the default setting.
Default: 60 seconds

timeout

Specifies the response timeout duration in seconds, and must be an integer from 1 through 300.

Usage

Use this command to configure the Response Timeout parameter.

Example

The following command sets the response timeout to *100* seconds:

```
response-timeout 100
```

route-entry

This command creates an entry in the route table for Diameter peer.

Product

All

Privilege

Security Administrator, Administrator

Syntax

route-entry { [host *host_name* **] [peer** *peer_id* **[weight** *priority* **]] [realm** *realm_name* **[application credit-control peer** *peer_id* **] [weight** *value* **] | peer** *peer_id* **[weight** *value* **]] }**

no route-entry { [host *host_name* **] [peer** *peer_id* **] [realm** *realm_name* **{ application credit-control peer** *peer_id* **| peer** *peer_id* **}] }**

no

Disables the specified route-entry table configuration.

host *host_name*

Specifies the Diameter server's host name as an alphanumeric string of 1 through 63 characters.

realm *realm_name*

Specifies the realm name as an alphanumeric string of 1 through 127 characters. The realm may typically be a company or service name.

application credit-control

Specifies the credit control application — DCCA or RADIUS.

peer *peer_id*

Specifies the peer ID of the Diameter endpoint route as an alphanumeric string of 1 through 63 characters.

weight *priority*

Specifies the priority for a peer in the route table as an integer from 0 through 255. Default: 10
The peer with the highest weight is used. If multiple peers have the highest weight, selection is by round-robin mechanism.

Usage

Use this command to create a route table for Diameter application.
When a Diameter client starts to establish a session with a realm/application, the system searches the route table for the best match. If an entry has no host specified, the entry is considered to match the requested value. Similarly, if an entry has no realm or application specified, the entry is considered to match any such requested value. The best match algorithm is to prefer specific matches for whatever was requested, either realm/application or host/realm/application. If there are no such matches, then system looks for route table entries that have wildcards.

Example

The following command creates a route entry with the host name *dcca_host1* and peer ID *dcca_peer* with priority weight of *10*:

```
route-entry host dcca_host1 peer dcca_peer weight 10
```

route-failure

This command controls what action is performed for the route table after failure or recovery after failure.

Product

All

Privilege

Security Administrator, Administrator

Syntax

route-failure { deadtime *seconds* **| recovery-threshold percent** *percentage* **| result-code** *result_code* **| threshold** *counter* **}**

default route-failure { deadtime | recovery-threshold | threshold }

no route-failure result-code *result_code*

no

Disables the route-failure configuration.

default

Configures the default setting for the specified parameter.

deadtime *seconds*

Specifies the time duration (in seconds) for which the system keeps the route in FAILED status. When this time expires, the system changes the status to AVAILABLE.
seconds must be an integer from 1 through 86400. Default: 60

recovery-threshold percent *percentage*

Specifies the percentage value at which the failure counter is reset when provisionally changing the status from FAILED to AVAILABLE.
For example, if a failure counter of 16 caused the status to change to FAILED. After the configured deadtime expires, the status changes to AVAILABLE. If this keyword is configured with 75 percent, the failure counter will be reset to 12 (75 percent of 16).
percentage must be an integer from 1 through 99. Default: 90

result-code *result_code*

Configures which answer messages are to be treated as failures, in addition to requests that time out. Up to 16 different result codes can be specified.
result_code must be an integer from 0 through 4294967295.

threshold *counter*

Configures the number of errors that causes the status to become FAILED. The counter value must be an integer from 0 through 4294967295. Default: 16
The error counter begins at zero, and whenever there is a good response it decrements (but not below zero) or increments (but not above this threshold).

Usage

Use this command to control how failure/recovery is performed for the route table. After a session is established, it is possible for the session to encounter errors or Diameter redirection messages that cause the Diameter protocol to re-use the route table to switch to a different route.
Each Diameter client within the chassis maintains counters relating to the status of each of its connections to different hosts (when the destination is realm/application without a specific host, the host name is kept as “”, i.e., blank).
Moreover, those counters are further divided according to which peer is used to reach each host. Each Diameter client maintains a status of each peer-to-host combination. Under normal good conditions the status will be AVAILABLE, while error conditions might cause the status to be FAILED.
Only combinations that are AVAILABLE will be used. If none are AVAILABLE, then system attempts the secondary peer if failover is configured and system can find an AVAILABLE combination there. If nothing is AVAILABLE, the system uses a FAILED combination.

Example

The following command configures the time duration for route failure to *90* seconds:

```
route-failure deadtime 90
```

server-mode

This command configures the Diameter endpoint to establish the system as the server side endpoint of the connection.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
server-mode [ demux-mode ]
```

demux-mode

Specifies that the Diameter proxy is to use the demux manager to identify the appropriate session manager. If this keyword is not enabled, the proxy will route the request directly to a session manager.

Usage

Use this command to configure the Diameter endpoint to establish this system as the server side endpoint of the connection. When the Diameter proxy receives an incoming request, the proxy identifies the endpoint for the request. If the system is in client mode, the proxy extracts the instance ID of the session manager which serves as the session-ID of the request. If this command is enabled, the extraction of the instance ID is disabled.

Example

The following command sets the system as the server side of the Diameter endpoint and instructs the Diameter proxy to use the demux manager to identify the appropriate session manager where the request is to be routed:

```
server-mode demux-mode
```

tls

This command enables/disables the Transport Layer Security (TLS) support between a Diameter client and Diameter server node.

Product

All

Privilege

Security Administrator, Administrator

Syntax

tls { certificate *certificate* **| password** *password* **| privatekey** *private_key* **}**

default tls

default

Disables the TLS support at Diameter endpoint.

certificate *certificate*

Specifies the certificate for TLS support. The certificate must appear encrypted, and must be an alphanumeric string of 700 through 900 characters.

password *password*

Specifies the password for TLS support. The password must be encrypted, and must be an alphanumeric string of 6 through 50 characters.

privatekey *private_key*

Specifies the private key for TLS support. The private key must be encrypted, and must be an alphanumeric string of 900 through 1500 characters.

Usage

Use this command to configure TLS support between a Diameter client and Diameter server node. By default, TLS is disabled.

Important: Both the Diameter client and server must be configured with TLS enabled or TLS disabled; otherwise, the Diameter connection will be rejected.

Example

The following commands enable the TLS between a Diameter client and Diameter server node:

```
tls certificate "-----BEGIN CERTIFICATE-----
\nMIICGDCCAYECAgEBMA0GCSqGSIb3DQEBBAUAMFcxCzAJBgNVBAYTAlVTMRMwEQYD\nVQQKE
wpSVEZNLCBJbmMuMRkwFwYDVQQLExBXaWRnZXRzIERpdmlzaW9uMRgwFgYD\nVQQDEw9UZXN0

```

use-proxy

This command enables/disables Diameter proxy for the Diameter endpoint. By default this command is disabled.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
use-proxy [ server-mode [ demux-mode ] ]

no use-proxy
```

no

Disables Diameter proxy for the current endpoint.
This command at endpoint level will equip an application to use Diameter proxy to route all its messages to an external peer.

server-mode

Specifies that the Diameter endpoint to establish the Diameter proxy as the server side endpoint of the connection.

demux-mode

Specifies that the Diameter endpoint to establish the Diameter proxy to use the Demux manager to identify the appropriate session manager. If this keyword is not enabled, the proxy will route the request directly to a session manager.
IPCF uses BindMux to identify the appropriate session manager.

Usage

Use this command to establish a Diameter proxy to route all its messages to an external peer. The proxy acts as an application gateway for Diameter. It gets the configuration information at process startup and decides which Diameter peer has to be contacted for each application. It establishes the peer connection upon finding no peer connection already exists.
IPCF uses Bindmux as a Demux manager to help distribute new incoming sessions across available Sessmgrs on the system.
All the incoming Diameter requests/responses land on Diamproxy. Diamproxy checks if a Sessmgr is already serving this session based on parameters like session-id and peer-id of the request/response.
If no Sessmgr is allocated to the request and the Demux mode is ON, the DiamProxy forwards the new request to Demux/Bindmux for sessmgr allocation. Demux/Bindmux has updated information about the load on all the Sessmgrs and assigns the optimal Sessmgr to the Diameter session. Once a Sessmgr is allocated for the session, a mapping of session-id to Sessmgr is added at Diamproxy. All further requests for this session will be directly routed to Sessmgr.
Each proxy task will automatically select one of the host names configured with the **origin host** command. Multiple proxy tasks will not use the same host names, so there should be at least as many host names as proxy tasks. Otherwise, some proxy tasks will not be able to perform Diameter functionality. The

chassis automatically selects which proxy tasks are used by which managers (i.e., ACSMgrs, Sessmgrs), without verifying whether the proxy task is able to perform Diameter functionality.
To be able to run this command, the Diameter proxy must be enabled. In the *Global Configuration Mode Commands* chapter, see the description of the **require diameter-proxy** command.

Example

The following command enables Diameter proxy for the current endpoint:

```
use-proxy
```

The following command disables Diameter proxy for the current endpoint:

```
no use-proxy
```

vsa-support

This command allows DIABASE to use vendor IDs configured in the dictionary for negotiation of the Diameter peers' capabilities regardless of the supported vendor IDs received in Capabilities-Exchange-Answer (CEA) messages.

Product

GGSN, PDSN

Privilege

Security Administrator, Administrator

Syntax

```
vsa-support { all-from-dictionary | negotiated-vendor-ids }

default vsa-support
```

default

Configures this command with the default setting.
Default: **negotiated-vendor-ids**

all-from-dictionary

Allows DIABASE to use the vendor IDs from the dictionary as indicated in the Capabilities-Exchange-Request (CER) messages from Diameter peers.

negotiated-vendor-ids

Allows DIABASE to use the supported vendor IDs satisfying capability negotiation.

Usage

Use this command to set DIABASE to use the vendor IDs from the dictionary or use the vendor IDs satisfying the capabilities negotiation.

Example

The following command enables DIABASE to use the vendor IDs specified in the dictionary:

```
vsa-support all-from-dictionary
```

watchdog-timeout

This command configures the Watchdog Timeout parameter.

Product

All

Privilege

Security Administrator, Administrator

Syntax

watchdog-timeout *timeout*

{ default | no } watchdog-timeout

no

Disables the watchdog timeout configuration.

default

Configures this command with the default setting.
Default: 30 seconds

timeout

Specifies the timeout duration (in seconds) as an integer from 6 through 30.

Usage

Use this command to configure the Watchdog Timeout parameter for the Diameter endpoint. If this timer expires before getting a response from the destination, other route to the same destination is tried, as long as the retry count setting has not exceeded (see the device-watchdog-request CLI command) and as long as the response timer has not expired (see the response-timeout CLI command).

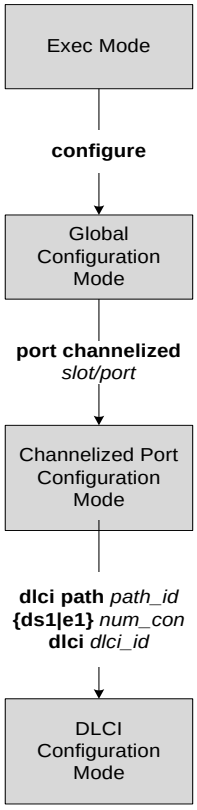
Example

The following command sets the watchdog timeout setting to *15* seconds:

```
watchdog-timeout 15
```

Chapter 101
DLCI Configuration Mode Commands

The DLCI configuration mode provides the commands to configure, bind and manage the DLCI associated with a specific port defined in the parent configuration mode, Channelized Port configuration mode.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

bind link

This command configures an association (binds) between an IP interface or a pre-configured routing SS7/Frame Relay link and the specific port being configured with the Channelized Port configuration commands.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

[no] bind link peer-nsei *nse_id* **ns-vci** *ns-vc_id*

peer-nsei *nse_id*

Defines the end-point network service entity identifier (NSEI). The NSEI must be an integer from 0 to 65535.

ns-vc-id *ns-vc_id*

Defines the network service virtual circuit identifier (NSVCI). The NSVCI must be an integer from 0 to 65535.

no

Deletes the bind configuration from the Operator Policy.

Usage

Bind this port to network service entity 2 and network service VC 234.

Example

```
bind link peer-nsei 2 ns-vci 234
```

end

Exits this sub-configuration mode and returns to the Exec mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Change the mode and return to the Exec mode.

exit

Exits the this sub-configuration mode and returns to the parent configuration mode.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Return to the previous configuration mode.

shaping

Defines egress traffic shaping to control flow for this DLCI.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

shaping *type*

default shaping

shaping *type*

The following types of shaping provide flow management:

- **cir:** Commited Info Rate
- **cir-eir:** Commited Info Rate with Excess Rate
- **ppr:** Peak Packet Rate
- **wfq:** Weighted Fair Queuing

default

Resets the DLCI configuration to the system default.

Usage

Use this command to identify the type of signal shaping to be used on the DLCI.

Example

shaping *cir*

shutdown

Terminates all processes supporting the port or blocks the shutting down of the port. Conversely, this command with the **no** keyword enables the port.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] shutdown
```

no

Enables the port's administrative state. When omitted the card is shutdown (removed from service).

Usage

Shut down a port prior to re-cabling and/or other maintenance activities.
This command with the **no** keyword is required to bring a port into service.

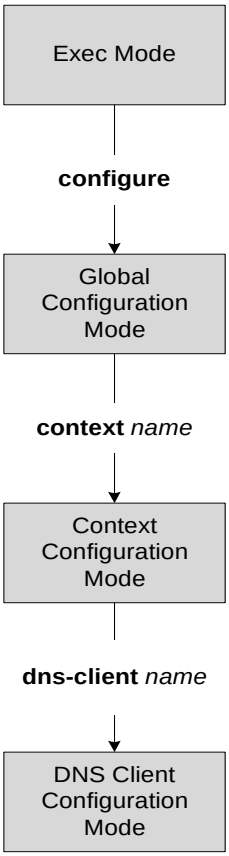
Example

Use the following command to disable the DLCI:

```
no shutdown
```

Chapter 102
DNS Client Configuration Mode Commands

The DNS Client Configuration Mode is used to manage the system's DNS interface and caching parameters.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

bind

Binds the DNS client to a pre-configured logical IP interface.

Product

MME, SCM, SGSN

Privilege

Security Administrator, Administrator

Syntax

bind { address *ip_address* **[port** *number* **] | query-over-gtp }**

no bind address

no

Removes the binding of the client to a specified interface.

bind address *ip_address*

Specifies the IP address of the interface to which the DNS client is being bound in IPv4 dotted-decimal notation.

bind port *number*

Specifies the UDP port number of the interface to which the DNS client is being bound as an integer from 1 to 65535. Default: 6011

bind query-over-gtp

Specifies that DNS client query is to be performed over GTP.

Usage

Use this command to associated the client with a specific logical IP address.

Example

The following command binds the DNS client to a logical interface with an IP address of *10.2.3.4* and a port number of *6000*:

```
bind address 10.2.3.4 port 6000
```

cache algorithm

Configures the method of use for the DNS VPN and session cache.

Product

MME, SCM, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
cache algorithm { central | local } { FIFO | LRU | LFU }

default cache algorithm { central | local }
```

default

Sets the DNS VPN and session cache method to default setting.

central | local

central: Specifies the central proclet (VPN manager)
local: Specifies the local proclet (session manager)

FIFO | LRU | LFU

FIFO: First in first out. This is the default setting for the central proclet.
LRU: Least recently used. This is the default value for the local proclet.
LFU: Least frequently used.

Usage

Use this command to configure the method by which entries are added and removed from the DNS cache.

Example

The following command configures the cache algorithm for the central proclet to least frequently used (LFU):

```
cache algorithm central lfu
```

cache size

Configures the maximum number of entries allowed in the DNS cache.

Product

MME, SCM, SGSN

Privilege

Security Administrator, Administrator

Syntax

cache size { central | local } *max_size*

default cache size { central | local }

default

Sets the maximum number of entries allowed in the DNS cache to default setting.

{ central | local } *max_size*

central *max_size*: Specifies the maximum number of entries allowed in the central proclet cache as an integer from 100 through 65535. Default: 50000.
local *max_size*: Specifies the maximum number of entries allowed in the local proclet cache as an integer from 100 through 65535. Default: 1000.

Usage

Use this command to configure the maximum number of entries allowed in the DNS cache.

Example

The following command configures the cache size of the central proclet to *20000*:

```
cache size central 20000
```

cache ttl

Configures the DNS cache time to live (TTL) for positive and negative responses.

Product

MME, SCM, SGSN

Privilege

Security Administrator, Administrator

Syntax

cache ttl { negative | positive } *seconds*

default cache ttl { negative | positive }

no cache [ttl { negative | positive }]

no

Disables any or all configured DNS cache parameters.

default

Sets the DNS cache time to live for positive and negative responses to the default setting.

{ negative | positive } *seconds*

negative *seconds*: Specifies the time to live for negative responses as an integer from 60 through 86400. Default: 60.
positive *seconds*: Specifies the time to live for positive responses. as an integer from 60 through 86400. Default: 86400 (1 day).

Usage

Use this command to adjust the DNS cache time to live.

Example

The following commands set the TTL DNS cache to *90* seconds for negative responses and *43200* seconds for positive responses:

```
cache ttl negative 90

cache ttl positive 43200
```

case-sensitive

Configures the case sensitivity requirement for responses to DNS requests.

Product

MME, SCM, SGSN

Privilege

Administrator

Syntax

```
[ default | no ] case-sensitive response
```

default

Returns the command to its default setting of disabled.

no

Disables the requirement for case sensitivity in DNS responses.

case-sensitive response

Enables the requirement for case sensitivity in DNS responses.

Usage

Use this command to require case sensitivity (identical case usage between request and response) on all responses to DNS request messages.

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

resolver

Configures the number of DNS query retries and the retransmission interval once the response timer expires.

Product

MME, SGSN

Privilege

Security Administrator, Administrator

Syntax

resolver { number-of-retries *retries* **| retransmission-interval** *time* **}**

default { number-of-retries | retransmission-interval }

default

Resets the specified resolver configuration to the default.

number-of-retries *retries*

Configures the number of DNS query retries on DNS response timeout as an integer from 0 through 4. Default: 2.

retransmission-interval *time*

Configures the initial retransmission interval (in seconds) for retransmission after the DNS response timeout as an integer from 2 to 5. Default is 3 seconds. The retransmission interval doubles after each retry when only one server is configured. In case both primary and secondary servers are configured, the retransmission time is doubled for the last retry.

Usage

Set the DNS retransmission retries or the retransmission interval. Issue the command twice to configure both parameters, one-at-a-time.

Example

The following command sets the DNS resolver retries to *4*:

```
resolver number-of-retries 4
```

round-robin answers

Configures the DNS client to return the DNS results in round-robin fashion if multiple results are available for a DNS query.

Product

MME, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no | default ] round-robin-answers
```

no

Removes the configured round robin method for DNS answer.

default

Disables the round robin method for DNS answer.

round-robin-answers

Enables the round robin method for DNS answer.

Usage

Use this command to configure the DNS client to return the DNS results in round-robin fashion if multiple results are available for a DNS query.

Example

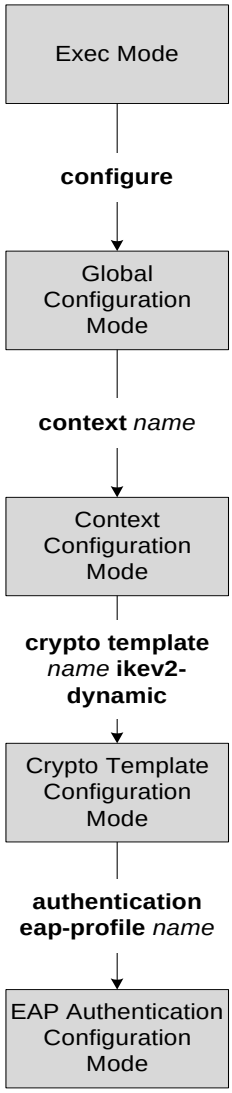
The following command configures the DNS client to use round robin method for DNS query answers:

```
default ] round-robin-answers
```

Chapter 103
EAP Authentication Configuration Mode Commands

The EAP Authentication Configuration Mode is used to configure the Extensible Authentication Protocol (EAP) authentication methods for the crypto template.

Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).



eap-aka

Configures shared key values for the Extensible Authentication Protocol-Authentication and Key Agreement (EAP-AKA) authentication method used by subscribers using this crypto template.

Product

PDIF

Privilege

Security Administrator, Administrator

Syntax

eap-aka { encrypted key *hex* **| key** *hex* **}**

encrypted key *hex*

Specifies that the shared key is to be encrypted as a 16-character alphanumeric string or a hexadecimal number beginning with “0x”.

key *hex*

Specifies that the shared key is to be transmitted in clear text as a 16-character alphanumeric string or a hexadecimal number beginning with “0x”.

Usage

Use this command to set shared key parameters for subscribers using the EAP-AKA authentication method.

Example

The following command configures a clear-text shared key value for the EAP-AKA method:

```
eap-aka key aa11223344556677
```

eap-gtc

Configures shared key values for the EAP-GTC authentication method used by subscribers using this crypto template.

Product

PDIF, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

eap-gtc { encrypted key *value* **| key** *value* **}**

encrypted key *value*

Specifies that the shared key is to be encrypted as a 16-character alphanumeric string.

key *value*

Specifies that the shared key is to be transmitted in clear text as a 16-character alphanumeric string.

Usage

Use this command to set shared key parameters for subscribers using the EAP-GTC authentication method.

Example

The following command configures a clear-text shared key value for the EAP-GTC method:

```
eap-GTC key aa11223344556677
```

eap-md5

Configures shared key values for the EAP-MD5 authentication method used by subscribers using this crypto template.

Product

PDIF, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
eap-md5 { encrypted key value | key value }
```

encrypted key *value*

Specifies that the shared key is to be encrypted as a 16-character alphanumeric string.

key *value*

Specifies that the shared key is to be transmitted in clear text as a 16-character alphanumeric string.

Usage

Use this command to set shared key parameters for subscribers using the EAP-MD5 authentication method.

Example

The following command configures a clear-text shared key value for the EAP-MD5 method:

```
eap-md5 key aa11223344556677
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

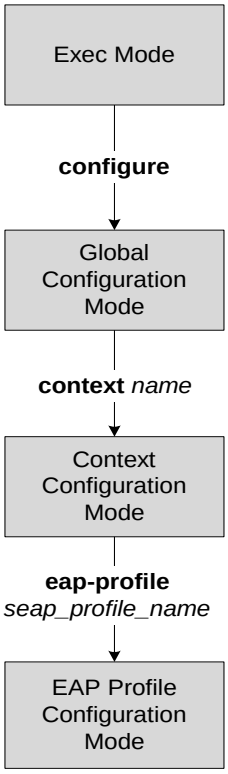
```
exit
```

Usage

Use this command to return to the parent configuration mode.

Chapter 104
EAP Configuration Mode Commands

The EAP Configuration Mode is used to configure parameters comprising an Extensible Authentication Protocol (EAP) used to support authentication on the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

max-retry

Configures the maximum number of times the system will retry communicating with another EAP device.

Product

PDIF, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

max-retry *num*

default max-retry

max-retry *num*

Specifies the number of times to retry EAP communication with another device as an integer from 1 to 65535. Default: 16

Usage

Use this command to set a maximum retry number for communicating with other EAP devices.

Example

The following command sets the maximum number of retries to *50*:

```
max-retry 50
```

mode

Configures the system as one of three types of EAP devices: authenticator pass-through, authenticator server, or peer.

Product

PDIF, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
mode { authenticator-pass-through | authenticator-server | peer }

default mode
```

default

Configures the default mode of Authenticator-pass-through.

authenticator-pass-through

Configures the system as an authenticator pass-through allowing EAP authentication to be performed by another server.
This is the default setting for this command.

authenticator-server

Configures the system as an authenticator server. This allows the system to respond to EAP requests.

peer

Configures the system as a peer device requiring it to make EAP requests of another server or pass-through device.

Usage

Use this command to configure the system to perform as one of three types of EAP devices and configure settings in an EAP mode.
EAP Mode Configuration Mode commands are defined in the EAP Mode Configuration Mode Commands chapter.

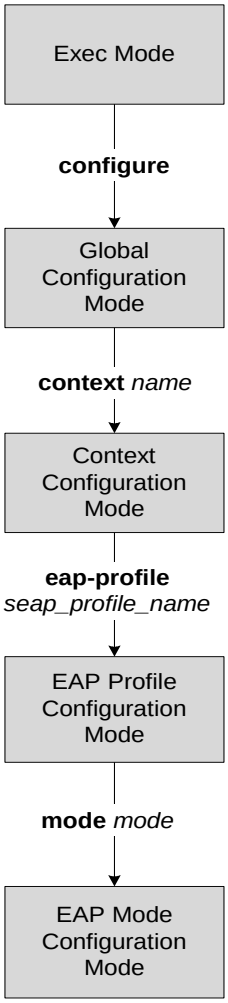
Example

The following command configures the system to perform as an authenticator pass-through:

```
mode authenticator-pass-through
```

Chapter 105
EAP Mode Configuration Mode Commands

The EAP Mode Configuration Mode is used to configure the Extensible Authentication Protocol (EAP) authentication method supported by the system.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

exit

Usage

Use this command to return to the parent configuration mode.

method

Configures the EAP method used for authentication.

Product

PDIF, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

method { eap-aka | eap-gtc | eap-md5 } [priority *num* **]**

eap-aka | eap-gtc | eap-md5

Specifies one of the following methods:

- **eap-aka**: Specifies that the EAP-AKA method is to be used for authentication.
- **eap-gtc**: Specifies that the EAP-GTC method is to be used for authentication.
- **eap-md5**: Specifies that the EAP-MD5 method is to be used for authentication.

priority *num*

Specifies a priority order for a specific EAP authentication method an integer from 1 though 65535.

Usage

Use this command to specify the EAP authentication method(s) to use and to place multiple methods in priority order.

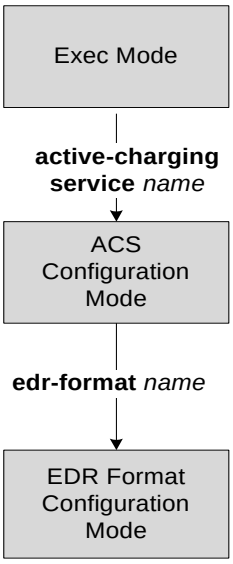
Example

The following command sets EAP-AKA as one of the EAP authentication methods and places it as priority of 3:

```
method eap-aka priority 3
```

Chapter 106
EDR Format Configuration Mode Commands

The EDR Format Configuration Mode enables configuring Event Data Record (EDR) formats.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

attribute

This command allows you to specify the fields and their order in EDRs.

Product

All

Privilege

Security Administrator, Administrator

Syntax

attribute *attribute* **{ [format { MM/DD/YY-HH:MM:SS | MM/DD/YYYY-HH:MM:SS | YYYY/MM/DD-HH:MM:SS | YYYYMMDDHHMMSS | seconds }] [localtime] | [{ ip | tcp } { bytes | pkts } { downlink | uplink }] priority** *priority* **}**

no attribute *attribute* **[{ ip | tcp } { bytes | pkts } { downlink | uplink }] [priority** *priority* **]**

no

If added previously, removes the specified attribute from the EDR format.

attribute

Specifies the attribute.
attribute must be one of the following:

Attributes	Description
radius-called-station-id	This attribute reports the Called Station ID of the mobile handling the flow.
radius-calling-station-id	This attribute reports the Calling Station ID of the mobile handling the flow.
radius-fa-nas-identifier	This attribute reports the RADIUS NAS identifier of Foreign Agent (FA).
radius-fa-nas-ip-address	This attribute reports the RADIUS IP address of Foreign Agent (FA).
radius-nas-identifier	This attribute reports the RADIUS NAS identifier.
radius-nas-ip-address	This attribute reports the RADIUS NAS IP address.
radius-user-name	This attribute reports the user name associated with the flow.
sn-3gpp2-always-on	This option has been deprecated. To configure this attribute see the rule-variable command.
sn-3gpp2-bsid	This option has been deprecated. To configure this attribute see the rule-variable command.
sn-3gpp2-esn	This option has been deprecated. To configure this attribute see the rule-variable command.

Attributes	Description
sn-3gpp2-ip-qos	This option has been deprecated. To configure this attribute see the rule-variable command.
sn-3gpp2-ip-technology	This option has been deprecated. To configure this attribute see the rule-variable command.
sn-3gpp2-release-indicator	This option has been deprecated. To configure this attribute see the rule-variable command.
sn-3gpp2-service-option	This option has been deprecated. To configure this attribute see the rule-variable command.
sn-3gpp2-session-begin	This option has been deprecated. To configure this attribute see the rule-variable command.
sn-3gpp2-session-continue	This option has been deprecated. To configure this attribute see the rule-variable command.
sn-acct-session-id	This attribute reports the unique session identifier for accounting.

Attributes	Description
sn-app-protocol	This attribute reports the application protocol for the flow. A value indicating the protocol, such as one of the following: • ACS_PROTO_UNKNOWN = 0 • ACS_PROTO_GTP = 1 • ACS_PROTO_IP = 2 • ACS_PROTO_TCP = 3 • ACS_PROTO_UDP = 4 • ACS_PROTO_HTTP = 5 • ACS_PROTO_HTTPS = 6 • ACS_PROTO_FTP = 7 • ACS_PROTO_FTP_CONTROL = 8 • ACS_PROTO_FTP_DATA = 9 • ACS_PROTO_WTP = 10 • ACS_PROTO_WSP = 11 • ACS_PROTO_WTP_WSP_CONNECTION_ORIENTED = 12 • ACS_PROTO_WSP_CONNECTION_LESS = 13 • ACS_PROTO_DNS = 14 • ACS_PROTO_ICMP = 15 • ACS_PROTO_POP3 = 16 • ACS_PROTO_SIP = 17 • ACS_PROTO_SDP = 18 • ACS_PROTO_SMTP = 19 • ACS_PROTO_EMAIL = 20 • ACS_PROTO_MMS = 21 • ACS_PROTO_FILE_TRANSFER = 22 • ACS_PROTO_WWW = 23 • ACS_PROTO_RTP = 24 • ACS_PROTO_RTSP = 25 • ACS_PROTO_IMAP = 26 • ACS_PROTO_FLOW = 27 • ACS_PROTO_CCA = 28 • ACS_PROTO_P2P = 29 • ACS_PROTO_RTCP = 30 • ACS_PROTO_ICMPV6 = 31 • ACS_PROTO_TFTP = 32 • ACS_PROTO_PPTP = 33

Attributes	Description
	• ACS_PROTO_GREv1 = 34 • ACS_PROTO_PPTP_GRE = 35 • ACS_PROTO_SIP_ADV = 36 • ACS_PROTO_SIP_BASIC_ADV = 37 • ACS_PROTO_H323 = 38
sn-cf-category-classification-used	For Category-based Content Filtering, this attribute reports the last classification used by system for the flow, or blank if classification was never successfully performed. For URL Blacklisting, specifies category of the blacklisted URL in the Blacklist database.
sn-cf-category-flow-action	For Category-based Content Filtering, this attribute reports the last action taken for the flow, or blank if content filtering was never performed. The following are the possible values: • allow • content-insert • discard • redirect-url • terminate-flow For URL Blacklisting, this attribute reports the last action taken for the flow, or blank if Blacklist matching was never performed. The following are the possible values: • discard • terminate-flow • redirect-url • www-reply-code-terminate-flow
sn-cf-category-policy	For Category-based Content Filtering, this attribute reports the category policy identifier that was used for the flow, or blank if content filtering was never attempted for the flow.
sn-cf-category-rating-type	For Category-based Content Filtering, this attribute reports the type, either “static” or “dynamic” that was last successfully performed for the flow, or blank if content filtering was never successful for the flow. For URL Blacklisting, specifies “blacklisting”.
sn-cf-category-unknown-url	This attribute reports the identifier for unknown URL under content filtering action. It holds either “1” for unknown URLs or “0” for the URLs having static rating in its database.
sn-charge-volume	This attribute reports the total charge volume excluding bytes/packets dropped/retransmitted by ECS. This behavior can be changed by configuring to allow dropped/retransmitted bytes/packets to be included in the net volume. See the **edr sn-charge-volume** command in the *ACS Rulebase Configuration Mode Commands* chapter.

Attributes	Description
sn-closure-reason	This attribute reports the reason for termination of the flow/EDR: • 0: Normal end of flow • 1: End of flow by handoff processing • 2: Subscriber session terminated • 3: Inter-chassis Session Recovery switchover • 12: Completion of transaction
sn-correlation-id	This attribute reports the RADIUS correlation identifier.
sn-direction	This attribute reports the direction of the first packet for the flow. It has following values: • **toMobile**: This value appears when direction of first packet is towards mobile node. • **fromMobile**: This value appears when direction of first packet is towards mobile node. • **unknown**: This value appears when the original originator of a flow can not be determined (for example, a flow that is interrupted due to a Inter-chassis Session Recovery switchover).
sn-duration	This attribute reports the duration between the last and first packet for the record.
sn-end-time [format *format* **] localtime**	This attribute reports the timestamp for last packet of flow in UTC.
sn-fa-correlation-id	This attribute reports the RADIUS Correlation Identifier of the Foreign Agent (FA).
sn-fa-ip-address	This attribute reports IP address of the Foreign Agent (FA).
sn-filler-blank	This attribute inserts a blank filler field, generates an empty EDR field.
sn-filler-zero	This attribute inserts a “0” in the EDR field.
sn-flow-end-time	This attribute reports the time of flow-end EDR generation—when EDRs are generated at hagr, session-end, timeout, or normal-end-signaling conditions. **sn-start-time** and **sn-end-time** fields of flow end-condition EDRs cannot be used to determine the duration of the flow if intermediate EDRs are generated (rule-match or transaction-complete or any other intermediate EDR). **sn-start-time** field in an EDR gives the time the first packet was received after the last EDR was generated. So, whenever an EDR is generated, this field is reset to the time the EDR gets generated. So the **sn-start-time** field in flow end-condition EDRs may not have the time of the first packet received on that flow. It will have the time at which the last EDR was generated or the first packet time if no EDR was generated for that flow. **sn-end-time** field gives the time at which the last packet on the flow was received. Flow end-condition EDRs may not be generated immediately after receiving the last packet. For example, in case of session-end or timeout EDRs, last packet time and EDR generation time may be different. **sn-flow-start-time** gives the time of the first packet of the flow (irrespective of whether intermediate EDRs were generated), and **sn-flow-end-time** gives the time when EDRs are generated at hagr, session-end, timeout or normal-end-signaling conditions. The values of these fields will be populated in EDRs only for hagr, session-end, timeout and normal-end-signaling EDRs.
sn-flow-id	This attribute reports the flow-id assigned internally by the ECS module to each flow.

Attributes	Description
sn-flow-start-time	This attribute reports the time of the first packet of the flow (irrespective of whether intermediate EDRs were generated). Also see, **sn-flow-end-time**.
sn-format-name	This attribute reports the name of the EDR/UDR format used.
sn-group-id	This attribute reports the sequence group ID of the record.
sn-ha-ip-address	This attribute reports IP address of the Home Agent (HA).
sn-nat-binding-timer	For Network Address Translation (NAT) in-line service, this attribute reports the port chunk hold timer.
sn-nat-gmt-offset	For NAT in-line service, this attribute reports the GMT offset of the node generating NAT bind record.
sn-nat-ip	For NAT in-line service, this attribute reports the NAT IP address of the port chunk.
sn-nat-last-activity-time-gmt	For NAT in-line service, this attribute reports the time when the last flow in a specific NAT set of flows was seen.
sn-nat-port-block-end	For NAT in-line service, this attribute reports the last port number of the port chunk.
sn-nat-port-block-start	For NAT in-line service, this attribute reports the starting port number of the port chunk.
sn-nat-port-chunk-alloc-dealloc-flag	For NAT in-line service, this attribute reports whether the port chunk is allocated or released.
sn-nat-port-chunk-alloc-time-gmt	For NAT in-line service, this attribute reports when the port chunk was allocated.
sn-nat-port-chunk-dealloc-time-gmt	For NAT in-line service, this attribute reports when the port chunk was released.
sn-nat-realm-name	For NAT in-line service, this attribute reports the name of the NAT realm.
sn-nat-subscribers-per-ip-address	For NAT in-line service, this attribute reports the subscriber(s) per NAT IP address.
sn-parent-protocol	This attribute reports the parent protocol of the flow. An integer value like in **sn-app-protocol**; for RTCP/RTP flows, the parent protocol may be RTSP or SIP; for GRE flows, the parent protocol will be PPTP, and so on.
sn-rulebase	This attribute reports the name of the ECS rulebase applied.
sn-sequence-no	This attribute reports the unique sequence number (per **sn-sequence-group** and **radius-nas-ip-address**) of EDR identifier and linearly increasing in EDR file.
sn-server-port	This attribute reports the TCP/UDP port number of the server in a subscriber's data flow.
sn-start-time [format *format* **] localtime**	This attribute reports the timestamp for last packet of flow in UTC.
sn-subscriber-nat-flow-ip	For NAT in-line service, this attribute reports the NAT IP address of NAT-enabled subscriber.
sn-subscriber-nat-flow-port	For NAT in-line service, this attribute reports the NAT port number of NAT-enabled subscriber.

Attributes	Description
sn-subscriber-port	This attribute reports the TCP/UDP port number of the Mobile handling subscriber data flow.
sn-volume-amt { ip | tcp } { bytes | pkts } { uplink | downlink }	This attribute reports IP/TCP protocol-specific volume amount of downlink/uplink bytes/packets during a flow. This includes all the bytes/packets received by ECS, including the bytes/packets dropped and retransmitted by ECS.
sn-volume-dropped-amt { ip | tcp } { bytes | packets } { downlink | uplink }	For Stateful Firewall in-line service, this attribute reports IP/TCP protocol-specific volume amount of downlink/uplink bytes/packets dropped by Stateful Firewall during a flow.
sn-volume-ip-with-rtsp-or-rtp bytes { downlink | priority | uplink }	This attribute reports the IP volume amount of downlink/uplink bytes of an RTSP flow and the RTP flows controlled by it, or Comma Separated Value (CSV) position priority of this field. If **uplink** or **downlink** is not specified it shows the total of both.
transaction-downlink-bytes	This attribute reports the total downlink bytes for the transaction.
transaction-downlink-packets	This attribute reports the total downlink packets for the transaction.
transaction-uplink-bytes	This attribute reports the total uplink bytes for the transaction.
transaction-uplink-packets	This attribute reports the total uplink packets for the transaction.

format { MM/DD/YY-HH:MM:SS | MM/DD/YYYY-HH:MM:SS | YYYY/MM/DD-HH:MM:SS | YYYYMMDDHHMMSS | seconds }

Specifies the timestamp format.

localtime

Specifies timestamps with the local time. By default, timestamps are displayed in GMT/UTC.

{ ip | tcp } { bytes | pkts } { downlink | uplink }

Specifies bytes/packets sent/received from/by mobile.

priority *priority*

Specifies the position priority of the value within the EDR record. Lower numbered priorities (across all attribute, event-label, and rule-variable) occur first.
priority must be an integer from 1 through 65535. Up to 50 position priorities (across all attribute, event-label, and rule-variable) can be configured.

Usage

Use this command to set the attributes and priority for EDR file format.
A particular field in EDR format can be entered multiple times at different priorities. While removing the EDR field using the **no attribute** command either you can remove all occurrences of a particular field by specifying the field name or a single occurrence by additionally specifying the optional **priority** keyword.

Example

The following is an example of this command:

```
attribute radius-user-name priority 12
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

event-label

This command allows you to specify an optional event label/identifier to be used as an attribute in the EDRs.

Product

All

Privilege

Security Administrator, Administrator

Syntax

event-label *event_label* **priority** *priority*

no event-label

no

If previously configured, removes the event label configuration.

event_label

Specifies the event label/identifier to be used as EDR attribute.
event_label must be an alphanumeric string of 1 through 63 characters.

priority *priority*

Specifies the Comma Separated Value (CSV) position of the attribute (label/identifier) in the EDR.
priority must be an integer from 1 through 65535.

Usage

Use this command to configure an optional event label/identifier as an attribute in the EDR and its position in the EDR.

Example

The following is an example of this command:

```
event-label radius_csv1 priority 23
```

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

rule-variable

This command allows you to specify fields and their order in EDRs.

Product

All

Privilege

Security Administrator, Administrator

Syntax

rule-variable *rule_variable* **priority** *priority* **[in-quotes]**

no rule-variable *rule_variable* **[priority** *priority* **]**

---

no

If previously configured, removes the specified rule variable configuration.

---

rule_variable

Specifies the rule variable for the EDR format.
rule_variable must be one of the following options:

- **bearer 3gpp**: 3GPP bearer-related fields:
  - **charging-id**: Charging ID of the bearer flow
  - **imei**: IMEI or IMEISV (depending on the case) associated with the bearer flow. Only available in StarOS 8.1 and later releases.
  - **imsi**: Specific Mobile Station Identification number.
  - **rat-type**: RAT type associated with the bearer flow. Only available in StarOS 8.1 and later releases.
  - **sgsn-address**: SGSN associated with the bearer flow. Only available in StarOS 8.1 and later releases. For MIPv6 calls, sgsn-address field is populated with HSGW address.
  - **user-location-information**: User location information associated with the bearer flow. Only available in StarOS 8.1 and later releases.
- **bearer 3gpp2**: 3GPP2 bearer-related fields:
  - **always-on**: 3GPP2 always on indicator
  - **bsid**: 3GPP2 BSID
  - **esn**: 3GPP2 ESN
  - **ip-qos**: 3GPP2 IP QoS
  - **ip-technology**: 3GPP2 IP technology
  - **release-indicator**: 3GPP2 release indicator
  - **service-option**: 3GPP2 service option
  - **session-begin**: 3GPP2 session begin indicator
  - **session-continue**: 3GPP2 session continue indicator

- **bearer ggsn-address**: GGSN IP address field. For MIPv6 calls, ggsn-address field in EDR will be populated with PGW address.
- **dns**: Domain Name System (DNS) related fields:
  - **answer-name**: DNS answer name. This depends upon query type.
  - **previous-state**: DNS previous state information
  - **query-name**: DNS query name
  - **return-code**: DNS query response code
  - **state**: DNS current state information
  - **tid**: DNS Transaction Identifier
- **file-transfer**: File Transfer related fields:
  - **chunk-number**: Number of chunks
  - **current-chunk-length**: Length of current chunk
  - **declared-chunk-length**: Declared size of the chunk
  - **declared-file-size**: Declared size of the file
  - **filename**: Name of the file being transferred
  - **previous-state**: Previous state of session
  - **state**: Current state of session
  - **transferred-file-size**: Transferred size of the file
- **flow**:Flow related fields:
  - **tethered**: Tethering detected on flow. Enables/disables tethering detection result field in EDRs sent to MUR.
- **ftp**: File Transfer Protocol (FTP) related fields:
  - **client-ip-address**:
  - **client-port**
  - **command name**: Command sent
  - **connection-type**
  - **filename**: File name being transferred in any of the FTP-related FTP command
  - **pdu-length**: FTP PDU length
  - **pdu-type**
  - **previous-state**: Previous state of FTP session
  - **reply code**
  - **server-ip-address**
  - **server-port**
  - **session-length**: Total length of FTP session
  - **state**: Current state of FTP session
  - **url**: URL of file
  - **user**: User identifier

- **http**: Hypertext Transport Protocol (HTTP) related fields:
  - **ad-delivered**: advertisement delivered using TPO text-with-click
  - **ad-replaced**: advertisement replaced with TPO 0-byte response
  - **attribute-in-data**: dynamic header field in application payload
  - **attribute-in-url**: dynamic header field in URL
  - **compression-bytes-in**: TPO compression bytes in
  - **compression-bytes-out**: TPO compression bytes out
  - **content disposition**
  - **content length**
  - **content type**
  - **domain**
  - **dns-resolution-locally**: TPO DNS resolution done locally
  - **dns-resolution-remotely**: TPO DNS resolution done remotely
  - **header-length**: HTTP header length
  - **host**
  - **payload-length**: Payload length
  - **pdu-length**
  - **previous-state**: Previous state of session
  - **referer**
  - **reply code**: HTTP response
  - **request method**: HTTP request method
  - **session-length**: Total length of HTTP session
  - **state**: Current state of session
  - **tpo-enabled**: TPO enabled/disabled for HTTP
  - **transaction-length**: Total length of HTTP transaction
  - **transfer-encoding**: Transfer encoding
  - **uri**: Uniform Resource Identifier
  - **url**: Uniform Resource Locator
  - **user-agent**
  - **version**
  - **x-header**: extension header
- **icmp**: Internet Control Message Protocol (ICMP) related fields:
  - **code**: ICMP code
  - **type**: ICMP type
- **icmpv6**: Internet Control Message Protocol Version 6 (ICMPv6) related fields:
  - **code**: ICMPv6 code
  - **type**: ICMPv6 type

- **imap**: Internet Message Access Protocol (IMAP) related fields:
  - **cc**: IMAP e-mail CC field
  - **command**: IMAP command
  - **content**
  - **date**: IMAP e-mail Date field
  - **final-reply**: IMAP final reply
  - **from**: IMAP e-mail From field
  - **mail-size**: IMAP size of e-mail in RFC822 format
  - **mailbox-size**: IMAP number of e-mails in the mailbox
  - **message-type**: IMAP message type
  - **previous-state**: IMAP session previous state
  - **session-length**: IMAP session length
  - **session-previous-state**: IMAP session previous state
  - **session-state**: IMAP session state
  - **state**: IMAP state
  - **subject**: IMAP e-mail Subject field
  - **to**: IMAP e-mail To field
- **ip**: Internet Protocol (IP) related fields:
  - **dst-address**: destination IP address
  - **protocol**: Protocol being transported by IP packet
  - **server-ip-address**: IP address of server. This field in EDR contains either the IPv4 or IPv6 address of the server for a particular flow (flow level). The maximum length of this field is 48 characters. For an IPv6 address, the maximum length is 45 characters; for an IPv4 address, the maximum length is 15 characters.
  - **src-address**: Source IP address
  - **subscriber-ip-address**: IP address of subscriber. This field in EDR contains either the IPv4 or IPv6 address of the client/subscriber for a particular call (subscriber level). The value of this field does not change for a particular call. The maximum length of this field is 48 characters. For an IPv6 address, the maximum length is 45 characters. For an IPv4 address, the maximum length is 15 characters.
  - **total-length**: Total length of packet, including payload
  - **version**: IP version
- **mms**: Multimedia Message Service (MMS) related fields:
  - **bcc**
  - **cc**
  - **content location**
  - **content type**
  - **date [format { MM/DD/YYYY-HH:MM:SS | YYYY/MM/DD-HH:MM:SS }]**
  - **from**

- **message-size**
- **previous-state**
- **response status**
- **state**
- **subject**
- **tid**
- **to**

- **p2p protocol:** Peer-to-peer protocol field.
- **pop3**: Post Office Protocol version 3 (POP3) related fields:
  - **command name**: Command of POP3 session
  - **mail-size**: Mail size
  - **pdu-length**: Length of POP3 PDU
  - **pdu-type**: Type of packet
  - **previous-state**: Previous state of POP3 session
  - **reply status**: Reply for the POP3 command
  - **session-length**: Total length of POP3 session
  - **state**: Current state of POP3 session
  - **user-name**: User of POP3 session
- **rtcp:** RTP Control Protocol (RTCP) related fields:
  - **control-session-flow-id**: Flow ID of the controlling RTSP/SIP session
  - **jitter**: RTCP interarrival jitter
  - **rtsp-id**: RTSP ID of the RTCP flow
  - **uri**: URI of the control protocol related to the RTCP flow
- **rtp**: Real-time Transfer Protocol (RTP) related fields:
  - **control-session-flow-id**: Flow ID of the controlling RTSP/SIP session
  - **pdu-length**: Length of RTP PDU
  - **rtsp-id**: RTSP ID of the flow
  - **session-length**: Total length of RTP session
  - **uri**: URI of the control protocol related to the RTP flow
- **rtsp**: Real Time Streaming Protocol (RTSP) related fields:
  - **command-id**: RTSP command ID
  - **content type**
  - **date**: RTSP Date field
  - **previous-state**: RTSP previous state
  - **reply code**
  - **request method 1**: play method
  - **request method 2**: setup method

- **request method 3**: pause method
- **request method 4**: record method
- **request method 5**: options method
- **request method 6**: redirect method
- **request method 7**: describe method
- **request method 8**: announce method
- **request method 9**: teardown method
- **request method 10**: get-parameter method
- **request method 11**: set-parameter method
- **request packet**
- **rtp-uri**: RTSP RTP-Info stream-uri field
- **session-id**: RTSP session-id field
- **session-length**: Total number of bytes passed through the RTSP data session
- **state**: RTSP state
- **uri**: RTSP uri field
- **uri sub-part**
- **user-agent**: RTSP user-agent field

- **sdp**: Session Description Protocol (SDP) related fields:
  - **connection-ip-address**: IP address in SDP connection field
  - **media-audio-port**: Port used for audio media
  - **media-video-port**: Port used for video media
- **secure-http**: HTTPS related field.
- **sip**: Session Initiation Protocol (SIP) related fields:
  - **call-id**: SIP call-id field
  - **content type**
  - **from**: SIP From field
  - **previous-state**: SIP previous state
  - **reply code**
  - **request method**
  - **request packet**
  - **state**: SIP state
  - **to**: SIP To field
  - **uri**: SIP URI field
  - **uri sub-part**
- **smtp**: Simple Mail Transfer Protocol (SMTP) related fields:
  - **command name**: Command of SMTP session
  - **mail-size**: Size of given mail

- **pdu-length**: Length of SMTP PDU
- **previous-state**: Previous state of SMTP session
- **recipient**: SMTP e-mail Recipient field
- **reply status**: Response for the SMTP command
- **sender**: SMTP e-mail Sender field
- **session-length**: Total length of SMTP session
- **state**: Current state of SMTP session

- **tcp**: Transmission Control Protocol (TCP) related fields:
  - **dst-port**: TCP destination port
  - **duplicate**: TCP retransmitted/duplicate packet
  - **flag**: Current packet TCP flag
  - **os-signature**: OS signature string for TCP flow. Enables/disables OS Signature field in EDRs sent to MUR.
  - **out-of-order**: TCP out of order packet analyzed
  - **payload-length**: TCP payload length
  - **previous-state**: Previous state of MS
  - **src-port**: TCP source port
  - **state**: Current state of MS
  - **tpo-enabled**: TPO enabled/disabled for TCP
- **traffic-type**: Traffic type of flow (voice or non-voice depending upon flow type).
- **udp**: User Datagram Protocol (UDP) related fields:
  - **dst-port**: UDP destination port
  - **src-port**: UDP source port
- **voip-duration**: Duration of voice call, in seconds. For a flow in which voice call end is detected, output will be a non-zero value. For other flows it will be zero.
- **wsp**: Wireless Session Protocol (WSP) related fields:
  - **content type**
  - **domain**: WSP domain name
  - **host**: WSP host name
  - **pdu-length**: WSP PDU length
  - **pdu-type**: WSP PDU type
  - **reply code**
  - **session-length**: WSP total packet length
  - **tid**: WSP transaction identifier
  - **total-length**: WSP total packet length
  - **url**: WSP URL
  - **user-agent**: WSP user agent

- **wtp**: Wireless Transaction Protocol (WTP) related fields:
  - **gtr**: Group Transmission Flag
  - **pdu-length**: PDU length of the WTP packet
  - **pdu-type**: WTP protocol data unit information
  - **previous-state**: WTP previous state information
  - **state**: WTP current state information
  - **tid**: WTP transaction identifier
  - **transaction class**: WTP transaction class
  - **ttr**: WTP Trailer Transmission flag

Important: For more information on protocol-based rules, see the *ACS Ruledef Configuration Mode Commands* chapter.

priority *priority*

Specifies the CSV position of the field (protocol rule) in the EDR.
priority must be an integer from 1 through 65535.

in-quotes

Specifies placing double quotes (“ ”) around the specified field in the EDR.

Important: In this release, this keyword is only valid for the MMS protocol **to** and **subject** fields. **rule-variable mms to priority** *priority* **[in-quotes] rule-variable mms subject priority** *priority* **[in-quotes]**

Usage

Use this command to specify what field appears in which order in the EDR.
A particular field in an EDR format can be entered multiple times with different priorities. While removing the EDR field using the **no rule-variable** command you can remove all occurrences of a particular field by specifying the field name or a single occurrence by additionally specifying the optional **priority** keyword.

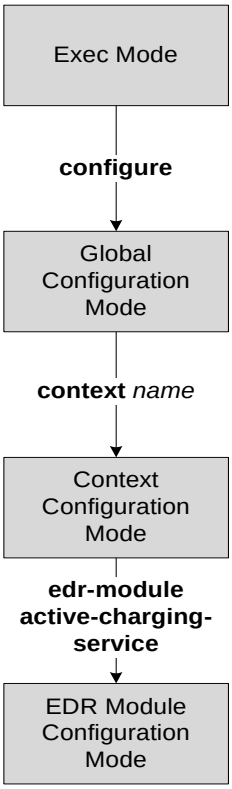
Example

The following is an example of this command:

```
rule-variable tcp dst-port priority 36
```

Chapter 107
EDR Module Configuration Mode Commands

The EDR Module Configuration Mode allows you to configure Event Data Record (EDR) file transfer parameters.



Important: The commands or keywords/variables that are available are dependent on platform type, product version, and installed license(s).

cdr

This command allows you to configure EDR/UDR file transfer parameters.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
cdr { purge { storage-limit storage_limit | time-limit time_limit } [ max-files
max_records_to_purge ] | push-interval push_interval | push-trigger space-usage-percent
trigger_percentage | remove-file-after-transfer | transfer-mode { pull [ module-only ] |
push primary { encrypted-url encrypted_url | url url } [ [ max-files max_records ] [
module-only ] [ secondary { encrypted-secondary-url encrypted_secondary_url | secondary-
url secondary_url } ] [ via local-context ] + ] | use-harddisk }

default cdr [ purge | push-interval | push-trigger space-usage-percent | remove-file-
after-transfer | transfer-mode [ module-only | push via ] | use-harddisk ] +

no cdr [ purge | remove-file-after-transfer | use-harddisk ] +
```

default

Configures the default setting for the specified keyword(s):

- **purge**: Disabled
- **push-interval**: 300 seconds
- **push-trigger**: 80 percent
- **remove-file-after-transfer**: Disabled
- **transfer mode**: Pull
- **push via**: LC is used for push
- **use-harddisk**: Disabled

Important: The **use-harddisk** keyword is available only on the ASR 5000 chassis.

no

If previously configured, disables the specified configuration:

- **purge**: Disables purging of records.
- **remove-file-after-transfer**: Retains a copy of the file even after it has been pushed or pulled to another server.
- **use-harddisk**: Disables data storage on the SMC hard disk.

Important: The **use-harddisk** keyword is available only on the ASR 5000 chassis.

purge { storage-limit *storage_limit* **| time-limit** *time_limit* **} [max-files** *max_records_to_purge* **]**

Specifies to purge/delete the CDR/EDR records based on "time" or "volume" limit.

- **storage-limit** *storage_limit*: Specifies to start deleting files when the specified megabytes of space is used for storage. *storage_limit* specifies the volume limit for the record files, in megabytes, and must be an integer from 10 through 143360.
- **time-limit** *time_limit*: Specifies to start deleting files older than the specified time limit. *time_limit* specifies the time limit for the record files, and must be an integer from 600 through 2592000.
- **max-files** *max_records_to_purge*: Specifies the maximum number of records to purge. *max_records_to_purge* must be an integer from 1000 through 10000.

push-interval *push_interval*

Specifies the transfer interval (in seconds) to push EDR and UDR files to an external file server. *push_interval* must be an integer from 60 through 3600.
Default: 300

push-trigger space-usage-percent *trigger_percentage*

Specifies the EDR/UDR disk space utilization percentage, upon reaching which an automatic push is triggered and files are transferred to the configured external server.
trigger_percentage specifies the EDR/UDR disk utilization percentage for triggering push, and must be an integer from 10 through 80.
Default: 80

remove-file-after-transfer

Specifies that the system must delete EDR/UDR files after they are transferred to the external file server.
Default: Disabled

transfer-mode { pull [module-only] | push primary { encrypted-url *encrypted_url* **| url** *url* **} [[max-files** *max_records* **] [module-only] [secondary { encrypted-secondary-url** *encrypted_secondary_url* **| secondary-url** *secondary_url* **}] [via local-context] +]**

Specifies the EDR/UDR file transfer mode—how the EDR and UDR files are transferred to an external file server.

- **pull**: Specifies that the L-ESS is to pull the CDR files.
- **push**: Specifies that the system is to push CDR files to the configured L-ESS.
- **max-files** *max_records*: Specifies the maximum number of files sent per iteration based on configured file size.

  Default: 4000
- **module-only**: Specifies that the transfer-mode is only applicable to the EDR module; if not configured it is applicable to both EDR and UDR modules. This enables to support individual record transfer-mode configuration for each module.
- **primary encrypted-url** *encrypted_url*: Specifies the primary URL location in encrypted format to which the system pushes the CDR files.

  encrypted_url must be the location in an encrypted format, and must be an alphanumeric string of 1 through 1024 characters.

- **primary url** *url*: Specifies the primary URL location to which the system pushes the CDR files.

  url must be the location, and must be an alphanumeric string of 1 through 1024 characters in the "*//user:password@host:[port]/directory*" format.

- **secondary encrypted-secondary-url** *encrypted_secondary_url*: Specifies the secondary URL location in encrypted format to which the system pushes the CDR files when the primary location is unreachable or fails.

  encrypted_secondary_url must be the secondary location in an encrypted format, and must be an alphanumeric string of 1 through 1024 characters in the "*//user:password@host:[port]/directory*" format.

- **secondary secondary-url** *secondary_url*: Specifies the secondary location to which the system pushes the CDR files when the primary location is unreachable or fails.

  secondary_url must be the secondary location, and must be an alphanumeric string of 1 through 1024 characters in the "*//user:password@host:[port]/directory*" format.

- **via local-context**: Configuration to select LC/SPIO for transfer of CDRs. The system pushes the EDR files via SPIO in the local context.

use-harddisk

Important: The **use-harddisk** keyword is available only on the ASR 5000 chassis.

Specifies that on the ASR 5000 chassis the hard disk on the SMC be used to store EDR/UDR files. On configuring to use the hard disk for EDR/UDR storage, EDR/UDR files are transferred from packet processing cards to the hard disk on the SMC. Default: Disabled

+

Indicates that more than one of the previous keywords can be entered within a single command.

Usage

Use this command to configure how the charging data records (CDR) are moved and stored.
On the ASR 5000 chassis, you must run this command only from the local context. If you run this command in any other context it will fail and result in an error message.
If PUSH transfer mode is configured, the L-ESS server URL to which the CDR files need to be transferred to must be specified. The configuration allows a primary and a secondary server to be configured. Configuring the secondary server is optional. Whenever a file transfer to the primary server fails for four consecutive times, the files will be transferred to the secondary server. The transfer will switch back to the original primary server when:

- Four consecutive transfer failures to the secondary server occur.
- After switching from the primary server, 30 minutes elapses.

When changing the transfer-mode from pull to push, disable the PULL from L-ESS and then change the transfer mode to push. Make sure that the push server URL configured is accessible from the local context. Also, make sure that the base directory that is mentioned contains udr directory created within it.
When changing the transfer mode from push to pull, after changing, enable PULL on the L-ESS. Any of the ongoing PUSH activity will continue till all the scheduled file transfers are completed. If there is no PUSH activity going on at the time of this configuration change, all the PUSH related configuration is nullified immediately.

The **cdr use-harddisk** command is available only on the ASR 5000 chassis. This command can be run only in a context where CDRMOD is running. Configuring in any other context will result in failure with the message *"Failure: Please Check if CDRMOD is running in this context or not."*
The **cdr use-harddisk** command can be configured either in the EDR or UDR module, but will be applicable to both record types. Configuring in one of the modules will prevent the configuration to be applied in the other module. Any change to this configuration must be done in the module in which it was configured, the change will be applied to both record types.
The VPNMgr can send a maximum of 4000 files to the remote server per iteration. However if the individual file size is big (say when compression is not enabled), then while transferring 4000 files SFTP operation takes a lot of time. To prevent this, the **cdr transfer-mode push** command can be configured with the keyword **max-files**, which allows operators to configure the maximum number of files sent per iteration based on configured file size.

Example

The following command retains a copy of the data file after it has been transferred to the storage location:

```
no cdr remove-file-after-transfer
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

file

This command allows you to configure EDR file parameters.

Product

All

Privilege

Security Administrator, Administrator

Syntax

file [charging-service-name { include | omit }] [compression { gzip | none }] [current-prefix *string* **] [delete-timeout** *seconds* **] [directory** *directory_name* **] [edr-format-name] [exclude-checksum-record] [field-separator { hyphen | omit | underscore }] [file-sequence-number rulebase-seq-num] [headers] [name** *file_name* **] [reset-indicator] [rotation [num-records** *number* **| time** *seconds* **| volume** *bytes* **]] [sequence-number { length** *length* **| omit | padded | padded-six-length | unpadded }] [storage-limit** *limit* **] [single-edr-format] [time-stamp { expanded-format | rotated-format | unix-format }] [trailing-text** *string* **] [trap-on-file-delete] [xor-final-record] +**

default file [charging-service-name] [compression] [current-prefix] [delete-timeout] [directory] [edr-format-name] [field-separator] [file-sequence-number] [headers] [name] [reset-indicator] [rotation { num-records | time | volume }] [sequence-number] [storage-limit] [time-stamp] [trailing-text] +

---

default

Configures the default setting for the specified keyword(s).

---

charging-service-name { include | omit }

Specifies to include/exclude name of the charging service in the file name.

- **include**: Include name of the charging service in the EDR file name.
- **omit**: Exclude name of the charging service in EDR file name.

---

compression { gzip | none }

Specifies compression of EDR files.

- **gzip**: Enables GNU zip compression of the EDR file at approximately 10:1 ratio.
- **none**: Disables Gzip compression.

---

current-prefix *string*

Specifies a string to add to the beginning of the EDR file that is currently being used to store EDR records.
string must be an alphanumeric string of 1 through 31 characters.
Default: **curr**

---

delete-timeout *seconds*

Specifies a timeout period (in seconds) when completed EDR files are deleted. By default, files are never deleted.
seconds must be an integer from 3600 through 31536000.

Default: Disabled

directory *directory_name*

Specifies a subdirectory in the default directory in which to store EDR files.
directory_name must be an alphanumeric string of 1 through 191 characters.
Default: **/records/edr**

edr-format-name

Specifies creation of separate files for EDRs that have different formats. Name of the EDR format is included in the file name.

exclude-checksum-record

When entered, this keyword excludes the final record containing #CHECKSUM followed by the 32-bit Cyclic redundancy check (CRC) of all preceding records from the EDR file.
Default: Disabled (inserts checksum record into the EDR file header)

field-separator [hyphen | omit | underscore]

Specifies the field inclusion/exclusion type of separators between two fields of EDR file name:

- **hyphen**: Specifies to use "-" (hyphen) as the field separator.
- **omit**: Excludes the field separator.
- **underscore**: Specifies to use "_" (underscore) as the field separator.

file-sequence-number rulebase-seq-num

Specifies that the file name sequence numbers must be unique per rulebase and EDR format name combination.

headers

Includes a file header summarizing the record layout.

name *file_name*

Specifies a string to be used as the base file name for EDR files.
Default: **edr**
file_name must be an alphanumeric string of 1 through 31 characters. The file name format is as follows:
base_rulebase_format_sequencenum_timestamp

- *base*: Specifies the type of record in file or contains the operator-specified string.

  Default: edr

- *rulebase*: Specifies the name of the ACS rulebase. EDRs from different rulebases go into different EDR files.
- *format*: Specifies the name of the EDR format if **single-edr-format** is specified, else the format field (and the trailing underscore) is omitted from the file name.
- *sequencenum*: This is a 5-digit sequence number to detect the missing file sequence. It is unique among all EDR files on the system.
- *timestamp*: Contains a timestamp based on file creation time in UTC time in MMDDYYYYHHMMSS format.

EDR files that have not been closed have a string added to the beginning of their filenames.

Filename for an EDR file in CSV format that contains information for rulebase named *rulebase1* and an EDR schema named *edr_schema1* appears as follows:
edr_rulebase1_edr_schema1_00005_01302006143409
If the file name is not configured the system will create files for EDRs/UDRs/FDRs (xDRs) using the following template with limits to 256 characters:
basename_ChargSvcName_timestamp_SeqNumResetIndicator_FileSeqNumber

- *basename*: A global-based configurable text string that is unique per system that uniquely identifies the global location of the system running ACS.
- *ChargSvcName*: A system context-based configurable text string that uniquely identifies a specific context-based charging service
- *timestamp*: Date and time at the instance of file creation. Date and time in the form of "MMDDYYYYHHmmSS" where HH is a 24-hour value from 00-23
- *SeqNumResetIndicator*: A one-byte counter used to discern the potential for duplicated FileSeqNumber with a range of 0 to 255, which is incremented by a value of 1 for the following conditions:
  - Failure of an ACS software process on an individual PSC.
  - Failure of the system such that a second system takes over. For example, a backup or standby system put in place according to Interchassis Session Recovery.
  - File Sequence Number (FileSeqNumber) rollover from 999999999 to 0
- *FileSeqNumber*: Unique file sequence number for the file with 9 digit integer having range from 000000000 to 999999999. It is unique on each system.

File name for a closed xDR file in CSV format that contains information for ACS system *xyz_city1* and charging service name *preapaid2* with timestamp *12311969190000*, and file sequence number counter reset indicator to *002* for file sequence number *034939002* appears as follows:
xyz_city1_preapaid2_12311969190000_002_034939002
File name for a running xDR file, not closed, in CSV format that contains information for the same parameters for file sequence number *034939003* prefixed with *curr_* and appears as follows:
curr_xyz_city1_preapaid2_12311969190000_002_034939002

---

reset-indicator

Specifies inclusion of the reset indicator counter value, from 0 through 255, in the EDR file name, and is incremented (by one) whenever any of the following conditions occur:

- An ACSMgr/SessMgr process fails.
- A peer chassis has taken over in compliance with our Interchassis Session Recovery feature.
- The sequence number, see the **sequence-number** keyword, has rolled over to zero.

---

rotation { num-records *number* **| time** *seconds* **| volume** *bytes* **}**

Specifies when to close an EDR file and create a new one.

- **num-records** *number*: Specifies the number of records that should be added to the file. When the number of records in the file reaches the specified value, the file is complete.

  number must be an integer from 100 through 10240.

  Default: 1024

- **time** *seconds*: Specifies the period of time (in seconds) to wait before closing the EDR file and creating a new one.

  seconds must be an integer from 30 through 86400.

Default: 3600

- **volume** *bytes*: Specifies the maximum size (in bytes) of the EDR file before closing it and creating a new one.

  bytes must be an integer from 51200 through 62914560.

  Note that a higher setting may improve the compression ratio when the compression keyword is set to gzip.

---

sequence-number { length *length* **| omit | padded | padded-six-length | unpadded }**

Specifies including/excluding sequence number in the file name.

- **length** *length*: Includes the sequence number with the specified length.

  length must be the length of the file sequence number, with preceding zeroes, in the file name, and must be an integer from 1 through 9.

  > ***Important:*** The **length** keyword is applicable in both EDR and UDR modules. When applied in both modules without the **file udr-seq-num** configuration, the minimum among the two values will come into effect for both the modules. With the **file udr-seq-num** keyword, each module will use its own value of length.

- **omit**: Excludes the sequence number from the file name.
- **padded**: Includes the padded sequence number with preceding zeros in the file name. This is the default setting.
- **padded-six-length**: Includes the padded sequence number with six preceding zeros in the file name.
- **unpadded**: Includes the unpadded sequence number in the file name.

---

single-edr-format

Creates separate files for EDRs having different formats.
Default: Disabled

---

storage-limit *limit*

Specifies deleting files when the specified amount of space (in bytes) is used up for EDR/UDR file storage RAM on packet processing cards.
limit must be an integer from 10485760 through 536870912. Default: 33554432

---

time-stamp { expanded-format | rotated-format | unix-format }

Specifies the timestamp of when the file was created be included in the file name.

- **expanded-format**: Specifies the UTC MMDDYYYYHHMMSS format.
- **rotated-format**: Specifies the time stamp format to YYYYMMDDHHMMSS format.
- **unix-format**: Specifies the UNIX format of *x.y*, where *x* is the number of seconds since 1/1/1970 and *y* is the fractional portion of the current second that has elapsed.

---

trailing-text *string*

Specifies the inclusion of an arbitrary text string in the file name.
string must be an alphanumeric string of 1 through 30 characters.

trap-on-file-delete

Instructs the system to send an SNMP notification (trap) when an EDR/UDR file is deleted due to lack of space.
Default: Disabled

xor-final-record

Specifies inserting an XOR checksum (in place of the CRC checksum) into the EDR file header if the **exclude-checksum-record** is left at its default setting.
Default: Disabled

+

Indicates that more than one of the keywords can be entered in a single command.

Usage

Use this command to configure EDR file characteristics.

Example

The following command sets the prefix of the current active EDR file to *Current*:

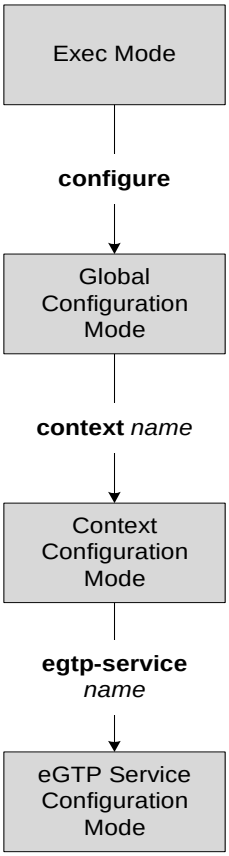
```
file current-prefix Current
```

The following command sets the base file name to *EDRfile*:

```
file name EDRfile
```

Chapter 108
eGTP Service Configuration Mode Commands

The eGTP Service Configuration Mode is used to create and manage Evolved GPRS Tunneling Protocol (eGTP) interface types and associated parameters.



associate

Configures an association with a GTP-U service where parameters are applied to the GTP-U data flow.

Product

P-GW

Privilege

Administrator

Syntax

associate gtpu-service *name*

no associate gtpu-service

no

Removes the association to the configured GTP-U service from this service.

gtpu-service *name*

Associates a GTP-U service with this eGTP service. *name* must be an alphanumeric string of 1 through 63 characters.

Usage

Use this command to associate a GTP-U service with this eGTP service.

Example

The following command associates this eGTP service with a GTP-U service named *gtpu3*:

```
associate gtpu-service gtpu3
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

gtpc

Configure the GPRS Tunneling Protocol Control (GTP-C) plane settings for this service.

Product

MME, P-GW, S-GW

Privilege

Administrator

Syntax

gtpc { bind { ipv4-address *ipv4_address* **[ipv6-address** *ipv6_address* **] | ipv6-address** *ipv6_address* **[ipv4-address** *ipv4_address* **] } | echo-interval** *seconds* **| ip qos-dscp {** *forwarding_type* **} | max-retransmissions** *num* **| path-failure detection-policy echo | retransmission-timeout** *seconds* **}**

no gtpc { bind { ipv4-address *ipv4_address* **[ipv6-address** *ipv6_address* **] | ipv6-address** *ipv6_address* **[ipv4-address** *ipv4_address* **] } | echo-interval | path-failure detection-policy }**

default gtpc { echo-interval | ip qos-dscp | max-retransmissions | path-failure detection-policy | retransmission-timeout }

---

no

Disables or removes the configured GTP-C setting.

---

default

Resets the specified parameter to its default value.

---

bind { ipv4-address *ipv4_address* **[ipv6-address** *ipv6_address* **] | ipv6-address** *ipv6_address* **[ipv4-address** *iv4p_address* **] }**

Binds the service to an interface with an IPv4 address, IPv6 address or both.
ipv4-address *ipv4_address* **[ipv6-address** *ipv6_address* **]**: Binds this service to the IPv4 address of a configured interface. Optionally, bind the service to a configured interface with an IPv6 address. *ipv4_address* must be entered using IPv4 dotted-decimal notation. *ipv6_address* must be entered using IPv6 colon-separated notation.
ipv6-address *ipv6_address* **[ipv4-address** *ipv4_address* **]**: Binds this service to the IPv6 address of a configured interface. Optionally, bind the service to a configured interface with an IPv4 address. *ip6_address* must be entered using IPv6 colon-separated notation. *ipv4_address* must be entered using IPv4 dotted-decimal notation.

---

echo-interval *seconds*

Configures the duration (in seconds) between the sending of echo messages as an integer from 60 through 3600. Default: 60

ip qos-dscp { *forwarding_type* **}**

Specifies the IP QoS DSCP per-hop behavior to be marked on the outer header of signalling packets originating from the LTE component. This is a standards-based feature (RFC 2597). The following forwarding types are supported:
af11: Designates the use of Assured Forwarding 11 per-hop behavior. This is the default setting.
af12: Designates the use of Assured Forwarding 12 per-hop behavior.
af13: Designates the use of Assured Forwarding 13 per-hop behavior.
af21: Designates the use of Assured Forwarding 21 per-hop behavior.
af22: Designates the use of Assured Forwarding 22 per-hop behavior.
af23: Designates the use of Assured Forwarding 23 per-hop behavior.
af31: Designates the use of Assured Forwarding 31 per-hop behavior.
af32: Designates the use of Assured Forwarding 32 per-hop behavior.
af33: Designates the use of Assured Forwarding 33 per-hop behavior.
af41: Designates the use of Assured Forwarding 41 per-hop behavior.
af42: Designates the use of Assured Forwarding 42 per-hop behavior.
af43: Designates the use of Assured Forwarding 43 per-hop behavior.
be: Designates the use of Best Effort forwarding per-hop behavior.
ef: Designates the use of Expedited Forwarding per-hop behavior typically dedicated to low-loss, low-latency traffic.
The assured forwarding behavior groups are listed in the table below.

	Class 1	Class 2	Class 3	Class 4
Low Drop	AF11	AF21	AF31	AF41
Medium Drop	AF12	AF22	AF32	AF42
High Drop	AF13	AF23	AF33	AF43

Traffic marked with a higher class is given priority during congestion periods. If congestion occurs to traffic with the same class, the packets with the higher AF value are dropped first.

max-retransmissions *num*

Configures the maximum number of retries for packets as an integer from 0 through 15. Default: 4

path-failure detection-policy echo

Enables session cleanup upon path failure detected via ECHO timeout toward a peer. Default: enabled
If disabled, there is no session cleanup upon path failure detected via ECHO timeout toward a peer; however, SNMP trap/logs will continue to indicate path failure.

retransmission-timeout *seconds*

Configures the control packet (echo message) retransmission timeout in GTP (in seconds) as an integer from 1 through 20. Default: 5

Usage

Use this command to configure GTP-C settings for the current service. This interface assumes the characteristics of an S11 reference point on the S-GW or MME.

Example

The following command binds the service to a GTP-C interface with an IP address of *112.334.556.778*:

```
gtpc bind address 112.334.556.778
```

interface-type

Configures the interface type used by this service.

Product

MME, P-GW, S-GW

Privilege

Administrator

Syntax

```
interface-type { interface-mme | interface-pgw-ingress | interface-sgsn | interface-sgw-egress | interface-sgw-ingress }
```

{ interface-mme | interface-pgw-ingress | interface-sgsn | interface-sgw-egress | interface-sgw-ingress }

interface-mme: Specifies that the interface has the characteristics of an eGTP MME S11 reference point to/from an S-GW or an eGTP MME Sv reference point to/from a Mobile Switching Center (MSC).
interface-pgw-ingress: Specifies that the interface has the characteristics of an eGTP P-GW S5/S8 reference point from an S-GW. The interface assumes the characteristics of either a GTP-C (control Plane) or GTP-U (user plane) reference point.
interface-sgsn: Specifies that the interface has the characteristics of an eGTP S-GW S4 reference point to/from an SGSN.
interface-sgw-egress: Specifies that the interface has the characteristics of an eGTP S-GW S5/S8 reference point to an eGTP P-GW. The interface assumes the characteristics of either a GTP-C (control Plane) or GTP-U (user plane) reference point.
interface-sgw-ingress: Specifies that the interface has the characteristics of:

- an eGTP-C S-GW S11 reference point from the MME.
- an eGTP-U S-GW S1-U reference point from the eNodeB.

Usage

Use this command to specify the type of interface this service uses. By configuring this command, the interface takes on the characteristics of the selected type.

Example

The following command configures the interface bound to this service to maintain the characteristics of an eGTP-C S-GW S11 reference point from an MME:

```
interface-type interface-sgw-ingress
```

validation-mode

Configures the type of validation to be performed on messages received by this service.

Product

P-GW

Privilege

Administrator

Syntax

```
validation-mode { custom1 | standard }

default validation-mode
```

default

Returns the command to the default setting of **standard**.

{ custom1 | standard }

custom1: Specifies that the message should be validated based on a vendor-specific set of mandatory elements.
standard: Specifies that the message should be validated based on the set of mandatory elements as defined in 3GPP 29.274.

Usage

Use this command to specify the type of validation performed on messages received by this service. The information elements contained in messages have mandatory elements and conditional elements. The standard set of elements, as defined by 3GPP 29.274 is checked if this command is set to “standard”. The custom1 setting is for a vendor-specific set of mandatory elements.

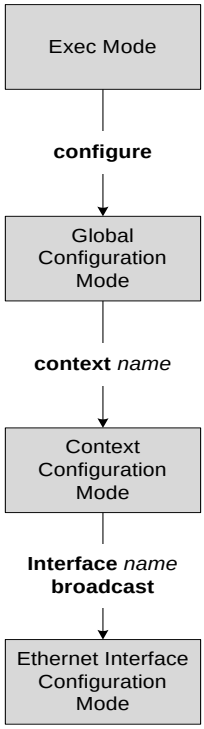
Example

The flowering command sets the validation mode for incoming messages to *standard*:

```
validation-mode standard
```

Chapter 109
Ethernet Interface Configuration Mode Commands

The Ethernet Interface Configuration Mode is used to create and manage the IP interface parameters within a specified context.



crypto-map

Applies the specified IPSec crypto-map to this interface.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

crypto-map *map_name* **[secondary-address** *sec_ip_addr* **]**

no

Deletes the application of the crypto map on this interface.

map_name

Specifies the name of the crypto map being applied as an alphanumeric string of 1 through 127 characters that is case sensitive.

secondary-address *sec_ip_addr*

Applies the crypto map to the secondary address for this interface. *sec_ip_addr* must be specified using the IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

In order for ISAKMP and/or manual crypto maps to work, they must be applied to a specific interface using this command. Dynamic crypto maps should **not** be applied to interfaces.
The crypto map must be configured in the same context as the interface.

Example

To apply the IPSec crypto map named cmap1 to this interface, use the following command:

```
crypto-map cmap1
```

description

Sets the descriptive text for the current interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

description *text*

no description

no

Clears the description for the interface.

text

Specifies the descriptive text as an alphanumeric string of 0 through 79 characters.

Usage

Set the description to provide useful information on the interface's primary function, services, end users, etc. Any information useful may be provided.

Example

```
description sampleInterfaceDescriptiveText
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
end
```

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

ip

Configures the IP options for the current interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

ip { access-group *acl_name* **{ in | out } [** *priority-value* **] | address** *ip_address ip_mask* **[secondary | srp-activate] | arp { arpa | timeout** *seconds* **} }**

no ip { access-group *acl_name* **{ in | out } | address** *ip_address* **| arp { arpa | timeout } }**

no

Disables and/or restores the option to the system default.

access-group *acl_name* **{ in | out } [** *priority-value* **]**

Specifies the access control list to be added/removed from the group. The ACL rules must be configured in the same context as the interface.
In Release 8.1 and later, *acl_name* must be an alphanumeric string of 1 through 47 characters.
In Release 8.0 and earlier, *acl_name* must be an alphanumeric string of 1 through 79 characters.
The direction must also be specified as either inbound or outbound using the keywords **in** and **out**, respectively.
priority-value: Default: 0. If more than one ACL is applied, *priority-value* specifies the priority in which they will be compared against the packet. If not specified, the priority is set to 0. *priority-value* must be an integer from 0 through 4294967295. If access groups in the list have the same priority, the last one entered is used first.

Important: Up to eight ACLs can be applied to a group provided that the number of rules configured within the ACL(s) does not exceed the 128-rule limit for the interface.

address *ip_address ip_mask* **[secondary | srp-activate]**

Configures the IP address for the interface specifying the networking mask as well. *ip_address* and *ip_mask* must be entered using IPv4 dotted-decimal or IPv6 colon-separated notation.

Important: For IPv4 addresses, 31-bit subnet masks are supported per RFC 3021.

The **secondary** keyword configures a secondary IP address on the interface. This is referred to as multi-homing of the interface.
The **srp-activate** keyword activates the IP address for Interchassis Session Recovery (ICSR).

arp { arpa | timeout *seconds* **}**

Important: These keywords have been replaced by the **R_arp** command in the Global Configuration Mode. For backwards compatibility, however, these keywords are accepted as valid.

Usage

Create and manage the IP interfaces for the associated context.

Example

The following command configures the access group for the current context:

```
ip access-group sampleAccessGroup
```

```
ip address 10.2.3.4 0.0.0.128 secondary
```

The following command sets the address resolution protocol timeout.

```
ip arp timeout 1800
```

The following commands remove the associated IP address and disable ARP for the interface, respectively.

```
no ip address 10.2.3.4
```

```
no ip arp arpa
```

ip mtu

Configures the Maximum Transmission Unit (MTU) for this IP interface.

Product

All

Privilege

Security Administrator, Administrator

Syntax

[no] ip mtu *mtu-size*

no

Deletes the MTU value.

Usage

IP MTU is supported for a normal interface and point-to-point interface (OLC ports).
The maximum MTU size allowed with an OLC port is 1600. The maximum MTU size allowed with an Ethernet port is 2048. The default MTU size is 1500.

Example

The following command sets the MTU value to *2048*.

```
ip mtu 2048
```

ip ospf authentication-key

Configures the password for authentication with neighboring Open Shortest Path First (OSPF) routers.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

ip ospf authentication-key [encrypted] password *auth_key*

no ip ospf authentication-key

no

Deletes the authentication key.

encrypted

Use this keyword if you are pasting a previously encrypted authentication key into the CLI command.

password *auth_key*

Specifies the password to use for authentication as an alphanumeric string of 1 through 16 characters entered in clear text format.

Usage

Use this command to set the authentication key used when authenticating with neighboring routers.

Example

To set the authentication key to 123abc, use the following command;

```
ip ospf authentication-key password 123abc
```

Use the following command to delete the authentication key;

```
no ip ospf authentication-key
```

ip ospf authentication-type

Configures the OSPF authentication method to be used with OSPF neighbors over the logical interface.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf authentication-type { message-digest | null | text }

no ip ospf authentication-type { message-digest | null | text }
```

no

Disable this function.

message-digest

Uses the message digest (MD) authentication method.

null

Uses no authentication, thus disabling either MD or clear text methods.

text

Uses the clear text authentication method.

Usage

Use this command to set the type of authentication to use when authenticating with neighboring routers.

Example

To set the authentication type to use clear text, enter the following command;

```
ip ospf authentication-type text
```

ip ospf cost

Configures the cost associated with sending a packet over the OSPF logical interface.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

ip ospf cost *value*

no ip ospf cost

no

Disable this function.

value

Specifies the cost to assign to OSPF packets as an integer from 1 through 65535. Default: 10

Usage

Use this command to set the cost associated with routes from the interface.

Example

Use the following command to set the cost to *20*;

```
ip ospf cost 20
```

Use the following command to disable the cost setting;

```
no ip ospf cost
```

ip ospf intervals

Configures the interval or delay type, and the interval or delay time in seconds, for OSPF communications.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
ip ospf { dead-interval value | hello-interval value | retransmit-interval value |
transmit-delay value }

no ip ospf { dead-interval | hello-interval | retransmit-interval | transmit-delay }
```

no

Deletes the value set and returns the value to its default.

dead-interval *value*

Specifies the interval (in seconds,) that the router should wait, during which time no packets are received and after the router considers a neighboring router to be off-line. *value* must be an integer from 1 through 65535. Default: 40

hello-interval *value*

Specifies the interval (in seconds) between sending hello packets as an integer from 1 through 65535. Default: 10

retransmit-interval *value*

Specifies the interval in (seconds) between LSA (Link State Advertisement) retransmissions as an integer from 1 through 65535. Default: 5

transmit-delay *value*

Specifies the interval (in seconds) that the router should wait before transmitting a packet. *value* must be an integer from 1 through 65535. Default: 1

Usage

Use this command to set the intervals or delays for OSPF communications.

Example

To set the dead-interval to *100*, use the following command;

```
ip ospf dead-interval 100
```

To delete the setting for the dead-interval and reset the dead-interval value to its default of 40, use the following command'

```
no ip ospf dead-interval
```

ip ospf message-digest-key

Enables or disables the use of MD5-based OSPF authentication.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

ip ospf message-digest-key *key_id* **md5 [encrypted] password** *authentication_key*

no ip ospf message-digest-key *key_id*

no

Deletes the key.

message-digest-key *key_id*

Specifies the key identifier number as an integer from 1 through 255.

encrypted

Use this if you are pasting a previously encrypted authentication key into the CLI command.

password *authentication_key*

Specifies the password to use for authentication as an alphanumeric string of 1 through 16 characters entered in clear text format.

Usage

Use this command to create an authentication key that uses MD5-based OSPF authentication.

Example

To create a key with the ID of *25* and a password of *123abc*, use the following command;

```
ip ospf message-digest-key 25 md5 password 123abc
```

To delete the same key, enter the following command;

```
no ip ospf message-digest-key 25
```

ip ospf network

Configures the Open Shortest path First (OSPF) network type.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

ip ospf network { broadcast | non-broadcast | point-to-multipoint | point-to-point }

no ip ospf network

no

Disable this function.

broadcast

Sets the network type to broadcast.

non-broadcast

Sets the network type to non-broadcast multi access (NBMA).

point-to-multipoint

Sets the network type to point-to-multipoint.

point-to-point

Sets the network type to point-to-point.

Usage

Use this command to specify the OSPF network type.

Example

To set the OSPF network type to *broadcast*, enter the following command;

```
ip ospf network broadcast
```

To disable the OSPF network type, enter the following command;

```
no ip ospf network
```

ip ospf priority

Designates the OSPF router priority.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

ip ospf priority *value*

no ip ospf priority *value*

no

Disable this function.

value

Sets the priority value as an integer from 0 through 255.

Usage

Use this command to set the OSPF router priority.

Example

To set the priority to *25*, enter the following command:

```
ip ospf priority 25
```

To disable the priority, enter the following command:

```
no ip ospf priority
```

ipv6 access-group

Specifies the name of the access control list (ACL) group to assign to this interface. You can filter for either inbound or outbound traffic.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

`[ no ] ipv6 access-group` *`group name`* **`{ in | out } { priority-value`** *`priority_value`* **`}`**

`no`

Removes a previously configured access group association.

`group_name`

Specifies the name of the access group as an alphanumeric string of 1 to 79 characters.

`in`

Applies the filter to the inbound traffic.

`out`

Applies the filter to the outbound traffic.

`priority-value`

Specifies the priority of the access group as an integer from 0 to 4294967295. 0 is the highest priority. If priority-value is not specified, the priority is set to 0.
If access groups in the list have the same priority, the last one entered is used first.

Usage

Use this command to specify the ACL group to assign the interface to. Specify an ACL group name with this command.

Important: Up to eight ACLs can be applied to a group provided that the number of rules configured within the ACL(s) does not exceed the 128-rule limit for the interface.

Example

Use the following command to associate the *`group_1`* access group with the current IPv6 profile for inbound access:

```
ipv6 access-group group_1 in 1
```

ipv6 address

Specifies the address and subnet mask.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

ipv6 address *ip_address*

ip_address

Specifies an individual host IP address to add to this host pool in IPv6 colon-separated notation.

Usage

Configures the IPv6 address and subnet mask for a specific interface.

ipv6 ospf

Enables Open Shortest Path First Version 3 (OSPFv3) functionality on this interface.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator

Syntax

[no] ipv6 ospf [area { *integer_value* | *ipv4-address* } | cost *cost-value* | dead-interval *dead-intrv* | hello-interval *hello-intrvl* | priority *p-value* | retransmit-interval *retx-interval* | transmit-delay *td-interval*]

no

Removes a previously configured access group association.

area { *integer_value* | *ipv4-address*

Specifies an OSPFv3 area.
decimal_value: Specifies the identification number of the area as an integer from 0 through 4294967295.
ipv4address: Specifies the IP address of the area in IPv4 dotted-decimal notation.

cost *cost-value*

Specifies a link cost as an integer from 1 through 65535. The link cost is carried in the LSA updates for each link. The cost is an arbitrary number.

dead-interval *dead-intrv*

Specifies the interval (in seconds) after which a neighbor is declared dead when no hello packets as an integer from 1 through 65535.

hello-interval *hello-intrvl*

Specifies the interval (in seconds) between hello packets that OSPFv3 sends on an interface as an integer from 1 through 65535.

priority *p-value*

Specifies the of the interface as an integer from 0 through 255.

retransmit-interval *retx-interval*

Specifies the time (in seconds) between link-state advertisement (LSA) retransmissions for adjacencies belonging to the OSPFv3 interface as an integer from 1 through 65535.

transmit-delay *td-interval*

Specifies the estimated time (in seconds) required to send a link-state update packet on the interface as an integer from 1 through 65535.

Usage

Configure an OSPFv3 interface in this context.

Example

```
ipv6 ospf area 334 cost 555 dead-interval 40 hello-interval 10 priority
10 retransmit-interval 5 transmit-delay 10
```

ipv6 router advertisement

Enables or disables the system to send IPv6 router advertisements.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ipv6 router advertisement
```

Usage

Enables sending of router advertisements on the interface. All of the pool prefixes in the context (belonging to the interface) will be advertised in the router advertisement.
The router-lifetime in the advertisement is sent as 0 to indicate to the receiver that the sender cannot be a default-router. For all the prefixes (pools), the valid and preferred lifetime are sent as default. The router-advertisement is sent every 600 seconds.
If the pool-prefix is deleted, then an router-advertisement is sent for that particular prefix with the valid and preferred time set to 0.

policy-forward

Configures the system for redirecting the HA packets to new HA during existing HA upgrade.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

policy-forward { icmp unreachable next-hop *ip address* **| unconnected-address next-system** *ip_address* **}**

no policy-forward unconnected-address

no

Deletes the policy forwarding configuration for unconnected address for the current interface.

icmp unreachable next-hop *ip address*

Specifies routing of Internet Control Message Protocol (ICMP) unreachable is required in overlapping pool configuration. *ip_address* must be an IP address expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

unconnected-address next-system *ip address*

Specifies the IP address of the next system HA to handle processing during HA upgrade. *ip_address* must be an IP address expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Use this command to set the redirecting policy for IP packets from an existing HA to a new HA during upgrade. To configure this command both keywords will be in separate interface.

Important: This is a customer specific command.

Example

To configure existing HA system for redirecting the HA packets to new HA during existing HA upgrade enter the following commands:

policy-forward unconnected-address next-system *ip_address*

policy-forward icmp unreachable next-hop *ip_address*

pool-share-protocol

Configures the primary or secondary system for the IP pool sharing protocol and enter IPSP configuration mode.

Product

PDSN, HA

Privilege

Security Administrator, Administrator

Syntax

```
pool-share-protocol { primary ip_address | secondary ip_address } [ mode { active |
inactive | check-config } ]

no pool-share-protocol
```

no

Deletes the IP pool sharing protocol information from the current interface.

primary *address*

On the secondary system, defines the IP address of an interface on the primary system that has identical IP pools configured for use with the IP pool sharing protocol. *ip_address* must be expressed in IP v4 dotted-decimal notation.

secondary *ip_address*

On the primary system, define the IP address of an interface on the secondary system that has identical IP pools configured for use with the IP pool sharing protocol. *ip_address* must be expressed in IP v4 dotted-decimal notation.

mode {active | inactive | check-config}

This is an optional command to manage the mode for IP pool sharing protocol for primary or secondary HA.
active: Activates the IP pool sharing protocol mode.
inactive: Inactivates the IP pool sharing protocol mode.
check-config: Verifies the IP pool sharing protocol configuration.

Usage

Use this command to set the IP address of the primary or secondary system for use with the IP pool sharing protocol and enter ipsp configuration mode. This command must be configured for an interface in each context that has IP pools configured. Refer to the System Administration and Configuration Guide for information on configuring and using the IP pool sharing protocol.

Important: Both the primary and secondary systems must be in the same subnet.

Important: For information on configuring and using IP Pool Sharing Protocol (IPSP), refer to the *Packet Data Serving Node Administration Guide*.

Important: Reserve free addresses on the primary HA for this command via the **reserved-free-percentage** command as described in the *IPSP Configuration Mode Commands* chapter of this guide.

Example

To configure a secondary system with an IP address of *192.168.100.10* for use with the IP pool sharing protocol, enter the following command:

```
pool-share-protocol secondary 192.168.100.10
```

To inactivate a secondary system with an IP address of *192.168.100.10* for use with the IP pool sharing protocol, enter the following command:

```
pool-share-protocol secondary 192.168.100.10 mode inactive
```

port-switch-on-L3-fail

Causes the line card port to which the current interface is bound to switch over to the port on the redundant line card when connectivity to the specified IP address is lost.

Product

All

Privilege

Security Administrator, Administrator

Syntax

port-switch-on-L3-fail address { *ip_address* **|** *ipv6_address* **} [minimum-switchover-period** *switch_time* **] [interval** *int_time* **] [timeout** *time_out* **] [num-retry** *number* **]**

no port-switch-on-L3-fail

no

Disable port switchover on failure.

ip_address

The IP address to monitor for connectivity, entered in IPv4 dotted-decimal or IPv6 colon-separated notation.

minimum-switchover-period *switch_time*

After a switchover occurs, another switchover cannot occur until the specified amount of time (in seconds) has elapsed. *switch_time* must be an integer from 1 through 3600. Default: 120

interval *int_time*

Specifies how often (in seconds) monitoring packets are sent to the IP address being monitored. *int_time* must be an integer from 1 through 3600. Default: 60

timeout *time_out*

Specifies how long to wait (in seconds) without a reply before resending monitoring packets to the IP address being monitored. *time_out* must be an integer from 1 through 10. Default: 3

num-retry *number*

Specifies how many times to retry sending monitor packets to the IP address being monitored before performing the switchover. *number* must be an integer from 1 through 100. Default: 5

Usage

Use this command to monitor a destination in your network to test for L3 connectivity. The destination being monitored should be reachable from both the active and standby line cards.

Example

The following command enables port switchover on connectivity failure to the IP address *192.168.10.100* using default values:

```
port-switch-on-L3-fail address 192.168.10.100
```

The following command disables port switchover on connectivity failure:

```
no port-switch-on-L3-fail
```

vlan-map

Sets a single next-hop IP address so that multiple VLANs can use a single next-hop gateway. The vlan-map is associated with a specific interface.

Product

PDSN, HA, SGSN

Privilege

Security Administrator, Administrator

Syntax

vlan-map next-hop *ip_address*

next-hop *ip_address*

Defines an IP address for the next-hop gateway in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Use this command to combine multiple VLAN links to go through a single IP address. This feature is used in conjunction with nexthop forwarding and overlapping IP pools.
After configuring the vlan-map, move to the Port Ethernet Configuration mode to attach the vlan-map to a specific VLAN.

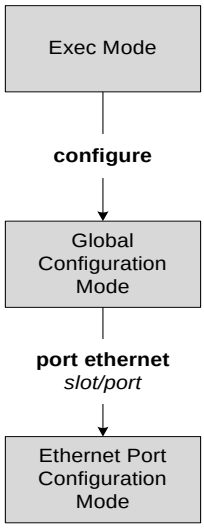
Example

The following command sets an IPv4 address for a next-hop gateway.

```
vlan-map next-hop 123.123.123.1
```

Chapter 110
Ethernet Port Configuration Mode Commands

The Ethernet Port Configuration Mode is used to create and manage Ethernet ports and their bindings between contexts.



bind interface

Configures an association (binds) between a virtual IP interface, an SS7 or Frame Relay link to a specific context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

[no] bind interface *interface_name context_name*

no

Indicates the virtual interface specified is to be unbound from the context.

interface_name

Specifies the name of the virtual interface to be bound to the context as an alphanumeric string of 1 through 79 characters.

context_name

Specifies the name of the context to be bound to the virtual port. *context_name* must refer to a previously configured context.

Usage

Bind an interface to a context to allow the context to provide service.

Example

```
bind interface sampleVirtual sampleContext

no bind interface sampleVirtual sampleContext
```

default

Restores the speed and communication mode of the default interface for the specified context.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
default { flow-control | link-aggregation { lacp | redundancy } | medium | preferred slot
| threshold { high-activity | monitoring | rx-utilization | tx-utilization } }
```

flow-control

Restores the default behavior to advertise symmetric flow control.

link-aggregation { lacp | redundancy }

Restores the default values for link-aggregation as follows:

- **lacp**: Active – sends out LACP packets periodically.
- **redundancy**: Standard – treats all cards in the group as one group.

medium

Restores the default values for the medium options as follows:

- SPIO and fast ethernet line cards: auto
- Gigabit ethernet line card: auto

preferred slot

Sets the port for non-revertive operation for port redundancy auto-recovery; requiring an administrative user to manually issue a port switch to command to return service to the original port.

threshold { high-activity | monitoring | rx-utilization | tx-utilization }

Restores the specified port-level threshold parameters to its default value(s). The possible values are:

- **high-activity**: High port activity threshold settings. Default: 50 percent
- **monitoring**: Threshold monitoring configuration settings. Default: Disabled
- **rx-utilization**: Receive port utilization threshold settings. Default: 80 percent
- **tx-utilization**: Transmit port utilization threshold settings. Default: 80 percent

Usage

Restores port-level parameters to their default values.

Example

```
default medium
```

description

Sets the port descriptive text.

Product

All

Privilege

Security Administrator, Administrator

Syntax

description *text*

no description

no

Clears the description for the port.

text

Specifies the descriptive text as an alphanumeric string of 1 to 79 characters.

Usage

The description should provide useful information on the port's primary function, services, end users, etc.

Example

```
description samplePortDescriptiveText

description "This is a sample description"
```

end

Exits the current configuration mode and returns to the Exec mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

end

Usage

Use this command to return to the Exec mode.

exit

Exits the current mode and returns to the parent configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
exit
```

Usage

Use this command to return to the parent configuration mode.

fault-unidirect-mode

Configures the unidirectional mode that generates fault messages for the connection's peer when local faults are detected and remote faults are received.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] fault-unidirect-mode ( clause-46 | clause-66 }
```

no fault-unidirect-mode

Disables fault message generation.

(clause-46 | clause-66 }

clause-46: On local fault reception, continuous remote faults are sent. On remote fault reception, continuous idles are sent. [IEEE 802.3, Clause 46, Reconciliation Sublayer (RS) and 10 Gigabit Media Independent Interface (XGMII)]
clause-66: On local fault reception, frame transmit is continued, remote fault indication is sent during Inter-Frame Gap (IFG). On remote fault reception, frame transmit is continued. [IEEE 802.3, Clause 66, Extensions of the 10 Gb/s Reconciliation Sublayer (RS), 100BASE-X PHY, and 1000BASE-X PHY for unidirectional transport]

Usage

Configure the unidirectional mode that generates fault messages for the connection's peer when local faults are detected and remote faults are received.

Example

After flow control has been disabled, use the following command to enable flow control:

```
fault-unidirect-mode clause-46
```

flow-control

Enables and disables flow control on the Quad Gig-E line card (QGLC).

Product

PDSN, SGSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] flow-control
```

no

Disables flow control on the specified port.

Usage

Flow control is enabled by default on the QGLC and can be disabled using the **no** command on a per-port basis. This command does not work on the Fast Ethernet Line Card (FELC), Gigabit Ethernet Line Card (GELC/GLC2) or 10 GigE Line Card (XGLC) which do not support flow control.

Example

After flow control has been disabled, use the following command to enable flow control:

```
flow-control
```

ingress-mode

Labels this port as an ingress port.

Product

IPSG

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] ingress-mode
```

no

Disables ingress port tag.

Usage

Use this command to label this port in order for the session manager to recognize the interface from which IP data packets are being received. This command should be used in single context configurations. In single context configurations, the ingress port can only be identified if labeled.

link-aggregation

Aggregates ports on a Quad Gig-E line card (QGLC) or 10 Gig-E line card (XGLC) and set related parameters in accordance IEEE 802.3ad.

Product

WiMAX, PDSN, HA, FA, GGSN, SGSN

Privilege

Security Administrator, Administrator

Syntax

```
link-aggregation { distribution { block | random | rotate | simple } | lacp { active |
passive } [ rate { auto | fast | slow } ] [ timeout { long | short } ] | master { global
group group_number | group group_number | local group group_number } | member { global
group group_number | group group_number | local group group_number } | redundancy {
standard | switched } [ hold-time sec ] [ preferred slot { card_number | none } ] |
toggle-link }

no link-aggregation [ toggle-link ]

default link-aggregation { distribution | lacp | redundancy | toggle-link }
```

distribution { block | random | rotate | simple }

Configures link aggregation distribution and controls how a Link Aggregation Group (LAG) hash map is generated. This method is required for Equal Cost Multi-Path (ECMP) routing over LAG. Set this option on the master port for use with the whole group. The following list defines the distribution options (assuming port index 0,1,2,3 were selected.
block: Blocks of the same port index (Example: 0000111122223333)
random: Based on pseudo random number
rotate: Repetition of rotated port index (Example: 0123123023013012…)
simple: Repetition of all selected port indexes (Example: 0123012301230123…)

lacp { active | passive }

Configures the Link Aggregation Control Protocol (LACP). Set this option on the master port for use with the whole group.
active mode sends out LACP packets periodically. (Default)
passive mode only responds to LACP packets received.

rate { auto | fast | slow }

Configures the rate at which the LACP sends packets.
auto: rate is controlled by the peer
fast: 1 seconds
slow: 30 seconds (Default)

timeout { long | short }

Configures LACP timeout events. Set this option on the master port for use with the whole group.
long: Set LACP to long timeout
short: Set LACP to short timeout

master { global group *group_number* **| group** *group_number* **| local group** *group_number* **}**

This command creates the Master port for the aggregated group.
global: Set group global across slots.
group *group_number*: Set link aggregation group number. *group_number* must be an integer between 1 and 1023.
local: Set group local within same slot.

member { global group *group_number* **| group** *group_number* **| local group** *group_number* **}**

This command makes the port a member of the aggregated group.
global: Set group global across slots.
group *group_number*: Set link aggregation group number. *group_number* must be an integer from 1 through 1023.
local: Set group local within same slot.

redundancy { standard | switched } [hold-time *sec* **] [preferred slot {** *card_number* **| none }]**

Connects top and bottom QGLCs and side-by-side XGLCs to different switches. The master port must be set to make this effective for the group.
standard: Treats all cards in the group as one group. (Default)
switched: Assumes cards are connected to different switches.
hold-time *sec*: Sets the amount of time to hold (in seconds) before switching between cards. Applies to standard and switched modes. *sec* must be an integer from 0 through 3600. Default: 10
preferred slot*card_number*: Specifies revertive/non-revertive preference including preferred slot for standard LAG for two switches. Applies to standard and switched modes. *card_number* is an integer between 1 and 48
none: Specifies no preferred slot.

toggle-link

Set to toggle link on port switch.

default

Restores the default values.

no

This command deletes the Ethernet port from any group it might be in. If the port was the Master of a group, the whole group would be deleted.

Usage

Configure from one to four ports on a QGLC (vertical aggregation) or the single port on XGLCs (horizontal aggregation) to be in an aggregation group on the chassis that links to an aggregation group on a remote switch. Very large files can be downloaded across all ports in a group, which makes for a faster download when compared to serial downloads over a single link. For additional information, refer to the *System Administration Guide*.

Example

The following example configures the port to be the Master for Group *2*:

```
link aggregation master group 2
```

media

Configures the port interface type.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
media { rj45 | sfp }
```

{ rj45 | sfp}

rj45: Sets the physical interface to copper RJ-45 connectors.
sfp: Sets the physical interface connection to optical Small Form Factor (SFP) gigabit via an SFP transceiver.

Usage

Set the media option when the physical cabling interface is changed.

Example

The following commands are entered one-at-a-time to set the physical interface to RJ-45 and SFP:

```
media rj45

media sfp
```

medium

Configures the port speed and communication mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
medium { auto | speed { 10 | 100 | 1000 | 10000 } duplex { full | half } }
```

{ auto | speed { 10 | 100 | 1000 | 10000 } duplex { full | half } }

Default: **auto**
Optionally sets the speed of the interface and the communication mode.
auto: configures the interface to auto negotiate the interface speed.
speed { 10 | 100 | 1000 | 10000 }: specifies the speed to use at all times.
duplex { full | half }: sets the communication mode of the interface to either **full** or **half** duplex.

Important: Ethernet networking rules dictate that if a device whose interface is configured to auto-negotiate is communicating with a device that is manually configured to support full duplex, the first device will negotiate to the manually configured speed of the second device but will only communicate in half duplex mode.

Usage

Set the medium options when the physical interface changes.

Example

The following configures the port's speed and communication mode to be auto negotiated.

```
medium auto
```

The following command configures the port's interface speed to gigabit with full duplex communication.

```
medium speed 1000 duplex full
```

preferred slot

Assigns revertive or non-revertive control to port redundancy auto-recovery.

Default: non-revertive operation

Product

PDSN, FA, HA, SGSN, GGSN

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] preferred slot slot#
```

no

Disables revertive or auto-recovery operation for the selected port.

preferred slot *slot#*

Identifies the physical chassis slot where the line card or SPIO card is installed.

Usage

This command enables or disables revertive port redundancy, wherein after a port failover, when the original port is restored to service (such as link up) the system will return service to that port automatically.
Disabled, which is the default setting, causes non-revertive operation; requiring an administrative user to manually issue a **port switch** to command to return service to the original port.
This command must be issued on a per port basis, allowing you to configure specific ports to be used on individual line or SPIO cards. For example, ports 1 through 4 could be configured as "preferred" on the LC in slot 17 while ports 5 through 8 are "preferred" on the LC in slot 33. In this scenario, both LCs would be in an Active operational state while still providing LC and port redundancy for the other.

Important: This command is not supported on all platforms.

Example

```
preferred slot 17
```

shutdown

Terminates all processes supporting the port or blocks the shutting down of the port. Conversely, the port is enabled with the use of the **no** keyword.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] shutdown
```

no

Enables the port and places it in service.

Usage

Shut down a port prior to re-cabling and/or other maintenance activities.
This command is necessary to bring a port into service by enabling it via the **no** keyword.

Example

Use the following command to disable the port:

```
shutdown
```

Use the following command to enable the port for service:

```
no shutdown
```

snmp trap link-status

Enables or disables the generation of an SNMP trap for link status changes.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] snmp trap link-status
```

no

Disables the sending of traps for link status changes.

Usage

Enable link status change traps when a monitoring facility can use the information or if there are troubleshooting activities in progress.

Example

Use the following command to disable sending of traps:

```
no snmp trap link-status
```

srp virtual-mac-address

Configures the Standby Router Protocol (SRP) virtual MAC address for the port.

Product

All

Privilege

Security Administrator, Administrator

Syntax

srp virtual-mac-address *MAC_Address*

no srp virtual-mac-address

no

Disables the SRP virtual MAC addressing for Ethernet ports. The block of virtual MAC addresses is not saved.

MAC_Address

Enables SRP virtual addressing for the specified MAC address.

Usage

The SRP virtual MAC address is applied to the port when the chassis is in SRP ACTIVE state. The default is **no srp virtual-mac-address**.

Important: This command is not supported on all platforms.

Example

Use the following command to enable the SRP's virtual MAC addressing:

srp virtual-mac-address *MAC_Address*

threshold high-activity

Configures thresholds for high port activity for the port.

Product

All

Privilege

Security Administrator, Administrator

Syntax

threshold high-activity *high_thresh* **[clear** *low_thresh* **]**

high_thresh

Specifies the high threshold high port activity percentage that must be met or exceeded within the polling interval to generate an alert or alarm. The percentage is expressed as an integer from 0 through 100. Default: 50

clear

Allows the configuration of the low threshold.

low_thresh

Specifies the low threshold high port activity percentage that maintains a previously generated alarm condition. If the activity percentage falls below the low threshold within the polling interval, a clear alarm will be generated. The percentage is expressed as an integer from 0 through 100. Default: 50

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

High port activity thresholds generate alerts or alarms based on the utilization percentage of each configured port during the specified polling interval. This threshold is configured on a per-port basis.
Alerts or alarms are triggered for high port activity based on the following rules:

- **Enter condition**: Actual percent utilization of a port is greater than High Threshold.
- **Clear condition**: Actual percent utilization of a port is less than Low Threshold.

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.
Refer to the **threshold poll** command in the *Global Configuration Mode Commands* chapter to configure the polling interval and the **threshold monitoring** command in this chapter to enable thresholding for this value.

Example

The following command configures a high port utilization threshold percent of *70* and a low threshold percent of *50* for a system using the Alarm thresholding model:

```
threshold high-activity 70 clear 50
```

threshold monitoring

Enables or disables thresholding for port-level values.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
[ no ] threshold monitoring
```

no

Disables threshold monitoring for port-level values. This is the default setting.

Usage

Thresholding on the system is used to monitor the system for conditions that could potentially cause errors or outage. Typically, these conditions are temporary (such as high-activity) and are quickly resolved. However, continuous or large numbers of these error conditions within a specific time interval may be indicative of larger, more severe issues. Thresholding helps identify potentially severe conditions so that immediate action can be taken to minimize and/or avoid system downtime.

Thresholding reports conditions using one of the following mechanisms:

- **SNMP traps**: SNMP traps have been created that indicate the condition (high threshold crossing and/or clear) of each of the monitored values. Complete descriptions and other information pertaining to these traps is located in the starentMIB(8164).starentTraps(2) section of the *SNMP MIB Reference*. The generation of specific SNMP traps can be enabled or disabled on the system allowing you to view only those traps that are most important to you.
- **Logs**: The system provides a facility called threshold for which active and event logs can be generated. As with other system facilities, logs are generated Log messages pertaining to the condition of a monitored value are generated with a severity level of WARNING.
- **Alarm System**: High threshold alarms generated within the specified polling interval are considered "outstanding" until a the condition no longer exists and/or a condition clear alarm is generated.

"Outstanding" alarms are reported to through the system's alarm subsystem and are viewable through the system's CLI.

The following table indicates the reporting mechanisms supported by each of the above models.

Table 18. Thresholding Reporting Mechanisms by Model

Model	SNMP Traps	Logs	Alarm System
Alert	X	X	
Alarm	X	X	X

This command enables thresholding for port-level values. Refer to the **threshold high-activity**, **threshold rx-utilization**, and **threshold tx-utilization** commands in this chapter for information on configuring these values. In addition, refer to the **threshold poll** command in the *Global*

Configuration Mode Commands chapter for information on configuring the polling interval over which these values are monitored.

threshold rx-utilization

Configures thresholds for receive port utilization.

Product

All

Privilege

Security Administrator, Administrator

Syntax

threshold rx-utilization *high_thresh* **[clear** *low_thresh* **]**

high_thresh

Specifies the high threshold receive port utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm. The percentage is expressed as an integer from 0 through 100. Default: 80

clear

Allows the configuration of the low threshold.

low_thresh

Specifies the low threshold receive port utilization percentage that maintains a previously generated alarm condition. If the utilization percentage falls below the low threshold within the polling interval, a Clear Alarm will be generated. The percentage is expressed as an integer from 0 through 100. Default: 80

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Receive port utilization thresholds generate alerts or alarms based on the utilization percentage of each configured port in relation to data received during the specified polling interval. This threshold is configured on a per-port basis.

Important: Ports configured for half-duplex do not differentiate between data received and data transmitted. Therefore, to avoid redundant alarms, it is recommended that only the receive **or** transmit utilization threshold be configured.

Alerts or alarms are triggered for receive port utilization based on the following rules:

- **Enter condition**: Actual percent utilization of a port for received data is greater than High Threshold
- **Clear condition**: Actual percent utilization of a port for received data is less than Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command in the *Global Configuration Mode Commands* chapter to configure the polling interval and the **threshold monitoring** command in this chapter to enable thresholding for this value.

Example

The following command configures a receive port high utilization threshold percent of *70* and a low threshold percent of *50* for an system using the Alarm thresholding model:

```
threshold rx-utilization 70 clear 50
```

threshold tx-utilization

Configures thresholds for transmit port utilization.

Product

All

Privilege

Security Administrator, Administrator

Syntax

threshold tx-utilization *high_thresh* **[clear** *low_thresh* **]**

high_thresh

The high threshold transmit port utilization percentage that must be met or exceeded within the polling interval to generate an alert or alarm. The percentage is expressed as an integer from 0 through 100. Default: 80

clear

Allows the configuration of the low threshold.

low_thresh

The low threshold transmit port utilization percentage that maintains a previously generated alarm condition. If the utilization percentage falls below the low threshold within the polling interval, a clear alarm will be generated. The percentage is expressed as an integer from 0 through 100. Default: 80

Important: This value is ignored for the Alert model. In addition, if this value is not configured for the Alarm model, the system assumes it is identical to the high threshold.

Usage

Transmit port utilization thresholds generate alerts or alarms based on the utilization percentage of each configured port in relation to data transmitted during the specified polling interval. This threshold is configured on a per-port basis.

Important: Ports configured for half-duplex do not differentiate between data received and data transmitted. Therefore, to avoid redundant alarms, it is recommended that only the receive **or** transmit utilization threshold be configured.

Alerts or alarms are triggered for transmit port utilization based on the following rules:

- **Enter condition**: Actual percent utilization of a port for transmit data is greater than High Threshold
- **Clear condition**: Actual percent utilization of a port for transmit data is less than Low Threshold

If a trigger condition occurs within the polling interval, the alert or alarm will not be generated until the end of the polling interval.

Refer to the **threshold poll** command in the *Global Configuration Mode Commands* chapter to configure the polling interval and the **threshold monitoring** command in this chapter to enable thresholding for this value.

Example

The following command configures a transmit port high utilization threshold percent of *70* and a low threshold of *50* for an system using the Alarm thresholding model:

```
threshold tx-utilization 70 clear 50
```

vlan

Creates or deletes a VLAN tag and enters VLAN Configuration mode.

Product

All

Privilege

Security Administrator, Administrator

Syntax

vlan *tag* **[inline-process] [subscriber-vlan] [-noconfirm]**

no vlan *tag*

no

Deletes the VLAN with the specified tag.

tag

Specifies a tag that identifies the VLAN an integer from 1 through 4095. The tag must be unique and not used by any other VLANs on any other ports in the system.

inline-process

Do not use this restricted keyword. It sets this VLAN for special processing for packets received from an external inline server.

subscriber-vlan

Designates the VLAN type as a subscriber VLAN. This keyword must be specified if the VLAN is to be associated with specific subscribers. Refer to the **ip vlan** command in the *Subscriber Configuration Mode* chapter of this reference for additional information on Subscriber-VLAN associations.

Important: To maintain optimal performance, this keyword should not be specified for VLANs that are not to be associated with subscribers.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Virtual LANs (VLANs) provide greater flexibility in the configuration and use of contexts and services. They are configured as “tags” on a per-port basis and allow more complex configurations to be implemented. The VLAN tag allows a single physical port to be bound to multiple logical interfaces that can be configured in different contexts. Therefore, each Ethernet port can be viewed as containing many logical ports when VLAN tags are employed.

Important: VLANs are supported in conjunction with ports on the Ethernet 10/100 and Ethernet 1000 line cards, as well as on the four-port Quad Gig-E Line Card (QGLC) and the single port 10 GigE Line Card (XGLC). (VLAN tagging is not supported for SPIO ports.) The system supports the configuration of VLANs as follows:

Important: Ethernet 1000 Line Card/QGLC: 1024 VLANs per card. QGLC supports 511 VLANs per port.

Important: Ethernet 10/100 Line Card: Maximum of 256 VLANs per port and a maximum of 1016 VLANs per Line Card. (VLANs on all the ports of a single 10/100 Line Card can not add up to more than 1016.)

Important: In order to change the type (using/removing the **subscriber-vlan** keyword) for VLANs that are already configured, the VLAN must first be deleted and then reconfigured as desired.

Example

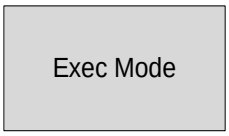
The following example creates a VLAN and assign it the tag of *100*:

```
vlan 100
```

Chapter 111
Exec Mode Commands (A-C)

This section includes the commands **aaa test** through **crypto-group**.

The Exec Mode is the initial entry point into the command line interface system. Exec mode commands are useful in troubleshooting and basic system monitoring.



aaa test

Tests Authentication, Authorization and Accounting (AAA) functionality between this system and a remote server.

Product

PDSN, HA, GGSN, SGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

aaa test { accounting username *user_name* **| authenticate** *user_name password* **| session** *user_name password* **}**

accounting username *user_name*

Tests RADIUS or GTPP accounting functionality for the specified user.
user_name must be the name of a user configured on the RADIUS or CFG server.

Important: GTPP is used only in conjunction with the GGSN or SGSN product.

authenticate *user_name password*

Tests RADIUS authentication functionality for the specified user.
user_name is the name of a user configured on the RADIUS server. *password* is the user's password.

session *user_name password*

Tests both RADIUS authentication and RADIUS or GTPP accounting functionality for the specified user.
user_name is the name of a user configured on the RADIUS server. *password* is the user's password.

Important: GTPP is used only in conjunction with the GGSN or SGSN product.

Usage

This command is used to test RADIUS-based authentication and RADIUS or GTPP accounting. This command may be useful for diagnosing problems with subscribers and access to the system and/or billing data.

Example

The following command verifies accounting for a user named *user1*:

```
aaa test accounting username user1
```

The following command tests authentication for a user named *user1* with the password *abc123*:

```
aaa test authentication user1 abc123
```

The following command tests both accounting and authentication for the user named *user1* with the password *abc123*:

```
aaa test session user1 abc123
```

active-charging service

Creates an active charging service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

active-charging service *ecs_service_name* **[-noconfirm]**

active-charging service *ecs_service_name*

Specifies name of the active charging service as an alphanumeric string of 1 through 15 characters.
If the named service does not exist, it is created and the CLI mode changes to the ACS Configuration Mode wherein the service can be configured.
If the named service already exists, the CLI mode changes to the ACS Configuration mode wherein the specified active charging service can be configured.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to create an active charging service in the system. This command can be used directly in Exec Mode after issuing the **require active-charging** command in the Global Configuration Mode. This command allows an operator (rather than security administrators and administrators) to configure the ACS functionality only.

Important: Operators need special CLI privilege for ACS functionality to be able to use this CLI command.

Example

The following command creates an active charging service named *test*:

```
active-charging service test
```

alarm

Disables the internal audible alarm on the system management card.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
alarm cutoff
```

Usage

Alarm cutoff disables the audible alarm. The alarm may be enabled following this command if an event within the system results in the audible alarm being enabled.

Example

```
alarm cutoff
```

aps

Allows the operator to perform SONET Automatic Protection Switching (APS) administrative operations.

Important: Use of this command is limited to the OLC2 and the CLC2 line cards.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

aps { clear *slot#/port#* **| exercise** *slot#/port#* **| lockout** *slot#/port#* **| switch { force | manual }** *slot#/port#* **}**

clear *slot#/port#*

Clears the last switch command on the specified channelized port.
slot#/port# is the CLC2/OLC2 slot number (valid range is 17 - 48) and appropriate port number (CLC2 valid range is 1 - 4; OLC2 valid value is 1).

exercise *slot#/port#*

Tests the APS protocol on line connected to port.
slot#/port# is the CLC2/OLC2 slot number (valid range is 17 - 48) and appropriate port number (CLC2 valid range is 1 - 4; OLC2 valid value is 1)

lockout *slot#/port#*

Prevents the working port from switching to the protection port.
slot#/port# is the CLC2/OLC2 slot number (valid range is 17 - 48) and appropriate port number (CLC2 valid range is 1 - 4; OLC2 valid value is 1)

switch { force | manual } *slot#/port#*

Switch to either the working port or the protection port:

- **force**: Forces a switch of ports, even if there is an active alarm state.
- **manual**: Implements a switch of ports if there are no active alarms.

slot#/port# is the CLC2/OLC2 slot number (valid range is 17 - 48) and appropriate port number (CLC2 valid range is 1 - 4; OLC2 valid value is 1)

Usage

This command allows an operator to perform administrative/maintenance APS tasks such as testing the APS protocol, switching the working port to the protection port, and locking out the switching function.

Example

The following command starts an APS protocol test on port 2 of card 27:

```
aps exercise 27/2
```

autoconfirm

Enables or disables confirmation for certain commands. This command affects the current CLI session only.

Important: Use the **autoconfirm** command in the Global Configuration Mode to change the behavior for all future CLI sessions.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
autoconfirm

no autoconfirm
```

Usage

When **autoconfirm** is enabled, certain commands ask you to answer yes or no to confirm that you want to execute the command. When **autoconfirm** is disabled, the confirmation questions never appear. Disabling **autoconfirm** is active for the current session only.
By default **autoconfirm** is enabled.

Example

The following command enables command confirmation:

```
autoconfirm
```

The following command disables command confirmation for the duration of the current CLI session:

```
no autoconfirm
```

bulkstats force

Manages the collection and delivery of system statistics (bulkstats) to the configured server.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
bulkstats force { gather | transfer }
```

bulkstats force gather

Immediately collects the system statistics.

bulkstats force transfer

Immediately sends the currently collected statistics to the configured server.

Usage

When the current system statistics are desired immediately as opposed to the normal scheduled collection and delivery intervals issue this command.
Troubleshooting the system may require the review of statistics at times when the scheduled delivery is not timely.

Example

The following causes the chassis to immediately collect system statistics. This would be in anticipation of a transfer command.

```
bulkstats force gather
```

The following command causes the chassis to immediately send all collected statistics to the configured server.

```
bulkstats force transfer
```

call-home send

Manages how Cisco Smart Call Home messages are sent to alert groups.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

call-home send alert-group { configuration profile *profile name* **| inventory profile** *profile name* **}**

configuration profile *profile name*

Sends configuration messages to the previously defined profile, expressed as an alphanumeric string of 1 through 31 characters.

inventory profile *profile name*

Sends inventory messages to the previously defined profile, expressed as an alphanumeric string of 1 through 31 characters.

Usage

Use this command to send specified alert-group call-home message from the CLI to all profiles subscribed to the specified alert group, or to a specified profile which does not need to be subscribed to the specified alert-group. For additional information, refer to the *Call-Home Configuration Mode Commands* and *Call-Home Profile Configuration Mode Commands* chapters.

Example

The following command sets the system to send configuration related call-home messages to the profile named *Profile1*.

```
call-home send alert-group configuration profile Profile1
```

call-home test

Sends a test Smart Call Home event message to a specified profile.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

call-home test message { *test_message_content* **| profile** *profile name* **}**

call-home test message message *test_message_content*

Defines the message to send to the defined profile as an alphanumeric string of 1 through 128 characters.

profile *profile_name*

Specifies the previously defined profile to which the message will be sent, expressed as an alphanumeric string of 1 through 31 characters.

Usage

Use this command to send test call-home messages from the CLI to a specified profile. If a message is not specified, the system sends out a default message.

Example

The following command sets the system to send a test call-home message *Test_Message_1* to the profile named *Profile1*.

```
call-home test message Test_Message_1 profile Profile1
```

card busy-out

Moves processes from the source packet processing card to the destination packet processing card, or disables the packet processing card from accepting any new calls. When busy-out is enabled, the packet processing card stops receiving new calls but continues to process calls until they are completed. The command prompt is returned once the command is initiated. The busy-out procedure is completed in background.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
card busy-out { migrate from src_slot to dst_slot } [ -noconfirm ]

no card busy-out
```

no card busy-out

Disables busy-out. The packet processing card is re-enabled to accept new calls.

migrate from *src_slot* **to** *dst_slot*

Moves processes from the specified source packet processing card to the specified destination packet processing card. The command prompt is returned once the command is initiated. The card migration is completed in background.
src_slot indicates the source slot number of the card from which processes will be migrated. *dst_slot* indicates the destination slot number of the card to which processes will be migrated.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Migrating a packet processing card changes the active/standby status of a packet processing card. This results in the active sessions/processes being moved to the newly active card. This is useful when there is a maintenance activity on the active card which requires removing the card from service.
The destination slot specified must contain a packet processing card which is in the standby state for the command to complete successfully.

Caution: Be cautious when executing this command. Depending on the number of active sessions being migrated, some subscribers may experience service interruptions.

Using busy-out to refuse new calls on a packet processing card allows you to take a card out of service without any interruptions to the end user. An individual system can be taken completely out of service gracefully by enabling busy-out on all packet processing cards and waiting for current calls to complete. The **show card info** command shows if busy-out is enabled.

Important: When a packet processing card fails, is migrated, or is restarted for any reason, busy-out is reset to disabled, the default behavior.

Important: This command is not supported on all platforms.

Example

The following command migrates the active processes from the packet processing card in slot *12* to the card in slot *14*. This command executes after you provide confirmation of the request.

```
card migrate from 12 to 14
```

```
card migrate from 1 to 8
```

The following command sets the packet processing card in slot 1 to stop accepting new calls:

```
card busy-out 1
```

card halt

Halts all StarOS processes on a card. A **card reboot** command must be issued to bring the card back into service after it is halted.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

card halt *slot_num* **[-force] [-noconfirm]**

slot_num

Indicates the slot number of the card of interest.

-force

Over-rides any warnings to force the card to be halted.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Halt a card to stop the card for maintenance or emergency situations.

Caution: Caution should be taken in using this command. Halting a card which has no redundant card available may cause a service interruption and loss of active sessions.

Caution: The **-force** and **-noconfirm** options should only be used concurrently by experienced users as this will cause an immediate halt regardless of warnings and no confirmation from the user.

Important: This command is not supported on all platforms.

Example

The following command temporarily stops the card in slot 1.

```
card halt 1
```

The following commands force the card to halt and indicate no confirmation is to take place, respectively.

```
card halt 1 -force -noconfirm
```

```
card halt 1 -noconfirm
```

card migrate

Migrates StarOS processes from an active packet processing card to a standby packet processing card.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

card migrate from *src_slot* **to** *dst_slot* **[-noconfirm]**

src_slot

Indicates the slot number of the packet processing card from which processes will be migrated. **The packet processing card in this slot must be in Active mode.**

dst_slot

Indicates the slot number of the packet processing card to which processes will be migrated.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

This command allows an operator to move processes from an active to a standby packet processing card.

Example

The following will cause processes currently running on the card in slot 8 to migrate to the standby card in slot 9. The migration will not occur if any warnings are generated.

```
card migrate from 8 to 9
```

card reboot

Resets of the target card. Rebooting a packet processing or line card will result in the card downloading the image from the active system management card.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

card reboot *target_slot* **[-force] [-noconfirm]**

card reboot *target_slot*

Initiates a reboot of the card in the specified the slot number.

-force

Indicates that the reboot is to take place ignoring any state or usage warnings that might be generated.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

A reboot is used to reset the card and receive a new download. This may be useful when a card is not responding or when it is necessary to cause the card to reload its image and restart.

Important: Caution should be taken in using this command. Rebooting a card which has no redundant card available may cause a service interruption and loss of active sessions.

Caution: The **-force** and **-noconfirm** options should only be used concurrently by experienced users as this will cause an immediate reboot regardless of warnings and no confirmation from the user.

Important: This command is not supported on all platforms.

Example

The following will cause the card in slot 8 to reboot without any confirmation from the user. The card will not reboot if there are any warnings generated.

```
card reboot 8 -noconfirm
```

The following command will cause the card in slot 8 to reboot regardless of any warnings. The user must provide confirmation prior to this command executing.

```
card reboot 8 -force
```

The following command will cause the card in slot 8 to reboot regardless of any warnings with no additional user confirmation.

```
card reboot 8 -force -noconfirm
```

card restart

Performs a soft-reset of the target card causing all application processes to restart.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
card restart target_slot [ -force ] [ -noconfirm ]
```

card restart *target_slot*

Initiates a restart of the card in the specified slot number.

-force

Indicates the restart is to take place ignoring any state or usage warnings that might be generated.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Restarting a card may be useful when a card is not performing as expected (performance drop, increased response delays, etc.). A restart may be preferred to a reboot as the card becomes available in less time than a reboot.
When this command is issued for an active card, the user is prompted for confirmation unless the **-force** and/or **-noconfirm** keywords are used. Because the reboot of standby or redundant cards is non-service impacting, the reboot proceeds immediately after the command execution without user confirmation.

Important: Caution should be taken in using this command. Restarting a card which has no redundant card available may cause a service interruption and loss of active sessions.

Important: This command is not supported on all platforms.

Caution: The **-force** and **-noconfirm** options should only be used concurrently by experienced users as this will cause an immediate restart regardless of warnings and no confirmation from the user.

Example

The following will cause the card in slot 8 to restart without any confirmation from the user. The card will not reboot if there are any warnings generated.

```
card restart 8 -noconfirm
```

The following command will cause the card in slot 8 to restart regardless of any warnings. The user must provide confirmation prior to this command executing.

```
card restart 8 -force
```

The following command will cause the card in slot 8 to restart regardless of any warnings with no additional user confirmation.

```
card restart 8 -force -noconfirm
```

card switch

Manages card pairs and their active/standby status.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
card switch { from target_slot | to target_slot } [ -noconfirm ]
```

from *target_slot*

Specifies the slot number of a currently active card that is to be switched. The slot number must be valid and contain a card in active mode.

to *target_slot*

Specifies the slot number of a standby card which is to become the active card. The slot number must be valid and contain a card in standby.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Card switch-overs change the active/standby status of a card. This is useful when there is a maintenance activity on the active card which requires removing the card from service.

Caution: Caution should be taken in using this command. Depending on the amount of bandwidth/traffic being switched, some subscribers may experience service interruptions.

Important: This command is not supported on all platforms.

Example

The following command switches the active/standby status of the line cards in slots 17 and 18. This command only executes after you provide confirmation of the request.

```
card switch from 17 to 18
```

card upgrade

Upgrades the programmable memory on a card.

Product

All

Privilege

Security Administrator, Administrator

Syntax

card upgrade *slot_number*[**-noconfirm**]

slot_number

The slot number of the card to be upgraded, from 1 through 16.

--noconfirm

Executes the command without any additional prompt and confirmation from the user.

Caution: Use this command only if instructed by or working with Technical Assistance Center personnel.

Usage

You can only initiate an upgrade if:

- there is no migration occurring,
- the card is active or standby,
- there is no online upgrade in progress.

Important: The following operations are not allowed while a card is upgrading: change edc requirement (config), change card [no] shutdown (config), change card active (config), change card redundancy (config), card halt (exec), card reboot (exec), start an online upgrade.

Important: Level unlock operations are ignored while a card is upgrading.

Important: This command is not supported on all platforms.

Example

The following command initiates a packet processing card upgrade on slot number 10:

```
card upgrade 10
```

cdr-push

Initiates a manual push of CDR files to a configured URL or Local - External Storage System (L-ESS).

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

cdr-push { all | local-filename *file_name* **}**

all

Pushes all CDR files to the configured URL.

local-filename *file_name*

Pushes only the specified file to the configured URL. *file_name* must define the absolute path of a local file name to push, expressed as an alphanumeric string of 1 through 1023 characters.

Usage

Use this command to manually push CDR files to the a configured URL or L-ESS.
For information on configuring the L-ESS, see the **cdr** command in the *EDR Module Configuration Mode Commands* and the *UDR Module Configuration Mode Commands* chapters.
Run this command only from the local context. If you are in any other context, you will see this failure message: “Failure: Manual PUSH of CDRs supported only in the local context”

Example

The following command pushes all CDR files to the URL:

```
cdr-push all
```

chassis

Identifies the chassis that can encrypt and decrypt encrypted passwords in the configuration file. If two or more chassis are configured with the same chassis key value, the encrypted passwords can be decrypted by any of the chassis sharing the same chassis key value. As a corollary to this, a chassis key value will not be able to decrypt the passwords that were encrypted using a different chassis key value.

Product

All

Privilege

Security Administrator, Administrator

Syntax

[no] chassis { key value *key_string* **| keycheck** *key_string* **}**

no chassis key

Resets the chassis key to the factory default value. The factory default value is unique to the chassis. Once this command is executed, the **chassis key value** command can be used to change the default chassis key.

key value *key_string*

Specifies the chassis key value as an alphanumeric string of 1 through 16 characters.

The chassis key value is stored as a one-way encrypted value, much like a password. It is never displayed in its plain-text form.

keycheck *key_string*

Generates a one-way encrypted key value based on the entered alphanumeric string of 1 through 16 characters.

The generated encrypted key value is compared against the encrypted key value of the previously entered chassis key value. If the encrypted values match, then the command succeeds and key check passes. If the comparison fails, a message is displayed indicating that the key check has failed. Note that if the default chassis key (no chassis key) is currently being used, this key check will always fail since there will be no chassis key value to compare against.

Usage

Establish multiple, unique chassis keys to encrypt and decrypt passwords in configuration files.

Example

The following command generates a one-way encrypted key based on the string *tewks367*.

```
chassis key value tewks367
```

clear aaa

Clears all Authentication, Authorization and Accounting (AAA) statistics in the current context.

Product

PDSN, GGSN, ASN-GW, P-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear aaa local counters
```

Usage

Clearing the AAA statistics may be useful when monitoring the statistics manually. Clearing resets the counters to zero.
The keyword **local** is not intended to imply the local context defined for all systems. Rather, it indicates the statistics within the current context are to be cleared.

Example

The following command zeroes out all the AAA statistics in the current context.

```
clear aaa local counters
```

clear active-charging analyzer statistics

Clears protocol analyzer statistics.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging analyzer statistics [name *protocol_name* **] [| { grep** *grep_options* **| more }]**

---

name *protocol_name*

Clears statistics for the specified protocol analyzer.
If this keyword is not specified all statistics are cleared.
protocol_name must be one of the following:

- **dns**
- **file-transfer**
- **ftp**
- **http**
- **icmp**
- **icmpv6**
- **imap**
- **ip**
- **ipv6**
- **mms**
- **p2p [application]**: Peer-to-peer analyzer. The supported applications are:
  - **actsync**
  - **aimini**
  - **antsp2p**
  - **applejuice**
  - **ares**
  - **armagettron**
  - **battlefld**
  - **bittorrent**
  - **blackberry**
  - **citrix**
  - **clubpenguin**
  - **crossfire**

- **ddlink**
- **directconnect**
- **dofus**
- **edonkey**
- **facebook**
- **facetime**

> ***Important:*** The **facetime** protocol is available only in releases 9.0 and 11.0. This protocol is not available in release 10.0.

- **fasttrack**
- **feidian**
- **fiesta**
- **filetopia**
- **florensia**
- **freenet**
- **fring**
- **funshion**
- **gadu_gadu**
- **gamekit**

> ***Important:*** The **gamekit** protocol is available only in releases 9.0 and 11.0. This protocol is not available in release 10.0.

- **gmail**
- **gnutella**
- **gtalk**
- **guildwars**
- **halflife2**
- **hamachivpn**
- **iax**
- **icecast**
- **imesh**
- **imo**
- **iptv**
- **irc**
- **isakmp**
- **iskoot**
- **itunes**

- **jabber**
- **kontiki**
- **manolito**
- **maplestory**
- **meebo**
- **mgcp**
- **msn**
- **mute**
- **mypeople**
- **myspace**
- **netmotion**

- **tcp**
- **tftp**
- **udp**
- **wsp**
- **wtp**

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear ACS analyzer statistics.

Example

The following command clears active charging service analyzer information for TCP analyzer:

```
clear active-charging analyzer statistics name tcp
```

clear active-charging charging-action statistics

Clears ACS charging action statistics.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear active-charging charging-action statistics [ name string ] [ | { grep grep_options
| more } ]
```

name *string*

Clears detailed information for an existing protocol analyzer.
string must be the name of an existing charging action.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear active charging action statistics.

Example

The following command clears active charging action statistics information for charging action named **pre-paid**:

```
clear active-charging charging-action statistics name pre-paid
```

clear active-charging content-filtering server-group statistics

Clears content filtering statistics for all CF server groups or a named CF server group.

Product

CF

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear active-charging content-filtering server-group statistics [ name srvrgrp_name ] [ |
{ grep grep_options | more } ]
```

name *srvrgrp_name*

Clears statistics for an existing CF server group, expressed as an alphanumeric string of 1 through 15 characters.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear content filtering statistics for CF server groups.

Example

The following command clears category-based content filtering statistics information for Rulebase named *cf_rule1*:

```
clear active-charging content-filtering category statistics rulebase name
cf_rule1
```

clear active-charging credit-control statistics

Clears credit control statistics.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging credit-control statistics [group *grp_name* **| server { ip-address** *ip_address* **| name** *name* **}]**

---

clear active-charging credit-control statistics

Clears statistics for all credit control groups.

---

group *grp_name*

Clears statistics for the credit control group specified as an alphanumeric string of 1 through 63 characters.

---

server { ip-address *ip_address* **| name** *name*

Clears statistics for the credit control server specified as:

- **ip-address**: an IP address for the credit control group entered in IPv4 dotted-decimal or IPv6 colon-separated notation
- **name**: name of the credit control group server entered as an alphanumeric string of 1 through 127 characters.

Usage

Use this command to clear credit control statistics.

Example

The following command clears statistics information for credit control:

```
clear active-charging credit-control statistics
```

clear active-charging dns-learnt-ip-addresses

Clears DNS learnt IP address statistics for the DNS Snooping feature.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging dns-learnt-ip-addresses statistics sessmgr { all | instance *sessmgr_instance* **} [| { grep** *grep_options* **| more }]**

sessmgr { all | instance *sessmgr_instance* **}**

Clears statistics for all or the specified Session Manager (SessMgr) instance.

- **all**: Clears statistics for all SessMgr instances.
- **instance** *sessmgr_instance*: Clears statistics for the specified SessMgr instance.

  sessmgr_instance must be an integer from 1 through 65535.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear DNS learnt IP address statistics for the DNS Snooping feature.
On clearing the statistics using this command, only the entries-flushed, entries-replaced, and IP-Overflows statistics are cleared as these are cumulative statistics. Total-entries will not be cleared as it is an instantaneous statistic of the current total entries in that rule line.

Example

The following command clears all DNS learnt IP address statistics:

```
clear active-charging dns-learnt-ip-addresses statistics sessmgr all
```

clear active-charging edr-format statistics

Clears ACS statistics for all Event Data Record (EDR) formats or a named EDR format.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear active-charging edr-format statistics [ name edr_format ]
```

name *edr_format*

Specifies name of the preconfigured EDR format for which you want to clear the statistics, expressed as an alphanumeric string of 1 through 63 characters.

Important: If an EDR format name is not specified, statistics for all EDR formats are cleared.

Usage

Use this command to clear the accumulated statistics for the specified EDR format.

Example

The following command clears the statistics for all EDR formats:

```
clear active-charging edr-format statistics
```

clear active-charging edr-udr-file statistics

Clears Event Data Record (EDR) and Usage Data Record (UDR) file related statistics.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear active-charging edr-udr-file statistics
```

Usage

Use this command to clear EDR and UDR file statistics.

Example

The following command clears statistical information for EDR and UDR files:

```
clear active-charging edr-udr-file statistics
```

clear active-charging firewall statistics

Clears Stateful Firewall statistics.

Product

FW

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear active-charging firewall statistics [ callid call_id | domain-name domain_name |
nat-realm nat_realm | protocol { icmp | icmpv6 | ip | ipv6 | other | tcp | udp } |
username user_name ] [ acsmgr instance instance_id ] [ | { grep grep_options | more } ]
```

acsmgr instance *instance_id*

Specifies an ACS Manager instance ID as an integer from 1 through 65535.

callid *call_id*

Specifies a call identification number as an eight-byte hexadecimal number.

domain-name *domain_name*

Specifies a domain name as an alphanumeric string of 1 through 127 characters.

nat-realm *nat_realm*

Specifies a NAT realm name as an alphanumeric string of 1 through 31 characters.

protocol { icmp | ip | other | tcp | udp }

Specifies a protocol for the statistics.

- **icmp**: ICMPv4
- **icmpv6**
- **ip**: IPv4
- **ipv6**
- **other**: Protocols other than TCP, UDP, and ICMPv4/ICMPv6
- **tcp**
- **udp**

username *user_name*

Specifies a user name as an alphanumeric string of 1 through 127 characters.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear Stateful Firewall statistics.

Example

The following command clears all Stateful Firewall statistics:

```
clear active-charging firewall statistics
```

clear active-charging firewall track-list

Clears the list of servers being tracked for involvement in any Denial-of-Service (DOS) attacks.

Product

FW

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear active-charging firewall track-list attacking-servers
```

Usage

Use this command to clear the list of servers being tracked for involvement in any DOS attacks.

Example

The following command clears the list of servers being tracked for involvement in any DOS attacks:

```
clear active-charging firewall track-list attacking-servers
```

clear active-charging fw-and-nat policy statistics

Clears statistics for all or a specific Firewall-and-NAT policy.

Product

FW, NAT

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging fw-and-nat policy statistics { all | name *policy_name* **} [| { grep** *grep_options* **| more }]**

all

Clears information for all configured firewall-and-NAT policies.

name *policy_name*

Clears information for the specified firewall-and-NAT policy, expressed as expressed as an alphanumeric string of 1 through 63 characters.

grep *grep_options***| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear statistics for all or a specific firewall-and-NAT policy.

Example

The following command clears statistics for the firewall-and-NAT policy named *test123*:

```
clear active-charging fw-and-nat policy statistics name test123
```

clear active-charging group-of-ruledefs statistics

Clears ACS group of ruledefs statistics.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging group-of-ruledefs statistics [name *group_of_ruledefs* **] [| { grep** *grep_options* **| more }]**

name *group_of_ruledefs*

Specifies the name of the group of ruledefs for which statistics must be cleared. *group_of_ruledefs* must be the name of an existing group of ruledefs expressed as an alphanumeric string of 1 through 63 characters.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear statistical information related to all or specified Active Charging Service group of ruledefs.

Example

The following command clears statistical information related to the group of ruledefs named *ruledef_group12*:

```
clear active-charging group-of-ruledefs statistics name ruledef_group12
```

clear active-charging nat statistics

Clears NAT realm statistics.

Product

NAT

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging nat statistics [nat-realm *nat_realm* **] [| { grep** *grep_options* **| more }]**

clear active-charging nat statistics

This command when issued in the local context clears statistics for all NAT realms in all contexts. When issued in a specific context, this command clears statistics for all NAT realms in that context.

clear active-charging nat statistics nat-realm *nat_realm*

This command when issued in the local context clears statistics for the specified NAT realm in all contexts. When issued in a specific context, this command clears statistics for the specified NAT realm in that context.

nat-realm *nat_realm*

Specifies name of the NAT realm as an alphanumeric string of 1 through 31 characters.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear NAT realm statistics.

Example

The following command when issued in the local context, clears NAT realm statistics for NAT realms named *test135* in all contexts:

```
clear active-charging nat statistics nat-realm test135
```

clear active-charging rulebase statistics

Clears ACS rulebase statistics.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging rulebase statistics [name *rulebase_name* **] [| { grep** *grep_options* **| more }]**

rulebase_name

Clears statistics for an existing ACS rulebase expressed as an alphanumeric string of 1 through 15 characters.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear ACS rulebase statistics.

Example

The following command clears statistics for the ACS rulebase named *postpaid*:

```
clear active-charging rulebase statistics name postpaid
```

clear active-charging ruledef statistics

Clears statistics for rule definitions configured in the Active Charging Service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear active-charging ruledef statistics [ charging | firewall | name ruledef_name | tpo
] [ | { grep grep_options | more } ]
```

charging

Clears statistics for all configured Charging ruledefs.

firewall

Clears statistics for all configured Stateful Firewall ruledefs.

name *ruledef_name*

Clears statistics for the specified ruledef.
ruledef_name must be the name of an existing ruledef expressed as an alphanumeric string of 1 through 63 characters.

tpo

Important: The **tpo** keyword is available only in 12.2 and later releases.

Clears statistics for all configured Traffic Performance Optimization (TPO) ruledefs.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear ACS ruledef statistics.

Example

The following command clears all ruledef statistics:

```
clear active-charging ruledef statistics
```

clear active-charging subsystem

Clears all ACS subsystem information.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear active-charging subsystem
```

Usage

Use this command to clear all ACS subsystem information.

Example

The following command clears all ACS subsystem information:

```
clear active-charging subsystem
```

clear active-charging tcp-proxy statistics

Clears ACS TCP Proxy statistics.

Product

ACS

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging tcp-proxy statistics [all | ip-layer | proxy-fac | rulebase *rulebase_name* **| socket-migration | tcp-layer]**

all

Clears all TCP Proxy statistics.

ip-layer

Clears TCP Proxy statistics for IP layer.

proxy-fac

Clears TCP Proxy Flow Admission Control statistics.

rulebase *rulebase_name*

Clears TCP Proxy statistics for the rulebase specified as an alphanumeric string of 1 through 63 characters.

socket-migration

Clears TCP Proxy Socket Migration related statistics.

tcp-layer

Clears TCP Proxy statistics for TCP layer.

Usage

Use this command to clear TCP Proxy statistics.

Example

The following command clears TCP Proxy statistics for the rulebase named *test14*:

```
clear active-charging tcp-proxy statistics rulebase test14
```

clear active-charging tethering-detection statistics

Clears statistics pertaining to the Tethering Detection feature.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
clear active-charging tethering-detection statistics
```

Usage

Use this command to clear statistics pertaining to the Tethering Detection feature.

clear active-charging tpo policy statistics

Clears Traffic Performance Optimization (TPO) policy statistics.

Product

TPO

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging tpo policy statistics [name *tpo_policy_name* **]**

name *tpo_policy_name*

Clears statistics for an existing TPO policy specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear TPO policy statistics.

- **clear active-charging tpo policy statistics** command clears statistics for all TPO policies configured in the active charging service.
- **clear active-charging tpo policy statistics name** *tpo_policy_name* command clears statistics for the specified TPO policy.

Example

The following command clears statistics for the TPO policy named *policy12*:

```
clear active-charging tpo policy statistics name policy12
```

clear active-charging tpo profile statistics

Clears Traffic Performance Optimization (TPO) profile statistics.

Product

TPO

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging tpo profile statistics [name *tpo_profile_name* **]**

name *tpo_profile_name*

Clears statistics for an existing TPO profile specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear TPO profile statistics.

- **clear active-charging tpo profile statistics** command clears statistics for all TPO profiles configured in the active charging service.
- **clear active-charging tpo profile statistics name** *tpo_profile_name* command clears statistics for the specified TPO profile.

Example

The following command clears statistics for the TPO profile named *profile12*:

```
clear active-charging tpo profile statistics name profile12
```

clear active-charging url-blacklisting statistics

Clears URL Blacklisting feature related statistics.

Product

CF

Privilege

Security Administrator, Administrator, Operator

Syntax

clear active-charging url-blacklisting statistics [rulebase name *rulebase_name* **] [| { grep** *grep_options* **| more }]**

rulebase name *rulebase_name*

Clears URL Blacklisting information for an existing rulebase specified as an alphanumeric string of 1 through 63 characters.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear URL Blacklisting feature related statistics, optionally for a specific rulebase.

Example

The following command clears URL Blacklisting feature related statistics for *rulebase12*:

```
clear active-charging url-blacklisting statistics rulebase name
rulebase12
```

clear active-charging video detailed-statistics

Resets the detailed statistics for TCP video flows.

Product

MVG

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear active-charging video detailed-statistics
```

Usage

Use this command to reset the detailed statistics for TCP video flows.

Example

The following command resets the detailed statistics for TCP video flows:

```
clear active-charging video detailed-statistics
```

clear administrator

Ends the session of an administrative user specified by either user name or session ID.

Product

All

Privilege

Security Administrator, Administrator

Syntax

clear administrator { name *user_name* **| session id** *id_num* **}**

name *user_name*

Identifies the user name of the administrative user.

session id *id_num*

Identifies the ID number of the administrative user session as displayed in the output of the **show administrators session id** command.

Usage

This command is used to terminate command line interface sessions for other administrative users.

Example

The following command ends the session of the administrative user identified as *user1*:

```
clear administrator name user1
```

The following command ends the session of the administrative user with the session ID of *3*:

```
clear administrator session id 3
```

clear alarm

Clears outstanding alarm conditions

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear alarm { all | chassis | id *num* **| port** *slot/port* **| slot** *slot* **}**

all

Clear all outstanding alarms

chassis

Clears chassis-wide and fan tray alarms

id *num*

Clears a specific alarm by its internal alarm ID. *num* is the internal alarm identification number.

port *slot/port*

Clears alarms for the specified port. *slot/port* is the card slot and port on the card for which to clear alarms.

slot *slot*

Clears alarms for the specified slot. *slot* is the card slot for which to clear alarms.

Usage

Use this command to clear outstanding alarm conditions.

Example

To clear all outstanding alarms, use the following command:

```
clear alarm all
```

To clear all alarms for slot 7, enter the following command:

```
clear alarm slot 7
```

clear alcap

Clears the Access Link Control Application Part (ALCAP) session statistics of an ALCAP service associated with a Home-NodeB Gateway (HNB-GW) service instance configured and running on a system.

Product

HNB-GW

Privilege

Operator

Syntax

clear alcap statistics [alcap-service *alcap_svc_name* **[aal2-node** *aal2_node_name* **[aal2-path** *aal2_path_id* **]]]**

alcap-service *alcap_svc_name*

Specifies the name of the ALCAP service for which statistics are to be cleared.

aal2-node *aal2-node*

Specifies the name of the ATM Adaptation Layer 2 (AAL2) node for which ALCAP service statistics will be cleared.

aal2-path *aal2_path_id*

Specifies the identity number of the AAL2 path on a specific ATM Adaptation Layer 2 (AAL2) node for which ALCAP service statistics will be cleared.

Usage

This command is used to clear the sessions statistics and counters for ALCAP service.

Example

The following command clears the service session statistics of ALCAP service named as *alcap_hnb_svc1*:

```
clear alcap statistics alcap-service alcap_hnb_svc1
```

clear asngw-service

Clears the service session statistics for an Access Service Network Gateway (ASN-GW) service specified by either service name or trusted peer address.

Product

ANS-GW

Privilege

Security Administrator, Administrator

Syntax

clear asngw-service statistics [name *svc_name* **| peer-address** *ip_address* **]**

name *svc_name*

Identifies the name of the ASN-GW service for which statistics will be cleared. *svc_name* must be an alphanumeric string of 1 through 63 characters.

peer-address *ip_address*

Identifies the IP address of the ASN-GW peer for which service statistics will be cleared. *ip_address* must be entered in IPv4 dotted-decimal notation.

Usage

This command is used to terminate command line interface sessions for ASN GW services.

Example

The following command clears the service session statistics of the ASN-GW service named *aasn_svc1*:

```
clear asngw-service statistics name asn_svc1
```

clear asnpc-service

Clears the service session statistics of an ASN paging controller service specified by either ASN PC service name or trusted paging controller peer address.

Product

ANS-GW

Privilege

Security Administrator, Administrator

Syntax

clear asnpc-service statistics [name *svc_name* **| peer-address** *ip_address* **]**

name *svc_name*

Identifies the name of the ASN PC service for which session statistics will be cleared. *svc_name* must be an alphanumeric string of 1 through 63 characters.

peer-address *ip_address*

Identifies the IP address of the ASN PC peer for which all service statistics will be cleared. *ip_address* must be entered in IPv4 dotted-decimal notation.

Usage

This command is used to terminate command line interface sessions for ASN PC services.

Example

The following command clears the service session statistics of ASN PC service named as *asnpc_svc1*:

```
clear asnpc-service statistics name asnpc_svc1
```

clear apn statistics

Deletes all previously gathered statistics for either a specific Access Point Name (APN) or all APNs configured with the given context.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

clear apn statistics [name *apn_name* **| smgr-instance** *instance* **] [| { grep** *grep_options* **| more }]**

name *apn_name*

Specifies the name of a specific APN configured in the context for which to clear statistics. *apn_name* is the name of the APN expressed as an alphanumeric string of 1 through 63 characters that is case sensitive.

smgr-instance *instance*

Specifies a particular Sessmgr instance in the context for which to clear APN statistics. *instance* must be an integer from 1 to 4294967295.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Statistics for a single APN can be cleared using the **name** keyword. Statistics for all APNs in the context can be deleted by entering the command with no keywords.
If this command is executed from within the local context with no keywords, statistics will be cleared for every APN configured on the system regardless of context. In addition, if the **name** keyword is used when executing from within the local context, statistics for all APNs configured with the specified name will be cleared regardless of context.

Example

The following command clears statistics for an APN called *isp1*:

```
clear apn statistics name isp1
```

clear bcmcs statistics

Clears Broadcast Multicast Service (BCMCS) statistics.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear bcmcs statistics [pdsn-service *service_name* **]**

pdsn-service *service_name*

Specifies a specific PDSN service for which to clear BCMCS-specific statistics. This value must be an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear accumulated BCMCS statistics. You may specify an individual PDSN or peer to selectively clear statistics.

Example

```
clear bcmcs statistics

clear bcmcs statistics pdsn-service service_name
```

clear blacklisted-gtpu-bind-address

Clears the GTP-U loopback address blacklisted by a specific radio network controller (RNC) as defined for a specific IuPS Service configuration.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear blacklisted-gtpu-bind-address *ip_address* **rnc-id** *rnc_id* **mcc** *mcc_num* **mnc** *mnc_num* **iups-service** *name*

ip_address

Specifies the IP loopback address that has been blacklisted in IPv4 dotted-decimal notation. This loopback address was originally defined with the **associate-gtpu-bind-addfress** command in the Radio-Network-Controller Configuration mode of the IuPS Service.

Usage

This command enables this loopback address to be used for future RAB-assignment requests.

Example

```
clear blacklisted-gtpu-bind-address 1.1.1.1 rnc-id 2 mcc 123 mnc 321
iups-service iups1
```

clear bssap+ statistics

Clears the BSSAP+ protocol (base station subsystem GPRS protocol) statistics collected for the Gs interface between the SGSN and the MSC/VLR.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear bssap+ statistics [gs-service *gs_svc_name* **] [vlr { isdn-number** *ISDN_Num*| **name** *vlr_name* **}] [| { grep** *grep_options* **| more }]**

gs-service *gs_svc_name*

Specifies the name of a preconfigured Gs service handling BSSAP+ information as an alphanumeric string of 1 through 63 characters that is case sensitive.

vlr { isdn-number *ISDN_Num*| **name** *vlr_name*

Specifies a VLR (by ISDN number or name) handling BSSAP+ information.
isdn-number *ISDN_num* is the configured E.164-type ISDN number for the VLR. Enter a numerical string of 1 to 15 digits.
name *vlr_name* is the configured name of the VLR entered as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to delete or clear collected BSSAP+ protocol statistics for the entire SGSN or for a specified Gs interface. Using the keywords of this command, the interface can be identified by defining a specific VLR connected to the SGSN or by identifying the Gs service to which the interface has been configured.

Example

The following command clears the BSSAP+ statistics collected for the Gs interface configured for the Gs service named *gssvc1*.

```
clear bssap+ statistics gs-service gssvc1
```

clear bssgp statistics

Clears collected BSSGP protocol (base station subsystem GPRS protocol) statistics for traffic between the base station subsystem (BSS) and the SGSN.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear bssgp statistics [gprs-service *gprs_svc_name* **| nse** *nse_id* **[bvc** *bvc_id* **] [| { grep** *grep_options* **| more }]**

gprs-service *gprs_svc_name*

Specifies the name of a preconfigured GPRS service for which the BSSGP statistics have been collected as an alphanumeric string of 1 through 63 characters that is case sensitive.

nse *nse_ID*

Clears the BSSGP statistics collected for the network service entity (NSE) specified as an integer from 0 through 65535.

bvc *bvc_ID*

Enter this keyword to clear the BSSGP statistics collected for the identified BSSGP virtual connection (BVC) specified as n integer from 0 through 65000.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear the BBSGP statistics for a particular GPRS service or NSEI.

Example

The following command deletes the collected BSSGP statistics for the GPRS service named *gprs1*.

```
clear bssgp statistics gprs-service gprs1
```

clear bulkstats

Clears counters and accumulated bulk statistics related information.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear bulkstats { counters | data }
```

counters

Clears the counters maintained by the system's "bulkstats" facility.

data

Clears any accumulated data that has not been transferred. This includes any "completed" files that have not been successfully transferred.

Usage

Once bulk statistics collection is enabled, the system stores the information until the specified transfer criteria is met or until a manual transfer is initiated. The system maintains counters for the "bulkstats" software facility. (Refer to the **data** keyword for the **show bulkstats** command for information on viewing the counters.)
This command can be used to delete bulk statistics information that has been collected but not transferred and/or to clear the counters that have been maintained.

Example

The following command clears bulk statistics-related counters:

```
clear bulkstats counters
```

clear cae-group statistics server

This command resets the discardable statistics, which are the Hit Count, Timeout Consecutive (Cumulative), and Last Failure statistics, for all CAEs or for a specific CAE. The CAE (Content Adaptation Engine) is an optional component of the Mobile Videoscape.

Product

MVG

Privilege

Security Administrator, Administrator

Syntax

clear cae-group statistics server { all | name *cae_name* **}**

all

Resets the discardable statistics for all CAEs.

name*cae_name*

Specifies the name of a CAE.

Usage

Use this command to reset the discardable statistics for all CAEs or for a specific CAE. This command must be issued in the same context in which the associated CAE group is defined.

Example

The following command clears the discardable statistics for the CAE named *server_1*:

```
clear cae-group statistics server name server_1
```

clear config

Replaces the active configuration source file with an empty configuration where possible.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
clear config [ -noconfirm ]
```

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

This command clears the current configuration when a complete overwrite is desired or if it is necessary to start from an empty configuration.

Important: Clearing the configuration will cause the active configuration source file to be empty and of no use in configuring the system to an active state providing service.

Important: This command should only be performed on configurations that have been previously backed up for easy restoration.

Example

The following command clears the active configuration after the user provides confirmation of the request.

```
clear config
```

The following command clears the active configuration source file immediately with no user confirmation.

```
clear config -noconfirm
```

clear congestion-control statistics

Clears the congestion control statistics for all instances of the specified manager type.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear congestion-control statistics {**a11mgr** | **asngwmgr** | **asnpcmgr** | **bindmux**|**hamgr** | **hnbmgr** | **gtpcmgr** | **ipsecmgr** | **imsimgr** | **l2tpmgr**}

a11mgr

Clears the statistics for all A11 Manager instances.

asngwmgr

Clears the statistics for all ASN GW Manager instances

asnpcmgr

Clears the statistics for all ASN PC-LR Manager instances

bindmux

Clears the statistics for all IPCF BindMux-Demux Manager instances.

hamgr

Clears the statistics for all HA Manager instances.

hnbmgr

Clears the statistics for all HNB Manager instances.

gtpcmgr

Clears the statistics for all GTPC Manager instances.

ipsecmgr

Clears the statistics for all IPSEC Manager instances.

imsimgr

Clears the statistics for all IMSI Manager instances.

l2tpmgr

Clears the statistics for all L2TP Manager instances.

Usage

Use this command to statistics for all instances of the specified manager.

Important: When this command is issued in any context other than the local context, only instances of the specified manager for the current context have the statistics cleared. When the current context is the local context, all instances of the specified manager type in all contexts have the statistics cleared.

Example

Clear the statistics for all instances of the A11 manger, by entering the following command:

```
clear congestion-control statistics a11mgr
```

clear content-filtering category statistics

Clears the Category-based Content Filtering application statistics.

Product

CF

Privilege

Security Administrator, Administrator, Operator

Syntax

clear content-filtering category statistics [facility srdbmgr instance *instance_value* **]**

facility srdbmgr instance *instance_value*

Clears logged events for the specified SRDB Manager instance.
instance_value must be an integer from 1 through 8.
In StarOS 9.0 and later releases, *instance_value* must be an integer from 1 through 10000.

Usage

Use this command to clear all Category-based Content Filtering application statistics, or statistics for a specific SRDB Manager instance.

Example

The following command clears all Category-based Content Filtering application statistics:

```
clear content-filtering category statistics
```

clear crash

Removes a specific crash file or all crash files.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear crash [list | number *crash_num* **]**

list | number *crash_num*

list: removes all crash files.
number *crash_num*: removes only the crash file specified as an integer from 1 through 30.

Usage

Clear crashes for general maintenance activities in cleaning out old, unused, or files which are of no importance.

Example

The following will remove all crash files.

```
clear crash list
```

The following command will remove only crash file *27*.

```
clear crash numer 27
```

clear credit-control statistics

Clears credit control statistics.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear credit-control statistics cc-service *cc_service_name*

cc-service *cc_service_name*

Specifies an existing Credit Control service name as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear active credit control statistics.

Example

The following command clears the configured credit control statistics for a service named *service1*:

```
clear credit-control statistics cc-service service1
```

clear crypto

Clears crypto associations or crypto statistics.

Product

PDSN, HA, GGSN, PDG/TTG, PDIF, SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

clear crypto { isakmp [tag *map_name* **| peer** *peer_ip* **] | security-association { counters tag** *map_name* **[tx | rx] | tag** *map_name* **| peer** *peer_ip* **} | statistics { ikev2 | ipsec-3gpp-cscf | srtp } [service-ip-address** *ip-address* **| service-name** *name* **] }**

isakmp [tag *map_name* **| peer** *peer_ip* **]**

When no keywords are specified, this command clears all of the ISAKMP security associations for the current context.
tag *map_name*: Clears the ISAKMP SAs for the specified crypto map. *map_name* is the name of an existing crypto map.
peer *peer_ip*: Deletes the ISAKMP SAs for the specified peer. *peer_ip* must be entered in IPv4 dotted-decimal or IPv6 colon-separated notation.

security-association { counters map *map_name* **[tx | rx] | tag** *map_name* **| peer** *peer_ip* **}**

counters tag *map_name* **[tx | rx]**: Resets the counters for the specified crypto map. *map_name* is the name of an existing crypto map. **tx** specifies that only the transmit SA counters are reset. **rx** specifies that only the receive SA counters are reset. If neither **tx** or **rx** are specified, both transmit and receive SA counters are reset.
tag *map_name*: Tears down a Security Association (SA) for the specified crypto map. *map_name* is the name of an existing crypto map.
peer *peer_ip*: Clears the SAs for all tunnels who have the peer at the specified IP address. *peer_ip* must be entered in Pv4 dotted-decimal or IPv6 colon-separated notation.

Caution: Modification(s) to an existing crypto map and/or ISAKMP policy configuration will not take effect until the related security association has been cleared.

statistics { ikev2 | ipsec-3gpp-cscf | srtp } [service-ip-address *ip-address* **| service-name** *name* **]**

ikev2: Clears global IKEv2 statistics for the current context.
ipsec-3gpp-cscf: Clears global CSCF IPSec statistics for the current context.
srtp: Clears global CSCF SRTP (Secure Real-time Transport Protocol) statistics for the current context.
service-ip-address *ip-address*: Clears statistics for the specified service-ip address. **service-name** *name*: Clears statistics for the specified service name.

Usage

Clear SAs and apply changes to the crypto map or clear the crypto statistics for this context.

Example

The following clears all IKEv2 crypto statistics for the current context:

```
clear crypto statistics ikev2
```

clear cs-network statistics

Clears the HNB-Circuit Switched (CS) network service associated for an HNB-GW service instance.

Product

HNB-GW

Privilege

Operator

Syntax

clear cs-network statistics [name *cs_svc_name* **| ranap-only | rtp-only | sccp-only]**

name *cs_svc_name*

Clears the session statistics for an HNB-CS Network service name configured and running on this system. *cs_svc_name* must be an alphanumeric string of 1 through 63 characters.

ranap-only

Clears the session statistics limited to Radio Access Network Application Protocol (RANAP) traffic only for the specified HNB-CS Network service.

rtp-only

Clears the session statistics limited to Real Time Protocol (RTP) traffic only for the specified HNB-CS Network service.

sccp-only

Clears the session statistics limited to Signaling Connection Control Part (SCCP) traffic only for the specified HNB-CS Network service.

Usage

Use this command to clear the session statistics for overall session or in selected part of user session for HNB-CS Network services configured and running on a system.

Example

The following command clears the session statistics for RANAP part of session for the HNB-CS Network service *hnb_CS_1*:

```
clear cs-network statistics name hnb_CS_1 ranap-only
```

clear cscf service

Resets statistics counters for a specific Call/Session Control Function (CSCF) service, all CSCF services, or for all services within a specified context (VPN).

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

clear cscf service { diameter { location-info | policy-control } statistics [service-name *service_name* **| vpn-name** *name* **] | li-packet-cable statistics [service-name** *service_name*] **| performance-counters name** *service_name* **| statistics name** *service_name* **{ all | calls | ip-security | message | package-name { message-summary | presence | reg | winfo } | registrations | sigcomp | tcp { msrp | sip } | vpn-name** *name* **{ all | calls | ip-security | message | package-name { message-summary | presence | reg | winfo } | registrations | sigcomp | tcp { msrp | sip } } }**

---

diameter { location-info | policy-control } statistics [service-name *service_name* **| vpn-name** *name* **]**

Clears Diameter (DPECA) statistics on the CSCF Rx interface with the configuration information.
service-name *service_name*: Specifies the name of an existing CSCF service for which the statistics will be reset as an alphanumeric string of 1 through 63 characters.
vpn-name *name*: Specifies the name of an existing context in which all statistics for all services will be reset as an alphanumeric string of 1 through 79 characters.

---

li-packet-cable statistics [service-name *service_name* **]**

Refer to the *Lawful Intercept Configuration Guide* for a description of this command.

---

performance-counters name *service_name*

Clears all CSCF performance counters for an existing CSCF service specified as an alphanumeric string of 1 through 63 characters.

---

statistics name *service_name* **{ all | calls | ip-security | message | package-name { message-summary | presence | reg | winfo } | registrations | sigcomp | tcp tcp { msrp | sip } | vpn-name** *name* **{ all | calls | ip-security | message | package-name { message-summary | presence | reg | winfo } | registrations | sigcomp | tcp tcp { msrp | sip } } }**

Clears service statistics for an existing CSCF service specified as an alphanumeric string of 1 through 63 characters.
all: Clears all CSCF service statistics.
calls: Clears statistics related to CSCF calls.
ip-security: Clears statistics related to CSCF IPSec.
message: Clears statistics for the SIP method MESSAGE.
package-name: Clears statistics for the associated event package.

- **message-summary**: Clears statistics for the “message-summary” event package.
- **presence**: Clears statistics for the “presence” event package.

- **reg**: Clears statistics for the “reg” event package.
- **winfo**: Clears statistics for the “watcher-info” event package.

registrations: Clears statistics related to CSCF registrations, re-registrations, and de-registrations.
sigcomp: Clears statistics related to CSCF sigcomp.
tcp: Displays session statistics related to CSCF TCP.

- **msrp**: Clears statistics related to CSCF MSRP TCP.
- **sip**: Clears statistics related to CSCF SIP TCP.

vpn-name *name*: Clears statistics for a specific CSCF service configured in a specific context on this system. *name* must be an existing context expressed as an alphanumeric string of 1 through 79 characters.

Important: This keyword must be followed by another statistics-related keyword.

Usage

Use this command to reset statistics counters for CSCF services. This command will reset the counters in the output of the **show cscf service statistics** command.

Important: This command will not clear current registered users and current CSCF sessions.

Example

The following command resets all statistics for a service named *cscf1*:

```
clear cscf service statistics name cscf1 all
```

clear cscf sessions

Clears statistics for Call/Session Control Function (CSCF) sessions on this system.

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

clear cscf sessions { counters { calls | subscription } service *service_name* **| service** *service_name* **{ all | aor** *aor* **| session-id** *id* **}**

---

counters { calls | subscription } service *service_name*

Clears counters for all CSCF sessions matching the filter criteria.
calls: Counters associated with calls in CSCF service.
subscription: Counters associated with subscriptions in CSCF service.
service *service_name*: Counters on specific CSCF service. *service_name* must be an existing CSCF service expressed as an alphanumeric string of 1 through 63 alphanumeric characters.

---

service *service_name* **{ all | aor** *aor* **| session-id** *id* **}**

Clears session information for all CSCF sessions matching the filter criteria.
service *service_name*: Session statistics on specific CSCF service. *service_name* must be an existing CSCF service expressed as an alphanumeric string of 1 through 63 alphanumeric characters.

- **all**: Specifies that session statistics are to be cleared for all sessions on this service.
- **aor** *aor*: Specifies that session statistics are to be cleared for sessions at this specific AoR. *aor* must be an existing AoR expressed as an alphanumeric string of 1 through 79 characters.
- **session-id** *id*: Specifies that session statistics are to be cleared for sessions with this ID. *id* must be an existing session ID expressed as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear session information for CSCF sessions.

Example

The following command resets all session statistics for a service named *cscf1*:

```
clear cscf sessions service cscf1 all
```

clear cscf sip

Resets SIP statistics counters for a specific CSCF service, all CSCF services, or for all services within a specified context (VPN) or interface.

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

clear cscf sip statistics [name *service_name* **[interface { domain name** *domain_name* **| ip address** *ip_address* **} | vpn-name** *name* **]**

name *service_name*

Specifies the name of an existing CSCF service for which the SIP statistics will be reset as an alphanumeric string of 1 through 63 characters.

interface { domain name *domain_name* **| ip address** *ip_address* **}**

SIP statistics will be reset in this interface.
domain name *domain_name*: Specifies an existing domain associated with the CSCF service as an alphanumeric string of 1 through 64 characters.
ip address *ip_address*: Specifies the destination or source ip address associated with the CSCF service.

vpn-name *name*

Specifies the name of an existing context in which all SIP statistics for all services will be reset as an alphanumeric string of 1 through 79 characters.

Usage

Use this command to reset SIP counters found in the output of the **show cscf sip** command.

Example

The following command resets the SIP statistics for a service named *cscf1*:

```
clear cscf sip statistics name cscf1
```

clear cscf subscription

Clears all subscriptions for a named service or for individual subscribers within the service.

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

clear cscf subscription service *service_name* **{ all | from-aor** *subscriber_aor* **to-aor** *resource_aor* **}**

service *service_name*

Specifies the name of an existing CSCF service for which the subscription(s) will be cleared as an alphanumeric string of 1 through 63 characters.

all | from-aor *subscriber_aor* **to-aor** *resource_aor*

all: Removes all CSCF subscriptions for the specified service.
from-aor *subscriber_aor*: Removes all CSCF subscriptions for a specified subscriber in a specified service.
subscribed-to *resource_aor*: Removes all CSCF subscriptions for a specified subscriber in a specified service with a specified subscribed-to resource AoR.

Usage

Use this command to clear subscriptions to enforce policies. This command initiates a SUBSCRIBE request with Expires as 0 in the corresponding subscription dialog.

Example

The following command clear all subscriptions for a CSCF service named *cscf1*:

```
clear cscf subscription service cscf1 all
```

clear diameter-service

Clears information pertaining to configured Diameter services.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear diameter-service { eap { all | session-id *session_id* **} | lte-s6b { all | session-id** *session_id* **} | lte-sta { all | session-id** *session_id* **} | mbms { bearer-contexts { all | bmsc-bearer-service name** *service_name* **} | ue-context { all | bmsc-bearer-service name** *service_name* **} } | statistics name** *service_name* **[vpn-name** *vpn context_name* **] }**

---

eap { all | session-id *session_id* **}**

Clears subscribers from the EAP interface.
all: Clears all subscribers.
session-id *session_id*: Clears a call for the session ID specified as an alphanumeric string of 1 through 63 characters.

---

lte-s6b { all | session-id *session_id* **}**

Clears subscribers from the S6b interface.
all: Clears all subscribers.
session-id *session_id*: Clears a call for the session ID specified as an alphanumeric string of 1 through 63 characters.

---

lte-sta { all | session-id *session_id* **}**

Clears subscribers from STa interface.
all: Clears all subscribers.
session-id *session_id*: Clears a call for the session ID specified as an alphanumeric string of 1 through 63 characters.

---

mbms { bearer-contexts { all | bmsc-bearer-service name *service_name* **} | ue-context { all | bmsc-bearer-service name** *service_name* **} }**

Clears information from the SGSN-APP interface.
bearer-contexts { all | bmsc-bearer-service name *service_name* **}**: Clears information from the bearer-context gmb-interface.
all: Clears all subscribers.
bmsc-bearer-service name *service_name* **}**: Specifies the name of a bmsc-bearer-service as an alphanumeric string of 1 through 63 characters.
ue-context { all | bmsc-bearer-service name *service_name* **}**: Clear information UE context for gmb-interface.
all: Clears all subscribers.
bmsc-bearer-service name *service_name* **}**: Specifies the name of a bmsc-bearer-service as an alphanumeric string of 1 through 63 characters.

service_name

service_name must be a name of a Diameter service expressed as an alphanumeric string of 1 through 63 characters.

statistics name *service_name* **[vpn-name** *vpn context_name* **]**

Clears the Diameter service associated with the specified statistics.
name *service_name*: Specifies the name of a Diameter service as an alphanumeric string of 1 through 63 characters.
vpn-name *vpn context_name*: Clears statistics for the vpn-context name specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear information pertaining to configured Diameter services.

Example

The following command clears Diameter service information for all subscribers associated with EAP interface:

```
clear diameter-service eap all
```

clear diameter aaa-statistics

Clears Diameter AAA statistics.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear diameter aaa-statistics [all | [group *aaa_group* **] server** *diameter_server* **] [| { grep** *grep_options* **| more }]**

all

Clears all Diameter server statistics.

group *aaa_group*

Clears Diameter server statistics for the AAA group specified as an alphanumeric string of 1 through 64 characters.

server *diameter_server*

Clears Diameter server statistics for the Diameter server specified as an alphanumeric string of 1 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear Diameter AAA statistics.

Example

The following command clears Diameter server statistics for the specified AAA group:

```
clear diameter aaa-statistics group aaagroup3
```

clear diameter statistics

Clears Diameter statistics.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear diameter statistics [[proxy] endpoint *endpoint_name* **[peer-host** *host_id* **[peer-realm** *realm_id* **]]] [| { grep** *grep_options* **| more }]**

endpoint *endpoint_name*

Clears endpoint-related statistics for the endpoint expressed as an alphanumeric string of 1 through 63 character.

proxy

Clears proxy related statistics.

peer-host *host_id*

Clears statistics for the Diameter peer host ID specified as an alphanumeric string of 1 through 255 characters.

peer-realm *realm_id*

Clears statistics for the Diameter peer realm specified as an alphanumeric string of 1 through 127 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear Diameter statistics.

Example

The following command clears all Diameter statistics for the specified endpoint:

```
clear diameter statistics endpoint endpt345
```

clear dhcp statistics

Deletes all previously gathered statistics for either a specific DHCP server or all DHCP servers configured within the given context.

Product

GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear dhcp statistics [ dhcp-service svc_name | server ip_address ]
```

dhcp-service *svc_name*

Specifies the name of a specific DHCP service for which to clear statistics as an alphanumeric string of 1 through 63 characters that is case sensitive.

server *ip_address*

Specifies the IP address of a DHCP server in IPv4 dotted-decimal notation as configured in the context for which to clear statistics.

Usage

Statistics for a single server can be cleared using the **server** keyword. Statistics for all DHCP servers in the context can be deleted by entering the command with no keywords.
This command can be executed from any context configured on the system.
If this command is executed from within the local context with no keywords, statistics will be cleared for every DHCP server configured on the system regardless of context. In addition, if the server keyword is used when executing from within the local context, statistics for all DHCP servers configured with the specified name will be cleared regardless of context.

Example

The following command clears statistics for all configured DHCP servers within the context:

```
clear dhcp statistics
```

clear dns-client

Clears DNS cache and/or statistics for a specified DNS client.

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

clear dns-client *name* **{ cache [query-name** *name* **| query-type { A | AAAA | NAPTR | SRV }] | statistics }**

dns-client *name*

Specifies the name of an existing DNS client whose cache and/or statistics are being cleared as an alphanumeric string of 1 through 255 characters.

cache [query-name *name* **| query-type { A | AAAA | NAPTR | SRV }]**

Specifies that the cache for the defined DNS client is to be cleared.
query-name *name*: Filters DNS results based on the domain name. The name is an alphanumeric string of 1 through 255 characters. that is the domain name used to perform the DNS query. This name is different from the actual domain name which is resolved. For example, to resolve the SIP server for *service.com*, the query name is *_sip._udp.service.com* and the query type is **SRV**.
query-type:

- **A**: Filters DNS results based on domain IP address records (A records).
- **AAAA**: Filters DNS results based on AAAA records (AAAA resource records).
- **NAPTR**: Filters DNS results based on Name Authority Pointer records.
- **SRV**: Filters DNS results based on service host records (SRV records).

statistics

Specifies that statistics for the defined DNS client are to be cleared.

Usage

Use this command to clear DNS cache and/or statistics for a specified DNS client.

Example

The following command clears statistics for a DNS client named *domain1.com*:

```
clear dns-client domain1.com statistics
```

clear egtpc

Clears enhanced GPRS Tunneling Protocol control plane (eGTP-C) statistics and counters found in **show** command outputs and bulk statistics associated with all eGTP-C-related services or those defined by the parameters in this command.

Product

MME, P-GW, S-GW

Privilege

Operator

Syntax

clear egtpc statistics [egtp-service *name* **| interface-type { interface-mme | interface-pgw-ingress | interface-sgw-egress | interface-sgw-ingress } | mme-address** *ip_address* **| pgw-address** *ip_address* **| sgw-address** *ip_address* **]**

---

egtp-service *name*

Clears all statistics and counters associated with an existing eGTP service name specified as an alphanumeric string of 1 through 63 characters.

---

interface-type { interface-mme | interface-pgw-ingress | interface-sgw-egress | interface-sgw-ingress }

interface-mme: Clears statistics and counters derived from all MME interface types associated with this system.
interface-pgw-ingress: Clears statistics and counters derived from all P-GW ingress interface types associated with this system.
interface-sgw-egress: Clears statistics and counters derived from all S-GW egress interface types associated with this system.
interface-sgsn: Clears statistics and counters derived from all SGSN S4 interface types associated with this system.
interface-sgw-ingress: Clears statistics and counters derived from all S-GW ingress interface types associated with this system.

---

mme-address *ip_address*

Clears all statistics and counters derived from an existing MME IP address specified in IPv4 dotted-decimal or IPv6 colon-separated notation.

---

pgw-address *ip_address*

Clears all statistics and counters derived from an existing P-GW IP address specified in IPv4 dotted-decimal or IPv6 colon-separated notation.

---

sgw-address *ip_address*

Clears all statistics and counters derived from an existing S-GW IP address specified in IPv4 dotted-decimal or IPv6 colon-separated notation.

sgsn-address *ip_address*

Clears all statistics and counters derived from an existing SGSN S4 IP address specified in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Use this command to clear running statistics and counters found in show command and bulk statistics outputs for all eGTP-C-related services or for specific interfaces, services, or IP addresses as specified by parameters in this command.

Example

The following command clears eGTP-C statistics and counter associated with all P-GW ingress interfaces configured on this system:

```
clear egtpc statistics interface-type interface-pgw-ingress
```

The following command clears eGTP-C statistics and counter associated with all MME interfaces configured on this system:

```
clear egtpc statistics interface-type interface-mme
```

clear event-notif statistics

Clears the statistical information collected over a configured Event Notification (SNMP) interface based on specific criteria.

Product

All

Privilege

Inspector

Syntax

```
clear event-notif statistics
```

Usage

Use this command to clear the statistical information collected over configured Event Notification interface based on specific criteria.

Example

The following command clears the counter information for all Event Notification collection servers configured in a context:

```
clear event-notif server all
```

clear firewall

This command is obsolete.

clear fng-service statistics

Deletes all previously gathered statistics for a specific Femto Network Gateway (FNG) service or all FNG services configured within a context.

Product

FNG

Privilege

Security Administrator, Administrator, Operator

Syntax

clear fng-service statistics {name *service_name***}**

name *service_name*

Specifies the name of a specific FNG service configured in the context for which to clear statistics as an alphanumeric string of 1 through 63 characters that is case sensitive.

Usage

Statistics for a single FNG service can be cleared using the **name** keyword. Statistics for all FNG services in the context can be deleted by entering the command with no keywords.
If this command is executed from within the local context with no keywords, statistics will be cleared for every FNG service configured on the system regardless of context. In addition, if the **name** keyword is used when executing from within the local context, statistics for all FNG services configured with the specified name will be cleared regardless of context.

Example

The following command clears statistics for an FNG service named fng1:

```
clear fng-service statistics name fng1
```

clear gmm-sm statistics

Deletes the collected statistics for the GPRS Mobility Management and Session Management (GMM/SM) configurations for various SGSN services.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

clear gmm-sm statistics [gmm-only | plmn-id mcc *mcc* **mnc** *mnc* **[access-type { gprs | umts }] | sm-only] [gprs-service** *srvc_name* **| iups-service** *srvc_name* **| sgsn-service** *srvc_name* **]**

Keywords are presented below. First are the primary keywords in the order one is selected, as displayed in the syntax. Secondary or filtering keywords are presented alphabetically after the primary keywords.

gmm-only

Deletes only GPRS mobility management (GMM) information for the specified keyword parameters.

plmn-id mcc *mcc* **mnc***mnc* **[access-type { gprs | umts }]**

Deletes the statistics for services within a specified PLMN.
Enter the **access-type** keyword to fine-tune the delete procedure and only delete GMM/SM statistics for the IuPS (select access-type UMTS) and/or the GPRS (select access-type GPRS) services belonging to the PLMN.

sm-only

Deletes only session management (SM) information for the specified keyword parameters.

gprs-service *srvc_name*

Deletes the statistics for a 2.5G GPRS service specified as an alphanumeric string of 1 through 63 characters that uniquely identifies a preconfigured GPRS service. The delete request can be narrowed by adding either the **nsei** or **routing-area** keywords.

iups-service *srvc_name*

Deletes the statistics for a IuPS service specified as an alphanumeric string of 1 through 63 characters that uniquely identifies a preconfigured IuPS service. The delete request can be narrowed by adding either the **rnc** or **routing-area** keywords.

sgsn-service *srvc_name*

Deletes the statistics for a 3G SGSN service specified as an alphanumeric string of 1 through 63 characters that uniquely identifies the SGSN service. The delete request can be narrowed by adding either the **rnc** or **routing-area** keywords.

access-type *type*

Defines the type of access to be allowed or restricted.

- **eps**
- **gprs**
- **umts**

If this keyword is not included, both access types are allowed by default.

lac *lac_id*

Specifies the location area code (LAC) as part of the identification of the RNC or RA. *lac_id* must be an integer from 1 through 65535.

mcc *mcc_id*

Specifies the mobile country code (MCC) as part of the identification of the RNC or RA. *mcc_id* must be an integer from 100 through 999.

mnc *mnc_id*

Specifies the mobile network code (MNC) as part of the identification of the RNC or RA. *mnc_id* must be a 2- or 3-digit integer from 00 through 999.

nsei*nse_id*

Deletes the GMM/SM session statistics for the identified network service entity (NSEI). *nse_id* must be an integer from 0 through 65535 that uniquely identifies a configured NSEI.

rnc*rnc_id*

Fine-tunes the deletion of GMM/SM session statistics just for the specified radio network controller (RNC). *rnc_id* must be an integer from 0 through 4095.

rac *rac_id*

Specifies the routing area code (RAC) as part of the identification of the RNC or RA. *rac_id* must be an integer from 1 through 255.

routing-area mcc *mcc_id* **mnc** *mnc_id* **lac** *lac_id* **rac** *rac_id*

Enter the **routing-area** keyword to fine-tune the clearing of the GMM/SM statistics for a specified routing area (RA) identified by the MCC, MNC, LAC and RAC.

Usage

Use this command to delete usage statistics for the GMM/SM session configurations for SGSN services, including a BSC's attaches, activations, and throughput.

Example

The following command deletes GMM/SM statistics for a specific routing area defined for the SGSN's GPRS service:

```
clear gmm-sm statistics gprs-service gprs1 routing-area mcc 123 mcc 131
lac 24 rac 11
```

The following command displays all possible information for GMM/SM statistics:

show gmm-sm statistics verbose

Important: Output descriptions for **show** commands are available in the *Statistics and Counters Reference*.

clear gprsns statistics

Deletes collected statistics for the 2.5G SGSN's General Packet Radio Service (GPRS) Network Service (NS) layer (link level).

Product

SGSN

Privilege

Inspector

Syntax

clear gprsns statistics { msg-stats nse *nse_id* **| sns-msg-stats }[| { grep** *grep_options* **| more }]**

msg-stats

Deletes collected transmit (tx) and receive (rx) message statistics for the NS layer.

consolidated nse *nse_id*

nse_id: Enter an integer from 0 to 65535.

nse *nse_id*

Deletes statistics for an NSE specified as an integer from 0 to 65535.

sns-msg-stats

Deletes subnetwork service (SNS) sublayer message statistics.

| { grep *grep_options* **| more }**

You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command is used to display Frame Relay statistics configured for the NSE/NSVC with the commands documented in the *Network Service Entity - Peer NSEI Configuration Mode* chapter.
Collected statistics are cleared (deleted) with the **clear gprsns statistics** described in the *Exec Mode Commands (A-C)* chapter.

Example

The following command displays the collected message statistics for NSEI *1422*:

```
show gprsns statistics msg-stats nse 1422
```

Important: Output descriptions for **show** commands are available in the *Statistics and Counters Reference*.

clear gprsssf statistics

Deletes all Customized Applications for Mobile networks Enhanced Logic (CAMEL) service gprsSSF statistics collected since the last reset or **clear** command.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear gprsssf statistics [camel-service *srvc_name* **| gprs [2g-sgsn-app | 3g-sgsn-app] | gsmscf-address {** *address* **| all } | sms] [| { grep | more }]**

camel-service *srvc_name*

Clears only CAMEL service statistics for the configured CAMEL service specified as an alphanumeric string of 1 through 63 characters.

gprs [2g-sgsn-app | 3g-sgsn-app]

Clears only CAMEL service statistics for either a 2.5G or 3G SGSN.

gsmscf-address { *address* **| all }**

Filters the command to only clear CAMEL service statistics for specified GSM service control function (gsmSCF) addresses. *address* is a standard ISDN E.164 address of 1 to 15 digits.

sms

Filters the command to only clear CAMEL service statistics for SMS protocol information.

| { grep *grep_options* **| more }**

For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command instructs the SGSN to delete collected CAMEL service statistics for either specified CAMEL services, or for SMS or GPRS applications in all contexts.

Example

The following command will delete gprsSSF statistics collected for the CAMEL service residing at SCP identified by the gsmSCF address:

```
clear gprsssf statistics gsmscf-address 412211411151
```

clear gtpc statistics

Deletes all previously gathered GTPC (GTPv0, GTPv1-C, GTPv1-U) statistics within the given context based on the specified criteria.

Product

GGSN, MSEG

Privilege

Security Administrator, Administrator, Operator

Syntax

clear gtpc statistics [[custom1 | gtpcmgr-instance *gtpcmgr_instance_number* **| smgr-instance** *sessmgr_instance_number* **] [apn** *apn_name* **| ggsn-service** *ggsn_service_name* **| mseg-service** *mseg_service_name* **| sgsn-address** *sgsn_ipv4_address* **]]**

custom1

Clears the statistics of GTP-C messages for preservation mode and free of charge service.
This keyword is a customer-specific function used for Preservation-Mode and Free-of-Charge Service that is enabled under customer-specific license. For more information on this support, contact your Cisco account representative.

gtpcmgr-instance *gtpcmgr_instance_number*

Clears GTP-C statistics for a GTPC Manager instance specified as an integer from 1 through 4294967295.

smgr-instance *sessmgr_instance_number*

Clears GTP-C statistics for a Session Manager instance specified as an integer from 1 through 4294967295.

apn *apn_name*

Clears GTP-C statistics for an existing APN specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

ggsn-service *ggsn_service_name*

Clears GTP-C statistics for an existing GGSN service specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

mseg-service *mseg_service_name*

Important: This keyword is not supported in this release. For more information please contact your Cisco account representative.

Clears GTP-C statistics for an existing MSEG service specified as an alphanumeric string of 1 through 63 characters.

sgsn-address *sgsn_ipv4_address*

Clears GTP-C statistics for an existing SGSN specified by IP address in IPv4 dotted-decimal notation.

Usage

GTPC statistics can be cleared for a single APN, GGSN service, or SGSN. All GTPC statistics in the context can be deleted by entering the command with no keywords.
This command can be executed from any context configured on the system.
If this command is executed from within the local context with no keywords, all GTPC statistics will be cleared regardless of context.
GTPP statistics are not affected by this command.

Example

The following command clears all GTPC statistics context:

```
clear gtpc statistics
```

clear gtpp statistics

Deletes all previously gathered GTPP statistics within the given context based for either single or all charging gateway functions (CGFs).

Product

GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear gtpp statistics [cgf-address *ip-address* **]**

cgf-address *cgf_address*

Deletes statistics for a CGF identified by its IP address entered in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Statistics for a single CGF can be cleared using the **cgf-address** keyword. Statistics for all CGFs in the context can be deleted by entering the command with no keywords.
This command can be executed from any context configured on the system.
If this command is executed from within the local context with no keywords, statistics will be cleared for every CGF configured on the system regardless of context. In addition, if the cgf-address keyword is used when executing from within the local context, statistics for all CGFs configured with the specified name will be cleared regardless of context.

Example

The following command deletes all GTPP statistics for a CGF with an IP address of 192.168.1.42:

```
clear gtpp statistics cgf-address 192.168.1.42
```

clear gtpp storage-server local file statistics

Clears AAA proxy GTPP group level statistics for CDRs stored on the local SMC hard disk.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear gtpp storage-server local file statistics [ group name name ]
```

Usage

If executed from the local context, this command clears statistics for all GTPP groups configured on the system. If executed from the context within which the storage servers (SMC hard disk) is configured, statistics are deleted for only that context.

clear gtpp storage-server statistics

Clears statistics for configured GTPP storage servers (GSS).

Product

GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear gtpp storage-server statistics
```

Usage

If executed from the local context, this command clears statistics for all GTPP storage servers configured on the system. If executed from the context within which the servers are configured, statistics are deleted for only those servers.

clear gtpu statistics

Clears enhanced GPRS Tunneling Protocol user plane statistics and counters found in **show** command outputs and bulk statistics associated with all GTP-U-related services or those defined by the parameters in this command.

Product

P-GW, S-GW, MSEG

Privilege

Operator

Syntax

clear gtpu statistics [gtpu-service *gtpu_service_name* **| mseg-service** *mseg_service_name* **| peer-address** *ipv4/ipv6_address* **]**

gtpu-service *gtpu_service_name*

Clears GTP-U statistics for an existing GTP-U service specified as an alphanumeric string of 1 through 63 characters.

mseg-service *mseg_service_name*

Important: This keyword is not supported in this release. For more information please contact your Cisco account representative.

Clears GTP-U statistics for an existing MSEG service specified as an alphanumeric string of 1 through 63 characters.

peer-address *ipv4/ipv6_address*

Clears GTP-U statistics for an existing peer IP address entered in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Use this command to clear running statistics and counters found in show command and bulk statistics outputs for all GTP-U-related services or for specific services or IP addresses as specified by parameters in this command.

Example

The following command clears GTP-U statistics and counter associated with a GTP-U service name *gtpu-12* configured on this system:

```
clear gtpu statistics gtpu-service gtpu-12
```

clear hd-storage-policy

Clears statistic information for HD storage policies configured on the system.

Product

HSGW, P-GW, S-GW

Privilege

Operator

Syntax

clear hd-storage-policy statistics { all | name *name* **}**

statistics { all | name *name* **}**

all: Clears ACR statistical information for all HD storage policies configured on the system.
name *name*: Clears ACR statistical information for an existing HD storage policy specified as an alphanumeric string of 0 through 63 characters.

Usage

Use this command to clear statistics for HD storage policies configured on the system.

Example

The following command clears statistics for an HD storage policy named *pgwsgw*:

```
clear hd-storage-policy statistics name pgwsgw
```

clear hnbgw sessions

Clears the active/dormant session information about registered Nabs) on Home-NodeB Gateway (HNB-GW) service instances configured and running on this system based on different filter criteria.

Product

HNB-GW

Privilege

Operator

Syntax

clear hnbgw sessions {**all** | **cell-id** *cell_id* | **hnb-address** *hnb_ip_address* | **hnb-local-id** *hnb_id* | **hnbgw-service** *hnbgw_svc_name* | **hnbid** *hnb_glbl_id* | **mcc** *mcc* **mnc** *mnc* [**noconfirm**] [**lac** *lac* | **rac** *rac*]}

all

Clears the summarized or full information for all registered HNB sessions on an HNB-GW service instance running on system. Clearing the statistics can be filtered based on given filtering.

cell-id *cell_id*

Clears HNB session statistics for a registered cell ID on an HNB-GW service instance. *cell_id* is the identification number of the Femto cell where the user/subscriber is geographically located expressed as an integer from 0 through 268435455.

hnb-address *hnb_ip_address*

Clears the session statistics for HNB session(s) based on a registered HNB IP address entered in IPv4 dotted-decimal notation.

hnb-local-id *hnb_id*

Clears the session statistics of HNB session(s) for a registered local id of HNB specified as as an integer from 1 through 255.

hnbgw-service *hnbgw_svc_name*

Clears the session statistics for registered HNB session(s) on an existing HNB-GW service name specified as an alphanumeric string of 1 through 63 characters.

hnbid *hnb_glbl_id*

Clears the statistics for HNB session(s) based on the registered HNB global id specified as an integer from 1 through 255

mcc *mcc*

Clears statistics for HNB session(s) based on the registered Mobile Country Code (MCC) identification number of the UE. *mcc* must be an integer from 101 through 999.

mnc *mnc*

Clears the statistics for HNB session(s) based on the registered Mobile Network Code (MNC) identification number of the UE. *mnc* must be a 2- or 3-digit integer from 00 through 999

lac *lac*

Clears the statistics for HNB session(s) based on the registered Location Area Code (LAC) identification number of the UE. *lac* must be an integer from 1 through 65535.

rac *rac*

Clears the statistics for HNB session(s) based on the registered Radio Access Code (RAC) identification number of the UE. *rac* must be an integer from 1 through 255.

rnc *rnc*

Clears the statistics for HNB session(s) based on the registered Radio Network Code (RAC) identification number of the HNB. *rnc* must be an integer from 1 through 65535.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Important: The Operator privilege does not have access to this keyword.

Usage

Use this command to clear the session statistics of all or specific registered HNB session(s) or in selected part of user session for HNB-GW services configured and running on this system.

Example

The following command clears the session statistics for all registered HNBs on the HNB-GW service named *hnbgw1*:

```
clear hnbgw sessions hnbgw-service hnbgw1
```

clear hnbgw statistics

Clears the HNB-GW service and HNB related statistics from an HNB-GW node.

Product

HNB-GW

Privilege

Operator

Syntax

```
clear hnbgw statistics { hnbgw-service hnbgw_svc_name [ gtpu-only | hnbap-only | ranap-
only | rtp-only | rua -only | sccp-only | sctp-only ] | hnbid hnb_identifier [ gtpu-only
| hnbap-only | ranap-only | rtp-only | rua -only ] }
```

hnbgw-service *hnbgw_svc_name*

Clears the session statistics for an existing \HNB-GW service name specified as an alphanumeric string of 1 through 63 characters.

hnbid *hnb_identifier*

Clears the session statistics for an existing Home-NodeB identifier specified as an alphanumeric string of 1 through 255 characters.

gtpu-only

Clears the statistics for GTP-U traffic only for the selected HNB/HNB-GW service.

hnbap-only

Clears the statistics for Home NodeB Application Part (HNBAP) traffic only for the selected HNB/HNB-GW service.

ranap-only

Clears the session statistics for Radio Access Network Application Protocol (RANAP) traffic only for the selected HNB/HNB-GW service.

rtp-only

Clears the session statistics for Real Time Protocol (RTP) traffic only for the selected HNB/HNB-GW service.

rua-only

Clears the session statistics for RANAP User Adaptation (RUA) traffic only for the selected HNB/HNB-GW service.

sccp-only

Clears the session statistics for Signaling Connection Control Part (SCCP) traffic only for the selected HNB-GW service.

sctp-only

Filters the session statistics to display only Stream Control Transmission Protocol (SCTP) traffic for the selected HNB-GW service.

Usage

Use this command to clear the session statistics for an overall session or in a selected part of a user session for HNB-GW services and/or HNBs configured and running on this system.

Example

The following command clear the session statistics for the HNBAP portion of session details for the HNB-GW service named *hnbgw1*:

```
clear hnbgw statistics hnbgw-service hnbgw1 hnbap-only
```

The following command clears the session statistics for the RANAP portion of session details for the HNB identified as *102*:

```
clear hnbgw statistics hnbid 102 ranap-only
```

clear hsgw-service

Clears HRPD Serving Gateway (HSGW) statistics and counters found in **show** command outputs and bulk statistics associated with all HSGW services or a specific service defined by the parameter in this command.

Product

HSGW

Privilege

Operator

Syntax

clear hsgw-service statistics [name *service_name* **] [| { grep** *grep_options* **| more }]**

name *name*

Clears statistics and counters for a an existing HSGW service name specified as an alphanumeric string of 1 through 63 characters.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear statistics for HSGW services configured on the system.

Example

The following command clears statistics for an HSGW service named *hsgw3*:

```
clear hsgw-service statistics name hsgw3
```

clear hss-peer-service

Clears statistic information for Home Subscriber Service (HSS) peer services configured on the system.

Product

MME

Privilege

Operator

Syntax

clear hss-peer-service statistics [service *name* **]**

statistics [service *name* **]**

statistics: Clears HSS peer service statistical information for all HSS peer services configured on the system.
service *name*: Clears HSS peer service statistic information for an existing HSS peer service specified as an alphanumeric string of 1 through 64 characters.

Usage

Use this command to clear statistics for HSS peer services configured on the system.

Example

The following command clears statistics for an HSS peer service named *hss4*:

```
clear hss-peer-servicey statistics service name hss4
```

clear ims-authorization

Clears statistics for all or for a specified IP Multimedia System (IMS) Authorization Service.

Product

GGSN, SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear ims-authorization { policy-control statistics [ ims-auth-service service_name ] |
service statistics [ name service_name ] } [ | { grep grep_options | more } ]
```

ims-auth-service *service_name*

Clears statistics for the IMSA service specified as an alphanumeric string of 1 through 64 characters.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear IMSA Service statistics.

Example

The following command clears IMSA policy-control statistics for an IMSA service named *test_service*:

```
clear ims-authorization policy-control statistics ims-auth-service
test_service
```

clear ip access-group statistics

Clears all interface access control list (ACL) statistics and the context level ACL statistics that have been configured in the current context. Be aware that updating an access list also causes all ip access-groups utilizing the list to be cleared.

Product

PDSN, GGSN ASN-GW

Privilege

Security Administrator, Administrator

Syntax

```
clear ip access-group statistics
```

Usage

Use this command to clear all interface ACL statistics and the context level ACL statistics that have been configured in the current context.

Example

The following command clears the ACL statistics:

```
clear ip access-group statistics
```

clear ip arp

Clears the address resolution protocol (ARP) cache for a given IP address.

Product

All

Privilege

Security Administrator, Administrator

Syntax

clear ip arp *ip_address*

ip_address

Specifies the IP address for which to clear the ARP cache in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Clear the ARP cache when network changes have occurred for the case where the cached data may cause undue overhead in routing packets.

Example

The following command clears the ARP cache for the IP address *10.2.3.4*:

```
clear ip arp 10.2.3.4
```

clear ip bgp peer

Resets Border Gateway Protocol (BGP) connections for all peers or for specified peers in the current context.

Product

HA

Privilege

Security Administrator, Administrator

Syntax

clear ip bgp peer { *ip_address* | all | as *as_num* } [in | out | soft | vpnv4]

ip_address

Specifies the IP address of the neighbor for which BGP connections should be reset in IPv4 dotted-decimal notation.

all

Resets BGP connections for all peers.

as *as_num*

Resets BGP connections for all peers in the specified autonomous system (AS). *as_num* must be an integer from 1 through 65535.

in

Softly reconfigures inbound updates.

out

Softly reconfigures outbound updates.

soft

Softly reconfigures inbound and outbound updates.

vpnv4

Clears BGP sessions within the vpnv4 address family.

Usage

Use this command to BGP information for the current context.

Example

The following command resets BGP connections for all neighbors:

```
clear ip bgp peer all
```

clear ip localhosts

Removes the host specified from the current context's local host list for IP address mappings.

Product

All

Privilege

Security Administrator, Administrator

Syntax

clear ip localhosts [*host_name* **]**

host_name

Specifies the name of the host to be removed as an alphanumeric string of 1 through 127 characters. When omitted, all local host name mappings will be removed.

Usage

Clears a host name when it is no longer valid for the current context to access. The host name specified will be unrecognized by the current context once the command is performed.

Example

```
clear ip localhosts

clear ip localhosts 10.2.3.4

clear ip localhosts remoteABC
```

clear ip ospf process

Clears Open Shortest Path FIrst (OSPF) database information for the current context and re-establishes neighbor adjacency.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
clear ip ospf process
```

Usage

Use this command to clear the OSPF database information for the current context and re-establishes neighbor adjacency.

Example

The following command clears the OSPF database information for the current context and re-establishes neighbor adjacency:

```
clear ip ospf process
```

clear ipv6 neighbors

Clears an IPv6 address from the neighbor cache.

Product

PDIF

Privilege

Administrator, Security Administrator

Syntax

clear ipv6 neighbors *ip_address*

ip_address

Specifies the IP address in IPv6 colon-separated notation.

Usage

Clears a specific address from the neighbor cache.

Example

Use the following example to clear *3ffe:ffff:101::230:6eff:fe04:d9aa/48*:

```
clear ipv6 neighbors 3ffe:ffff:101::230:6eff:fe04:d9aa/48
```

clear ipv6 ospf process

Restarts Open Shortest Path First Version 3 (OSPFv3) with available configuration.

Product

PDSN, HA GGSN

Privilege

Administrator, Security Administrator

Syntax

```
clear ipv6 ospf process
```

Usage

Force a restart of OSPFv3 process using the available configuration.

Example

```
clear ipv6 ospf process
```

clear l2tp

Clears all or specific Layer 2 Tunnelling Protocol (L2TP) statistics or clears and disconnects all or specified sessions or tunnels.

Product

PDSN, GGSN, LNS

Privilege

Security Administrator, Administrator, Operator

Syntax

clear l2tp { statistics [lac-service *service_name* **| lns-service** *service_name* **| peer-address** *ip_address* **] | tunnels { all [clear-sa] | callid call_id | lac-service** *service_name* **[clear-sa] | lns-service** *service_name* **| peer-address** *ip_address* **[clear-sa] } }**

statistics [lac-service *service_name* **| lns-service** *service_name* **| peer-address** *ip_address* **]**

With no optional keywords specified, this command clears all L2TP statistics for the current context.
lac-service *service_name*: Clears all L2TP statistics for the specified LAC service in the current context.
lns-service *service_name*: Clears all L2TP statistics for the specified LNS service in the current context.
peer-address *ip_address*: Clears all L2TP statistics for the destination (peer LNS) at the specified IP address. The IP address is entered using IPv4 dotted-decimal notation.

tunnels { all [clear-sa] | callid *call_id* **| lac-service** *service_name* **[clear-sa] | peer-address** *ip_address* **[clear-sa] }**

all: Clears all tunnels in the current context.
lac-service service_name: Clears all tunnels in the current context that belong to the specified LAC service and closes the tunnels.
lns-service service_name: Clears all tunnels in the current context that belong to the specified LNS service and closes the tunnels.
peer-address ip_address: Clears all tunnels in the current context whose destination (peer LNS) is the system at the specified IP address. The IP address is specified using IPv4 dotted-decimal notation.
callid call_id: Uses the unique identifier that specifies a particular tunnel in the system to clear that tunnel and disconnect it. The output of the command **show l2tp tunnels** contains a field labeled Callid Hint which lists the call id information to use with this command. This is an 8-byte hexadecimal number.
clear-sa: If any security associations have been established they are cleared.

Usage

Clear L2TP all or specific L2TP statistics or clear sessions in a tunnel and disconnect the tunnel.

Example

To clear all L2TP statistics for the current context, use the following command:

```
clear l2tp statistics
```

To clear all L2TP statistics for the LAC service named *lac1*, use the following command:

```
clear l2tp statistics lac-service lac1
```

Use the following command to clear L2TP statistics for the LNS peer at the IP address *10.10.10.100*:

```
clear l2tp statistics peer-address 10.10.10.100
```

The following command clears and closes all tunnels in the current context:

```
clear l2tp tunnels all
```

The following command clears and closes all tunnels for the LAC service named *lac2*:

```
clear l2tp tunnels lac-service lac2
```

The following command clears and closes all tunnels the peer at the IP address *10.10.10.110*:

```
clear l2tp tunnels peer-address 10.10.10.110
```

clear lawful-intercept

Refer to the *Lawful Intercept Configuration Guide* for a description of this command.

clear llc statistics

Deletes collected traffic statistics for the GPRS logical link-control (LLC) layer.

Product

SGSN

Privilege

Inspector

Syntax

clear llc statistics [gprs-service *srvc_name* **] [| { grep grep_options | more }]**

gprs-service *srvc_name*

Clears the collected statistics for an existing GPRS service specified as an alphanumeric string of 1 through 63 characters.

| grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For more information on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference*.

Usage

This command deletes statistics collected for the traffic that has gone through the LLC layer for either all GPRS services or for a specified GPRS service.

Example

The following command deletes all LLC statistics for GPRS service *gprs1*:

```
clear llc statistics gprs-service gprs1
```

clear lma-service statistics

Clears Local Mobility Anchor (LMA) statistics and counters found in **show** command outputs and bulk statistics associated with all LMA services or a specific service defined by the parameter in this command.

Product

P-GW

Privilege

Operator

Syntax

clear lma-service statistics [name *service_name* **]**

name *service_name*

Clears statistics and counters for an existing LMA service name specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear statistics and counters in show command outputs and bulk statistics for all LMA services or for a specific LMA service.

Example

The following command clears statistics and counters for an LMA service named *lma3*:

```
clear lma-service statistics name lma3
```

clear local-policy

Clears local Quality of Service (QoS) policy service statistics and counters found in **show** command outputs and bulk statistics associated with all local QoS policy services or a specific service defined by the parameter in this command.

Product

P-GW

Privilege

Operator

Syntax

clear local-policy statistics [service *service_name* **]**

service *service_name*

Clears statistics and counters for an existing local policy service name specified as an alphanumeric string of 1 through 64 characters.

Usage

Use this command to clear statistics and counters in **show** command outputs and bulk statistics for all local QoS policy services or a specific service.

Example

The following command clears statistics and counters for a local QoS policy service named *lp3*:

```
clear local-policy statistics service lp3
```

clear local-user

Clears information pertaining to local-user administrative accounts.

Product

All

Privilege

Security Administrator

Syntax

clear local-user { database [-noconfirm] | statistics | username *name* **lockout }**

clear local-user database

Clears the local-user database by deleting all information for all local-user accounts.

Caution: Use this command only in the event of security concerns or to address concerns of the local-user account database integrity.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

clear local-user statistics

Clears statistics pertaining to local-user accounts.

clear local-user userame *name* **lockout**

Removes lockouts associated with the local-user account expressed as an alphanumeric string of 3 through 16 characters that is case sensitive.

Usage

This command can be used to remove local-user account lockouts, reset local-user-related statistics to 0, or to delete the local-user database.

Example

The following command removes the lockout placed on a local-user account named *SecureAdmin*:

```
clear local-user username SecureAdmin lockout
```

clear mag-service statistics

Clears Mobile Access Gateway (MAG) statistics and counters found in **show** command outputs and bulk statistics associated with all MAG services or a specific service defined by the parameter in this command.

Product

HSGW, S-GW

Privilege

Operator

Syntax

clear mag-service statistics [name *service_name* **]**

name *service_name*

Clears statistics and counters for an existing MAG service name specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clears statistics and counters in show command outputs and bulk statistics for all MAG services or for a specific MAG service.

Example

The following command clears statistics and counters for a MAG service named *mag1*

```
clear mag-service statistics name mag1
```

clear maximum-temperatures

Clears information pertaining to component maximum temperatures.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear maximum-temperatures
```

Usage

Reset the timestamp to the current time and clear previous maximum temperatures for all temperature monitored components. This may be useful when preparing to study system performance, monitor usage, or trouble shoot the administrative interfaces.

Example

The following command resets the maximum temperature statistics for all monitored chassis components.

```
clear maximum-temperatures
```

clear mipfa statistics

Clears the statistics for the mobile IP foreign agent (MIPFA). The statistics for a specific foreign agent service may be cleared by an explicit command.

Product

PDSN, GGSN,ASN-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

clear mipfa statistics [fa-service *name* **| peer-address** *ip_address* **]**

fa-service *name* **| peer-address** *ip_address*

fa-service *name*: Clears the statistics for an existing FA service specified as an alphanumeric string of 1 through 63 characters. “Total sessions” counters for all peers associated with the service are also reset.
peer-address *ip_address*: Clears the statistics for the peer IP address specified in IPv4 dotted-decimal notation. “Total sessions” counter for the specified peer is also reset.

Usage

Clear all statistics for the MIP foreign agent or for a specific service. This may be useful in monitoring performance and troubleshooting as the statistics may be cleared at a well known time and then collected and transferred for review.

Example

The following clears all statistics for the mobile IP foreign agent.

```
clear mipfa statistics
```

The following commands clear the statistics for the example service only.

```
clear mipfa statistics fa-service sampleService
```

```
clear mipfa statistics peer-address 10.2.3.4
```

clear mipha statistics

Clears the statistics for the mobile IP home agent (MIPHA). The statistics for a home agent service may be cleared by explicit command.

Product

HA

Privilege

Security Administrator, Administrator, Operator

Syntax

clear mipha statistics [ha-service *name* **| peer-address** *ip_address* **]**

ha-service *name* **| peer-address** *ip_address*

ha-service *name*: Clears the statistics for an existing HA service name specified as an alphanumeric string of 1 through 63 characters. "Total sessions" counters for all peers associated with the service are also reset.
peer-address *ip_address*: Clears the statistics for an IP address specified using IPv4 dotted-decimal notation. "Total sessions" counter for the specified peer is also reset.

Usage

Clear all statistics for the MIP home agent or for a specific service. This may be useful in monitoring performance and troubleshooting as the statistics may be cleared at a well known time and then collected and transferred for review.

Example

The following clears all statistics for the mobile IP foreign agent.

```
clear mipha statistics
```

The following command clears the statistics for the example service only.

```
clear mipha statistics ha-service sampleService
```

```
clear mipha statistics peer-address 10.2.3.4
```

clear mme-service db record

Clears the MME database records all instances of session manager running for an MME service filtered with IMSI or GUTI as criteria.

Product

MME

Privilege

Inspector

Syntax

clear mme-service db record { all | guti plmn *plmn_id* **group-id** *mme_grp_id* **code** *mme_code* **m-tmsi** *mtmsi_value* **| imsi** *imsi_identifier* **| instance** *instance_id* **}**

all

Clears all detached database records.

guti plmn *plmn_id* **group-id** *mme_grp_id* **code** *mme_code* **m-tmsi** *mtmsi_value*

This set of keywords specifies the filter criteria as a Globally Unique Temporary Identifier (GUTI) to clear the database records for MME service.
The GUTI is constructed from the GUMMEI and the M-TMSI where GUMMEI is constructed from PLMN (MMC and MNC) *plmn_id* and MME Identifier is constructed from an MME Group ID (MMEGI) *mme_grp_id* and an MME Code (MMEC) *mme_code*.
Within the MME, the mobile is identified by the M-TMSI *mtmsi_value*

imsi *imsi_identifier*

Specifies the filter criteria as International Mobile Subscriber Identity (IMSI) to clear the database records of a session instance. *imsi_identifier* is a 15-character IMSI field that identifies the subscriber's home country and carrier.

instance *instance_id*

Clears all detached database records in an existing session manager instance specified as an integer from 1 through 4294967295.

Usage

Use this command to clear/remove database records for all or a particular instance of session manager for MME services on this system.

Example

The following command clears the summary database records of a session instance for subscriber having IMSI as *123455432112345* in the MME service:

```
clear mme-service db record imsi 123455432112345
```

clear mme-service db statistics

Clears the MME database statistics for MME sessions for all or specific session instances on this system.

Product

MME

Privilege

Inspector

Syntax

clear mme-service db statistics [instance *smgr_instance* **]**

instance *smgr_instance*

Specifies that MME database statistics for a specific instance of session manager running for MME service are to be remove. The instance ID expressed is an integer from 0 through 4294967295. If an instance is not specified, database statistics of all instances will be removed.

Usage

Use this command to clear/remove database statistics for all or a particular instance of session manager for MME services on this system.

Example

The following command removes/clears the database statistics of all instances of the MME service on a system:

```
clear mme-service db statistics
```

clear mme-service statistics

Clears the service statistics of an MME service specified by various criteria.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

```
clear mme-service statistics [ emm-only | esm-only | handover | mme-service mme_svc_name
[ emm-only | esm-only | s1ap | sctp ] | peer-id peer_identifier [ emm-only | esm-only |
s1ap | sctp ] | s1ap | sctp  ]
```

emm-only

Clears all EPS mobility management (EMM) related statistics for a specific MME service name, a specific peer MME identifier, or all EMM statistic instances.

esm-only

Clears all EPS session management (ESM) related statistics for a specific MME service name, a specific peer MME identifier, or all ESM statistic instances.

handover

Clears all handover statistics for this service.

mme-service *mme_svc_name*

Filters by MME service name to clear all service statistics.

peer-id *peer_identifier*

Filters by the identifier of an MME peer to clear all service statistics.

s1ap

Filters by the MME service name of a peer MME identifier to clear all S1-AP statistics.

sctp

Filters by the MME service name of a peer MME identifier to clear all SCTP statistics.

Usage

This command is used to clear the statistical information of an MME service based on various filter criteria.

Example

The following command clears the service session statistics of all MME service on a system:

```
clear mme-service statistics
```

clear multicast-sessions

Disconnects broadcast-multicast sessions based on specified criteria.

Product

PDSN, GGSN

Privilege

Security Administrator Operator

Syntax

clearmulticast-sessions [-noconfirm] [*keywords* **] [verbose]**

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

---

all

Disconnects all multicast sessions.

---

callid *call_id*

Clears the call specified by *call_id*. The call ID is as an 8-byte hexadecimal number.

---

card-num *slot_num*

Specifies the slot number of the packet processing card by which the multicast session is processed as a number from 1 through 7 or 10 through 16.

---

flowid *id*

Clears calls for a specific Broadcast/Multicast Service (BCMCS) flow id, specified as a hexadecimal numbe.r

---

flowid-type [flow | program]

Clears multicast sessions according to the type of flow.
flow: Clears all multicast sessions for the flow ID type “flow”.
program: Clears all multicast sessions for the flow ID type “program”.

---

mcast-address *ipv4_address*

Clears multicast sessions for a specific multicast address. Must be followed by the IP address of an interface in IPv4 dotted-decimal notation.

---

pcf *ipv4_address*

Clears multicast sessions connected via the packet control function defined by an IP address in IPv4 dotted-decimal notation.

---

pdsn_service *name*

Clears multicast sessions connected to an existing packet data service name.

verbose

Displays as much information as possible. If this option is not specified, the output is the standard level which is the concise mode.

Usage

Clear multicast sessions to aid in troubleshooting the system when no additional subscribers may connect or when a specific service or remote address may be having connection problems. This command may also be useful when preparing for maintenance activities such that connects may be cleared to perform any necessary procedures.

The keywords are filters that modify or filter the criteria for deciding which sessions to clear and are described below. Multiple keywords can be entered on a command line.

When multiple keywords are specified, the multicast sessions deleted must meet the specifications of all of the keywords.

Example

The following command clears the broadcast-multicast sessions having multicast address *10.2.3.4*:

```
clear multicast-sessions mcast-address 10.2.3.4
```

The following command clears the broadcast-multicast session(s) having call id *00004e22*:

```
clear multicast-sessions callid 00004e22
```

clear orbem statistics

Clears the interface statistics for the object request broker element manager (ORBEM) interface.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear orbem statistics
```

Usage

Clear the statistics to reset them to zero for the ORBEM interface. This may be useful when preparing to study system performance, monitor usage, or troubleshoot the administrative interfaces.

Example

The following command resets the statistics for the ORB element manager.

```
clear orbem statistics
```

clear pcc-policy service statistics

Clears statistical information of all or a specific policy control and charging (PCC) service configured in a context.

Product

IPCF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

clear pcc-policy statistics [**name** *pcc_plcy_svc_name*

name *pcc_plcy_svc_name*

Clears information only for an existing PCC-Policy service in the current context, expressed as an alphanumeric string of 1 through 79 characters.

Usage

Use this command to clears the statistical information of all or an specific PCC-Policy services configured in a context.
Clearing of statistics can further be filtered for specific PCC-Policy service name as well.

Example

The following command clears the statistical information for the PCC-Policy service named *pcc_policy1* in summarized output:

```
clear pcc-policy service statistics name pcc_policy1
```

clear pcc-policy session

Clears the active/dormant session information about PCC-Policy service instances configured and running on this system based on different filter criteria.

Product

IPCF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

clear pcc-policy sessions [**all**] [**apn** | **call-id** *call_id* | **imsi** *imsi_id* | **ip-address** *pcc_pcef_ip_address* | **service** *pcc_plcy_svc_name*] [**local-purge**]

all

Clears the session information of all registered IP-CAN session(s) on a PCC-Policy service instance running on the system. The display can be filtered based on given filtering criteria.

apn *apn_name*

Clears the session information for PCC-Policy service sessions connected via an existing APN,

imsi *imsi_id*

Clears the session information of IP-CAN session(s) based on the IMSI identifier of a subscriber on a PCC-Policy service instance. *imsi_id* is the International Mobile Subscriber Identity (IMSI) and must be a 15-character field which identifies the subscriber's home country and carrier.

ip-address *pcc_pcef_ip_address*

Clears the session statistics of IP-CAN session(s) based on the registered PCEF (Policy and Charging Enforcement Function) node IP address expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

call-id *call_id*

Clears the session statistics of IP-CAN session(s) based on the existing registered call id of an IP-CAN session subscriber specified in eight-bye hexadecimal format.

pcc-policy-service *pcc_plcy_svc_name*

Clears the session statistics of registered IP-CAN session(s) based on an existing PCC-Policy service name, expressed as an alphanumeric string of 1 through 63 characters.

local-purge

Clears the session information for PCC-Policy service sessions locally only.

Usage

Use this command to clear the session statistics of all or specific registered IP-CAN session(s) or in selected part of user session for PCC-Policy services configured and running on this system.

Example

The following command clears the session statistics for all registered PCC-Policy service instances on a system/context locally only:

```
clear pcc-policy sessions all local-purge
```

clear pcc-sp-endpoint statistics

Clears the statistical information of all or specific PCC-Sp-Endpoint instance configured in a context.

Product

IPCF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

clear pcc-sp-endpoint statistics [**name** *sp_endpt_name*]

name *sp_endpt_name*

Clears information only for an existing PCC-Sp-Endpoint instance specified as an alphanumeric string of 1 through 79 characters.

Usage

Use this command to clears the statistical information of all or an specific PCC-Sp-Endpoint interface configured in a context.
Clearing of statistics can further be filtered for specific PCC-Sp-Endpoint instance name as well.

Example

The following command clears the statistical information for the PCC-Sp-Endpoint instance named *sp1* in summarized output:

```
clear pcc-sp-endpoint statistics name sp1
```

clear pdg-service statistics

Deletes all previously gathered statistics for a specific Packet Data Gateway (PDG) service or all PDG services configured within a context.

Product

PDG/TTG

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear pdg-service statistics [ name service_name ]
```

name *service_name*

Clears the statistics for the PDG service name configured in the context, expressed as an alphanumeric string of 1 through 63 characters that is case sensitive.

Usage

Usage Statistics for a single PDG service can be cleared using the name keyword. Statistics for all PDG services in the context can be deleted by entering the command with no keywords.
If this command is executed from within the local context with no keywords, statistics will be cleared for every PDG service configured on the system regardless of context. In addition, if the name keyword is used when executing from within the local context, statistics for all PDG services configured with the specified name will be cleared regardless of context.

Example

Example(s) The following command clears statistics for a PDG service named *pdg1*:

```
clear pdg-service statistics pdg1
```

clear pgw-service

Clears PDN Gateway (P-GW) statistics and counters found in **show** command outputs and bulk statistics associated with all P-GW services or a specific service defined by the parameter in this command.

Product

P-GW

Privilege

Operator

Syntax

clear pgw-service statistics [name *service_name* **] [| { grep** *grep_options* **| more }]**

name *service_name*

Clears statistics and counters for an existing P-GW service name, expressed as an alphanumeric string of 1 through 63 characters.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear statistics and counters in show command outputs and bulk statistics for all P-GW services or for a specific P-GW service.

Example

The following command clears statistics and counters for an P-GW service named *pgw5*:

```
clear pgw-service statistics name pgw5
```

clear port

Clears port related statistics.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear port { datalink counters { all | *slot/port* } | npu counters { all | *slot/port* [untagged | vlan *tag_id*] }

clear port datalink counters

Clears data link port statistics.

clear port npu counters

Clears statistics for the network processing unit(s).

all

Clears counters for all datalink or NPU ports.

slot/port

Clears the statistics for the specified slot and port number.

untagged

Clears NPU statistics for all ports that do not have a VLAN tag.

vlan *tag_id*

Clears NPU statistics for the port that has a previously configured VLAN tag ID.

Usage

Manually clear the statistics for a specified port. This is useful when preparing to trouble shoot or monitor the system.

Example

The following command clears the data link related statistics for port 1 in slot 17.

```
clear port datalink counters 17/1
```

The following command clears the network processing unit related statistics for port 1 in slot 17.

```
clear port npu counters 17/1
```

The following command clears the network processing unit related statistics for port 10 in slot 5.

```
clear port npu counters 5/10
```

clear ppp statistics

Clears point-to-point protocol (PPP) related statistics. All PPP statistics may be cleared or just those for a specific packet data service may be cleared.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear ppp statistics [ggsn-service *ggsn_name* **| lns-service** *lns_name* **| pcf-address [** *pcf_ip_addr* **| all] | pdsn-service** *pdsn_name* **]**

ggsn-service *ggsn_name*

Clears statistics only for the time the session is connected to the named GGSN service.

lns-service *lns_name*

Clears statistics only for the time the session is connected to the named LNS service.

pcf-address [*pcf_ip_addr* **| all]**

Clears statistics only for the time the session is connected to the specified PCF (Packet Control Function) or for all PCFs. *pcf_ip_addr* must be entered using IPv4 dotted-decimal notation.

pdsn-service *pdsn_name*

Clears statistics only for the named PDSN service.

Usage

Allows you to manually reset PPP statistics when it is desired to have counts begin again from a specific point in time.

Example

The following clears the statistics for all PPP counters and services.

```
clear ppp statistics
```

The following clears only the point-to-point protocol statistics for the service named *sampleService*.

```
clear ppp statistics pdsn-service sampleService
```

clear prepaid 3gpp2 statistics

Clears all of the statistics counters for 3GPP2 Pre-paid accounting. Statistics may be cleared for all services or for an individual service.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear prepaid 3gpp2 statistics { all | { ggsn-service | ha-service | lns-service | pdsn-service } { all | name *service_name* **} }**

all

Clears prepaid statistics for all services.

ggsn-service

Clears statistics for GGSN service(s).

ha-service

Clears statistics for HA service(s).

lns-service

Clears statistics for LNS service(s).

pdsn-service

Clears statistics for PDSN service(s).

{ all | name *service_name* **}**

all: Clears statistics for all services of the specified type.
name *service_name*: Clears statistics for the named service of the specified service type.

Usage

Use this command to clear Pre-paid statistics for a particular named service or for all services.

Example

To clear statistics for a PDSN service name *PDSN1*, enter the following command:

```
clear prepaid 3gpp2 statistics pdsn-service name PDSN1
```

clear prepaid wimax

Clears all of the statistical counters for WiMAX prepaid accounting. Statistics may be cleared for all services or for an individual service.

Product

ASN-GW

Privilege

Operator

Syntax

clear prepaid wimax statistics { all | asngw-service { all | name *service_name* **} | ha-service { all | name** *service_name* **} }**

all

Clears prepaid statistics for all services.

asngw-service

Clears prepaid statistics for ASN-GW service(s).

ha-service

Clears prepaid accounting statistics for HA service(s).

{ all | name *service_name* **}**

all: Clears statistics for all services of the specified type.
name *service_name*: Clears statistics for the named service of the specified service type.

Usage

Use this command to clear prepaid WiMAX accounting statistics for named service or for all services.

Example

The following command clears prepaid WiMAX accounting statistics for an ASN-GW service name *asn1*:

```
clear prepaid wimax statistics asngw-service name asn1
```

clear ps-network statistics

Clears the HNB-Packet Switched (PS) network service associated with an HNB-GW service instance.

Product

HNB-GW

Privilege

Operator

Syntax

clear ps-network statistics [name *cs_svc_name* **| gtpu-only | ranap-only | rtp-only | sccp-only]**

name *ps_svc_name*

Clears the session statistics based on an existing HNB-PS network service name, expressed as an alphanumeric string of from 1 through 63 characters.

gtpu-only

Clears the session statistics for GTP-U traffic only for the specified HNB-PS Network service.

ranap-only

Clears the session statistics for Radio Access Network Application Protocol (RANAP) traffic only for the specified HNB-PS Network service.

sccp-only

Clears the session statistics for Signaling Connection Control Part (SCCP) traffic only for the specified HNB-PS Network service.

Usage

Use this command to clear the session statistics for overall session or in selected part of user session for HNB-CS Network services configured and running on a system.

Example

The following command clears the session statistics for RANAP part of session for the HNB-PS Network service *hnb_PS_1*:

```
clear ps-network statistics name hnb_PS_1 ranap-only
```

clear qos npu stats

Clears information pertaining to NPU QoS priority queue bandwidth allocation and sharing.

Product

GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear qos npu stats inter-subscriber traffic slot *slot_num*

inter-subscriber traffic slot *slot_num*

Clears inter-subscriber traffic statistics for the application or line card installed in the specified slot. *slot_num* indicates the number of the chassis slot in which the card is installed and can be configured to an integer value from 1 through 48.

Usage

Allows you to manually reset statistics pertaining to NPU QoS priority queue bandwidth allocation.

Example

The following command clears statistics for a card installed in chassis slot *3*:

```
clear qos npu stats inter-subscriber traffic slot 3
```

clear radius accounting archive

Clears archived RADIUS accounting messages associated with an AAA group, or all the archived RADIUS accounting messages in the context in which the command is executed depending on the option chosen. The scope of the command is limited to the context in which it is executed (including the local context).

Important: This command is only available in StarOS 8.3 and later. For more information, please contact your local service representative.

Product

All

Privilege

Security Administrator, Administrator

Syntax

clear radius accounting archive { all | radius group *group_name* **} [-noconfirm]**

all

Clears all archived RADIUS accounting messages in the context.

radius group *group_name*

Clears all archived RADIUS accounting messages for the RADIUS group specified as an alphanumeric string of 0 through 64 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to clear the archived RADIUS accounting messages associated with an AAA group, or all the archived RADIUS accounting messages in the context in which the command is executed.

Example

Use the following command to clear all archived RADIUS accounting messages for the group named *test12*.

```
clear radius accounting archive radius group test12
```

clear radius counters

Clears statistics for RADIUS servers or a server group. The statistics for all RADIUS servers or a server group may be cleared.

Product

PDSN, GGSN, ASN-GW, P-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

clear radius counters { all | radius group *group_name* **| server** *ip_address* **[port** *number* **] }**

all | radius group *group_name* **| server** *ip_address* **[port** *number* **]**

all: Clears statistics for all servers.
radius group *group_name*: Clears all configured authentication/accounting servers in the specified RADIUS group. *group_name* must be the name of server group configured in a specific context for authentication/accounting, expressed as an alphanumeric string of 1 through 63 characters.
server *ip_address* **[port** *number* **]**: Clears statistics only for the server specified using IPv4 dotted-decimal or IPv6 colon-separated notation. Optionally, you can specify the port which is to have its RADIUS statistics cleared as an integer from 0 through 65535.

Usage

Clear the statistics to reset them to zero prior to logging or monitoring the system for troubleshooting, performance measurements, etc.

Example

The following command clears the statistics for all RADIUS servers.

```
clear radius counters all
```

The following command resets the statistics only for the server *10.2.3.4*.

```
clear radius counters server 10.2.3.4
```

The following command resets the statistics only for the server group named *star1*.

```
clear radius counters radius group star1
```

clear rohc statistics

Clears statistics and counters collected since the last reload or **clear** command was issued for RObust Header Compression (ROHC) [RFC 3095].

Product

PDSN, ASN-GW, HSGW

Privilege

Administrator, Config-administrator, Operator, Inspector

Syntax

clear rohc statistics [pdsn-service *pdsnsvc_name* **| asngw-service** *asngwsvc_name*

pdsn-service *pdsnsvc_name*

Clears ROHC statistics and counters for the specified PDSN service.

asngw-service *asngwsvc_name*

Clears ROHC statistics and counters for the specified ASN-GW service.

Usage

Use this command to clear ROHC statistics for all services or for a specific PDSN or ASNGW service.

Example

The following command clears ROHC statistics and counters for the PDSN service named *pdsn1*:

```
clear rohc statistics pdsn-service pdsn1
```

clear rp service-option

Clears the radio-packet (R-P) interface service option statistics.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear rp service-option statistics [number *option_num* **| pdsn-service** *pdsn_name* **]**

number *option_num* **| pdsn-service** *pdsn_name*

Default: clears the statistics for all service options and all packet data services.
number *option_num*: Specifies the R-P service option number for which the statistics are to be cleared as an integer from 0 through 1000.
pdsn-service *pdsn_name*: Specifies the PDSN service name for which statistics will be cleared.

Usage

Clear the R-P service option statistics prior to monitoring the system for bench marking or for detecting areas of further research.

Example

The following resets the service option statistics for service option *23* and packet data service *sampleService*, respectively.

```
clear rp service-option statistics number 23

clear rp service-option statistics pdsn-service sampleService
```

clear rp statistics

Clears the radio-packet (R-P) interface statistics. The statistics for a specific packet data server or peer node may be cleared if specified.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear rp statistics [pdsn-service *name* **| peer-address [** *peer_address* **| all]]**

pdsn-service *name* **| peer-address [** *peer_address* **| all]**

Default: clears all R-P associated statistics.
pdsn-service *name*: Specifies the packet data service name that is to have its statistics reset.
peer-address [*ip_address* **| all]**: Specifies that statistics for the specified peer, or all peers, are to be cleared. The *ip_address* must be specified using IPv4 dotted-decimal notation.

Usage

Clear the statistics to prepare for monitoring the system.

Example

The following command resets all the associated statistics for the R-P interfaces.

```
clear rp statistics
```

The following command clears the statistics for the packet data service *sampleService*.

```
clear rp statistics pdsn-service sampleService
```

The following command resets the statistics associated with peer node with IP address *10.2.3.4*.

```
clear rp statistics peer-address 10.2.3.4
```

clear sccp statistics

Clears SS7 Signaling Connection Control Part (SCCP) statistics collected for services that use the SCCP protocol.

Product

SGSN

Privilege

Inspector

Syntax

clear sccp statistics [iups-service *iups_srvc_name* **| map-service** *map_srvc_name* **| sccp-network** *ntwk_index* **[dpc** *dpc* **[ssn** *ssn* **] | global-title-translation { address-map instance** *add_map_inst* **| association instance** *assoc_inst* **} [sessmgr instance** *sessmgr_inst* **]] [| { grep** *grep_options* **| more }]**

iups-service *iups_srvc_name*

Deletes collected SCCP protocol statistics for an existing Iu-PS service in the current context specified as an alphanumeric string of 1 through 63 characters.

map-service *map_srvc_name*

Deletes collected SCCP protocol statistics for an existing MAP service specified as an alphanumeric string of 1 through 63 characters.

sccp-network *ntwk_index*

Deletes collected SCCP protocol statistics for the SSCP network configuration with the a network index specified as an integer from 1 through 12.
The following filters can be added to limit the clearing of SCCP network statistics:

- **dpc** *dpc*: Specifies a differentiated pointcode address to limit the deletion of collected SCCP network statistics to those for the identified destination.
- **ssn** *ssn*: Specifies a subsystem number as an integer from 1 to 255 to limit the deletion of collected SCCP network statistics.
- **global-title-translation address-map instance** *add_map_inst*: Specifies an identified GTT address-map as an integer from 1 to 4096 to limit the deletion of collected SCCP network statistics.
- **global-title-translation association instance** *assoc_inst*: Specifies an identified GTT association as an integer from 1 to 16 to limit the deletion of collected SCCP network statistics.
- **sessmgr instance** *sessmgr_inst*: Specifies an identified session manager instance as an integer from 1 to 384 to limit the deletion of collected SCCP network statistics.

Usage

Use this command to delete all collected SCCP statistics or to delete SCCP statistics for a specified service, SCCP network, or session manager.

Example

The following command deletes all collected SCCP statistics:

```
clear sccp statistics
```

The following command clears all collected SCCP statistics for the IuPS service named *iups-serv1*:

```
clear sccp statistics iups-service iups-serv1
```

clear session disconnect-reasons

Clears the session disconnect reason statistics for all sessions on the system.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear session disconnect-reasons
```

Usage

Sets the counters for session disconnect reasons to zero (0) in preparation for a monitoring or troubleshooting session.

Example

```
clear session disconnect-reasons
```

clear session-event-record statistics

Clears statistics collected during session event module transfers.

Product

S-GW

Privilege

Operator

Syntax

```
clear session-event-record statistics
```

Usage

Use this command to delete all collected session event record statistics.

clear session setuptime

Clears the session setup time statistics for Packet Control Functions (PCFs) or SGSNs. If no keyword is specified the summary statistics displayed by the **show session setuptime** command are cleared.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear session setuptime { pcf { *pcf_addr* | all } | sgsn { *sgsn_addr* | all } }

pcf { *pcf_addr* | all }

pcf_addr: Clears the setup time counters for the PCF at the IP address specified in IPv4 dotted-decimal notation.
all: Clears the setup time counters for all PCFs.

sgsn { *sgsn_addr* | all }

sgsn_addr: Clears the setup time counters for the SGSN at the IP address specified in IPv4 dotted-decimal notation.
all: Clears the setup time counters for all SGSNs.

Usage

Sets the counters for session disconnect reasons to zero (0) in preparation for a monitoring or troubleshooting session.

Example

To clear the statistics for the PCF at IP address *192.168.100.10*, enter the following command:

```
clear session setuptime pcf 192.168.100.10
```

clear session subsystem

Clears all session subsystem statistics for the current context.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear session subsystem
```

Usage

Clear the statistics in preparation for a troubleshooting or monitoring session so that the counters are at a well known values.

Example

```
clear session subsystem
```

clear sgsn-fast-path statistics

Clears information related to SGSN fast-path.

Product

SGSN

Privilege

Inspector

Syntax

show sgsn-fast-path statistics [all | smgr-instance *smgr_inst* **] [| { grep** *grep_options* **| more }]**

all

Deletes collected fast-path statistics for all session managers.

smgr-instance *smgr_inst*

Clears collected fast-path statistics for a session manager instance specified as an integer from 1 to 65535.

| grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Please refer to the *Regulating the Command Output* section in this reference for details on the usage of **grep** and **more**.

Usage

Use this command to clear all statistics for SGSN fast-path configurations.

Example

The following command deletes all collected fast-path statistics for all SGSN session managers:

```
clear sgsn-fast-path statistics
```

clear sgsn-map-app

Deletes collected statistics for the SGSN Mobile Application Part (MAP).

Product

SGSN

Privilege

Inspector

Syntax

clear sgsn-map-app statistics [| { grep *grep_options* **| more }]**

clear sgsn-map-app statistics

Clears all collected statistics for the SGSN MAP application.

| grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Please refer to the *Regulating the Command Output* section in this reference for details on the usage of **grep** and **more**.

Usage

Use this command to deleted collected statistics for the SGSN MAP application.

Example

The following command clears all collected SGSN MAP statistics:

```
clear sgsn-map-app statistics
```

clear sgs-service

Clears SGs interface statistics associated with a Visitor Location Register (VLR).

Product

All

Privilege

Operator

Syntax

clear sgs-service { statistics [name *name* **] | vlr-status [service-name** *name* **] [vlr-name** *name* **] }**

---

statistics [name *name* **]**

Clears statistics for all SGs services or a specific SGs service.
name *name*: Clears the statistics for an existing SGs service specified as an alphanumeric string of 1 through 63 characters.

---

vlr-status [service-name *name* **] [vlr-name** *name* **] }**

Clears statistics for all VLRs, a VLR related to a SGs service, or a specific VLR.
service-name *name*: Clears the SGs statistics for an existing VLR specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear statistics for all SGs services, Visitor Location Registers (VLRS), or a specific SGs service or VLR name.

Example

The following command clears statistics for an SGs service named *sgs2*:

```
clear sgs-service statistics name sgs2
```

clear sgtpc statistics

Clears all SGSN GTP-C (SGTPC) statistics for the current context.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear sgtpc statistics [gsn-address *ipv4_address* **| sgtp-service** *sgtp_srvc_name* **]**

gsn-address *ipv4_address*

Clears GTPC packet statistics for the interface specified as an IP address in IPv4 dotted-decimal notation.

sgtp-service *sgtp_srvc_name*

Clears GTPC packet statistics for an existing SGTP service specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear the statistics in preparation for a troubleshooting or monitoring session.

Important: Statistics are vital for troubleshooting. We recommend that you check with your Cisco support personnel prior to clearing these statistics.

Example

```
clear sgtpc statistics sgtp-service SGSN1sgtp12
```

clear sgtpu statistics

Clears all SGSN GTP-U (SGTPU) statistics for the current context.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear sgtpu statistics [ggsn-address *ipv4_address* **| gprs-service** *gprs_srvc_name* **nsei** *nse_id* **| iups-bind-address** *ipv4_address* **| iups-service** *iups_srvc_name* **| rnc-address** *ipv4_address* **| sgtp-service** *sgtp_srvc_name* **]**

ggsn-address *ipv4_address*

Clears GTPU packet statistics for a specific GGSN specified as an IP address in IPv4 dotted-decimal notation.

gprs-service *gprs_srvc_name* **nsei** *nse_id*

gprs-service *gprs_srvc_name*: Clears GTPU packet statistics for the interface for a specific GPRS service specified as an alphanumeric string of 1 through 63 characters.
nsei *nse_id*: Specifies a network service entity (NSEI) as an integer from 0 through 65535.

iups-bind-address *ipv4_address*

Clears GTPU packet statistics for the bind address of an IuPS interface specified as an IP address in IPv4 dotted-decimal notation.

iups-service *iups_srvc_name*

Clears GTPU packet statistics for an active IuPS service interface specified as an alphanumeric string of 1 through 63 characters.

rnc-address *ipv4_address*

Clears GTPU packet statistics for an RNC specified as an IP address in IPv4 dotted-decimal notation.

sgtp-service *sgtp_srvc_name*

Clears GTPU packet statistics for an active SGTP service interface specified as n alphanumeric string of 1 through 63 characters.

Usage

Use this command to clear the statistics in preparation for a troubleshooting or monitoring session.

Important: Statistics are vital for troubleshooting. We recommend that you check with your Cisco support personnel prior to clearing these statistics.

Example

Use this command to clear collected SGTPU statistics for a specific NSEI of a configured GPRS service:

```
clear sgtpu statistics gprs-service SGSN1Gprs1 nsei 2445
```

clear sgw-service statistics

Clears Serving Gateway (S-GW) statistics and counters found in **show** command outputs and bulk statistics associated with all S-GW services or a specific service defined by the parameter in this command.

Product

S-GW

Privilege

Operator

Syntax

clear sgw-service statistics { all | name *service_name* **}**

all

Clears statistics and counters for all S-GW services configured on the system.

name *service_name*

Clears statistics and counters for an existing S-GW service name specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to clears statistics and counters in show command outputs and bulk statistics for all S-GW services or for a specific S-GW service.

Example

The following command clears statistics and counters for an S-GW service named *sgw3*:

```
clear sgw-service statistics name sgw3
```

clear sms statistics

Deletes collected traffic statistics for the Short Message Service (SMS).

Product

SGSN

Privilege

Administrator, Security Administrator, Operator

Syntax

clear sms statistics [name *map_srvc* **] [| { grep** *grep_options* **| more }]**

name *map_srvc*

Specifies a MAP Service as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to delete collected traffic statistics for SMS. It is possible to clear the statistics of a specific MAP service associated with the SMS by including the **name** filter.

Example

Use the following command to clear SMS statistics for MAP service *MAP-LONDON1*:

```
clear sms statistics name MAP-LONDOND1
```

clear sndcp statistics

Deletes all collected statistics for the packet traffic going through the Subnetwork Dependent Convergence Protocol (SNDCP) layer.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear sndcp statistics [ gprs-service srvc_name ] [ | { grep grep_options | more } ]
```

gprs-service *srvc_name*

Specifies a GPRS service as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to delete all collected SNDCP traffic statistics. Include the **gprs-service** keyword to filter the clearing action to only deleted statistics for one GPRS service.

Example

Use the following command to clear all collected SNDCP layer traffic statistics:

```
clear sndcp statistics
```

Use the following command to delete SNDCP layer traffic statistics for the *test1* GPRS service:

```
clear sndcp statistics gprs-service test1
```

clear snmp trap

Clears all SNMP event trap notifications from the buffer.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear snmp trap { history | statistics }
```

history

Clears all SNMP historical trap information from the system buffer.

statistics

Clears all SNMP event trap information from the system buffer.

Usage

Use this command to empty the buffer of all SNMP trap notifications.

Example

The following command clears the all historical SNMP traps from the system buffer:

```
clear snmp trap history
```

clear srp

Clears system Service Redundancy Protocol (SRP) statistics.

Product

All products that support Interchassis Session Recovery (ICSR)

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear srp { audit-statistics | call-loss statistics | checkpoint statistics | statistics
}
```

audit-statistics

Clears SRP audit statistics.

call-loss statistics

Clears SRP call loss history.

checkpoint statistics

Clears SRP checkpoint interface statistics.

statistics

Clears SRP statistics.

Usage

Clears the SRP statistics to prepare the system for SRP monitoring.

Example

The following command resets all the associated statistics for SRP checkpoints.

```
clear srp checkpoint statistics
```

The following command resets all the associated statistics for SRP.

```
clear srp statistics
```

clear ssl statistics

Deletes all previously gathered Secure Sockets Layer (SSL) statistics for a specific P-CSCF service or all P-CSCF services, either system-wide or within a context.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear ssl statistics [ service-name name ]
```

service-name *name*

Specifies the name of a P-CSCF service for which to clear SSL statistics as an alphanumeric string of 1 through 63 characters that is case sensitive.

Usage

SSL statistics for a single P-CSCF service can be cleared using the **service-name** keyword. SSL statistics for all P-CSCF services can be deleted by entering the command with no keywords.
If this command is executed from within the local context with no keywords, SSL statistics will be cleared for every P-CSCF service configured on the system regardless of context. In addition, if the **service-name** keyword is used when executing from within the local context, SSL statistics for all P-CSCF services configured with the specified name will be cleared regardless of context.

Example

The following command clears SSL statistics for the P-CSCF service *pcscf_service_1*:

```
clear ssl statistics service-name pcscf_service_1
```

clear subscribers

Disconnects subscribers based on specified criteria.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

clear subscribers [*keywords* **] [verbose] [-noconfirm]**

The keywords are filters that modify or filter the criteria for deciding which subscriber sessions to clear and are described below. Multiple keywords can be entered on a command line.
When multiple keywords are specified, the subscriber sessions deleted must meet the specifications of all of the keywords.
For example; if you enter the following command:

```
clear subscribers ip-pool pool1 card-num 1
```

Only subscriber sessions that were assigned an IP address from the IP pool named *pool1* and are also being processed by the processing card in slot *1* are cleared. All other subscriber sessions that do not meet these criteria remain and are not cleared.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Important: The Operator privilege does not have access to this keyword.

active

Only disconnects subscribers who currently have active sessions.

active-charging-service *ecs_service_name*

Clears information for subscribers using the Active charging Service.
ecs_service_name must be the name of the Active Charging Service, expressed as an alphanumeric string of 1 through 15 characters.

all

Disconnects all subscribers.

Important: The Operator privilege does not have access to this keyword.

apn *name*

Clears all PDP contexts accessing a specific access point name (APN).
apn_name is the name of the APN expressed as an alphanumeric string of 1 through 63 characters that is case sensitive.

asn-peer-address *ip_address*

Clears information for subscribers on an ASN-GW trusted peer.
ip_address is the address of the ASN-GW peer server entered using IPv4 dotted-decimal notation.

asngw-service *service_name*

Clears counters for subscribers accessing the ASN-GW service.
service_name must be an existing service expressed as an alphanumeric string of 1 through 63 characters.

asnpc-service *service_name*

Clears counters for subscribers accessing the ASN PC service.
service_name must be an existing service expressed as an alphanumeric string of 1 through 63 characters.

bandwidth-policy *bandwidth_policy_name*

Clears information for subscribers using the specified bandwidth policy.
bandwidth_policy_name must be the name for an existing bandwidth policy, expressed as an alphanumeric string of 1 through 63 characters.

callid *id*

Clears the call specified by *call_id*. The call ID must be specified as a 4-byte hexadecimal number.

card-num *card_num*

The slot number of the processing card by which the subscriber session is processed. *card_num* is a slot number from 1 through 7 or 10 through 16.

cbb-policy *cbb_policy_name*

Clears information for subscribers using the specified CBB policy.
cbb_policy_name must be the name for an existing CBB policy expressed as an alphanumeric string of 1 through 63 characters.

ccoa-only

This option clears the subscribers that registered a MIP co-located COA directly with the HA.
This option is only valid when MIPHA session license is enabled.

configured-idle-timeout [< | > | greater-than | less-than] *value*

Disconnects subscribers whose idle timeout matches the specified criteria. A value of 0 (zero) indicates that the subscribers idle timeout is disabled.
<: Filters output so that only information less than the specified value is cleared.
>: Filters output so that only information greater than the specified value is cleared.
greater-than: Filters output so that only information greater than the specified value is cleared.
less-than: Filters output so that only information less than the specified value is cleared.
value: If no other filtering options are specified only output matching *value* is cleared. If *value* is not specified all data is cleared. *value* must be an integer from 0 through 4294967295.

connected-time [< | > | greater-than | less-than] *value*

Disconnects subscribers who have been connected for the specified length of time.
<: Filters output so that only information less than the specified value is cleared.
>: Filters output so that only information greater than the specified value is cleared.

greater-than: Filters output so that only information greater than the specified value is cleared.
less-than: Filters output so that only information less than the specified value is cleared.
value: If no other filtering options are specified only output matching *value* is cleared. If *value* is not specified all data is cleared. *value* must be an integer from 0 through 4294967295.

---

cscf-service *service_name*

Clears all subscribers from the specified CSCF service.
service_name must be an existing service expressed as an alphanumeric string of 1 through 63 characters.

---

css-delivery-sequence *name*

Important: This is a restricted keyword. In StarOS 9.0 and later, this keyword is obsoleted.

---

css-service *name*

Important: This is a restricted keyword. In StarOS 9.0 and later, this keyword is obsoleted.

---

dhcp-server *address*

Clears all PDP contexts that currently possess an IP address assigned from a specific DHCP server.
dhcp_address is the IP address of the DHCP server expressed in IPv4 dotted-decimal notation.

---

dormant

Only disconnects subscriber sessions that are dormant (not transmitting or receiving data).

---

ebi *number*

Clears subscribers based on an EPS bearer identity (EBI). *number* must be a valid EBI and an integer value from 5 to 15.

---

enodeb-address *ip_address*

Clears subscribers based on the eNodeB to which they are attached. *ip_address* must be a valid IP address of an existing eNodeB entered using IPv4 dotted-decimal or IPv6 colon-separated notation.

---

fa *ip_address*

Disconnects all subscribers connected to the foreign agent specified by the IP address in IPv4 dotted-decimal notation.

---

fa-service *fa_name*

Disconnects all subscribers connected to an existing foreign agent name.

---

firewall { not-required | required }

Clears all subscriber information for the specified subscribers:
not-required: Subscribers for whom firewall processing is not-required.
required: Subscribers for whom firewall processing is required.

firewall-policy *fw_policy_name*

This keyword is obsolete.

fw-and-nat policy *fw&nat_policy_name*

Clears information for subscribers using the specified Firewall-and-NAT policy.
fw&nat_policy_name must be the name of an existing Firewall-and-NAT policy expressed as an alphanumeric string of 1 through 63 characters.

fng-service *service_name*

Clears subscriber sessions connected to the FNG service. *service_name* must be an existing service expressed as an alphanumeric string of 1 through 63 characters.

ggsn-service *name*

Clears all PDP contexts accessing an existing GGSN service specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

gprs-service *name*

Clears all PDP contexts associated with the 2G SGSN. This keyword can be used with filtering keywords that are part of the **clear subscriber** command set.
Using this keyword can trigger a network-initiated service request (paging) procedure.
name identifies a specific GPRS service configuration expressed as an alphanumeric string of 1 through 63 characters.

gsm-traffic-class { background | conversational | interactive { *priority* **} | streaming }**

Subscribers whose traffic matches the specified 3GPP traffic class.

- **background**: 3GPP QoS background class.
- **conversational**: 3GPP QoS conversational class.
- **interactive**: 3GPP QoS interactive class. Must be followed by a traffic priority. priority can be configured to any integer value from 1 to 3.
- **streaming**: 3GPP QoS streaming class.

gtp-version

Displays the specific GTP version number. Must be followed by one of the supported GTP versions (0 or 1).
The following filter keywords are valid with this command:
active-charging-service, apn, asngw-service, asnpc-service, asn-peer-address, bearer-establishment, callid, card-num, coaa-only, configured-idle-timeout, connected-time, cscf-service, dhcp-server, fa, fa-service, firewall, ggsn-service, gprs-service, gsm-traffic-class, gtp-version, ha, ha-ipsec-service, ha-service, idle-time, ims-auth-service, imsi, ip-address, ip-alloc-method, ip-pool, ipv6-address, ipv6-prefix, l3-tunnel-local-addr, lac, lac-service, lns, lns-service, long-duration-time-left, mip-udp-tunnel-only, mipv6ha-service, msid, msisdn, network-requested, network-type, pcf, pdg-service, pdif-service, pdsn-service, plmn-type, rulebase, rx-data, session-time-left, sgsn-address, sgsn-service, tx-data, username, grep, more

ha *address*

Disconnects all subscribers connected to the home agent specified by *ha_address* must be specified using IPv4 dotted-decimal notation.

ha-ipsec-only

Disconnects all MIP HA sessions with IPSec tunnels.

ha-service *name*

Disconnects all subscribers connected to the home agent specified by *ha_name* must have been previously defined.

hsgw-service *name*

Disconnects subscribers using this HRPD Serving Gateway (HSGW) service configured on this system. *name* must be an existing HSGW service expressed as an alphanumeric string of 1 through 63 characters.

idle-time [< | > | greater-than | less-than] *value*

Disconnects subscribers whose idle time matches the specified length of time.
<: Filters output so that only information less than the specified value is cleared.
>: Filters output so that only information greater than the specified value is cleared.
greater-than: Filters output so that only information greater than the specified value is cleared.
less-than: Filters output so that only information less than the specified value is cleared.
value: If no other filtering options are specified only output matching *value* is cleared. If *value* is not specified all data is cleared. *value* must be an integer from 0 through 4294967295.

ims-auth-service *imsa_service_name*

Disconnects subscribers using this IMS Authorization Service configured on this system.
imsa_service_name must be an existing IMS Authorization Service expressed as an alphanumeric string of 1 through 63 characters.

imsi *id*

Disconnects the subscriber with the specified id. The IMSI (International Mobile Subscriber Identity) ID is a 50-bit field which identifies the subscriber's home country and carrier. Wildcard characters $ and * are allowed. The * wildcard matches multiple characters and the $ wildcard matches a single character. If you do not want the wildcard characters interpreted as a wildcard enclose them in single quotes (‘). For example; ‘$’.

ip-alloc-method {aaa-assigned | dhcp [relay-agent | proxy-client] | dynamic-pool | l2tp-lns-assigned | mip-ha-assigned | ms-provided-static | not-ms-provided-static | static pool }

Displays the specific IP Allocation Method. Must be followed by one of the IP Allocation Methods:

- **aaa-assigned**: Selects subscribers whose IP Addresses were assigned by AAA.
- **dhcp**: Selects subscribers whose IP Addresses were assigned by DHCP.
- **relay-agent**: Selects subscribers whose IP Addresses were assigned by the DHCP Relay Agent
- **proxy-client**: Selects subscribers whose IP Addresses were assigned by the DHCP Proxy Client
- **dynamic-pool**: Selects subscribers whose IP Addresses were assigned from a dynamic IP address pool.
- **l2tp-lns-assigned**: Selects subscribers whose IP Addresses were assigned by the Layer 2 Tunnelling Protocol Network Server.
- **mip-ha-assigned**: Selects subscribers whose IP Addresses were assigned by the Mobile IP Home Agent.

- **ms-provided-static**: Selects subscribers whose IP Addresses were provided by the Mobile Station.
- **not-ms-provided-static**: Selects subscribers whose IP Addresses were not provided by the Mobile Station.
- **static-pool**: Selects subscribers whose IP Addresses were assigned from a static IP address pool.

---

ip-address *address*

Disconnects all subscribers connected to the specified *ip_address*. The address must be specified using IPv4 dotted-decimal notation.

---

ip-pool *name*

Disconnects all subscribers assigned addresses from the IP address pool *pool_name*. *pool_name* must be the name of an existing IP pool or IP pool group.

---

ipv4

Clears all subscribers with IPv4 Firewall enabled/disabled.

---

ipv6

Clears all subscribers with IPv6 Firewall enabled/disabled.

---

ipv6-address *address*

Clears all subscribers connected to the specified IPv6 *address*.

---

ipv6-prefix *prefix*

Clears subscribers from a specific IPv6 address prefix.

---

lac *address*

Disconnects all calls to the peer LAC (L2TP access concentrator) specified by *address* must be specified using IPv4 dotted-decimal notation.

---

lac-service *name*

Disconnects all calls for this LAC service. *name* is an alphanumeric string of 1 through 63 characters.

---

lma-service *name*

Disconnects subscribers using this LMA service configured on this system. *name* must be an existing LMA service expressed as an alphanumeric string of 1 through 63 characters.

---

lns *address*

Disconnects calls to the peer LNS (L2TP network server) specified by *address* must be specified using IPv4 dotted-decimal notation.

---

lns-service *name*

Disconnects calls associated with the LNS service named *name*. *name* is an alphanumeric string of 1 through 63 characters.

long-duration-time-left [< | > | greater-than | less-than] *value*

Disconnects subscriber sessions whose time left for the maximum duration of their session matches the length of time specified.
<: Filters output so that only information less than the specified value is cleared.
>: Filters output so that only information greater than the specified value is cleared.
greater-than: Filters output so that only information greater than the specified value is cleared.
less-than: Filters output so that only information less than the specified value is cleared.
value: If no other filtering options are specified only output matching *value* is cleared. If *value* is not specified all data is cleared. *value* must be an integer from 0 through 4294967295.

mag-service *name*

Disconnects subscribers using this Mobile Access Gateway (MAG) service configured on this system. *name* must be an existing MAG service and be from 1 to 63 alphanumeric characters.

mip-udp-tunnel-only

This option clears the subscribers that negotiated MIP-UDP tunneling with the HA.
This option is only valid when MIP NAT Traversal license is enabled.

mme-address *ipv4_addr*

Disconnects subscribers using this peer Mobility Management Entity (MME). *ipv4_addr* must be an existing peer MME IP address entered using IPv4 dotted-decimal notation.

mme-only

Disconnects all MME subscriber sessions on the system.

mme-service *name*

Disconnects subscribers using this MME service configured on this system. *name* must be an existing MME service expressed as an alphanumeric string1 through 63 characters.

mseg-only

Important: This keyword is not supported in this release. For more information please contact your Cisco account representative.

Clears subscriber information for all MSEG service subscribers.

mseg-service *mseg_service_name*

Important: This keyword is not supported in this release. For more information please contact your Cisco account representative.

Clears subscriber information for subscribers using the specified MSEG service.
mseg_service_name must be name of an existing MSEG service expressed as an alphanumeric string of 1 through 63 characters.

msid *id*

Disconnects the mobile user identified by *ms_id*. *ms_id* must be from 7 to 16 digits specified as an IMSI, MIN, or RMI. Wildcard characters $ and * are allowed. The * wildcard matches multiple characters and the $ wildcard matches a single character. If you do not want the wildcard characters interpreted as a wildcard enclose them in single quotes (‘). For example; ‘$’.
In case of **enforce imsi-min equivalence** is enabled on the chassis and MIN or IMSI numbers supplied, this filter will clear subscribers with a corresponding MSID (MIN or IMSI) whose lower 10 digits matches to lower 10 digits of the supplied MSID.
clear subscribers msid *111110123456789* or
clear subscribers msid *0123456789*
will clear any subscriber with a MSID that match the lower 10 digits of MSID supplied, i.e. 0123456789.

msisdn *msisdn*

Clears information for the mobile user identified by Mobile Subscriber ISDN Number (MSISDN). *msisdn* must be from 7 to 16 digits specified as an IMSI, MIN, or RMI.

nat { not-required | required [nat-ip *nat_ip_address* **| nat-realm** *nat_realm* **] }**

Clears all subscriber information for the specified subscribers:
not-required: Subscribers for whom NAT processing is not required.
required: Subscribers for whom NAT processing is required.

Important: The **nat-ip** keyword is only available in StarOS 8.3 and later.

nat-ip *nat_ip_address*: Subscribers for whom NAT processing is enabled and are using the specified NAT IP address. *nat_ip_address* specifies the NAT IP address using IPv4 dotted-decimal notation.
nat-realm *nat_realm*: Subscribers for whom NAT processing is enabled and are using the specified NAT realm. *nat_realm* specifies the NAT realm name expressed as an alphanumeric string of 1 through 63 characters.

network-requested

Disconnect subscriber sessions that were initiated by the GGSN network requested create PDP context procedure.

network-type { gre | ipv4 | ipv6 | ipip | l2tp | mobile-ip | proxy-mobile-ip }

Disconnects subscriber sessions based on the network type. The following network types can be selected:

- **gre**: Generic Routing Encapsulation (GRE) per RFC 2784
- **ipv4**: Internet Protocol version 4 (IPv4)
- **ipv6**: Internet Protocol version 6 (IPv6)
- **ipip**: IP-in-IP encapsulation per RFC 2003
- **l2tp**: Layer 2 Tunneling Protocol encryption per RFC 2661
- **mobile-ip**: Mobile IP
- **proxy-mobile-ip**: Proxy Mobile IP

pcf [< | > | less-than | greater-than] *ipv4_address* **[[< | > | less-than | greater-than]** *ipv4_address* **]**

Displays information for subscribers connected via the packet control function with a specific or range of IP address *ipv4_ddress*. The address must be specified using IPv4 dotted-decimal notation.

- **<**: Filters output so that only information less than the specified IPv4 address value is displayed.
- **>**: Filters output so that only information greater than the specified IPv4 address value is displayed.
- **less-than**: Filters output so that only information less than the specified IPv4 address value is displayed.
- **greater-than**:Filters output so that only information greater than the specified IPv4 address value is displayed.

Note: It is possible to define a limited range of IP addresses by using the less-than and greater-than options to define minimum and maximum values.

pdsn-service *name*

Disconnect all subscribers connected to the packet data service *pdsn_name*. The packet data service must have been previously configured.

pdg-service *service_name*

Disconnects subscriber sessions that are using the PDG service.
service_name must be an existing service expressed as an alphanumeric string of 1 through 63 characters.

pdif-service *service_name*

Clears counters for subscribers accessing the Packet Data Interworking Function (PDIF) service.
service_name must be an existing service expressed as an alphanumeric string of 1 through 63 characters.

pgw-only { all | imsi *id* **ebi** *id* **| pgw-service** *name* **| sgw-address** *ipv4_addr* **}**

all: Disconnects all subscribers for all P-GW services on this system.
imsi *id* **ebi** *id*: Disconnects subscribers based on their International Mobile Subscriber Identification (IMSI). *id* must be the 3-digit MCC (Mobile Country Code), follow by the 2 or 3 digits of the MNC (Mobile Network Code) and the MSIN (Mobile Subscriber Identification Number). *id* should not exceed 15 digits.
Example: 123-45-678910234 must be entered as 12345678910234
The EBI (EPS Bearer Identity) *id* must be a valid EBI and be an integer value from 5 to 15.
pgw-service*name*: Disconnects all subscribers using this P-GW service. *name* must be an existing P-GW service expressed as an alphanumeric string of 1 through 63 characters.
sgw-address*ipv4_addr*: Disconnects all subscribers using this S-GW IP address. *ipv4_addr* must be an existing IP address entered using IPv4 dotted-decimal notation.

plmn-type { home | roaming |visiting }

For GGSN, disconnects subscribers whose subscriber type matches the specified type.

qci { *number* **}**

Disconnects subscribers based on their QCI identity. *number* must be an integer from 0 to 9.

rulebase *rulebase_name*

Clears information for subscribers using the specified rulebase.

rulebase_name must be name of an existing rulebase expressed as an alphanumeric string of 1 through 63 characters.

---

rx-data [< | > | greater-than | less-than] *value*

Disconnects subscribers who have received the specified number of bytes of data.
<: Filters output so that only information less than the specified value is cleared.
>: Filters output so that only information greater than the specified value is cleared.
greater-than: Filters output so that only information greater than the specified value is cleared.
less-than: Filters output so that only information less than the specified value is cleared.
value: If no other filtering options are specified only output matching *value* is cleared. If *value* is not specified all data is cleared. *value* must be an integer from 0 through 18446744073709551615.

---

s5-proto { gtp | pmip }

Disconnects subscribers based on their S5 interface protocol type.
gtp: Indicates that the GTP protocol is used on the S5 interface for the subscribers being disconnected.
pmip: Indicates that the PMIP protocol is used on the S5 interface for the subscribers being disconnected.

---

session-time-left [< | > | greater-than | less-than] *value*

The amount of time left for the subscriber session.
<: Filters output so that only information less than the specified value is cleared.
>: Filters output so that only information greater than the specified value is cleared.
greater-than: Filters output so that only information greater than the specified value is cleared.
less-than: Filters output so that only information less than the specified value is cleared.
value: If no other filtering options are specified only output matching *value* is cleared. If *value* is not specified all data is cleared. *value* must be an integer from 0 through 4294967295.

---

sgsn-address *address*

Clears all PDP contexts currently being facilitated by a specific SGSN.
address is the IP address of the SGSN entered using IPv4 dotted-decimal notation.

---

sgsn-service *name*

Clears all PDP contexts associated with SGSN. This keyword can be used with filtering keywords that are part of the **clear subscriber** command set.
Using this keyword can trigger a network-initiated service request (paging) procedure.
name identifies a specific SGSN-service configuration expressed as an alphanumeric string of 1 through 63 characters.

---

sgw-only

Disconnects all S-GW subscriber sessions on the system.

---

sgw-service *name*

Disconnects subscribers using this Serving Gateway (S-GW) service configured on this system. *name* must be an existing S-GW service expressed as an alphanumeric string of 1 through 63 characters.

---

tpo { not-required | required }

Clears all subscriber information for the specified subscribers:
not-required: Subscribers for whom TPO processing is not required.
required: Subscribers for whom TPO processing is required.

tx-data [< | > | greater-than | less-than] *value*

Disconnects subscribers who have transmitted the specified number of bytes of data.
<: Filters output so that only information less than the specified value is cleared.
>: Filters output so that only information greater than the specified value is cleared.
greater-than: Filters output so that only information greater than the specified value is cleared.
less-than: Filters output so that only information less than the specified value is cleared.
value: If no other filtering options are specified only output matching *value* is cleared. If *value* is not specified all data is cleared. value must be an integer from 0 through 18446744073709551615.

username *name*

Disconnect the subscriber with the specified username
name is the username of the subscriber to be cleared. *name* must be a sequence of characters and/or wildcard characters ('$' and '*') from 1 to 127 characters. The * wildcard matches multiple characters and the $ wildcard matches a single character. If you do not want the wildcard characters interpreted as wildcard enclose them in single quotes (‘). For example; ‘$’.

verbose

Indicates the output should provide as much information as possible. If this option is not specified then the output is the standard level which is the concise mode.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command’s Output* section of the *Command Line Interface Overview* chapter.

Usage

Clear subscribers sessions to aid in troubleshooting the system when no additional subscribers may connect or when a specific service or remote address may be having connection problems. This command may also be used to clear connections when preparing for maintenance activities.
Related commands to clear subscription data - *for SGSN use only*

- For a 2G SGSN, the **admin-disconnect-behavior clear-subscription** command in the GPRS Service Configuration mode enables the SGSN to clear subscription data after the administrative disconnect - **clear subscribers all** has been issued.
- For a 3G SGSN, the **admin-disconnect-behavior clear-subscription** command in the SGSN Service Configuration mode enables the SGSN to clear subscription data after the administrative disconnect - **clear subscribers all** has been issued.

Example

The following examples illustrate the basic command usage as well as the redirection of the command output. Not all options are exemplified as all options follow the same basic constructs.
The following are basic subscriber clearing examples.

```
clear subscribers username ser1

clear subscribers ha sampleService

clear subscribers ip-pool pool2 verbose
```

The following command disconnects users connected to the foreign agent with IP address *10.2.3.4*.

```
clear subscribers fa 10.2.3.4
```

clear super-charger

Deletes the subscriber's backed-up subscription data.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
clear super-charger { imsi | all }
```

imsi

Specifies a subscriber's international mobile subscriber identity (IMSI) number. This 15-digit number includes the MCC (mobile country code), the MNC (mobile network code) and the MSIN (mobile station identification number),

all

Instructs the SGSN to delete subscription data for all super charger subscribers.

Usage

Use this command to clear (delete) the subscription data records for one or all subscribers within a super charger subscription configuration.

Example

The following command deletes the backed up records for the subscriber identified by the IMSI *90121882144672*.

```
clear super-charger imsi 90121882144672
```

clear tcap statistics

Deletes the collected statistics for traffic that has passed through the TCAP (Transaction Capabilities Application Part) layer.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

clear tcap statistics [camel-service [all | name *camel_srvc* **] | map-service [all | name** *map_srvc* **]] [| { grep** *grep_options* **| more }]**

camel-service [all | name *camel_srvc* **]**

Deletes TCAP statistics for either all CAMEL (Customized Applications for Mobile Network Enhanced Logic, GSM 09.78) services or only for the named CAMEL service.

map-service [all | name *mapl_srvc* **]**

Deletes TCAP statistics for either all MAP services or only for the named MAP service.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to clear (delete) the collected TCAP statistics for MAP or CAMEL services.

Example

The following command deletes the collected statistics for a MAP service named *MAP-Tewk*.

```
clear tcap statistics map-service name MAP-Tewk
```

cli

Specifies command line interface (CLI) session behavior

Product

All

Privilege

Security Administrator, Administrator, Operator, inspector

Syntax

```
cli { history | stop-on-first-error }

no cli { history | stop-on-first-error }
```

no

Disables the specified keyword functionality.

history

Enables command line history for the current command line session. Default: Enabled

stop-on-first-error

When enabled and a configuration file is loaded, the system stops loading the configuration file on the first syntax error. Default: Disabled

Usage

This command controls CLI settings pertaining to the maintenance of a per-session command history and syntax error monitoring during configuration file loading.
By default, the system maintains a list of commands executed during each CLI session. This list is referred to as a history.
In addition, the system can be configured to stop loading a configuration if a syntax error is detected. By default, the system identifies the error but continues to process the configuration file.

Example

The following command disables the keeping of a CLI history for the current session:

```
no cli history
```

clock set

Sets the system time.

Product

All

Privilege

Security Administrator, Administrator

Syntax

clock set *date_time*

clock set *date_time*

Specifies the date and time to set the system clock in the format YYYY:MM:DD:HH:mm or YYYY:MM:DD:HH:mm:ss. Where:

- YYYY = 4-digit year
- MM = 2-digit month in the range 01 through 12
- DD = 2-digit day in the range 01 through 31
- HH = 2-digit hour in the range 00 through 23
- mm = 2-digit minute in the range 00 through 59
- ss = 2-digit second in the range 00 through 59

Usage

Set the clock to adjust the system clock for such things as timing drift, day-light savings adjustment, etc. New settings are immediately applied to all CPUs in the system.

Important: This command should only be used if there is no NTP server enabled for any context. If NTP is running on the system, this command returns a failure.

Example

The following commands set the system clock where one sets the exact second as well.

```
clock set 2011:08:05:02:30

clock set 2011:08:05:02:31:30
```

configure

Sets the mode to the global configure mode. May also be used to set the mode to the configure mode and pre-load the configuration referred to by the options.

Product

All

Privilege

Security Administrator, Administrator

Syntax

configure [*url* **[verbose]]**

url

Specifies the location of a configuration file to pre-load. *url* may refer to a local or a remote file. *url* must be entered using the following format:

- **[file:]{ /flash | /pcmcia1 | /hd } [/***directory* **]/***file_name*
- **tftp://{** *host***[** *:port#* **] } [/***directory* **]/***file_name*
- **[http: | ftp: | sftp:]//[** *username* **[** *:password***] @] {** *host* **} [** *:port#* **] [/***directory* **]/***file_name*

Important: Use of the SMC hard drive is not supported in this release.

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name.
filename is the actual file of interest.
username is the user to be authenticated.
password is the password to use for authentication.
host is the IP address or host name of the server.
port# is the logical port number that the communication protocol is to use.

verbose

Displays the line number and actual line content from the configuration as it is processed.

Usage

If no URL is specified, executing this command causes the CLI to enter the Global Configuration Mode. If a URL is specified, executing this command loads the specified configuration file.

Example

The following simply changes the mode to the command line interface global configuration mode.

```
configure
```

The following command loads a configuration file from the node *sampleNode* given the path specified and a local file, respectively.

```
configure ftp://sampleNode/pub/glob.cfg

configure /pcmcia1/pub/glob.cfg verbose
```

context

Sets the current context to the context specified.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

context *name*

context *name*

Specifies the context of interest as an alphanumeric string of 1 through 79 characters. Must be a previously defined context.

Usage

Change the current context when it is desired to configure and/or manage a specific context.

Example

The following sets the current context to the *sampleContext* context.

```
context sampleContext
```

copy

Copies files from one location to another. Allows files to be copied to/from locally, as well as from one remote location to another.

Product

All

Privilege

Security Administrator, Administrator

Syntax

copy *from_url to_url* **[passive] [-noconfirm]**

from_url

Specifies the source of the copy. *url* may refer to a local or a remote file. *url* must be entered using the following format:

- **[file:]{ /flash | /pcmcia1 | /hd }[/***directory* **]/***file_name*
- **tftp://{** *host*[*:port#* **] }[/***directory* **]/***file_name*
- **[http: | ftp: | sftp:]//[** *username* **[** *:password* **]@] {** *host* **}[** *:port#* **][/***directory* **]/***file_name*

Important: Use of the SMC hard drive is not supported in this release.

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name.
filename is the actual file of interest.
username is the user to be authenticated.
password is the password to use for authentication.
host is the IP address or host name of the server.
port# is the logical port number that the communication protocol is to use.

to_url

Specifies the destination of the copy. *url* may refer to a local or a remote file. *url* must be entered using the following format:

- **[file:]{ /flash | /pcmcia1 | /hd }[/***directory* **] /***file_name*
- **tftp://{** *host***[** *:port#* **] } [/***directory* **] /***file_name*
- **[ftp: | sftp:] / / [** *username* **[** *:password* **] @] {** *host* **} [** *:port#* **] [/***directory* **] /***file_name*

Important: Use of the SMC hard drive is not supported in this release.

directory is the directory name.
filename is the actual file of interest.
username is the user to be authenticated.
password is the password to use for authentication.
host is the IP address or host name of the server.
port# is the logical port number that the communication protocol is to use.

passive

Indicates the file copy is to use the passive mode.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Important: Use of the **-noconfirm** option allows the over writing of an existing file if the destination file already exists.

Usage

Copy configuration files, log files, etc.,to provide backups of data through the network.

Example

The following copies files from the local */flash/pub* directory to remote node *remoteABC*'s */pcmcia2/pub* directory with and without confirmation respectively.

```
copy http://remoteABC/pub/june.cfg /flash/pub/june.cfg

copy tftp://remoteABC/pub/june.cfg /pcmcia2/pub/june.cfg -noconfirm
```

The following copies files from remote node *remoteABC* to remote node *remote123*.

```
copy ftp://remoteABC/pub/may.cfg ftp://remote123/pub/may.cfg
```

crash copy

Copies individual crash files (one-at-a-time) and optionally the core dump file from the stored crash records on the chassis to a user-specified location.

Product

All

Privilege

Security Administrator, Administrator

Syntax

crash copy number *number* **url** *to_url* **[core]**

number *number*

Specifies the identification number of the crash record as an integer representing a valid record number from 1 through 120. To determine the numeric identity of a specific crash file, use the **show crash list** command in Exec mode.

url *to_url*

Specifies the destination of the copy. *url* may refer to a local or a remote file and must be entered using the following format:

- **[file:] { /flash | /pcmcia1 | /hd } [/***directory* **] /**
- **tftp://{** *host***[** *:port#* **] } [/***directory* **] /**
- **[ftp: | sftp:]//[** *username* **[** *:password* **] @] {** *host* **} [** *:port#* **] [/***directory* **] /**

Important: Use of the SMC hard drive is not supported in this release.

directory: the name of the target directory.
username: the username to be authenticated to provide access to targeted server.
password: the username's password to be authenticated.
host: the IP address or host name of the targeted server.
port#: the number of the target server's logical port used for the selected communication protocol.

Important: Do **not** specify a target filename as this will prevent the file from writing to the target server. The system generates and provides a timestamp-based filename that appears at the destination when the **copy** command completes.

core

Copies the core dump to the targeted storage server. The core cannot be copied alone; it must be part of a **crash copy** action included when copying a crash file.

Usage

Copy crash files of core dump to another location for backup or analysis.

Example

The following uses FTP to copy stored record number *5* and the core dump from the crash record list to a targeted remote node directory called *crasharchive* through port *22* of the targeted server *remoteABC* with access through user *homeboy* whose password is *secret.7.word*.

```
crash copy number 5 url ftp://homeboy:secret.7.word@
remoteABC:22/crasharchive/ core
```

crypto-group

Allows the manual switchover of redundant IPSec tunnels belonging to a specific crypto group.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

crypto-group name *group_name* **activate { primary | secondary }**

---

crypto-group name *group_name*

Specifies the name of an existing crypto group with which the tunnels to be switched are associated.

---

activate { primary | secondary }

Allows you to specify which tunnel to activate:

- **primary**: Switches traffic to the primary tunnel in the group.
- **secondary**: Switches traffic to the secondary tunnel in the group.

Usage

This command is used in conjunction with the Redundant IPSec Tunnel Fail-over feature.
Use this command to manually switch traffic to a specific tunnel in a crypto group if the automatic switchover options have been disabled. Refer to the **switchover** command in the Crypto Group configuration mode for more information.

Example

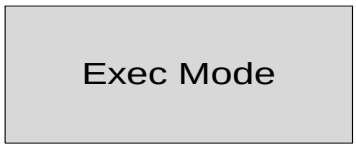
The following command manually switches user traffic to the secondary tunnel in the crypto group called *group1*:

```
crypto-group group1 activate secondary
```

Chapter 112
Exec Mode Commands (D-S)

This chapter contains the commands in the Exec Mode from **debug** to **system**.

The Exec Mode is the initial entry point into the command line interface system. Exec mode commands are useful in troubleshooting and basic system monitoring.



debug

The following commands send information to the logging facility for review:

- debug bfd
- debug ip
- debug ip bgp
- debug ip ospf all
- debug ip ospf event
- debug ip ospf ism
- debug ip ospf lsa
- debug ip ospf nsm
- debug ip ospf packet
- debug ip ospf route
- debug ip ospf router
- debug ipv6 ospf all (OSPFv3)
- debug ipv6 ospf event (OSPFv3)
- debug ipv6 ospf ifsm (OSPFv3)
- debug ipv6 ospf lsa (OSPFv3)
- debug ipv6 ospf nsm (OSPFv3)
- debug ipv6 ospf packet (OSPFv3)
- debug ipv6 ospf route (OSPFv3)

debug bfd

Enables or disables the debug options for Bidirectional Forwarding Detection BFD) debugging. If logging is enabled, results are sent to the logging system.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

`[ no ] debug bfd { all | events ipc-error | ipc-events | nsm | packet | session }`

`no`

Indicates the IP debugging is to be disabled for the IP interfaces/function specified.

`bfd | interface` *`name`* **`| route`**

Specifies which IP interfaces/function to debug.
`all`: enables debug for all BFD items.
`events`: enables debug for BFD events.
`ipc-error`: enables debug for BFD Inter-process communication (IPC) errors.
`ipc-events`: enables debug for BFD Inter-process communication (IPC) events.
`nsm`: enables debug for BFD Network Service Manager messages.
`packet`: enables debug for BFD packets.
`session`: enables debug for BFD sessions.

Usage

The debug bfd command is valuable when troubleshooting network problems with BFD-enabled BGP routers. The debugging is stopped by using the **`no`** keyword.

Caution: Issuing this command could negatively impact system performance depending on system configuration and/or loading.

Example

The following commands enable/disable debugging for BFD.

```
debug bfdno debug bfd
```

debug ip

Enables or disables the debug options for IP debugging. If logging is enabled, results are sent to the logging system.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip { arp | interface | route }
```

no

Indicates the IP debugging is to be disabled for the IP interfaces/function specified.

arp | interface *name* **| route**

Specifies which IP interfaces/function to debug.
arp: indicates debug is to be enabled for the address resolution protocol.
interface: indicates debug is to be enabled for the IP interfaces.
route: indicates debug is to be enabled for the route selection and updates.

Usage

The debug IP command is valuable when troubleshooting network problems between nodes. The debugging is stopped by using the **no** keyword.

Caution: Issuing this command could negatively impact system performance depending on system configuration and/or loading.

Example

The following commands enable/disable debugging for ARP.

```
debug ip arpno debug ip arp
```

The following enables/disables debugging for IP interfaces.

```
debug ip interface
```

```
no debug ip interface
```

The following enables/disables debugging for routing.

```
debug ip routeno debug ip route
```

debug ip bgp

Enables or disables BGP (Border Gateway Protocol) debug flags. If logging is enabled, results are sent to the logging system.

Product

HA

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip bgp { all | event | filters | fsm | keepalives | updates { inbound | outbound } }
```

no

Disables the specified BGP debug flags.

all

Enables all BGP debug flags.

event

Enables debugging of all BGP protocol events.

filters

Enables debugging of all BGP filters.

fsm

Enables debugging of BGP Finite State Machine

keepalives

Enables debugging of all BGP keepalives.

updates {inbound | outbound}

Enables debugging of BGP updates.
inbound: Debug all BGP inbound updates.
outbound: Debug all BGP outbound updates.

Usage

Use this command to enable or disable BGP debug flags.

Example

The following command disables all BGP debug flags enabled by any of the **debug ip bgp** commands:

```
no debug ip bgp all
```

The following command enables all BGP debug flags:

```
debug ip bgp all
```

debug ip ospf all

Enables or disables all OSPF (Open Shortest Path First) debug flags. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

`[ no ] debug ip ospf all`

`no`

Disable all OSPF debug flags.

Usage

Use this command to enable or disable all OSPF debug flags.

Example

The following command disables all OPSF debug flags enabled by any of the **`debug ip ospf`** commands:

```
no debug ip ospf all
```

The following command enables all OSPF debug flags:

```
debug ip ospf all
```

debug ip ospf event

Enables or disables debugging of OSPF protocol events. If logging is enabled, results are sent to the logging system. If no keywords are specified, all events are enabled for debugging.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip ospf event [ abr | asbr | vl | lsa | os | router ]
```

no

Disables debugging the specified OSPF event. If no keywords are specified, all events are disabled.

abr

Enables debugging of Area Border Router (ABR) events.

asbr

Enables debugging of Autonomous System Boundary Router (ASBR) events.

vl

Enables debugging of Virtual Link (VL) events.

lsa

Enables debugging of link state advertisement (LSA) events.

os

Enables debugging of operating system (OS) events.

router

Enables debugging of router events.

Usage

Use this command to output debug information for OSPF events.

Example

To enable all event debug information, enter the following command;

```
debug ip ospf event
```

To disable all event debug information, enter the following command;

```
no debug ip ospf event
```

debug ip ospf ism

Enables or disables OSPF Interface State Machine (ISM) troubleshooting, based on ISM information type. If no keywords are specified all ISM information types are enabled. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip ospf ism [ events | status | timers ]
```

no

Disables debugging the specified ISM information. If no keywords are specified, all information is disabled.

events

Enables debugging ISM event information.

status

Enables debugging ISM status information.

timers

Enables debugging ISM timer information.

Usage

Use this command to output ISM debug information.

Example

To enable all ISM debug information, enter the following command;

```
debug ip ospf ism
```

To disable all ISM debug information, enter the following command;

```
no debug ip ospf ism
```

debug ip ospf lsa

Enables or disables troubleshooting on OSPF Link State Advertisements (LSAs), based on the specific LSA option. If no keywords are specified, all options are enabled. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip ospf lsa [ flooding | generate | install | refresh | maxage | refresh ]
```

no

Disables the specified LSA debug information. If no keyword is specified, all LSA debug information is disabled.

flooding

Enables LSA flooding information.

generate

Enables LSA generation information.

install

Enables LSA install information.

maxage

Enables LSA maximum age information in seconds. The maximum age is 3600 seconds.

refresh

Enables LSA refresh information.

Usage

Use this command to output debug information for LSAs.

Example

To enable all LSA debug information, enter the following command;

```
debug ip ospf lsa
```

To disable all LSA debug information, enter the following command;

```
no debug ip ospf lsa
```

debug ip ospf nsm

Enables or disables troubleshooting OSPF Neighbor State Machines (NSMs), based on the specific NSM information type. If no keyword is specified, all NSM information types are enabled. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip ospf nsm [ status | events | timers ]
```

no

Disables the debugging the specified NSM information type. If no keyword is specified, all information types are disabled.

events

Enables debugging NSM event information.

status

Enables debugging NSM status information.

timers

Enables debugging NSM timer information.

Usage

Use this command to output debug information for OSPF NSMs

Example

To enable all NSM debug information, enter the following command;

```
debug ip ospf nsm
```

To disable all NSM debug information, enter the following command;

```
no debug ip ospf nsm
```

debug ip ospf packet

Enables or disables troubleshooting of specific OSPF packet information. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip ospf packet { all | dd | hello | ls-ack | ls-request | ls-update } [ send
| recv ] [ detail ]
```

no

Disable debugging of the specified packet information.

all

Enables debugging all OSPF packet information.

dd

Enables debugging database descriptions.

hello

Enables debugging hello packets.

ls-ack

Enables debugging link state acknowledgements.

ls-request

Enables debugging link state requests.

ls-update

Enables debugging link state updates.

send

Enables debugging only on sent packets.

recv

Enables debugging only on received packets.

detail

Enables detailed information in the debug output.

Usage

Use this command to output specific OSPF packet information.

Example

To enable all packet debug information, enter the following command;

```
debug ip ospf packet all
```

To disable all route debug information, enter the following command;

```
no debug ip ospf packet all
```

debug ip ospf route

Sets the route calculation method to use in debugging OSPF routes. If no route calculation method is specified, all methods are enabled. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip ospf route [ ase | ia | install | spf ]
```

no

Disables debugging of route information. If no keyword is specified all information types are disabled.

ase

Enables debugging information on autonomous system external (ASE) route calculations.

ia

Enables debugging information on Inter-Area route calculations.

install

Enables debugging information on route installation.

spf

Enables debugging information on Shortest Path First (SPF) route calculations.

Usage

Use this command to output debug information for OSPF routes.

Example

To enable all route debug information, enter the following command;

```
debug ip ospf route
```

To disable all route debug information, enter the following command;

```
no debug ip ospf route
```

debug ip ospf router

Sets the debug option for OSPF router information. If no keyword is specified, all router information is enabled. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip ospf router [ interface | redistribute ]
```

no

Disables the specified router debug information. If no keyword is specified, all router information is disabled.

interface

Enables router interface information.

redistribute

Enables router redistribute information.

Usage

Use this command to output debug information for the OSPF router.

Example

To enable all router debug information, enter the following command;

```
debug ip ospf router
```

To disable all router debug information, enter the following command;

```
no debug ip ospf router
```

debug ipv6 ospf all

Enables or disables all OSPFv3 (Open Shortest Path First Version 3) debug flags. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ipv6 ospf all
```

no

Disable all OSPFv3 debug flags.

Usage

Use this command to enable or disable all OSPFv3 debug flags.

Example

The following command disables all OPSFv3 debug flags enabled by any of the **debug ip ospf** commands:

```
no debug ipv6 ospf all
```

The following command enables all OSPFv3 debug flags:

```
debug ipv6 ospf all
```

debug ipv6 ospf event

Enables or disables debugging of OSPFv3 protocol events. If logging is enabled, results are sent to the logging system. If no keywords are specified, all events are enabled for debugging.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ipv6 ospf event [ abr | asbr | os | router ]
```

no

Disables debugging the specified OSPFv3 event. If no keywords are specified, all events are disabled.

abr

Enables debugging of Area Border Router (ABR) events.

asbr

Enables debugging of Autonomous System BOundary Router (ASBR) events.

os

Enables debugging of operating system (OS) events.

router

Enables debugging of router events.

Usage

Use this command to output debug information for OSPFv3 events.

Example

To enable all event debug information, enter the following command;

```
debug ipv6 ospf event
```

To disable all event debug information, enter the following command;

```
no debug ipv6 ospf event
```

debug ipv6 ospf ifsm

Enables or disables OSPFv3 Interface State Machine (ISM) troubleshooting, based on ISM information type. If no keywords are specified all ISM information types are enabled. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ipv6 ospf ism [ events | status | timers ]
```

no

Disables debugging the specified ISM information. If no keywords are specified, all information is disabled.

events

Enables debugging ISM event information.

status

Enables debugging ISM status information.

timers

Enables debugging ISM timer information.

Usage

Use this command to output ISM debug information.

Example

To enable all ISM debug information, enter the following command;

```
debug ipv6 ospf ism
```

To disable all ISM debug information, enter the following command;

```
no debug ipv6 ospf ism
```

debug ipv6 ospf lsa

Enables or disables troubleshooting on OSPFv3 Link State Advertisements (LSAs), based on the specific LSA option. If no keywords are specified, all options are enabled. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ip ospf lsa [ flooding | generate | install | maxage | refresh ]
```

no

Disables the specified LSA debug information. If no keyword is specified, all LSA debug information is disabled.

flooding

Enables LSA flooding information.

generate

Enables LSA generation information.

install

Enables LSA install information.

maxage

Enables LSA maximum age information in seconds. The maximum age is 3600 seconds.

refresh

Enables LSA refresh information.

Usage

Use this command to output debug information for LSAs.

Example

To enable all LSA debug information, enter the following command;

```
debug ipv6 ospf lsa
```

To disable all LSA debug information, enter the following command;

```
no debug ipv6 ospf lsa
```

debug ipv6 ospf nsm

Enables or disables troubleshooting OSPFv3 Neighbor State Machines (NSMs), based on the specific NSM information type. If no keyword is specified, all NSM information types are enabled. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ipv6 ospf nsm [ interface | redistribute ]
```

no

Disables the debugging the specified NSM information type. If no keyword is specified, all information types are disabled.

interface

Enables debugging NSM on this interface.

redistribute

Enables debugging NSM redistribution information.

Usage

Use this command to output debug information for OSPFv3 NSMs

Example

To enable all NSM debug information, enter the following command;

```
debug ipv6 ospf nsm
```

To disable all NSM debug information, enter the following command;

```
no debug ipv6 ospf nsm
```

debug ipv6 ospf packet

Enables or disables troubleshooting of specific OSPFv3 packet information. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ipv6 ospf packet { dd | hello | ls-ack | ls-request | ls-update } [ recv | send ] [ detail ]
```

no

Disable debugging of the specified packet information.

dd

Enables debugging database descriptions.

hello

Enables debugging hello packets.

ls-ack

Enables debugging link state acknowledgements.

ls-request

Enables debugging link state requests.

ls-update

Enables debugging link state updates.

recv

Enables debugging only on received packets.

send

Enables debugging only on sent packets.

detail

Enables detailed information in the debug output.

Usage

Use this command to output specific OSPFv3 packet information.

Example

To enable all packet debug information, enter the following command;

```
debug ipv6 ospf packet all
```

To disable all route debug information, enter the following command;

```
no debug ipv6 ospf packet all
```

debug ipv6 ospf route

Sets the route calculation method to use in debugging OSPFv3 routes. If no route calculation method is specified, all methods are enabled. If logging is enabled, results are sent to the logging system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] debug ipv6 ospf route [ ase | ia | install | spf ]
```

no

Disables debugging of route information. If no keyword is specified all information types are disabled.

ase

Enables debugging information on autonomous system external (ASE) route calculations.

ia

Enables debugging information on Inter-Area route calculations.

install

Enables debugging information on route installation.

spf

Enables debugging information on Shortest Path First (SPF) route calculations.

Usage

Use this command to output debug information for OSPF routes.

Example

To enable all route debug information, enter the following command;

```
debug ipv6 ospf route
```

To disable all route debug information, enter the following command;

```
no debug ipv6 ospf route
```

default terminal

Restores the system default value for the terminal options.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
default terminal { length | width }
```

length | width

length: Resets the terminal length to the system default.
width: Resets the system default terminal width.

Usage

Restore the default terminal settings when the current paging and display wraps inappropriately or pages to soon.

Example

The following sets the default length then width in two commands.

```
default terminal length

default terminal width
```

delete

Removes the specified file(s) permanently from the local.

Product

All

Privilege

Security Administrator, Administrator

Syntax

delete *filepath* **[-noconfirm]**

filepath

Specifies the location of the file to rename. The path must be formatted as follows:
[**file:**]{ **/flash** | **/pcmcia1** | **/hd** }[**/***directory*]**/***file_name*

Important: Use of the SMC hard drive is not supported in this release.

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name
filename is the actual file of interest

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Important: Use of the **-noconfirm** option should be done with extra care to ensure the file is specified accurately as there is no method of recovering a file that has been deleted.

Usage

Deleting files is a maintenance activity which may be part of periodic routine procedures to reduce system space utilization.

Example

The following removes files from the local */flash/pub* directory.

```
delete /flash/pub/june03.cfg
```

dhcp force

Tests the lease-renewal for DHCP-assigned IP addresses for a particular subscriber.

Product

GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

dhcp force lease-renewal { **callid** *id* | **imsi** *imsi* [**nsapi** *nsapi*] | **msid** *msid* }

callid *id*

Clears the call ID specified as a 4-byte hexadecimal number.

imsi *msid*

Disconnects the subscriber with the specified msid. The IMSI (International Mobile Subscriber Identity) ID is a 50-bit field which identifies the subscriber's home country and carrier. Wildcard characters $ and * are allowed. The * wildcard matches multiple characters and the $ wildcard matches a single character. If you do not want the wildcard characters interpreted as a wildcard enclose them in single quotes (‘). For example; ‘$’.

nsapi *nsapi*

Specifies a Network Service Access Point Identifier (NSAPI) an integer from 5 to 15.

msid *id*

Disconnects the mobile user identified by *ms_id*. *ms_id* must be from 7 to 16 digits specified as an IMSI, MIN, or RMI. Wildcard characters $ and * are allowed. The * wildcard matches multiple characters and the $ wildcard matches a single character. If you do not want the wildcard characters interpreted as a wildcard enclose them in single quotes (‘). For example; ‘$’.

Usage

Use this command tests a forced IP address lease renewal for a specific subscriber.

Example

The following command tests DHCP lease renewal for a subscriber with an MSID of *1234567*:

```
dhcp force lease-renewal msid 1234567
```

dhcp test

Tests DHCP (Dynamic Host Configuration Protocol) functions for a particular DHCP service.

Product

GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

dhcp test dhcp-service *svc_name* [**all** | **server** *ip_address*]

dhcp-service *svc_name*

Specifies the name of the DHCP service as an alphanumeric string of 1 through 63 characters that is case sensitive.

all

Tests DHCP functionality for all servers.

server *ip_address*

Tests DHCP functionality for the server specified by an IP address entered using IPv4 dotted-decimal notation.

Usage

Once DHCP functionality is configured on the system, this command can be used to verify that it is configured properly and that it can successfully communicate with the DHCP server.
Executing this command causes the system to request and allocate an IP address and then release it.
If a specific DHCP server is not specified, then each server configured in the service is tested.

Example

The following command tests the systems ability to get an IP address from all servers a DHCP service called *DHCP-Gi* is configured to communicate with:

```
dhcp test dhcp-service DHCP-Gi all
```

diameter disable endpoint

Disables a Diameter endpoint without removing the peer's configuration.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter disable endpoint *endpoint_name* **peer** *peer_id*

endpoint *endpoint_name*

Specifies the endpoint in which the peer is configured as an alphanumeric string of 1 through 63 characters.

peer *peer_id*

Specifies the Diameter peer host name to be disabled as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to administratively disable a Diameter peer without removing the peer configuration. This command will tear down all connections on the specified peer (by sending a DPR if the configuration demands the same at peer level configuration). The peer will remain in disabled state until it is enabled again. Also see the **diameter enable endpoint** command.

Example

This command disables the Diameter peer *peer12*:

```
diameter disable endpoint endpoint1 peer peer12
```

diameter enable endpoint

Enables a Diameter endpoint that is disabled.

Product

All

Privilege

Security Administrator, Administrator

Syntax

diameter enable endpoint *endpoint_name* **peer** *peer_id*

endpoint *endpoint_name*

Specifies the endpoint in which the peer is configured as an alphanumeric string of 1 through 63 characters.

peer *peer_id*

Specifies the Diameter peer host name to be enabled as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to administratively enable a Diameter peer. Also see the **diameter disable endpoint** command.

Example

This command enables the Diameter peer *peer12*:

```
diameter enable endpoint endpoint1 peer peer12
```

diameter reset connection

Resets individual TCP/SCTP connections for a specified Diameter endpoint.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

diameter reset connection { endpoint *endpoint_name* **peer** *peer_id* **}**

endpoint *endpoint_name*

Resets connection to the endpoint specified as an alphanumeric string of 1 through 63 characters.

peer *peer_id*

Resets connection to the Diameter peer host name specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to reset the TCP/SCTP connections for the specified endpoint/peer. With this command, the connection will be closed temporarily after DPR/DPA. If there is any traffic to be sent to the particular peer, then the connection will be re-established.
This command overrides the endpoint configured in any other configuration mode.
This command is applicable only when the specified peer is enabled.

Example

This command resets connection to the endpoint named *test123*:

```
diameter reset connection endpoint test123
```

diameter reset route failure

Resets the failed route status of a Diameter destination-host combination via peer to AVAILABLE status.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

diameter reset route failure [endpoint *endpoint_name* **] [host** *host_name* **] [peer** *peer_id* **]**

endpoint *endpoint_name*

Resets paths to the endpoint specified as an alphanumeric string of 1 through 63 characters.

host *host_name*

Resets the FAILED status of all Diameter destination-host combination routes via peer for every Diameter client within the chassis having a specific host name to AVAILABLE.
Specifies the Diameter host name as an alphanumeric string of 1 through 63 characters.

peer *peer_id*

Resets the FAILED status of all Diameter destination-host combination routes via a peer having specific peer-Id for every Diameter client within the chassis to AVAILABLE.
Specifies the Diameter peer host name as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to reset the FAILED status of all Diameter destination-host combination routes via peer for every Diameter client within the chassis to AVAILABLE status.
This command also resets the failure counts used to determine the AVAILABLE/FAILED status of a destination-host combination.
When executed from local context, this command matches all contexts. If an optional keyword is not supplied, a wildcard is used for the value.
The status of every matching combination of destination-host via peer for every matching Diameter client within the chassis will be reset to AVAILABLE. The failure counts that are used to determine AVAILABLE/FAILED status will also be reset.
Also see the **route-entry** and **route-failure** commands in the *Diameter Endpoint Configuration Mode Commands* chapter.
Default value: N/A

Example

The following command resets the FAILED status of all Diameter destination-host combination routes via peer for every Diameter client within the chassis for specified endpoint name to AVAILABLE.

```
diameter reset route failure endpoint endpoint123
```

directory

Lists the files in a specified location.

Product

All

Privilege

Security Administrator, Administrator

Syntax

directory *filepath* **[-size] [-reverse] [-time]**

filepath

Specifies the directory path to list the contained files using the following format:
[**file:**]{ **/flash** | **/pcmcia1** | **/hd** }[**/***directory*]**/***file_name*

Important: Use of the SMC hard drive is not supported in this release.

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name
filename is the actual file of interest

-size

Indicates the size of each file should be displayed in the output.

-reverse

Indicates the order of files listed should be in descending order (z-aZ-A9-0). Default is to sort in ascending order (0-9A-Za-z).

-time

Indicates the last modification timestamp of each file should be displayed in the output.

Usage

Lists such things as log and crash files from multiple nodes within the network.
The optional arguments may be specified individually or in any combination.

Example

The following command will list the files in the local */flash/pub* directory sorted in reverse order.

```
directory /flash/pub -reverse
```

disable radius

Prevents the system from making requests of a selected RADIUS server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

disable radius { [charging] [accounting] server *ipv4/ipv6_address* **[group** *group_name* **| port** *port_number* **+] }**

[charging] [accounting]

Specifies the type of RADIUS server to disable.

- **accounting**: Specifies accounting servers
- **charging**: Specifies charging servers
- **charging accounting**: Specifies charging accounting servers

server *ipv4/ipv6_address*

Specifies the RADIUS server by IP address entered using IPv4 dotted-decimal or IPv6 colon-separated notation.

port *port_number*

Specifies the port number of the RADIUS server being disabled an integer from 0 through 65535. Default: 1812 (authentication) 1813 (accounting)

group *group_name*

Specifies the RADIUS group to which the server belongs as an alphanumeric string of 1 through 63 characters. Use this option in the event that the RADIUS server belongs to multiple groups and you only want to disable the server within the specific group. Default: **default**

Usage

Use this command to gracefully stop the system from making requests of a specific RADIUS server.

Example

The following command disables a RADIUS accounting server with an IP address of *10.2.3.4*, the default accounting server port number, and that resides in the *Group5* server group:

```
disable radius accounting server 10.2.3.4 group Group5
```

dns-client

Performs DNS (Domain Name System) query on the basis of specified DNS client name, DNS query domain name, and type of query criteria.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

dns-client *dns_client_name* **[query-type { A | AAAA | NAPTR | SRV }] query-name** *query_domain_name*

dns-client *dns_client_name*

Specifies the name of the DNS client whose cache and/or statistics are to be queried. It must be an existing DNS client expressed as an alphanumeric string of 1 through 64 characters.

query-type { A | NAPTR | SRV }]

Specifies that the type of query to perform for the defined DNS client is to be displayed.

- **A**: Filters DNS results based on domain IPv4 address records (A records). This is the default query type.
- **AAAA**: Filters DNS results based on domain IPv6 address records (AAAA records).
- **NAPTR**: Filters DNS results based on Naming Authority Pointer records (NAPTR).
- **SRV**: Filters DNS results based on service host records (SRV records).

query-name *query_domain_name*

Filters the DNS results based on the query domain name expressed as an alphanumeric string of 1 trough 255 characters.
query_domain_name is the domain name used to perform the DNS query and is different from the actual domain name which is resolved. For example, to resolve the SIP server for *service.com*, the query name is *_sip._udp.service.com* and the query type is **SRV**.

Usage

Use this command to perform DNS query on the basis of DNS Client name and filters the query results based on query type and query name. This command also populates the result into DNS Cache. This command used the current context to DNS request.

Example

The following command displays statistics for a DNS client named *test_dns* with query type for IP address as *A* and query name as *domain1.com*:

```
dns-client test_dns query-type A query-name domain1.com
```

enable radius

Enables the system to start making requests of a specific RADIUS server.

Product

All

Privilege

Security Administrator, Administrator

Syntax

enable radius { [charging] [accounting] server *ipv4/ipv6_address* **[group** *group_name* **| port** *port_number* **+] }**

[charging] [accounting]

Specifies the type of RADIUS server to enable.

- **accounting**: Specifies accounting servers
- **charging**: Specifies charging servers
- **charging accounting**: Specifies charging accounting servers

server *ipv4/ipv6_address*

Specifies the RADIUS server by an IP address entered using IPv4 dotted-decimal or IPv6 colon-separated notation.

port *port_number*

Specifies the port number of the RADIUS server being enabled as an integer from 0 through 65535. Default: 1812 (authentication) 1813 (accounting)

group *group_name*

Specifies the RADIUS group to which the server belongs as an alphanumeric string of 1 through 63 characters. Use this option in the event that the RADIUS server belongs to multiple groups and you only want to disable the server within the specific group. Default: **default**

Usage

Use this command to allow the system to start making requests of a specific RADIUS server.

Example

The following command enables a RADIUS accounting server with the IP address *10.2.3.4*, the default accounting server port number, and in the *Group5* server group:

```
enable radius accounting server 10.2.3.4 group Group5
```

exit

Terminates the current CLI session.

Product

All

Privilege

Any

Syntax

```
exit
```

Usage

Use this command to terminate the current CLI session.

filesystem

Use this command to check, format or repair the filesystem on internal and external storage devices.

Product

All

Privilege

Security Administrator, Administrator

Syntax

filesystem { check | format | repair } { /flash | /pcmcia1 | /hd-raid } [card *card_num* **]**

filesystem { check | format | repair } { /flash | /usb1 | /hd-raid } [card *card_num* **]**

Usage

Check, format, or repair all directories and files from on an internal or external storage device and re-establish the file system.

Example

The following command formats the PCMCIA card located in slot 1 on the SMC:

```
filesystem format /pcmcia1
```

filesystem synchronize

Use this command to manage the Switch Processor Cards (SPCs) or System Management Cards (SMCs) and their active/standby status, and to synchronize the filesystem between the active device and the standby device.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

filesystem synchronize [/flash | /pcmcia1 | all] [checkonly] [from *card_num* **| to** *card_num* **] [-noconfirm]**

Usage

Synchronize the file system between the active device and the standby device.

gtpc test echo

Tests the ability of a GGSN service to exchange GTP-C echo request messages with the specified SGSN(s).

Product

GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

gtpc test echo src-address *gn_address* { **all** | **sgsn-address** *ip_address* }

src-address *gn_address*

Specifies the IP address of a Gn interface configured on the system in IPv4 dotted-decimal notation.

Important: The IP address of the system's Gn interface must be bound to a configured GGSN service prior to executing this command.

all

Specifies that GTP-C echo requests will be sent to all SGSNs that currently have sessions with the GGSN service.

sgsn-address *ip_address*

Specifies that GTP-C echo requests will be sent to a SGSN specified by an IP address in IPv4 dotted-decimal notation.

Usage

This command tests the GGSN's ability to exchange GPRS Tunneling Protocol control plane (GTP-C) packets with the specified SGSNs. This command is useful for troubleshooting and/or monitoring. This command must be executed from within the context in which the GGSN service is configured. Refer also to the **gtpu test** command.

Example

The following command issues GTP-C echo packets from a GGSN service bound to address *192.168.157.32* to an SGSN with an address of *192.168.157.2*:

```
gtpc test echo src-address 192.168.157.32 sgsn-address 192.168.157.2
```

gtpp interim now

Check points current GTPP accounting messages and identifies which types of interim CDRs are to be generated and sent to the external charging/storage servers (for example, a CFG or a GSS). The impact of this command is immediate.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

gtpp interim now [**active-charging egcdr** | **apn** *apn_name* | **callid** *call_id* | **cdr-types** { **gcdr** | **mcdr** | **scdr** } | **dhcp-server** *ip_address* | **gprs-service** *svc_name*| **ggsn-address** *ggsn_ip_addr* | **ggsn-service** *svc_name* | **imsi** *imsi* [**ip-address** *sub_address* [**username** *name*] **now** | **nsapi** *nsapi* [**ip-address** *sub-address* [**username** *name*] | **username** *name*]] | **ip-address** *sub_address* [**username** *name*] | **ip-pool** *pool_name* | **mcc** *mcc_number* **mnc** *mnc_number* | **msisdn** *msisdn_num* | **sgsn-address** *ip_address* | **sgsn-service** *svc_name* | **username** *name*] +

active-charging

This feature is specific to the GGSN and is documented separately. .

apn *apn_name*

Initiates GTPP interim accounting for all PDP contexts accessing the APN specified as an alphanumeric string of 1 through 62 characters that is case sensitive.

callid *call_id*

Identifies a specific call id as an 8-digit hexadecimal number.

cdr-types { mcdr | scdr }

Specifies the CDR types to be generated by the SGSN:
gcdr - Instructs the GGSN to only generate G-CDRs.
mcdr - Instructs the SGSN to only generate M-CDRs
scdr - Instructs the SGSN to only generate S-CDRs.
This keyword is specific to the SGSN.

dhcp-server *ip_address*

Identifies the DHCP server where the IP address (defined with the **ip address** keyword) was allocated by the IP address of the DHCP server entered using IPv4 dotted-decimal notation.

ggsn-address *ggsn_ip_addr*

Specifies the IP address of the interface to the GGSN using IPv4 dotted-decimal notation. This keyword is specific to the GGSN.

ggsn-service *svc_name*

Initiates GTPP interim accounting for all PDP contexts currently being facilitated by the GGSN service specified as an alphanumeric string of 1 through 63 characters that is case sensitive. This keyword is specific to the GGSN.

gprs-service *svc_name*

Initiates GTPP interim accounting for all PDP contexts currently being facilitated by an existing GPRS service specified as an alphanumeric string of 1 through 63 characters that is case sensitive. This keyword is specific to the SGSN.

imsi *imsi* **[ip-address** *sub_address* **[username** *name* **] | nsapi** *nsapi* **[ip-address** *sub-address* **[username** *name* **] | username** *name* **]]**

Initiates GTPP interim accounting for a specific International Mobile Subscriber Identity (IMSI) number. The request could be further filtered using any of the following keywords:

- **ip-address**: Interim accounting will be performed for the IP address specified by *sub_address*. The command can be further filtered by specifying a specific username with that address.
- **nsapi**: Interim accounting will be performed for a Network Service Access Point Identifier (NSAPI) specified as an integer from 5 to 15. The command can be further filtered by specifying a specific ip address and/or a username with that address, or just a specific username.

ip-address *sub_address* **[username** *name* **]**

Initiates GTPP interim accounting for the IP address of the subscriber specified in IPv4 dotted-decimal notation.
The command can be further filtered by specifying a username with that address. The name is the subscriber's name and can be a sequence of characters and/or wildcard characters ('$' and '*') from 1 to 127 characters. The * wildcard matches multiple characters and the $ wildcard matches a single character. If you do not want the wildcard characters interpreted as wildcard enclose them in single quotes (‘). For example; ‘$’.

ip-pool *pool_name*

Initiates GTPP interim accounting for all PDP contexts that were allocated IP addresses from an existing pool specified as an alphanumeric string of 1 through 31 characters that is case sensitive. This keyword is applicable to the GGSN only.

mcc *mcc_number* **mnc** *mnc_number*

mcc_number: Specifies the mobile country code (MCC) portion of the PLMN identifier and can be configured to any 3-digit integer value between 100 and 999.
mnc_number: Specifies the mobile network code (MNC) portion of the PLMN identifier and can be configured to any 2- or 3-digit integer between 00 and 999.

msisdn *msisdn_num*

Configures the SGSN to include the Mobile Subscribers Integrated Services Digital Network identifier in generated CDRs (M-CDRs and/or the S-CDRs). This keyword is applicable for SGSN only.
msisdn_number must be followed by a valid MSISDN number, consisting of 1 to 15 digits.

sgsn-address *ip_address*

Initiates GTPP interim accounting for all PDP contexts currently being facilitated by the SGSN specified by an IP address in IPv4 dotted-decimal notation. This keyword is specific to the GGSN.

sgsn-service *svc_name*

Initiates GTPP interim accounting for all PDP contexts currently being facilitated by an existing SGSN service specified an alphanumeric string of 1 through 63 characters that is case sensitive. This keyword is specific to the SGSN.

username *name*

Initiates GTPP interim accounting for all PDP contexts for the subscriber name specified as an alphanumeric string of 1 through 127 characters that is case sensitive.

+

More than one of the above keywords can be entered within a single command.

Usage

This command causes GTPP accounting CDRs to immediately be generated for all active sessions that are in the current context. If executed within the local context, CDRs will be generated for all active sessions regardless of context.
The sending of the CDRs is paced so as not to overload the accounting server.

Example

The following command causes CDRs to immediately be generated:

```
gtpp interim now
```

gtpp interim now active-charging egcdr

Check points current GTPP accounting messages for active charging immediately.

Product

GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
gtpp interim now active-charging egcdr [ callid call_id | imsi imsi | msid msid |
rulebase rbase_name | session-id sess_id | username name ]
```

callid *call_id*

Initiates GTPP interim accounting for a session for the call ID specified as an 8-digit hexadecimal number.

imsi *imsi*

Initiates GTPP interim accounting for a International Mobile Subscriber Identity (IMSI) number. specified as a sequence of hexadecimal digits and wildcard characters - $ matches a single character and * matches multiple characters

msid *msid*

Initiates GTPP interim accounting for a Mobile Station Identifier (MSID) number specified as a sequence of up to 24 digits and wildcard characters - $ matches a single character and * matches multiple characters

rulebase *rbase_name*

Initiates GTPP interim accounting for sessions that use the named active charging rulebase specified as an alphanumeric string of 1 through 24 characters.

session-id *sess_id*

Initiates GTPP interim accounting for a current active charging session.

username *name*

Initiates GTPP interim accounting for all PDP contexts for the subscriber name specified as an alphanumeric string of 1 through 127 characters that is case sensitive.

Usage

This command causes GTPP accounting eG-CDRs to immediately be generated for active charging sessions that meet the specified criteria.
The sending of the CDRs is paced so as not to overload the accounting server.

Example

The following command causes eG-CDRs to immediately be generated for active charging sessions using the rulebase named rulbase1:

```
gtpp interim now active-charging egcdr rulebase rulebase1
```

gtpp storage-server commit

Causes the GTPP storage server to archive all buffered packets.

Product

GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

```
gtpp storage-server commit now [ group name group_name ]
```

group name *group_name*

Commits Storage Server for an existing group name expressed as an alphanumeric string of 1 through 63 characters.

Usage

This command sends a request to the GTPP Storage Server to archive all buffered packets. It also deletes all CDRs that have been acknowledged by the charging gateway function (CGF). The deleted CDRs are saved in a separate file.

Note that this command must be executed from within the context in which the GTPP Storage Server is configured.

Refer to the **gtpp storage-server** command in the *Context Configuration Mode Commands* chapter for more information.

gtpp test

Tests communication with configured charging gateway function (CGF) severs or a GTPP Storage-Server.

Product

GGSN

Privilege

Operator, Config-Administrator, Administrator

Syntax

```
gtpp test { accounting { all | cgf-server cgf_address | group name group_name } |
storage-server [ address ip-addr port udp-port |  group name group_name ] }
```

all

Tests all CGFs configured within the given context.

cgf-server *cgf_address*

Tests a CGF configured within the given context and specified by the IP address of the CGF entered using IPv4 dotted-decimal notation.

group name *group_name*

Tests the storage server for an existing group name specified as an alphanumeric string of 1 through 63 characters.

storage-server [address *ip-address* **port** *udp-port*]

Tests the connectivity and provides round trip time for the echo request sent to the GTPP Storage-Server configured in the requested context. The IP address of the GSS is entered using IPv4 dotted-decimal notation and the UPD port is the one defined for the GTPP Storage Server.

Usage

This command is used to verify the configuration of and test the system's ability to communicate with one or all configured GSS/CGFs for monitoring or troubleshooting purposes.
When executed, this command causes the system to send GTPP echo packets to the specified GSS/CGF(s). The command's response will display whether the GSS/CGF is active or unreachable.

Example

The following command tests communication with a CGF having an IP address of *192.168.1.5*:

```
gtpp test accounting cgf-server 192.168.1.5
```

The following command tests communication with a GSS configured in requested context

```
gtpp test storage-server
```

The following command verify communication with a GSS, having IP address *192.156.12.10* and port *50000*, without configuring it in a context

```
gtpp test storage-server address 192.156.12.10 port 50000
```

gtpu test echo

Tests the ability of a GGSN service to exchange GTP-U echo request messages with the specified SGSN(s).

Product

GGSN

Privilege

Operator, Config-Administrator, Administrator

Syntax

gtpu test echo src-address *gn_address* { **all** | **sgsn-address** *ip_address* }

src-address *gn_address*

Specifies the IP address of a Gn interface configured on the system using IPv4 dotted-decimal notation.

Important: The IP address of the system's Gn interface must be bound to a configured GGSN service prior to executing this command.

all

Sends GTP-U echo requests to all SGSNs that currently have sessions with the GGSN service.

sgsn-address *ip_address*

Sends GTP-U echo requests to an SGSN specified by its IP address in IPv4 dotted-decimal notation.

Usage

This command tests the GGSN's ability to exchange GPRS Tunneling Protocol user plane (GTP-U) packets with the specified SGSNs. This command is useful for troubleshooting and/or monitoring.
This command must be executed from within the context in which the GGSN service is configured.
Refer also to the **gtpc test** command.

Example

The following command issues GTP-U echo packets from a GGSN service bound to address *192.168.157.43* to an SGSN with an address of *192.168.1.52*:

```
gtpu test echo src-address 192.168.157.43 sgsn-address 192.168.1.52
```

gtpv0 test echo

Tests the ability of a GGSN service to exchange GTPv0 echo request messages with the specified SGSN(s).

Product

GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

gtpv0 test echo src-address *gn_address* { **all** | **sgsn-address** *ip_address* }

src-address *gn_address*

Specifies the IP address of a Gn interface configured on the system using IPv4 dotted-decimal notation.

Important: The IP address of the system's Gn interface must be bound to a configured GGSN service prior to executing this command.

all

Sends GTPv0 echo requests to all SGSNs that currently have sessions with the GGSN service.

sgsn-address *ip_address*

Sends GTPv0 echo requests to an SGSN specified by its IP address in IPv4 dotted-decimal notation.

Usage

This command tests the GGSN's ability to exchange GPRS Tunneling Protocol version 0 (GTPv0) packets with the specified SGSNs which can be useful troubleshooting and/or monitoring.
This command must be executed from within the context in which the GGSN service is configured.
Refer also to the gtpc test and gtpu test commands.

Example

The following command issues GTPv0 echo packets from a GGSN service bound to address *192.168.1.33* to an SGSN with an address of *192.168.1.42*:

```
gtpv0 test echo src-address 192.168.1.33 sgsn-address 192.168.1.42
```

hd raid

Performs RAID management operations on the hard drives of redundant SMCs.

Product

All

Privilege

Security Administrator, Administrator

Syntax

hd raid { check | create { *local1* **|** *remote1* **} | overwrite {** *local1* **|** *remote1* **} | select {** *local1* **|** *remote1* **} | insert {** *local1* **|** *remote1* **} | { remove {** *local1* **|** *remote1* **} } [-force] [-noconfirm]**

check

Starts a background check on RAID disks unless the RAID is running in degraded mode.

create *local1* **|** *remote1*

Creates a new RAID that could run in degraded mode on the specified drive:
local1 specifies the RAID is to be established on the primary SMC. *remote1* specifies the RAID is to be established on the backup SMC.

overwrite *local1* **|** *remote1*

Overwrites the specified disk and adds it to the current running RAID to construct a fully mirrored array.
local1 specifies the primary SMC is to be added to the current RAID. *remote1* specifies the backup SMC is to be added to the current RAID.

select *local1* **|** *remote1*

Selects the specified disk to assemble a RAID when two unrelated RAID disks are present in the system. The resulting RAID runs in degraded mode.
local1: specifies the primary SMC is to assemble the RAID. *remote1:* specifies the backup SMC is to assemble the RAID.

insert *local1* **|** *remote1*

Inserts the specified disk to the running RAID causing it to recover from degraded mode.
local1: specifies the primary SMC is to be inserted into the RAID. *remote1:* specifies the backup SMC is to be inserted into the RAID.

remove local1 | remote1

Removes the specified disk from the running RAID causing it to run in degraded mode or to fail.
local1: specifies the primary SMC is to be removed from the RAID. *remote1:* specifies the backup SMC is to be removed from the RAID.

-noconfirm

Executes the command without displaying “are you sure” prompts.

-force

Executes the command and overrides warnings.

Usage

All commands need confirmation unless the **-noconfirm** is included in the command. If the result will bring down a running RAID, you have to force the command using **-force**.
RAID commands are needed to intervene in the following situations:

- the hard disk controller task can not determine the correct operation,
- administrator action is required by policy
- the administrator wants to wipe out an unused disk.

In an automated system, the policies created with this CLI address the possibility of a manually partitioned disk, a disk resulting from a different version of software, a partially constructed disk, or the case of two unrelated disks in the system.
To reduce administrator intervention, a set of policies can be configured to set the default action using the commands in the HD RAID configuration mode. These **hd raid** commands are described in the *HD RAID Configuration Mode* chapter of this guide.

Example

The following instructs the system to setup a RAID on the primary SMC hard drive.

```
hd raid create local1 -force
```

host

Used to resolve the IP address or logical host name information via a DNS query.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

host { *host_name* | *host_ip_address* }

host_name | *host_ip_address*

Specifies the host for which IP information is to be displayed.
host_name: Specifies the logical host name for which the IP address is to be displayed (via DNS lookup). This is an alphanumeric string of 1 through 127 characters.
host_ip_address: Specifies the IP address for which the associated logical host name(s) are to be displayed (via reverse DNS lookup) using IPv4 dotted-decimal notation.

Usage

Verify DNS information which affects connections and packet routing.

Example

The following commands will resolve the host information for *remoteABC* and *10.2.3.4* respectively.

```
host remoteABC

host 10.2.3.4
```

interface

Configures the system to generate gratuitous ARP (G-ARP) requests in case of a failure during an inter-node online upgrade. If the chassis is not active, an error message displays.

Product

All

Privilege

Security Administrator, Administrator, Operator, or Inspector with li-administrator permissions

Syntax

interface *name* **send gratuitous-arp** *ip-address*

Usage

This command generates a G-ARP for the IP address specified and sends it over the interface.

Example

The following generate a G-ARP for IP address *192.168.100.10*.

```
interface interface_1 send gratuitous-arp 192.168.100.10
```

lawful-intercept

Refer to the *Lawful Intercept Configuration Guide* for a description of this command.

lawful-intercept packet-cable

Refer to the *Lawful Intercept Configuration Guide* for a description of this command.

lawful-intercept ssdf

Refer to the *Lawful Intercept Guide* for a description of this command.

link-aggregation port switch to

When a link aggregation group (LAG) contains two sets of ports with each connecting to a different Ethernet switch, this command allows you to change the status of the active distributing ports.

Default: none.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

link-aggregation port switch to *slot#* **/** *port#*

slot#

Identifies the physical chassis slot where the line card is installed.

port#

Identifies the physical port on the line card to automatically switch to.

Usage

This command is subject to the following restrictions:

- *slot#/port#* must support LAG.
- *slot#/port#* must be configured with LAG.
- *slot#/port#* must not be actively distributing.
- *slot#/port#* must have negotiated a partner while in standard mode.
- *slot#/port#*'s partner must have a priority equal to or greater than itself.
- *slot#/port#*'s partner bundle must have bandwidth in standard mode equal to or greater than itself.
- Switching to *slot#/port#* must not violate preference within hold-time in standard mode.

Example

```
link-aggregation port switch to 17/2
```

logging active

Enables or disables logging for active internal log files.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
logging active [ copy runtime filters ] [ event-verbosity event_level ] [ pdu-data format
] [ pdu-verbosity pdu_level ]

no logging active
```

no

Indicates the internal logging is to be disabled.

copy runtime filters

Copies the runtime filters and uses that copy to filter the current logging session.

event-verbosity *event_level*

Specifies the level of verboseness to use in logging of events as one of:

- *min*: Displays minimal information about the event. Information includes event name, facility, event ID, severity level, date, and time.
- *concise*: Displays detailed information about the event, but does not provide the event source within the system.
- *full*: Displays detailed information about event, including source information, identifying where within the system the event was generated.

pdu-data *format*

Specifies output format for packet data units when logged as one of:

- *none*: raw format (unformatted).
- *hex*: hexadecimal format.
- *hex-ascii*: hexadecimal and ASCII similar to a main-frame dump.

pdu-verbosity *pdu_level*

Specifies the level of verboseness to use in logging of packet data units as an integer from 1 through 5, where 5 is the most detailed.

Usage

Adjust the active logging levels when excessive log file sizes are being generated or, conversely, not enough information is being sent to the active log files for adequate troubleshooting support. The **no** keyword is used to disable internal logging.

Important: A maximum of 50,000 events may be stored in each log. Enabling more events for logging may cause the log to be filled in a much shorter time period. This may reduce the effectiveness of the log data as a shorter time period of event data may make troubleshooting more difficult.

Important: Once a log has reached the 50,000 event limit the oldest events will be discarded as new log entries are created.

Example

The following sets the active logging for events to the maximum.

```
logging active event-verbosity full
```

The following command sets the active logging for packet data units to level *3* and sets the output format to the main-frame style *hex-ascii*.

```
logging active pdu-data hex-ascii pdu-verbosity 3
```

The following disables internal logging.

```
no logging active
```

logging filter

Sets the logging filtering options for all or individual facilities.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
logging filter active facility facility level severity_level [ critical-info | no-
critical-info ]
```

active

Indicates only active processes are to have logging options set.

facility *facility*

Specifies the facility to modify the filtering of logged information. Valid facilities for this command are:

- **a10**: A10 interface facility
- **a11**: A11 interface facility
- **a11mgr**: A11 Manager facility
- **aaa-client**: AAA client facility
- **aaamgr**: AAA manager logging facility
- **aaaproxy**: AAA Proxy facility
- **aal2**: AAL2 protocol logging facility
- **acl-log**: Access Control List logging facility
- **acsctrl**: Active Charging Service (ACS) Controller facility
- **acsmgr**: Active Charging Service (ACS) Manager facility
- **alarmctrl**: Alarm Controller facility
- **alcap**: ALCAP protocol logging facility
- **alcapmgr**: ALCAPMgr logging facility
- **all**: All facilities
- **asngwmgr**: ASN Gateway Manager facility
- **asnpcmgr**: ASN Paging Controller Manager facility
- **bfd**: BFD protocol logging facility
- **bgp**: Border Gateway Protocol (BGP) facility
- **bindmux**: IPCF BindMux-De-mux Manager logging facility
- **bssap+**: Base Station Sub-system Application Part+ protocol facility for the login interface between the SGSN and the MSC/VLR (2.5G and 3G)
- **bssgp**: Base Station Sub-system GPRS Protocol logging facility handles exchange information between the SGSN and the BSS (2.5G only)

- **callhome**: Call home application logging facility
- **cap**: CAMEL Application Part (CAP) logging facility for protocol used in prepaid applications (2.5G and 3G)
- **cli**: CLI logging facility
- **credit-control**: Credit Control facility
- **cscf**: IMS/MMD CSCF
- **cscfmgr**: SIP CSCF Manager facility
- **cscfttmgr**: SIP CSCFTT Manager facility
- **csp**: Card Slot Port controller facility
- **css**: Content Service Selection (CSS) facility
- **css-sig**: Content Service Selection (CSS) RADIUS Signaling facility
- **cx-diameter**: Cx Diameter Messages facility
- **dcardctrl**: IPSEC Daughter Card Controller logging facility
- **dcardmgr**: IPSEC Daughter Card Manager logging facility
- **demuxmgr**: Demux Manager API facility
- **dgmbmgr**: Diameter Gmb Application Manager logging facility
- **dhcp**: Dynamic Host Configuration Protocol logging facility
- **dhcpv6**: DHCPv6
- **dhost**: Distributed Host logging facility
- **diabase**: Diabase messages facility
- **diameter**: Diameter endpoint logging facility
- **diameter-acct**: Diameter Accounting
- **diameter-auth**: Diameter Authentication
- **diameter-dns**: Diameter DNS subsystem
- **diameter-ecs**: ACS Diameter signaling facility
- **diameter-hdd**: Diameter HDD Interface facility
- **diameter-svc**: Diameter Service
- **diamproxy**: DiamProxy logging facility
- **dpath**: IPSEC Data Path facility
- **drvctrl**: Driver Controller facility
- **eap-ipsec**: EAP
- **eap-sta-s6a-s13-s6b-diameter**: EAP/STA/S6A/S13/S6B Diameter messages facility
- **ecs-css**: ACSMGR <-> Session Manager Signalling Interface facility
- **egtpc**: eGTP-C logging facility
- **egtpmgr**: eGTP manager logging facility
- **egtpu**: eGTP-U logging facility
- **epdg**: ePDG logging facility

- **evlog**: Event log facility
- **famgr**: Foreign Agent manager logging facility
- **firewall**: Firewall logging facility
- **fng**: FNG logging facility
- **gmm**:
  - For 2.5G: Logs the GPRS Mobility Management (GMM) layer (above LLC layer)
  - For 3G: Logs the access application layer (above the RANAP layer)
- **gprs-app**: GPRS Application logging facility
- **gprs-ns**: GPRS Network Service Protocol (layer between SGSN and the BSS) logging facility
- **gq-rx-tx-diameter**: Gq/Rx/Tx Diameter messages facility
- **gss-gcdr**: GTPP Storage Server GCDR facility
- **gtpc**: GTP-C protocol logging facility
- **gtpcmgr**: GTP-C protocol Manager logging facility
- **gtpp**: GTP-PRIME protocol logging facility
- **gtpu**: GTP-U protocol logging facility
- **gtpumgr**: GTPU Demux manager
- **gx-ty-diameter**: Gx/Ty Diameter messages facility
- **gy-diameter**: Gy Diameter messages facility
- **hamgr**: Home Agent manager logging facility
- **hat**: High Availability Task (HAT) process facility
- **hdctrl**: HD Controller logging facility
- **hnb-gw**: HNB-GW (3G Femto GW) logging facility
- **hnbmgr**: HNBMGR (3G Femto GW DemuxMgr) logging facility
- **hss-peer-service**: HSS Peer Service facility
- **igmp**: IGMP
- **ikev2**: IKEv2
- **ims-authorizatn**: IMS Authorization Service facility
- **ims-sh**: HSS SH Service facility
- **imsimgr**: SGSN IMSI Manager facility
- **imsue**: IMSUE
- **ip-arp**: IP Address Resolution Protocol facility
- **ip-interface**: IP interface facility
- **ip-route**: IP route facility
- **ipms**: IPMS logging facility
- **ipsec**: IP Security logging facility
- **ipsg**: IP Service Gateway interface logging facility
- **ipsgmgr**: IP Services Gateway facility

- **ipsp**: IP Pool Sharing Protocol logging facility
- **kvstore**: KV Store facility
- **l2tp-control**: L2TP control logging facility
- **l2tp-data**: L2TP data logging facility
- **l2tpdemux**: L2TP Demux Manager logging facility
- **l2tpmgr**: L2TP Manager logging facility
- **lagmgr**: LAGMGR logging facility
- **ldap**: Lightweight Directory Access Protocol (LDAP) messages logging facility
- **li**: Refer to the *Lawful Intercept Interface Reference* for a description of this command.
- **linkmgr**: SGSN/BSS SS7 Link Manager logging facility (2.5G only)
- **llc**: Logical Link Control (LLC) Protocol logging facility; for SGSN: logs the LLC layer between the GMM and the BSSGP layers for logical links between the MS and the SGSN
- **local-policy**: Local Policy Service facility
- **m3ua**: M3UA Protocol logging facility
- **magmgr**: Mobile Access Gateway manager logging facility
- **map**: MAP Protocol logging facility
- **megadiammgr**: Megadiameter Manager (SLF Service) logging facility
- **mme-app**: Mobility Management Entity Application logging facility
- **mme-misc**: MME miscellaneous logging facility
- **mmedemux**: Mobility Management Entity Demux Manager logging facility
- **mmemgr**: MME Manager facility
- **mmgr**: Master Manager logging facility
- **mobile-ip**: Mobile IP processes
- **mobile-ip-data**: Mobile IP data facility
- **mobile-ipv6**: Mobile IPv6 logging facility
- **mpls**: MPLS protocol logging facility
- **mseg-app**: MSEG application logging facility
- **mseg-gtpc**: MSEG GTPC application logging facility
- **mseg-gtpu**: MSEG GTPU application logging facility
- **msegmgr**: MSEGMgr (MSEG DemuxMgr) logging facility
- **mtp2**: MTP2 Service logging facility
- **mtp3**: MTP3 Protocol logging facility
- **multicast-proxy**: Multicast Proxy logging facility
- **npuctrl**: Network Processor Unit Control facility
- **npumgr**: Network Processor Unit Manager facility
- **npumgr-acl**: NPUMGR ACL logging facility
- **npumgr-flow**: NPUMGR FLOW logging facility

- **npumgr-fwd**: NPUMGR FWD logging facility
- **npumgr-init**: NPUMGR INIT logging facility
- **npumgr-port**: NPUMGR PORT logging facility
- **npumgr-recovery**: NPUMGR RECOVERY logging facility
- **ntfy-intf**: Notification Interface logging facility
- **orbs**: Object Request Broker System logging facility
- **ospf**: OSPF protocol logging facility
- **ospfv3**: OSPFv3 protocol logging facility
- **p2p**: Peer-to-Peer Detection logging facility
- **pccmgr**: IPCF PCC Manager library
- **pdg**: PDG logging facility
- **pdgdmgr**: PDG Demux Manager logging facility
- **pdif**: PDIF logging facility
- **pgw**: PDN Gateway logging facility
- **phs**: Payload Header Suppression
- **phs-control**: PHS X1/X5 and X2/X6 Interface logging facility
- **phs-data**: PHS Data logging facility
- **phs-eapol**: PHS EAPOL logging facility
- **phsgwmgr**: PHS Gateway Manager facility
- **phspcmgr**: PHS Paging Controller Manager facility
- **pmm-app**: PMM application logging facility
- **ppp**: PPP link and packet facilities
- **pppoe**: PPPOE logging facility
- **push**: VPNMGR CDR push logging facility
- **radius-acct**: RADIUS accounting logging facility
- **radius-auth**: RADIUS authentication logging facility
- **radius-coa**: RADIUS change of authorization and radius disconnect
- **ranap**: Radio Access Network Application Part (RANAP) Protocol facility logging info flow between SGSN and RNS (3G)
- **rct**: Recovery Control Task logging facility
- **rdt**: Redirect Task logging facility
- **resmgr**: Resource Manager logging facility
- **rf-diameter**: Rf Diameter messages facility
- **rip**: RIP logging facility (RIP is not supported at this time.)
- **rohc**: RObust Header Compression facility
- **rsvp**: Reservation Protocol logging facility
- **rua**: RUA (3G Femto GW - RUA messages) logging facility

- **s1ap**: S1AP Protocol logging facility
- **sccp:** SCCP Protocol logging connection-oriented messages between RANAP and TCAP layers.
- **sct**: Shared Configuration Task logging facility
- **sctp**: SCTP Protocol logging facility
- **sessctrl**: Session Controller logging facility
- **sessmgr**: Session Manager logging facility
- **sesstrc**: session trace logging facility
- **sft**: Switch Fabric Task logging facility
- **sgs**: SGs protocol logging facility
- **sgsn-app**: SGSN-APP logging various SGSN 'glue' interfaces, e.g., between PMM, MAP,. GPRS-FSM, SMS.
- **sgsn-failures**: SGSN call failures (attach/activate rejects) logging facility (2.5G)
- **sgsn-gtpc**: SGSN GTP-C Protocol logging control messages between the SGSN and the GGSN
- **sgsn-gtpu**: SGSN GTP-U Protocol logging user data messages between the SGSN and GGSN
- **sgsn-mbms-bearer**: SGSN MBMS Bearer app (SMGR) logging facility
- **sgsn-misc**: Used by stack manager to log binding and removing between layers
- **sgsn-system**: SGSNs System Components logging facility; used infrequently
- **sgsn-test**: SGSN Tests logging facility; used infrequently
- **sgtpcmgr**: SGSN GTPC Manager logging information exchange through SGTPC and the GGSN
- **sgw**: Serving Gateway facility
- **sh-diameter**: Sh Diameter messages facility
- **sitmain**: System Initialization Task main logging facility
- **sm-app**: SM Protocol logging facility
- **sms**: Short Message Service (SMS) logging messages between the MS and the SMSC
- **sndcp**: SNDCP Protocol logging facility
- **snmp**: SNMP logging facility
- **sprmgr**: IPCF SPR Manager logging facility
- **srdb**: Static Rating Database
- **srp**: Service Redundancy Protocol (SRP) logging facility
- **sscfnni**: SSCFNNI Protocol logging facility
- **sscop**: SSCOP Protocol logging facility
- **ssh-ipsec**: SSH IP Security logging facility
- **ssl**: SSL (Secure socket layer messages) logging facility
- **stat**: Statistics logging facility
- **system**: System logging facility
- **tacacsplus**: TACACS+ Protocol logging facility
- **tcap**: TCAP Protocol logging facility

- **testctrl**: Test Controller logging facility
- **testmgr**: Test Manager logging facility
- **threshold**: threshold logging facility
- **ttg**: TTG logging facility
- **tucl**: TUCL logging facility
- **udr**: User detail record facility (used with the Charging Service)
- **user-data**: User data logging facility
- **user-l3tunnel**: User layer-3 tunnel logging facility
- **usertcp-stack**: User TCP Stack
- **vpn**: Virtual Private Network logging facility
- **wimax-data**: WiMAX DATA
- **wimax-r6**: WiMAX R6

---

level *severity_level*

Specifies the level of information to be logged from the following list which is ordered from highest to lowest:

- critical - display critical events
- error - display error events and all events with a higher severity level
- warning - display warning events and all events with a higher severity level
- unusual - display unusual events and all events with a higher severity level
- info - display info events and all events with a higher severity level
- trace - display trace events and all events with a higher severity level
- debug - display all events

---

critical-info | no-critical-info

critical-info: Specifies that events with a category attribute of critical information are to be displayed. Examples of these types of events can be seen at bootup when system processes and tasks are being initiated. This is the default setting.
no-critical-info: Specifies that events with a category attribute of critical information are not to be displayed.

Usage

Apply filters for logged data to collect only that data which is of interest.

Important: A maximum of 50,000 events may be stored in each log. Enabling more events for logging may cause the log to be filled in a much shorter time period. This may reduce the effectiveness of the log data as a shorter time period of event data may make troubleshooting more difficult.

Important: Once a log has reached the 50,000 event limit the oldest events will be discarded as new log entries are created.

Caution: Issuing this command could negatively impact system performance depending on the amount of system activity at the time of execution and/or the type of facility(ies) being logged.

Example

The following are selected examples used to illustrate the various options. Not all facilities will be explicitly shown as each follows the same syntax for options.
The following sets the level to log only *warning* information for *all* facilities.

```
logging filter active facility all level warning
```

The following enables the logging of critical information for the SNMP facility while setting the level to *error*.

```
logging filter active facility snmp level error critical-info
```

logging trace

Enables or disables the logging of trace information for specific calls, mobiles, or network addresses.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

logging trace { **callid** *call_id* | **ipaddr** *ip_address* | **msid** *ms_id* | **username** *user_name* }

no logging trace { **callid** *call_id* | **ipaddr** *ip_address* | **msid** *ms_id* | **username** *user_name* }

no

Indicates the logging of trace information is to be disabled.

callid *call_id* **| ipaddr** *ip_address* **| msid** *ms_id* **| username** *user_name*

callid *call_id*: Specifies the exact call instance ID which is to have trace data logged.as a 4-byte hexadecimal number.
ipaddr *ip_address*: Specifies the IP address in IPv4 dotted-decimal notation for which trace information is to be logged.
msid *ms_id*: Specifies the mobile subscriber ID for which trace information is to be logged as 7 to 16 digits of an IMSI, MIN, or RMI.
username *user_name*: Specifies a previously configured user who is to have trace information logged.

Usage

A trace log is useful in troubleshooting subscriber problems as well as for system verification by using a test subscriber. The **no** keyword is used to stop the logging of trace information.

Important: A maximum of 50,000 events may be stored in each log. Enabling more events for logging may cause the log to be filled in a much shorter time period. This may reduce the effectiveness of the log data as a shorter time period of event data may make troubleshooting more difficult.

Important: Once a log has reached the 50,000 event limit the oldest events will be discarded as new log entries are created.

Caution: Issuing this command could negatively impact system performance depending on the number of subscribers connected and the amount of data being passed.

Example

The following commands enables/disables trace information for user *user1*.

```
logging trace username user1no logging trace username user1
```

The following commands will enable/disable trace information logging for the user assigned IP address *10.2.3.4*.

```
logging trace ipaddr 10.2.3.4no logging trace ipaddr 10.2.3.4
```

The following enables/disables logging of trace information for call ID *fe80AA12*.

```
logging trace callid fe80AA12no logging trace callid fe80AA12
```

logs checkpoint

Performs check pointing operations on log data. Check pointing identifies logged data as previously viewed or marked. Check pointing results in only the log information since the last check point being displayed; check pointed log data is not available for viewing.

Individual logs may have up to 50,000 events in the active log. Check pointing the logs will then result in at most 50,000 events being in the inactive log files. This gives a maximum of 100,000 events in total which are available for each facility logged.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
logs checkpoint
```

Usage

Check point log data to a set the log contents to a well know point prior to special activities taking place. This command may also be a part of periodic regular maintenance to manage log data.
The check pointing of logs moves the current log data to the inactive logs. Only the most recently check pointed data is retained in the inactive logs. A subsequent check pointing of the logs will result in the prior check pointed inactive log data being cleared and replaced with the newly check pointed data.
The check pointing of log data moves the active log data to be retained as the inactive log data. This results in the active log data, if displayed, having no data earlier than the point in time when the check pointing occurred.

Important: Check pointing of logs should be done periodically to avoid the logs becoming full. Logs which have 50,000 events logged will discard the oldest events first when new events are to be logged.

Example

```
logs checkpoint
```

lsp-ping

Checks Multi Protocol Label Switching (MPLS) label switch path (LSP) connectivity for the specified forwarding equivalence class (FEC). It must be followed by an IPv4 FEC prefix.

Product

All

Privilege

Security Administrator, Administrator

Syntax

lsp-ping *ip_prefix_FEC* [**count** *ping_packets*] [| **verbose**] [| **grep** *grep_options*]

ip_prefix_FEC

is an IPv4 prefix FEC with or without subnet mask entered using IPv4 dotted-decimal or CIDR notation.

count *ping_packets*

Sets the number of ping packets to be sent as an integer from 1 through 16. Default: 4.

Important: The timeout interval for the packets is 5 seconds by default.

verbose

Sets the verbose (detailed) output mode.

grep*grep_options*

Pipes (sends) the output of this command to the **grep** command.

Usage

This command is used to verify the MPLS LSP connectivity for the specified FEC.

Example

Following are the examples for using this command with all possible options for IPv4 address *13.13.13.1* and mask *32* (CIDR notation):

```
lsp-ping 13.13.13.1/32

lsp-ping 13.13.13.1/32 count 15

lsp-ping 13.13.13.1/32 verbose
```

lsp-traceroute

Discovers MPLS LSP routes that packets actually take when traveling to their destinations. It must be followed by an IPv4 or IPv6 FEC prefix.

Product

All

Privilege

Security Administrator, Administrator

Syntax

lsp-traceroute *ip_prefix_FEC* [**maxttl** *time_to_live*] [| **verbose**] [| **grep** *grep_options*]

ip_prefix_FEC

Specifies the destination IP address in IPv4 dotted-decimal or IPv6 colon-separated with or without mask (CIDR notation).

maxttl *time_to_live*

Sets the maximum time to live in hops. TTL is an integer from 1 through 255. Default: 30.

verbose

Sets the verbose (detailed) output mode.

grep*grep_options*

Pipes (sends) the output of this command to the **grep** command.

Usage

This command is used or the router to discover the MPLS LSP routes through which the packets will travel to their IPv4 destinations.

Example

The following command specifies the destination IP address *13.13.13.13* for which the MPLS routes will be discovered for packets to traverse:

```
lsp-traceroute 13.13.13.13/32
```

mkdir

Creates a new directory in the local file system or in remote locations as specified.

Product

All

Privilege

Security Administrator, Administrator

Syntax

mkdir *filepath*

filepath

Specifies the directory path to create. The path must be formatted as follows:
`[file: ]{ /flash | /pcmcia1 | /hd }[ /directory ]/file_name`

Important: Use of the SMC hard drive is not supported in this release.

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name
filename is the actual file of interest

Usage

Create new directories as part of periodic maintenance activities to better organize stored files.

Example

The following creates the directory */flash/pub* in the local flash storage.

```
mkdir /flash/pub
```

mme offload

Initiates or stops the offload of UEs associated with a specified MME service.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

mme offload mme-service *name* **{ start mme-init-release-timeout** *seconds* **paging-init-timeout** *seconds* **| stop }**

mme-service *name*

Specifies the name of an existing MME service from which UEs will be offloaded as an alphanumeric string of 1 trough 63 characters.

start mme-init-release-timeout *seconds* **paging-init-timeout** *seconds* **| stop } [-noconfirm]**

Sets the timeout for the initial release procedure and the paging procedure.
start mme-init-release-timeout *seconds*: Configures the timeout (in seconds) for triggering the IDLE MODE ENTRY procedure for UEs that are in the ECM_CONNECTED state as an integer from 1 to 120. The cause of the IDLE MODE ENTRY will be "Load balancing TAU required".
paging-init-timeout *seconds*: Configures the timeout (in seconds) for triggering the PAGING procedure for UEs in the ECM_IDLE state as an integer from 1 to 120. After returning the UEs to the ECM_CONNECTED state, the IDLE MODE ENTRY procedure is triggered with the "Load balancing TAU required" cause.
stop: Ends the off-load process.

-noconfirm

Executes the command without any additional prompts or confirmation from the user.

Usage

Use this command to initiate or stop the off-loading of UEs associated with a specified MME service.

Important: If all subscribers are to be off-loaded, and prior to initiating this command, you must set the **relative-capacity** command in the MME Service Configuration Mode to zero (0). This allows all new calls to be re-directed to other MMEs in the pool while existing calls on the off-loading MME are removed.

Example

The following command sets the trigger to start off-loading UEs from a service named *mme3* at *60* seconds and the paging trigger at *90* seconds:

```
mme offload mme-service mme3 start mme-init-release-timeout 60 paging-
init-timeout 90
```

mme reset

Sends an S1 RESET message to a designated EnodeB to reset all UE-associated S1 connections.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

mme reset s1-peer *peer_ID*

s1-peer *peer-ID*

Specifies an existing EnodeB peer ID to which the REST message is to be sent as an integer from 1 through 4294967295.

Usage

Use this command to send an S1 RESET message to a designated EnodeB to reset all UE-associated S1 connections.
The S1 peer ID for an EnodeB can be identified by executing the **show mme-service enodeb-association** command available in this mode. The peer ID is presented in the "Peerid" field.

Example

The following command initiates the sending of an S1-peer reset message to an EnodeB with a peer ID of *22315734*:

```
mme rest s1-peer 22315734
```

monitor protocol

Enters the system's protocol monitoring utility.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
monitor protocol
```

Usage

Useful for troubleshooting, this command provides a tool for monitoring protocol transactions between the system and other network nodes including the mobile station(s).
The following protocols can be monitored:

- SNMP
- RADIUS Authentication
- RADIUS Accounting
- A11 (R-P Interface) (PDSN only)
- Mobile IPv4
- A11MGR
- PPP
- A10
- User L3 (User Layer 3 protocols)
- USERTCP STACK
- L2TP
- L2TPMGR
- L2TP Data
- GTPC
- GTPCMGR
- GTPU
- GTPP

Important: If the hard disk drive (HDD) is used for CDR storage, the CDR option must be used and not GTPP option (27).

- DHCP (GGSN only)
- CDR
- DHCPV6

- MIP Tunnel
- L3 Tunnel (Layer 3 Tunnel Protocols)
- CSS Data
- CSS Signaling

> ***Important:*** In StarOS 9.0 and later releases the CSS Data Signaling option is not supported.

- EC Diameter (Diameter Enhanced Charging)
- SIP (IMS)
- IPSec IKE Inter-Node
- IPSec IKE Subscriber
- IPSG RADIUS Signal
- ROHC (Robust Header Compression)
- WiMAX R6
- WiMAX Data
- SRP
- BCMCS SERV AUTH
- RSVP
- Mobile IPv6
- ASNGWMGR
- STUN
- SCTP: Enabling this option will display the SCTP protocol message packets on HNB-GW node.
- M3UA
- SCCP
- TCAP
- MAP
- RANAP
- GMM
- GPRS-NS
- BSSGP
- CAP
- SSCOP
- SSCFNNI
- MTP3
- LLC
- SNDCP
- BSSAP+

- SMS
- PHS-Control (Payload Header Compression)
- PHS-Data
- DNS Client
- MTP2
- HNBAP: Enabling this option will display the HNB Application Part (HNBAP) protocol packets.
- RUA: Enabling this option will display the RANAP User Adaptation (RUA) protocol packets.
- EGTPC
- App Specific Diameter
- PHS-EAPOL
- ICAP
- Micro-Tunnel
- ALCAP: Enabling this option will display the Access Link Control Application Part (ALCAP) protocol message packets on HNB-GW node.
- SSL
- S1-AP
- NAS
- LDAP
- SGS
- AAL2: Enabling this option will display the ATM Adaptation Layer 2 (AAL2) protocol message packets on HNB-GW node.
- PHS (Payload Header Suppression)
- PPPOE
- RTP (IMS)
- RTCP (IMS)

Once the protocol has been selected, the utility monitors and displays every relative protocol message transaction.
Protocol monitoring is performed on a context-by-context-basis. Therefore, the messages displayed are only those that are transmitted/received within the system context from which the utility was executed.
For additional information on using the monitor utility, refer to the *System Amdinistration Guide*.

Caution: Protocol monitoring can be intrusive to subscriber sessions and could impact system performance. Therefore, it should only be used as a troubleshooting tool.

Example

The following command opens the *protocol* monitoring utility:

```
monitor protocol
```

monitor subscriber

Enables the system's subscriber monitoring utility. Available keywords vary based on the licenses installed on the system.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

monitor subscriber [asn-peer-address *bs_peer_address* **| callid** *call_id* **fng-peer-address** *ipv4_address* **| imei** *imei_value* **| imsi** *imsi_value* **| ipaddr** *ip_address* **| ipv6addr** *ipv6_address* **| ipsg-peer-address** *ipsg_peer_address*| **msid** *ms_id* **| msisdn** *msisdn* **| next-call | pcf** *pcf_address* **| pdif-peer-address** *pdif_peer_address* **| peer-fa** *peer_fa_address* **| peer-lac** *lac_peer_address* **| sgsn-address** *sgsn_address* **| type { 1xrtt | asngw | asnpc | closedrp | evdorev0 | evdoreva | interrogating-cscf | ggsn [Next-Call By APN] | ha | ipsg | lns | mme | pdif | proxy-cscf | rfc3261-proxy | serving-cscf } next-call | type bcmcs { next-call | next-service-request } | username** *user_name*| **Next-Call By APN]**

asn-peer-address *bs_peer_address*

Specifies the peer ASN Base Station IP address in IPv4 address in dotted-decimal notation.

callid *call_id*

Specifies the call identification number assigned to the subscriber session by the system to be monitored as a 4-byte hexadecimal number.

fng-peer-address *ipv4_address*

Specifies the specific FNG WLAN IP address in IPv4 dotted-decimal notation.

imei *imei_value*

International Mobile Equipment Identification (IMEI). Must be followed by 8 digits of TAC (Type Allocation Code) and 6 digits of SNR (Serial Number). Only the first 14 digit of IMEI/IMEISV is used to find the equipment ID.

imsi *imsi_value*

Specifies the International Mobile Subscriber Identity (IMSI) of the subscriber session to be monitored an integer from 1 though 15 characters.

ipaddr *ip_address*

Specifies the IP address of the subscriber session to be monitored in IPv4 dotted-decimal notation.

ipv6addr *ipv6_address*

Specifies the IPv6 address of the subscriber session to be monitored in IPv6 colon-separated notation.

ipsg-peer-address *ipsg_peer_address*

Specifies the peer IPSG IP address. Must be followed by an IPv4 address in dotted -decimal notation.

msid *ms_id*

Specifies the mobile subscriber identification number to be monitored as 7 to 16 digits of an IMSI, MIN, or RMI.

msisdn *msisdn*

Specifies the Mobile Subscriber ISDN number to be monitored as 7 to 16 digits of an IMSI, MIN, or RMI.

next-call

Specifies that the system will monitor the next incoming subscriber session.
Entering this keyword will display the available options of protocols to select. For a list of supported protocols with this keyword, refer to the **monitor protocol** command.

pcf *pcf_address*

Specifies the PCF IP address in IPv4 dotted-decimal notation.

pdif-peer-address *pdif_peer_address*

Specifies the peer PDIF IP address in IPV4 dotted-decimal notation.

peer-fa *peer_fa_address*

Specifies the peer FA IP address in IPv4 dotted-decimal notation.

peer-lac *lac_peer_address*

Specifies the peer LAC IP address in IPv4 dotted-decimal notation.

sgsn-address *sgsn_address*

Specifies the SGSN IP address in IPv4 dotted-decimal notation.

type { 1xrtt | asngw | asnpc | evdorev0 | evdoreva | | fng | interrogating-cscf | ggsn [Next-Call By APN] | ha | ipsg | lns | mme | openrp | | pdif | proxy-cscf | rfc3261-proxy | serving-cscf } next-call

Allows monitoring for specific subscriber types established in the system when next call occurs.

- **1xrtt**: Displays logs for cdma2000 1xRTT call session subscriber
- **asngw**: Displays logs for ASN-GW call session subscriber
- **asnpc**: Displays logs for ASN PC/LR call session subscriber
- **evdorev0**: Displays logs for cdma2000 EVDO Rev0 call session subscriber
- **evdoreva**: Displays logs for cdma2000 EVDO RevA call session subscriber
- **fng**: Displays logs for the FNG session subscriber
- **interrogating-cscf**: Displays logs for Interrogating CSCF subscriber
- **ggsn**: Displays logs for UMTS GGSN call session subscriber

- **Next-Call By APN**: Display logs for next call on APN basis, where APN name can be any Gi or Gn APN.
- **ha**: Displays logs for Home Agent call session subscriber
- **ipsg**: Displays logs for IPSG call session subscriber
- **lns**: Displays logs for LNS call session subscriber
- **mme**: Displays logs for MME session subscribers.
- **pdif**: Displays logs for PDIF call session subscriber
- **proxy-cscf**: Displays logs for Proxy CSCF subscriber
- **rfc3261-proxy-cscf**: Displays logs for non-ims-proxy (RFC-3261 proxy) subscriber
- **serving-cscf**: Displays logs for Serving CSCF subscriber

type bcmcs {*next-call* | *next-service-request***}**

Specifies the type of BCMCS call for the subscriber.

username *user_name*

Specifies the username of an existing subscriber to be monitored.

Usage

The monitor subscriber utility provides a useful tool for monitoring information about and the activity of either a single subscriber or all subscribers with active sessions within a given context.
The following items can be monitored:

- Control events
- Data events
- Event ID information
- Inbound events
- Outbound events
- Protocols (identical to those monitored by command)

Once the criteria has been selected, the utility will monitor and display every relative piece of information on the subscriber(s).
For additional information on using the monitor utility, refer to the *System Amdinistration Guide*.

Important: Option Y for performing multi-call traces is only supported for use with the GGSN. This option is available when monitoring is performed using the “Next-Call” option. It allows you monitor up to 11 primary PDP contexts for a single subscriber.

Subscriber monitoring is performed on a context-by-context-basis. Therefore, the information displayed will be only that which is collected within the system context from which the utility was executed.

Caution: Subscriber monitoring can be intrusive to subscriber sessions and could impact system performance. Therefore, it should only be used as a troubleshooting tool.

Example

The following command enables monitoring for user *user1*.

```
monitor subscriber username user1
```

The following command will enable monitoring for the user assigned IP address *10.2.3.4*.

```
monitor subscriber ip-address 10.2.3.4
```

The following enables monitoring for call ID *FE80AA12*.

```
monitor subscriber callid fe80aa12
```

newcall policy

Configures new call policies for busy-out conditions.

Product

PDSN, GGSN,, HNB-GW, IPCF, MME, HA, LNS, P-CSCF, ASN-GW, ASN PC/LR, SGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

newcall policy { asngw-service | asnpc-service | sgsn-service } { all | name *service_name* **} reject**

newcall policy cscf-service { all | name *service_name* **} { redirect** *target_ip_address* **[weight** *weight_num* **] [** *target_ipaddress2* **[weight** *weight_num* **] ...** *target_ip_address16* **[weight** *weight_num* **] | reject }**

newcall policy { fa-service | lns-service | mipv6ha-service } { all | name *service_name* **} reject**

newcall policy { ha-service | pdsn-service} { all | name *service_name* **} { redirect** *target_ip_address* **[weight** *weight_num* **] [** *target_ipaddress2* **[weight** *weight_num* **] ...** *target_ip_address16* **[weight** *weight_num* **] | reject }**

newcall policy ggsn-service {**apn name** *apn_name* | **all** | **name** *service_name*}**reject**

newcall policy hnbgw-service {**all** | **name** *service_name*}**reject**

newcall policy {**pcc-af-service** | **pcc-policy-service**} {**all** | **name** *service_name*}**reject**

newcall policy mme-service {all | name *service_name* **} reject**

no newcall policy { fa-service | ggsn-service | ha-service | mipv6ha-service | pdsn-service| pdsnclosedrp-service| lns-service } { all | name *service_name* **}**

no newcall policy { ha-service | pdsn-service } { all | name *service_name* **} redirect** *target_ip_address* **[weight***weight_num* **] [** *target_ip_address2* **[weight** *weight_num* **] ...** *target_ip_address16* **[weight***weight_num* **]**

no newcall policy ggsn-service { **apn***apn_name* | **all** | **name** *service_name*} **reject**

no newcall policy { asngw-service | asnpc-service } { all | name *service_name* **}**

no newcall policy hnbgw-service {**all** | **name** *service_name*}

no newcall policy mme-service { all | name *service_name* **}**

no newcall policy {**pcc-af-service** | **pcc-policy-service**} {**all** | **name** *service_name*}

no

Disables the new call policy for all or specified service of a service type.

newcall policy { asngw-service | asnpc-service } { all | name *service_name* **} reject**

Creates a new call policy to reject the calls based on the specified ASN-GW or ASN PC/LR service name or all services of this type.
asngw-service: Specifies the type of service as ASN GW for which new call policy is configured.
asnpc-service: Specifies the type of service as ASN PC/LR for which new call policy is configured.
name *service_name*: Specifies the name of the service for which new call policy is configured. service_name is name of a configured ASN GW or ASN PC/LR service.
reject: Specifies that the policy rejects new incoming calls. Depending on the type of service that the policy is applied to, the reason codes are reported as part of the reply to indicate the rejection. For ASN-GW and ASN PC/LR service rejection code is 81H (Registration Denied - administratively prohibited).

newcall policy { cscf-service | fa-service | lns-service | mipv6ha-service } { all | name *service_name* **} reject**

Creates a new call policy that rejects calls based on the specified access point name.

no newcall policy { cscf-service | fa-service | ggsn-service| ha-service | mipv6ha-service | pdsn-service | } { all | name *service_name* **}**

Removes a previously configured new call policy for the specified service

no newcall policy { ha-service | pdsn-service } { all | name *service_name* **} redirect** *target_ip_address* **[weight** *weight_num* **] [** *target_ip_address2* **[weight** *weight_num* **] ...** *target_ip_address16* **[weight** *weight_num* **]**

Deletes up to 16 IP addresses from the redirect policy. The IP addresses must be expressed in IPv4 dotted-decimal notation

cscf-service | fa-service | ha-service | lns-service | mipv6ha-service | mme-service | pdsn-service | pdsnclosedrp-service

Specifies the type of service for which to configure a new call policy. The following services are supported:

- **cscf-service**: A Call/Session Control Function service
- **fa-service**: A Foreign Agent service
- **ha-service**: A Home Agent service
- **lns-service**: An L2TP Network Server service
- **mipv6ha-service**: A Mobile IPv6 Home Agent service
- **pdsn-service**: A Packet Data Serving Node service

{ all | name *service_name* **}**

Specifies a filter for the new call policy. Whether the new call policy will be applied to all configured services or a specific one.

- **all**: Specifies that the new call policy will be applied to all instances of the selected service type.
- **name**: *service_name*: Specifies the name of a specific instance of the selected service type as an alphanumeric string of 1 through 63 characters that is case sensitive.

redirect *target_ip_address* **[weight** *weight_num* **]** **[** *target_ip_address2* **[weight** *weight_num* **]** ... *target_ip_address16* **[weight** *weight_num* **]**

Configures the busy-out action. When a redirect policy is invoked, the service rejects new sessions and provides the IP address of an alternate destination. This command can be issued multiple times.
target_ip_address# is the IP address of an alternate destination expressed in IPv4 dotted-decimal notation. Up to 16 IP addresses can be specified either in one command or by issuing the redirect command multiple times. If you try to add more than 16 IP addresses to the redirect policy the CLI issues an error message. If you specify an IP address and weight that already exists in the redirect policy the new values override the existing values.
weight *weight_num*: When multiple addresses are specified, they are selected in a weighted round-robin scheme. Entries with higher weights are more likely to be chosen. If a weight is not specified the entry is automatically assigned a weight of 1. *weight_num* must be an integer from 1 through 10.
Depending on the type of service that the policy is applied to, the following reason codes are reported as part of the reply:

- **ha service:** 88H (Registration Denied - unknown home agent address)
- **pdsn service:** 88H (Registration Denied - unknown PDSN address)

Important: The redirect option is not supported for use with FA and GGSN services.

newcall policy hnbgw-service { all | name *service_name***} reject**

Creates a new call policy to reject the calls in a specified HNB-GW service name instance or all HNB-GW services on the system.
name *service_name*: Specifies the name of the HNB-GW service for which new call policy is configured.
reject: Specifies that the policy rejects all new incoming calls. Depending on the type of service that the policy is applied to, the reason codes are reported as part of the reply to indicate the rejection. For HNB-GW service rejection code is 81H (Registration Denied - administratively prohibited).

newcall policy mme-service { all | name *service_name* **} reject**

Creates a new call policy to reject the calls based on the specified MME service name or all MME services on the system.
name *service_name*: Specifies the name of the MME service for which new call policy is configured.
reject: Specifies that the policy rejects new incoming calls. Depending on the type of service that the policy is applied to, the reason codes are reported as part of the reply to indicate the rejection. For MME service rejection code is 81H (Registration Denied - administratively prohibited).

newcall policy {pcc-af-service | pcc-policy-service} {all | name *service_name***}reject**

Creates a new call policy to reject the calls for PCC services on the system for any of the following PCC services:

- **pcc-af-service name** *service_name*: Specifies the Policy and Charging Control-Application Function (PCC-AF) service for which new call policy is to be configured on the system.

  name *service_name*: Specifies the name of an existing PCC-AF service for which new call policy is configured.

- **pcc-policy-service name** *service_name*: Specifies the Policy and Charging Control-Policy (PCC-Policy) service for which new call policy is to be configure on the system.

name *service_name*: Specifies the name of an existing PCC-Policy service for which new call policy is configured.

reject: Specifies that the policy rejects new incoming calls. Depending on the type of service that the policy is applied to, the reason codes are reported as part of the reply to indicate the rejection. For PCC services rejection code is 81H (Registration Denied - administratively prohibited).

reject

Specifies that the policy rejects new incoming calls. Depending on the type of service that the policy is applied to, the following reason codes are reported as part of the reply to indicate the rejection:

- **asngw service**: 81H (Registration Denied - administratively prohibited)
- **fa service:** 41H (administratively prohibited)

Important: When **newcall policy** is set to reject for the FA service, the Busy Bit is set in the Agent Advertisement. Any further RRQs will be rejected with this code value.

- **ggsn service:** C7H (Rejected - no resources available)
- **ha service:** 81H (Registration Denied - administratively prohibited)
- **mipv6ha-service**: 81H (Registration Denied - administratively prohibited)
- **mme service:** 81H (Registration Denied - administratively prohibited)
- **pdsn service:** 81H (Registration Denied - administratively prohibited)

Usage

This command is used to busy-out specific system services prior to planned maintenance or for troubleshooting. This is required when operator find out that the system is somehow overloaded, or needs some kind of maintenances or so.

Example

The following command creates a new call policy to re-direct all new calls for all PDSN services to a device having an IP address of *192.168.1.23*:

```
newcall policy pdsn-service all redirect 192.168.1.23
```

The following command creates a new call policy to reject all new calls for a GGSN service called *ggsn1*:

```
newcall policy ggsn-service name ggsn1 reject
```

The following command creates a new call policy to reject all new calls for an MME service called *MME1*:

```
newcall policy mme-service name MME1 reject
```

The following command creates a new call policy to reject all new calls for an HNB-GW service called *hnbgw1*:

```
newcall policy hnbgw-service name hnbgw1 reject
```

The following command creates a new call policy to reject all new calls for a PCC Policy service called *pcrf1*:

```
newcall policy pcc-policy-service name pcrf1 reject
```

password change

Provides a mechanism for local-user administrative users to change their passwords.

Product

All

Privilege

All local-user administrative levels except as noted below

Syntax

password change [local-user *name* **]**

local-user *name*

Specifies the name of an existing local-user administrative user for which to change the password as an alphanumeric string of 3 through 144 characters that is case sensitive.

Important: This keyword is only available to local-users with an authorization level of security-administrator.

Usage

This command provides a mechanism for local-user administrative users to change their passwords. In addition, it also provides a mechanism for security-administrator local-users to change the password for other local-user accounts.

If the **local-user** keyword is not entered, the system prompts the user for their current password and for the new password. New passwords take effect at the next login. Users that have had their password changed by a security-administrator are prompted to change their passwords at their next login.

New passwords must meet the criteria dictated by the **local-user password** command options in the Global Configuration Mode.

Important: The system does not allow the changing of passwords unless the time limit specified by the **local-user password min-change-interval** has been reached.

Example

The following command, executed by a security-administrator, resets the password for a local-user name *operator12*:

```
password change local-user operator12
```

ping

Verifies ability to communicate with a remote node in the network by passing data packets between and measuring the response. This is accomplished by sending Internet Control Message Protocol (ICMP) echo request packets to the target node (pinging) and waiting for an ICMP response.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Important: Inspector privileges are granted for all variables except **count**. To initiate a ping count, you must have a minimum privilege level of Operator.

Syntax

ping *host* **[broadcast] [count** *num_packets* **] [pattern** *packet_pattern* **] [size** *octet_count* **] [src {** *src_host_name* **|** *src_host_ip_address* **}] [| { grep** *grep_options* **| more }]**

ping *host*

Sends ICMP echo request packets to the remote node specified the node's name (up to 127 alphanumeric characters) or assigned IPv4 address in dotted-decimal notation.

broadcast

Sends ping packets to broadcast addresses.

count *num_packets*

Specifies the number of packets to send to the remote host for verification as an integer from 1 through 10000. Default: 5

pattern *packet_pattern*

Specifies a pattern to use to fill the internet control message protocol packets in hexadecimal format with a value in the range of 0x0000 through 0xFFFF. By default each octet of the packet is encoded with the octet number of the packet.

size *octet_count*

Specifies the number of bytes in each IP datagram as an integer from 40 through 18432. Default: 56

src { src_*host_name* **| src** *host_ip_address* **}**

Specifies an IP address to use in the packets as the source node. Default: originating system's IP address
src_host_name: Specifies the source node using the node's logical host name which must be resolved via DNS lookup.
src_host_ip_address: Specifies the source node using the node's assigned IPv4 address in dotted-decimal notation.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in *Command Line Interface Reference*.

Usage

This command is useful in verifying network routing and if a remote node is able to respond at the IP layer.

Example

The following command is the most basic and will report the results of trying to communication with remote node *remoteABC*.

```
ping remoteABC
```

The following command verifies communication with the remote node *10.2.3.4* using *1000* packets.

```
ping 10.2.3.4 count 1000
```

The following command verifies communication with remote node *remoteABC* while making it appears as though the source is remote node with IP address *10.2.3.4*.

```
ping remoteABC src 10.2.3.4
```

Important: The responses from the remote host to the ping packets will be rerouted to the host specified as the source.

ping6

Specifies ping options for IPv6 addresses.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

ping6 { *hostname* **|** *ipv6 address* **} [count** *num* **] [flood] [pattern** *val* **] [size** *val* **] [src** *ip_address* **] [interface** *string* **] [vrf** *vrf_name*

hostname

Name of the host to be pinged.

ipv6 address

IPv6 address of host to be pinged in colon-separated notation.

count*num*

Sets the number of ping packets to be sent as an integer from 1 through 10000.

flood

Configures ping6 to send packets as quickly as possible, or 100 per second, whichever is faster.

pattern *val*

Specifies the hexadecimal pattern to fill ICMP packets as a hexadecimal number from 0x0 through 0ffff

size *val*

Specifies the size of ICMP datagram (in bytes) as an integer from 40 through 18432. Default: 56.

src *ip_address*

Specifies the source IP address in IPv4 dotted-decimal or IPv6 colon-separated notation.

interface *string*

Specifies the originating source interface name as an alphanumeric string of 1 through 79 characters.

vrf *name*

Specifies the name of an existing VFR as an alphanumeric string of 1 through 63 characters.

Usage

Ping command for IPv6. Note that the command is just “ping6, and not “pingv6.”

Example

Use this command to ping the IPv6 address *2001:0db8:85a3:0000:0000:8a2e:0370:7334*

```
ping6 2001:0db8:85a3:0000:0000:8a2e:0370:7334
```

port switch to

Performs a manual switchover to an available redundant/standby line card or SPIO port.

Default: none.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

port switch to *slot#* **/** *port#*

slot#

Identifies the physical chassis slot where the line card or SPIO card is installed.

port#

Identifies the physical port on the line card or SPIO to automatically switch to.

Usage

This command is used to specify the redundant port on a Line Card (LC). When port redundancy is enabled, if an external network device or cable failure occurs that causes a link down failure on the port, then the redundant port is used.

Important: This command is not supported on all platforms.

Example

```
port switch to 17/1

port switch to 6/11
```

ppp echo-test

Sends link control protocol (LCP) keep-alive echo packet to the peer point-to-point protocol (PPP) connection to verify proper communication between PPP connections, and awaits a response.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator

Syntax

ppp echo-test { callid *call_id* | **imsi** *imsi_id*use | **ipaddr** *ip_address* | **msid** *ms_id* | **username** *user_name* } [*num_packets*] [| { **grep** *grep_options* | **more** }]

callid *call_id*

Specifies the call instance ID for which the PPP link must be verified as a 4-byte hexadecimal number.

imsi *imsi_id*

Specifies the International Mobile Subscriber Identifier (IMSI) for which the PPP link must be verified.

ipaddr *ip_address*

Specifies the IP address for which the PPP link must be verified in IPv4 dotted-decimal notation.

msid *ms_id*

Specifies the mobile subscriber ID for which the PPP link must be verified as 7 to 16 digits of an MIN, or RMI.

username *user_name*

Specifies an existing user for which the PPP link must be verified as an alphanumeric string of 1 through 127 characters.

num_packets

Specifies the number of test packets to generate an integer from 1 through 1000000. Default: 1

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in *Command Line Interface Reference*.

Usage

Use this command to verify the point-to-point protocol communications. This command sends LCP keep-alive echo packet to the peer PPP connection to verify proper communication between PPP connections. **ppp echo-test** command waits for LCP echo response for configured numbers of tries, if response is not

received it will retry configured no of times with an interval of *5* seconds. This command accepts the parameters call ID, IMSI, IP address, MSID, and user name to specify which active PPP session to consider. **ppp echo-test** command makes the dormant session active.

Caution: Issuing this command could negatively impact system performance depending on the number of subscribers using the same name and/or if the number of packets used in the test is large.

LCP includes Echo-Request and Echo-Reply codes in order to provide a Data Link Layer loopback mechanism for use in exercising both directions of the link. This is useful as an aid in debugging, link quality determination, performance testing, and for numerous other functions. Upon reception of an Echo-Request in the LCP Opened state, an Echo-Reply is transmitted.

Example

The following command tests the PPP link to user *user1*.

```
ppp echo-test username user1
```

The following command tests the PPP link to the user assigned IP address *10.2.3.4*.

```
ppp echo-test ipaddr 10.2.3.4
```

The following tests the PPP link associated with call ID *fe80AA12*.

```
ppp echo-test callid fe80aa12
```

radius interim accounting now

Check points current RADIUS accounting messages immediately.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

```
radius interim accounting now
```

Usage

The interim command may be part of a regiment of periodic activities to maintain the chassis.
This command may also be useful in preparation for system monitoring or troubleshooting to set the list of messages to be displayed at a well known time.

radius test

Verifies the RADIUS servers functions for accounting and authentication.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

radius test { accounting | admin authentication | authentication | probe authentication server *ip_addr* **port** *port_no* **[username** *username* **password** *password* **] } { all | [on] | off] | radius group** *group_name user_name* **| server** *server_name* **port** *server_port* **}** *user_name password*

---

accounting

Tests accounting server functionality.

---

admin authentication *name_admin admin_password*

Tests the RADIUS admin authentication.
name_admin: Specifies he name of the administrator as an alphanumeric string of 1 through 127 characters.
admin_password: Specifies the password for the administrator as an alphanumeric string of 1 through 63 characters.

---

authentication

Tests authentication server functionality.

---

all | radius group *group_name user_name* **| server** *server_name* **port** *server_port*

all: Tests all configured servers.
server *server_name* **port** *server_port*: Tests only the server specified by *server_name* and *server_port*. The server must have been previously configured.
radius group *group_name user_name*: Tests all configured authentication servers in a specific RADIUS group for a specific user. Must be followed by the RADIUS group name and user name.
group_name is an alphanumeric string of 1 through 63 characters that specifies the name of server group configured in the specific context for authentication/accounting.

---

on/off

Allows the user to turn RADIUS test accounting on or off.

---

user_name

Specifies the RADIUS user who is to be verified. The user must have been previously configured.

---

password

Specifies the RADIUS user who is to have authentication verified. *password* is only applicable when the **authentication** keyword is specified.

Usage

Test the RADIUS accounting for troubleshooting the system for specific users or to verify all the system RADIUS accounting functions.

Example

The following verifies all RADIUS servers.

```
radius test accounting all

radius test authentication all
```

The following verifies the RADIUS accounting and authentication for user *user1* for the *sampleServer*.

```
radius test accounting server sampleServer port 5000 user1

radius test authentication server sampleServer port 5000 user1 dumyPwd
```

The following commands will verify the RADIUS accounting and authentication for RADIUS server group *star1* for the current context:

```
radius test accounting server sampleServer port 5000 user1

radius test authentication server sampleServer port 5000 user1 dummyPwd

radius test authentication all
```

The following verifies the RADIUS authentication server group *star1* for user *user1*.

```
radius test authentication radius group star1 user1
```

reload

Invokes a full system reboot. All processes are terminated and the system initiates a hardware reset (reboot). This command is identical to the **shutdown** command.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
reload [ -noconfirm ]
```

-noconfirm

Executes the command without any additional prompts or confirmation from the user.

Usage

The system performs a hardware reset and reloads the highest priority boot image and configuration file specified in the boot.sys file. Refer to the **boot system priority** command in the Global Configuration Mode for additional information on configuring boot images, configuration files and priorities.

Important: To avoid the abrupt termination of subscriber sessions, it is recommended that a new call policy be configured and executed prior to invoking the **reload** command. This policy sets busy-out conditions for the system and allows active sessions to terminate gracefully. Refer to the **newcall** command in the Exec Mode for additional information.

Caution: Issuing this command causes the system to become unavailable for session processing until the reboot process is complete.

Example

The following command performs a hardware reset on the system:

```
reload
```

rename

Changes the name of an existing local file.

Product

All

Privilege

Security Administrator, Administrator

Syntax

rename *from_filepath to_filepath* **[-noconfirm]**

from_filepath

Specifies the path to the file/directory to be renamed. The path must be formatted according to the following format:
`[file: ]{ /flash | /pcmcia1 | /hd }[ /directory ]/file_name`

Important: Use of the SMC hard drive is not supported in this release.

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name
filename is the actual file of interest

to_filepath

Specifies the new name of file/directory. The path must be formatted as follows:
`[file: ]{ /flash | /pcmcia1 | /hd }[ /directory ]/file_name`

Important: Use of the SMC hard drive is not supported in this release.

directory is the directory name
filename is the actual file of interest

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Important: Extreme caution should be taken when using the **-noconfirm** option. The paths to the source and the destination should be verified prior to performing the command.

Usage

Rename files as part of regular system maintenance in conjunction with the delete command.

Example

The following renames the directory */pub* in the local PCMCIA1 device.

```
rename /pcmcia1/pub /pcmcia1/pub_old
```

reveal disabled commands

Enables or disables the input of commands for features that do not have license keys installed. The output of the command **show cli** indicates when this feature is enabled. This command effects the current CLI session only and is disabled by default.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

```
[ no ] reveal disabled commands
```

no

Does not show disabled commands.

reveal disabled commands

Shows disabled commands.

Usage

When this command is enabled and a disabled command is entered, a message is displayed that informs you that the required feature is not enabled and also lists the name of the feature that you need to support the command.
When this command is disabled and a disabled command is entered, the CLI does not acknowledge the existence of the command and displays a message that the keyword is unrecognized.

Example

The following command sets the CLI to accept disabled commands and display the required feature for the current CLI session with the following command:

```
reveal disabled commands
```

The following command sets the CLI to reject disabled commands and return an error message for the current CLI session:

```
no reveal disabled commands
```

rlogin

Attempts to connect to a remote host.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

rlogin { *host_name* | *host_ip_address* } [user *user_name*]

host_name* | *host_ip_address

Identifies the remote node with which to attempt connection.
host_name: Specifies the remote node using the node's logical host name which must be resolved via DNS lookup.
host_ip_address: Specifies the remote node using its assigned IP address in IPv4 dotted-decimal notation.

user *user_name*

Specifies a user name attempting connection as an alphanumeric string of 1 through 1023 characters.

Usage

Connect to remote network elements using rlogin.

Important: **rlogin** is not a secure method of connecting to a remote host. **ssh** should be used whenever possible for security reasons.

Example

The following connects to remote host *remoteABC* as user *user1*.

```
rlogin remoteABC user user1
```

The following connects to remote host *10.2.3.4* without any default user.

```
rlogin 10.2.3.4
```

rmdir

Removes (deletes) a local directory.

Product

All

Privilege

Security Administrator, Administrator

Syntax

rmdir *path* **[force]**

path

Specifies the directory path to remove. The must be formatted according as follows:
[**file:**]{ **/flash** | **/pcmcia1** | **/hd** }[**/***directory*]**/***file_name*

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name
filename is the actual file of interest

force

Over-rides any warnings to force deletion of the directory and any files contained therein.

Important: Use of the **force** keyword should be done with care to ensure the directory is specified accurately as there is no method to recover a directory which has been removed.

Usage

Remove old directories as part of regular maintenance.

Example

The following removes the local directory */pcmcia1/pub*.

```
rmdir /pcmcia1/pub
```

rotate-hd-file

Rotates the Diameter files stored on the hard disk drive.

Product

SGW, PGW, HSGW

Privilege

Security Administrator, Administrator

Syntax

rotate-hd-file diameter [name *policy_name* **]**

name *policy_name*

Specifies the hd-storage policy name of an existing HD Storage Policy as an alphanumeric string of 0 through 63 characters.

Usage

Use this command to manually rotate the Diameter HD stored files.

Example

The following command rotates Diameter files that were stored using the HD storage policy named CDR1:

rotate-hd-file diameter name *CDR1*

save configuration

Saves the configuration of current contexts to a local or remote location. The configuration contains the sequence of CLI commands that define system parameters and ends with the **.cfg** extension.

Product

All

Privilege

Security Administrator, Administrator

Syntax

save configuration *url* **[obsolete-encryption |showsecrets | verbose] [-redundant] [-noconfirm]**

url

Default: saves to the location of the active configuration currently loaded.
Specifies the location in which to store the configuration file. *url* may refer to a local or a remote file and must be entered in the following format:
[file:] { /flash | /pcmcia1 | /hd-raid } [/*directory***] /***file_name***
tftp:// {** *host* **[:** *port#* **] } [/***directory***] /***file_name***
[ftp: | sftp:] // [** *username* **[:***password***] @] {** *host* **} [:** *port#* **] [/***directory***] /** *file_name*

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name.
filename is the actual file of interest.
username is the user to be authenticated.
password is the password to use for authentication.
host is the IP address or host name of the server.

Important: *hostname* can **only** be used if the **networkconfig** parameter is configured for DHCP and the DHCP server returns a valid nameserver.

port# is the logical port number that the communication protocol is to use.

[obsolete-encryption |showsecrets | verbose]

Specifies options when saving the configuration file.

obsolete-encryption: Saves the configuration with encrypted values generated via an obsolete encryption method. This option may be required to preserve a configuration for a possible downgrade.

showsecrets: Saves the CLI configuration file with all passwords in plain text, rather than their default encrypted format.

verbose: Saves as much information as possible, including default values. If this option is not specified, the configuration will not include default values.

-redundant

Saves the configuration file to the local device on the System Management Card (SMC), defined by the *url* variable, and then automatically copies that same file to the like device on the standby SMC, if available.

Important: This keyword will only work for local devices that are located on both the active and standby SMCs. For example, if you save the file to the **/pcmcia1** device on the active SMC, that same type of device (**pcmcia1**) must be available on the standby SMC. Otherwise, a failure message is displayed. When saving the file to an external network (non-local) device, the system disregards this keyword.

Important: This keyword does not synchronize the local file system. If you have added, modified, or deleted other files or directories to or from a local device for the active SMC, then you must synchronize the local file system on both SMCs.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Important: Exercise caution when using the **-noconfirm** option as this will overwrite data if the URL targets an existing file.

Usage

Backup the current configuration as part of periodic maintenance activities in case of emergencies.

Important: Saving a configuration does not save the boot options as configured via the Global Configuration mode **boot** commands.

Example

The following saves the configuration data to the local file */flash/pub/juneconfig.cfg* with no confirmation from the user:

```
save configuration /flash/pub/juneconfig.cfg -noconfirm
```

The following saves the configuration data to remote host *remoteABC* as */pub/juneconfig.cfg*:

```
save configuration tftp://remoteABC/pub/juneconfig.cfg
```

save logs

Saves the current log file to a local or remote location.

Product

All

Privilege

Security Administrator, Administrator

Syntax

save logs { url } [active] [inactive] [callid *call_id* **] [event-verbosity** *evt_verboseness* **] [facility** *facility* **] [level** *severity_level* **] [pdu-data** *pdu_format* **] [pdu-verbosity** *pdu_verboseness* **] [since** *from_date_time* **[until** *to_date_time* **]] [| { grep** *grep_options* **| more }]**

url

Specifies the location to store the log file(s). *url* may refer to a local or a remote file and must be entered in the following format.
[**file:**] { **/flash** | **/pcmcia1** | **/hd** } [**/***directory*]**/***file_name*
tftp://{ *host*[*:port#*] } [**/***directory*]**/***file_name*
[ftp: | sftp:]//[*username*[*:password*]**@**] { *host* } [*:port#*] [**/***directory*]**/***file_name*

Important: Use of the SMC hard drive is not supported in this release.

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name.
filename is the actual file of interest.
username is the user to be authenticated.
password is the password to use for authentication.
host is the IP address or host name of the server.

Important: *hostname* can only be used if the **networkconfig** parameter is configured for DHCP and the DHCP server returns a valid nameserver.

port# is the logical port number that the communication protocol is to use.

active

Saves data from active logs.

inactive

Saves data from inactive logs.

callid *call_id*

Specifies a call ID for which log information is to be saved as a 4-byte hexadecimal number.

event-verbosity *evt_verboseness*

Specifies the level of verboseness to use in displaying of event data as one of:

- *min*: Logs minimal information about the event. Information includes event name, facility, event ID, severity level, date, and time.
- *concise*: Logs detailed information about the event, but does not provide the event source within the system.
- *full*: Logs detailed information about event, including source information, identifying where within the system the event was generated.

facility *facility*

Specifies the facility to modify the filtering of logged information. Valid facilities for this command are:

- **a10**: A10 interface facility
- **a11**: A11 interface facility
- **a11mgr**: A11 Manager facility
- **aaa-client**: AAA client facility
- **aaamgr**: AAA manager logging facility
- **aaaproxy**: AAA Proxy facility
- **aal2**: AAL2 protocol logging facility
- **acl-log**: Access Control List logging facility
- **acsctrl**: Active Charging Service (ACS) Controller facility
- **acsmgr**: Active Charging Service (ACS) Manager facility
- **alarmctrl**: Alarm Controller facility
- **alcap**: ALCAP protocol logging facility
- **alcapmgr**: ALCAPMgr logging facility
- **all**: All facilities
- **asngwmgr**: ASN Gateway Manager facility
- **asnpcmgr**: ASN Paging Controller Manager facility
- **bfd**: BFD protocol logging facility
- **bgp**: Border Gateway Protocol (BGP) facility
- **bindmux**: IPCF BindMux-De-mux Manager logging facility
- **bssap+**: Base Station Sub-system Application Part+ protocol facility for the login interface between the SGSN and the MSC/VLR (2.5G and 3G)
- **bssgp**: Base Station Sub-system GPRS Protocol logging facility handles exchange information between the SGSN and the BSS (2.5G only)
- **callhome**: Call home application logging facility
- **cap**: CAMEL Application Part (CAP) logging facility for protocol used in prepaid applications (2.5G and 3G)

- **cli**: CLI logging facility
- **credit-control**: Credit Control facility
- **cscf**: IMS/MMD CSCF
- **cscfmgr**: SIP CSCF Manager facility
- **cscfttmgr**: SIP CSCFTT Manager facility
- **csp**: Card Slot Port controller facility
- **css**: Content Service Selection (CSS) facility
- **css-sig**: Content Service Selection (CSS) RADIUS Signaling facility
- **cx-diameter**: Cx Diameter Messages facility
- **dcardctrl**: IPSEC Daughter Card Controller logging facility
- **dcardmgr**: IPSEC Daughter Card Manager logging facility
- **demuxmgr**: Demux Manager API facility
- **dgmbmgr**: Diameter Gmb Application Manager logging facility
- **dhcp**: Dynamic Host Configuration Protocol logging facility
- **dhcpv6**: DHCPv6
- **dhost**: Distributed Host logging facility
- **diabase**: Diabase messages facility
- **diameter**: Diameter endpoint logging facility
- **diameter-acct**: Diameter Accounting
- **diameter-auth**: Diameter Authentication
- **diameter-dns**: Diameter DNS subsystem
- **diameter-ecs**: ACS Diameter signaling facility
- **diameter-hdd**: Diameter HDD Interface facility
- **diameter-svc**: Diameter Service
- **diamproxy**: DiamProxy logging facility
- **dpath**: IPSEC Data Path facility
- **drvctrl**: Driver Controller facility
- **eap-ipsec**: EAP
- **eap-sta-s6a-s13-s6b-diameter**: EAP/STA/S6A/S13/S6B Diameter messages facility
- **ecs-css**: ACSMGR <-> Session Manager Signalling Interface facility
- **egtpc**: eGTP-C logging facility
- **egtpmgr**: eGTP manager logging facility
- **egtpu**: eGTP-U logging facility
- **epdg**: ePDG logging facility
- **evlog**: Event log facility
- **famgr**: Foreign Agent manager logging facility
- **firewall**: Firewall logging facility

- **fng**: FNG logging facility
- **gmm**:
  - For 2.5G: Logs the GPRS Mobility Management (GMM) layer (above LLC layer)
  - For 3G: Logs the access application layer (above the RANAP layer)
- **gprs-app**: GPRS Application logging facility
- **gprs-ns**: GPRS Network Service Protocol (layer between SGSN and the BSS) logging facility
- **gq-rx-tx-diameter**: Gq/Rx/Tx Diameter messages facility
- **gss-gcdr**: GTPP Storage Server GCDR facility
- **gtpc**: GTP-C protocol logging facility
- **gtpcmgr**: GTP-C protocol Manager logging facility
- **gtpp**: GTP-PRIME protocol logging facility
- **gtpu**: GTP-U protocol logging facility
- **gtpumgr**: GTPU Demux manager
- **gx-ty-diameter**: Gx/Ty Diameter messages facility
- **gy-diameter**: Gy Diameter messages facility
- **hamgr**: Home Agent manager logging facility
- **hat**: High Availability Task (HAT) process facility
- **hdctrl**: HD Controller logging facility
- **hnb-gw**: HNB-GW (3G Femto GW) logging facility
- **hnbmgr**: HNBMGR (3G Femto GW DemuxMgr) logging facility
- **hss-peer-service**: HSS Peer Service facility
- **igmp**: IGMP
- **ikev2**: IKEv2
- **ims-authorizatn**: IMS Authorization Service facility
- **ims-sh**: HSS SH Service facility
- **imsimgr**: SGSN IMSI Manager facility
- **imsue**: IMSUE
- **ip-arp**: IP Address Resolution Protocol facility
- **ip-interface**: IP interface facility
- **ip-route**: IP route facility
- **ipms**: IPMS logging facility
- **ipsec**: IP Security logging facility
- **ipsg**: IP Service Gateway interface logging facility
- **ipsgmgr**: IP Services Gateway facility
- **ipsp**: IP Pool Sharing Protocol logging facility
- **kvstore**: KV Store facility
- **l2tp-control**: L2TP control logging facility

- **l2tp-data**: L2TP data logging facility
- **l2tpdemux**: L2TP Demux Manager logging facility
- **l2tpmgr**: L2TP Manager logging facility
- **lagmgr**: LAGMGR logging facility
- **ldap**: Lightweight Directory Access Protocol (LDAP) messages logging facility
- **li**: Refer to the *Lawful Intercept Interface Reference* for a description of this command.
- **linkmgr**: SGSN/BSS SS7 Link Manager logging facility (2.5G only)
- **llc**: Logical Link Control (LLC) Protocol logging facility; for SGSN: logs the LLC layer between the GMM and the BSSGP layers for logical links between the MS and the SGSN
- **local-policy**: Local Policy Service facility
- **m3ua**: M3UA Protocol logging facility
- **magmgr**: Mobile Access Gateway manager logging facility
- **map**: MAP Protocol logging facility
- **megadiammgr**: Megadiameter Manager (SLF Service) logging facility
- **mme-app**: Mobility Management Entity Application logging facility
- **mme-misc**: MME miscellaneous logging facility
- **mmedemux**: Mobility Management Entity Demux Manager logging facility
- **mmemgr**: MME Manager facility
- **mmgr**: Master Manager logging facility
- **mobile-ip**: Mobile IP processes
- **mobile-ip-data**: Mobile IP data facility
- **mobile-ipv6**: Mobile IPv6 logging facility
- **mpls**: MPLS protocol logging facility
- **mseg-app**: MSEG application logging facility
- **mseg-gtpc**: MSEG GTPC application logging facility
- **mseg-gtpu**: MSEG GTPU application logging facility
- **msegmgr**: MSEGMgr (MSEG DemuxMgr) logging facility
- **mtp2**: MTP2 Service logging facility
- **mtp3**: MTP3 Protocol logging facility
- **multicast-proxy**: Multicast Proxy logging facility
- **npuctrl**: Network Processor Unit Control facility
- **npumgr**: Network Processor Unit Manager facility
- **npumgr-acl**: NPUMGR ACL logging facility
- **npumgr-flow**: NPUMGR FLOW logging facility
- **npumgr-fwd**: NPUMGR FWD logging facility
- **npumgr-init**: NPUMGR INIT logging facility
- **npumgr-port**: NPUMGR PORT logging facility

- **npumgr-recovery**: NPUMGR RECOVERY logging facility
- **ntfy-intf**: Notification Interface logging facility
- **orbs**: Object Request Broker System logging facility
- **ospf**: OSPF protocol logging facility
- **ospfv3**: OSPFv3 protocol logging facility
- **p2p**: Peer-to-Peer Detection logging facility
- **pccmgr**: IPCF PCC Manager library
- **pdg**: PDG logging facility
- **pdgdmgr**: PDG Demux Manager logging facility
- **pdif**: PDIF logging facility
- **pgw**: PDN Gateway logging facility
- **phs**: Payload Header Suppression
- **phs-control**: PHS X1/X5 and X2/X6 Interface logging facility
- **phs-data**: PHS Data logging facility
- **phs-eapol**: PHS EAPOL logging facility
- **phsgwmgr**: PHS Gateway Manager facility
- **phspcmgr**: PHS Paging Controller Manager facility
- **pmm-app**: PMM application logging facility
- **ppp**: PPP link and packet facilities
- **pppoe**: PPPOE logging facility
- **push**: VPNMGR CDR push logging facility
- **radius-acct**: RADIUS accounting logging facility
- **radius-auth**: RADIUS authentication logging facility
- **radius-coa**: RADIUS change of authorization and radius disconnect
- **ranap**: Radio Access Network Application Part (RANAP) Protocol facility logging info flow between SGSN and RNS (3G)
- **rct**: Recovery Control Task logging facility
- **rdt**: Redirect Task logging facility
- **resmgr**: Resource Manager logging facility
- **rf-diameter**: Rf Diameter messages facility
- **rip**: RIP logging facility (RIP is not supported at this time.)
- **rohc**: RObust Header Compression facility
- **rsvp**: Reservation Protocol logging facility
- **rua**: RUA (3G Femto GW - RUA messages) logging facility
- **s1ap**: S1AP Protocol logging facility
- **sccp:** SCCP Protocol logging connection-oriented messages between RANAP and TCAP layers.
- **sct**: Shared Configuration Task logging facility

- **sctp**: SCTP Protocol logging facility
- **sessctrl**: Session Controller logging facility
- **sessmgr**: Session Manager logging facility
- **sesstrc**: session trace logging facility
- **sft**: Switch Fabric Task logging facility
- **sgs**: SGs protocol logging facility
- **sgsn-app**: SGSN-APP logging various SGSN 'glue' interfaces, e.g., between PMM, MAP,. GPRS-FSM, SMS.
- **sgsn-failures**: SGSN call failures (attach/activate rejects) logging facility (2.5G)
- **sgsn-gtpc**: SGSN GTP-C Protocol logging control messages between the SGSN and the GGSN
- **sgsn-gtpu**: SGSN GTP-U Protocol logging user data messages between the SGSN and GGSN
- **sgsn-mbms-bearer**: SGSN MBMS Bearer app (SMGR) logging facility
- **sgsn-misc**: Used by stack manager to log binding and removing between layers
- **sgsn-system**: SGSNs System Components logging facility; used infrequently
- **sgsn-test**: SGSN Tests logging facility; used infrequently
- **sgtpcmgr**: SGSN GTPC Manager logging information exchange through SGTPC and the GGSN
- **sgw**: Serving Gateway facility
- **sh-diameter**: Sh Diameter messages facility
- **sitmain**: System Initialization Task main logging facility
- **sm-app**: SM Protocol logging facility
- **sms**: Short Message Service (SMS) logging messages between the MS and the SMSC
- **sndcp**: SNDCP Protocol logging facility
- **snmp**: SNMP logging facility
- **sprmgr**: IPCF SPR Manager logging facility
- **srdb**: Static Rating Database
- **srp**: Service Redundancy Protocol (SRP) logging facility
- **sscfnni**: SSCFNNI Protocol logging facility
- **sscop**: SSCOP Protocol logging facility
- **ssh-ipsec**: SSH IP Security logging facility
- **ssl**: SSL (Secure socket layer messages) logging facility
- **stat**: Statistics logging facility
- **system**: System logging facility
- **tacacsplus**: TACACS+ Protocol logging facility
- **tcap**: TCAP Protocol logging facility
- **testctrl**: Test Controller logging facility
- **testmgr**: Test Manager logging facility
- **threshold**: threshold logging facility

- **ttg**: TTG logging facility
- **tucl**: TUCL logging facility
- **udr**: User detail record facility (used with the Charging Service)
- **user-data**: User data logging facility
- **user-l3tunnel**: User layer-3 tunnel logging facility
- **usertcp-stack**: User TCP Stack
- **vpn**: Virtual Private Network logging facility
- **wimax-data**: WiMAX DATA
- **wimax-r6**: WiMAX R6

---

level *severity_level*

Specifies the level of information to be logged from the following list which is ordered from highest to lowest:

- *critical*: Logs critical events
- *error*: Logs error events and all events with a higher severity level
- *warning*: Logs warning events and all events with a higher severity level
- *unusual*: Logs unusual events and all events with a higher severity level
- *info*: Logs info events and all events with a higher severity level
- *trace*: Logs trace events and all events with a higher severity level
- *debug*: Logs all events

---

pdu-data *pdu_format*

Specifies output format for the display of packet data units as one of:

- *none* - raw format (unformatted).
- *hex* - hexadecimal format.
- *hex-ascii* - hexadecimal and ASCII similar to a main-frame dump.

---

pdu-verbosity *pdu_verboseness*

Specifies the level of verboseness to use in displaying of packet data units as a value from 1 to 5, where 5 is the most detailed.

---

since *from_date_time* **[until** *to_date_time* **]**

Default: no limit.

since *from_date_time*: Saves only the log information which has been collected more recently than *from_date_time*.

until *to_date_time*: Saves no log information more recent than *to_date_time*. Defaults to current time when omitted.

from_date_time and *to_date_time* must be formatted as YYYY:MM:DD:HH:mm or YYYY:MM:DD:HH:mm:ss. Where:

- YYYY = 4-digit year
- MM = 2-digit month in the range 01 through 12
- DD = 2-digit day in the range 01 through 31

- HH = 2-digit hour in the range 00 through 23
- mm = 2-digit minute in the range 00 through 59
- ss = 2 digit second in the range 00 through 59

to_date_time must be a time which is more recent than *from_date_time*.
Using the **until** keyword allows for a time range of log information; using only the **since** keyword will display all information up to the current time.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in *Command Line Interface Reference*.

Usage

Backup the current log file as part of periodic maintenance activities.

Example

The following saves the log to the local file */flash/pub/junelogs.logs* with no confirmation from the user:

```
save logs /flash/pub/junelogs.logs -noconfirm
```

The following saves the configuration data to remote host *remoteABC* as */pub/junelogs.logs*:

```
save logs tftp://remoteABC/pub/junelogs.logs
```

session trace

Enable or disables the subscriber session trace functionality based on a specified subscriber device or ID on one or all instance of session on a specified UMTS/EPS network element. It also clears/resets the statistics collected for subscriber session trace on a system.

Product

GGSN, MME, P-GW, S-GW

Privilege

Operator

Syntax

session trace { reset statistics | subscriber network-element { mme | pgw | sgw | ggsn } { imei *id* **| imsi** *id* **| interface { all |** *interface* **} } trace-ref** *id* **collection-entity** *ip_address***}**

no session trace subscriber network-element [mme | pgw | sgw | ggsn] [trace-ref *id* **]**

no

Disables the entire session trace or for a specific network element and/or trace reference.

reset statistics

Clears/resets the entire session trace statistical data collected on a system.

Caution: This is a system wide command that affects all statistical data.

session trace subscriber network-element { mme | pgw | sgw | ggsn }

Identifies the network element that, in turn, identifies the interfaces where the session trace is to occur. Specific interfaces can be specified using the interface keyword described below.
ggsn: Specifies that the session trace is to occur on one or all interfaces on the GGSN.
mme: Specifies that the session trace is to occur on one or all interfaces on the MME.
pgw: Specifies that the session trace is to occur on one or all interfaces on the P-GW.
sgw: Specifies that the session trace is to occur on one or all interfaces on the S-GW.

imei *id*

Specifies the International Mobile Equipment Identification number of the subscriber UE. *id* must be the 8-digit TAC (Type Allocation Code) and 6-digit serial number. Only the first 14 digits of the IMEI/IMEISV are used to find the equipment ID.

imsi *id*

Specifies the International Mobile Subscriber Identification (IMSI). *id* must be the 3-digit MCC (Mobile Country Code), 2- or 3- digit MNC (Mobile Network Code), and the MSIN (Mobile Subscriber Identification Number). The total should not exceed 15 digits.

interface { all | *interface* **}**

Specifies the interfaces where the session trace application will collect data.

all: Specifies all interfaces associated with the selected network element
interface: Specifies the interface type where the session trace application will collect trace data. The following interfaces are applicable for the network element type:

- GGSN:
  - **gi**: Specifies that the interface where the trace will be performed is the Gi interface between the GGSN and RADIUS server.
  - **gmb**: Specifies that the interface where the trace will be performed is the Gmb interface between the GGSN and BM-SC.
  - **gn**: Specifies that the interface where the trace will be performed is the Gn interface between the GGSN and the SGSN.
  - **gx**: Specifies that the interface where the trace will be performed is the Gx interface between the GGSN and PCRF.
- MME:
  - **s1mme**: Specifies that the interface where the trace will be performed is the S1-MME interface between the MME and the eNodeB.
  - **s3**: Specifies that the interface where the trace will be performed is the S3 interface between the MME and an SGSN.
  - **s6a**: Specifies that the interface where the trace will be performed is the S6a interface between the MME and the HSS.
  - **s10**: Specifies that the interface where the trace will be performed is the S10 interface between the MME and another MME.
  - **s11**: Specifies that the interface where the trace will be performed is the S11 interface between the MME and the S-GW.
- P-GW:
  - **gx**: Specifies that the interface where the trace will be performed is the Gx interface between the P-GW and the PCRF.
  - **s2a**: Specifies that the interface where the trace will be performed is the S2a interface between the P-GW and the HSGW.
  - **s2b**: Specifies that the interface where the trace will be performed is the S2b interface between the P-GW and an ePDG.
  - **s2c**: Specifies that the interface where the trace will be performed is the S2c interface between the P-GW and a trusted, non-3GPP access device.
  - **s5**: Specifies that the interface where the trace will be performed is the S5 interface between the P-GW and the S-GW.
  - **s6b**: Specifies that the interface where the trace will be performed is the S6b interface between the P-GW and the 3GPP AAA server.
  - **s8b**: Specifies that the interface where the trace will be performed is the S8b interface between the P-GW and the S-GW.
  - **sgi**: Specifies that the interface where the trace will be performed is the SGi interface between the P-GW and the PDN.
- S-GW:
  - **gxc**: Specifies that the interface where the trace will be performed is the Gxc interface between the S-GW and the PCRF.

- **s11**: Specifies that the interface where the trace will be performed is the S11 interface between the S-GW and the MME.
- **s4**: Specifies that the interface where the trace will be performed is the S4 interface between the S-GW and an SGSN.
- **s5**: Specifies that the interface where the trace will be performed is the S5 interface between the S-GW and the P-GW.
- **s8b**: Specifies that the interface where the trace will be performed is the S8b interface between the S-GW and the P-GW.

trace-ref *id*

Specifies the trace reference for the trace being initiated. *id* must be the MCC (3 digits), followed by the MNC (3 digits), then the trace ID number (3-byte octet string).

collection-entity *ip_address*

Specifies the IP address of the collection entity where session trace data is pushed in IPv4 dotted-decimal notation.

Usage

Use this command to initiate a session trace for a specified subscriber device or ID on one or all interfaces on a specified network element.

Important: Session trace configuration is performed in the *Global Configuration Mode* using the **session trace** command. Refer to the *Global Configuration Mode Commands* chapter for more information.

Example

The following command initiates a session trace on a P-GW S5 interface for a subscriber with an IMSI of *322233123456789* and sets the trace reference as *322233987654* and the collection entity IP address as *10.2.3.4*:

```
session trace subscriber network-element pgw imsi 322233123456789
interface s5 trace-ref 322233987654 collection-entity 10.2.3.4
```

The following command initiates a session trace on an MME S6a interface for a subscriber with an IMSI of *322233123456789* and sets the trace reference as *322233987654* and the collection entity IP address as *10.2.3.4*:

```
session trace subscriber network-element mme imsi 322233123456789
interface s6a trace-ref 322233987654 collection-entity 10.2.3.4
```

The following command initiates a session trace on a Gn interface on GGSN between GGSN and SGSN for a subscriber with an IMSI of *322233123456789* and sets the trace reference as *322233987654* and the collection entity IP address as *1.2.3.4*:

```
session trace subscriber network-element ggsn imsi 322233123456789
interface gn trace-ref 322233987654 collection-entity 10.2.3.4
```

setup

Enters the system setup wizard which guides the user through a series of questions regarding the system basic configuration options, such as initial context-level administrative users, host name, etc.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
setup
```

Usage

The setup wizard provides a user friendly interface for initial system configuration.

Important: If the configuration script generated by the setup wizard is applied when an existing configuration is in use, the options which are common to both are updated and all remaining options are left unchanged.

Example

```
setup
```

sgs offload

This command starts/stops the marking of subscribers associated with the specified Visitor Location Register (VLR) to an offload state. This enables the MME to preemptively move subscribers away from an MSS which is scheduled to be put in maintenance mode.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

sgs offload sgs-service *sgs_svc_name* **vlr** *vlr_name* **{ start time-duration** *minutes* **| stop } [-noconfirm]**

sgs-service *sgs_svc_name*

Specifies the SGs service to which the VLR belongs.
sgs_svc_name specifies the name for a pre-configured SGs service to associate with the MME service and must be an alphanumeric string of 1 through 63 characters. For more information on the SGs service, refer to the **sgs-service** command in the *Context Configuration Mode Commands* chapter and refer to the *MME SGs Service Configuration Mode Commands* chapter.

vlr *vlr_name*

Specifies the VLR service which should be marked in an offload state.
vlr_name specifies the name for a pre-configured VLR to associate with the SGs service and must be an alphanumeric string of 1 through 63 characters. For more information, refer to the **vlr** command in the *MME SGs Service Configuration Mode Commands* chapter.

start time-duration *minutes*

Specifies that the offload state should be set for the specified the VLR.
time-duration defines the period in *minutes* over which all qualifying subscribers will be marked in offload state. For example, a setting of 40 minutes with 40000 subscribers will result in a release rate of 1000 per minute. *minutes* must be an integer from 1 to 1000.
Note: While the **time-duration** value is not used in Release 12.2 or earlier, it is required for completion of the **start** command.

stop

Specifies that the offload state should no longer be set for the specified the VLR.

-noconfirm

Indicates that the command is to execute without additional prompt and confirmation from the user.

Usage

When this offload command is set on the MME, all sessions matching this VLR are marked with an ‘offload’ flag. During the next UE activity, the MME requires each UE to perform a combined TAU/LAU.

When issuing the command to place a VLR in an offload state, the MME notifies the operator if this is the last available VLR in a pool.
More than one VLR may be offloaded at the same time.
Related Commands:

- To display VLR offload information and statistics for a specified SGs service name, refer to the **show sgs-service offload service-name** *sgs_svc_name* command.

Example

The following command starts marking the subscribers associated with *vlr1* for offload.

```
sgs offload sgs-service sgs1 vlr vlr1 start time-duration 60 -noconfirm
```

sgsn clear-detached-subscriptions

Clears subscription data belonging to a subscriber who has already detached.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

```
sgsn clear-detached-subscriptions imsi imsi
```

imsi *imsi*

Specifies the international mobile subscriber identity (IMSI) of the subscriber session identifying the subscription data to be cleared.

Usage

This command can be issued on either a 2G or 3G SGSN to clear subscription data (including subscription information, and information for P-TMSI allocated, received authorization vectors, and NGAF flag values). This command is only effective if the subscriber has already detached.
After the data is purged, the SGSN sends an appropriate message to the HLR.
Related Commands:

- To clear subscription data for subscribers that are currently attached, refer to the **admin-disconnect-behavior clear-subscription** commands described in the chapters for *GPRS Service Configuration Mode* or the *SGSN Service Configuration Mode*.

Example

```
sgsn clear-detached-subscriptions imsi 040501414199978
```

sgsn imsimgr

Initiates an audit for managing the SGSN's IMSI manager's (IMSIMgr) IMSI table.

Important: These commands are used primarily for troubleshooting purposes and are intended for the use of specially trained service representatives.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

sgsn imsimgr { add-record *imsi* **sessmgr instance** *sessmgr#* **| audit-with sessmgr { all | instance** *sessmgr#* **} | remove-record** *imsi* **}**

add-record *imsi*

Adds a record for an IMSI to the IMSI manager's table and associates a specific session manager (SessMgr) with the IMSI.
imsi: Enter up to 15 digits. An IMSI consists of the 3-digit MCC (mobile country code) + the 2- or 3-digit MNC (mobile network code) + the MSIN (mobile station identification number) for the remaining 10 or 9 digits (depending on the length of the MNC).

sessmgr instance *sessmgr#*

Specifies a Session Manager (SessMgr) instance associated with the IMSI as an integer from 0 through 4095.

audit-with sessmgr { all | instance *sessmgr#* **}**

Initiates an IMSI audit with all SessMgrs or a Session Manager (SessMgr) instance specified as an integer from 0 to 4095.

remove-record *imsi*

Deletes a specific IMSI from the IMSI table.
imsi: Enter up to 15 digits. An IMSI consists of the 3-digit MCC (mobile country code) + the 2- or 3-digit MNC (mobile network code) + the MSIN (mobile station identification number) for the remaining 10 or 9 digits (depending on the length of the MNC).

Usage

Use this command to manage the IMSIMgr's IMSI table, and to initiate an audit of one or more SessMgrs with the IMSIMgr so that the IMSI table has the correct IMSI-SessMgr association. After this audit, any IMSI in the IMSIMGR which is not found in any Sessmgr is deleted and similarly any missing entries at the IMSIMgr are created.

Example

Delete IMSI *044133255524211* from the audit table:

```
sgsn imsimgr remove-record 044133255524211
```

sgsn offload

Instructs the SGSN to begin the offloading procedure and actually starts and stops the offloading of subscribers which is part of the SGSN Gb (2G) or Iu (3G) Flex load redistribution functionality.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

sgsn offload [gprs-service *srvc_name* **| sgsn-service** *srvc_name* **}** *srvc_name* **{ activating [nri-value** *nri_value* **| stop nri-value** *nri_value* **] | connecting [nri-value** *nri_value* **| stop [nri-value** *nri_value* **| target-nri** *target_nri* **target-count** *target_count* **] | t3312-timeout** *seconds* **| target-nri** *target_nri* **target-count** *target_count* **] }**

gprs-service *srvc_name*

Specifies a unique alphanumeric string of 1 through 63 characters that identifies a GPRS service that has already been defined for the 2G SGSN configuration.

sgsn-service *srvc_name*

Specifies a unique alphanumeric string of 1 through 63 characters that identifies an SGSN service that has already been defined for the 3G SGSN configuration.

activating

Instructs the SGSN to off load any subscribers sending an “activate request” message.

connecting

Instructs the SGSN to off load any subscribers sending either an “attach request” or a “RAU request” message.

nri-value *nri-value*

Sets the local NRI. Including this keyword in the configuration instructs the SGSN to check the P-TMSI and use the SGSN matching the configured NRI value to off load subscribers.

Important: **nri-value** and **target-nri** are mutually exclusive.

nri-value is an integer from 1 through 63 that identifies a specific, already defined, SGSN in a pool. (NRI defined in the service configuration.)
Use of 0 (zero) value is not recommended.

stop

Instructs the SGSN to stop offloading subscribers from the pool area.

target-nri *target_nri*

Instructs the SGSN to begin dynamically load balancing across a network of pooled SGSNs.
target_nri is an integer from 0 through 63 that identifies an already defined target NRI (SGSN) to which the subscribers are to be offloaded. (NRI previously defined in the service configuration.)
Use of 0 (zero) value is not recommended.

target-count *target_count*

Identifies the number of subscribers to be offloaded as an integer from 0 through 4000000.

t3312-timeout *seconds*

Configures the timer (in seconds) for sending period RAUs to the MS as an integer from 2 through 60.
Default: 4

Usage

Use this command to configure the offloading of subscribers which is a part of the SGSN's load redistribution operation. This command can be used anytime an SGSN is to be taken out of service. Commands, with different NRI values, are repeated to expand/contract the radius of the offloading.
When targeted offloading is to be used, you should choose an algorithm to control offloading from the perspective of the IMSIMGR and SESSMGR. This is done with the **target-offloading** command in the SGSN-Global configuration mode.

Example

Command 1: The following command instructs the SGSN to begin offloading for the local NRI id *1* in the *gprs1* GPRS service configuration:

```
sgsn offload gprs-service gprs1 connecting nri-value 1
```

Command 2: Enter this second command to add offloading for NRI *2* to the offloading already occurring for NRI *1*:

```
sgsn offload gprs-service gprs1 connecting nri-value 2
```

Command 1: The following command instructs the SGSN to begin offloading for all local NRIs to the target NRIs *5* and *6* for *100000* and *200000* subscribers respectively:

```
sgsn offload sgsn-service sgsnserv4 connecting target-nri 5 target-count
100000 target-nri 6 target-count 200000
```

Command 2: The following command instructs the SGSN to add target NRI *4* to the offloading and also to change the subscriber offload number for target NRI *5*:

```
sgsn offload sgsn-service sgsnserv4 connecting target-nri 4 target-count
100000 target-nri 5 target-count 300000
```

sgsn op

Instructs the SGSN to begin specific operations or functions.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

sgsn op { auth-ptmsi-counters imsi *imsi* **| convert | nse { fr | ip | sgsn-invoke-trace } | show | ss7-rd** *ss7-rd_id* **{ destination | link | linkset | peer } }**

---

auth-ptmsi-counters imsi *imsi*

Displays the authentication, P-TMSI reallocation, and P-TMSI signature reallocation counters for the specified IMSI.
imsi: Enter a unique 15-digit number associated with a mobile phone.

---

convert point-code *pt_code* **variant** *variant*

Converts SS7 point codes, according to identified variants, from dotted-decimal format to decimal format and vice versa.
point-code *pt_code*: Enters an SS7 point code in either dotted-decimal format or decimal format.
variant *variant*: Identifies the appropriate variant for the point code:

- **ansi**
- **itu**
- **ttc**

---

nse { fr *operation* **| ip** *operation* **| sgsn-invoke-trace nse-id** *nse_id* **}**

Enables the operator to perform a range of live control functions (for example, reset, block, unblock) for various types of virtual connections based on the signalling type of the NSE:
fr: Identifies a Frame Relay NSE.
ip: Identifies an IP NSE.
operation: Identifies the operation to be performed for the NSE connection (if available for the selected signalling type):

- **block nse-id** *nse_id*: Blocks signal flow through all network service virtual connections (NSVC) for the specified NSE:
  - *nse_id*: an integer from 0 to 65535.
- **bvc-flc-limit rate** *rate* **bvc-id** *bvc_id* **nse-id** *nse_id* - SGSN initiates flow control at the defined percentage rate to limit the flow through the BSSGP virtual connection (BVC) for the specified NSE and optionally for a specified BVC.
  - *rate*: an integer from 0 to 100.
  - *bvc_id*: an integer from 0 to 65000.
  - *nse_id*: an integer from 0 to 65535.
- **bvc-reset bvc-id** *bvc_id* **nse-id** *nse_id*: SGSN initiates a BVC-Reset on the specified BVC and NSE:

- *bvc_id*: an integer from 0 through 65000.
- *nse_id*: an integer from 0 through 65535.

- **nsvc** *nsvc_id* **{ block | enable | disable | unblock }***nse_id* - SGSN initiates NS-Block or NS-Unblock for the specified NSVC of the specified NSE:
  - *nsvc_id*: an integer from 0 through 65535.
  - *nse_id*: an integer from 0 through 65535.
- **reset nse-id** *nse_id* - SGSN initiates NS-Reset for all NSVC configured in the NSE. *nse_id* is an integer from 0 through 65535.
- **unblock nse-id** *nse_id* - SGSN initiates NS-Unblock for all NSVC configured for the specified NSE. *nse_id* is an integer from 0 through 65535.

sgsn-invoke-trace nse-id *nse_id* **record-type** *record_type* **trace-reference** *reference* **[mobile-id type** *id_type* **| trace-transaction-id** *trace_id* **]** :

Important: This command can be used for troubleshooting/debugging purposes and is primarily intended for the use of specially trained service representatives.

Instructs the SGSN (1) to send the BSSGP message SGSN-INVOKE-TRACE to the BSC to initiate a BSC trace of a particular MS and (2) to define the type and triggering of the trace.

- *nse_id*: Identifies the peer NSE, enter an integer from 0 to 65535.
- *record_type*: Specifies the type of trace to be performed:
  - **basic**
  - **handover**
  - **no-bss-trace**
  - **radio**
- **trace-reference** *reference* : Specifies the trace reference ID as an integer from 0 to 65535.
- **mobile-id type** *id_type*: Select the appropriate mobile ID type for the MS that is to be traced:
  - **imei value** *value* - Specifies the mobile ID type as the unique International Mobile Equipment Identity.

    value: 15-digit IMEI value.
  - **imeisv value** *value*: Specifies the mobile ID type as the unique International Mobile Equipment Identity with the two-digit software version number.

    value: 16-digit IMEISV value.
  - **imsi value** *value* - Specifies the mobile ID type as a network unique International Mobile Subscriber Identity as a 15-digit IMSI value.
- **trace-transaction-id** *trace_id*: Specifies the trace transaction ID as an integer from 0 through 65535.

show plmn-list smgr-inst *sessmgr#*

Important: This function is only available in release 8.1.

SGSN displays the configured PLMN list for the specified session manager (SessMgr):

sessmgr#: Enter up to 4 digits, 0 to 4095.

---

ss7-rd *ss7-rd_id* **{ destination | link | linkset | peer }**

The **ss7-rd** commands assist with troubleshooting connections between the SGSN and the peer server.
ss7-rd_id: Specifies the configured SS7 routing domain as an integer from 1 through 12.

- **destination audit asp-instance** *asp_id* **peer-server-id** *peer_id* **psp-instance-id** *psp_id*

  Initiates destination audit (DAUD) messages for all point codes reachable via the identified peer-server, which is in restricted/unavailable/congested state due to DRST/DUNA/SCON messages respectively from the far end.

  - *asp_id*: Specifies the relevant ASP configuration ID as an integer from 1 through 4.
  - *peer_id*: Specifies the relevant peer server configuration ID as an integer from 1 through 144.
  - *psp_id*: Specifies the relevant PSP configuration ID as an integer from 1 through 4

- **link** *procedure* **linkset-id** *linkset_id* **link-id** *link_id*

  Initiates MTP3 network link management procedures for the specified link:

  - **activate**: Activates the deactivated link.
  - **deactivate**: Deactivates specified link.
  - **deactivate-l2-only**: Deactivates the link only at the MTP3 layer.
  - **inhibit**: Inhibits the link only if it does *not* make any destination unreachable.
  - **uninhibit**: Uninhibits the inhibited link.
  - *linkset_id*: an integer between 1 and 144.
  - *link_id*: an integer between 1 and 16.

- **linkset-id** *procedure* **linkset-id** *linkset_id*

  Initiates MTP3 network link management procedures for all the links in the specified linkset:

  - **activate**: Activates the deactivated linkset.
  - **deactivate**: Deactivates the linkset.
  - **deactivate-l2-only**: Deactivates the linkset only at MTP3 layer.
  - *linkset_id*: an integer between 1 and 144.

- **peer** *message* **asp-instance** *asp_id* **peer-server-id** *peer_id* **psp-instance-id** *psp_id*

  Initiates one of the following SCTP/M3UA management messages from the identified link:

  - **abort**: Sends an SCTP Abort message which aborts the SCTP association ungracefully.
  - **activate**: Sends an M3UA ASP Active message to activate the link.
  - **down**: Sends an M3UA ASP Down message to bring down the M3UA link.
  - **establish**: Sends an SCTP INIT message to start the SCTP association establishment.
  - **inactivate**: Sends an M3UA ASP Inactive message to deactivate the link.
  - **inhibit**: Inhibits the M3UA link locally when the operator wants to lockout the link.
  - **terminate**: Sends SCTP Shutdown message which closes the SCTP association gracefully.
  - **un-inhibit**: Uninhibits the M3UA link.
  - **up**: Sends an M3UA ASP UP message to bring up the M3UA link.
  - *asp_id*: Specifies a relevant ASP configuration ID as an integer from 1 through 4.

- *peer_id*: Specifies the relevant peer server configuration ID as an integer from 1 through 144.
- *psp_id*: Specifies the relevant PSP configuration ID as an integer from 1 through 4

Usage

In most cases, an operator will block/unblock/reset from the BSC-side. The **nse** commands cause the SGSN to initiate actions, usually for one of the following reasons:

- to resolve issues on the BSC-side,
- as part of an upgrade to the BSC,
- as part of link expansion,
- to resolve NSVC/BVC status mismatches observed between the SGSN and BSC.

The **sgsn-invoke-trace** command initiates the trace procedure where the BSC begins a trace record on a specified MS.

Example

The following command instructs the SGSN to initiate an NS-Block for all NSVC associated with Frame Relay NSE ID *2422*:

```
sgsn op nse fr unblock nse-id 2422
```

Activate linkset *1* configured in SS7 routing domain *1*:

```
sgsn op ss7-rd 1 linkset activate linkset-id 1
```

sgsn retry-unavailable-ggsn

Marks the GGSN as available for further activation.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

sgsn retry-unavailable-ggsn *ip_address*

ip_address

Specifies the IP address of a GGSN in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

This command allows the operator to directly inform both the session manager and the SGTPC manager that the GGSN has been removed from a blacklist and is now available for activations. This action would override the GGSN blacklist timer configuration with **ggsn-fail-retry-timer** in the SGTP service configuration mode.

Example

The following command indicates that the GGSN identified by its IP address is now available for activation:

```
sgsn retry-unavailable-ggsn 198.168.128.8
```

sgtpc test echo sgsn-address

Initiates SGTPC echo test procedure.

Product

SGSN

Privilege

Security Administrator, Administrator

Syntax

sgtpc test echo sgsn-address *sgsn_ip_address* **{ all | ggsn-address** *ggsn_ip_address* **}**

sgsn-address *sgsn_ip_address*

Identifies the IP address of the SGSN issuing the test in IPv4 dotted-decimal notation.

all

Sends GTPC echo requests to all GGSNs having current sessions with the SGTP service.

ggsn-address *ggsn_ip_address*

Sends a GTPC echo request to the specified GGSN whether or not the GGSN has active sessions with the SGTP service. *ggsn_ip_address*is entered using IPv4 dotted-decimal notation.

Usage

This command initiates a test for the GTPC echo procedure -- echo from the specified SGSN to a specified GGSN or to all GGSNs that have sessions with the SGTP service. Issue the command from the Exec Mode within the context in which the SGTP service is configured.
Note that if the GGSN does not respond to the initial echo request, the echo requests will be retried for the max-retransmissions times.

Example

This SGSN with IP address of *10.1.1.1* sends an echo test to all GGSNs attached to the SGTP service:

```
sgtpc test echo sgsn-address 10.1.1.1 all
```

shutdown

Terminates all processes within the chassis. After all processes are terminated, the system initiates a hardware reset (reboot). This command is identical to the **reload** command.

Product

All

Privilege

Security Administrator, Administrator

Syntax

```
shutdown [ -noconfirm ]
```

-noconfirm

Executes the command without any additional prompts or confirmation from the user.

Usage

The system performs a hardware reset and reloads the highest priority boot image and configuration file specified in the boot.sys file. Refer to the **boot system priority** command in the Global Configuration Mode for additional information on configuring boot images, configuration files and priorities.

Important: To avoid the abrupt termination of subscriber sessions, it is recommended that a new call policy be configured and executed prior to invoking the **shutdown** command. This policy sets busy-out conditions for the system and allows active sessions to terminate gracefully. Refer to the **newcall** command in the Exec Mode for additional information.

Caution: Issuing this command causes the system to become unavailable for session processing until the reboot process is complete.

Example

The following command performs a hardware reset on the system:

```
shutdown
```

sleep

Pauses the command line interface (CLI).

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

sleep *seconds*

sleep *seconds*

Specifies the number of seconds to pause as an integer from 1 through 3600.

Usage

Sleep is a command delay which is only useful when creating command line interface scripts such as predefined configuration files/scripts.

Example

The following will cause the CLI to pause for *30* seconds.

```
sleep 30
```

srp initiate-switchover

Changes the device status on the primary and backup systems configured for Interchassis Session Recovery (ICSR) support employing Service Redundancy Protocol (SRP).

Product

All products that support ICSR

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

srp initiate-switchover [post-processing-timeout | reset-route-modifier | timeout *seconds* **] [-noconfirm]**

post-processing-timeout

Specifies the timeout value (in seconds) to initiate the post-switchover process as an integer from 0 through 3600.

reset-route-modifier

During a switchover, resets the route-modifier to the initial value.

timeout *seconds*

Specifies the number of seconds before a forced switchover occurs as an integer from 0 through 65535. Default: 300

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

This command executes a forced switchover from active to inactive. The command must be executed on the active system and switches the active system to the inactive state and the inactive system to an active state.

Example

The following initiates a switchover in *30* seconds.

```
srp initiate-switchover timeout 30
```

srp reset-auth-probe-fail

Resets Service Redundancy Protocol (SRP) authentication probe monitor failure information.

Product

All products that support Interchassis Session Recovery (ICSR)

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
srp reset-auth-probe-fail
```

Usage

This command resets the auth probe monitor failure information to 0.

srp reset-diameter-fail

Resets Service Redundancy Protocol (SRP) Diameter monitor failure information.

Product

All products that support Interchassis Session Recovery (ICSR)

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
srp reset-diameter-fail
```

Usage

This command resets the Diameter monitor failure information to 0.

srp terminate-post-process

forcibly terminates post-switchover processing by primary and backup systems configured for Interchassis Session Recovery (ICSR) support employing Service Redundancy Protocol (SRP).

Product

All products that support ICSR

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
srp terminate-post-process [ -noconfirm ]
```

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to force the termination of post-switchover process.

Example

```
srp terminate-post-process
```

srp validate-configuration

Initiates a configuration validation check from the active chassis via Service Redundancy Protocol (SRP).

Product

All products that support Interchassis Session Recovery (ICSR)

Privilege

Security Administrator, Administrator

Syntax

```
srp validate-configuration
```

Usage

Validates the configuration for an active chassis.

srp validate-switchover

Validates both active and standby systems are ready for a planned Service Redundancy Protocol (SRP) switchover.

Product

All products that support Interchassis Session Recovery (ICSR)

Privilege

Security Administrator, Administrator

Syntax

```
srp validate-switchover
```

Usage

Validates that both active and standby systems are ready for a planned SRP switchover.

ssh

Connects to a remote host using a secure shell (SSH) interface.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

ssh { *host_name* | *host_ip_address* } [port *port_num*] [user *user_name*]

host_name | *host_ip_address*

Identifies the remote node with which to attempt connection.
host_name: specifies the remote node using its logical host name which must be resolved via DNS lookup.
host_ip_address: specifies the remote node using its assigned IP address in IPv4 dotted-decimal notation.

port *port_num*

Specifies a specific port for connection as an integer from 1025 through 10000.

user *user_name*

Specifies the user name attempting connection.

Usage

SSH connects to a remote network element using a secure interface.

Example

The following connects to remote host *remoteABC* as user *user1*.

```
ssh remoteABC user user1
```

The following connects to remote host *10.2.3.4* without any default user.

```
ssh 10.2.3.4
```

The following connects to remote host *10.2.3.4* via port *2047* without any default user.

```
ssh 10.2.3.4 port 2047
```

start crypto security-association

Initiates Internet Key Exchange (IKE) negotiations.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

start crypto security-association *cryptomap*

cryptomap

Specifies the name of an existing crypto map policy to use when starting the IKE negotiations as an alphanumeric string of 1 through 127 characters.

Usage

Use this command to start IKE negotiations for IPSEC.

Example

The following command starts the IKE negotiations using the parameters set in the crypto map named *crytpomap1*:

```
start crypto security-association cryptomap1
```

system

Configures information about the system that will be accessible by the SNMP agent.

Product

P-GW

Privilege

Security Administrator, Administrator

Syntax

```
system { carrier-id mcc mcc_num mnc mnc_num | contact name | description description |
hostname name | location location }

default system { contact | description | hostname | location }

no system carrier-id
```

carrier-id mcc *mcc_num* **mnc** *mnc_num*

Specifies the system's Carrier ID via the three-digit MCC (mobile country code) and three-digit MNC (mobile network code).

contact *name*

Specifies the system's contact name as an alphanumeric string from 0 through 255 characters.

description *description*

Defines description text that as an alphanumeric string from 1 through 255 characters that includes text and some parameters, including:

- **%version%** - software version
- **%build%** - software build number
- **%chassis%** - chassis type ("asr5000")
- **%staros%** - ID of the kernel revision
- **%ostype%** - os type
- **%hostname%** - system name
- **%release%** - release
- **%kerver%** - kernel version
- **%machine%** - machine hardware name

Default: "%ostype% %hostname% %release% %kerver% %machine%"
After replacing the parameters with values, the string will be truncated if the length is greater than 255.

hostname *name*

Specifies the system's host name (name of system) as an alphanumeric string of 1 through 63 characters.

location *location*

Specifies the system's geographic or referenced location as an alphanumeric string of 0 through 255 characters.

default system { contact | description | hostname | location }

Sets/restores the default value assigned for specified parameter.

no system carrier-id

Removes the Carrier ID established for the system.

Usage

Use this command to configure information about the system that is accessible by the SNMP agent.

Example

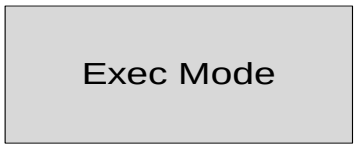
The following command identifies the system's location as *boston*:

```
system location boston
```

Chapter 113
Exec Mode (T-Z)

This section includes the commands **`telnet`** through **`upgrade url-blacklisting database`**.

The Exec Mode is the initial entry point into the command line interface system. Exec mode commands are useful in troubleshooting and basic system monitoring.



telnet

Connects to a remote host using the terminal-remote host protocol.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

telnet { *host_name* | *host_ip_address* } [port *port_num*]

host_name | *host_ip_address*

Identifies the remote node with which to attempt connection.
host_name: specifies the remote node using its logical host name which must be resolved via DNS lookup.
host_ip_address: specifies the remote node using its assigned IP address entered using the IPv4 dotted-decimal notation.

port *port_num*

Specifies a specific port for connect connection as an integer from 1025 through 10000.

Usage

Telnet to a remote node for maintenance activities and/or troubleshooting when unable to do so directly.

Important: **telnet** is not a secure method of connecting between two hosts. **ssh** should be used whenever possible for security reasons.

Example

The following connects to remote host *remoteABC*.

```
telnet remoteABC
```

The following connects to remote host *10.2.3.4* port *2047*.

```
telnet 10.2.3.4 port 2047
```

terminal

Sets the number of rows or columns for display output.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

terminal { length *lines* **| width** *characters* **}**

length *lines* **| width** *characters*

length *lines*: sets the terminal length in number of lines (rows) of text from 5 to 4294967295 lines or the special value of 0 (zero). The value 0 sets the terminal length to infinity.
width *characters*: sets the terminal width in number of characters from 5 to 512 characters.

Usage

Set the length to 0 (infinite) when collecting the output of a command line interface session which is part of a scripted interface.

Example

The following sets the length then width in two commands.

```
terminal length 66

terminal width 160
```

The following command sets the number of rows of the terminal to infinity.

```
terminal length 0
```

test alarm

Tests the alarm capabilities of the chassis.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
test alarm { audible | central-office { critical | major | minor } }
```

audible | central-office { critical | major | minor }

audible: Tests the internal alarm on the System Management Card (SMC) for 10 seconds. The alarm status is returned to its prior state, such as if the audible alarm was enabled prior to the test, the alarm will again be enabled following the test.
central-office { **critical** | **major** | **minor** }: Tests the specified central office alarm type.

Usage

Test the alarm capabilities of the chassis as periodic maintenance to verify the hardware for generation of the internal audible alarms is functional.

Caution: The use of test commands could adversely affect the operation of your system. It is recommended that they only be used under the guidance and supervision of qualified support representative.

Example

```
test alarm audible

test alarm central-office critical

test alarm central-office major

test alarm central-office minor
```

test ipcf bindmux

Tests the status of the IPCF BindMux Manager instance and also starts or stops the BindMux Manager instance on the chassis.

Product

IPCF

Privilege

Security Administrator, Administrator, Operator

Syntax

```
test ipcf bindmux [ start | stop ]
```

start

Starts the IPCF BindMux Manager on the chassis. If already an instance of IPCF BindMux Manager is running it prompts accordingly.

stop

Stops the IPCF BindMux Manager instance running on the chassis.

Usage

Use this command to test the status of IPCF BindMux Manager instance and also to start or stop the BindMux Manager instance on the chassis.

Caution: The use of test commands could adversely affect the operation of your system. It is recommended that they only be used under the guidance and supervision of qualified support representative.

Example

The following command stops the BindMux Manager instance running on the chassis:

```
test ipcf bindmux stop
```

test ipsec tunnel

Tests a specified IPSec tunnel.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

test ipsec tunnel { ip pool | *pool_name* destination-ip *ip_address* }

ip pool *pool_name* **destination-ip** *ip_address*

ip pool *pool_name*: Specifies the name of an existing IP pool as an alphanumeric string of 1 through 32 characters.
destination-ip *ip_address*: Specifies a destination IP address in IPv4 dotted-decimal or IPv6 colon-separated notation

Usage

Use this command to test a specified IPSec tunnel.

Caution: The use of test commands could adversely affect the operation of your system. It is recommended that they only be used under the guidance and supervision of qualified support representative.

Example

```
test ipsec tunnel ip pool pool3 destination-ip 10.2.3.4
```

test mobile tunnel

Tests for the existence of a specified mobile tunnel.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

test mobile tunnel { callid *call_id* **| imsi** *imsi_value* **| ipaddr** *ip_address* **| msid** *msid_num* **| nai** *nai_value* **}**

callid *call_id*

Specifies the exact call instance ID which is to have trace data logged.as a 4-byte hexadecimal number.

imsi *imsi_value*

Specifies the International Mobile Subscriber Identity (IMSI) of the subscriber session to be monitored an integer from 1 though 15 characters.

ipaddr *ip_address*

Specifies the IP address of the subscriber session to be monitored in IPv4 dotted-decimal or IPv6 colon-separated notation.

msid *msid_num*

Specifies the mobile subscriber identification number to be monitored as 7 to 16 digits of an IMSI, MIN, or RMI.

nai *nai_value*

Specifies the mobile session Network Access Identifier as an alphanumeric string of 1 through 256 characters. The NAI is the user identity submitted by the client during network access authentication.

Usage

Use this command to test a specified mobile tunnel.

Caution: The use of test commands could adversely affect the operation of your system. It is recommended that they only be used under the guidance and supervision of qualified support representative.

Example

```
test mobile tunnel ipaddr 192.64.66.9
```

timestamps

Enables or disables the generation of a timestamp in response to each command entered. The timestamp does not appear in any logs as it is a CLI output only. This command affects the current CLI session only. Use the **timestamps** command in the Global Configuration Mode to change the behavior for all future CLI sessions.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
[ no ] timestamps
```

no

Disables generation of timestamp output for each command entered. When omitted, the output of a timestamp for each entered command is enabled.

Usage

Enable timestamps when logging a CLI session on a remote terminal such that each command will have a line of text indicating the time when the command was entered.

traceroute

Collects information on the route data will take to a specified host.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Important: Inspector privileges are granted for all variables except **count and port**. To initiate a traceroute count or to target a specific port for a traceroute, you must have a minimum privilege level of Operator.

Syntax

traceroute { *host_name* | *host_ip_address* } [**count** *packets*] [**df**] [**maxttl** *max_ttl*] [**minttl** *min_ttl*] [**port** *port_num*] [**size** *octet_count*] [**src** { *src_host_name* | *src_host_ip_address* }] [**timeout** *seconds*] [| { **grep** *grep_options* | **more** }]

host_name | *host_ip_address*

Identifies the remote node to trace the route to.
host_name: specifies the remote node using its logical host name which must be resolved via DNS lookup.
host_ip_address: specifies the remote node using its assigned IP address entered using the IPv4 dotted-decimal notation.

count *packets*

Specifies the number of UDP probe packets to send. Default: 3

df

Indicates the packets for the tracing of the route should not be fragmented. If a packet requires fragmenting, it is dropped and the result is the ICMP response “Unreachable, Needs Fragmentation” is received.

maxttl *max_ttl*

Specifies the maximum time to live for the route tracing packets as an integer from 1 through 255. *max_ttl* must be greater than *min_ttl* whether *min_ttl* is specified or defaulted. Default: 30
The time to live (TTL) is the number of hops through the network; it is not a measure of time.

minttl *min_ttl*

Specifies the minimum time to live for the route tracing packets as an integer from 1 through 255. *min_ttl* must be less than *max_ttl* whether *max_ttl* is specified or defaulted. Default: 1
The time to live (TTL) is the number of hops through the network; it is not a measure of time.

port *port_num*

Specifies a specific port for connection as an integer from 1 through 65535. Default: 33434

size *octet_count*

Specifies the number of bytes for each packet as an integer from 40 through 32768. Default: 40

src { *src_host_name* | *src_host_ip_address* }

Specifies an IP address to use in the packets as the source node. Default: originating system's IP address
src_host_name: specifies the remote node using its logical host name which must be resolved via a DNS lookup.
src_host_ip_address: specifies the remote node using its assigned IP address specified entered using IPv4 dotted-decimal notation.

timeout *seconds*

Specifies the maximum time (in seconds) to wait for a response from each route tracing packet as an integer from 2 through 100. Default: 5

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in this guide.

Usage

Trace an IP route when troubleshooting network problems where certain nodes are having significant packet delays or packet loss. This can also be used to identify bottlenecks in the routing of data within the network.

Example

The following command traces the route to remote host *remoteABC* and sends the output to the more command.

```
traceroute remoteABC | more
```

The following command traces the route to remote host *10.2.3.4*'s port *2047* waiting a maximum of *2* seconds for responses.

```
traceroute 10.2.3.4 port 2047 timeout 2
```

update active-charging

Updates specified active charging option(s) for the matching sessions.

Product

ACS, FW, NAT, TPO

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

update active-charging { switch-to-fw-and-nat-policy *fw_nat_policy_name* **| switch-to-rulebase** *rulebase_name* **| switch-to-tpo-policy** *tpo_policy_name* **} { all | callid** *call_id* **| fw-and-nat-policy** *fw_nat_policy_name* **| imsi** *imsi* **| ip-address** *ip_address* **| msid** *msid* **| rulebase** *rulebase_name* **| tpo-policy** *tpo_policy_name* **| username** *user_name* **} [-noconfirm] [| { grep** *grep_options* **| more }]**

switch-to-fw-and-nat-policy *fw_nat_policy_name*

Specifies an existing Firewall-and-NAT policy to switch to as an alphanumeric string of 1 through 63 characters.

switch-to-rulebase *rulebase_name*

Specifies an existing rulebase to switch to as an alphanumeric string of 1 through 63 characters.

switch-to-tpo-policy *tpo_policy_name*

Specifies an existing TPO policy to switch to as an alphanumeric string of 1 through 63 characters.

all

Updates rulebase/policy for all subscribers.

callid *call_id*

Updates rulebase/policy for the Call Identification number specified as an eight-digit hexadecimal number.

fw-and-nat-policy *fw_nat_policy_name*

Updates the rulebase/policy for sessions matching an existing Firewall-and-NAT policy specified as an alphanumeric string of 1 through 63 characters.

imsi *imsi*

Updates rulebase/policy for International Mobile Subscriber Identification (IMSI) specified here. *imsi* must be 3 digits of MCC (Mobile Country Code), 2 or 3 digits of MNC (Mobile Network Code), and the rest with MSIN (Mobile Subscriber Identification Number). The total should not exceed 15 digits. For example, 123-45-678910234 can be entered as 12345678910234.

ip-address *iP_address*

Updates rulebase/policy for the IP address specified in IPv4 dotted-decimal or IPv6 colon-separated notation.

msid *msid*

Updates rulebase/policy for an MSID specified as a string of 1 through 24 characters.

rulebase *rulebase_name*

Updates rulebase/policy for sessions matching an existing rulebase specified as an alphanumeric string of 1 through 63 characters.

tpo-policy *tpo_policy_name*

Updates rulebase/policy for sessions matching an existing TPO policy specified as an alphanumeric string of 1 through 63 characters.

username *user_name*

Updates rulebase/policy for user specified as a an alphanumeric of characters and/or wildcard characters ('$' and '*') of 1 through 127 characters.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the Regulating a Command's Output section of the Command Line Interface Overview chapter in the Command Line Interface Reference.

Usage

Use this command to change specified active charging option(s) for the matching sessions.

Example

The following command changes the rulebase for sessions using the rulebase named *standard* to use the rulebase named *super*:

```
update active-charging switch-to-rulebase super rulebase standard
```

update cscf

Causes a NOTIFY to be triggered from CSCF based on registration state and event and indicating the expiry timer value for each contact as “reauthentication-time” provided from the CLI. The subscriber is supposed to send a fresh REGISTER message within “reauthentication-time”, which will be challenged by CSCF as part of reauthentication. If reauthentication fails, the subscriber will be cleared after “reauthentication-time”.

Product

SCM (P-CSCF, S-CSCF)

Privilege

Administrator

Syntax

update cscf subscriber { all | username *user_name* **} cscf-service** *service_name* **{ { [contact** *contact_address* **] reg-state { active event { refreshed | shortened } time** *sec* **} | terminated event { deactivated | expired | rejected | unregistered } } | reauthentication-time** *sec* **} [verbose]**

---

subscriber { all | username *user_name* **}**

Updates CSCF subscriber data.
all: Updates data for all subscribers within a specified CSCF service.
username *user_name*: Specifies the name of a user within the current context as an alphanumeric string of 1 through 127 characters that is case sensitive.

---

cscf-service *service_name*

Specifies a configured CSCF service as an alphanumeric string of 1 and 63 characters that is case sensitive.

---

contact *contact_address*

Specifies the contact address of the subscriber as an alphanumeric string of 1 through 255 characters.

---

reg-state

Specifies the registration state of the subscriber.

---

active event { refreshed | shortened } time *sec* **}**

Specifies the registration state active event type.

- **refreshed**: Specifies registration state active event as refreshed.
- **shortened**: Specifies registration state active event as shortened.

time *sec*: Specifies the time (in seconds) within which subscriber is expected to re-authenticate as an integer from 1 to 86400.

---

terminated event { deactivated | expired | rejected | unregistered }

Specifies the registration state terminated event type.
deactivated: Specifies registration state terminated event as deactivated.
expired: Specifies registration state terminated event as expired.
rejected: Specifies registration state terminated event as rejected.
unregistered: Specifies registration state terminated event as unregistered.

reauthentication-time *sec*

Specifies the time (in seconds) within which the subscriber is expected to re-authenticate as an integer from 1 to 86400.

verbose

Show detailed information.

Usage

This command is only applicable for a P-CSCF and S-CSCF service. When optional contact ID is not specified, all the contact IDs associated with specified user or all users will be updated and trigger NOTIFY.

Important: reauthentication-time should be greater than the current expiry time of the contact so that CSCF will initiate the NOTIFY message.

Example

The following command sets the reauthentication time for all CSCF subscribers in the *scscf1* S-CSCF service to *500* seconds:

```
update cscf subscriber all cscf-service scscf1 reauthentication-time 500
```

update firewall policy

This command is obsolete.

update ip

When you update an IP Access list, this command forces the new version of the access list to be applied to any subscriber sessions that are currently using that list.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator

Syntax

update ip access-list *list_name* **subscribers [** *command_keyword* **] [** *filter_keywords* **] [| { grep** *grep_options* **| more }]**

list_name

Specifies the name of an existing IP Access list that you want to apply to the subscriber as an alphanumeric string of 1 through 47 characters.

[*command_keyword* **] [** *filter_keywords* **]**

These are the same command keywords and filter keywords available for the **show subscribers** command.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output section* of the *Command Line Interface Overview* chapter in this guide.

Usage

Use this command to force existing subscriber sessions that are already using a specific IP Access list to have that IP Access list reapplied. This is useful when you edit an IP Access list and want to make sure that even existing subscriber sessions have the new changes applied.

Example

To apply the IP Access list named *ACLlist1* to all existing subscribers that are already using that IP Access list, enter the following command:

```
update ip access-list ACLlist1 subscribers all
```

update qos policy map

Updates QoS profile information based on specific subscriber policy maps.

Product

All

Privilege

Security Administrator, Administrator

Syntax

update qos policy-map *map_name* **use-granted-profile-id** *id1* **[** *id2* **] [** *id3* **] subscribers [** *command_keyword* **] [** *filter_keywords* **] [-noconfirm] [verbose] [match-requested-profile-id] [| { grep** *grep_options* **| more }]**

map_name

Specifies the name of an existing policy map as an alphanumeric string of 1 through 15 characters.

use-granted-profile-id *id1* **[** *id2* **] [** *id3* **]**

Specifies the profile IDs to update. Up to three different profile IDs can be specified.
Each profile ID is specified as a hexadecimal value from 0x0 and 0xFFFF.

subscribers [*command_keyword* **] [** *filter_keywords* **]**

These are the same command keywords and filter keywords available for the **show subscribers** command.

[-noconfirm]

Updates matching subscribers without prompting for confirmation.

[verbose]

Displays details for the profile updates.

[match-requested-profile-id]

Sends session-updates only to profile-ids matching the profile-ids in the requested list.

grep *grep_options* **| more**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in this guide.

Usage

Use this command to update subscriber session profile IDs based on the specified criteria.

Example

The following command updates profile IDs *0x3E* and *0x4C* for all subscriber sessions and sends session-updates with the IDs:

```
update qos policy-map test use-granted-profile-id 0x3E 0x4C subscribers
all match-requested-profile-id
```

update qos tft

Updates the subscriber traffic flow template (TFT) associated with the flow ID and direction.

Product

All

Privilege

Security Administrator, Administrator

Syntax

update qos tft flow-id *flow-id* **flow-dir { forward | reverse } use-granted-profile-id** *id1* **[** *id2* **] [** *id3* **] subscribers [** *command_keyword* **] [** *filter_keywords* **] [-noconfirm] [verbose] [match-requested-profile-id] [| { grep** *grep_options* **| more }**

flow-id *flow-id*

Sends session updates only when the flow ID matches the flow-id and flow-direction. *flow-id* must be specified as an integer from 1 through 255.

flow-dir { forward | reverse }

Specifies the direction of the TFT flow.

subscribers [*command_keyword* **] [** *filter_keywords* **]]**

These are the same command keywords and filter keywords available for the **show subscribers** command.

Usage

Supports QoS updates based on subscriber TFTs.

Example

```
update qos tft flow-id 0 flow-dir reverse use-granted-profile-id 0x0
subscribers all -noconfirm
```

upgrade

Installs major software releases to the system.

Product

All

Privilege

Security Administrator, Administrator

Syntax

upgrade { online | patch } *image_url* **config** *cfg_url* **[-noconfirm]**

online

Perform a software upgrade from one release version to another. The online upgrade is only available for software release 3.5 and higher.

patch

Install an interim, or patch, software release.

Important: Software Patch Upgrades are not supported in this release.

image_url

Specifies the location of a image file to use for system startup. The URL may refer to a local or a remote file. The URL must be formatted as follows:
[**file:**]{ **/flash** | **/pcmcia1** | **/hd** }[**/***directory*]**/***file_name*
[http: | tftp:]//{ *host*[*:port#*] }[**/***directory*]**/***file_name*

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name.
filename is the actual file of interest.
host is the IP address or host name of the server.
port# is the logical port number that the communication protocol is to use.

Important: A file intended for use on an ASR 5000 uses the convention xxxxx.ASR5000.bin, where xxxxx is the software build information.

Important: When using the TFTP, you should use a server that supports large blocks, per RFC 2348. This can be implemented by using the "block size option" to ensure that the TFTP service does not restrict the file size of the transfer to 32MB.

config *config_path*

Specifies the location of a configuration file to use for system startup. This must be formatted as follows:

[**file:**]{ **/flash** | **/pcmcia1** | **/hd** }[**/***path*]**/***filename*
Where *path* is the directory structure to the file of interest, and *filename* is the name of the configuration file. This file typically has a **.cfg** extension.

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use the **upgrade online** command to perform a software upgrade when upgrading from one software release version to another, providing that both versions support this feature. For example, you can use this method to upgrade from release version 3.5 (any build number) to version 4.0 (any build number), but you cannot use this method to upgrade from release version 3.0 to version 3.5 since version 3.0 does not support the feature.

Important: Software Patch Upgrades are not supported in this release.

Important: This command is not supported on all platforms.

Example

The following command performs a major software release upgrade from an older version to a newer version. In this example the new software image file is in a subdirectory on a tftp server, and the configuration file is in a subdirectory on the local flash at tftp://host[/path]/filename.

```
upgrade online tftp://imageserver/images/image.bin config
/flash/configurations/localconfig.cfg
```

upgrade content-filtering

Upgrades the Static Rating Database (SRDB) for Category-based Content Filtering application.

Product

CF

Privilege

Security Administrator, Administrator

Syntax

```
upgrade content-filtering category { database | rater-pkg }
```

upgrade content-filtering category database

Triggers the upgrade of the Category-based Content Filtering Static Rating Database (SRDB).

upgrade content-filtering category rater-pkg

Triggers manual upgrade of the Dynamic Content-Filtering Rater Package (**rater.pkg** file).
The **rater.pkg** file contains the models and feature counters that are used to return the dynamic content rating. The upgrade will trigger distribution of the **rater.pkg** to all the SRDBs.

Important: This command is customer specific. For more information, please contact your local sales representative.

Usage

Use this command to load the Static Rating Database (SRDB) in to memory for Category-based Content Filtering application, and/or to load the *rater.pkg* file.
If the default directory of /cf does not exist on the flash, it will create the same. It also locates the recent full database and loads it into memory. This command also clears the old and excess incremental databases.

Important: This command is not supported on all platforms.

Example

The following command upgrades the SRDB for the Category-based Content Filtering application:

```
upgrade content-filtering category database
```

upgrade tethering-detection

Upgrades the Tethering Detection feature's database(s).

Product

ACS

Privilege

Security Administrator, Administrator

Syntax

```
upgrade tethering-detection database { all | os-signature | tac | ua-signature } [ -
noconfirm ]
```

all

Upgrades all Tethering Detection databases—OS, TAC and UA.

os-signature

Upgrades only the OS database.

tac

Upgrades only the TAC database.

ua-signature

Upgrades only the UA database.

- noconfirm

Executes the command without any prompts and confirmation from the user.

Usage

Use this command to upgrade the database(s) used by the Tethering Detection feature.
This command upgrades the database(s) from file(s) kept in designated path. The name of the existing source file is prefixed with the word "new-". For example for OS DB, if the existing file name is "os-db", the upgrade file name is "new-os-db".
If there is a file named "new-xxx-db", it is verified that it is a valid Tethering Detection database and then loaded it into memory. If successful, the files is renamed "xxx-db" to "xxx-db-<number>" and then renamed "new-xxx-db" to "new-xxx-db".
For example, the command **upgrade tethering-database ua-signature -noconfirm** results in loading the file by name "new-ua-db" if it is present in the designated directory. In case of a successful upgrade, the previous version of the database is stored as backup in a file named "ua-db-1". Also, the newly uploaded database file is renamed as "ua-db".
Also see the **tethering-database** command in the *ACS Configuration Mode Commands* chapter.

Example

The following command upgrades all Tethering Detection databases:

```
upgrade tethering-detection database all -noconfirm
```

upgrade url-blacklisting database

Upgrades the URL blacklisting database.

Product

CF

Privilege

Security Administrator, Administrator

Syntax

```
upgrade url-blacklisting database [ -noconfirm ]
```

-noconfirm

Executes the command without any additional prompt and confirmation from the user.

Usage

Use this command to upgrade and load a URL blacklisting database whenever required.

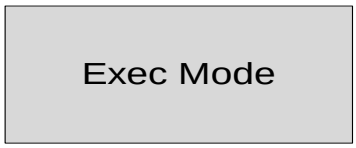
Example

```
upgrade url-blacklisting database
```

Chapter 114
Exec Mode Show Commands (A-C)

This section includes the commands **`show aaa`** through **`show css service`**.

The Exec Mode is the initial entry point into the command line interface system. Exec mode **show** commands are useful in troubleshooting and basic system monitoring.



show aaa

Displays AAA (Authentication Authorization and Accounting) statistics for the current context.

Product

PDSN, GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show aaa { group { all | name *aaa_group_name* **} | local counters } [| { grep** *grep_options* **| more }]**

group { all | name *aaa_group_name* **}**

Displays AAA information.

- **all**: If the exec context is local, information for all the default AAA groups, and the AAA groups configured in all the contexts are displayed. If the exec context is not local, information for only the context-specific AAA groups are displayed.
- **name** *aaa_group_name*: Displays information for an existing AAA group specified as an alphanumeric string of 0 through 64 characters.

local counters

Displays information for current context.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command.You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command is used to view accounting and authentication statistics for the current context.

Example

The following command displays AAA statistics for the current context:

```
show aaa local counters
```

The following command displays AAA statistics for the AAA group *aaa_group1*:

```
show aaa group name aaa_group1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging analyzer statistics

Displays statistical information for protocol analyzers.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging analyzer statistics [name *protocol* **[verbose]] [| { grep** *grep_options* **| more }]**

---

name *protocol*

Displays detailed information for the specified protocol analyzer:

- **dns**
- **file-transfer**
- **ftp**
- **http**
- **icmp**
- **icmpv6**
- **imap**
- **ip**
- **ipv6**
- **mms**
- **p2p**
- **pop3**
- **pptp**
- **rtcp**
- **rtp**
- **rtsp**
- **sdp**
- **secure-http**
- **sip**
- **smtp**
- **tcp**
- **tftp**
- **udp**
- **wsp**
- **wtp**

verbose

Displays as much information as possible. If this option is not specified then the output is the standard level which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command.You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display statistic information for active charging protocol analyzers.

Example

The following command displays detailed statistic information for all P2P protocol analyzers:

```
show active-charging analyzer statistics name p2p verbose
```

The following command displays detailed statistic information for all TCP protocol analyzers:

```
show active-charging analyzer statistics name tcp verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging bandwidth-policy

Displays information on bandwidth policies configured in a service.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging bandwidth-policy { all | name *bandwidth_policy_name* **} [| { grep** *grep_options* **| more }]**

all

Displays information for all bandwidth policies configured in the service.

name *bandwidth_policy_name*

Displays detailed information for an existing bandwidth policy specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command.You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view information on bandwidth policies configured in a service.

Example

The following command displays detailed information for the bandwidth policy named *standard*:

```
show active-charging bandwidth-policy nam standard
```

show active-charging charging-action

Displays information for charging actions configured in the Active Charging Service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging charging-action { { { all | name charging_action_name } [ service
name acs_service_name ] } | statistics [ name charging_action_name ] } [ | { grep
grep_options | more } ]
```

all

Displays information for each configured charging action.

name *charging_action_name*

Displays detailed information for an existing charging action specified as an alphanumeric string of 1 through 63 characters.

statistics

Displays statistical information for all configured charging actions.

service name *acs_service_name*

Displays information for all or a specific charging action in the specified ACS. *acs_service_name* is an alphanumeric string of 1 through 15 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command.You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for charging actions configured in a service.

Example

The following command displays a detailed information for all charging actions:

```
show active-charging charging-action all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging content-filtering category policy-id

Displays Content Filtering (CF) category policy definitions. This command is not available on StarOS 8.0 and earlier releases.

Product

CF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging content-filtering category policy-id { all | id *policy_id* **} [| { grep** *grep_options* **| more }]**

all

Displays definitions of all Content Filtering category policies.

id *policy_id*

Displays definitions of an existing Content Filtering category policy specified as an integer from 1 through 4294967295.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view Content Filtering category definitions for a specific/all Policy IDs.

Example

The following command displays Content Filtering category definitions for policy ID *3*:

```
show active-charging content-filtering category policy-id id 3
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging content-filtering category statistics

Displays category-based content filtering statistics.

Product

CF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging content-filtering category statistics [rulebase { name *rulebase_name* **| all }] [verbose] [| { grep** *grep_options* **| more }]**

rulebase { name *rulebase_name* **| all }**

Displays category-based content filtering statistics, either for all or for a specific rulebase.

- **name** *rulebase_name*: Specifies an existing rulebase as an alphanumeric string of 1 through 63 characters.
- **all**: Displays category-based content filtering statistics for each rulebase in the ACS.

verbose

Displays as much information as possible. If this option is not specified then the output is the standard level, which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view category-based content filtering statistics for a specific rulebase, or cumulative statistics for all rulebases in the ACS.

Example

The following command displays category-based content filtering statistics for the rulebase named *consumer*:

```
show active-charging content-filtering category statistics rulebase name
consumer
```

The following command displays cumulative category-based content filtering statistics for all rulebases in verbose mode:

```
show active-charging content-filtering category statistics verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging content-filtering server-group

Displays information for Content Filtering Server Group (CFSG) configured in the service.

Product

CF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging content-filtering server-group [name *cfsg_name* **| statistics [name** *cfsg_name* **[acsmgr instance** *instance* **[priority** *priority* **]] | verbose**] [**| { grep** *grep_options* **| more }]**

name *cfsg_name*

Specifies name of an existing CFSG as an alphanumeric string of 1 through 63 characters.

acsmgr instance*instance*

Specifies the manager instance as an integer from 1 through 65535.

priority *priority*

Specifies the priority of the server for which statistics has to be displayed as an integer from 1 through 65535.

verbose

Displays all available statistics of each Internet Content Adaptation Protocol (ICAP) server connection at each instance. If this option is not specified then the output is at the standard level, which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view CFSG information/statistics.
show active-charging content-filtering server-group name *cfsg_name*: The output of this command displays detailed information for the specified CFSG.
show active-charging content-filtering server-group statistics name *cfsg_name*: The output of this command displays cumulative statistics for the specified CFSG. This will include all the instances and all the servers configured in the CFSG.
show active-charging content-filtering server-group statistics name *cfsg_name* **acsmgr instance** *instance*: The output of this command displays the cumulative statistics of all the ICAP server connections on the specified manager instance.

show active-charging content-filtering server-group statistics name *cfsg_name* **acsmgr instance** *instance* **priority** *priority*: The output of this command displays the statistics for the specified ICAP server connection on the specified manager instance.
show active-charging content-filtering server-group statistics verbose: The output of this command displays statistics of each ICAP server connection at each instance.

Example

The following command displays information for the CFSG named *test12*:

```
show active-charging content-filtering server-group name test12
```

The following command displays detailed information for all CFSGs:

```
show active-charging content-filtering server-group statistics verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging credit-control

D displays statistics for Diameter/RADIUS Prepaid Credit Control Service in the Active Charging Service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging credit-control { statistics [all | group *group_name* **] | session-states [rulebase** *rulebase_name* **] [content-id** *content_id* **] } [| { grep** *grep_options* **| more }]**

---

statistics [all | group *group_name* **]**

Displays prepaid credit control statistics.

- **all**: Displays all available statistics.
- **group** *group_name*: Displays statistics for an existing credit control group specified as an alphanumeric string of 1 through 63 characters.

---

session-states [rulebase *rulebase_name* **] [content-id** *content_id* **]**

Displays prepaid CCA session status based on rulebase and/or content ID.

- **rulebase** *rulebase_name*: Displays the Credit Control Application (CCA) session state counts for an existing rulebase specified as an alphanumeric string of 1 through 63 characters.
- **content-id** *content_id*: Displays CCA session state counts for a content ID of a credit control service specified as an integer from 1 through 65535.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view statistics for Diameter/RADIUS prepaid credit control service in the ACS.

Example

The following command shows ACS statistics of configured Diameter or RADIUS Credit Control Application:

```
show active-charging credit-control statistics
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging dns-learnt-ip-addresses

Displays DNS learnt IP address statistics for the DNS Snooping feature.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging dns-learnt-ip-addresses statistics { sessmgr { all | instance *sessmgr_instance* **} [verbose] | summary } [| { grep** *grep_options* **| more }]**

---

sessmgr { all | instance *sessmgr_instance* **} [verbose]**

Displays information for all or the specified Session Manager (SessMgr) instance.

- **all**: Displays information for all SessMgr instances.
- **instance** *sessmgr_instance*: Displays information for a SessMgr instance specified as an integer from 1 through 65535.
- **verbose**: Displays detailed statistics for specified criteria. Use this keyword to view the learnt IP addresses.

---

summary

Displays summary information.

| { grep *grep_options* **| more }**

Specifies that the output of this command is to be piped (sent) to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view statistics for the DNS Snooping feature related DNS learnt-ip-addresses.
This command displays the number of learnt IP entries per rule line. It displays on a service level the number of resolved (learnt) IP addresses per rule line per rulebase (once if a rule line is used multiple times in the same rulebase as it is shared across rulebase) per destination context per SessMgr instance. It also displays the number of entries flushed due to TTL expiry. The field entries_replaced gives the number of entries replaced (same IP returned again) in the pool due to a DNS response by same/another subscriber for same domain-name, wherein the TTL of the entry will be replaced.
IPv4-overflows will start incrementing when the maximum limit of 51200 across system is reached OR limit of 200 per pattern is reached.
Ipv6-overflows will start incrementing when maximum limit of 25600 across system is reached OR limit of 100 per pattern is reached.
Limits are:

- Maximum of 51,200 IPv4 entries per instance shared across IPv4 all pools.
- Maximum of 200 IPv4 entries per pool (pool is same as discussed before (per rule-line pattern)).
- Maximum of 25,600 IPv6 entries per instance shared across all IPv6 pools.

- Maximum of 100 IPv6 entries per pool.

Example

The following command displays summary statistics for DNS learnt IP addresses:

```
show active-charging dns-learnt-ip-addresses statistics summary
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging edr-format

Displays information about Event Data Record (EDR) formats configured in the Active Charging Service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging edr-format [statistics] [all | name *edr_format_name* **] [| { grep** *grep_options* **| more }]**

all

Displays information for all EDR formats.

statistics

Displays statistics for all or an existing EDR format.
If neither **all** nor **name** is specified, summarized statistics over all EDR formats is displayed.

name *edr_format_name*

Displays information for an existing EDR format specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for EDR format(s) in the ACS.

Example

The following command displays all configured EDR formats in the ACS.

```
show active-charging edr-format all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging edr-udr-file

Displays CDR flow control information. This command also displays the Event Data Record (EDR) and Usage Data Record (UDR) file information.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging edr-udr-file { flow-control-counters [ verbose ] | statistics } [ |
{ grep grep_options | more } ]
```

flow-control-counters [verbose]

Displays the counters for dropped EDR/UDR records. These counters are for when CDRMOD uses flow control to stop ACS/Session Managers from sending the records.
verbose displays detailed information.

statistics

Displays EDR and UDR file statistics.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command.You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view CDR flow control information.

Example

The following command displays EDR and UDR files statistics:

```
show active-charging edr-udr-file statistics
```

The following command displays CDR flow control information:

```
show active-charging edr-udr-file flow-control-counters
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging file-space-usage

Displays the file space used by Charging Data Record (CDR) and Event Data Record (EDR) files.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging file-space-usage [| { grep *grep_options* **| more }]**

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view CDR/EDR file space usage information. The context in which this command is used is not relevant.

show active-charging firewall statistics

Displays Active Charging Stateful Firewall statistics.

Product

FW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging firewall statistics [callid *call_id* **| domain-name** *domain_name* **| nat-realm** *nat_realm* **| protocol { icmp | icmpv6 | ip | ipv6 | other | tcp | udp } | username** *user_name* **] [acsmgr instance** *instance_id* **] [verbose] [| { grep** *grep_options* **| more }]**

acsmgr instance *instance_id*

Specifies the ACS/Session Manager instance ID as an integer from 1 through 65535.

callid *call_id*

Specifies the call identification number as an 8-digit hexadecimal number.

domain-name *domain_name*

Specifies the domain name as an alphanumeric string of 1 through 127 characters.

nat-realm *nat_realm*

Specifies the NAT realm name as an alphanumeric string of 1 through 31 characters.

protocol { icmp | ip | other | tcp | udp }

Specifies the protocol:

- **icmp**: ICMPv4
- **icmpv6**
- **ip**: IPv4
- **ipv6**
- **other**: Protocols other than TCP, UDP, and ICMPv4/ICMPv6.
- **tcp**
- **udp**

username *user_name*

Specifies the user name as an alphanumeric string of 1 through 127 characters.

verbose

Displays all available information. If this option is not specified then the output is the standard level, which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view Stateful Firewall statistics. If you are in the local context, statistics for all contexts are displayed. Otherwise, only statistics of your current context are displayed.

Example

The following command displays Stateful Firewall statistics:

```
show active-charging firewall statistics
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging firewall track-list

Displays the list of servers being tracked for involvement in any Denial-of-Service (DOS) attacks.

Product

FW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging firewall track-list attacking-servers [ | { grep grep_options | more } ]
```

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view details of servers being tracked for involvement in any DOS attack.

Example

The following command displays the list of servers being tracked for involvement in any DOS attacks:

```
show active-charging firewall track-list attacking-servers
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging flows

Displays information for active charging flows.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging flows { all | [connected-time [< | > | greater-than | less-than] *seconds* **] [flow-id** *flow_id* **] [full] [idle-time [< | > | greater-than | less-than]** *seconds* **] [ip-address [server | subscriber] [< | > | IPv4 | greater-than | less-than]** *address* **] [nat { not-required | required [nat-ip** *nat_ip_address* **] }] [pacing-bitrate [< | > | = | greater-than | less-than | equal-to]** *number* **[port-number [server | subscriber] [< | > | IPv4 | greater-than | less-than]** *number* **] [rx-bytes [< | > | greater-than | less-than]** *number* **] [rx-packets [< | > | greater-than | less-than]** *number* **] [session-id** *session_id* **] [summary] [trans-proto { icmp | tcp | udp }] [tx-bytes [< | > | greater-than | less-than]** *number* **] [tx-packets [< | > | greater-than | less-than]** *number* **] [type** *flow_type* **] } [| { grep** *grep_options* **| more }]**

---

all

Displays information for all active charging flows.

---

connected-time [< | > | greater-than | less-than] *seconds*

Displays information for flows filtered by connected time period.

- **<** *seconds*: Displays flows that have been connected less than the specified number of seconds.
- **>** *seconds*: Displays flows that have been connected more than the specified number of seconds.
- **greater-than** *seconds*: Displays flows that have been connected more than the specified number of seconds.
- **less-than** *seconds*: Displays flows that have been connected less than the specified number of seconds.

seconds is an integer from 0 through 4294967295.

---

flow-id *flow_id*

Displays concise information for specified active charging flow ID.

---

full

Displays all available information for the specified flows.

---

idle-time [< | > | greater-than | less-than] *seconds*

Displays information for flows filtered by idle time period.

- **<** *seconds*: Displays flows that have been idle less than the specified number of seconds.
- **>** *seconds*: Displays flows that have been idle more than the specified number of seconds.

- **greater-than** *seconds*: Displays flows that have been idle more than the specified number of seconds.
- **less-than** *seconds*: Displays flows that have been idle less than the specified number of seconds.

seconds is an integer from 0 through 4294967295.

---

ip-address [server | subscriber] [< | > | IPv4 | greater-than | less-than] *address*

Displays information for flows filtered by IPv4 IP address.

- **server**: Specifies the IP address for a specific server.
- **subscriber**: Displays subscriber details for the IP address specified in IPv4 dotted-decimal format.
- **<** *address*: Specifies an IPv4 IP address that is less than *address*.
- **>** *address*: Specifies an IPv4 IP address that is greater than *address*.
- **greater-than** *address*: Specifies an IPv4 IP address that is greater than *address*.
- **less-than** *address*: Specifies an IPv4 IP address that is less than *address*.

address is an IP address expressed in IPV4 dotted-decimal notation.

---

nat { not-required | required [nat-ip *nat_ip_address* **[nat-port** *nat_port* **]] }**

Important: The **nat** keyword and options are only available in StarOS 8.3 and later releases.

Displays information for flows filtered by Network Address Translation (NAT) required or not required setting.

- **not-required**: Sessions with NAT processing are not required.
- **required**: Sessions with NAT processing are required.
- **nat-ip** *nat_ip_address*: Sessions using the NAT IP address expressed in IPv4 dotted-decimal notation.
- **nat-port** *nat_port*: Sessions using the specified NAT IP address and NAT port number specified as an integer from 0 through 65535.

---

pacing-bitrate [< | > | = | greater-than | less-than | equal-to] *number*

Displays information on video flows filtered by a video pacing bit rate specified an integer from 1 to 256000000.

- **<** *number*: Specifies a number that is less than the specified video pacing bit rate.
- **>** *number*: Specifies a number that is greater than the specified video pacing bit rate.
- **=** *number*: Specifies a number that is equal to the specified video pacing bit rate.
- **greater-than** *number*: Specifies a number that is greater than the specified video pacing bit rate.
- **less-than** *number*: Specifies a number that is less than the specified video pacing bit rate
- **equal-to** *number*: Specifies a number that is equal to the specified video pacing bit rate.

---

port-number [server | subscriber] [< | > | IPv4 | greater-than | less-than] *_number*

Displays information on flows filtered by port number.

- **server**: Specifies the port-number for a specific server.

- **subscriber**: Specifies subscriber details for this port-number expressed as an integer from 0 through 65535.
- **<** *number*: Specifies a port number that is less than the specified port-number.
- **>** *number*: Specifies a port number that is greater than the specified port-number.
- **greater-than** *number*: Specifies a port number that is greater than the specified port-number.
- **less-than** *number*: Specifies a port number that is less than the specified port-number.

---

rx-bytes [< | > | greater-than | less-than] *number*

Displays information on flows filtered by the number of bytes received in the flow.

- **<** *number*: Specifies the number of bytes that is less than the specified rx-bytes.
- **>** *number*: Specifies number of bytes that is greater than the specified rx-bytes.
- **greater-than** *number*: Specifies number of bytes that is greater than the specified rx-bytes.
- **less-than** *number*: Specifies number of bytes that is less than the specified rx-bytes.

number must be an integer from 0 through 18446744073709551615.

---

rx-packets [< | > | greater-than | less-than] *number*

Displays information on flows filtered by the number of packets received in the flow.

- **greater-than** *number*: Specifies the number of packets that is greater than the specified rx-packets.
- **less-than** *number*: Specifies the number of packets that is less than the specified rx-packets.

number must be an integer from 0 through 18446744073709551615.

---

session-id *session_id*

Displays detailed information for specific active charging session ID.

---

summary

Displays summary information for defined sessions, based on defined parameters.

---

trans-proto { icmp | tcp | udp }

Displays information on flows filtered by the transport protocol.

- **icmp**: ICMP protocol type flow
- **tcp**: TCP protocol type flow
- **udp**: User Datagram Protocol (UDP) flows

---

tx-bytes [< | > | greater-than | less-than] *number*

Displays information on flows filtered by the number of bytes received in the flow.

- **<** *number*: Specifies the number of bytes that is less than the specified tx-bytes.
- **>** *number*: Specifies number of bytes that is greater than the specified tx-bytes.
- **greater-than** *number*: Specifies number of bytes that is greater than the specified tx-bytes.
- **less-than** *number*: Specifies number of bytes that is less than the specified tx-bytes.

number must be an integer from 0 through 18446744073709551615.

tx-packets [< | > | greater-than | less-than] *number*

Displays information on flows filtered by the number of packets received in the flow.

- **greater-than** *number*: Specifies the number of packets that is greater than the specified tx-packets.
- **less-than** *number*: Specifies the number of packets that is less than the specified tx-packets.

number must be an integer from 0 through 18446744073709551615.

type *flow_type*

Displays information on flows filtered by flow type of application protocol.
flow_type must be one of the following:

- **dns**
- **ftp**
- **http**
- **icmp**
- **icmpv6**
- **imap**
- **ip**
- **ipv6**
- **mms**
- **p2p**: P2P protocol type flows including one or more of the following applications:
  - **actsync**
  - **aimini**
  - **antsp2p**
  - **applejuice**
  - **ares**
  - **armagettron**
  - **battlefd**
  - **bittorrent**
  - **blackberry**
  - **citrix**
  - **clubpenguin**
  - **crossfire**
  - **ddlink**
  - **directconnect**
  - **dofus**
  - **edonkey**
  - **facebook**
  - **facetime**

Important: The **facetime** protocol is available only in releases 9.0 and 11.0. This protocol is not available in release 10.0.

- **fasttrack**
- **feidian**
- **fiesta**
- **filetopia**
- **florensia**
- **freenet**
- **fring**
- **funshion**
- **gadu_gadu**
- **gamekit**

Important: The **gamekit** protocol is available only in releases 9.0 and 11.0. This protocol is not available in release 10.0.

- **gmail**
- **gnutella**
- **gtalk**
- **guildwars**
- **halflife2**
- **hamachivpn**
- **iax**
- **icecast**
- **imesh**
- **imo**

- **wsp-connection-oriented**

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display charging flow type information.

Example

The following command displays a detailed flow information for a session ID of *test*:

```
show active-charging flows session-id test
```

The following command displays a detailed flow information for a P2P type session:

```
show active-charging flows full type p2p
```

The following command displays a detailed information for a P2P type flow:

```
show active-charging flows type p2p
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging flow-mappings

Displays information about all the active flow mappings based on the applied filters.

Product

FW, NAT

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging flow-mappings [all | call-id *callid* **| [nat { not-required | required [nat-realm** *realm_name* **] } | trans-proto { tcp | udp }] + [| { grep** *grep_options* **| more }]**

all

Displays the all the available active charging flow-mapping information.

call-id *callid*

Displays detailed information for a call ID specified as an 8-digit hexadecimal number.

nat { required [nat-realm *string* **] not-required }**

Displays the active charging flow mappings for which NAT is enabled or disabled.

trans-proto { tcp | udp }

Displays the transport layer.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view the Active Charging flow-mapping details.

Example

The following command displays the total number of Active Charging flow-mappings:

```
show active-charging flow-mappings all
```

The following command displays the flow-mappings for which NAT is enabled and the NAT-realm used is *natpool3*:

```
show active-charging flow-mappings nat required nat-realm natpool3
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging fw-and-nat policy

Displays Firewall-and-NAT Policy information.

Important: This command is only available in StarOS 8.1, and in StarOS 9.0 and later. For more information on this command please contact your local service representative.

Product

ACS, FW, NAT

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging fw-and-nat policy { { { all | name *fw_nat_policy_name* **} [service name** *acs_service_name* **] } | { statistics { all | name** *fw_nat_policy_name* **} } } [| { grep** *grep_options* **| more }]**

all

Displays information for all Firewall-and-NAT policies configured, optionally all in a specified service.

name *fw_nat_policy_name*

Displays detailed information for an existing Firewall-and-NAT policy specified as an alphanumeric string of 1 through 63 characters.

service name *acs_service_name*

Displays information for all or the specified Firewall-and-NAT policy in the specified ACS.
acs_service_name must be the name of the ACS expressed as an alphanumeric string of 1 through 15 characters.

statistics

Displays statistics for all or the specified Firewall-and-NAT policy.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view Firewall-and-NAT Policy information.

Example

The following command displays detailed information for the Firewall-and-NAT policy named *standard*:

```
show active-charging fw-and-nat policy name standard
```

show active-charging group-of-prefixed-urls

D displays information on group of prefixed URLs configured in an Active Charging Service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging group-of-prefixed-urls { all | name *prefixed_url_group* **} [service name** *acs_service_name* **] [| { grep** *grep_options* **| more }]**

all

Displays information for all group of prefixed URLs configured in an ACS.

name *prefixed_url_group*

Displays detailed information for the group of prefixed URLs specified as an alphanumeric string of 1 through 63 characters.

service name *acs_service_name*

Displays information for all or the specified group of prefixed URLs in the specified ACS. *acs_service_name* must be the name of the ACS expressed as alphanumeric string of 1 through 15 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter

Usage

Use this command to view information on group of prefixed URLs configured in the ACS.

Example

The following command displays for the group of prefixed URLs named *test123*:

```
show active-charging group-of-prefixed-urls name test123
```

show active-charging group-of-ruledefs

Displays information for all groups or a specified group of ruledefs configured in the Active Charging Service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging group-of-ruledefs { { all | name *group_of_ruledefs* **} [service name** *acs_service_name* **] | statistics name** *group_of_ruledefs* **} [| { grep** *grep_options* **| more }]**

all

Displays information for all groups of ruledefs configured, optionally all in a specified ACS.

name *group_of_ruledefs*

Displays detailed information for an existing group of ruledefs specified as an alphanumeric string of 1 through 63 characters.

service name *acs_service_name*

Displays information for all groups or the specified group of ruledefs within the ACS. *acs_service_name* must be the name of the ACS expressed as an alphanumeric string of 1 through 15 characters.

statistics name *group_of_ruledefs*

Displays statistics for an existing group of ruledefs specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view information on group of ruledefs configured in a ACS.

Example

The following command displays information on all groups of ruledefs configured:

```
show active-charging group-of-ruledefs all
```

show active-charging nat statistics

Displays Network Address Translation (NAT) realm statistics.

Product

NAT

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging nat statistics [nat-realm *nat_realm* **[summary]] [| { grep** *grep_options* **| more }]**

show active-charging nat statistics

When issued in the local context, this command displays statistics for all NAT realms in all contexts. When issued in a specific context, this command displays statistics for all NAT realms in that context.

show active-charging nat statistics nat-realm *nat_realm*

When issued in the local context, this command displays statistics for the specified NAT realm in all contexts. When issued in a specific context, this command displays statistics for the specified NAT realm in that context.

nat-realm *nat_realm*

Specifies the NAT realm's / NAT realm group's name as an alphanumeric string of 1 through 31 characters.

summary

When the *nat_realm* specified is a "pool group" and the **summary** option is used, summary statistics of all pools in the pool group are displayed.
When the *nat_realm* specified is a pool and the **summary** option is not used, all available statistics for the specified pool are displayed.
When the *nat_realm* specified is a "pool group" and the **summary** option is not used, all available statistics of each pool in the specified "pool group" are displayed.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view NAT realm statistics.

Example

The following command when issued in the local context, displays NAT realm statistics for NAT realms named *test135* in all contexts:

```
show active-charging nat statistics nat-realm test135
```

show active-charging packet-filter

D displays information on packet filters configured in an Active Charging Service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging packet-filter { all | name *packet_filter_name* **} [service name** *acs_service_name* **] [| { grep** *grep_options* **| more }]**

all

Displays information for all packet filters configured, optionally all configured in an ACS.

name *packet_filter_name*

Displays detailed information for an existing packet filter specified as an alphanumeric string of 1 through 63 characters.

service name *acs_service_name*

Displays information for all filters or the specified packet filter in the specified ACS. *acs_service_name* must be the name of the ACS expressed as an alphanumeric string of 1 through 15 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view information on packet filters configured in an ACS.

Example

The following command displays information for the packet filter *filter12*:

```
show active-charging packet-filter name filter12
```

show active-charging rulebase

Displays information for ACS rulebases.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging rulebase { { { all | name rulebase_name } [ service name
acs_service_name ] } | statistics [ name rulebase_name ] } | [ | { grep grep_options |
more } ]
```

all

Displays details of all rulebases configured in the system.

name *rulebase_name*

Displays details of an existing rulebase specified as an alphanumeric string of 1 through 63 characters.

service name *acs_service_name*

Displays details of all or the specified rulebase configured in the specified ACS. *acs_service_name* must be the name of the ACS expressed as an alphanumeric string of 1 through 15 characters.

statistics

Displays statistical information for all or the specified rulebase.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view various statistics for a specific charging rulebase.

Example

The following command displays active charging rulebase statistics.

```
show active-charging rulebase statistics
```

The following command displays configurations and statistics for a rulebase named *rulebase_1*.

```
show active-charging rulebase name rulebase_1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging ruledef

Displays information for rule definitions (ruledefs) configured in the Active Charging Service (ACS).

Product

ACS, FW, TPO

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging ruledef { all | charging | firewall | name *ruledef_name* **| post-processing | routing | statistics [all { charging | firewall [wide] | post-processing | tpo } | name** *ruledef_name* **[wide]] | tpo } [| { grep** *grep_options* **| more }]**

all

Displays information for all ruledefs configured in the ACS.

charging

Displays information for all Charging ruledefs configured in the ACS.

firewall

Displays information for all Stateful Firewall ruledefs configured in the ACS.

name *ruledef_name*

Displays detailed information for an existing ruledef specified as an alphanumeric string of 1 through 63 characters.

post-processing

Important: This keyword is only available in StarOS 8.3 and later.

Displays information for all post-processing ruledefs configured in the ACS.

routing

Displays information for all Routing ruledefs configured in the ACS.

service *service_name*

This keyword is obsolete.

statistics [all { charging | firewall [wide] | post-processing | tpo } | name *ruledef_name* **[wide]]**

Displays statistical information for all/specified ruledefs configured in the ACS. If none of the optional arguments are supplied, statistics totaled for all ruledefs will be displayed.

- **all**: Displays statistics for all ruledefs of the specified type configured in the ACS.
- **charging**: Displays statistics for all Charging ruledefs configured in the ACS.

- **firewall**: Displays statistics for all Firewall ruledefs configured in the service.
- **post-processing**: Displays statistics for all Post-processing ruledefs configured in the ACS.

> **Important:** The **post-processing** keyword is available only in StarOS 8.3 and later releases.

- **tpo**: Displays statistics for all Traffic Performance Optimization (TPO) ruledefs configured in the ACS.

> **Important:** The **tpo** keyword is available only in 12.2 and later releases.

- **name** *ruledef_name*: Displays statistics for an existing ruledef specified as an alphanumeric string of 1 through 63 characters.
- **wide**: Displays all available information in a single wide line.

tpo

> **Important:** The **tpo** keyword is available only in 12.2 and later releases.

Displays information for all Traffic Performance Optimization (TPO) ruledefs configured in the ACS.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view information for ruledefs configured in the ACS.

Example

The following command displays ACS ruledef statistics.

```
show active-charging ruledef statistics
```

> **Important:** Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging service

Displays detailed information about an Active Charging Service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging service { all | name acs_service_name } [ | { grep grep_options |
more } ]
```

all

Displays information for all configured ACSs.

name *acs_service_name*

Displays detailed information for the ACS specified as an alphanumeric string of 1 through 15 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view ACS details.

Example

The following command displays details for the ACS named *test1*.

```
show active-charging service name test1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging sessions

Displays statistics for Active Charging Service (ACS) sessions.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging sessions [ full [ wide ] | summary | display-dynamic-charging-rules
| dynamic-charging ] { [ all ] | [ filter_keyword ] + } [ | { grep grep_options | more }
]
```

full [wide]

Displays all available information for the specified session.
Optionally all available information can be displayed in a single wide line.

summary

Displays summary information for defined sessions based on defined parameters.

display-dynamic-charging-rules

Displays information for the dynamic charging rules configured per session under Gx interface support.

dynamic-charging

Displays information for dynamic charging sessions.

filter_keyword

The following keywords are filters that modify or filter the output of the Command Keywords. Not all filters are available for all command keywords. Multiple filter keywords can be entered on a command line.
When multiple filter keywords are specified, the output conforms to all of the filter keywords specifications. For example, if you enter the following command:
show active-charging sessions full active-charging-service acs_!
Counters for active charging sessions active in ACS *acs_1* with full details is displayed. Information for all other services is not displayed.

acsmgr instance *instance*

Displays session information for a specific ACS/Session Manager instance.

active-charging-service *acs_service_name*

Displays session information for the ACS specified as an alphanumeric string of 1 through 15 characters.

all

Displays session information for all active charging sessions.

callid

Specifies the call identification number.

display-dynamic-charging-rules

Displays dynamic charging rules configured.

dynamic-charging

Displays session information for all dynamic charging sessions.

firewall { not-required | required }

Displays session information for sessions with Firewall Processing required or not required, as specified.

fw-and-nat policy *fw_nat_policy_name*

Displays information for the Firewall-and-NAT Policy specified as an alphanumeric string of 1 through 63 characters.

imsi

Specifies the International Mobile Subscriber Identity (IMSI) of the subscriber session.

ip-address

Specifies the IP address for the specific charging service.

msid

Displays active charging session information for a specific subscriber's Mobile Station Identification (MSID) number.

ipv4

Displays active charging session information with IPv4 Firewall enabled/disabled.

ipv6

Displays active charging session information with IPv6 Firewall enabled/disabled.

nat { not-required | required [nat-realm *nat_realm* **] } [ipv4 | ipv6]**

Displays session information for sessions with NAT required or not required, as specified.
nat-realm *nat_realm* specifies the name of a NAT realm as an alphanumeric string of 1 through 63 characters.
ipv4: Displays active-charging sessions for which NAT44 processing is required.
ipv6: Displays active-charging sessions for which NAT64 processing is required.

rulebase

Displays information for a rulebase that is configured in an active charging session.

rx-data

Displays the bytes received in the session.

session-id

Displays detailed session information for a specific session identification.

tx-data

Displays the bytes sent in the session.

type

Displays session information for specified DNS application type(s).

- **dns**
- **ftp**
- **http**
- **icmp**
- **icmpv6**
- **imap**
- **ip**
- **ipv6**
- **mms**
- **p2p**: Displays session information for a P2P application type:
  - **actsync**
  - **aimini**
  - **antsp2p**
  - **applejuice**
  - **ares**
  - **armagettron**
  - **battlefd**
  - **bittorrent**
  - **blackberry**
  - **citrix**
  - **clubpenguin**
  - **crossfire**
  - **ddlink**
  - **directconnect**
  - **dofus**
  - **edonkey**
  - **facebook**
  - **facetime**

Important: The **facetime** protocol is available only in releases 9.0 and 11.0. This protocol is not available in release 10.0.

- **fasttrack**
- **feidian**
- **fiesta**
- **filetopia**
- **florensia**
- **freenet**
- **fring**
- **funshion**
- **gadu_gadu**
- **gamekit**

Important: The **gamekit** protocol is available only in releases 9.0 and 11.0. This protocol is not available in release 10.0.

username

Displays session information for a specific user name.

dynamic-charging

Displays the all sessions having received at least one Gx message from Session Manager/IMS Authorization.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display the configuration information for an active charging session.

Example

The following command displays full information of an active charging session.

```
show active-charging sessions full all
```

The following command displays an active charging session summary.

```
show active-charging sessions summary
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging subsystem

Displays service and configuration counters for the ACS.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging subsystem { all | facility acsmgr { all | instance instance_value }
[ rulebase name rulebase_name ] | sip } [ | { grep grep_options | more } ]
```

all

Displays ACS subsystem information.

facility acsmgr [all | instance *instance_value*]

Displays logged events for all ACS/Session Managers or for a specific instance expressed as an integer from 1 through 65535.

rulebase name *rulebase_name*

Displays rulebase statistics for the specified rulebase expressed as an alphanumeric string of 1 through 63 characters.

sip

Displays SIP related statistics.

| { grep *grep_options* | more }

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view ACS/Session Manager information.

Example

The following command displays ACS subsystem information:

```
show active-charging subsystem all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging tcp-proxy statistics

Displays TCP Proxy statistics.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging tcp-proxy statistics [all | ip-layer | proxy-fac | rulebase *rulebase_name* **| socket-migration | tcp-layer] [verbose] [| { grep** *grep_options* **| more }]**

all

Displays all TCP Proxy statistics aggregated over all rulebases, including for both IP and TCP layers.

ip-layer

Displays TCP Proxy statistics for IP layer.

proxy-fac

Displays TCP Proxy Flow Admission Control statistics.

rulebase *rulebase_name*

Displays TCP Proxy statistics for the rulebase specified as an alphanumeric string of 1 through 63 characters.

socket-migration

Displays TCP Proxy statistics for socket migration.

tcp-layer

Displays TCP Proxy statistics for TCP layer.

verbose

Displays detailed TCP Proxy statistics.

| { grep *grep_options* **| more }**

Specifies that the output of this command is to be piped (sent) to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view TCP Proxy statistics.

Example

The following command displays detailed TCP proxy statistics for the rulebase named *test14*:

```
show active-charging tcp-proxy statistics rulebase test14 verbose
```

show active-charging tethering-detection

Displays information/statistics pertaining to Tethering Detection databases.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging tethering-detection { database [ os-signature | tac | ua-signature
]+ [ sessmgr { all | instance instance } ] [ | { grep grep_options | more } ] |
statistics }
```

database [os-signature | tac | ua-signature]+ [sessmgr { all | instance *instance* }]

Displays information pertaining to the specified Tethering Detection database(s).

- **os-signature**: Displays Tethering Detection OS (Operating System) database information.
- **tac**: Displays Tethering Detection TAC (Transaction Authorization Code) database information.
- **ua-signature**: Displays Tethering Detection UA (User Agent) database information.
- **+**: Indicates that more than one of the preceding keywords can be entered in a single command.
- **sessmgr { all | instance** *instance* **}**: Displays SessMgr Tethering Detection database status.
  - **all**: Displays status for all SessMgr instances.
  - **instance** *instance*: Displays status for the SessMgr instance specified as an integer from 1 through 10000.

statistics

Displays Tethering Detection related statistics.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view information/statistics pertaining to Tethering Detection databases.

Example

The following command displays information pertaining to Tethering Detection UA and OS databases:

```
show active-charging tethering-detection database ua-signature os-
signature
```

The following command displays information pertaining to all Tethering Detection databases:

show active-charging tethering-detection database

show active-charging timedef

Displays the details of timeslots configured in specified time definition(s).

Important: This command is only available in StarOS 8.1 and in StarOS 9.0 and later.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging timedef { all | name timedef_name } [ service name acs_service_name
] [ | { grep grep_options | more } ]
```

all

Displays information for all timedefs configured in the service.

name *timedef_name*

Displays detailed information for the timedef specified s an alphanumeric string of 1 through 63 characters.

service name *acs_service_name*

Displays information for all or a specific timedef configured in the specified ACS. *acs_service_name* must be the name of the ACS expressed as an alphanumeric string of 1 through 15 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view details of timeslots configured in specified timedef(s) that have been configured for the Time-of-Day Activation/Deactivation of Rules feature.

Example

The following command displays timeslot details of all timedefs configured in the ACS:

```
show active-charging timedef all
```

show active-charging tpo policy statistics

Displays Traffic Performance Optimization (TPO) policy statistics.

Product

TPO

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging tpo policy statistics [all | name *tpo_policy_name* **] [| { grep** *grep_options* **| more }]**

name *tpo_policy_name*

Displays detailed statistics for an existing TPO policy specified as an alphanumeric string of 1 through 63 characters.

all

Displays statistics for all TPO policies configured in the active charging service.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view TPO policy statistics.

- "**show active-charging tpo policy statistics all**" command displays statistics for each TPO policy configured in the active charging service.
- "**show active-charging tpo policy statistics name** *tpo_policy_name*" command displays statistics for the specified TPO policy.
- "**show active-charging tpo policy statistics**" command displays aggregated statistics for all TPO policies configured in the active charging service.

Example

The following command displays statistics for the TPO policy named *policy12*:

```
show active-charging tpo policy statistics name policy12
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging tpo profile statistics

Displays Traffic Performance Optimization (TPO) profile statistics.

Product

TPO

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging tpo profile statistics [name *tpo_profile_name* **| all] [| { grep** *grep_options* **| more }]**

name *tpo_profile_name*

Displays detailed statistics for an existing TPO profile specified as an alphanumeric string of 1 through 63 characters.

all

Displays statistics for all TPO profiles configured in the active charging service.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view TPO profile statistics.

- "**show active-charging tpo profile statistics all**" command displays statistics for each TPO profile configured in the active charging service.
- **show active-charging tpo profile statistics name** *tpo_profile_name* command displays statistics for the specified TPO profile.
- **show active-charging tpo profile statistics** command displays aggregated statistics for all TPO profiles configured in the active charging service.

Example

The following command displays statistics for the TPO profile named *profile12*:

```
show active-charging tpo profile statistics name porfile12
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging udr-format

Displays information about UDR formats configured in an Active charging Service (ACS).

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging udr-format { all | name udr_fromat_name } [ | { grep grep_options |
more } ]
```

all

Displays information for all UDR formats.

name *udr_fromat_name*

Displays information for an existing UDR format specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for UDR format(s) in an ACS.

Example

The following command displays all configured UDR formats in an ACS.

```
show active-charging udr-format all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging url-blacklisting statistics

Displays URL Blacklisting statistics.

Product

CF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging url-blacklisting statistics [ rulebase { all | name rulebase_name }
] [ verbose ] [ | { grep grep_options | more } ]
```

rulebase { all | name *rulebase_name* }

Displays URL Blacklisting statistics for all or a specific rulebase.

- **all**: Displays URL Blacklisting statistics for all configured rulebases.
- **name** *rulebase_name*: Displays URL Blacklisting statistics for the rulebase specified as an alphanumeric string of 1 through 63 characters.

verbose

Displays detailed URL Blacklisting statistics.

| { grep *grep_options* | more }

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view URL Blacklisting hits and misses statistics.

Example

The following command displays cumulative URL Blacklisting statistics:

```
show active-charging url-blacklisting statistics
```

The following command displays URL Blacklisting statistics for the rulebase *rulebase_1*:

```
show active-charging url-blacklisting statistics rulebase name rulebase_1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show active-charging video detailed-statistics

Displays detailed statistics for TCP video flows. The command options enable you to collect statistical data for video per UE device type, per radio access type, and per video container type.

Product

MVG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show active-charging video detailed-statistics [ container { flv | mp4 | others } | rat {
cdma | gprs | hspa | lte | others | umts | wlan } | ue { android | ios | laptop | others
} ]
```

container { flv | mp4 | others }

Displays detailed statistics for TCP video flows based on the specified container file format.

rat { cdma | gprs | hspa | lte | others | umts | wlan }

Displays detailed statistics for TCP video flows based on the specified radio access type.

ue { android | ios | laptop | others }

Displays detailed statistics for TCP video flows based on the specified UE device type.

Usage

Use this command to display detailed statistics about video usage. Use the command options to display detailed statistics based on the UE device type, radio access type, or container file format.

Example

The following command displays detailed statistics about video usage based on the UE device type *ios*:

```
show active-charging video detailed-statistics ue ios
```

show active-charging xheader-format

Displays x-header format configurations for an Active Charging Service (ACS).

Important: This is a customer-specific command. Please contact your local sales representative for more information.

Product

ACS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show active-charging xheader-format { all | name *xheader_format* **} [| { grep** *grep_options* **| more }]**

all

Displays information for all x-header formats configured.

name *xheader_format*

Displays information for the x-header format specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view details of x-header formats configured in an ACS.

Example

The following command displays information for the x-header format named *test12*:

```
show active-charging xheader-format test12
```

show administrators

Displays information regarding all CLI users currently connected to the system.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show administrators [session id] [| { grep *grep_options* **| more }]**

session id

Indicates the output is to contain additional information about the CLI user session including the assigned session ID.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command displays a list of administrative users that have command line interface sessions active.

Example

show administratorsshow administrators session id

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show alarm

Displays alarm information.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show alarm { all | audible | central-office | facility | outstanding [ all | chassis |
port slot/port | slot slot ] [ verbose ] | statistics } [ | { grep grep_options | more }
]
```

all

Displays the state of all alarms in one screen.

audible

Displays the state of the internal audible alarm buzzer on the SMC.

central-office

Displays the state of the CO Alarm relays on the SPIO.

facility

Displays the state of the facility (audible and CO) alarms.

outstanding [all | chassis | port *slot/port* **| slot** *slot* **] [verbose]**

Displays information on currently outstanding alarms.

- **all**: Displays all alarm information.
- **chassis**: Displays chassis/power/fan alarms.
- **port** *slot/port*: Shows the alarm information for the specified port.
- **slot** *slot*: Shows the alarm information for the card in the specified slot.
- **verbose**: Displays more verbose output, including the internal alarm ID

statistics

Displays basic statistics on the alarming subsystem, including the current number of outstanding alarms of different severities and a cumulative total of alarms generated.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command Output* section of the *Command Line Interface Overview* chapter.

Usage

View alarms to verify system status or to periodically check the general health of the system.

Important: This command is not supported on all platforms.

Example

The following command displays all alarms that are currently outstanding:

```
show alarm outstanding all
```

The following command displays more detailed information on all alarms that are currently outstanding:

```
show alarm outstanding all verbose
```

The following command displays alarm statistics:

```
show alarm statistics
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show alcap counters

Displays the Access Link Control Application Part (ALCAP) protocol message counters related to ALCAP protocol sessions associated with a Home-NodeB Gateway (HNB-GW) service instance configured and running on a system.

Product

HNB-GW

Privilege

Inspector

Syntax

show alcap counters [alcap-service *alcap_svc_name* **[aal2-node** *aal2_node_name* **[aal2-path** *aal2_path_id* **]]] [| { grep** *grep_options* **| more }]**

name *alcap_svc_name*

Specifies the name of the ALCAP service for which ALCAP protocol session counters are to be displayed.

aal2-node *aal2-node*

Specifies the name of the ATM Adaptation Layer 2 (AAL2) node for which protocol session counters will be filtered.

aal2-path *aal2_path_id*

Specifies the identity number of the AAL2 path on a specific ATM Adaptation Layer 2 (AAL2) node for which ALCAP protocol counters will be filtered.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *Command Line Interface Overview* chapter.

Usage

This command is used to display the sessions statistics and counters for ALCAP service.

Example

The following command displays the ALCAP protocol session counters for ALCAP service named as *alcap_hnb_svc1*:

```
show alcap counters alcap-service alcap_hnb_svc1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show alcap-service

Displays the Access Link Control Application Part (ALCAP) session statistics of an ALCAP service associated with a Home-NodeB Gateway (HNB-GW) service instance configured and running on a system.

Product

HNB-GW

Privilege

Inspector

Syntax

show alcap-service { all | name *alcap_svc_name* **[aal2-node** *aal2_node_name* **[aal2-path** *aal2_path_id* **[aal2-channel** *aal2_channel_num***]] | endpoint** *aal2_endpoint_name* **] } [| { grep** *grep_options* **| more }]**

name *alcap_svc_name*

Specifies the name of the ALCAP service for which service statistics are to be displayed.

aal2-node *aal2-node*

Specifies the name of the ATM Adaptation Layer 2 (AAL2) node that will be used to filter the display of the ALCAP service statistics.

aal2-path *aal2_path_id*

Specifies the identity number of the AAL2 path on a specific ATM Adaptation Layer 2 (AAL2) node that will be used to filter the display of the ALCAP service statistics.

aal2-channel *aal2_channel_num*

Specifies the AAL2 channel number of the AAL2 path on a specific ATM Adaptation Layer 2 (AAL2) node that will be used to filter the display of the ALCAP service statistics.

endpoint *atm_endpoint_name*

Specifies the ATM endpoint name that will be used to filter the display of the ALCAP service statistics for a specific ATM endpoint.

Usage

This command is used to clear the sessions statistics and counters for ALCAP service.

Example

The following command displays the service statistics of ALCAP service named as *alcap_hnb_svc1*:

```
show alcap-service name alcap_hnb_svc1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show alcap statistics

Displays the session statistics related to Access Link Control Application Part (ALCAP) protocol sessions associated with a Home-NodeB Gateway (HNB-GW) service instance configured and running on a system.

Product

HNB-GW

Privilege

Inspector

Syntax

show alcap statistics [alcap-service *alcap_svc_name* **[aal2-node** *aal2_node_name* **[aal2-path** *aal2_path_id* **]]] [verbose] [| { grep** *grep_options* **| more }]**

name *alcap_svc_name*

Specifies the name of the ALCAP service for which statistics are to be displayed.

aal2-node *aal2-node*

Specifies the name of the ATM Adaptation Layer 2 (AAL2) node for which ALCAP service related statistics will be displayed.

aal2-path *aal2_path_id*

Specifies the identity number of the AAL2 path on a specific ATM Adaptation Layer 2 (AAL2) node for which ALCAP service statistics counters will be displayed.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *Command Line Interface Overview* chapter of the *Command Line Interface Reference*.

Usage

This command is used to display the sessions statistics and counters for ALCAP service.

Example

The following command displays the service session statistics counters for ALCAP service named as *alcap_hnb_svc1*:

```
show alcap counters alcap-service alcap_hnb_svc1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show apn

Displays configuration information for either a specific or all configured Access Point Names (APNs).

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show apn { all | name *apn_name* **} [| { grep** *grep_options* **| more }]**

all

Displays information on all APNs configured on the system.

name *apn_name*

Displays information for an APN specified as an alphanumeric string of 1 through 62 characters that is case sensitive.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more** options, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command is used to verify the configuration of one or all APNs for monitoring or troubleshooting purposes. The output is a concise listing of APN parameter settings.
If this command is executed from within the local context with the all keyword, information for all APNs configured on the system will be displayed.

Example

The following command displays configuration information for all APNs:

```
show apn all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show apn counters ip-allocation

Displays the IP allocation method information/statistics counters on per Access Point name (APN) basis for all currently active calls.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show apn counters ip-allocation [all | name *apn_name* **] [| { grep** *grep_options* **| more }]**

all

Displays statistics for all APNs.

name *apn_name*

Displays statistics for the APN specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command is used to display the IP allocation counters on per APN basis for all currently active calls. Output of this command gives the user clear idea of how many sessions in each APN are using a particular type of ip-allocation method.
If this command is issued from within the local context, the statistics displayed will be cumulative for all APNs configured on the system regardless of context. If no APN name is specified and the command is executed from a context with multiple APNs configured, the output will be cumulative for all APNs in the context.

Example

The following command displays statistics for all APN on a system:

```
show apn counter ip-allocation all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show apn statistics

Displays statistics for either a specific Access Point Name (APN) or all configured APNs.

Product

GGSN, P-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show apn statistics [all | name *apn_name* **] [| { grep** *grep_options* **| more }]**

all

Displays statistics for all APNs.

name *apn_name*

Displays statistics for the APN specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command is used to view statistics for one or all APNs within a context for monitoring or troubleshooting purposes.
If this command is issued from within the local context, the statistics displayed will be cumulative for all APNs configured on the system regardless of context. If no APN name is specified and the command is executed from a context with multiple APNs configured, the output will be cumulative for all APNs in the context.

Example

The following command displays statistics for an APN named *isp2*:

```
show apn statistics name isp2
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show apn-profile

Displays information for configured Access Point Name (APN) profiles.

Product

MME, SGSN

Privilege

Inspector

Syntax

show apn-profile { all | full { all | name *apn_name* **} | name** *apn_name* **} [| { grep** *grep_options* **| more }]**

---

all

Lists all APN profiles configured on the system.

---

full { all | name *apn_name* **}**

full: Displays all information in the APN profile(s).
all: Displays full information for all APN profiles configured on the system.
name *apn_name*: Displays full information for an APN profile specified as an alphanumeric string of 1 through 64 characters.

---

name *apn_name*

Displays information for an APN profile specified as an alphanumeric string of 1 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for APN profiles configured on the system. APN profiles are configured through the global configuration mode and in the APN profile configuration mode. For more information regarding APN profile commands, refer to the *APN Profile Configuration Mode Commands* chapter.

Example

The following command displays all available information for an APN profile named *apn-prof3*:

```
show apn-profile full name apn-prof3
```

show aps

Displays information for configured Automatic Protection Switching (APS) parameters.

Product

SGSN

Privilege

Inspector

Syntax

show aps { all | card-stats *slot_number* **[clear] | info** *slot_number/port_number* **| port-stats** *slot_number/port_number* **[clear] | port-status } [| { grep** *grep_options* **| more }]**

---

all

Lists APS information for all cards configured with APS.

---

card-stats*slot_number* **[clear]**

Displays the APS statistics for the identified card. If the **clear** keyword is included with the command, the APS statistics for the specified card are cleared (reset to zero).
slot_number is an integer that identifies the chassis slot holding the card.

---

info*slot_number/port_number*

Displays APS information for a specific port.
slot_number/port_number: The first number must be an integer that identifies the chassis slot holding the specified card. The slot number must be followed by a slash '/', which must be followed immediately by the port number - an integer from 1 to 4 depending upon the type of card.

---

port-stats*slot_number/port_number* **[clear]**

Displays APS statistics for a specific port. If the **clear** keyword is included with the command then the APS statistics for the specified port are cleared (reset to zero).
slot_number/port_number: The first number must be an integer from 1 to 48 to identify the chassis slot holding the specified card. The slot number must be followed by a slash '/', which must be followed immediately by the port number - an integer from 1 to 4 depending upon the type of card.

---

port-status*slot_number/port_number*

Displays APS status information for a specific port.
slot_number/port_number: The first number must be an integer from 1 to 48 to identify the chassis slot holding the specified card. The slot number must be followed by a slash '/', which must be followed immediately by the port number - an integer from 1 to 4 depending upon the type of card.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display APS redundancy configuration, APS card and port status, and APS card and port statistics. APS is configured at the card level. For details on configuring APS, refer to the *Card Configuration Mode Commands* chapter in this reference.

Important: APS is only relevant for the CLC2 and OLC2 line cards supporting SONET/SDH.

Example

The following command displays all available APS configuration information for a specific port 1 on the line card in slot 27:

```
show aps info 27/1
```

show apn-remap-table

Displays information for Access Point Name (APN) remap tables configured on the system.

Product

MME, SGSN

Privilege

Inspector

Syntax

show apn-remap-table { all | full { all | name *remap_table_name* **} | name** *remap_table_name* **} [| { grep** *grep_options* **| more }]**

all

Lists all APN remap tables configured on the system.

full { all | name *remap_table_name* **}**

full: Displays a full set (all) of available information for the configured APN remap table(s).
all: Displays the full set of available information for all APN remap tables configured on the system.
name *remap_table_name*: Displays the full set of available information for an existing APN remap table specified as alphanumeric string of 1 through 64 characters.

name *remap_table_name*

Displays information for an existing APN remap table specified as an alphanumeric string of 1 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for APN remap tables configured on the system. APN remap tables are configured through the Global Configuration mode and in the APN remap table configuration mode. For more information regarding APN remap table commands, refer to the *APN Remap Table Configuration Mode Commands* chapter.

Example

The following command displays all available information for an APN remap table named *remap-table12*:

```
show apn-remap-table full name remap-table12
```

show asngw-service

Displays information about selected Access Service Network Gateway (ASN-GW) calls/services.

Product

ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show asngw-service { all | name service_name | session | statistics } [ bs-status [
address ip_address | filter { all | icmp-monitored | no-calls | summary | up ] ] [ | {
grep grep_options | more } ]
```

---

all

Displays information for all configured ASN-GW services.

---

name *service_name*

Displays information only for an existing ASN-GW service in the current context specified as an alphanumeric string of 1 through 63 characters.

---

session

Displays information about configured ASN-GW sessions. See the **show asngw-service session** command

---

statistics

Total of collected information for specific protocol since the last **restart** or **clear** command.

---

bs-status { address *ip_address* **| filter { all | icmp-monitored | no-calls | summary | up } }**

Displays the ASN base station (BS) status based on IP address and various filters.
address *ip_address* specifies the IP address of ASN base station whose status is requested. *ip_address* must be entered in IPv4 dotted-decimal or IPv6 colon-separated notation.
filter { all | icmp-monitored | no-calls | summary | up }: Filters the requested BS's status on the basis of following criteria:

- **all**: Displays the status of all ASN base stations.
- **icmp-monitored**: Displays the status of ASN base stations that are monitored through ICMP ping messages.
- **no-calls**: Displays the status of an ASN base station that has no active calls.
- **summary**: Displays a summary of the status of requested ASN base stations.
- **up**: Displays the of status of ASN base stations that are in active state.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view information for selected configured ASN-GW services.

Example

The following command displays available information for all active ASN-GW services.

```
show asngw-service all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show asngw-service session

Displays statistics for specific Access Service Network Gateway (ASN-GW) sessions.

Product

ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show asngw-service session [all | anchor-only [full] | callid *call_id* **| counters | full | ip-address** *ipv4_address* **| msid** *msid_number* **| non-anchor-only [full] | peer-address** *ipv4_address* **| summary | username** *user_name* **] [| { grep** *grep_options* **| more }]**

all

Displays all related information for all active ASN-GW service sessions.

anchor-only

Displays all available information for all active ASN-GW service sessions on an anchor ASN-GW only.

callid *call_id*

Displays available information for the call identification number specified as an 8-digit hexadecimal number.

full

Displays all available information for the associated display or filter keyword.

ip-address *ipv4_address*

Specifies the IP address of the subscriber in IPv4 dotted-decimal notation.

msid *msid_number*

Displays available information for the specific mobile station identification number (MSID).

non-anchor-only

Displays all available information for all active ASN-GW service sessions on a non-anchor ASN-GW only.

peer-address *ipv4_address*

Specifies the Ip address of an IP peer in dotted-decimal notation.

summary

Displays summary of available information for associated display or filter keyword (previous keyword).

username *user_name*

Specifies the name of a user within current context as an alphanumeric string of 1 through 127 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view configuration information for an ASN-GW session.

Example

The following command displays all available ASN-GW sessions.

```
show asngw-service session all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show asngw-service session counters

Displays statistics for specific Access Service Network Gateway (ASN-GW) sessions.

Product

ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show asngw-service session counters [[**function-type** { **auth-relay** | **context-transfer** | **data-path** | **handoff** | **im-operation** | **ms-state-change** | **paging** | **qos** }] | [**anchor-only** | **callid** *call_id* **| ip-address** *ipv4_address* **| msid** *msid_number* | **non-anchor-only** | **peer-address** *ipv4_address* **| username** *user_name*] [**r4-only** | **r6-only** | **verbose**]] [| { **grep** *grep_options* | **more** }]

anchor-only

Displays all available information for all active anchor sessions in an ASN-GW service.

callid *call_id*

Displays available information for the call identification number specified as an 8-digit hexadecimal number.

function-type { auth-relay | context-transfer | data-path | handoff | im-operation | ms-state-change | paging | qos }

Displays the counters for specific type of functions in an ASN-GW session.
auth-relay: Displays information about authentication relay messages.
context-transfer: Displays information about context-transfer messages.
data-path: Displays information about data-path registration messages.
handoff: Displays information about hand-off messages.
im-operations: Displays information about idle mode state operation messages.
ms-state-change: Displays information about MS state change messages.
paging: Displays information about paging messages.
qos: Displays information about RR messages.

ip-address *ipv4_address*

Specifies the IP address of the subscriber in IPv4 dotted-decimal notation.

msid *msid_number*

Displays available information for the specific mobile station identification (MSID) number.

non-anchor-only

Displays all available information for all active non-anchor sessions in an ASN-GW service.

peer-address *ipv4_address*

Specifies the IP address of an IP peer in IPv4 dotted-decimal notation.

r6-only

Displays all available counters for R6 interface in an ASN-GW session.

r4-only

Displays all available counters for R4 interface in an ASN-GW session.

username *user_name*

Displays available session information for the specific WiMAX user in ASN-GW service session.
user_name is an alphanumeric string of 1 through 127 characters.

verbose

Indicates the output should provide as much information as possible. If this option is not specified then the output will be the standard level which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view the counters of an ASN-GW session.

Example

The following command displays the counters for data path type function.

```
show asngw-service session counters function-type data-path
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show asngw-service statistics

Displays statistics for all Access Service Network Gateway (ASN-GW) sessions.

Product

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show asngw-service statistics [function-type { auth-relay | context-transfer | data-path | handoff | im-operations | ms-state-change | paging | qos | capability }] [name *service_name* **| r4-only | r6-only | verbose | peer-address** *ipv4_address*] [**peer-id** *id*][**verbose**] [{ **grep** *grep_options* | **more** }]

function-type

Displays information about selected function type on R4 or R6 interface.

function-type { auth-relay | context-transfer | data-path | handoff | im-operations | ms-state-change | paging | qos | capability} [r4-only | r6-only]

Displays the counters for specific type of functions in an ASN-GW session.
auth-relay: Displays information about authentication relay messages.
context-transfer: Displays information about context-transfer messages.
data-path: Displays information about data-path registration messages.
handoff: Displays information about hand-off messages.
im-operations: Displays information about idle mode state operation messages.
ms-state-change: Displays information about MS state change messages.
paging: Displays information about paging messages.
qos: Displays information about RR messages.
capability: Displays the capability negotiation between the ASNGW and the base station.
r4-only: Displays information about selected function on R4 interface.
r6-only: Displays information about selected function on R6 interface.

name *service_name*

Displays information for an existing service specified as an alphanumeric string of 1 through 63 characters.

r4-only

Displays statistics of R4 interface in ASN-GW services.

r6-only

Displays statistics of R6 interface in ASN-GW services.

peer-address *ipv4_address*

Specifies the IP address of an IP Peer in IPv4 dotted-decimal notation.

peer-id < *id* >

Display the statistics based on the 6-byte BSID or ASNGW ID in addition to the IPv4 address.

verbose

Indicates the output should provide as much information as possible. If this option is not specified then the output will be the standard level which is the concise mode.

| { grep *grep_options* | more }

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display ASN-GW statistics.

Example

The following command displays information about selected MS-State-Change function.

```
show asngw-service statistics function-type ms-state-change
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show asnpc-service

Displays information about selected Access Service Network Paging Controller and Location Registry (ASN PC/LR) services.

Product

ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show asnpc-service { all | id | name *service_name* **| session | statistics } [| { grep** *grep_options* **| more }]**

all

Displays information for all configured ASN PC services.

paging-group

Displays all the configured paging-groups and associated paging nodes, and the offset count. For a specific paging group, enter the paging group id number.

name *service_name*

Displays information only for an existing ASN PC service specified as an alphanumeric string of 1 through 63 characters.

session

Displays information about configured ASN PC sessions.

statistics

Total of collected information for specific protocol since last restart or clear command.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view information for selected configured ASN PC services.

Example

The following command displays available information for all active ASN PC services.

```
show asnpc-service all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show asnpc-service session

Displays statistics for specific Access Service Network Paging Controller (ASN PC) service sessions.

Product

ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show asnpc-service session [all | callid *call_id* **| counters | full | msid** *msid_number* **| peer-address** *ipv4_address* **| summary] [| { grep** *grep_options* **| more }]**

all

Displays all related information for all active ASN PC service sessions.

callid *call_id*

Displays available information for the call identification number specified as an 8-digit hexadecimal number.

full

Displays all available information for the associated display or filter keyword.

msid *msid_number*

Displays available information for the specific mobile station identification (MSID) number.

peer-address *ipv4_address*

Specifies the IP address of an IP peer in IPv4 dotted-decimal notation.

summary

Displays summary of available information for associated display or filter keyword (previous keyword).

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view configuration information for an ASN PC session.

Example

The following command displays all available ASN PC session counters in verbose mode.

```
show asnpc-service session all
```

The following command displays full ASN PC session counters in verbose mode.

```
show asnpc-service session full
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show asnpc-service session counters

Displays session counters for Access Service Network Paging Controller (ASN PC) service sessions.

Product

ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show asngw-service session counters [all | callid *call_id* **| msid** *msid_number* **| peer-address** *ipv4_address* **| verbose]] [| { grep** *grep_options* **| more }]**

all

Displays all available counters for all ASN PC service sessions.

callid *call_id*

Displays available information for the call identification number specified as an 8-digit hexadecimal number.

msid *msid_number*

Displays available information for the specific mobile station identification (MSID) number.

peer-address *ipv4_address*

Specifies the IP address of an IP peer in IPv4 dotted-decimal notation.

verbose

Indicates the output should provide as much information as possible. If this option is not specified then the output will be the standard level which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view the counters of an ASN PC session.

Example

The following command displays the counters for ASN PC service sessions in verbose mode.

```
show asnpc-service session counters verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show asnpc-service session counters verbose

Displays session counters for Access Service Network Paging Controller (ASN PC) service sessions in complete detail.

Product

ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show asngw-service session counters verbose [function-type { context-transfer | im-operations | ms-state-change | paging }] [all | callid *call_id* **| msid** *msid_number* **| peer-address** *ipv4_address* **]] [| { grep** *grep_options* **| more }]**

---

all

Displays all available counters for all ASN PC service sessions in verbose mode.

---

callid *call_id*

Displays full information for the call identification number specified as an 8-digit hexadecimal number.

---

function-type { context-transfer | im-operations | ms-state-change | paging }

Displays the counters for specific type of functions in an ASN-GW session.
context-transfer: Displays information about context-transfer messages.
im-operations: Displays information about idle mode state operation messages.
ms-state-change: Displays information about MS state change messages.
paging: Displays information about paging messages.

---

msid *msid_number*

Displays full information for the specific mobile station identification (MSID) number.

---

peer-address *ipv4_address*

Specifies the IP address of an IP peer IPv4 dotted-decimal notation.

---

r4-only

Displays statistics of R4 interface in ASN PC services in verbose mode.

---

r6-only

Displays statistics of R6 interface in ASN PC services in verbose mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view the counters of an ASN PC session in verbose mode.

Example

The following command displays the counters for data path type function.

```
show asnpc-service session counters verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show asnpc-service statistics

Displays statistics for all ASN PC service sessions.

Product

ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show asnpc-service statistics [ name service_name | peer-address ipv4_address | verbose ]
[ r4-only | r6-only [ | { grep grep_options | more } ]
```

name *service_name*

Specifies an existing service name as an alphanumeric string of 1 through 63 characters.

peer-address *ipv4_address*

Specifies the IP address of an IP Peer in IPv4 dotted-decimal notation.

verbose

Indicates the output should provide as much information as possible. If this option is not specified then the output will be the standard level which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display ASN PC statistics.

Example

The following command displays information about ASN PC service in verbose mode.

```
show asnpc-service statistics verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show asnpc-service statistics verbose

Displays statistics for all Access Service Network Paging Controller (ASN PC) service in verbose mode.

Product

ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show asnpc-service statistics verbose [ function-type { context-transfer | im-operations
| ms-state-change | paging } ] | all | r4-only | r6-only ] [ | { grep grep_options | more
} ]
```

function-type { context-transfer | ms-state-change | paging }

Displays the statistics for specific type of functions in an ASN PC service in verbose mode.
context-transfer: Displays information about context-transfer messages.
im-operations: Displays information about idle mode state operation messages.
ms-state-change: Displays information about MS state change messages.
paging: Displays information about paging messages.

all

Displays statistics of all ASN PC services in verbose mode.

r4-only

Displays statistics of R4 interface in ASN PC services.

r6-only

Displays statistics of R6 interface in ASN PC services.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display ASN PC service statistics in verbose mode.

Example

The following command displays information about selected MS-State-Change function.

```
show asnpc-service statistics verbose function-type ms-state-change
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show banner

Displays the configured banner message for the current context.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show banner { all | charging-service | motd | lawful-intercept | pre-login } [| { grep *grep_options* **| more }]**

all

Displays all banners configured for a service in a system including the enhanced charging service (ECS).

charging-service

Displays banner message configured for an enhanced charging service in the current context.

motd

Display the banner message that is configured for the current context.

lawful-intercept

Refer to the *Lawful Intercept Configuration Guide* for a description of this command.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Show the configured banner to verify the message of the day contents for possible change

Example

```
show banner
```

show bcmcs counters

Displays Broadcast and Multicast Service (BCMCS)-specific counters and statistics.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show bcmcs counters { all | callid *call_id* **| flow-id** *flow_id* **}**

all

Displays BCMCS-specific counters and statistics for all multicast sessions.

callid *call_id*

Displays BCMCS-specific counters and statistics for a specific call ID.

flow_id *flow_id*

Displays BCMCS-specific counters and statistics for a specific BCMCS flow, defined by a flow ID.

Usage

Use this command to view BCMCS-specific statistics. You may narrow the results of the command output by specifying a specific call ID or flow ID.

Example

```
show bcmcs counters all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show bcmcs statistics

Displays Broadcast and Multicast Service (BCMCS)-specific statistics for the current PDSN-service.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show bcmcs statistics [pdsn-service *service_name* **]**

pdsn-service *service_name*

Defines a specific PDSN service from which to gather BCMCS-specific statistics.

Usage

Shows several sets of BCMCS-specific statistics, and may be configured to show statistics only for a certain PDSN service.

Example

show bcmcs statistics pdsn-service *service_name*

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show boot

Displays information on the current boot image in use.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show boot [initial-config | { grep *grep_options* **| more }]**

initial-config

Identifies the OS image, configuration file, and boot priority used during the initial start up of the system.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Show the boot information in preparing for maintenance activities by verifying current boot data. The boot image in use may not be the same as the boot image stored on the SMC due to upgrades and pending reboots. **show boot initial-config** displays the actual boot image and configuration file loaded during boot. This may or may not be the highest priority image and makes this command useful when comparing the loaded image to the priority list.

Important: This command is not supported on all platforms.

Example

The following command displays the boot system configuration priority list:

```
show boot
```

The following command displays the initial configuration after a system boot:

```
show boot initial-config
```

show bssap+ statistics

Displays Base Station system Application Part (BSSAP+) protocol statistics for the Gs interface between the SGSN and the Mobile services Switching Centre, Visitor Location Register (MSC/VLR).

Product

SGSN

Privilege

Inspector

Syntax

show bssap+ statistics [gs-service *gs_svc_name* **] [vlr { isdn-number** *ISDN_Num*| **name** *vlr_name* **}] [verbose] [| { grep** *grep_options* **| more }]**

gs-service *gs_svc_name*

Specifies the name of a specific Gs service to filter the BSSAP+ information as an alphanumeric string of 1 through 63 characters that is case sensitive.

vlr { isdn-number *ISDN_Num*| **name** *vlr_name*

Identifies a specific VLR (by name or ISDN number) to filter BSSAP+ information.
vlr_name is the configured name of the VLR expressed.
VLR_num is the configured E.164-type ISDN number for the VLR. Enter a numerical string of 1 to 15 digits.

verbose

Indicates the output should provide as much information as possible. If this option is not specified then the output will be limited to a concise summary.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display the BSSAP+ statistics for the SGSN's Gs interface(s). Based on how the command is entered, this command displays collected BSSAP+ protocol statistics for the entire SGSN or for a specified Gs interface. Using the keywords of this command, the interface can be identified by defining a specific VLR connected to the SGSN or by identifying the Gs service to which the interface has been configured.

Example

The following command displays all BSSAP+ information for the Gs interface configured for the Gs service named *gssvc1*.

```
show bssap+ statistics gs-service gssvc1 verbose
```

Important: Descriptions for show command outputs are available in the **Statistics and Counters Reference**.

show bssgp statistics

Displays base station subsystem GPRS protocol statistics for traffic between the base station subsystem (BSS) and the SGSN over the Gb interface.

Product

SGSN

Privilege

Inspector

Syntax

show bssgp statistics [gprs-service *gprs_svc_name* **| nse** *nse_id* **[bvc** *bvc_id* **[sessmgr | verbose]]] [verbose] [| { grep** *grep_options* **| more }]**

gprs-service *gprs_svc_name*

Specifies the name of an existing GPRS service for which the BSSGP information will be filtered as an alphanumeric string of 1 through 63 characters that is case-sensitive.

nse*nse_ID*

Enter this keyword to display the BSSGP statistics for the network service entity (NSE) specified as an integer from 0 through 65535.

bvc*bvc_ID*

Enter this keyword to display the BSSGP statistics for the BSSGP virtual connection (BVC) specified as an integer from 0 through 6500.

sessmgr instance *sessmgr_instance*

Enter this keyword to display the BSSGP statistics for a session manager instance specified as an integer from 1 through 4294967295.

verbose

Indicates the output should provide as much information as possible. If this option is not specified then the output will be the standard level which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display the BBSGP statistics for a particular GPRS service or NSEI.

Example

The following command displays BSSGP statistics for the GPRS service named *gprs1*.

```
show bssgp statistics gprs-service gprs1
```

Important: Descriptions for show command outputs are available in the **Statistics and Counters Reference**.

show bssgp status

Displays the traffic status through the BSSGP (base station subsystem GPRS protocol) layer between the base station subsystem (BSS) and the SGSN over the Gb interface.

Product

SGSN

Privilege

Inspector

Syntax

show bssgp status { bvc-bucket nsei *nse_id* **bvci** *bvc_id* **| bvc-stat nsei** *nse_id* **bvci** *bvc_id* **} [| { grep** *grep_options* **| more }]**

bvc-bucket nsei*nse_id* **bvci** *bvc_id*

Displays traffic status for a specific BVC bucket identified by the NSEI (network service entity ID) and BVCI (BSSGP virtual connection ID).
nse_ID is an integer from 0 through 65535.
bvc_ID is an integer from 0 through 65000.

bvc-stat nsei*nse_id* **bvci** *bvc_id*

Displays traffic status for a BVC identified by the NSEI (network service entity ID) and BVCI (BSSGP virtual connection ID).
nse_ID is an integer from 0 through 65535.
bvc_ID is an integer from 0 through 65000.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display BVC status of the BBSGP layer for specified NSEI and BVCI.

Example

The following command displays BSSGP traffic status for the BVC bucket for NSEI *2556* BVCI *241*.

```
show bssgp status bvc-bucket nsei 2556 bvci 241
```

Important: Descriptions for show command outputs are available in the **Statistics and Counters Reference**.

show bulkstats

Displays the information on bulk statistics.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show bulkstats [[data] | [schemas] | [variables [*schema_name* **] [obsolete]] [| { grep** *grep_options* **| more }]]**

data

Displays collected bulk statistical data.

schema

Displays the configuration of the statistics to be collected on a per-schema basis.

Important: For information on available schemas, refer to the *Bulk Statistics Configuration Mode Commands* chapter.

variables *schema_name*

Displays all valid bulkstat schema statistics, or only the statistics for the specified schema. *schema_name* specifies the name of the schemas available on system. The following is the list of available schemas in this release.

- aal2
- alcap
- apn
- asngw
- asnpc
- bcmcs
- card
- closedrp
- common
- context
- cs-network-ranap
- cs-network-rtp
- cscf
- cscfintf

- dcca
- diameter-acct
- diameter-auth
- diameter-acct
- dlci-util
- dpca
- ecs
- egtpc
- epdg
- fa
- fng
- gprs
- gtpc
- gtpp
- gtpu
- ha
- hnbgw-hnbap
- hnbgw-ranap
- hnbgw-rtp
- hnbgw-rua
- hnbgw-sctp
- hsgw
- imsa
- ippool
- ipsg
- lac
- lma
- lns
- mag
- map
- mipv6ha
- mme
- mvs
- nat-realm

- pcc-af
- pcc-policy
- pcc-service
- pcc-sp-endpt
- pdg
- pdif
- pgw
- phsgw
- phspc
- port
- ppp
- ps-network-ranap
- radius
- rp
- sccp
- sgs
- sgsn
- sgtp
- sgw
- ss7link
- ss7rd
- system
- vpn

obsolete

This keyword shows the obsolete (but still available) schema variables. An asterisk (*) is displayed next to schema variables that have been obsoleted.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For information on usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command is used to display information on bulk statistics supported by the system.
The **variable** keyword can be used to list statistics supported by the system either for all schemas, or for an individual schema.

The **schema** keyword can be used to display the configuration of settings for bulk statistics, including the schema.
The **data** keyword can be used to display bulk statistic data collected up to that point.

Example

The following command displays the bulk statistics data:

```
show bulkstats data
```

The following command displays the bulk statistics schema configuration:

```
show bulkstats data schemas
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ca-certificate

Displays information for Certificate Authority (CA) digital certificates on this system.

Product

All

Privilege

Inspector

Syntax

show ca-certificate { all | name *name* **}**

all

Displays CA certificate information for all CA certificates known to this system.

name *name*

Displays CA certificate information for an existing CA certificate name specified as n alphanumeric string of 1 through 128 characters.

Usage

View information for CA certificates on this system.

Example

The following command displays information for a CA certificate named *cert-1*:

```
show ca-certificate name cert-1
```

Important: Output descriptions for some commands are available in the *Statistics and Counters Reference*.

show ca-crl

Displays information for Certificate Authority (CA) Certificate Revocation List (CRL) on this system.

Product

All

Privilege

Inspector

Syntax

show ca-crl { all | name *name* **}**

all

Displays CA-CRL information for all CA-CRLs known to this system.

name *name*

Displays CA-CRL information for an existing CA-CRL name specified as an alphanumeric string of 1 through 128 characters.

Usage

View information for CA-CRLs on this system.

Example

The following command displays information for a CA-CRL named *crl-5*:

```
show ca-crl name crl-5
```

Important: Output descriptions for some commands are available in the *Statistics and Counters Reference*.

show cae-group server

Displays configuration information, including the name of the associated CAE group, for all CAEs or for a specific CAE. The CAE (Content Adaptation Engine) is an optional component of the Mobile Videoscape.

Product

MVG

Privilege

Security Administrator, Administrator

Syntax

show cae-group server { all | name *cae_name* **}**

all

Shows the configuration information, including the associated CAE group, for all CAEs.

name *cae_name*

Shows the configuration information for a specific CAE.

Usage

Use this command to display configuration information for all CAEs or for a specific CAE. This command can be issued from either the local context or the context in which the associated CAE group is defined.

Example

The following command displays configuration information for the CAE named *server_1*:

```
show cae-group server name server_1
```

show call-control-profile

Displays information for call control profiles configured on the system.

Product

MME, SGSN

Privilege

Inspector

Syntax

```
show call-control-profile { all | full { all | name profile_name } | name profile_name }
[ | { grep grep_options | more } ]
```

all

Lists all call-control profiles configured on the system.

full { all | name *profile_name* **}**

full: Displays a full set (all) of available information in the call-control profile.
all: Displays a full set of available information for all call-control profiles configured on the system.
name *profile_name*: Displays full information for an existing call-control profile specified as an alphanumeric string of 1 through 64 characters.

name *profile_name*

Displays information for an existing call-control profile specified as an alphanumeric string of 1 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for call-control profiles configured on the system. Call-control profiles are configured through the global configuration mode and in the call-control profile configuration mode. For more information regarding call-control profile commands, refer to the *Call-Control Profile Configuration Mode Commands* chapter.

Example

The following command displays all available information for a call-control profile named *call-prof2*:

```
show call-control-profile full name call-prof2
```

show call-home

Displays information for Smart Call Home settings configured on the system.

Product

All

Privilege

Security Administrator, Administrator

Syntax

show call-home [alert-group | detail | mail-server status | profile [all | name *profile_name* **] | statistics [| { grep** *grep_options* **| more }]]**

alert-group

Displays information for all alert groups configured on the system. It also indicates if an alert-group has been disabled by the user.

detail

Displays general information and alert-group settings for all configured call-home profiles.

mail-server status

Displays status information for call-home mail servers that are configured on the system.

profile { all | name *profile_name* **}**

Displays all available information for all call-home profiles on the system or a specified call-home profile.
all: Displays all available information for all call-home profiles configured on the system.
name *profile_name*: Displays all available information for an existing call-home profile specified as an alphanumeric string of 1 through 31 characters.

name *profile_name*

Displays information for a call-home profile specified as an alphanumeric string of 1 through 31 characters.

statistics

Displays statistical information for call-home statistics configured on the system.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display profile and notification policy information associated with the call-home profiles configured on the system. Call-home profiles are configured through the Context Configuration

Mode and in the Call-home Configuration Mode. For more information regarding call-home commands, refer to the *Call Control Profile Configuration Mode Commands* chapter.

Example

The following command displays all available information for a call-home profile named *call-home-prof1*:

```
show call-home profile name call-home-prof1
```

show call-control-profile

Displays information for call control profiles configured on the system.

Product

MME, SGSN

Privilege

Inspector

Syntax

```
show call-control-profile { all | full { all | name profile_name } | name profile_name }
[ | { grep grep_options | more } ]
```

all

Lists all call-control profiles configured on the system.

full { all | name *profile_name* **}**

full: Displays all available information in the call-control profile.
all: Displays a full set of available information for all call-control profiles configured on the system.
name *profile_name*: Displays a full set of available information for a an existing call-control profile specified as an alphanumeric string of 1 through 64 characters.

name *profile_name*

Displays information for an existing call-control profile specified as an alphanumeric string of 1 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for call-control profiles configured on the system. Call-control profiles are configured through the global configuration mode and in the call-control profile configuration mode. For more information regarding call-control profile commands, refer to the *Call-Control Profile Configuration Mode Commands* chapter in this reference.

Example

The following command displays all available information for a call-control profile named *call-prof2*:

```
show call-control-profile full name call-prof2
```

show camel-service

Displays configuration details for Customized Applications for Mobile networks Enhanced Logic (CAMEL) services configured for this SGSN.

Product

SGSN

Privilege

Inspector

Syntax

show camel-service { all | name *service_name* **} [| grep** *grep_options* **| more]**

all

Displays the configuration details for all configured CAMEL services.

name

Displays the configuration details for an existing CAMEL service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View configuration information for CAMEL services.

Example

The following command displays the configuration information for a CAMEL service identified as *camel4sgsnTO*:

```
show camel-service name camel4sgsnTO
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show certificate

Displays information for local node certificates configured on this system.

Product

All

Privilege

Inspector

Syntax

```
show certificate { all | name name }
```

all

Displays certificate information for all node certificates configured on this system.

name *name*

Displays information for a certificate name specified as an existing certificate name expressed as an alphanumeric string of 1 through 128 characters.

Usage

View information for local node certificates on this system.

Example

The following command displays information for a node certificate named *certificate-3*:

```
show certificate name certificate-3
```

Important: Output descriptions for some commands are available in the *Statistics and Counters Reference*.

show cli

Displays current command line interface (CLI) users and associated session information.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show cli { session | history } [| { grep *grep_options* **| more }]**

session

Displays information about the current CLI session.

history

Displays CLI command history for this CLI session.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Show current command line interface sessions when there is some unexpected output from a chassis and a check of current CLI users may reveal other activities in progress.

Example

```
show cli
```

show clock

Displays the current system data and time.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show clock [universal] [| { grep *grep_options* **| more }]**

universal

Displays the date and time in universal coordinated time (UTC/GMT) format.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command Output* section of the *Command Line Interface Overview* chapter.

Usage

Check the current time of a chassis to compare with network wide time or for logging purposes if network accounting and/or event records appear to have inconsistent timestamps.

Important: This command is not supported on all platforms.

Example

The following displays the system time in local time and UTC, respectively.

```
show clock

show clock universal
```

show configuration

Displays current configuration information for various subcomponents of the system.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

show configuration [card *card_num* **| checksum | context** *name* **| obsolete-encryption | port** *slot/port* **| rohc | showsecrets | srp | url** *url* **| verbose] [| { grep** *grep_options* **| more }]**

show configuration card *card_num* **[obsolete-encryption | showsecrets | verbose]**

show configuration checksum [obsolete-encryption | showsecrets | verbose]

show configuration context *name* **[obsolete-encryption | showsecrets | verbose]**

show configuration obsolete-encryption

show configuration port *slot/port* **[obsolete-encryption | showsecrets | verbose]**

show configuration rohc [all | profile-name *name* **] [verbose]**

show configuration showsecrets [obsolete-encryption]

show configuration srp [checksum [obsolete-encrpytion] | showsecrets [obsolete-encrption] | verbose]

show configuration url *url*

show configuration verbose [obsolete-encrpytion | showsecrets [obsolete-encrption]]

---

card *card_num* **[obsolete-encryption | showsecrets | verbose]**

Specifies a card for which configuration information is to be displayed as an integer from 1 through 48. Additional display options include:

- **obsolete-encryption**: Shows encrypted values using a weaker, obsolete encryption method.
- **showsecrets**: Shows unencrytpted secrets
- **verbose**: Shows all available details.

checksum [obsolete-encryption | showsecrets | verbose]

Generates and displays a checksum value for the configuration data.

Additional display options include:

- **obsolete-encryption**: Shows encrypted values using a weaker, obsolete encryption method.
- **showsecrets**: Shows unencrytpted secrets
- **verbose**: Shows all available details.

context *name* **[obsolete-encryption | showsecrets | verbose]**
Specifies an existing context for which configuration information is to be displayed as an alphanumeric string of 1 through 79 characters.

Additional display options include:

- **obsolete-encryption**: Shows encrypted values using a weaker, obsolete encryption method.
- **showsecrets**: Shows unencrytpted secrets
- **verbose**: Shows all available details.

obsolete-encryption
Shows encrypted values using a weaker, obsolete encryption method.

port *slot/port* **[obsolete-encryption | showsecrets | verbose]**
Displays configuration information for a port identified by its slot and port numbers.

Additional display options include:

- **obsolete-encryption**: Shows encrypted values using a weaker, obsolete encryption method.
- **showsecrets**: Shows unencrytpted secrets
- **verbose**: Shows all available details.

rohc [all | profile-name *name* **] [verbose]**
Specifies that information for all robust header compression (RoHC) profiles or the named profile is to be displayed.

Additional display option includes:

- **verbose**: Shows all available details.

showsecrets [obsolete-encryption]
Shows encrypted and unencrytpted secret keys saved in the configuration. If this keyword is not specified, secret keys are not displayed.

Additional display option includes:

- **obsolete-encryption**: Shows encrypted values using a weaker, obsolete encryption method.

---

srp [checksum [obsolete-encrpytion] | showsecrets [obsolete-encrption] | verbose]

Shows the Service Redundancy Protocol (SRP) configuration.
checksum [obsolete-encryption]: Displays checksum information with the option to display encrypted values using a weaker obsolete encryption method.
showsecrets [obsolete-encrption]: Displays unencrytpted secrets with the option to display encrypted values using a weaker obsolete encryption method.
Additional display option includes:
- **verbose**: Shows all available details.

---

url *url*

Default: configuration which is currently in use.
This keyword is not available to users with Operator level permissions. Specifies the location of the configuration data to use for information display. The *url* may refer to a local or a remote file and must be entered in the following format:
[file:]{ /flash | /pcmcia1 | /hd }[/*directory* **]/***file_name*
tftp://{ *host***[** *:port#* **] }[/***directory* **]/***file_name*

[http: | ftp: | sftp:]//[*username***[** *:password* **]@] { ***host* **}[** *:port#* **][/***directory* **]/***file_name*

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name.
filename is the actual file of interest.

Important: Configuration files should be named with a **.cfg** extension.

username is the user to be authenticated.
password is the password to use for authentication.
host is the IP address or host name of the server.
port# is the logical port number that the communication protocol is to use.

verbose

Indicates the output should provide as much information as possible. If this option is not specified then the output will be the standard level which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View the current configuration to review recent changes.

Important: This command is not supported on all platforms.

Example

The following command displays the local in-use port configuration information for port *24/1* in verbose mode.

```
show configuration port 24/1 verbose
```

The following command displays the card configuration for card *17* on host *remoteABC* stored in the configuration file in */pub/config.cfg*.

```
show configuration card 17
```

The following command displays the card configuration for card *5* on host *remoteABC* stored in the configuration file in */pub/config.cfg*.

```
show configuration card 5
```

The following command displays the configuration of all RADIUS server groups configured in context *local*

```
show configuration context local radius group all
```

The following command shows the configuration for a context named PDIF.

```
show configuration context pdif
```

show configuration errors

Displays current configuration errors and warning information for the target configuration file as specified for a service.

Product

All

Privilege

Security Administrator, Administrator, Operator

Syntax

show configuration errors [section *section_name* **] [verbose] [| { grep** *grep_options* **| more }]**

---

section {*section_name***}**

Specifies the services and section for which to display and validate a configuration.
The following services and sections are supported:

- **aaa-config**: Displays configuration errors/warnings for the AAA service(s) configured on the system.
- **active-charging**: Displays configuration errors/warnings for the Enhanced Charging Service(s) and the Personal Stateful Firewall service(s) configured on the system.
- **apn**: Displays configuration errors/warnings for the APN configuration(s) on the system.
- **apn-profile**: Displays configuration errors/warnings for the APN Profile configuration(s) on the system.
- **apn-remap-table**: Displays configuration errors/warnings for the APN Remap Table configuration(s) on the system.
- **asngw-service**: Displays configuration errors/warnings for the Access Service Network Gateway (ASN-GW) Service configured in a specific context for which configuration errors/warnings is to be displayed.
- **asnpc-service**: Displays configuration errors/warnings for the ASN Paging Controller and Location Registry (ASN PC-LR) Service(s) configured on the system.
- **call-control-profile**: Displays configuration errors/warnings for the Call Control Profile configuration(s) on the system.
- **camel-service**: Displays configuration errors/warnings for the CAMEL Service configuration(s) on the system.
- **closed-rp-service**: Displays configuration errors/warnings for the closed RP service(s) configured on the system.
- **cs-network**: Displays configuration errors/warnings for the CS Network configuration(s) on the system.
- **cscf-service**: Displays configuration errors/warnings for the Call Session Control Function (CSCF) service(s) configured on the system.
- **diameter**: Displays configuration errors/warnings for the Diameter configuration(s) on the system.
- **dns-client**: Displays configuration errors/warnings for the DNS Client configuration(s) on the system.

- **egtp-service**: Displays configuration errors/warnings for the eGTP Service configuration(s) on the system.
- **event-notif**: Displays configuration errors/warnings for the event notification (SNMP) interface client.
- **fa-service**: Displays configuration errors/warnings for the Foreign Agent (FA) service(s) configured on the system.
- **fng-service**: Displays configuration errors/warnings for the Femto Network Gateway (FNG) configuration(s) on the system.
- **ggsn-service**: Displays configuration errors/warnings for the GGSN service(s) configured on the system.
- **gprs-service**: Displays configuration errors/warnings for the GPRS service(s) configured on the system.
- **gs-service**: Displays configuration errors/warnings for the GS service(s) configured on the system.
- **ha-service**: Displays configuration errors/warnings for the Home Agent (HA) service(s) configured on the system.
- **hnbgw-service**: Displays configuration errors/warnings for the Home Evolved Node B Gateway (HNB-GW) Service configuration(s) on the system.
- **hsgw-service**: Displays configuration errors/warnings for the HRPD Serving Gateway (HSGW) service(s) configured on the system.
- **imei-profile**: Displays configuration errors/warnings for the International Mobile Equipment Identity (IMEI) Profile configuration(s) on the system.
- **imsa-config**: Displays configuration errors/warnings for the IMS Authorization (IMSA) configuration(s) on the system.
- **imssh-service**: Displays configuration errors/warnings for the IMS Sh (IMSSh) service(s) configured on the system.
- **imsue-service**: Displays configuration errors/warnings for the IMS UE service(s) configured on the system.
- **ipms**: Displays configuration errors/warnings for the Intelligent Packet Monitoring System (IPMS) service(s) configured on the system.
- **ipsg-service**: Displays configuration errors/warnings for the IP Security Gateway (IPSG) service(s) configured on the system.
- **iups-service**: Displays configuration errors/warnings for the IuPS service(s) configured on the system.
- **lac-service**: Displays configuration errors/warnings for the Layer 2 Tunneling Protocol (L2TP) Access Concentrator (LAC) service(s) configured on the system.
- **lns-service**: Displays configuration errors/warnings for the L2TP Network Server (LNS) service(s) configured on the system.
- **local-policy**: Displays configuration errors/warnings for the Local Policy configuration(s) on the system.
- **map-service**: Displays configuration errors/warnings for the SS7 Mobile Application Part (MAP) service(s) configured on the system.

- **mme-service**: Specifies the configuration errors for a Mobility Management Entity (MME) service configured in a specific context for which configuration errors/warnings are to be displayed.
- **operator-policy**: Displays configuration errors/warnings for the Operator Policy configuration(s) on the system.
- **pcc-policy-service**: Displays configuration errors/warnings for the Policy and Charging Control (PCC) Policy Service configuration(s) on the system.
- **pcc-service**: Displays configuration errors/warnings for the PCC Service configuration(s) on the system.
- **pdg-service**: Displays configuration errors/warnings for the Packet Data Gateway (PDG) Service configuration(s) on the system.
- **pdif-service**: Displays configuration errors/warnings for the Packet Data Interworking Function (PDIF) service(s) configured on the system.
- **pdsn-service**: Displays configuration errors/warnings for the PDSN service(s) configured on the system.
- **pgw-service**: Displays configuration errors/warnings for the P-GW Service configuration(s) on the system.
- **phsgw-service**: Displays configuration errors/warnings for the PHS Gateway service(s) configured on the system.
- **policy-grp-config**: Displays configuration errors/warnings for the Policy Group configuration(s) on the system.
- **ps-network**: Displays configuration errors/warnings for the PS Network configuration(s) on the system.
- **sccp-network**: Displays configuration errors/warnings for the SCCP network configuration(s) on the system.
- **sgs-service**: Displays configuration errors/warnings for the SGs Service configuration(s) on the system.
- **sgsn-mode**: Displays configuration errors/warnings for the SGSN Mode configuration(s) on the system.
- **sgsn-service**: Displays configuration errors/warnings for the SGSN service(s) configured on the system.
- **sgtp-service**: Displays configuration errors/warnings for the SGSN GPRS Tunneling Protocol (SGTP) service(s) configured on the system.
- **sgw-service**: Displays configuration errors/warnings for the S-GW Service configuration(s) on the system.
- **subscriber-config**: Displays configuration errors/warnings for the Subscriber configuration(s) on the system.
- **subscriber-map**: Displays configuration errors/warnings for the Subscriber Map configuration(s) on the system.

verbose

Indicates the output should provide as much information as possible. If this option is not specified then the output will be the standard level which is the concise mode.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For more information on the usage of **grep** and **more**, refer *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view the current configuration errors and warning to review recent changes.

Example

The following command displays configuration errors and warnings for all services configured in a context/system:

```
show configuration errors verbose | more
```

The following command displays configuration errors and warnings for Enhanced Charging service and Personal Stateful Firewall service configured in a context:

```
show configuration errors section active-charging verbose
```

show congestion-control

Displays information pertaining to congestion control functionality on the system

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show congestion-control {**configuration** | **statistics** {*demux_mgr* } [**all** | **instance** *task_instance*] } [| { **grep** *grep_options* | **more** }]

configuration

Displays congestion control configuration information including threshold parameters and policy settings for the configured services.

statistics

Displays congestion control statistics for Demux managers *demux_mgr*.
all: Displays statistics based on the current state of all instances of the specified task.
instance *task_instance*: Displays statistics for a software task instance specified as an integer from 1 through 128. 8.

Important: The **inst** column of the **show task table** command output displays the instance of a particular task.

demux_mgr

Specifies the name of the service/session Demux manager for which statistics are displayed. The following types of *demux_mgr* services are supported:

- **a11mgr**: Specifies that statistics are displayed for PDSN services.
- **asngwmgr**: Specifies that statistics are displayed for ASN-GW services.
- **asnpcmgr**: Specifies that statistics are displayed for ASN PC-LR services.
- **bindmux**: Specifies that statistics are displayed for Bindmux Manager used by PCC service.
- **egtpinmgr**: Specifies that statistics are displayed for EGTP ingress demuxmgr.
- **gtpcmgr**: Specifies that statistics are displayed for GGSN services.
- **hamgr**: Specifies that statistics are displayed for HA services.
- **hnbmgr**: Specifies that statistics are displayed for HNB Manager used by HNB-GW service.
- **imsimgr**: Specifies that statistics are displayed for IMSI managers.
- **ipsecmgr**: Specifies that statistics are displayed for IPSec managers.
- **l2tpmgr**: Specifies that statistics are displayed for L2TP managers.

all

Displays the statistics based on the current state of all instances of the specified task.

instance *task_instance*

Displays statistics for a specified software task instance. *task_instance* can be configured to an integer from 1 to 128.

Important: The **inst** column of the **show task table** command output displays the instance of a particular task.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command displays congestion control configuration information or statistics for a particular service type. When the all keyword is used, the system compares the current state of all instances of the specified task. The state is based on whether or not any congestion control thresholds have been exceeded. If one or more instances are experiencing congestion, the state is displayed as "Applied", and the various thresholds that have been crossed are indicated.

Example

The following command displays congestion control statistics for a PDSN service using an **a11mgr** task with an instance of *2*:

```
show congestion-control statistics a11mgr instance 2
```

The following command displays congestion control statistics for an ASN-GW service using an **asngwmgr** task with an instance of *2*:

```
show congestion-control statistics asngwmgr instance 2
```

The following command displays congestion control statistics for an ASN PC-LR service using an **asnpcmgr** task with an instance of *2*:

```
show congestion-control statistics asnpcmgr instance 2
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show content-filtering category database

Displays details of the specified category based content filtering database for content filtering application configured in a system/service.

Product

CF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show content-filtering category database [active | all | facility srdbmgr { all | instance *instance_value* **} | url** *url_string* **] [verbose] [| { grep** *grep_options* **| more }]**

active

Displays the information about all active databases, for example databases in memory. This is the default setting for category database information.

all

Displays the information about all active databases, for example, databases in memory and all saved databases on a system.

facility

Displays logged events for a specific facility.

srdbmgr { all | instance *instance_value* **}**

Displays logged events for all static rating database managers or for all or for a specific instance.

- **all**: Displays the logged events for all Static Rating Database (SRDB) Manager instances.
- **instance** *instance_value*: Displays events logged for a specific SRDB Manager instance specified as an integer from 1 through 8.

url *url_string*

Displays the information of the database located at the URL that specifies the name/location of the category database from which to retrieve information as an alphanumeric string of 1 through 512 characters.

verbose

This option enables the detailed mode for additional information display for specific database.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information of database for category based content filtering application in a service.

Example

The following command displays a detailed information for all active databases in memory.

```
show content-filtering category database active all
```

The following command displays the CF database status of all running SRDB managers.

```
show content-filtering category database facility srdbmgr all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show content-filtering category policy-id

Displays Content Filtering category policy definitions.

Product

CF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show content-filtering category policy-id { all | id *cf_policy_id* **} [| { grep** *grep_options* **| more }]**

all

Displays definitions of all Content Filtering category policies.

id *cf_policy_id*

Displays definitions of an existing Content Filtering category policy ID specified as an integer from 1 through 4294967295.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view Content-Filtering Category definitions for a specific/all Policy IDs.

Example

The following command displays Content Filtering category definitions for policy ID *3*:

```
show content-filtering category policy-id id 3
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show content-filtering category statistics

Displays statistics for the category-based Content Filtering application configured in a system/service.

Product

CF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show content-filtering category statistics [ facility srdbmgr { all | instance
instance_value } ] [ | { grep grep_options | more } ]
```

facility

Displays logged events for a specific facility.

srdbmgr { all | instance *instance_value* }

Displays logged events for all Static Rating Database (SRDB) Manager instances or for the specified instance.

- **all**: Displays events logged for all SRDB Manager instances.
- **instance** *instance_value*: Displays events logged for the SRDB Manager instance specified as an integer from 1 through 8.

| { grep *grep_options* | more }

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view the statistics of Category Based Content Filtering application in a service. This command's output also indicates capability of the system to perform Content Filtering and Dynamic Content Filtering if configured.

Important: Content filtering cannot be performed if less than two PSCs are activated. Dynamic Content Filtering cannot be performed if less than three PSCs are activated.

Example

The following command displays the detailed statistics of configured category based content filtering application:

```
show content-filtering category statistics
```

The following command displays the detailed statistics of configured category based content filtering application based on running SRDB Manager *instance1*.

```
show content-filtering category statistics facility srdbmgr instance
instance1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show content-filtering category url

Displays the information about the categories of the database at the specific URL configured for the category-based content filtering application in a system/service.

Product

CF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show content-filtering category url *url_string* **[policy-id** *cf_policy_id* **| rulebase** *rulebase_name* **] [verbose] [| { grep** *grep_options* **| more }]**

url *url_string*

Displays the category information of the URL specified as an alphanumeric string of 1 through 512 characters.

policy-id *cf_policy_id*

Displays the category information of a URL configured with an existing content filtering category policy ID specified as n integer from 0 through 65535.

rulebase *rulebase_name*

Displays the category information of a URL configured in ACS Configuration Mode for category-based content filtering in specific rulebase. *rulebase_name* must be the name of an existing rulebase expressed as an alphanumeric string of 1 through 15 characters.

verbose

Enables the detailed mode for additional information display for a specific database.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information of a database URL for category based content filtering application in a service.

Example

The following command displays a detailed information for all active databases in memory.

```
show content-filtering category url /cf_server/cf/optcmd.bin verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show content-filtering server-group

Displays information for Content Filtering Server Group (CFSG) configured in the service.

Product

CF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show content-filtering server-group [name *cfsg_name* **| statistics] | [| { grep** *grep_options* **| more }]**

name *cfsg_name*

Displays information for an existing CFSG specified as an alphanumeric string of 1 through 63 characters.

statistics

Displays statistical information for all configured CFSGs.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for Content Filtering Server Group configured in a service.

Example

The following command displays a detailed information for all charging actions:

```
show content-filtering server-group statistics
```

The following command displays a details of a specific charging action:

```
show content-filtering server-group name test123
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show context

Displays information for currently configured contexts.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show context [ all | name context_name ] [ | { grep grep_options | more } ]
```

all | name *context_name*

all: Displays information for all currently configured contexts.
name *context_name*: Displays information for an existing context specified as an alphanumeric string of 1 through 79 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View configured contexts. This may be useful in verifying configuration or troubleshooting the system.

Example

The following command displays information for the configured context named *sampleContext*:

```
show context name sampleContext
```

The following command displays information for all contexts:

```
show context all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cpu

Displays information on system CPUs.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show cpu { info [card *card_num* **[cpu** *cpu_num* **]] [graphs] [verbose] | table } [| { grep** *grep_options* **| more }]**

---

info [card *card_num* **[cpu** *cpu_num* **]] [graphs] [verbose]**

Displays information for an entire card or a specific CPU.
card *card_num*: Specifies the card for which to display associated information. *card_num* must be a value in the range 1 through 48 and must refer to an installed card.
cpu *cpu_num*: Optionally selects a specific CPU on the card of interest to display specific information. *cpu_num* must be a value in the range 0 through 3 and must refer to an installed CPU.
graphs: In addition to textual CPU information display CPU utilization information in graphs.
verbose: Output is to display all information available.

---

table

Display, in tabular format, all cards and CPUs.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View CPU statistics to aid in diagnosing service problems for the case of overload conditions.

Important: This command is not supported on all platforms.

Example

The following command displays the CPU information in tabular format for all CPUs on all installed cards:

```
show cpu table
```

The following command displays CPU information for card *8* in verbose mode:

```
show cpu info card 8 verbose
```

The following command displays information for CPU *0* on card *1*:

```
show cpu info card 1 cpu 0
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show crash

Displays summary of system/task crashes or information on a specific crash.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crash { list | number *crash_num* **} [| { grep** *grep_options* **| more }]**

list | number *crash_num*

list: Displays a list of recent crash data.
number *crash_num* displays the information for an existing crash number. The crash number can be displayed using the **list** keyword.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

VIew the crash list to determine frequency of crashes or if crashes occur at some specific time of day. This may also be used to view information on a specific crash to aid in troubleshooting.

Example

The following displays the list of recent crashes.

```
show crash list
```

The following command will display the crash information for crash number *11*.

```
show crash number 11
```

show credit-control sessions

Displays credit control sessions information.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show credit-control session [all | callid | full | mdn | nai | summary] [| { grep *grep_options* **| more }]**

---

session [all | callid | full | mdn | nai | summary]

Displays the credit control session status based on the following keywords:
all: Displays all available information for Credit Control sessions
callid: Displays the Credit Control Session Call ID
full: Displays All available information for the associated display or the filter keyword
mdn: Displays the Credit Control Message Delivery Notification (MDN) information.
nai: Displays the Credit Control NI
summary: Displays the summary of Credit Control session information

---

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Please refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to show active credit control application for service sessions.

Example

The following command shows the configured Credit Control application sessions:

```
show credit-control sessions
```

show credit-control statistics

Displays credit control statistics.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show credit-control statistics cc-service *name*

cc-service

Specifies the Credit Control Service name.
name must be an existing Credit Control Service expressed as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to show active credit control statistics.

Example

The following command shows the configured credit control statistics for a service named *service1*:

```
show credit-control statistics cc-service service1
```

show crypto group

Displays information pertaining to configured crypto groups.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto group [name *group_name* **| summary]**

name *group_name*

Displays information for an existing crypto group specified as an alphanumeric string of 1 through 127 characters.

summary

Displays state and statistical information for configured crypto groups in this context.

Usage

Use this command to display information and statistics pertaining to one or all configured crypto groups within the current context.
If the **summary** keyword is not used, detailed information is displayed.
The following command displays detailed information for a crypto group called *group1*:

```
show crypto group name group1
```

show crypto ikev1

Displays pre-shared key information for peer security gateways configured within the context.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto ikev1 { keys | policy [*preference* **] | security-associations [summary] }**

keys

Displays the IKE pre-shared key information based on the peer security gateway.

policy [*preference* **]**

Displays configuration information for the Internet Exchange Key (IKE) policy priority specified as an integer from 1 through 100. If no preference is specified, information will be displayed for all configured policies.

security-associations [summary]

Displays information for established IPSec security associations (SAs).

Usage

Use this command to:

- Display pre-shared key information. This information can be used to verify configuration and/or for troubleshooting.
- Verify the configuration of IKE policies within the context.
- Display established IPSec SA information. This information can be used for troubleshooting.

Example

The following command lists the pre-shared keys received from peer security gateways as part of the Diffie-Hellman exchange:

```
show crypto ikev1 keys
```

The following command displays information for an IKE policy with a preference of *1*:

```
show crypto ikev1 policy 1
```

The following command displays the currently established SAs:

```
show crypto ikev1 security-associations summary
```

show crypto ikev2-ikesa security-associations summary

Displays a summary view of Internet Key Exchange v2 (IKEv2) IKE Security Associations (IKE SAs).

Product

PDIF

Privilege

Administrator, Security Administrator

Syntax

```
show crypto ikev2-ikesa security-associations summary
```

Usage

Shows a summary of the of the SAs configured for a crypto template. It shows the total configured SA lifetime in seconds and the number of seconds left on the timer.

Example

Use this command to create the SA summary:

```
show crypto ikev2-ikesa security-associations summary
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show crypto ikev2-ikesa transform-set

Displays IKEv2/IKESA (Internet Key Exchange v2/IKE Security Association) transform set configuration information.

Product

All using IKEv2/IPSec

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto ikev2-ikesa transform-set *transform_set_name*

show crypto ikev2-ikesa transform-set

Specifies the name of an existing IKEv2/IKSA transform set for which to display information as an alphanumeric string of 1 through 127 characters that is case sensitive.

Usage

Use this command to verify the configuration of IKEv2/IKESA transform sets within the context.
If no keyword is specified, information will be displayed for all IKEv2/IKESA transform sets configured within the context.

Example

The following command displays information for an IKEv2/IKESA transform set named *test1*:

```
show crypto ikev2-ikesa transform-set test1
```

show crypto ipsec

Displays IPSec security associations (SAs) configured within or facilitated by the context and can optionally display statistics for them.

Product

PDSN, GGSN, PDIF, SCM

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto ipsec security-associations map-type { ipsec-3gpp-cscf-subscriber | ipsec-dynamic | ipsec-ikev1 | ipsec-l2tp | ipsec-manual | ipsec-mobile-ip } | summary [distribution | ipsecmgr *ipsec_mgr_id* **| map-type** *map_type* **] | tag** *map_name*

---

map-type { ipsec-dynamic | ipsec-ikev1 | ipsec-l2tp | ipsec-manual | ipsec-mobile-ip }

Specifies that information for all crypto maps of a specific type configured within the context will be displayed. The following types can be specified:

- **ipsec-3gpp-cscf-subscriber**: P-CSCF Subscriber IPSec Tunnel
- **ipsec-dynamic**: Dynamic IPSec Tunnel
- **ipsec-ikev1**: IKEv1 IPSec Tunnel
- **ipsec-ikev2-subscriber**: IKEv2 Subscriber Tunnel
- **ipsec-l2tp**: L2TP IPSec Tunnel
- **ipsec-manual**: Manual (Static) IPSec Tunnel
- **ipsec-mobile-ip**: Mobile IP IPSec Tunnel

---

summary [distribution | ipsecmgr *ipsec_mgr_id* **| map-type** *map_type* **| template-map** *map_name* **]**

Displays only security association summary information.
distribution: Show IPSec Manager SA distribution information.
ipsecmgr *ipsec_mgr_id*: Displays summary SA information for the IPSec manager instance ID specified as an integer from 1 through 200.
map-type *map_type*: Displays summary SA information for the specified type of crypto map.The following types can be specified:

- **ipsec-3gpp-cscf-subscriber**: P-CSCF Subscriber IPSec Tunnel
- **ipsec-dynamic**: Dynamic IPSec Tunnel
- **ipsec-ikev1**: IKEv1 IPSec Tunnel
- **ipsec-l2tp**: L2TP IPSec Tunnel
- **ipsec-manual**: Manual (Static) IPSec Tunnel
- **ipsec-mobile-ip**: Mobile IP IPSec Tunnel

tag *map_name*

Displays the SAs for an existing crypto map specified as an alphanumeric string of 1 through 127 characters that is case sensitive.

Usage

Use this command to display IPSec SA information and statistics. This information can be used for performance monitoring and/or troubleshooting.
The displayed information categorizes control signal and data statistics. Data statistics are further categorized according to the encapsulation method, either GRE or IP-in-IP.

Example

The following command displays summary SA statistics for all IPSec managers.

```
show crypto ipsec security-associations summary
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show crypto ipsec transform-set

Displays IPSec transform set configuration information.

Product

PDG/TTG, PDIF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto ipsec transform-set [*transform_name* **]**

transform_name

Displays information for the IPSec transform set specified as an alphanumeric string of 1 through 127 characters that is case sensitive.

Usage

Use this command to verify the configuration of IPSec transform sets within the context.
If no keyword is specified, information will be displayed for all IPSec transform sets configured within the context.

Important: This command is used in PDIF Release 8.3 only.

Example

The following command displays information for an IPSec transform set named *test1*:

```
show crypto ipsec transform-set test1
```

show crypto isakmp keys

Displays pre-shared key information (Internet Security Association and Key Management Protocol, ISAKMP) for peer security gateways configured within the context.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show crypto isakmp keys
```

Usage

Use this command to display pre-shared key information based on the peer security gateway. This information can be used to verify configuration and/or for troubleshooting.

Example

The following command lists the pre-shared keys received from peer security gateways as part of the Diffie-Hellman exchange:

```
show crypto isakmp keys
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show crypto isakmp policy

Displays Internet Security Association and Key Management Protocol (ISAKMP) policy configuration information.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto isakmp policy [*preference* **]**

preference

Displays configuration information for the ISAKMP policy priority specified as an integer from 1 through 100.

Usage

Use this command to verify the configuration of ISAKMP policies within the context.
If no *preference* is specified, information will be displayed for all configured policies.

Example

The following command displays information for an ISAKMP policy with a preference of *1*:

```
show crypto isakmp policy 1 1
```

show crypto isakmp security-associations

Displays currently established Internet key Exchange (IKE) security associations (SAs) facilitated by the context.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show crypto isakmp security-associations [ cookies ]
```

cookies

Specifies that cookies should be displayed.

Usage

Use this command to display established IPSec SA information. This information can be used for troubleshooting.

Example

The following command displays the currently established SAs:

```
show crypto isakmp security-associations
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show crypto managers

Displays statistics per IPSec Manager.

Product

PDSN, GGSN, PDIF, SCM

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto managers [context *context_name* **| crypto-map** *map_name* **| instance** *instance_num* **| summary [distribution | ike-stats | ipsec-3gpp-cscf-stats | ikev2-stats [demux-stats] | ipsec-sa-stats | npu-stats]]**

context *context_id*

Displays IPSec manager statistics for an existing context specified as n alphanumeric string of 1 through 80 characters.

crypto-map *map_name*

Displays IPSec Managers for an existing crypto map specified as an alphanumeric string of 1 through 128 characters.

instance *instance_num*

Displays statistics for the IPSec manager instance specified as an integer from 1 through 366.

summary [distribution | ike-stats | ipsec-3gpp-cscf-stats | ikev2-stats [demux-stats] | ipsec-sa-stats | npu-stats]

Shows statistics per service IP address for each manager.
distribution: Displays a summary list of IPSec manager distribution.
ike-stats: Displays a summary list of IPSec IKE statistics. for each IPSec manager.
ipsec-3gpp-cscf-stats: Displays CSCF IPSec Statistics on each IPSec Manager.
ikev2-stats: Displays IKEv2 Statistics on each IPSec Manager.
- **demux-stats**: Displays session demux statistics on each IPSec Manager.

ipsec-sa-stats: Displays a summary list of IPSec Security Association (SA) statistics for each IPSec Manager.
npu-stats: Displays NPU statistics on each IPSec Manager.

Usage

Use this command to view statistics relating to IPSec managers.

Example

The following command displays summary information for all IPSec managers:

```
show crypto managers summary
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show crypto map

Displays crypto map configuration information.

Product

PDIF, PDSN, GGSN, SCM

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto map [map-type [ipsec-3gpp-cscf-subscriber | ipsec-dynamic | ipsec-ikev1 | ipsec-ikev2-subscriber | ipsec-l2tp | ipsec-manual | ipsec-mobile-ip] | tag *map_name* **| summary]**

map-type [ipsec-3gpp-cscf-subscriber | ipsec-dynamic | ipsec-ikev1 | ipsec-ikev2-subscriber | ipsec-l2tp | ipsec-manual | ipsec-mobile-ip]

Specifies that information for all crypto maps of a specific type configured within the context will be displayed. The following types can be specified:

- **ipsec-3gpp-cscf-subscriber**: P-CSCF subscriber IPSec Tunnel
- **ipsec-dynamic**: Dynamic IPSec Tunnel
- **ipsec-ikev1**: IKEv1 IPSec Tunnel
- **ipsec-ikev2-subscriber**: IKEv2 Subscriber Tunnel
- **ipsec-l2tp**: L2TP IPSec Tunnel
- **ipsec-manual**: Manual (Static) IPSec Tunnel
- **ipsec-mobile-ip**: Mobile IP IPSec Tunnel

tag *map_name*

Specifies the name of an existing crypto map in the current context for which to display configuration information as an alphanumeric string of 1 through 127 characters that is case sensitive.

summary

Displays summary information for all crypto maps configured in the context.

Usage

Use this command to verify the configuration of crypto maps within the context.
If no keyword is specified, information will be displayed for all maps configured within the context regardless of type.

Example

The following command displays configuration information for a dynamic crypto map named *test_map3*:

```
show crypto map tag test_map3
```

show crypto statistics

Displays Internet Protocol Security (IPSec) statistics.

Product

PDSN, GGSN, PDG/TTG, PDIF, SCM

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto statistics ikev1 | ikev2 [service-ip-address *ip-address* **] [service-name** *name* **] | ipsec-3gpp-cscf [service-ip-address** *ip-address* **] [service-name** *name* **]| srtp [service-ip-address** *ip-address* **] [service-name** *name* **]**

ikev1

Displays global ikev1 statistics for this context.

ikev2 [service-ip-address *ip-address* **] [service-name** *name* **]**

Displays global ikev2 statistics for this context.
service-ip-address *ip-address*: Specifies the Packet Data Interworking Function (PDIF) service IP address in IPv4 dotted-decimal or IPv6 colon-separated notation.
service-name *name*: Specified PDIF service name.

ipsec-3gpp-cscf [service-ip-address *ip-address* **] [service-name** *name* **]**

Displays global CSCF IPSec SA statistics for this context.
service-ip-address *ip-address*: Specifies the CSCF service IP address in IPv4 dotted-decimal or IPv6 colon-separated notation.
service-name *name*: Specifies the CSCF service name.

srtp [service-ip-address *ip-address* **] [service-name** *name* **]**

Displays global SRTP (Secure Real-time Transport Protocol) statistics for this context.
service-ip-address *ip-address*: Specifies the CSCF service IP address in IPv4 dotted-decimal or IPv6 colon-separated notation.
service-name *name*: Specifies the CSCF service name.

Usage

Use this command to display statistics for IPSec tunnels facilitated by the context. This information can be used for performance monitoring and/or troubleshooting

Example

The following command displays cumulative IPSec statistics for the current context:

```
show crypto statistics
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show crypto transform-set

Displays transform set configuration information.

Product

PDIF, PDSN, GGSN, SCM

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show crypto transform-set [*transform_name* **]**

transform_name

Specifies the name of an existing transform set for which to display information as an alphanumeric string of 1 through 127 characters that is case sensitive.

Usage

Use this command to verify the configuration of transform sets within the context.
If no keyword is specified, information will be displayed for all transform sets configured within the context.

Important: This command is used in PDIF Release 8.1. In PDIF Release 8.3, the syntax of this command is changed to **show crypto ipsec transform-set**.

Example

The following command displays information for a transform set named *test1*:

```
show crypto transform-set test1
```

show cs-network

Displays statistics for the Circuit Switched (CS)-network(s) instance configured on a chassis for HNB-GW service sessions.

Product

HNB-GW

Privilege

Security Administrator, Administrator, Operator

Syntax

show cs-network { all | name *cs_name* **} [status] [| { grep** *grep_options* **| more }]**

all

Displays status counters for all CS (circuit switched) networks configured for HNB-GW service sessions on a chassis.

name *cs_name*

Displays status counters for a CS network configured for HNB-GW service specified as an alphanumeric string of 1 through 127 characters that is case sensitive

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Refer to *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to display the status of any or all CS-network(s) instance configured on a chassis for HNB-GW service sessions.

Example

The following command displays the output for CS network instance status named *cs_1_hnb*:

```
show cs-network name cs_1_hnb status
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cs-network counters

Displays the session counter information for an HNB-CS Network associated with Home-NodeB Gateway (HNB-GW) services configured and running on a system.

Product

HNB-GW

Privilege

Inspector

Syntax

show cs-network counters [name *cs_svc_name* **[msc** *msc_point_code* **]] [| { grep** *grep_options* **| more }]**

name *cs_svc_name*

Filters the counter display based on an existing HNB-CS Network service name associated with an HNB-GW service running on system. *cs_svc_name* is an alphanumeric string of 1 through 63 characters.

msc *msc_point_code*

Filters the counter display filtered on the basis of MSC address provided in the SS7 point code that is connected to a particular HNB-CS Network service. *msc_point_code* must be the address of an MSC in SS7 point code notation.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *Command Line Interface Overview* chapter.

Usage

Use this command to view the session counter information for HNB-CS Network services configured and MSCs connected on a system.

Example

The following command displays the counters for the HNB-CS Network service named *hnb_cs_svc1*:

```
show cs-network counters name hnb_cs_svc1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cs-network statistics

Displays the Circuit Switched session statistics for Home-NodeB Gateway (HNB-GW) services configured and running on this system.

Product

HNB-GW

Privilege

Inspector

Syntax

show cs-network statistics [name *cs_svc_name* **| ranap-only | rtp-only | sccp-only] [| { grep** *grep_options* **| more }]**

name *cs_svc_name*

Filters the session statistics display based on an existing HNB-CS Network service name that is associated with an HNB-GW service running on this system. *cs_svc_name* is an alphanumeric string of 1 through 63 characters.

ranap-only

Filters the session statistics to display only Radio Access Network Application Protocol (RANAP) traffic for an HNB-CS Network service which is configured and associated with an HNB-GW service running on this system.

rtp-only

Filters the session statistics to display only Realtime Streaming Protocol (RTP) and Realtime Streaming Control Protocol (RTCP) traffic for the specified HNB-CS Network service which is configured and associated with an HNB-GW service running on this system.

sccp-only

Filters the session statistics to display only Signaling Connection Control Part (SCCP) traffic for the specified HNB-CS Network service which is configured and associated with an HNB-GW service running on this system.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *Command Line Interface Overview* chapter of the *Command Line Interface Reference*.

Usage

Use this command to view the session statistics for overall session or in selected part of user session for HNB-GW services configured and running on this system.

Example

The following command displays the session statistics for RTP and RTCP part of session for the HNB-CS Network service named *hnb_cs1*:

```
show cs-network statistics name hnbcs1 rtp-only
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cscf ifc

Displays the Initial Filter Criteria (iFC) for shared iFC functionality.

Product

SCM (S-CSCF, SIP Proxy)

Privilege

Security Administrator, Administrator

Syntax

show cscf ifc { all | id *fc_id* **} [| { grep** *grep_options* **| more }]**

all | id *fc_id*

all: Displays all iFC.
id *fc_id*: Displays information for an existing iFC specified as an alphanumeric string of 1 through 200 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Refer to *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to display configuration information for any or all iFC on this system.

Example

The following command displays the configuration information for all iFC on this system:

```
show cscf ifc all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cscf nat

Displays the Call Session Control Function (CSCF) mapping created for each of the media streams present in an established dialog.

Product

SCM (P-CSCF, A-BG)

Privilege

Security Administrator, Administrator

Syntax

show cscf nat media mapping { all | aor *aor* **} [| { grep** *grep_options* **| more }]**

media mapping { all | aor *aor* **}**

all: Displays the UE/Network origins and destinations, including their IP addresses/port numbers and associated contexts.
aor *aor*: Displays information for an Address of Record (AoR) specified as an alphanumeric string of 1 through 79 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Refer to *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to display the status of configured Network Address Translation (NAT) support.

Example

The following command displays the status of the mapping created for each of the media streams present on this system:

```
show cscf nat media mapping all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cscf npdb-servers

Displays the connection status of NPDB (Number Portability Data Base) servers in S-CSCF service.

Product

SCM (S-CSCF)

Privilege

Security Administrator, Administrator

Syntax

show cscf npdb-servers service *service_name* **[| { grep** *grep_options* **| more }]**

service *service_name*

Specifies the name of an existing CSCF service for which the statistics will be displayed as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Refer to *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to display the connection status of NPDB servers in S-CSCF service.

Example

The following command displays the connection status of NPDB servers for the S-CSCF service named *scscf1*:

```
show cscf npdb-servers service scscf1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cscf peer-servers

Displays name, IP address, and status of configured Call Session Control Function (CSCF) peer servers visible to the system.

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

show cscf peer-servers { all | full | name *service_name* **[server-name** *server_name* **] } [| { grep** *grep_options* **| more }]**

all | full | name *service_name* **[server-name** *server_name* **]**

all: Displays the peer server list names and the servers within those lists including their IP addresses/port numbers and domain names.
full: Displays additional details regarding the peer servers within the configured lists on the system.
name *service_name* **[server-name** *server_name* **]**: Displays the same information as the full keyword output, but for a peer server list or an existing peer server specified as an alphanumeric string of 1 through 80 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Refer to *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to display the status of configured peer servers.

Example

The following command displays the status of a peer server named *icscf3* that is a member of peer server list *cscf-main*:

```
show cscf peer-servers name cscf-main server-name icscf3
```

The following command displays the status of all peer servers in configured peer server groups in this context:

```
show cscf peer-servers full
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cscf service

Displays configuration and/or statistical information for Call Session Control Function (CSCF) services on this system.

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

show cscf service { all [counters] | diameter { location-info statistics service-name *service_name* **[vpn-name** *name* **] | policy-control statistics service-name** *service_name* **[vpn-name** *name* **] } | grey-list name** *name* **| li-packet-cable statistics service-name** *service_name* **| performance-counters name** *service_name* **| statistics name** *service_name* **[all | calls | ip-security | message | package-name { message-summary | presence | reg | winfo } | registrations | sigcomp | tcp { msrp | sip }] | subscription name** *service_name* **} [| { grep** *grep_options* **| more }]**

---

all [counters]

Displays configuration information for all CSCF services configured on this system.
counters: Displays statistics with the configuration information for all CSCF services configured on the system.

---

diameter { location-info statistics service-name *service_name* **[vpn-name** *name* **] | policy-control statistics service-name** *service_name* **[vpn-name** *name* **] }**

location-info statistics: Displays Diameter statistics on the E2 interface with the location information.
policy-control statistics: Displays Diameter (DPECA) statistics on the CSCF Rx interface with the configuration information.
service-name *service_name*: Specifies the name of an existing CSCF service for which the statistics will be displayed as an alphanumeric string of 1 through 63 characters.
vpn-name *name*: Specifies the name of an existing context in which all statistics for all services will be displayed as an alphanumeric string of 1 through 79 characters.

---

grey-list name *name*

Displays an existing list of run-time grey-listed users and their remaining barred period for the specified CSCF service as an alphanumeric string of 1 through 63 characters.

---

li-packet-cable statistics service-name *service_name*

Refer to the *Lawful Intercept Configuration Guide* for a description of this command.

---

name *service_name* **[counters]**

Displays configuration information for an existing CSCF service specified as an alphanumeric string of 1 through 63 characters.
counters: Displays statistics with the configuration information for the specific CSCF service.

performance-counters name *service_name*

Displays performance counters (3GPP TS 32.409) for an existing CSCF service specified as an alphanumeric string of 1 through 63 characters.

statistics name *service_name* **[all | calls | ip-security | message | package-name { message-summary | presence | reg | winfo } | registrations | sigcomp | tcp { msrp | sip }]**

Displays service statistics for an existing CSCF service specified as an alphanumeric string of 1 through 63 characters.
all: Displays all CSCF service statistics.
calls: Displays session statistics related to CSCF calls.
ip-security: Displays session statistics related to CSCF IPSec.
message: Displays session statistics for the SIP method MESSAGE.
package-name: Displays session statistics for the associated event package.

- **message-summary**: Displays session statistics for the "message-summary" event package.
- **presence**: Displays session statistics for the "presence" event package.
- **reg**: Displays session statistics for the "reg" event package.
- **winfo**: Displays session statistics for the "watcher-info" event package.

registrations: Displays session statistics related to CSCF registrations, re-registrations, and de-registrations.
sigcomp: Displays session statistics related to CSCF sigcomp.
tcp: Displays session statistics related to CSCF TCP.

- **msrp**: Displays statistics related to CSCF TCP MSRP statistics.
- **sip**: Displays statistics related to CSCF TCP SIP statistics.

Important: This keyword must be followed by another statistics-related keyword.

subscription name *service_name*

Displays service level subscription information for an existing CSCF service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display configuration information and/or statistics for any or all CSCF services on this system.

Example

The following command displays service statistics for the CSCF service named *cscf1*:

```
show cscf service statistics name cscf1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cscf sessions

Displays statistics for Call Session Control Function (CSCF) sessions on this system.

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

show cscf sessions { counters { calls { duration | first-response-time | invite-processing-time | post-answer-delay | post-dial-delay | service *service_name* **| session-release-delay | session-setup-delay } service** *service_name* **| subscription { duration | service** *service_name* **| setup-time } service** *service_name* **} | duration | full [callleg-id** *id* **| from-aor** *aor* **| service** *service_name* **| session-id** *id* **| to-aor** *aor* **] [media-type** *type* **] | summary [from-aor** *aor* **| service** *service_name* **| session-id** *id* **| to-aor** *aor* **] } [| { grep** *grep_options* **| more }]**

counters { calls { duration | first-response-time | invite-processing-time | post-answer-delay | post-dial-delay | service *service_name* **| session-release-delay | session-setup-delay } service** *service_name* **| subscription { duration | service** *service_name* **| setup-time } service** *service_name* **}**

Displays counters for all CSCF sessions matching the filter criteria.
calls: Counters associated with calls in CSCF service.

- **duration**: Displays the call duration time.
- **first-response-time**: Displays the time interval for the first response received for INVITE.
- **invite-processing-time**: Displays the INVITE message processing time in CSCF.
- **post-answer-delay**: Displays the time interval for post answer delay.
- **post-dial-delay**: Displays the time interval for the ringing or success response for INVITE.
- **service** *service_name*: Displays counters for an existing CSCF service specified as an alphanumeric string of 1 through 63 characters.

  Important: This keyword may be used alone with the **counters** keyword or following any other counters-specific keyword.

- **session-release-delay**: Displays the time interval for releasing the call.
- **session-setup-delay**: Displays the time interval for session setup.
- **subscription**: Counters associated with subscriptions in CSCF service.
  - **duration**: Displays the SIP Subscription duration time.
  - **service** *service_name*: Displays specific service. *service_name* must be an existing CSCF service and be from 1 to 63 alphanumeric characters.

    Important: This keyword may be used alone with the **subscription** keyword or following any other subscription-specific keyword.

- **setup-time**: Displays the SIP Subscription setup time.

duration

Displays the call duration for all CSCF sessions.

full [callleg-id *id* **| from-aor** *aor* **| service** *service_name* **| session-id** *id* **| to-aor** *aor* **] [media-type** *type* **]**

Displays all the session information for the active CSCF sessions matching the filter criteria.
callleg-id *id*: Displays session statistics for an existing call-leg ID expressed as an alphanumeric string of 1 through 63 characters.
from-aor *aor*: Displays session statistics for sessions originating from an existing Address of Record (AoR) specified as an alphanumeric string of 1 through 79 characters.
service *service_name*: Displays session statistics for sessions using an existing CSCF service specified as an alphanumeric string of 1 through 63 characters.
session-id *id*: Displays session statistics for sessions with an existing ID specified as an alphanumeric string of 1 through 63 characters.
to-aor *aor*: Displays session statistics for sessions sent to an existing AoR specified as an alphanumeric string of 1 through 79 characters.
media-type *type*: Displays information about an existing media type specified as an alphanumeric string of 1 through 9 characters.

summary [from-aor *aor* **| service** *service_name* **| session-id** *id* **| to-aor** *aor* **]**

Displays session summary information for sessions matching the filter criteria.
from-aor *aor*: Displays session statistics for sessions originating from an existing AoR specified as an alphanumeric string of 1 through 79 characters.
service *service_name*: Displays session statistics for sessions using an existing CSCF service specified as an alphanumeric string of 1 through 63 characters.
session-id *id*: Displays session statistics for sessions with an existing ID specified as an alphanumeric string of 1 through 63 characters.
to-aor *aor*: Displays session statistics for sessions sent to an existing AoR specified as an alphanumeric string of 1 through 79 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Refer to *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to display session information for any or all CSCF sessions.

Example

The following command displays the output for CSCF session duration:

```
show cscf sessions duration
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cscf sip

Displays Session Initiation Protocol (SIP) statistics for a specific Call Session Control Function (CSCF) service configured on this system.

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

show cscf sip statistics name *service_name* **[interface { domain { list | name** *domain_name* **} | ip { address** *ip_address* **| list } } | vpn-name** *name* **] [| { grep** *grep_options* **| more }]**

statistics name *service_name*

Specifies the name of an existing CSCF service as an alphanumeric string of 1 through 63 characters.

[interface { domain { list | name *domain_name* **} | ip { address** *ip_address* **| list } }**

SIP statistics will be displayed for this interface.
domain list: Displays list of interfaces associated with the CSCF service.
domain name *domain_name*: Specifies an existing domain associated with the CSCF service as an alphanumeric string of 1 through 80 characters.
ip address *ip_address*: Specifies the destination or source IP address associated with the CSCF service in IPv4 dotted-decimal or IPv6 colon-separated notation.
ip list: Displays a list of interfaces associated with the CSCF service.

vpn-name *name*

Specifies the name of an existing VPN as an alphanumeric string of 1 through 79 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Refer to *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to display SIP statistics for a specific CSCF service.

Important: This command displays counters for SIP statistics for a specified CSCF service. Counters are incriminated when SIP messages are sent (Tx) or received (Rx). SIP Request, Response, and Error counters are maintained at various levels in the SIP stack. These values are dependent on the packet flow. For example, if packets are dropped at an initial stage of parsing and error detection, the counters may not increment. All 2xx Response counters for individual requests are maintain outside the SIP layer and will not track re-transmissions and erroneous packets that are dropped. All other counters do keep track of re-transmissions.

Example

The following command displays SIP statistics for the CSCF service named *cscf1*:

```
show cscf sip statistics name cscf1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show cscf tcp

Displays TCP connection information for a specific Call Session Control Function (CSCF) service configured on this system.

Product

SCM

Privilege

Security Administrator, Administrator, Operator

Syntax

show cscf tcp connections service *service_name* **[facility { cscfmgr | sessmgr }] [full] [msrp] [remote-ip** *ip_address* **] [remote-port** *port_number* **] [sip] [| { grep** *grep_options* **| more }]**

---

connections service *service_name*

Specifies the name of an existing CSCF service as an alphanumeric string of 1 through 63 characters.

---

facility { cscfmgr | sessmgr }

Facility type for which connection details have to be retrieved.
cscfmgr: Facility type cscfmgr.
sessmgr: Facility type sessmgr.

---

full

Displays detailed information related to each connection.

---

msrp

Displays statistics related to CSCF TCP Message Session Relay Protocol (MSRP) statistics.

---

remote-ip *ip_address*

Specifies the remote IP address to match the connection in IPv4 dotted-decimal or IPv6 colon-separated notation.

---

remote-port *port_number*

Specifies the remote port to match the connection an integer from 1 through 65534.

---

sip

Displays statistics related to CSCF TCP SIP statistics.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Refer to *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to display TCP connection information for a specific CSCF service.

Important: More than one optional keyword may be used per command.

Example

The following command displays TCP connections for the CSCF service named *cscf1*:

```
show cscf tcp connections service cscf1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show css delivery-sequence

In StarOS 9.0 and later releases, this command is obsolete.

show css server

In StarOS 9.0 and later releases, this command is obsolete.

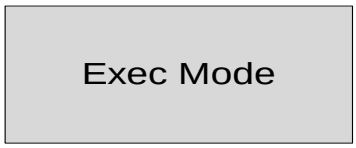
show css service

In StarOS 9.0 and later releases, this command is obsolete.

Chapter 115
Exec Mode Show Commands (D-G)

This section includes the commands **`show dhcp`** through **`show gtpu-service`**.

The Exec Mode is the initial entry point into the command line interface system. Exec mode **show** commands are useful in troubleshooting and basic system monitoring.



show dhcp

Displays counter information pertaining to Dynamic Host Configuration Protocol (DHCP) functionality based on specific criteria.

Product

GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show dhcp [**counters** | **full** | **summary**] [**all** | **apn** *apn_name* | **callid** *id* | **chaddr** *mac_address* | **dhcp-service** *svc_name* | **imsi** *imsi* | **user-address** *address* | **msid** *msid* | **server** *server_address* | **username** *name*]

counters

Displays DHCP counter information.

full

Displays all available information pertaining to the criteria specified.

summary

Displays a summary of the DHCP statistics.

all

Displays counter information for each active PDP context.

apn *apn_name*

Displays information based on an existing Access Point Name (APN) specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

callid *id*

Displays information for an existing call identification number specified as a 4-digit hexadecimal number.

chaddr *mac_address*

Displays information for a mobile node specified by its MAC address.

dhcp-service *svc_name*

Displays information for an existing DHCP service specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

imsi *imsi*

Displays information for an International Mobile Subscriber Identity (IMSI) specified as a string of 1 to 15 digits.

user-address *address*

Displays information for a DHCP-assigned user IP address specified in IPv4 dotted-decimal notation.

msid *msid*

Displays information for a Mobile Subscriber Identity (MSID) specified as a string of 1 to 15 digits.

server *server_address*

Displays information for a DHCP server specified by its IP address in IPv4 dotted-decimal notation.

username *name*

Displays information for a subscriber specified as an alphanumeric string of 1 through 127 characters (including wildcards "$" and "*") that is case sensitive.

Usage

Counters pertaining to DHCP functionality can be displayed as cumulative values or for specific APNs, PDP contexts, servers, or DHCP services.

Example

The following command displays DHCP counter information for a DHCP service called *DHCP-Gi*:

```
show dhcp dhcp-service DHCP-Gi
```

The following command displays DHCP counter information for a DHCP Call ID *01ca11a2*:

```
show dhcp call-id DHCP-Gi
```

The following command displays DHCP information for the specified mobile node:

```
show dhcp chaddr 00:05:47:00:37:44
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show dhcp statistics

Displays Dynamic Host Configuration Protocol (DHCP) statistics for the specified servers.

Product

GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show dhcp statistics [dhcp-service *svc_name* **| server** *ip_address* **]**

dhcp-service *svc_name*

Displays statistics for a DHCP service specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

server *ip_address*

Displays statistics for a DHCP server specified by its IP address in IPv4 dotted-decimal notation.

Usage

Statistics for a single DHCP service or DHCP server can be viewed using the **dhcp-service** or **server** keywords respectively.
Cumulative statistics for all DHCP services and servers within a context can be viewed by executing the command with no keywords from within the context in which they're configured.
If this command is issued from within the local context, the statistics displayed will be cumulative for all dhcp servers configured on the system regardless of context.

Example

The following command allows you to view statistics for all configured DHCP servers within the context:

```
show dhcp statistics
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show dhcp-service

Displays configuration information for either a specific, or for all Dynamic Host Configuration Protocol (DHCP) servers configured.

Product

GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show dhcp-service { all | name svc_name }
```

all

Displays information for all configured DHCP services.

name *svc_name*

Displays information for a DHCP service name specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

Usage

This command is used to verify the configuration of one or all DHCP services for monitoring or troubleshooting purposes. The output is a concise listing of DHCP service parameter settings.
If this command is executed from within the local context with the all keyword, information for all DHCP services configured on the system will be displayed.

Example

The following command displays configuration information for a DHCP service called *dhcp1*:

```
show dhcp-service name dhcp1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show dhcp status

Displays configuration information for either a specific, or for all Dynamic Host Configuration Protocol (DHCP) services and servers configured.

Product

GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show dhcp status [dhcp-service *svc_name* **] [server** *ip_addr* **]**

all

Displays information for all configured DHCP services.

dhcp-service *svc_name*

Displays information for a DHCP service name specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

server *ip_address*

Displays status for a DHCP server specified by its IP address in IPv4 dotted-decimal notation.

Usage

This command is used to show/verify the status or configuration of one or all DHCP services along with count of cumulative leased addresses and addresses leased at that time for monitoring or troubleshooting purposes. The output is a concise listing of DHCP service parameter settings.
If this command is executed from within the local context with the all keyword, information for all DHCP services configured on the system will be displayed.

Example

The following command displays status of a DHCP service called *ggsn_dhcp1*:

```
show dhcp status dhcp-service ggsn_dhcp1
```

State shown in display is consolidated across session managers, such as for each session manager, DHCP server have a timestamp value associated with its state.
For a DHCP server, its timestamp value is compared for each session manager and the state associated with the latest value is shown.

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show diameter aaa-statistics

Displays Diameter Authentication, Authorization and Accounting (AAA) statistics.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show diameter aaa-statistics [all | group *group_name* **[server** *server_name* **] | server** *server_name* **] [| { grep** *grep_options* **| more }]**

all

Displays all available Diameter server statistics.

group *group_name* **[server** *server_name* **]**

Displays all Diameter server statistics within an existing AAA group specified as an alphanumeric string of 1 through 64 characters.
server_name must be the name of a Diameter server, expressed as an alphanumeric string of 1 through 64 characters.

server *server_name*

Displays Diameter server statistics for the Diameter server name specified as an alphanumeric string of 1 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to view Diameter AAA statistics.

Example

The following command displays all available Diameter server statistics:

```
show diameter aaa-statistics all
```

show diameter accounting servers aaa-group

Displays Diameter accounting server information for an Authentication, Authorization and Accounting (AAA) group.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show diameter accounting servers [aaa-group *group_name* **] [| { grep** *grep_options* **| more }]**

aaa-group *group_name*

Specifies the name of an existing AAA group as an alphanumeric string of 0 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to view Diameter accounting server information for an AAA group.

Example

The following command displays Diameter accounting server information for an AAA group named in *group12*:

```
show diameter accounting servers aaa-group group12
```

show diameter authentication servers aaa-group

Displays Diameter Authentication server information for a specified AAA group.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show diameter authentication servers [aaa-group *group_name* **]**

aaa-group *group_name*

Specifies the name of an existing AAA group as an alphanumeric string of 0 through 64 characters.

Usage

Use this command to view Diameter authentication server information for an AAA group.

Example

The following command displays Diameter authentication server information for an AAA group named *group12*:

```
show diameter authentication servers aaa-group group12
```

show diameter endpoint

This command has been deprecated, and is replaced by the show diameter endpoints command.

show diameter endpoints

This command displays the status of Diameter client endpoint(s).

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show diameter endpoints { all | endpoint *endpoint_name* **} [| { grep** *grep_options* **| more }]**

all

Displays status of all Diameter client endpoints.

endpoint *endpoint_name*

Displays status of an existing Diameter client endpoint specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to view the status of Diameter client endpoints.
If you are in the local context, then all contexts are searched for the specified endpoint(s). Specify **all** to see all endpoints; otherwise, just the named endpoint will be displayed. If no argument is provided, a summary of all endpoints is displayed.
Default value: N/A

Example

The following command displays status of all Diameter client endpoints.

```
show diameter endpoints all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show diameter message-queue

Displays Diameter message queue statistics.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show diameter message-queue counters { inbound | outbound } [endpoint *endpoint_name* **[peer-host** *peer_id* **[peer-realm** *realm_id* **]] | session-id** *session_id* **] [| { grep** *grep_options* **| more }]**

counters { inbound | outbound }

Specifies the message counters:
inbound: Specifies Diameter inbound messages
outbound: Specifies Diameter outbound messages

endpoint *endpoint_name*

Specifies the Diameter endpoint as an alphanumeric string of 1 through 63 characters.

peer-host *peer_id*

Specifies the Diameter peer host as an alphanumeric string of 1 through 63 characters.

peer-realm *realm_id*

Specifies the Diameter peer realm as an alphanumeric string of 1 through 127 characters.

session-id *session_id*

Specifies the session ID as an alphanumeric string of 1 through 127 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to view the count of the messages in the Diameter message queue for specific counter type, session ID, or endpoint, peer host, and peer realm.

Example

The following command displays message queue statistics for outbound messages specific to the Diameter endpoint named *asr5k.testnetwork.com*:

```
show diameter message-queue counters outbound endpoint
asr5k.testnetwork.com
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show diameter peers

Displays Diameter peer information.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show diameter peers [full | summary] [all | [endpoint *endpoint_name* **] [peer-host** *peer_id* **] [peer-realm** *realm_id* **]+] [| { grep** *grep_options* **| more }]**

full

Displays full details of all or specified Diameter peers.

summary

Displays summary details of all or specified Diameter peer(s).

all

Displays details of all Diameter peers.

endpoint *endpoint_name*

Displays details of the origin Diameter endpoint specified as an alphanumeric string of 1 through 255 characters.

peer-host *peer_id*

Displays details of the Diameter peer host specified as an alphanumeric string of 1 through to 63 characters.

peer-realm *realm_id*

Displays details of the Diameter peer realm ID specified as an alphanumeric string of 1 through 127 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to view the details of Diameter peers.
If you are in the local context, then all contexts are searched for the specified peer(s).
This is similar to the **show subscribers** CLI command and supports multiple filter options specified at the same time.

If filter options are specified (e.g., **all**, **endpoint**, etc.), the default is for one line of output to be displayed per peer. Use **full** to get detailed information per peer, or **summary** to get summarized information about all matching peers.
If no filter options are specified, a summary output for all peers is displayed. Use the **full** option to get detailed information about every peer.
Default value: N/A

Example

The following command details of the Diameter endpoint named *endpoint12*:

```
show diameter peers endpoint wndpoint12
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show diameter route status

Displays Diameter route health status information.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show diameter route status [ endpoint endpoint_name | full [ endpoint endpoint_name ] ] [
host host_name | peer peer_id ] [ | { grep grep_options | more } ]
```

full

Displays information about which Diameter clients are using which peer/host combinations.

endpoint *endpoint_name*

Displays detailed information for the Diameter client endpoint specified as an alphanumeric string of 1 through 63 characters.

host *host_name*

Displays information for the Diameter host specified as an alphanumeric string of 1 through 63 characters.

peer *peer_id*

Displays information for the Diameter peer host specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to view the Diameter route health status.
The route status displays status of peer/host combinations. Refer to the **route-failure** CLI command in Diameter Endpoint Configuration mode. When no options are specified, the display will give one line per peer/host combination, indicating how many Diameter clients are using each combination, and for how many clients the combination is available or failed. Specify **full** to see which Diameter clients are using which peer/host combinations. Specify **host** or **peer** to see just combinations with the named host or peer. Specify **endpoint** to see detailed information about the named Diameter client.
Default value: N/A

Example

The following command displays route health status details of the Diameter client endpoint named *endpoint12*:

```
show diameter route status endpoint endpoint12
```

show diameter route table

Displays the Diameter routing table.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show diameter route table [ wide ] [ endpoint endpoint_name ] [ | { grep grep_options | more } ]
```

wide

Displays the route table information in wide-format.

endpoint *endpoint_name*

Displays the Diameter routing table for the Diameter endpoint specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view the status of Diameter client endpoints.
If you are in the local context, then the route information used by Diameter endpoints in all chassis contexts will be used in the display.
The route table displays all static and dynamic routes. Refer to the route-entry CLI command in Diameter Endpoint Configuration Mode.
Default value: N/A

Example

The following command displays status of the Diameter client endpoint named *endpoint12*.

```
show diameter route table endpoint endpoint12
```

show diameter statistics

Displays Diameter peer statistics.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show diameter statistics [[proxy] endpoint *endpoint_name* **[peer-host** *peer_id* **[peer-realm** *realm_id* **]]] [| { grep** *grep_options* **| more }]**

endpoint *endpoint_name*

Displays statistics for the DIameter endpoint specified as an alphanumeric string of 1 through 63 characters.

peer-host *peer_id*

Displays statistics for the Diameter host peer specified as an alphanumeric string of 1 through 255 characters.

peer-realm *realm_id*

Displays statistics for the Diameter peer realm specified as an alphanumeric string of 1 through 127 characters.

proxy

Displays proxy related statistics.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to view Diameter statistics for the specified endpoint or proxy.

Example

The following command displays Diameter peer statistics for the endpoint named *endpoint12*:

```
show diameter statistics endpoint endpoint12
```

show diameter-service

Displays information about configured Diameter services.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show diameter-service { all | lte-s6a trace-id { all | user-name *user_name* **} | name** *service_name* **| statistics name** *service_name* **[vpn-name** *vpn_context_name* **] } [| { grep** *grep_options* **| more }]**

all

Displays full information for all configured Diameter services.

lte-s6a trace-id { all | user-name *user_name* **}**

Displays user trace ID information for an LTE/S6a application.
all: Displays full information.
user-name *user_name*: Displays information for the user specified an alphanumeric string of 1 through 79 characters.

name *service_name*

Displays information for the Diameter service name specified as an alphanumeric string of 1 through 79 characters.

statistics name *service_name* **[vpn-name** *vpn_context_name* **]**

Displays statistics for the Diameter service name specified as an alphanumeric string of 1 through 79 characters.
vpn-name *vpn_context_name*: Specifies the name of VPN context as an alphanumeric string of 1 through 79 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to view information on configured Diameter services.

Example

The following command displays statistics for the Diameter service named *ggsn12*:

```
show diameter-service name ggsn2
```

show dns-client

Displays cache and/or statistics for a specified Domain Name System (DNS) client.

Product

P-CSCF, SIP Proxy, SGSN, HSGW, MME

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show dns-client { cache client *name* **[query-name** *name* **\| query-type { A \| AAAA \| NAPTR \| SRV }] \| statistics client** *name* **} [\| { grep** *grep_options* **\| more }]**

---

cache client *name* **[query-name** *name* **\| query-type { A \| AAAA \| NAPTR \| SRV }]**

displays statistics for the cache of an existing DNS client specified as an alphanumeric string of 1 through 255 characters.
query-name *name*: Filters DNS results based on the domain name specified as an alphanumeric string of 1 through 255 characters. *name* is the domain name used to perform the DNS query. It is different from the actual domain name which is resolved. For example, to resolve the SIP server for *service.com*, the query name is *_sip._udp.service.com* and the query type is **SRV**.
query-type:

- **A**: Filters DNS results based on 32-bit domain IPv4 address records (A records).
- **AAAA**: Filters DNS results based on 128-bit domain IPv6 address records (AAAA resource records).
- **NAPTR**: Filters DNS results based on Naming Authority Pointer records.
- **SRV**: Filters DNS results based on service locator records (SRV records).

---

statistics client *name*

Displays statistics for an existing DNS client specified as an alphanumeric string of 1 through 255 characters.

\| { grep *grep_options* **\| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display DNS cache and/or statistics for a specified DNS client.

Example

The following command displays statistics for a DNS client named *domain1.com*:

```
show dns-client statistics client domain1.com
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show dynamic-policy statistics

Displays policy control and charging (PCC) statistics from the interface communicating with the Policy and Charging Rules Function (PCRF) via Gx(x).

Product

HSGW, PDSN, S-GW

Privilege

Inspector

Syntax

show dynamic-policy statistics { hsgw-service *name* **| pdsn-service** *name* **| sgw-service** *name* **}**

hsgw-service *name*

Displays policy control and charging statistics from the Gxa interface communicating with the PCRF. *name* must be an existing HSGW service name and be from 1 to 63 alphanumeric characters.

pdsn-service *name*

Displays policy control and charging statistics from the Gx interface communicating with the PCRF. *name* must be an existing PDSN service name and be from 1 to 63 alphanumeric characters.

sgw-service *name*

Displays policy control and charging statistics from the Gxc interface communicating with the PCRF. *name* must be an existing S-GW service name and be from 1 to 63 alphanumeric characters.

Usage

Use this command to display PCC statistics for the specified service and its Gx interface communicating with the PCRF.

Example

The following command displays HSGW statistics for an HSGW service named *hsgw4*:

```
show dynamic-policy statistics hsgw-service hsgw4
```

The following command displays PCC statistics for a PDSN service named *cdma4*:

```
show dynamic-policy statistics pdsn-service cdma4
```

The following command displays S-GW statistics for an S-GW service named *sgw4*:

```
show dynamic-policy statistics sgw-service sgw4
```

show egtpc peers

Displays information about eGTP-C peers.

Product

P-GW, S-GW

Privilege

Inspector

Syntax

show egtpc peers [address *ip_address* **| egtp-service** *name* **] | interface { mme | pgw-ingress | sgsn | sgw-egress | sgw-ingress } [address** *ip_address* **] [wf1] }] [| { grep** *grep_options* **| more }]**

---

address *ip_address*

Displays information about a eGTP-C peer specified by its IP address in IPv4 dotted-decimal notation or IPv6 colon-separated notation.

---

egtp-service *name* **[address** *ip_address* **]**

Displays information about eGTP-C peers associated with an existing egtp-service name specified as an alphanumeric string of 1 through 63 characters.
address *ip_address*: Additionally, the results can be filtered based on the IP address associated with an existing eGTP-C peer service specified in IPv4 dotted-decimal notation or IPv6 colon-separated notation.

---

interface { mme | pgw-ingress| sgsn | sgw-egress | sgw-ingress } [address *ip_address* **] [wf1]**

Displays information about eGTP-C peers associated with the service interface configured on this system.
mme: Displays information about eGTP-C MME peers associated with the service interface configured on this system. Additionally, the results can be filtered based on the IP address associated with the MME peer.
pgw-ingress: Displays information about eGTP-C P-GW ingress peers associated with the service interface configured on this system. Additionally, the results can be filtered based on the IP address associated with the P-GW ingress peer.
sgsn: Displays information about eGTP-C SGSN peers associated with the S4 service interface configured on this system. Additionally, the results can be filtered based on the IP address associated with the SGSN peer.
sgw-egress: Displays information about eGTP-C S-GW egress peers associated with the service interface configured on this system. Additionally, the results can be filtered based on the IP address associated with the S-GW egress peer.
sgw-ingress: Displays information about eGTP-C S-GW ingress peers associated with the service interface configured on this system. Additionally, the results can be filtered based on the IP address associated with the S-GW ingress peer.
address *ip_address*: Specifies the IP address of the selected peer in IPv4 dotted-decimal notation or IPv6 colon-separated notation.
wf1: Specifies that the output is to be displayed in wide format number 1.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.

For details on using the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information about eGTP-C peers associated with the service interface configured on this system. The output contains the following information about the peer:

- Status of the peer
- Echo status
- Restart counter status
- Peer restart counter knowledge
- Service ID
- Peer IP address
- Current sessions
- Maximum sessions

Important: The primary command, **show egtpc peers**, when entered without additional keywords, displays information for all peers associated with the service operating on this system.

Example

The following command returns an output for an eGTP-C S-GW egress peers associated with the service interface configured on this system with an IP address of *10.2.3.4*:

```
show egtpc peers interface sgw-egress address 10.2.3.4
```

The following command returns an output for an eGTP-C MME peer associated with the service interface configured on this system with an IP address of *10.2.3.4*:

```
show egtpc peers interface mme address 10.2.3.4
```

show egtpc sessions

Displays eGTP-C session information.

Product

P-GW, S-GW

Privilege

Inspector

Syntax

show egtpc sessions [egtp-service *name* **| interface { mme | pgw-ingress | sgsn | sgw-egress | sgw-ingress }] [| { grep** *grep_options* **| more }]**

---

egtp-service *name*

Displays information about eGTP-C sessions associated with an existing egtp-service specified as an alphanumeric string of 1 through 63 characters.

---

interface { mme | pgw-ingress | sgsn | sgw-egress | sgw-ingress }

Displays information about eGTP-C sessions associated with the service interface configured on this system.
mme: Displays information about eGTP-C sessions associated with the MME interface configured on this system.
pgw-ingress: Displays information about eGTP-C sessions associated with the P-GW ingress interface configured on this system.
sgsn: Displays information about eGTP-C sessions associated with the SGSN eGTP-C S4 interface configured on this system.
sgw-egress: Displays information about eGTP-C sessions associated with the S-GW egress interface configured on this system.
sgw-ingress: Displays information about eGTP-C sessions associated with the S-GW ingress interface configured on this system.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on using the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display session information for a specific eGTP service or for sessions associated with an interface type configured on this system.

Example

The following command displays eGTP-C session information for sessions associated with all P-GW ingress interfaces configured on this system:

```
show egtpc sessions interface pgw-ingress
```

The following command displays eGTP-C session information for sessions associated with all MME interfaces configured on this system:

show egtpc sessions interface mme

show egtpc statistics

Displays evolved GPRS Tunneling Protocol Control (eGTP-C) plane statistics for a specific service name or interface type.

Product

P-GW, S-GW

Privilege

Inspector

Syntax

show egtpc statistics [egtp-service *name* **| interface { mme | pgw-ingress | sgsn | sgw-egress | sgw-ingess } | mme-address** *ip_address* **| pgw-address** *ip_address* **| sgsn-address** *ip_address* **| sgw-address** *ip_address* **] [verbose] [| { grep** *grep_options* **| more }]**

egtp-service *name*

Displays statistics for an existing eGTP service specified as an alphanumeric string of 1 through 63 characters.

interface { mme | pgw-ingress | sgw-egress | sgw-ingess }

mme: Displays eGTP-C statistics for all MME interfaces.
pgw-ingress: Displays eGTP-C statistics for all eGTP P-GW ingress interfaces.
sgsn: Displays eGTP-C statistics for all eGTP S4 SGSN interfaces.
sgw-egress: Displays eGTP-C statistics for all eGTP S-GW egress interfaces.
sgw-ingress: Displays eGTP-C statistics for all eGTP S-GW ingress interfaces.

mme-address *ip_address*

Displays eGTP-C statistics for an existing MME IP address expressed in IPv4 dotted-decimal notation or IPv6 colon-separated notation.

pgw-address *ip_address*

Displays eGTP-C statistics for an existing P-GW IP address expressed in IPv4 dotted-decimal notation or IPv6 colon-separated notation.

sgsn-address *ip_address*

Displays eGTP-C statistics for an existing SGSN S4 IP address expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

sgw-address *ip_address*

Displays eGTP-C statistics for an existing S-GW IP address expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

verbose

Displays the maximum amount of detail available for this commands output. If this option is not specified, the output is truncated to a more concise level.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on using the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display evolved GPRS Tunneling Protocol Control (eGTP-C) plane statistics for a specific service name or interface type.

Example

The following command displays eGTP-C statistics for interfaces configured as S-GW ingress interfaces:

```
show egtpc statistics interface sgw-ingess
```

The following command displays eGTP-C session information for sessions associated with all MME interfaces configured on this system:

```
show egtpc sessions interface mme
```

show egtp-service

Displays configuration information for evolved GPRS Tunneling Protocol (eGTP) services on this system.

Product

MME, P-GW, S-GW

Privilege

Inspector

Syntax

show egtp-service { all | name *service_name* **} [| { grep** *grep_options* **| more }]**

all

Displays configuration information for all eGTP services configured on this system.

name *service_name*

Displays configuration information for an existing eGTP service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference Guide*.

Usage

Use this command to view configuration information for eGTP services on this system.

Example

The following command displays service statistics for the eGTP service named *egtp1*:

```
show egtp-service name egtp1
```

show event-notif server

Displays the counter information of configured Event Notification servers based on specific criteria.

Product

All

Privilege

Inspector

Syntax

```
show event-notif server all [ | {grep grep_options | more }]
```

all

Displays counter information for each active Event Notification server in this context.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on using the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display the counters pertaining to the Event Notification collection servers configured in a context.

Example

The following command displays the counter information for all Event Notification collection servers configured in a context:

```
show event-notif server all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show event-notif statistics

Displays the statistical information collected over configured Event Notification interface based on specific criteria.

Product

All

Privilege

Inspector

Syntax

```
show event-notif statistics [ | {grep grep_options | more }]
```

| { grep *grep_options* | more }

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on using the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display the statistical information collected over configured Event Notification interface based on specific criteria.

Example

The following command displays the counter information for all Event Notification collection servers configured in a context:

```
show event-notif statistics
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show external-inline-servers

This command is obsolete.

show fa-service

Displays information on configured foreign agent (FA) services.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show fa-service { all | name *fa_name* **} [| { grep** *grep_options* **| more }]**

---

all | name *fa_name*

all: indicates information on all foreign agent services is to be displayed.
name *fa_name*: indicates only the information for the named FA service is to be displayed.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Display foreign agent service configuration information.

Example

The following commands display information on the FA service *sampleService* and all services, respectively.

```
show fa-service name sampleService

show fa-service all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show fans

Displays the current control status, speed, and temperature for the upper and lower fans in the system chassis.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show fans [| { grep *grep_options* **| more }]**

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

View the fan information to verify system hardware status as necessary.

Example

The following command displays information regarding the cooling fans in the system:

```
show fans
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show file

Displays the contents of the file specified. The contents are paginated as if it were normal ASCII output.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show file url *url* **[| { grep** *grep_options* **| more }]**

url *url*

Specifies the location of a file to display. *url* may refer to a local or a remote file. *url* must be entered using the following format:
[file:]{ /flash | /pcmcia1 | /hd }[/*directory* **]/***file_name*
tftp://{ *host***[** *:port#* **] }[/***directory* **]/***file_name*
[http: | ftp: | sftp:]//[*username***[** *:password* **]@] { ***host* **}[** *:port#* **][/***directory* **]/***file_name*

Important: Use of the SMC hard drive is not supported in this release.

Important: Do not use the following characters when entering a string for the field names below: "/" (forward slash), ":" (colon) or "@" (at sign).

directory is the directory name.
filename is the actual file of interest.
username is the user to be authenticated.
password is the password to use for authentication.
host is the IP address or host name of the server.
port# is the logical port number that the communication protocol is to use.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Display the contents of files to view such information as log data, trace information, etc.

Example

The following will display the contents of the local file */pub/log.txt*.

```
show file //pcmcia1/pub/log.txt
```

The following command will display the contents of the file */pub/log.txt* on remote host *remoteABC*.

show file ftp://remoteABC/pub/log.txt

show firewall flows

This command is obsolete.

show firewall ruledef

This command is obsolete.

show firewall statistics

This command is obsolete.

show fng-service

Displays information about specified Femto Network Gateway (FNG) service configuration, status, and counters, and includes information about all the sessions currently maintained by the FNG.

Product

FNG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show fng-service { all [counters] | name *service_name* **| session | statistics }**

all

Displays information for all configured FNG services.

counters

Displays counters associated with the FNG service.

name *service_name*

Displays information only for an existing FNG service specified as an alphanumeric string of 1 through 63 characters.

session

Displays information about configured FNG sessions.

Important: See **show fng-service session** for detailed options.

statistics *service_name*

Total of collected information for specific protocol since the last **restart** or **clear** command.

Important: See **show fng-service statistics** for detailed options.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the section *Regulating a Command's Output* in the chapter *Command Line Interface Overview* in the *Command Line Interface Reference*.

Usage

Use this command to view information for selected configured FNG services.

Example

The following command displays available information for all active FNG services.

```
show fng-service all
```

Important: Command output descriptions are available in the *Statistics and Counters Reference*.

show fng-service session

Displays statistics for specific Femto Network Gateway (FNG) sessions.

Product

FNG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show fng-service session [all | callid *call_id* **| counters | full [all | callid** *call_id* **| ip-address** *ip-address* **| peer-address** *ip_address* **| username** *name* **] | ip-address** *ip-address* **| peer-address** *ip-address* **| summary [all | callid** *call_id* **| ip-address** *ip-address* **| peer-address** *ip-address* **| username** *name* **] | username** *name* **]**

all

Displays all related information for all active FNG sessions.

callid

Displays PPP information for the call ID specified as a 4-digit hexadecimal number.

counters

Displays counters for the configured FNG sessions.

full

Displays all available information for the associated display or filter keyword.

ip-address *ipv4_address*

Displays information for the subscriber IP address specified in IPv4 dotted-decimal notation.

peer-address *ipv4_address*

Displays information for the IP peer specified by its IP address in IPv4 dotted-decimal notation.

summary

Displays summary information for FNG sessions.

username *user_name*

Displays information for a username within the current context specified as an alphanumeric string of 1 through 127 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the section *Regulating a Command's Output* in the *Command Line Interface Overview* chapter.

Usage

Use this command to view configuration information for an FNG session.

Example

The following command displays all available FNG sessions.

```
show fng-service session all
```

Important: Command output descriptions are available in the *Statistics and Counters Reference*.

show fng-service statistics

Displays statistics for the FNG since the last restart or clear command. The output includes the number of each type of protocol message. For example, the output includes the various types of EAP messages.

Product

FNG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show fng-service statistics [name *service_name* **| peer-address** *ipv4_address* **]**

name *service_name*

Displays statistics for an existing service name specified as an alphanumeric string of 1 through 63 characters.

peer-address *ipv4_address*

Displays statistics for an IP peer specified by its IP address in IPv4 dotted-decimal notation.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the section *Regulating a Command's Output* in the *Command Line Interface Overview* chapter.

Usage

Use this command to display FNG statistics.

Important: You may use more than one keyword per command line.

Example

The following command displays information about the FNG service.

```
show fng-service statistics
```

Important: Command output descriptions are available in the *Statistics and Counters Reference.*

show freeze-ptmsi imsi

Displays the P-TMSI (packet-temporary mobile subscriber identify) corresponding to the IMSI (international mobile subscriber identity) that has entered a frozen state after the purge timeout timer expires.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show freeze-ptmsi imsi *imsi_num*

imsi *imsi_num*

Specifies the IMSI that has been frozen as a sequence of up to 15 digits. The first three digits are the MCC (mobile country code). The next two or three digits are the MNC (mobile network code). The remaining digits are the MSIN (mobile station identification number).

Usage

This command enables the operator to know whether a frozen IMSI has an associated P-TMSI.

Example

The following command displays the P-TMSI corresponding to a frozen IMSI:

```
show freeze-ptmsi imsi 262090426000194
```

show ggsn-service

Displays configuration information for Gateway GPRS Support Node (GGSN) services on the system.

Product

GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ggsn-service { all | name *ggsn_svc_name* **} [| { grep** *grep_options* **| more }]**

all

Displays information for all GGSN services configured with the given context.

name *ggsn_svc_name*

Displays information for an existing GGSN service name specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For more information on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference*.

Usage

This command is used to verify the configuration of one or all GGSN services for monitoring or troubleshooting purposes. The output is a concise listing of GGSN service parameter settings.
If this command is executed from within the local context with the all keyword, information for all GGSN services configured on the system will be displayed.

Example

The following command displays configuration information for a GGSN service called *ggsn1*:

```
show ggsn-service name ggsn1
```

show ggsn-service sgsn-table

Lists all Serving GPRS Support Nodes (SGSNs) by IP addresses and shows the current number of subscribers to each SGSN.

Product

GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show ggsn-service sgsn-table
```

Usage

While there are existing commands to show SGSN subscriber information, this command is the only way to list all SGSNs by IP address and show the current number of subscribers to each SGSN.

Example

The following command will bring up a table showing the current active/inactive status, IP address, reboots/restarts and SGSN users.

```
show ggsn-service sgsn-table
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show global-title-translation

Displays configuration information for Global Title Translation (GTT).

Product

SGSN

Privilege

Inspector

Syntax

```
show global-title-translation { address-map { all | instance instance } | association {
all | instance instance } }
```

address-map { all | instance }

Displays configuration information for either the entire GTT address map database or for a specific instance of an address map. *instance* is an integer from 1 to 4096 which uniquely identifies the address map configuration.

association { all | instance }

Displays configuration information for either the entire database of GTT association lists for for a specific instance of GTT association configuration. *instance* is an integer from 1 to 16 which uniquely identifies the GTT association configuration.

Usage

This command displays the configuration for the GTT address maps and associations.

Example

The following command displays the address map *2047*.

```
show global-title-translation address-map 2047
```

show gmm-sm statistics

Displays statistics for the GPRS Mobility Management and Session Management (GMM/SM) configuration of the system's SGSN service. GMM/SM supports mobility to allow the SGSN to know the location of a Mobile Station (MS) at any time and to activate, modify and deactivate the PDP sessions required by the MS for user data transfer.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show gmm-sm statistics [ gmm-only | plmn-id mcc mcc mnc mnc [ access-type { gprs | umts } ] | sm-only ] [ gprs-service srvc_name | iups-service srvc_name | sgsn-service srvc_name ] [ verbose ] [ | { grep grep_options | more } ]
```

Keywords are presented below. Primary keywords are listed in the order of selection as shown in the syntax. Secondary or filtering keywords are presented alphabetically after the description of the primary keywords.

gmm-only

Displays only GPRS mobility management (GMM) information for other specified keyword parameters for the current context.

plmn-id mcc *mcc* **mnc***mnc* **[access-type { gprs | umts }]**

Filters the statistics display per PLMN.
Enter the **access-type** keyword to fine-tune the display of the GMM/SM statistics to an aggregate of the IuPS (select access-type UMTS) and/or the GPRS (select access-type GPRS) services belonging to the PLMN.

sm-only

Displays only session management (SM) information for other specified keyword parameters for the current context.

gprs-service *srvc_name*

Displays the statistics for an existing 2.5G GPRS service name specified as an alphanumeric string of 1 through 63 characters.
The display request can be narrowed by adding either the **nsei** or **routing-area** filter keywords.

iups-service *srvc_name*

Displays the statistics for an existing IuPS service specified as an alphanumeric string of 1 through 63 characters.
The display request can be narrowed by adding either the **rnc** or **routing-area** filter keywords.

sgsn-service *srvc_name*

Displays the statistics for an existing 3G SGSN service specified as an alphanumeric string of 1 through 63 characters.
The display request can be narrowed by adding either the **rnc** or **routing-area** filter keywords.

access-type *type*

Filters the display of service statistics by 2.5G GPRS services or 3G IuPS services for UMTS:

- **gprs**
- **umts**

If this keyword is not included, then statistics for both access types are displayed.

lac *lac_id*

Specifies the location area code (LAC) as part of the identification of the RNC or RA as an integer from 1 through 65535.

mcc *mcc_id*

Specifies the mobile country code (MCC) as part of the identification of the RNC or RA an integer from 100 through 999.

mnc *mnc_id*

Specifies the mobile network code (MNC) as part of the identification of the RNC or RA as a 2- or 3-digit integer from 00 through 999.

nsei *nse_id*

Displays the GMM/SM session statistics for an existing network service entity (NSEI) specified as an integer from 0 to 65535.

rac *rac_id*

Specifies the routing area code (RAC) as part of the identification of the RNC or RA as an integer from 1 through 255.

rnc *rnc_id*

Enter this keyword to fine-tune the display of the GMM/SM session statistics just for the radio network controller (RNC) specified as an integer from 0 through 4095.

routing-area mcc *mcc_id* **mnc** *mnc_id* **lac** *lac_id* **rac** *rac_id*

Enter the **routing-area** keyword to fine-tune the display of the GMM/SM statistics for a specified routing area (RA) identified by the MCC, MNC, LAC and RAC.

verbose

Displays all possible statistics for specified command or keyword.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.

For more information on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display usage statistics for the GMM/SM session configurations for SGSN services, including a BSC attaches, activations, and throughput.

Example

The following command displays GMM/SM statistics for a specific routing area defined for the 2.5G SGSN's GPRS service:

```
show gmm-sm statistics gprs-service gprs1 routing-area mcc 123 mcc 131
lac 24 rac 11
```

The following command displays all possible information for GMM/SM statistics:

```
show gmm-sm statistics verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gprsns statistics

Displays the statistics for the 2.5G SGSN's GPRS NS layer (link level).

Product

SGSN

Privilege

Inspector

Syntax

```
show gprsns statistics { msg-stats { consolidated nse nse_id | nse nse_id } | sns-msg-stats } | { grep grep_options | more }
```

msg-stats

Displays the transmit (Tx) and receive (Rx) message statistics (except for SNS messages) in the statistics output.

consolidated nse *nse_id*

nse_id: Enter an integer from 0 to 65535.

nse *nse_id*

Display statistics for a NSE specified as an integer from 0 to 65535.

sns-msg-stats

Display subnetwork service (SNS) sublayer message statistics.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

This command is used to display Frame Relay statistics configured for the NSE/NSVC with the commands documented in the *Network Service Entity - Peer NSEI Configuration Mode Commands* chapter.
Collected statistics are cleared (deleted) with the **clear gprsns statistics** described in the *Exec Mode Commands (A-C)* chapter.

Example

Use the following command to display the collected message statistics for NSEI *1422*:

```
show gprsns statistics msg-stats nse 1422
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gprsns status

Displays the status of the network service virtual circuits (NSVC) for the GPRS NS layer (link level).

Product

SGSN

Privilege

Inspector

Syntax

```
show gprsns status { nsvc-status-all nse nse_id | nsvc-status-consolidated nse nse_id |
nsvc-status-per-bvci bvci bvc_id nse nse_id } | { grep grep_options | more }
```

nsvc-status-all nse { all | nse*nse_id* **}**

Displays status information for all NSVCs included in the NSE specified as an integer from 0 to 65535.

nsvc-status-consolidated nse *nse_id*

nsvc-status-per-bvci bvci *bvc_id* **nse** *nse_id*

bvc_id is an integer from 0 to 65535.
nse_id is an integer from 0 to 65535.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

This command is used to display the status of the NSVC.

Example

Use the following command to display status of all NSVC for NSE 1422:

```
show gprsns status nsvc-status-all nse 1422
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gprs-service

Displays the statistics for GPRS services.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show gprs-service { all | name *gprs_srvc_name* **} [| { grep** *grep_options* **| more }]**

all

Displays information for all GPRS services configured with this context.

name *gprs_srvc_name*

Displays information for an existing GRPS service name specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For more information on the usage of **grep** and **more**, refer to the Regulating a Command's Output section of the Command Line Interface Reference.

Usage

This command is used to verify the configuration of one or all GPRS services for monitoring or troubleshooting purposes. The output is a concise listing of GPRS service parameter settings.
If this command is executed from within the local context with the all keyword, information for all GPRS services configured on the system will be displayed.

Example

The following command displays configuration information for all GPRS services configured in this context:

```
show gprs-service all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gprsssf

Displays statistics for various 3GPP Customised Applications for Mobile network Enhanced Logic (CAMEL) service GPRS Service Switching Function (gprsSSF) entities.

Product

SGSN

Privilege

Inspector

Syntax

show gprsssf { counters | statistics } [camel-service *srvc_name* **| gprs [2g-sgsn-app | 3g-sgsn-app] | gsmscf-address {** *address* **| all } | sms] [| { grep | more }]**

counters

Displays collected status counter information for CAMEL service entities.

statistics

Displays collected statistics for CAMEL service entities.

camel-service *srvc_name*

Filters the display of counters and statistics for an existing CAMEL service name in the SGSN configuration specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

gprs [2g-sgsn-app | 3g-sgsn-app]

Filters the counter/statistic output to display GPRS protocol information specific to either the 2.5G or 3G SGSN.

gsmscf-address { *address* **| all }**

The GSM service control function (gsmSCF) address is the ISDN address of the SCP where the CAMEL service resides. It is possible to display information for one or all of the configured CAMEL services. *address* is a standard ISDN E.164 address of 1 to 15 digits.

sms

Filters the display of counters and statistics for SMS protocol information.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Use this command to display CAMEL service status counter information and statistics collected since the last restart or clear command. If filters are not included with the command, then all statistics or counters are displayed for all CAMEL services in all contexts in which CAMEL services have been defined.
Collected statistics are cleared (deleted) with the **`clear gprsssf statistics`** command described in the chapter *Exec Mode Commands (A-C)*.

Example

Use the following command to display the status counter totals of the GPRS Dialogue parameters for a 3G SGSN:

```
show gprsssf counter gprs 3g-sgsn-app
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gs-service

Displays configuration information and statistics for Gs services configured on system.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show gs-service { all | name *svc_name* **} [| { grep** *grep_options* **| more }]**

all

Displays information for all Gs services configured with in the given context.

name *svc_name*

Displays information for an existing Gs service specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For more information on the usage of **grep** and **more**, refer to the Regulating a Command's Output section of the Command Line Interface Reference.

Usage

This command is used to verify the configuration of one or all Gs services for monitoring or troubleshooting purposes.
If this command is executed from within the local context with the all keyword, information for all Gs services configured on the system will be displayed.

Example

The following command displays configuration information for all Gs services configured on a system:

```
show gs-service all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gtpc

Displays GPRS Tunnelling Protocol-Control (GTPC) information for GTPv0, GTPv1-C, GTPv1-U with filtering options.

Product

GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show gtpc [**full** | **counters** | **summary**] { **all** | **apn** *apn_name* | **imsi***imsi_value* [**nsapi** *nsapi_value*] | **callid** *callid* | **sgsn-address** *ip_address* | **ggsn-service** *ggsn_name* | **user-address** *ip_address* | **username** *username* }

[full | counters | summary]

Specifies the level of information to be displayed. The following levels can be used:

- **full**: Indicates detailed information is to be displayed.
- **counters**: Indicates the output is to include the statistical counters.
- **summary**: Indicates only summary information is to be displayed.

{ all | apn *apn_name* **| imsi** *imsi_value* **[nsapi** *nsapi_value* **] | callid** *callid* **| sgsn-address** *ip_address* **| ggsn-service** *ggsn_name* **| user-address** *ip_address* **| username** *username* **}**

Specifies the filter criteria used when displaying GTP information. The following filters can be used:

- **all**: Specifies that all available information is to be displayed.
- **apn** *apn_name*: Specifies that GTP information for an APN specified as an alphanumeric string of 1 through 63 characters that is case sensitive.
- **imsi** *imsi_value* **[nsapi** *nsapi_value* **]**: Displays GTP information for an International Mobile Subscriber Identity (IMSI) specified as an integer from 1 through 15 characters. Optionally, the IMSI could be further filtered by specifying a particular PDP context using the Network Service Access Point Identifier (NSAPI) expressed as an integer from 5 through 15.
- **callid** *callid*: Displays GTP information for a call identification number specified as a 4-digit hexadecimal number.
- **sgsn-address** *ip_address*: Displays GTP information for an SGSN specified by its IP address in IPv4 dotted-decimal notation.
- **ggsn-service** *ggsn_name*: Displays GTP information for an existing GGSN service specified an alphanumeric string of 1 through 63 characters that is case sensitive.
- **user-address** *ip_address*: Displays GTP information for a user PDP context specified as an IP address in IPv4 dotted-decimal notation.
- **username** *username*: Displays GTP information for a username specified as an alphanumeric string of 1 through 127 characters (including wildcards '$' and '*') that is case sensitive.

Usage

This command displays statistics for every GTP message type based on the filter criteria. This information is useful for system monitoring or troubleshooting.

Example

The following command displays GTPC counters for a GGSN service named *ggsn1*:

```
show gtpc counters ggsn-service ggsn1
```

The following command displays GTPC full information:

```
show gtpc full
```

The following command displays GTPC summary information for a specific call identification number of *05f62f34*:

```
show gtpc summary callid 05f62f34
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gtpc statistics

Displays GTPv0, GTPv1-C, GTPv1-U statistics with filtering options.

Product

GGSN, MSEG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show gtpc statistics [[custom1 | custom2] [apn *apn_name* **| ggsn-service** *ggsn_service_name* **| mseg-service** *mseg_service_name* **| sgsn-address** *ipv4_address* **] [[verbose] format1] [| { grep** *grep_options* **| more }]**

custom1

Displays statistics of GTP-C messages for preservation mode and free of charge service.
This keyword is customer specific and license enabled. For more information, contact your Cisco sales representative.

custom2

Displays statistics for GTP-C messages related to overcharging protection on loss of radio coverage for a GGSN service.
This keyword is feature specific and license enabled. For more information, contact your Cisco sales representative.

apn *apn_name*

Displays GTP-C statistics for an existing APN specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

ggsn-service *ggsn_service_name*

Displays GTP-C statistics for an existing GGSN service specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

mseg-service *mseg_service_name*

Important: This keyword is not supported in this release. For more information please contact your Cisco account representative.

Displays GTP-C statistics for an existing Mobile Service Edge Gateway (MSEG) specified as an alphanumeric string of 1 through 63 characters that is case sensitive.

sgsn-address *ipv4_address*

Displays GTP statistics for an SGSN specified by its IP address in IPv4 dotted-decimal notation.

verbose

Displays detailed instead of concise statistics.

format1

Displays more detailed statistical breakouts.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

The information displayed by this command consists of session statistics such as the number of currently active sessions categorized by PDP context type, and statistics for every GTP message type. The statistics are cumulative.
If the verbose keyword is used, additional information will be displayed such as statistics for every type of error code.

Example

The following command displays verbose GTP statistics:

```
show gtpc statistics verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gtpp

Displays information on the GPRS Tunneling Protocol Prime (GTPP) for the selected charging gateway function (CGF) or GCDR storage server.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show gtpp [ accounting | counters { all | cgf-address | group } | group { all | name } |
statistics { cgf-address | group } | storage server { counters | group | local |
statistics | status | streaming} ] [ | { grep grep_options | more } ]
```

Usage

This command displays the GTPP related information for the selected CGF or the G-CDRs storage server. If this command is issued from within the local context, information for all GTPP accounting servers configured on the system is displayed regardless of context.

Example

The following command displays the GTPP counters for all the servers:

```
show gtpp counters all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gtpp accounting

Displays information on the GPRS Tunneling Protocol Prime (GTPP) accounting server configuration.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show gtpp accounting servers { group name group_name } [ | { grep grep_options | more } ]
```

Usage

This command is used to view the status of GTPP accounting servers configured within a context for monitoring or troubleshooting purposes.
If this command is issued from within the local context, information for all GTPP accounting servers configured on the system is displayed regardless of context.

Example

The following command displays the status of and information on configured GTPP accounting servers:

```
show gtpp accounting servers
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gtpp counters

Displays GTPP counters for configured charging gateway functions (CGFs) within the given context.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show gtpp counters { all{ gcdrs } | cgf-address cgf_address | group name group_name } [ |
{ grep grep_options | more } ]
```

all

Displays counters for all CGFs configured within the context.

cgf-address *cgf_address*

Displays counters for a CGF specified by its IP address in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

Counters for a single CGF can be viewed using the **cgf-address** keyword. Counters for all CGFs in the context can be viewed by entering the command with the **all** keyword.
If this command is issued from within the local context and no CGF-address is specified, the counters displayed will be cumulative for all CGFs configured on the system regardless of context.

Example

The following command displays counters for all CGF:

```
show gtpp counters all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gtpp group

Displays information pertaining to the configured GTPP storage server group.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show gtpp group [**name** *gtpp_group_name* | **all**] [| { **grep** *grep_options* | **more** }]

name *gtpp_group_name*

Displays information and CDR statistics for an existing GTPP server group name specified as an alphanumeric string of 1 through 64 characters.

all

Displays statistics for all configured GTPP storage server groups, including default group.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For more information on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display the CDR statistics on the basis of GTPP server groups. It shows the information for all or specific GTPP server group configured in the context from which this command is issued.

Example

The following command displays the status of the GTPP server group backup server configured in a context called *GTPP_Group1*:

```
show gtpp group name GTPP_Group1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gtpp statistics

Displays GTPP statistics for configured Charging Gateway Functions (CGFs) within the context.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show gtpp statistics [**cgf-address** *cgf_address* | **group name** *group_name*] [| { **grep** *grep_options* | **more** }]

cgf-address *cgf_address*

Displays statistics for a CGF specified by its IP address expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

group name *group_name*

Displays server statistics information of an existing GTPP server group name specified as an alphanumeric string of 1 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For more information on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Statistics for a single CGF can be viewed by specifying its IP address. Statistics for all CGFs in the context can be viewed by **not** specifying an IP address.
If this command is issued from within the local context, the statistics displayed will be cumulative for all CGFs configured on the system regardless of context.

Example

The following command displays statistics for a CGF with an IP address of *192.168.1.14*:

```
show gtpp statistics cgf-address 192.168.1.14
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gtpp storage-server

Displays information pertaining to the configured GTPP storage server (GSS).

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show gtpp storage-server [**counters** { **all** | **group name** *group_name* } | **group name** *group_name* | **local file** { **counters** { **all** | **group name** *group_name* } | **statistics** [**group name** *group_name*] } | **status** { **group name** *group_name* | **verbose** } | **streaming file** { **counters** { **all** | **group name** *group_name* } | **statistics** [**group name** *group_name*] }] [| { **grep** *grep_options* | **more** }]

counters

Displays counters for the external GTPP storage server.

group name *group_name*

Displays GTPP backup server information for the group name specified as an alphanumeric string of 1 through 64 characters.

local file

Displays statistics and counters for the local storage-server. This is the hard disk if hard disk support has been enabled with the **gtpp storage-server mode** command in the GTPP Group Configuration Mode.

statistics

Displays statistics for the GTPP storage server.

status [verbose]

Displays status of the GTPP storage server. **verbose** enables the detailed view.

streaming

Displays the status of Charging Data Record (CDR) backup on HDD while streaming mode is enabled.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Executing this command with no keywords displays status information for the GTPP backup server configured in the context from which this command is issued.

Example

The following command displays the GTPP CDR file statistics stored on the local SMC hard disk.

```
show gtpp storage-server local file counters all
```

The following command displays the status of the GTPP backup server configured in a context called ggsn1:

```
show gtpp storage-server
```

The following command displays statistics for the GTPP backup server configured in a context called ggsn1:

```
show gtpp storage-server statistics
```

The following command displays GCDR storage server counters:

```
show gtpp storage-server counters
```

The following command displays GCDR storage server status:

```
show gtpp storage-server status
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show gtpu statistics

Displays GPRS Tunneling Protocol user plane (GTP-U) statistics and counters on this system.

Product

P-GW, S-GW, MSEG

Privilege

Inspector

Syntax

show gtpu statistics [[gtpumgr-instance *instance_number* **] [gtpu-service** *gtpu_service_name* **| mseg-service** *mseg_service_name* **| peer-address** *ipv4/ipv6_address* **]] [| { grep** *grep_options* **| more }]**

gtpumgr-instance *instance_number*

Displays information for an existing GTP-U manager instance specified as an integer from 1 through 4294967295.

gtpu-service *gtpu_service_name*

Displays GTP-U statistics for an existing GTP-U service specified s an alphanumeric string of 1 through 63 characters.

mseg-service *mseg_service_name*

Important: This keyword is not supported in this release. For more information please contact your Cisco account representative.

Displays GTP-U statistics for an existing MSEG service specified as an alphanumeric string of 1 through 63 characters.

peer-address *ipv4/ipv6_address*

Displays GTP-U statistics and counters for an existing peer IP address specified in IPv4 dotted-decimal or IPv6 colon-separated notation.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference Guide*.

Usage

Use this command to view statistics and counters for GTP-U traffic on this system.

Example

The following command displays statistics for the GTP-U service named *egtp1*:

```
show egtpu statistics gtpu-service egtp1
```

show gtpu-service

Displays configuration information for GPRS Tunneling Protocol user plane (GTP-U) services on this system.

Product

P-GW, S-GW

Privilege

Inspector

Syntax

show gtpu-service { **all** | **name** *service_name* } [| { **grep** *grep_options* | **more** }]

all

Displays configuration information for all GTP-U services configured on this system.

name *service_name*

Displays configuration information for an existing GTP-U service specified an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to a specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference Guide*.

Usage

Use this command to view configuration information for GTP-U services on this system.

Example

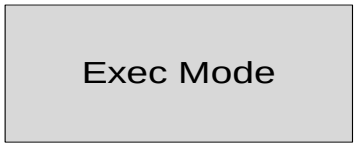
The following command displays service statistics for the GTP-U service named *egtp1*:

```
show egtp-service name egtp1
```

Chapter 116
Exec Mode Show Commands (H-L)

This section includes the commands **`show ha-service`** through **`show lte-policy`**.

The Exec Mode is the initial entry point into the command line interface system. Exec mode **show** commands are useful in troubleshooting and basic system monitoring.



show ha-service

Displays information on configured home agent services.

Product

HA

Privilege

Security Administrator Operator, Inspector

Syntax

show ha-service { all | name *ha_name* **} [| { grep** *grep_options* **| more }]**

---

all | name *ha_name*

all: Displays information on all Home Agent services is to be displayed.
name *ha_name*: Displays information for an existing HA service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Display home agent service configuration information.

Example

The following commands displays information on the HA service *sampleService* and all services, respectively.

```
show ha-service name sampleService

show ha-service all
```

show hardware

Displays information on the system hardware.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show hardware { card [*card_num* **] | inventory | version [board | diags | fans] } [| { grep** *grep_options* **| more }]**

card [*card_num* **]**

Provide the hardware information for all cards or the card specified by *card_num*. *card_num* must be a value in the range 1 through 48 and must refer to an installed card.

inventory

Display the hardware information for all slots in tabular format.

version [board | diags | fans]

Display the CPU information for all application cards and fan controller version for the upper and lower fan trays.
board: Only include the CPLD and FPGA version information.
diags: Only include the CFE diagnostics version information.
fans: Show the fan controller versions for the upper and lower fan trays.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Show the hardware information to verify part lists and hardware component versions with reserve stock

Example

The following displays the hardware information for a card installed in slot *1*.

```
show hardware card 1
```

The following command displays the hardware inventory for the entire chassis.

```
show hardware inventory
```

The following command results in the display of the CPU version for all application cards displaying only the CPLD and FPGA information.

```
show hardware version board
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show hd raid

Shows the output of the Redundant Array of Independent Disks (RAID) established on the SMCs.

Product

All

Privilege

Security Administrator, Administrator, Administrator, Operator

Syntax

```
show hd raid [ verbose ]
```

Example

```
show hd raid verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show hd-storage-policy

Displays Array Configuration Replicator (ACR) counter and statistic information.

Product

HSGW, P-GW, S-GW

Privilege

Inspector

Syntax

show hd-storage-policy { all | counters [all] [name *name* **] [verbose] | name** *name* **| statistics [all] [name** *name* **] [verbose] }**

all

Displays ACR information for all HD storage policies configured on the system.

counters [all] [name *name* **] [verbose]**

all: Displays ACR counter information for all HD storage policies configured on the system.
name *name*: Displays ACR counter information for an existing HD storage policy specified as an alphanumeric string of 0 through 63 characters.

statistics [all] [name *name* **] [verbose]**

all: Displays ACR statistical information for all HD storage policies configured on the system.
name *name*: Displays ACR statistical information for an existing HD storage policy specified as an alphanumeric string of 0 through 63 characters.

verbose

Displays HD storage statistics based on instance.

Usage

Use this command to display ACR counter and statistic information.

Example

The following command displays ACR statistic information for an HD storage policy named *pgwsgw*:

```
show hd-storage-policy statistics name pgwsgw
```

show hnbgw access-control-db

Displays the white list of IMSI records in the Access Control database residing on Home-NodeB Gateway (HNB-GW) service instances that control HNB and UE access to HNB-GW sessions.

Product

HNB-GW

Privilege

Inspector

Syntax

show hnbgw access-control-db { hnbgw-service*hnbgw_svc_name* **| imsi** *imsi_value***}**

hnbgw-service *hnbgw_svc_name*

Displays Access Control database records for an existing HNB-GW service specified as an alphanumeric string of 1 through 63 characters.

imsi *imsi_value*

Specifies the International Mobile Subscriber Identification (IMSI) number which is found on the Access Control database for he HNB-GW service.
imsi_value is an integer consisting of the 3-digit MCC (Mobile Country Code), the 2- or 3-digit MNC (Mobile Network Code) followed by the MSIN (Mobile Subscriber Identification Number). The total IMSI value must not exceed 15 digits.

Usage

This command displays the white list IMSI records in an Access Control database residing on Home-NodeB Gateway (HNB-GW) service instances. The white list controls HNB and UE access to HNB-GW sessions. Access Control database records can be filtered by HNB-GW service or IMSI value.

Example

The following command displays the information for registered IMSIs and their status in the HNB-GW database named *hnbgw1*:

```
show hnbgw access-control-db hnbgw-service hnbgw1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show hnbgw counters

Displays the session counter information for Home-NodeB Gateway (HNB-GW) services connected on this system.

Product

HNB-GW

Privilege

Inspector

Syntax

show hnbgw counters [hnbgw-service *hnbgw_svc_name* **| hnbid** *hnb_identifier* **] [| { grep** *grep_options* **| more }]**

hnbgw-service *hnbgw_svc_name*

Filters the counter display based on an existing HNB-GW service name specified as an alphanumeric string of 1 through 63 characters.

hnbid *hnb_identifier*

Filters the counter display based on a Home-NodeB identifier specified as an alphanumeric string of 1 through 255 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *Command Line Interface Overview* chapter.

Usage

Use this command to view the session counter information for HNB-GW services configured and HNBs connected on this system.

Example

The following command displays the counters for the HNB-GW service named *hnbgw1*:

```
show hnbgw counter hnbgw-service hnbgw1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show hnbgw sessions

Displays the active/dormant session information about registered HNB(s) on Home-NodeB Gateway (HNB-GW) service instances configured and running on this system based on different filter criteria.

Product

HNB-GW

Privilege

Inspector

Syntax

show hnbgw sessions [**full** | **summary**] [**all**] [**address** *hnb_ip_address* | **cell-id** *cell_id* | **hnb-access-mode** [**open** | **closed**] | **hnb-local-id** *hnb_id* | **hnbgw-service** *hnbgw_svc_name* | **hnbid** *hnb_glbl_id* | **mcc** *mcc* | **mnc** *mnc* [**lac** *lac* | **rac** *rac* | **rnc** *rnc*]] [| {**grep** *grep_options* | **more** }]

full

Displays the full information for a specific registered HNB session(s) on an HNB-GW service instance running on the system. The display can be filtered based on given filtering criteria.

summary

Displays summarized information for a specific registered HNB session(s) on an HNB-GW service instance running on the system. The display can be filtered based on given filtering criteria.

all

Displays summarized information for all registered HNB sessions on an HNB-GW service instance running on the system. The display can be filtered based on given filtering criteria.

address *hnb_ip_address*

Filters the display of full or summarized session statistics to show only HNB session(s) based on the registered HNB IP address expressed in IPv4 dotted-decimal notation.

cell-id *cell_id*

Filters the display of full or summarized session statistics to show only HNB session(s) based on the registered Femto cell ID where the user/subscriber is geographically located. and must be an integer from 0 through 268435455.*cell_id* is an integer from 0 through 268435455.

hnb-access-mode [open | closed]

Filters the display of full or summarized session statistics to show only HNB session(s) based on the HNB access mode in an HNB-GW service instance.

- **open** filters the session statistics for open HNBs connected with HNB-GW service instance in Open Access mode.
- **closed** filters the session statistics for closed HNBs connected with HNB-GW service instance in Closed Access mode.

hnb-local-id *hnb_id*

Filters the display of full or summarized session statistics to show only HNB session(s) based on the registered local ID of HNB specified as an integer from 1 through 25.

hnbgw-service *hnbgw_svc_name*

Filters the display of session statistics to show only registered HNB session(s) based on an existing HNB-GW service name specified as an alphanumeric string of 1 through 63 characters.

hnbid *hnb_glbl_id*

Displays summarized or full information of HNB session(s) based on the registered global ID of HNB specified as an integer between 1 through 255.

mcc *mcc*

Displays summary information of HNB session(s) based on the registered Mobile Country Code (MCC) identification number of the UE specified as an integer between 101 through 999.

mnc *mnc*

Displays summarized or full information of HNB session(s) based on the registered Mobile Network Code (MCC) identification number of the UE specified as a 2- or 3-digit integer between 00 through 999.

lac *lac*

Displays summarized or full information for HNB session(s) based on the registered Location Area Code (LAC) identification number of the UE specified as an integer between 1 through 65535.

rac *rac*

Displays summarized or full information for HNB session(s) based on the registered Radio Access Code (RAC) identification number of the UE specified as an integer between 1 through 255.

rnc *rnc*

Displays summarized or full information for HNB session(s) based on the registered Radio Network Code (RAC) identification number of the HNB specified as an integer between 1 through 65535.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *Command Line Interface Overview* chapter.

Usage

Use this command to view the session statistics of all or specific registered HNB session(s) or in selected part of user session for HNB-GW services configured and running on this system.

Example

The following command displays summarized session statistics for all registered HNBs on the HNB-GW service named *hnbgw1*:

```
show hnbgw sessions summary hnbgw-service hnbgw1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show hnbgw statistics hnbgw-service

Displays the session statistics for Home-NodeB Gateway (HNB-GW) services configured and running on this system.

Product

HNB-GW

Privilege

Inspector

Syntax

```
show hnbgw statistics hnbgw-service hnbgw_svc_name [ hnbap-only | ranap-only | rua-only |
sccp-only | sctp-only ] [ verbose] [ | { grep grep_options | more } ]
```

hnbgw-service *hnbgw_svc_name*

Filters the display of session statistics for an existing HNB-GW service name specified as an alphanumeric string of 1 through 63 characters.

hnbap-only

Filters the display of session statistics to show only Home NodeB Application Part (HNBAP) traffic for the selected HNB-GW service which is configured and running on this system.

ranap-only

Flitters the display of session statistics t to show only Radio Access Network Application Protocol (RANAP) traffic for the selected HNB-GW service which is configured and running on this system.

rua-only

Filters the display of session statistics to show only RANAP User Adaptation (RUA) traffic for the selected HNB-GW service which is configured and running on this system.

sccp-only

Filters the display of session statistics to show only Signaling Connection Control Part (SCCP) traffic for the selected HNB-GW service which is configured and running on this system.

sctp-only

Filters the display of session statistics to show only Stream Control Transmission Protocol (SCTP) traffic for selected HNB-GW service which is configured and running on this system.

verbose

Displays detailed statistics for all sessions on HNB-GW services or for a selected filtered and named HNB-GW service which is configured and running on this system.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *Command Line Interface Overview* chapter.

Usage

Use this command to view the session statistics for overall session or in selected part of user session for HNB-GW services configured and running on this system.

Example

The following command displays session statistics for the HNBAP part of session details for the HNB-GW service named *hnbgw1*:

```
show hnbgw statistics hnbgw-service hnbgw1 hnbap-only
```

The following command displays session statistics for the RANAP part of session with maximum details for the HNB-GW service named *hnbgw1*:

```
show hnbgw statistics hnbgw-service hnbgw1 ranap-only verbose
```

show hnbgw statistics hnbid

Displays the session statistics for Home-NodeB (HNB) connected to an HNB-GW service on this system.

Product

HNB-GW

Privilege

Inspector

Syntax

```
show hnbgw statistics hnbid hnb_identifier [ hnbap-only | ranap-only | rua -only] [
verbose] [ | { grep grep_options | more } ]
```

hnbid *hnb_identifier*

Filters the display of session statistics based on an existing Home-NodeB identifier specified as an alphanumeric string of 1 through 255 characters.

hnbap-only

Filters the display of session statistics display to show only Home NodeB Application Part (HNBAP) traffic for the selected HNB which is connected to this system through HNB-GW service.

ranap-only

Filters the display of session statistics display to show only Radio Access Network Application Protocol (RANAP) traffic for the selected HNB which is connected to this system through HNB-GW service.

rua-only

Filters the display of session statistics display to show only RANAP User Adaptation (RUA) traffic for the selected HNB which is connected to this system through HNB-GW service.

verbose

Displays detailed statistics for all HNB sessions or for the selected filter and HNB which is connected to this system through HNB-GW service.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *Command Line Interface Overview* chapter.

Usage

Use this command to view the session statistics for overall session or in selected part of user session for selected HNB which is connected to this system through HNB-GW service.

Example

The following command displays session statistics for the HNBAP part of session details for the HNB identified as *hnb112234* on this system:

show hnbgw statistics hnbid hnb112234 hnbap-only

The following command displays detailed session statistics for the RANAP part of session details for the HNB identified as *hnb112234* on this system:

show hnbgw statistics hnbid hnb112234 ranap-only verbose

show hnbgw-service

Displays the configuration details for configured HNB-GW service(s) on this system.

Product

HNB-GW

Privilege

Inspector

Syntax

```
show hnbgw-service { all | hnbgw-service hnbgw_svc_name }
```

all

Displays configuration and other default parameters for all HNB-GW service configured on this system.

hnbgw-service *hnbgw_svc_name*

Displays configuration and default parameters for an existing HNB-GW service name specified as an alphanumeric string of 1 through 63 characters.

Usage

Use this command to view the configuration and service parameters set for all or any specific HNB-GW service(s) on this system.

Example

The following command displays configuration parameters for all HNB-GW services configured on this system:

```
show hnbgw-service all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show hsgw-service

Displays information for HRPD Serving Gateway (HSGW) services on this system.

Product

HSGW

Privilege

Inspector

Syntax

show hsgw-service { all | name *service_name* **| statistics { all | name** *service _name* **} } [pcf-status [address** *IPv4_address* **| filter { all | icmp-monitored | no-calls | summary | up }] [| { grep** *grep_options* **| more }]**

---

all

Displays configuration information for all HSGW services configured on this system.

---

name *service_name*

Displays configuration information for an existing HSGW service specified as an alphanumeric string of 1 through 63 characters.

---

statistics

Displays node-level statistics for the HSGW.

---

pcf-status

Displays information about status of Packet Control Functions (PCFs) being monitored.

---

address *IPv4_address*

Displays status information for the specified PCF.
IPv4_address must be specified using IPv4 dotted-decimal notation.

---

filter { all | icmp-monitored | no-calls | summary | up }

Filters the PCF status information. Must be followed by the filter to be applied.
all: Shows all the PCFs.
icmp-monitored: Shows only PCFs which are ICMP monitored.
no-calls: Shows only PCFs which has no active sessions.
summary: Shows only a summary of the status of the PCFs.
up: Shows only PCFs which are alive.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the Regulating a Command's Output section of Chapter 1 of the Command Line Interface Reference Guide.

Usage

Use this command to view configuration information for HSGW services on this system.

Example

The following command displays service statistics for the HSGW service named *hsgw1*:

```
show hsgw-service name hsgw1
```

show hss-peer-service

Displays service, session, and statistics information for Home Subscriber Server (HSS) peer services configured on this system.

Product

MME

Privilege

Inspector

Syntax

show hss-peer-service { service { all | name *name* **} | session { all | callid** *id* **| full | mdn** *mdn* **| nai** *nai* **| summary } | statistics { all | service** *name* **| summary } } [| { grep** *grep_options* **| more }]**

service { all | name *name* **}**

Displays HSS peer service statistics for HSS peer services configured on this system.
all: Displays HSS peer service statistics for all configured HSS peer services on this system.
name *name*: Displays HSS peer service statistics for an existing HSS peer service specified as an alphanumeric string of 1 through 63 characters.

---

session { all | callid *id* **| full | mdn** *mdn* **| nai** *nai* **| summary }**

Displays HSS peer service statistics for sessions on this system.
all: Displays HSS peer service statistics for all sessions on this system.
This keyword is also used to further filter the **full** and **summary** options.
callid *id*: Displays summarized or detailed statistics of HSS peer service sessions running and filtered on the basis of the call identifier specified as an 8-digit hexadecimal number.
This keyword is also used to further filter the **full** and **summary** options.
mdn *mdn*: Displays summarized or detailed statistics of MME sessions running and filtered on the basis of an existing Mobile Directory Number (MDN) expressed as an alphanumeric string of 1 through 100 characters.
This keyword is also used to further filter the **full** and **summary** options.
nai *nai*: Displays summarized or detailed statistics of MME-HSS sessions running and filtered on the basis of an existing Network Access Identifier (NAI) expressed as an alphanumeric string of 1 through 128 characters.
This keyword is also used to further filter the **full** and **summary** options.
summary: Displays a summarized output of session information. This keyword can be further filtered by adding the following options:

- **full**
- **callid** *id*
- **mdn** *mdn*
- **nai** *nai*

---

statistics { all | service *name* **| summary }**

Displays statistics for HSS peer services configured on this system.
all: Displays statistics for all HSS peer services configured on this system.

service *name*: Displays statistics for a an existing HSS peer service expressed as an alphanumeric string of 1 through 63 characters.
summary: Displays summarized statistics for all HSS peer services configured on this system.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *CLI Overview* chapter of the *Command Line Interface Reference*.

Usage

Use this command to display service, session, and statistics information for HSS peer services configured on this system.

Example

The following command displays HSS peer service information and statistics for a session with a call ID of *08f11fa4*:

```
show hss-peer-service sessions full callid 08f11fa4
```

show imei-profile

Displays information for configured International Mobile Equipment Identity (IMEI) profiles.

Product

SGSN

Privilege

Inspector

Syntax

show imei-profile { all | full { all | name *imei_name* **} | name** *imei_name* **} [| { grep** *grep_options* **| more }]**

---

all

Lists all IMEI profiles configured on the system.

---

full { all | name *apn_name* **}**

full: Instructs the system to display all information in the IMEI profile(s).
all: Displays a full set of information for all IMEI profiles configured on the system.
name *imei_name*: Displays a full set of information for a specific IMEI profile.
apn_name: Must be an existing IMEI profile expressed as an alphanumeric string of 1 through 64 characters.

---

name *imei_name*

Displays information for a specific IMEI profile expressed as an alphanumeric string of 1 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for IMEI profiles configured on the system. APN profiles are configured through the global configuration mode and in the IMEI profile configuration mode. For more information regarding IMEI profile commands, refer to the *IMEI Profile Configuration Mode Commands* chapter.

Example

The following command displays all available information for an IMEI profile named *imeiprof1*:

```
show imei-profile full name imeiprof1
```

show ims-authorization policy-control

Displays information and statistics specific to the policy control in IP Multimedia Subsystem (IMS) authorization service.

Product

SCM, GGSN, IMS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show ims-authorization policy-control statistics [ service ims_auth_svc_name | server {
ip-address ip_address [ port port_value ] | name server_name } ] [ | { grep grep_options
| more } ]
```

statistics

Displays the total collected statistics of all policy control parameters of IMS authorization service sessions since the last system **restart** or **clear** command.

service *ims_auth_svc_name*

Displays the total collected statistics of all IMS authorization sessions processed by a specific IMS authorization service since the last system restart or clear command. *ims_auth_svc_name* must be an existing IMS authorization service name, expressed as an alphanumeric string of 1 through 64 characters.

server { ip-address *ip_address* **[port** *port_value* **] | name** *server_name* **}**

Displays the server-level message statistics and the server IP address.
Specify the PCRF server name (1 through 64 alphanumeric characters), or server IP address in IPv4 dotted-decimal or IPv6 colon-separated notation.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information and statistics about policy control configuration in existing IMS authorization services.

Example

The following command displays the existing IMS authorization service name *ims_auth_gx1* on the system:

```
show ims-authorization policy-control statistics service ims_auth_gx1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ims-authorization policy-gate

Displays information of installed Policy Gates for specific subscriber in an IP Multimedia Subsystem (IMS) authorization (IMSA) service.

Product

SCM, GGSN, IMS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ims-authorization policy-gate { { status [summary | full] [{ imsi *imsi_value* **[nsapi** *nsapi_value* **] } | callid** *call_id* **| { ims-auth-service** *ims_auth_svc* **} [rulename** *rule_name* **] } | { counters [all | { imsi** *imsi_value* **[nsapi** *nsapi_value* **] } | { rulename** *rule_name***} | { callid** *call_id* **}] } [| { grep** *grep_options* **| more }]]**

status [summary | full]

Displays the status of the installed policy gates and their flow definitions along with the run-time status in an IMS authorization service based on the specified criteria.
summary: Limits the display to a summary on the status of the installed policy gates and their flow definitions along with their run-time status in an IMS authorization service based on the specified criteria.
full: Displays the full information on status of the installed policy gates and their flow definitions along with their run-time status in an IMS authorization service based on the specified criteria.

counters all

Displays the counters/statistics of the installed policy gates and their flow definitions along with their run-time status in an IMS authorization service based on the specified criteria.
all displays all counters of the installed gates and their flow definitions along with their run-time status in an IMS authorization service based on the specified criteria.

imsi *imsi_value* **[nsapi** *nsapi_value* **]**

Displays all of the counters/status of the installed policy gates and their flow definitions along with the run-time status in an IMS authorization service based on the International Mobile Subscriber Identity (IMSI).
nsapi *nsapi_value* specifies the Network Service Access Point Identifier (NSAPI) and limits the display to a single PDP context of the subscriber.

callid *call_id*

Displays all of the counters/status of the installed policy gates and their flow definitions along with their run-time status in an IMS authorization service based on the call identifier.

ims-auth-service *ims_auth_svc*

Displays the status of the installed policy gates and their flow definitions along with their run-time status in the named IMS authorization service.

rulename *rule_name*

Displays all of the counters/status of the installed policy gates and their flow definitions along with their run-time status in an IMS authorization service based on the named dynamic charging rule.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Please refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference* for details on the usage of **grep** and **more**.

Usage

Use this command to display information/statistics/counters about all of the installed policy gates and their flow definitions along with the run-time status with specified criteria and filters in existing IMS authorization services.

Example

The following command displays the full status of the installed policy gates in an existing IMS authorization service on the system:

```
show ims-authorization policy-gate status full
```

The following command displays the all counters of the installed policy gates in an existing IMS authorization service on the system:

```
show ims-authorization policy-gate counters all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ims-authorization servers

Displays information and statistics specific to the authorization servers used for IP Multimedia Subsystem (IMS) authorization (IMSA) service.

Product

SCM, GGSN, IMS

Privilege

Security Administrator, Administrator

Syntax

show ims-authorization servers [ims-auth-service *ims_auth_svc_name* **[| { grep** *grep_options* **| more }]]**

server [ims-auth-service *ims_auth_svc_name* **]**

Displays the information and statistics for all authorization servers configured within an IMS authorization service in a system.
ims-auth-service *ims_auth_svc_name*: Displays the configured authorization servers for IMS authorization within the named IMS authorization service.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Please refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference* for details on the usage of **grep** and **more**.

Usage

Use this command to display information and statistics about IMS authorization servers configured on a system or IMS authorization service.

Example

The following command displays the information and statistics of the authorization servers in the IMS authorization service named in *ims_auth_gx1*:

```
show ims-authorization servers ims-auth-service ims_auth_gx1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ims-authorization service

Displays information, configuration, and statistics of all/specific IP Multimedia Subsystem (IMS) authorization (IMSA) service.

Product

SCM, GGSN, IMS

Privilege

Security Administrator, Administrator

Syntax

show ims-authorization service { { all [verbose] | name *ims_auth_svc_name* **| summary] } | { statistics [all | name** *ims_auth_svc_name* **] [verbose] } [| { grep** *grep_options* **| more }] }**

---

all [verbose]

Displays information and configuration for all configured IMS authorization services with a single line of information for each IMS authorization service.
verbose: Displays all information and configuration data for all IMS authorization services configured on system.

---

name *ims_auth_svc_name* **]**

Displays the information, statistics, and configuration data for the named IMS authorization service.

---

summary

Displays summarized information and configuration data for all IMS authorization services configured in a system.

---

statistics [all | name *ims_auth_svc_name* **] [verbose]**

Displays the IMS Authorization service statistics including following information:

- Initial authorization procedures
- Re-authorization procedures initiated by us
- Re-authorization procedures initiated by servers
- Various failure statistics

If no criteria are specified, only summarized statistics for all IMS Authorization services are displayed

- **all**: displays individual statistics for every IMS authorization service configured on system.
- name *ims_auth_svc_name*: Displays the statistics for the IMS authorization service named in *ims_auth_svc_name*
- verbose: displays detailed statistics for a configured IMS authorization service.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Please refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference* for details on the usage of **grep** and **more**.

Usage

Use this command to display the status, counters and configuration. for an IMS Authorization service. The status includes the state of a server table switchover. The Statistics option displays information about various processes.

Example

The following command displays the information and configuration data of the IMS authorization service named in *ims_auth_gx1*:

```
show ims-authorization service name ims_auth_gx1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ims-authorization sessions

Displays information, configuration, and statistics of sessions active in an IP Multimedia Subsystem (IMS) authorization (IMSA) service.

Product

SCM, GGSN, IMS

Privilege

Security Administrator, Administrator

Syntax

show ims-authorization session [**full** | **summary** | **ggsn-only**] | [**all** | [**ims-auth-service** *ims_auth_svc_name* | **imsi** *imsi_value* [**nsapi** *nsapi_value*] | **apn** *apn_name* | **ip-address** *ip_address* | **callid** *call_id*] [| { **grep** *grep_options* | **more** }]]

full

Displays complete information and configuration data for all sessions in IMS authorization services configured in a system.

summary

Displays summarized information and configuration data for all sessions in IMS authorization services configured in a system.

ggsn-only

Displays GGSN-specific information in addition to detailed information about the session.

all

Displays information and configuration for all sessions running in IMS authorization services with a single line of information for each IMS authorization session.

ims-auth-service *ims_auth_svc_name* **]**

Displays the information, statistics, and configuration data for sessions in the named IMS authorization service.

imsi *imsi_value* **[nsapi** *nsapi_value* **]**

Displays all of the counters/status of the running services in an IMS authorization service based on the specified International Mobile Subscriber Identity (IMSI) and Network Service Access Point Identifier (NSAPI). The display is limited to a single PDP context of the subscriber.

apn *apn_name*

Displays all of the counters/status for the running services in an IMS authorization service based on the specified Access Point Name (APN).

ip-address *ip_address*

Displays all of the counters/status for the running services in IMS authorization service based on the specified host IP address.

callid *call_id*

Displays all of the counters/status for the running services in IMS authorization service based on the named call identifier.

summary

Displays summarized information and configuration data for all IMS authorization services configured in a system.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
Please refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference* for details on the usage of **grep** and **more**.

Usage

Use this command to display the sessions running under IMS Authorization service on a system with different filter criteria.

Example

The following command displays the information and statistical data for a session in an IMS authorization service:

```
show ims-authorization sessions full
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ip

Displays information for the IP-based interface access group and access control list (ACL) along with the address resolution protocol (ARP) information for the current context.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ip { access-group [*statistics*] **| access-list [** *list_name* **] | arp [** *arp_ip_address* **] | [summary] | statistics]] | localhosts [** *host_name* **] | prefix-list [detail [** *list_name* **] | name** *list_name* **| summary [** *list_name* **]] | rip | route [** *route_ip_address* **[** *route_gw_address* **]] | static-route** *sroute_ip_address* **[** *sroute_gw_address* **] | vrf** *vrf-name***} [| { grep** *grep_options* **| more }]**

access-group [*statistics* **]**

Displays all configured access groups in the current context along with their priority values.
statistics: Displays all configured access groups along with packet and byte counters for each ACL rule hit for the current context. It also shows the priority values.

access-list [*list_name* **]**

Indicates the output is to display the information for all ACLs or the named ACL.

arp [*arp_ip_address* **]**

Displays the ARP table or the ARP information associated with the IP address specified using IPv4 dotted-decimal or IPv6 colon-separated notation.

Important: When it restarts, the VPN Manager removes all interfaces from the kernel; the kernel then removes all ARP entries. When this happens, the NPU still holds all of the ARP entries so that there is no traffic disruption. From a user point of view, **show ip arp** is broken since this command gathers information from the kernel and not the NPU.

localhosts [*host_name* **]**

Displays all the local host information or only for the named host.

prefix-list [detail [*list_name* **] | name** *list_name* **| summary [** *list_name* **]]**

Displays information on configured IP prefix lists. With no keyword supplied, a list of all prefix lists and their entries is displayed.
detail [*list_name* **]**: Lists detailed information for all prefix lists and their entries. If a list name is specified only the details for the specified prefix list are displayed. *list_name* is an alphanumeric string of 1 through 79 characters.
name *list_nam*: Lists the entries for an existing prefix list specified as an alphanumeric string of 1 through 79 characters.

summary [*list_name* **]**: Lists summary information for all prefix lists and their entries. If a list name is specified, only the summary for the specified prefix list are displayed. *list_name* is an alphanumeric string of 1 through 79 characters.

---

rip

Displays general Routing Information Protocol (RIP) routing process information. (RIP is not supported at this time.)

---

route [*route_ip_address* **[** *route_gw_address* **]]**

displays the route information to the specified IP address. The route gateway address may be specified as needed to identify the route. The IP addresses are specified using tIPv4 dotted-decimal or IPv6 colon-separated notation.

---

static-route *sroute_ip_address* **[** *sroute_gw_address* **]**

Displays the static route information for the specified IP address. The static route gateway address may also be specified to identify the route. the IP addresses are specified using IPv4 dotted-decimal or IPv6 colon-separated notation.

---

vrf *vrf_name*

Displays Virtual Routing and Forwarding (VRF) information for the named VRF.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Show the IP information to verify and/or troubleshooting communication difficulties between to a remote host/node.

Example

The following command displays the ACL for the list named *sampleACL*.

```
show ip access-list sampleACL
```

The following command will output the static route information to remote host *10.2.3.4*.

```
show ip static-route 10.2.3.4
```

show ip as-path-access-list

Displays the contents of a Border Gateway Protocol (BGP) router Autonomous System (AS) path access list in the current context.

Product

HA

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ip as-path-access-list *list_name*

list_name

Specifies the name of an existing AS path access list configured in the current context as an alphanumeric string of 1 through 79 characters.

Usage

Use this command to display the configured entries for the specified BGP router AS path access list in the current context.

Example

The following command displays the contents of an AS path access list named *ASlist1*:

```
show ip as-path-access-list ASlist1
```

show ip bgp

Displays Border Gateway Protocol (BGP) information for the current context.

Product

HA

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ip bgp [*ip_address/mask* **| debugging | filter-list** *list_name* **| neighbors [** *ip_adrress* **] | route-map** *map_name* **| vpnv4 { all [network | neighbors | summary] | vrf vrf-name [network] | route-distinguisher [network | neighbors | summary] } [| { grep grep_options | more }]**

ip_address/mask

Specifies the IP address and netmask bits for the network for which information should be displayed. The IP address and mask is the number of subnet bits, representing a subnet mask in CIDR notation. These must be entered in the IPv4 dotted-decimal or IPv6 colon-separated CIDR notation.

debugging

Displays debug flags that are enabled.

filter-list *list_name*

Displays routes that match the specified filter list.

neighbors [*ip_address***]**

Displays information for all neighbors or a neighbor specified as an IP address in IPv4 dotted-decimal or IPv6 colon-separated notation.

route-map *map_name*

Displays routes that match the specified route-map.

vpnv4 { all [network | neighbors | summary] | vrf *vrf-name* **[network] | route-distinguisher [network | neighbors | summary] }**

Displays all VPNv4 routing data, routing data for a VRF, or a route-distinguisher.

- **all**: Displays all VPN routing information. If this is specified, the information displayed is gathered from all the VRF's known to BGP and displayed. It could contain the list of neighbors, the list of networks, or a particular network
- **network**: Displays the network for which information in the BGP routing table.
- **neighbors**: Displays neighbor information for the all the VRFs including the default VRF or for the VRF with a matching RD value.
- **summary**: Displays summary information of neighbors for all the VRFs including the default VRF or for the VRF with a matching RD value.

- **vrf** *vrf name*: Displays information only gathered from the named VRF. If there is no such VRF, an error is reported.
- **network**: Displays the network for which information in the BGP routing table.
- **route-distinguisher**: If specified along with the RD value, the information displayed is gathered from the corresponding VRF whose RD value is the same as the specified value. If there is no VRF associated with such an RD, an error is reported.
- **network**: Displays the network for which information in the BGP routing table.
- **neighbors**: Displays neighbor information for the all the VRFs including the default vrf VRF for the VRF with a matching RD value.
- **summary**: shows summary information of neighbors for all the vrfs including the default vrf or for the VRF with a matching RD value.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command display to BGP information for the current context.

Example

The following command displays information for all BGP neighbors:

```
show ip bgp neighbors
```

show ip interface

Displays statistical and configuration information for the IP-based interfaces, including a Virtual Routing and Forwarding (VRF) table for a specific context.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ip interface [vrf *vrf-name* **] [name** *intfc_name* **[statistics] [tunnel [gre-keepalive]] [summary] [| { grep** *grep_options* **| more }]**

vrf *vrf_name*

Displays Virtual Routing and Forwarding (VRF) routing information for an existing VRF specified as an alphanumeric string of 1 through 63 characters.

name *intfc_name*

Displays information for an existing interface specified as an alphanumeric string of 1 through 79 characters. If no interface name is specified, the information for all IP interfaces is displayed.

tunnel [gre-keepalive]

Filters the IP interface information for GRE/IP-in-IP tunnel type interfaces.
gre-keepalive: Displays the keepalive information for a generic routing encapsulation (GRE) tunnel configured with this IP interface.

statistics

Displays the session statistics of all ingress and egress packets processed through this IP interface.

summary

Displays summarized information about requested IP interfaces.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display the summarized of detailed configuration and statistical information for a configured IP interface. This information can be used to verify and/or troubleshoot communication difficulties between to a remote host/node.

Example

The following command displays the interface information, including statistics, for the IP interface *sampleInterface*.

show ip interface sampleInterface statistics

The following command displays the GRE keepalive information for an IP interface named in *IP_gre1*.

show ip interface IP_gre1 unnel gre-keepalive

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ip ospf

Displays Open Shortest Path First (OSPF) routing information.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ip ospf [border-routers | database [verbose] [ls-id *ip_addr* **] [adv-router** *ip_addr* **] [ls-type { router | network | summary | asbr-summary | external | nssa |** *integer* **}] | debugging | interface | neighbor [details] | route | virtual-links]**

---

border-routers

Displays all known area border routers (ABRs) and autonomous system border routers (ASBRs) for OSPF.

---

database [verbose] [ls-id *ip_addr* **] [adv-router** *ip_addr* **] [ls-type { router | network | summary | asbr-summary | external | nssa |** *integer* **}]**

Displays a summary of the database information for OSPF.
verbose: Displays detailed OSPF database information.
ls-id *ip_addr*: Displays OSPF database information for the link state advertisements (LSAs) with the specified link state identifier (LSID). *ip_addr* is entered using IPv4 dotted-decimal notation.
adv-router *ip_addr*: Displays OSPF database information for the advertising router with the specified LSID. *ip_addr* is entered using IPv4 dotted-decimal notation.
ls-type { router | network | summary | asbr-summary | external | nssa | *LSA_Numerical_Type* **}]**: Displays OSPF database information for the specified LSA type.

---

debugging

Lists which debugging parameters are enabled.

---

interface

Displays interface information for OSPF.

---

neighbor [details]

Displays summarized information about all known OSPF neighbors.
details: Displays detailed information about all known OSPF neighbors.

---

route [summary]

Displays the OSPF routing table.
summary: Displays the number of intra-area, inter-area, external-1 and external-2 routes.

---

virtual-links

Displays the OSPF virtual links.

Usage

Use this command to display OSPF information.

Example

To display general OSPF information, enter the following command;

```
show ip ospf
```

show ip policy-forward

Displays information for IP packet redirecting policy for Home Agent (HA).

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show ip policy-forward
```

Usage

Use this command to see all the settings for IP packet redirection configuration from existing HA to new HA during upgrade.

Important: This is a customer specific command.

Example

The following command displays forward policy configuration for an HA:

```
show ip policy-forward
```

show ip pool

Displays statistics specific to IP pools.

Product

PDSN, GGSN, HA, ASN-GW, A-BG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ip pool [address { pool-name *pool_name* **\| group-name** *group_name* **} { used \| free \| hold \| release } [limit** *limit* **] \| group-name** *group_name* **\| groups \| hold-timer { imsi** *imsi* **\| msid** *msid* **\| username** *username* **[imsi** *imsi* **\| msid** *msid* **] } \| overlap \| pool-name** *pool_name* **\| private \| public \| resource \| static \| summary \| verbose \| wide]**

address { pool-name *pool_name* **\| group-name** *group_name* **} { used \| free \| hold \| release} [limit** *limit* **]**

Displays IP pool addresses for the specified IP pool or pool group that are currently in the specified state.
pool-name *pool_name*: Displays IP addresses from an existing IP pool name specified as an alphanumeric string of 1 through 31 characters.
group-name *group_name*: Displays IP addresses from an existing IP pool group name specified as an alphanumeric string of 1 through 31 characters.
used: Displays the IP addresses that are in a used state.
free: Displays the IP addresses that are in a free state.
hold: Displays the IP addresses that are in a hold state.
release: Displays the IP addresses that are in a release state.
limit *limit*: Specifies the maximum number of address to display as an integer from 1 through 524287.

group-name *group_name*

Displays information about an existing IP pool group name specified as an alphanumeric string of 1 through 31 characters.

groups

Lists information about all IP pool groups.

hold-timer {imsi *imsi* **\| msid** *msid* **\| username** *username* **[imsi** *imsi* **\| msid** *msid*]}

Displays hold timer address information for the specified IMSI, MSID, or username.
imsi *imsi*: Displays hold-timer information for a valid IMSI (International Mobile Subscriber Identity), specified as a 15-character field that identifies the subscriber's home country and carrier.
msid *msid*: Displays hold-timer information for the MSID specified as a number from 7 through 16 digits.
username *username*: Displays hold-timer information for an existing username specified as an alphanumeric string of 1 through 127 characters.

Important: Active users cannot be displayed. If an active ID or username is entered, the following error message appears: Failure: No address matching the specified information was found! Please confirm that the options used match the network architecture/deployment,i.e. IMSI/MSID only, Username only, or IMSI/MSID plus Username. Please note that this command does not apply for addresses in the used state.

overlap

Lists information on overlapping IP pools

pool-name *pool_name*

Displays information about an existing IP pool.

private

Displays information about IP pools marked Private.

public

Displays information about IP pools marked Public.

resource

Displays information about resource IP pools.

static

Displays information about static IP pools.

summary

Displays a summary of all IP pool information.

verbose

Displays detailed information about all IP pools.

wide

Displays detailed information formatted to more than 80 columns.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display statistics pertaining to IP Pools in the current context.

Example

The following command displays IP address information for an IP Pool named *pool1*:

```
show ip pool address pool-name pool
```

To display a summary list for all IP pools in the current context, enter the following command:

```
show ip pool summary
```

The following command displays IP pool information for all IP pools configured in the current context:

show ip pool verbose

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ip ipsp

Displays the names of IP pools that are enabled for the IP pool sharing protocol (IPSP) and lists the disposition of addresses in the pools.

Product

PDSN, HA, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show ip ipsp [ summary ]
```

summary

Displays only the disposition of the addresses in the participating IP pools. Does not show the names of the participating IP pools.

Usage

Use this command to list the names of IP pools that are participating in the IPSP and list the disposition of IP addresses in those pools.

Important: For information on configuring and using IPSP refer to the *System Administration Guide*.

Example

To list information on all IPSP participating pools and address disposition, enter the following command:

```
show ip ipsp
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ip traffic sctp

Displays statistics that track Stream Control Transmission Control (SCTP) packets. This command obtains kernel SCTP traffic information for the specified card and CPU in a particular context.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ip traffic sctp card *<slot_number>* **cpu** *<cpu_number>*

card *<slot_number>*

Displays SCTP traffic for the card in slot number 1, 2, 8 or 9.

cpu *<cpu_number>*

Displays SCTP traffic for CPU number 0, 1, 2 or 3 on the specified card.

Usage

Use this command to debug the flow of SCTP traffic to a CPU kernel.

Example

To display SCTP traffic statistics for CPU 0 on the SMC in slot 8 enter the following command:

```
show ip traffic sctp card 8 cpu 0
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ipms status

Displays the status of Intelligent Packet Monitoring System (IPMS) client service with information related to system and call events. It also displays the status of configured IPMS servers.

Product

IPMS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ipms status [summary | all | server address *ip_address* **]**

summary

Displays the summary of all configured IPMS client and IPMS servers.

all

Displays information for all configured IPMS client and IPMS servers.

server address *ip_address*

Displays status for the IPMS server specified as an IP address in IPv4 dotted-decimal or IPv6 colon-separated notation.

Usage

This command is used to show/verify the status or configuration of one or all IPMS server along with system and call event information.

Example

The following command displays status of an IPMS server with IP address *10.2.3.4*:

```
show ipms status server address 10.2.3.4
```

show ipsg

Displays information and statistics specific to the IP Services Gateway (IPSG) service.

Product

IPSG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ipsg { service { all [counters] | name *name* **} | sessions { all | callid** *num* **| counters {** *criteria* **} | full {** *criteria* **} | ip-address** *address* **| msid** *num* **| peer-address** *address* **| summary {** *criteria* **} | username** *name* **} | statistics [name** *name* **| peer-address** *address* **] } [| { grep** *grep_options* **| more }]**

---

service { all [counters] | name *name* **}**

Displays information about the configured IPSG service.
all [counters]: Displays information about all of the configured IPSG services on the system.
name *name*: Displays information about an existing IPSG service specified as an alphanumeric string of 1 through 63 characters.

---

sessions { all | callid *num* **| counters {** *criteria* **} | full {** *criteria* **} | imsi** *num* **| ip-address** *address* **| msid** *num* **| peer-address** *address* **| summary {** *criteria* **} | username** *name* **}**

all: Displays session information including call ID, NAI, and home address for all current IPSG sessions. This is the default behavior for the **sessions** keyword.
callid *num*: Displays session information for a current IPSG session based on the call ID specified as an 8-digit hexadecimal number.
counters { *criteria* }: Displays session counters for sessions matching the criteria. (See *criteria* below.)
full { *criteria* }: Displays all available session information for sessions matching the criteria. (See *criteria* below.)
ip-address *address*:
msid *num*: Displays session information for a current IPSG session based on the MSID. *num* must be an existing IPSG service session MSID, expressed as an 8-digit hexadecimal number.
peer-address *address*: Displays session information for a current IPSG session based on the IP address of the device sending the RADIUS accounting messages. *address* must be an existing IPSG service session IP address for the device sending the RADIUS accounting messages, entered using IPv4 dotted-decimal notation.
summary { *criteria* }: Displays a summary of available session information for sessions matching the criteria. (See *criteria* below.)
username *name*: Displays session information for a IPSG session based on the username of the subscriber specified as an alphanumeric string of 1 through 127 characters.
criteria:
all: Displays session information for all existing IPSG service sessions.
callid *num*: Displays session information for a specific IPSG session based on the call ID specified as an 8-digit hexadecimal number.
ip-address *address*: Displays session information for a specific IPSG session based on the IP address of the subscriber specified in IPv4 dotted-decimal notation.

msid *num*: Displays session information for an IPSG session based on the MSID.
peer-address *address*: Displays session information for a current IPSG session based on the IP address of the device sending the RADIUS accounting messages. *address* must be an existing IPSG service session IP address for the device sending the RADIUS accounting messages, entered using IPv4 dotted-decimal notation.
username *name*: Displays session information for a specific IPSG session based on the username of the subscriber. *name* is an existing IPSG service session subscriber username, expressed as an alphanumeric string of 1 through 127 characters.

statistics [name *name* **| peer-address** *address* **]**

Displays the total collected statistics of all IPSG sessions since the last system restart or clear command.
name *name*: Displays the total collected statistics of all IPSG sessions processed by a specific service since the last system restart or clear command. *name* must be an existing IPSG service name expressed as an alphanumeric string of 1 through 63 characters.
peer-address *address*: Displays the total collected statistics of all IPSG sessions associated with a specific IP address of the device responsible for sending the RADIUS accounting messages. Displayed statistics are from the last system restart or clear command.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information and statistics about existing IPSG services.

Example

The following command displays the existing IPSG services on the system:

```
show ipsg service all
```

The following command displays all the existing IPSG service sessions on the system:

```
show ipsg session all
```

The following command displays the cumulative IPSG session statistics on the system:

```
show ipsg statistics
```

The following command displays the cumulative IPSG session statistics on the system for an IPSG service named *ipsg1*:

```
show ipsg statistics name ipsg1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ipv6

Displays information for each rule in an IPv6 access control group.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ipv6 { **access-group** [**statistics**] [**|** { **grep** *grep_options* | **more** }] | **access-list** [*list_name*] [**|** { **grep** *grep_options* | **more** }] | **interface** [**name** *interface_name* [**statistics**] | **summary** | **vrf** *vrf_name* | **|** { **grep** *grep_options* | **more** }] | **neighbors** [*IPv6-ADDRESS*] [**vrf** *vrf_name*] | [**|** { **grep** *grep_options* | **more** }] }

access-group

Displays all configured access groups in the current context along with the priority values.

statistics

Displays statistics for each rule in an IPv6 access control group.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

access-list [*list_name* **]**

Displays IPv6 access control list information an existing access list name specified as an alphanumeric string of 1 through 47 characters.

interface

Displays interface information for the current context.

name *interface_name*

Displays detailed information for an existing interface name specified as an alphameric string of 1 through 79 characters.

statistics

Displays the number of inbound and outbound IP packets registered by kernel.

summary

Displays summary information about all IP interfaces.

vrf *vrf_name*

Displays information related to an existing VRF specified as an alphanumeric string of 1 through 63 characters.

neighbors [*ipv6_address* **]**

the IP address specified in IPv6 colon-separated notation.

Usage

Show the IPv6 information to verify and/or troubleshoot communication between/to a remote host/node.

Example

The following command displays the ACL for the list named *sampleACL*.

```
show ipv6 access-list sampleACL samplev6ACL
```

The following command displays the interface information, including statistics, for the IPv6 interface *samplev6interface*.

```
show ipv6 interface name samplev6interface statistics
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show ipv6 ospf

Displays information regarding the configuration of the OSPFv3 Protocol on this system.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ipv6 ospf [database | debugging | interface | nieghbor | route | virtual-links] [verbose [verbose] [| { grep *grep_options* **| more }]**

show ipv6 ospf database [adv-router*ipv4-address* **] [ls-type { external | inter-prefix | inter-router | intra-prefix | link | network | router }**

show ipv6 ospf debugging

show ipv6 ospf interface

show ipv6 ospf neighbor [details]

show ipv6 ospf route [summary]

show ipv6 ospf virtual-links

---

show ipv6 ospf database

Displays the OSPFv3 database including the following components.

- **adv-router** *ipv4-address*: Displays OSPF database information from the advertising router specified as an IP address in IPv4 dotted-decimal notation.
- **ls-type**: Displays the specified Link-State Advertisement (LSA) type, which can be one of the following:
  - **external**: Display External LSA information
  - **inter-prefix**: Displays Inter Area Prefix LSA information
  - **inter-router**: Displays Inter Area Router LSA information
  - **intra-prefix**: Displays Intra Area Prefix LSA information
  - **link**: Displays Link LSA information
  - **network**: Displays Network LSA information
  - **router**: Displays Router LSA information

---

show ipv6 ospf debugging

Displays OSPFv3 Debugging Flags.

---

show ipv6 ospf interface

Displays OSPFv3 Interfaces.

show ipv6 ospf neighbor [details]

Displays OSPFv3 neighbors with the option for full details.

show ipv6 ospf route [summary]

Displays OSPFv3 route information with the option for summarized information.

show ipv6 ospf virtual-links

Displays OSPFv3 virtual links.

verbose

Displays detailed information.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to see all OSPFv3 information.

Example

The following command displays ipv6 ospf information:

```
show ipv6 ospf
```

show ipv6 pool

Displays information related IPv6 Pool configuration/state.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ipv6 pool[**group-name***group-name*] [**pool-name***pool-name*] [**summary**] [**verbose**] [**|** { **grep** *grep_options* | **more** }]

group-name*group-name*

Displays IP address pool information for an existing group-name specified as an alphanumeric string of 1 through 31 characters.

pool-name *pool-name*

Displays IPv6 address pool information for an existing pool name specified as an alphanumeric string of 1 through 31 characters.

summary

Displays summary information about all IP address pools; this is the default.

verbose

Displays detailed information about all IP address pools.

| { grep *grep_options*|**more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to see all the ipv6 pool information.

Example

The following command displays ipv6 pool information:

```
show ipv6 pool
```

show ipv6 prefix-list

Displays information related to an IPv6 prefix list.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ipv6 prefix-list[**detail***prefix-list-name*] [**name***prefix-list-name* [*ip-address/mask* [**longer**] [**match-first**]] [**seq** *seq_value*]] [**summary** *prefix-list-name*] [**|** { **grep** *grep_options* | **more** }]

detail*prefix-list-name*

Displays detailed IP address information for an existing prefix-list specified as an alphanumeric string of 1 through 79 characters.

name*prefix-list-name*

Displays IP address information for an existing prefix-list specified as an alphanumeric string of 1 through 79 characters.

ip-address/mask

Specifies an IPv6 Network Address/Mask Bits combination in CIDR notation.

longer

Displays IP address prefix-list details in longer format.

match-first

Displays first matched IP address prefix-list details.

seq *seq_value*

Specifies the sequence number as an integer from 1 through 4294967295.

seq_value is the integer value between 1 through 4294967295.

summary *prefix-list-name*

Displays prefix-list summary for an existing prefix-list specified as an alphanumeric string of 1 through 79 characters.

| { grep *grep_options*|**more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to see all the ipv6 prefix-list information.

Example

The following command displays ipv6 prefix-list information:

```
show ipv6 prefix-list
```

show ipv6 route

Displays information related to specific route for current context.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ipv6 route [*ip-address/mask*] [**vrf** *vrf-name*] [**|** { **grep** *grep_options* | **more** }]

ip-address/mask

Specifies an IP address entered using IPv6 colon-separated and CIDR notation.

vrf *vrf-name*

Displays Virtual Routing and Forwarding (VRF) routing information for an existing VRF specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options*|**more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to see all the ipv6 route information.

Example

The following command displays ipv6 route information:

```
show ipv6 route 2001:0db8:85a3:0000:0000:8a2e:0370:7334/5
```

show ipv6 route-access-list

Displays the route access list.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ipv6 route-access-list [*route-access-list*] [**|** { **grep** *grep_options* | **more** }]

route-access-list

route-access-list is an alphanumeric string of 1 through 79 characters.

| { grep *grep_options*|**more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to see all the IPv6 route access list information.

Example

The following command displays ipv6 route access list information:

```
show ipv6 route-access-list
```

show iups-service

Displays information for Iu-PS services in the current context. The IuPS interface links the Radio Network Controller (RNC) with the Packet Switched Core Network.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show iups-service { all | name *srvc_name***} [gtpu-table | rnc { all | id** *rnc_id* **}] [| { grep** *grep_options* **| more }]**

all

Shows information for all configured IuPS services.

name *srvc_name*

Specifies an existing IuPS service as an alphanumeric string of 1 through 63 characters.

gtpu-table

Displays the configured GTPU database.

rnc all

Displays information for all configured RNCs.

rnc *rnc_id*

Specifies the identification number of an existing RNC configuration instance as an integer from 0 through 4095.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Iu-PS services control the interface between the SGSN and the RNCs in the UMTS radio access network (UTRAN). Iu-PS services include the control plane and the data plane between these nodes.
Use this command to display information for a specific Iu-PS service or for all Iu-PS services configured within the context. A filtering keyword can limit the display to only information for a specific RNC or for a GTPU table in the Iu-PS service configuration.

Example

The next command displays information for all Iu-PS services configured in the current context:

```
show iups-service all
```

This command displays information for a specific RNC for a specific Iu-PS services:

```
show iups-service name iups-svc-1 rnc 123name
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show l2tp sessions

Displays information for Layer 2 Tunneling Protocol (L2TP) tunnels.

Product

LNS, PDSN, GGSN, HA

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show l2tp sessions [full | summary | counters] [all | callid *id* **| username** *name* **| msid** *ms_id* **| lac-service** *service_name* **| lns-service** *service_name* **peer-address [** *operator* **]** *peer_address* **]**

full

Displays all available information for the specified sessions.

summary

Displays a summary of available information for the specified sessions.

counters

Displays counters for the specified L2TP sessions.

all

Displays all current sessions.

callid *id*

Displays session information for the call ID. specified an 8-byte hexadecimal number. The output of the command **show l2tp tunnels** contains a field labeled Callid Hint which lists the call ID information to use with this command.

username *name*

Displays session information for an existing subscriber specified as an alphanumeric string of 1 through 127 characters. Wildcard characters $ and * are allowed.

msid *ms_id*

Displays session information for the MSID specified as 7 to 16 digits for an IMSI, MIN, or RMI. Wildcard characters $ and * are allowed.

lac-service *service_name*

Displays all L2TP sessions in the specified LAC service.

lns-service *service_name*

Displays all L2TP sessions in the specified LNS service.

peer-address [*operator* **]** *peer_address*

Displays all L2TP sessions to the destination (peer LNS) specified as an IP address in IPv4 dotted-decimal notation.
In conjunction with **sessions** keyword, indicates a range of peers is to be displayed.
peer-address [*operator*] *peer_address* is specified using IPv4 dotted-decimal notation.
operator implies how to logically specify a range of peer-address and it must be one of the following:

- **<**: IP address less than the specified *peer_address*
- **>**: IP address less than the specified *peer_address*
- **greater-than**: IP address less than the specified *peer_address*
- **less-than**: IP address less than the specified *peer_address*

Usage

Use this command to show information for sessions in the current context.

Important: If this command is executed from within the local context, cumulative session information is displayed for all contexts.

Example

The following command displays cumulative statistics for all sessions processed within the current context:

```
show l2tp sessions
```

The following command displays all information pertaining to the L2TP session of a subscriber named *isp1vpnuser1*:

```
show l2tp session full username isp1vpnuser1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show l2tp statistics

Displays statistics for all Layer 2 Tunneling Protocol (L2TP) tunnels and sessions.

Product

LNS, PDSN, GGSN, HA

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show l2tp statistics [lac-service *service_name* **| lns-service** *service_name* **| peer-address** *peer_ip_address* **]**

lac-service *service_name*

Displays L2TP statistics for all tunnels and sessions in an existing L2TP Access Concentrator (LAC) service specified as an alphanumeric string of 1 through 63 characters.

lns-service *service_name*

Displays L2TP statistics for all tunnels and sessions in tan existing L2TP Network Server (LNS) service specified as an alphanumeric string of 1 through 63 characters.

peer-address *peer_address*

Displays L2TP statistics for all tunnels and sessions to the destination (peer LNS) at the IP address specified in IPv4 dotted-decimal notation.

Usage

Use this command to display statistics for L2TP services.

Example

The following command displays statistics for a specific LAC service named *vpn1*:

```
show l2tp statistics lac-service vpn1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show l2tp tunnels

Displays information for Layer 2 Tunneling Protocol (L2TP) tunnels.

Product

LNS, PDSN, GGSN, HA

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show l2tp tunnels [full | summary | counters] [all | callid *id* **| username** *name* **| msid** *ms_id* **| lac-service** *service_name* **| lns-service** *service_name* **| peer-address [** *operator* **]** *peer_address* **]**

full

Displays all available information for the specified tunnels.

summary

Displays a summary of available information for the specified tunnels.

counters

Displays counters for the specified L2TP tunnels.

all

Displays all current tunnels.

callid *id*

Displays tunnel information for the call id specified as an 8-digit hexadecimal number. The output of the command **show l2tp tunnels** contains a field labeled Callid Hint which lists the call id information to use with this command.

username *name*

Displays tunnel information for an existing subscriber specified as an alphanumeric string of 1 through 127 characters. Wildcard characters $ and * are allowed.

msid *ms_id*

Displays tunnel information for the MSID specified as 7 to 16 digits for an IMSI, MIN, or RMI. Wildcard characters $ and * are allowed.

lac-service *service_name*

Displays all L2TP tunnels in the specified LAC service.

lns-service *service_name*

Displays all L2TP tunnels in the specified LNS service.

peer-address [*operator* **]** *peer_address*

Displays all L2TP tunnels to the destination (peer LNS) at the IP address specified in IPv4 dotted-decimal notation.
In conjunction with **tunnels** keyword, indicates a range of peers is to be displayed.
peer-address [*operator*]: Specifies a peer address using IPv4 dotted-decimal notation.
operator implies how to logically specify a range of peer-address and it must be one of the following:

- **<**: IP address less than the specified *peer_address*
- **>**: IP address less than the specified *peer_address*
- **greater-than**: IP address less than the specified *peer_address*
- **less-than**: IP address less than the specified *peer_address*

Usage

Use this command to show information for tunnels in the current context.

Example

The following command displays all of the tunnels currently being facilitated by LAC services within the current context:

```
show l2tp tunnels all
```

The following command displays information pertaining to the L2TP tunnel(s) established for a LAC-service named vpn1:

```
show l2tp tunnels full lac-service vpn1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show lawful-intercept

Refer to the *Lawful Intercept Configuration Guide* for a full description of this command.

show lawful-intercept ssdf statistics

Refer to the *Lawful Intercept Configuration Guide* for a description of these statistics.

show lac-service

Displays the information for all L2TP Access Concentrator (LAC) services or for a particular LAC service.

Product

PDSN, HA, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show lac-service { all | name *service_name* **} [| { grep** *grep_options* **| more }]**

all

Display information for all LAC services.

name *service_name*

Display information only for an existing LAC service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to list information for LAC services configured on this system.

Example

The following commands display information for all LAC services and the LAC service named *lac1*, respectively.

```
show lac-service allshow lac-service name lac1
```

show leds

Displays the current status of the light emitting diodes (LEDs) for a specific card or all cards.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show leds { all | *card_num* } [| { grep *grep_options* | more }]

all | *card_num*

all: Displays the LED status for all cards.
card_num: Displays the LED status for the card specified by its slot number.

| { grep *grep_options* | more }

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Display the status of the LEDs as a part of an automated periodic script which checks the LEDs of the chassis.

Important: This command is not supported on all platforms.

Example

The following commands display the LED status for all cards and only card *8*, respectively.

```
show leds all

show leds 8
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show license information

Displays information about the licenses installed on this system, as well as the maximum number of sessions.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show license information { *key_name* | full } | { key } [| { grep *grep_options* | more }]

***key_name* | full**

key_name: Displays the information for an existing license key specified as an alphanumeric string of 1 of 1 through 500 characters.
full: Displays the full features and quantities without any hardware limits in place.

key:

Displays the installed keys in encrypted format.

| { grep *grep_options* | more }

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Displays the license information to verify the proper keys have been installed. This command is also helpful in troubleshooting user system access due to the maximum number of sessions being reached.

Example

The following displays the encrypted installed key and the information for *sampleKey* respectively.

```
show license information sampleKey
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show linecard

Displays information on the interface cards installed in the rear of the system chassis.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show linecard { dlci-utilization *card#* **| table } [| { grep** *grep_options* **| more }]**

dlci-utilization *card#*

SGSN only
In tabular format, displays current data link utilization (in 5 minute and 15 minute breakdowns) information for all Frame Relay ports on the specified CLC-type line card. Data links are referred to by data link connection identifiers (DLCI).
card# - Identifies the chassis slot number where the line card resides. Enter an integer from 1 to 48.

table

Displays information on all line card slots in tabular format.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to show the line card information

- to verify hardware inventories and installed components.
- to review DLCI utilization for a specific Frame Relay channelized line card.

Important: This command is not supported on all platforms.

Example

Use the following command to display a table with information identifying all line cards installed in the chassis:

```
show linecard table
```

Use the following command to display DLCI utilization information for all ports on CLC card in slot 27:

```
show linecard dlci-utilization 27
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show linkmgr

Displays statistics for the link manager (linkmgr).

Product

SGSN

Privilege

Inspector

Syntax

show linkmgr { all | instance *instance* **} [parser | |]**

all

Display statistics for all link managers.

instance *instance*

Display statistics for a single instance of a link manager specified as an integer from 1 to 4.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

This command displays statistical information for the SGSN's link manager which handles the layer between the session manager and the SS7 functionality downwards from layer 3.

Example

Use the following command to display the statistics for link manager *4*:

```
show linkmgr 4
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show llc statistics

Displays traffic statistics for the GPRS logical link-control (LLC) layer.

Product

SGSN

Privilege

Inspector

Syntax

show llc statistics [gprs-service *srvc_name* **] [verbose] [| { grep grep_options | more }]**

gprs-service *srvc_name*

Displays the statistics for an existing GPRS service specified as an alphanumeric string of 1 through 63 characters.

verbose

Displays all possible statistics for specified command or keyword.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For more information on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference*.

Usage

This command can display either a summarized or full (verbose) view of statistics collected for the traffic that has gone through the LLC layer for either all GPRS services or for a specified GPRS service.

Example

The following command displays the frame Tx/Rx LLC statistics for GPRS service *gprs1*:

```
show llc statistics gprs-service gprs1
```

show llc status

Displays status information for the GPRS logical link-control (LLC) layer.

Product

SGSN

Privilege

Inspector

Syntax

show llc status gprs-service *srvc_name* **sessmgr instance** *instance* **{ dlci ms-id** *ms_id* **sapi** *sapid* **| lsap sapid** *sapid* **| ms** *ms_id* **| usap sapid** *sapid* **[| { grep grep_options | more }]**

---

gprs-service *srvc_name*

Displays the LLC layer status for an existing GPRS service specified as an alphanumeric string of 1 through 63 characters.

---

sessmgr instance *instance*

Displays the LLC status for a session manager instance specified as an integer from 1 to 4294967295.

---

dlci ms-id *ms_id* **[sapi** *sapid* **]**

Displays the LLC status for a specific data link connection identifier (DLCI) between the LLC and the mobile station (MS). *ms_id* must be an integer from 0 to 65536 that identifies the DLCI interface connecting to a specific MS.
sapi: Filters the display of the LLC status information to focus on a specific service access point interface (SAPI) within the specified DLCI specified as.an integer from 1 to 11

---

lsap *sapid*

Refines the display of the LLC status to focus on a specific lower service access point interface (LSAP) specified as an integer from 0 to 65536.

---

ms-id *ms_id*

Displays the LLC status for a connected MS specified as an integer from 0 to 65536.

---

usap *sapid*

Refines the display of the LLC statistics to focus on a specific upper service access point interface (USAP) specified as an integer from 0 to 65536.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For more information on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Reference*.

Usage

This command can display either a summarized or full (verbose) view of statistics collected for the traffic that has gone through the LLC layer for either all GPRS services or for a specified GPRS service.

Example

The following command displays the frame Tx/Rx LLC statistics for GPRS service *gprs1*:

```
show llc statistics gprs-service gprs1
```

show lma-service

Displays statistic and counter information for Local Mobility Anchor (LMA) services on this system.

Product

P-GW

Privilege

Inspector

Syntax

show lma-service all

show lma-service name *service_name*

show lma-service session [all | callid *id* **| counters | full | ipv6-address { <** *address* **| >** *address* **|** *address* **| greater-than** *address* **[less-than** *address* **] | less-than** *address* **[greater-than** *address* **] } | summary | username** *name* **]**

show lma-service statistics [lma-service *name* **] } [| { grep** *grep_options* **| more }]**

---

all

Displays information about all configured LMA services on this system.

---

name *service_name*

Displays configuration information for an existing LMA service specified as an alphanumeric string of 1 through 63 characters.

---

session [all | callid *id* **| counters | full | ipv6-address { <** *address* **| >** *address* **|** *address* **| greater-than** *address* **[less-than** *address* **] | less-than** *address* **[greater-than** *address* **] } | summary | username** *name* **]**

Displays session information filtered by the following parameters:
all: Displays all active LMA sessions using LMA services on the system.
callid *id*: Displays available session information for the call identification number specified as an eight-byte hexadecimal number.
counters: Displays session counters for active LMA sessions using LMA services on the system. This keyword can also be filtered by the following:

- **all**
- **callid**
- **ipv6-address**
- **username**

Refer to the keyword descriptions in this command for information regarding these filters.
full: Displays additional session information for active LMA sessions using LMA services on the system. This keyword includes the information in the output of the **all** keyword plus additional information. This keyword can also be filtered by the following:

- **all**
- **callid**
- **ipv6-address**

- **username**

Refer to the keyword descriptions in this command for information regarding these filters.

ipv6-address:

- **<** *address* and **less-than** *address*: Displays summarized information for a group of IPv6 addresses that are less than the specified IPv6 address using one of these keywords. A range can be specified by including an address with the **greater-than** option. *address* must be specified in IPv6 colon-separated notation.
- **>** *address* and **greater-than** *address*: Displays summarized information for a group of IPv6 addresses that are greater than the specified IPv6 address using one of these keywords. A range can be specified by including an address with the **less-than** option. *address* must be specified in IPv6 colon-separated notation.
- *address*: Displays summarized information for a specific IPv6 address using an LMA service on this system. *address* must be specified in IPv6 colon-separated notation.

summary: Displays the number of LMA sessions currently active for LMA services configured on the system.

username *name*: Displays available session information for an existing user specified as an alphanumeric string of 1 through 127 characters.

---

statistics [lma-service *name* **]**

lma-service *name*: Displays LMA service statistics for an existing LMA service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.

For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of Chapter 1 of the *Command Line Interface Reference Guide*.

Usage

Use this command to view configuration information for LMA services on this system.

Example

The following command displays service statistics for the LMA service named *lma1*:

```
show lma-service name lma1
```

show lns-service

Displays the information for all L2TP Network Server (LNS) services or for a particular LNS service.

Product

PDSN, HA, GGSN, LNS

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show lns-service { all | name *service_name* **} [| { grep** *grep_options* **| more }]**

all

Display information for all LNS services.

name *service_name*

Displays information only for an existing LNS service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to list information for LNS services configured on this system.

Example

The following commands display information for all LNS services and the LNS service named *lns1*, respectively.

```
show lns-service all

show lns-service name lns1
```

show local-user

Displays information pertaining to local-user accounts.

Product

All

Privilege

Security Administrator

Syntax

show local-user [[username *name* **] [inactive** *filter* **] [verbose | wide] | statistics [verbose]]**

username *name*

Displays information for an existing local-user administrative account specified as an alphanumeric string of 3 through 16 characters that is case sensitive.

inactive *filter*

Specifies a filter for displaying inactive local-user accounts:

- **<** *days*: Displays accounts that have been inactive less than the specified number of days.
- **>** *days*: Displays accounts that have been inactive more than the specified number of days.
- **greater-than** *days*: Displays accounts that have been inactive more than the specified number of days.
- **less-than** *days*: Displays accounts that have been inactive less than the specified number of days.

days can be configured to an integer from 1 through 365.

[verbose | wide]

Specifies how the information is to be displayed as one of the following options:

- **verbose**: The data is displayed in list format. Additional information is provided beyond what is displayed when the **wide** option is used.
- **wide**: The data is displayed in tabular format. This is the default setting.

statistics [verbose]

Displays local-user statistics.
Using the **verbose** keyword displays additional statistics.

Usage

Use this command to display information and statistics on local-user administrative accounts.

Example

The following command displays detailed information on local-user administrative accounts that have been inactive for more than 10 days:

```
show local-user inactive greater-than 10 verbose
```

The following command displays detailed information for a local-user account named *Test*:

```
show local-user username Test verbose
```

The following command displays detailed local-user account statistics:

```
show local-user statistics verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show logging

Displays the defined logging filters for the current context.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show logging [active | verbose] [| { grep *grep_options* **| more }]**

active | verbose

active: Displays only active CLI logging filter information in concise format.
verbose: Displays as much information as possible.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View log filters to troubleshoot disk utilization issues.

Example

```
show logging

show logging active

show logging verbose

show logging active verbose
```

show logs

Displays active and inactive logs filtered by the options specified.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show logs [active] [inactive] [callid *call_id* **] [event-verbosity** *evt_verboseness* **] [facility** *facility* **] [level** *severity_level* **] [pdu-data** *pdu_format* **] [pdu-verbosity** *pdu_verboseness* **] [proclet** *facility* **] [since** *from_date_time* **[until** *to_date_time* **]] [| { grep** *grep_options* **| more }]**

active

Displays data from active logs.

inactive

Displays data from inactive logs.

callid *call_id*

Displays log information only for a call ID specified as a 4-digit hexadecimal number.

event-verbosity *evt_verboseness*

Specifies the level of verboseness to use in displaying of event data as one of:

- **min** - displays minimal information about the event. Information includes event name, facility, event ID, severity level, date, and time.
- **concise** - displays detailed information about the event, but does not provide the event source within the system.
- **full** - displays detailed information about event, including source information, identifying where within the system the event was generated.

facility *facility*

Specifies the facility to modify the filtering of logged information for as one of:

- **a10**: A10 interface facility
- **a11**: A11 interface facility
- **a11mgr**: A11 Manager facility
- **aaa-client**: AAA client facility
- **aaamgr**: AAA manager logging facility
- **aaaproxy**: AAA Proxy facility
- **aal2**: AAL2 protocol logging facility
- **acl-log**: Access Control List logging facility

- **acsctrl**: Active Charging Service (ACS) Controller facility
- **acsmgr**: Active Charging Service (ACS) Manager facility
- **alarmctrl**: Alarm Controller facility
- **alcap**: ALCAP protocol logging facility
- **alcapmgr**: ALCAPMgr logging facility
- **all**: All facilities
- **asngwmgr**: ASN Gateway Manager facility
- **asnpcmgr**: ASN Paging Controller Manager facility
- **bfd**: BFD protocol logging facility
- **bgp**: Border Gateway Protocol (BGP) facility
- **bindmux**: IPCF BindMux-De-mux Manager logging facility
- **bssap+**: Base Station Sub-system Application Part+ protocol facility for the login interface between the SGSN and the MSC/VLR (2.5G and 3G)
- **bssgp**: Base Station Sub-system GPRS Protocol logging facility handles exchange information between the SGSN and the BSS (2.5G only)
- **callhome**: Call home application logging facility
- **cap**: CAMEL Application Part (CAP) logging facility for protocol used in prepaid applications (2.5G and 3G)
- **cli**: CLI logging facility
- **credit-control**: Credit Control facility
- **cscf**: IMS/MMD CSCF
- **cscfmgr**: SIP CSCF Manager facility
- **cscfttmgr**: SIP CSCFTT Manager facility
- **csp**: Card Slot Port controller facility
- **css**: Content Service Selection (CSS) facility
- **css-sig**: Content Service Selection (CSS) RADIUS Signaling facility
- **cx-diameter**: Cx Diameter Messages facility
- **dcardctrl**: IPSEC Daughter Card Controller logging facility
- **dcardmgr**: IPSEC Daughter Card Manager logging facility
- **demuxmgr**: Demux Manager API facility
- **dgmbmgr**: Diameter Gmb Application Manager logging facility
- **dhcp**: Dynamic Host Configuration Protocol logging facility
- **dhcpv6**: DHCPv6
- **dhost**: Distributed Host logging facility
- **diabase**: Diabase messages facility
- **diameter**: Diameter endpoint logging facility
- **diameter-acct**: Diameter Accounting
- **diameter-auth**: Diameter Authentication

- **diameter-dns**: Diameter DNS subsystem
- **diameter-ecs**: ACS Diameter signaling facility
- **diameter-hdd**: Diameter HDD Interface facility
- **diameter-svc**: Diameter Service
- **diamproxy**: DiamProxy logging facility
- **dpath**: IPSEC Data Path facility
- **drvctrl**: Driver Controller facility
- **eap-ipsec**: EAP
- **eap-sta-s6a-s13-s6b-diameter**: EAP/STA/S6A/S13/S6B Diameter messages facility
- **ecs-css**: ACSMGR <-> Session Manager Signalling Interface facility
- **egtpc**: eGTP-C logging facility
- **egtpmgr**: eGTP manager logging facility
- **egtpu**: eGTP-U logging facility
- **epdg**: ePDG logging facility
- **evlog**: Event log facility
- **famgr**: Foreign Agent manager logging facility
- **firewall**: Firewall logging facility
- **fng**: FNG logging facility
- **gmm**:
    - For 2.5G: Logs the GPRS Mobility Management (GMM) layer (above LLC layer)
    - For 3G: Logs the access application layer (above the RANAP layer)
- **gprs-app**: GPRS Application logging facility
- **gprs-ns**: GPRS Network Service Protocol (layer between SGSN and the BSS) logging facility
- **gq-rx-tx-diameter**: Gq/Rx/Tx Diameter messages facility
- **gss-gcdr**: GTPP Storage Server GCDR facility
- **gtpc**: GTP-C protocol logging facility
- **gtpcmgr**: GTP-C protocol Manager logging facility
- **gtpp**: GTP-PRIME protocol logging facility
- **gtpu**: GTP-U protocol logging facility
- **gtpumgr**: GTPU Demux manager
- **gx-ty-diameter**: Gx/Ty Diameter messages facility
- **gy-diameter**: Gy Diameter messages facility
- **hamgr**: Home Agent manager logging facility
- **hat**: High Availability Task (HAT) process facility
- **hdctrl**: HD Controller logging facility
- **hnb-gw**: HNB-GW (3G Femto GW) logging facility
- **hnbmgr**: HNBMGR (3G Femto GW DemuxMgr) logging facility

- **hss-peer-service**: HSS Peer Service facility
- **igmp**: IGMP
- **ikev2**: IKEv2
- **ims-authorizatn**: IMS Authorization Service facility
- **ims-sh**: HSS SH Service facility
- **imsimgr**: SGSN IMSI Manager facility
- **imsue**: IMSUE
- **ip-arp**: IP Address Resolution Protocol facility
- **ip-interface**: IP interface facility
- **ip-route**: IP route facility
- **ipms**: IPMS logging facility
- **ipsec**: IP Security logging facility
- **ipsg**: IP Service Gateway interface logging facility
- **ipsgmgr**: IP Services Gateway facility
- **ipsp**: IP Pool Sharing Protocol logging facility
- **kvstore**: KV Store facility
- **l2tp-control**: L2TP control logging facility
- **l2tp-data**: L2TP data logging facility
- **l2tpdemux**: L2TP Demux Manager logging facility
- **l2tpmgr**: L2TP Manager logging facility
- **lagmgr**: LAGMGR logging facility
- **ldap**: Lightweight Directory Access Protocol (LDAP) messages logging facility
- **li**: Refer to the *Lawful Intercept Interface Reference* for a description of this command.
- **linkmgr**: SGSN/BSS SS7 Link Manager logging facility (2.5G only)
- **llc**: Logical Link Control (LLC) Protocol logging facility; for SGSN: logs the LLC layer between the GMM and the BSSGP layers for logical links between the MS and the SGSN
- **local-policy**: Local Policy Service facility
- **m3ua**: M3UA Protocol logging facility
- **magmgr**: Mobile Access Gateway manager logging facility
- **map**: MAP Protocol logging facility
- **megadiammgr**: Megadiameter Manager (SLF Service) logging facility
- **mme-app**: Mobility Management Entity Application logging facility
- **mme-misc**: MME miscellaneous logging facility
- **mmedemux**: Mobility Management Entity Demux Manager logging facility
- **mmemgr**: MME Manager facility
- **mmgr**: Master Manager logging facility
- **mobile-ip**: Mobile IP processes

- **mobile-ip-data**: Mobile IP data facility
- **mobile-ipv6**: Mobile IPv6 logging facility
- **mpls**: MPLS protocol logging facility
- **mseg-app**: MSEG application logging facility
- **mseg-gtpc**: MSEG GTPC application logging facility
- **mseg-gtpu**: MSEG GTPU application logging facility
- **msegmgr**: MSEGMgr (MSEG DemuxMgr) logging facility
- **mtp2**: MTP2 Service logging facility
- **mtp3**: MTP3 Protocol logging facility
- **multicast-proxy**: Multicast Proxy logging facility
- **npuctrl**: Network Processor Unit Control facility
- **npumgr**: Network Processor Unit Manager facility
- **npumgr-acl**: NPUMGR ACL logging facility
- **npumgr-flow**: NPUMGR FLOW logging facility
- **npumgr-fwd**: NPUMGR FWD logging facility
- **npumgr-init**: NPUMGR INIT logging facility
- **npumgr-port**: NPUMGR PORT logging facility
- **npumgr-recovery**: NPUMGR RECOVERY logging facility
- **ntfy-intf**: Notification Interface logging facility
- **orbs**: Object Request Broker System logging facility
- **ospf**: OSPF protocol logging facility
- **ospfv3**: OSPFv3 protocol logging facility
- **p2p**: Peer-to-Peer Detection logging facility
- **pccmgr**: IPCF PCC Manager library
- **pdg**: PDG logging facility
- **pdgdmgr**: PDG Demux Manager logging facility
- **pdif**: PDIF logging facility
- **pgw**: PDN Gateway logging facility
- **phs**: Payload Header Suppression
- **phs-control**: PHS X1/X5 and X2/X6 Interface logging facility
- **phs-data**: PHS Data logging facility
- **phs-eapol**: PHS EAPOL logging facility
- **phsgwmgr**: PHS Gateway Manager facility
- **phspcmgr**: PHS Paging Controller Manager facility
- **pmm-app**: PMM application logging facility
- **ppp**: PPP link and packet facilities
- **pppoe**: PPPOE logging facility

- **push**: VPNMGR CDR push logging facility
- **radius-acct**: RADIUS accounting logging facility
- **radius-auth**: RADIUS authentication logging facility
- **radius-coa**: RADIUS change of authorization and radius disconnect
- **ranap**: Radio Access Network Application Part (RANAP) Protocol facility logging info flow between SGSN and RNS (3G)
- **rct**: Recovery Control Task logging facility
- **rdt**: Redirect Task logging facility
- **resmgr**: Resource Manager logging facility
- **rf-diameter**: Rf Diameter messages facility
- **rip**: RIP logging facility (RIP is not supported at this time.)
- **rohc**: RObust Header Compression facility
- **rsvp**: Reservation Protocol logging facility
- **rua**: RUA (3G Femto GW - RUA messages) logging facility
- **s1ap**: S1AP Protocol logging facility
- **sccp:** SCCP Protocol logging connection-oriented messages between RANAP and TCAP layers.
- **sct**: Shared Configuration Task logging facility
- **sctp**: SCTP Protocol logging facility
- **sessctrl**: Session Controller logging facility
- **sessmgr**: Session Manager logging facility
- **sesstrc**: session trace logging facility
- **sft**: Switch Fabric Task logging facility
- **sgs**: SGs protocol logging facility
- **sgsn-app**: SGSN-APP logging various SGSN ‘glue’ interfaces, e.g., between PMM, MAP,. GPRS-FSM, SMS.
- **sgsn-failures**: SGSN call failures (attach/activate rejects) logging facility (2.5G)
- **sgsn-gtpc**: SGSN GTP-C Protocol logging control messages between the SGSN and the GGSN
- **sgsn-gtpu**: SGSN GTP-U Protocol logging user data messages between the SGSN and GGSN
- **sgsn-mbms-bearer**: SGSN MBMS Bearer app (SMGR) logging facility
- **sgsn-misc**: Used by stack manager to log binding and removing between layers
- **sgsn-system**: SGSNs System Components logging facility; used infrequently
- **sgsn-test**: SGSN Tests logging facility; used infrequently
- **sgtpcmgr**: SGSN GTPC Manager logging information exchange through SGTPC and the GGSN
- **sgw**: Serving Gateway facility
- **sh-diameter**: Sh Diameter messages facility
- **sitmain**: System Initialization Task main logging facility
- **sm-app**: SM Protocol logging facility

- **sms**: Short Message Service (SMS) logging messages between the MS and the SMSC
- **sndcp**: SNDCP Protocol logging facility
- **snmp**: SNMP logging facility
- **sprmgr**: IPCF SPR Manager logging facility
- **srdb**: Static Rating Database
- **srp**: Service Redundancy Protocol (SRP) logging facility
- **sscfnni**: SSCFNNI Protocol logging facility
- **sscop**: SSCOP Protocol logging facility
- **ssh-ipsec**: SSH IP Security logging facility
- **ssl**: SSL (Secure socket layer messages) logging facility
- **stat**: Statistics logging facility
- **system**: System logging facility
- **tacacsplus**: TACACS+ Protocol logging facility
- **tcap**: TCAP Protocol logging facility
- **testctrl**: Test Controller logging facility
- **testmgr**: Test Manager logging facility
- **threshold**: threshold logging facility
- **ttg**: TTG logging facility
- **tucl**: TUCL logging facility
- **udr**: User detail record facility (used with the Charging Service)
- **user-data**: User data logging facility
- **user-l3tunnel**: User layer-3 tunnel logging facility
- **usertcp-stack**: User TCP Stack
- **vpn**: Virtual Private Network logging facility
- **wimax-data**: WiMAX DATA
- **wimax-r6**: WiMAX R6

---

level *severity_level*

level *severity_level*: Specifies the level of information to be logged from the following list which is ordered from highest to lowest:

- **critical** - display critical events
- **error** - display error events and all events with a higher severity level
- **warning** - display warning events and all events with a higher severity level
- **unusual** - display unusual events and all events with a higher severity level
- **info** - display info events and all events with a higher severity level
- **trace** - display trace events and all events with a higher severity level
- **debug** - display all events

pdu-data *pdu_format*

Specifies output format for the display of packet data units as one of:

- **none** - output is in raw format (unformatted).
- **hex** - output being displayed in hexadecimal format.
- **hex-ascii** - output being displayed in hexadecimal and ASCII similar to a main-frame dump.

pdu-verbosity *pdu_verboseness*

Specifies the level of verboseness to use in displaying of packet data units as an integer from 1 through 5, where 5 is the most detailed.

proclet *facility*

Shows the logs from a specific proclet facility. The available facilities are the same as those listed earlier.

since *from_date_time* **[until** *to_date_time* **]**

Default: no limit.
since *from_date_time*: indicates only the log information which has been collected more recently than *from_date_time* is to be displayed.
until *to_date_time*: indicates no log information more recent than *to_date_time* is to be displayed. **until** defaults to current time when omitted.
from_date_time and *to_date_time* must be formatted as YYYY:MM:DD:HH:mm or YYYY:MM:DD:HH:mm:ss. Where:

- YYYY = 4-digit year
- MM = 2-digit month in the range 01 through 12
- DD = 2-digit day in the range 01 through 31
- HH = 2-digit hour in the range 00 through 23
- mm = 2-digit minute in the range 00 through 59
- ss = 2-digit second in the range 00 through 59

to_date_time must be a time which is more recent than *from_date_time*.
The use of the **until** keyword allows for a time range of log information while only using the **since** keyword will display all information up to the current time.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View log files for general maintenance or troubleshooting system issues.

Example

The following command displays log information for the *a11mgr* facility starting with July 1th, 2011 at midnight.

```
show logs facility allmgr since 2011:07:11:00:00
```

The following command displays the log information for call ID *FE881D32* only in active logs.

```
show logs active callid FE881D32
```

show lte-policy

Displays information for Long term Evolution (LTE) policy configurations on this system including handover restriction lists, subscriber maps, and tracking area identifiers (TAIs).

Product

MME

Privilege

Inspector

Syntax

show lte-policy { ho-restriction-list { name *name* **| summary } | subscriber-map { name** *name* **| summary } | tai-mgmt-db { name** *name* **| summary } } [| { grep** *grep_options* **| more }]**

ho-restriction-list { name *name* **| summary }**

Displays information about handover restriction lists configured on this system.
name *name*: Displays information about a specific handover restriction list configured on this system. *name* must be an existing HO restriction list, expressed as an alphanumeric string of 1 to 64 characters.
summary: Displays summarized information about all handover restriction lists configured on this system.

subscriber-map { name *name* **| summary }**

Displays information about subscriber maps configured on this system.
name *name*: Displays information about an existing subscriber map specified as an alphanumeric string of 1 through 64 characters.
summary: Displays summarized information about all subscriber maps configured on this system.

tai-mgmt-db { name *name* **| summary }**

Displays information about TAI management databases configured on this system.
name *name*: Displays information about an existing TAI management database specified as an alphanumeric string of 1 through 64 characters.
summary: Displays summarized information about all TAI management databases configured on this system.

| { grep *grep_options* **| more }**

Pipes (sends) the output of this command to the specified command. You must specify a command to which the output of this command will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in *CLI Overview* chapter.

Usage

Use this command to display information for LTE policy configurations on this system including handover restriction lists, subscriber maps, and tracking area identifiers (TAIs).

Example

The following command displays information about a subscriber map named *map3*:

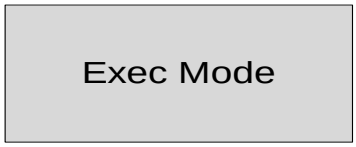
```
show lte-policy subscriber-map name map3
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

Chapter 117
Exec Mode Show Commands (M-P)

This section includes the commands **`show m3ua statistics`** through **`show profile-id-qci-mapping`**.

The Exec Mode is the initial entry point into the command line interface system. Exec mode **show** commands are useful in troubleshooting and basic system monitoring.



show mag-service

Displays statistic and counter information for Mobile Access Gateway (MAG) services on this system.

Product

HSGW, S-GW

Privilege

Inspector

Syntax

show mag-service { all | name *service_name* **| session [all | callid** *id* **| counters | full | ip-address** *home_ip_address* **| msid** *id* **| summary | username** *name* **] | statistics [name** *service_name* **] } [| { grep** *grep_options* **| more }]**

---

all

Displays information for all configured MAG services on this system.

---

name *service_name*

Displays configuration information for a specific MAG service configured on this system.
service_name must be an existing MAG service expressed as an alphanumeric string of 1 through 63 characters.

---

session [all | callid *id* **| counters | full | ip-address** *home_ip_address* **| msid** *id* **| summary | username** *name* **]**

all: Displays all active MAG sessions using MAG services on the system.
callid *id*: Displays available session information for the specific call identification number.
id must be an 8-digit hexadecimal number.
counters: Displays counters for all MAG services on the system.This keyword can also be filtered by the following:

- **all**
- **callid**
- **ip-address**
- **msid**
- **summary**
- **username**

Refer to the keyword descriptions in this command for information regarding these filters.
full: Displays additional session information for all active MAG sessions using MAG services on the system. This keyword includes the information in the output of the **all** keyword plus additional information. This keyword can also be filtered by the following:

- **all**
- **callid**
- **ip-address**
- **msid**
- **summary**

- **username**

Refer to the keyword descriptions in this command for information regarding these filters.
ip-address *home_ip_address*: Displays available session information for a specific home IPv4 or IPv6 address of a subscriber in a service session.
msid *id*: Displays available information for a specific mobile station identification number or group of numbers based on wildcard entry.
id must be a valid MSID number and can be a sequence of characters and/or wildcard characters ('$' and/or '*'). The * wildcard matches multiple characters and the $ wildcard matches a single character. If you do not want the wildcard characters interpreted as wildcard enclose them in single quotes (‘). For example: ‘$’.
summary: Displays the number of MAG sessions currently active for MAG services configured on the system.
username *name*: Displays available session information for a specific user in a service session.
name must be followed by an existing user name expressed as an alphanumeric string of 1 through 127 characters.

---

statistics [name *service_name* **]**

name *service_name*: Displays MAG service statistics for an existing MAG service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command’s Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view configuration information for MAG services on this system.

Example

The following command displays service statistics for the MAG service named *mag1*:

```
show mag-service name mag1
```

show map-service

Displays information configured for the Mobile Application Part (MAP) services, including MAP service features and operational configuration. Also includes some related configuration information for the HLR and EIR configuration parameters.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show map-service [all | name *srvc_name* **] [| { grep** *grep_options* **| more }]**

name *srvc_name*

Specifies an existing MAP service as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display all MAP service or the statistics for a particular MAP service.

Example

The following command displays configuration information for the MAP service named *map-svc-1*:

```
show map-service name map-srv-1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show map statistics

Displays Mobile Application Part (MAP) statistics.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show map statistics [name *srvc_name* **[| { grep** *grep_options* **| more }]**

name *srvc_name*

Specifies an existing MAP service as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display all MAP statistics or the statistics for a particular MAP service.

Example

The following command displays statistics for the MAP service named *map-svc-1*:

```
show map statistics name map-svc-1
```

The following command displays combined statistics for all MAP services in the current context:

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show maximum-temperatures

Shows the maximum temperature reached by each card since the last temperature timestamp reset.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show maximum-temperatures [verbose] [| { grep *grep_options* **| more }]**

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

verbose

Indicates that the output is to contain detailed information.

Usage

Verify the maximum temperature reached by components in the chassis since the indicated timestamp.

Important: This command is not supported on all platforms.

Example

```
show maximum-temperatures

show maximum-tempteratures verbose
```

show mbms bearer-service

Displays configuration information for bearer services configured for the multimedia broadcast multicast service (MBMS) running on this system.

Product

GGSN, SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show mbms bearer-service [all | apn *apn_name* **mcast-addr** *ip_address* **| service-type { broadcast | multicast } | full | instance** *instance_id* **| summary] + [| { grep** *grep_options* **| more }]**

all

Displays information on all bearer services configured on the system.

apn *apn_name* **mcast-addr** *ip_address*

Displays bearer service information of the MBMS for a specific Access Point Name (APN). *apn_name* is bound to a given BM-SC (Broadcast Multicast - Service Center) server address *ip_address*.
apn_name is the name of the APN expressed as an alphanumeric string of 1 through 62 characters that is case sensitive.
ip_address is the IP address of the BM-SC server in IPv4 dotted-decimal notation bound to the APN.

service-type { broadcast | multicast }

Displays information for a specific type of service for MBMS.
broadcast: Specifies the MBMS service type as broadcast only.
multicast: Specifies the MBMS service type as multicast only.

full

Displays full information for specific or all instances of bearer service in MBMS feature on system.

instance *instance_id*

Displays session information filtered for an instance of a bearer service running as an MBMS session and specified an integer from 1 through 64.

summary

Displays summary information for specific or all instances of a bearer service.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more** options, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to verify the configuration of one or all bearer services and active instances of bearer services under MBMS. It is also useful for monitoring or troubleshooting purposes.
If this command is executed from within the local context with the **all** keyword, information for all bearer service instances running under MBMS will be displayed.

Example

The following command displays configuration information for all bearer service instances running on system:

```
show mbms bearer-service full all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show mipfa

Displays information for specified Mobile IP Foreign Agent (MIP-FA) calls.

Product

PDSN, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show mipfa { [[counters | full | summary] { all | callid *call_id* **| msid** *ms_id* **| peer-address [** *operator* **]** *peer_address* **| reverse-tunnel { on | off } | username** *user_name* **} | statistics [fa-service** *fa_name* **| peer-address [** *peer_address* **| greater-than** *peer_address* **| less-than** *peer_address* **| >** *peer_address* **| <** *peer_address* **] }] | peers fa-service** *service_name* **[current-sessions { { >** *sessions* **[<** *sessions* **] | { <** *sessions* **[>** *sessions* **] |** *sessions* **}] [peer-address** *address* **] } [| { grep** *grep_options* **| more }]**

---

counters | full | summary

counters: Displayed output includes the statistical counters.
full: Displays detailed information.
summary: Displays only summary information. this is the default setting.
These options are not available in conjunction with the **statistics** keyword.

---

all | callid call_id | msid *ms_id* **| peer-address** *peer_ip_address* **| reverse-tunnel { on | off } | username** *user_name*

all: Displays all available information.
callid *call_id*: Displays information only for calls with the call ID specified as a 4-byte hexadecimal number.
msid *ms_id*: Displays information for a mobile subscriber ID expressed as a string from 7 to 16 digits for an IMSI, MIN, or RMI and/or characters $ and * for wildcard filter.
show mipha msid *01234567$$*
Shows any subscriber with an MSID that matches the upper 8 digits of the supplied MSID, such as 01234567, and any two digits at the remaining two places.
peer-address *peer_ip_address*: Displays information for the MIP call for the peer IP address specified using IPv4 dotted-decimal notation.
reverse-tunnel { **on** | **off** }: Enables the display of reverse IP tunnel information.
username *user_name*: Displays MIP call user information for the username specified as an alphanumeric string of 1 through 127 characters that may include wildcard characters ($ and *).

---

statistics [fa-service *fa_name* **| peer-address [peer_address | greater-than** *peer_address* **| less-than** *peer_address* **| >** *peer_address* **| <** *peer_address* **]**

Displays information for the foreign agent service specified by name or peer IP address.
fa-service *fa_name* must be an alphanumeric string of 1 through 63 characters.
peer-address *peer_address* must be specified using IPv4 dotted-decimal notation.
greater-than *peer_address*: Specifies the range of IPv4 addresses greater than *peer_address.*
less-than *peer_address*: Specifies the range of IPv4 addresses less than *peer_address.*
> *peer_address*: Specifies the range of IPv4 addresses greater than *peer_address.*
< *peer_address*: Specifies the range of IPv4 addresses less than *peer_address.*

peer-address [*operator* **]** *peer_address*

In conjunction with the **mipfa [summary] peer-address** keyword, indicates a range of peers is to be displayed.
peer-address [*operator* **]** *peer_address* must be specified using IPv4 dotted-decimal notation.
operator implies how to logically specify a range of peer-address and it must be one of the following:

- **<**: IP address is less than the specified *peer_address*
- **>**: IP address is greater than the specified *peer_address*
- **greater-than**: IP address is greater than the specified *peer_address*
- **less-than**: IP address is less than the specified *peer_address*

peers fa-service *service_name* **[current-sessions { { > | greater-than }** *sessions* **[<** *sessions* **] | { < | less-than }** *sessions* **[>** *sessions* **] |** *sessions* **}] [peer-address** *address* **]**

Displays peer servers for the specified FA service.
fa-service *service_name*: Specifies the name of an existing FA service for which the associated peer servers are to be displayed as an alphanumeric string of 1 through 63 characters.
current-sessions: Displays only peer servers with current sessions meeting the following criteria:

- > | greater-than *sessions*: Displays only peer servers currently running sessions higher than the value entered in this parameter. *sessions* must be an integer from 1 to 3000000. **Note**: the keyword "**greater-than**" and the "**>**" symbol are interchangeable in this instance of the command.
- **<** *sessions*: Displays only peer servers that are currently running sessions l than the **greater-than** parameter but less than the value entered in this parameter. *sessions* must be an integer from 1 to 3000000.
- < | less-than *sessions*: Displays only peer servers currently running sessions lower than the value entered in this parameter. *sessions* must be an integer from 1 to 3000000. **Note**: the keyword "**less-than**" and the "**<**" symbol are interchangeable in this instance of the command.
- > *sessions*: Displays only peer servers that are currently running sessions lower than the **less-than** parameter but more than the value entered in this parameter. *sessions* must be an integer from 1 to 3000000.
- *sessions*: Displays only peer servers currently running sessions that are equal to the value entered in this parameter. *sessions* must be an integer from 1 to 3000000.

peer-address *address*: Displays only peer servers matching the IP address entered in this parameter. *address* must be specified using IPv4 dotted-decimal notation and can be followed by the netmask of the address.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View MIP foreign agent information to support troubleshooting subscriber issues by viewing call information and filtering on the subscriber information using various methods.

Example

The following displays the call information for all mobile IP FA calls and statistics for *fa1*, respectively:

show mipfa all

The following command displays the statistics for the foreign agent service *fa1*:

show mipfa statistics fa-service fa1

The following commands displays call information for user *user6@aaa* in full detail and in summary:

show mipfa full username user6@aaa

show mipfa summary username user1

The following displays MIP FA call information for calls from mobile subscriber *4412345678* and peer address *10.2.3.4*, respectively:

show mipfa msid 4412345678 *4412345678*

show mipfa peer-address 10.2.3.4

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show mipha

Displays information for specified Mobile IP Home Agent (MIP-HA) calls.

Product

HA

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show mipha { [[counters | full | summary] { all | callid *call_id* **| imsi** *imsi_num* **| ip-address** *ip_addr* **| msid** *msid_num* **| peer-address [** *operator* **]** *peer_address* **| reverse-tunnel { on | off } | username** *user_name* **} | statistics [ha-service** *ha_name* **| peer-address** *peer_address* **] }] | peers ha-service** *service_name* **[current-sessions { { > | greater-than }** *sessions* **[<** *sessions* **] | { < | less-than }** *sessions* **[>** *sessions* **] |** *sessions* **}] [peer-address** *address* **] } [| { grep** *grep_options* **| more }]**

---

counters | full | summary

Default: concise output.
counters: Displayed output includes the statistical counters.
full: Displays detailed information.
summary: Displays only summary information.
These options are not available in conjunction with the **statistics** keyword.

---

msid *msid_num*

Displays information for the subscriber with the supplied MSID on HA.
msid *msid_num* specifies a mobile subscriber ID for which information is to be displayed. *ms_id* must be from 7 to 16 digits for an IMSI, MIN, or RMI and /or characters $ and * for wildcard filtering.
If **enforce imsi-min equivalence** is enabled on the chassis and MIN or IMSI numbers are supplied, this keyword/ filter will show subscribers with a corresponding MSID (MIN or IMSI) whose lower 10 digits matches the lower 10 digits of the supplied MSID.
show mipha msid *ABCD0123456789* or
show mipha msid *0123456789*
Shows any subscriber with a MSID that match the lower 10 digits of MSID supplied, such as 0123456789.
show mipha msid *01234567$$*
Shows any subscriber with a MSID that match the upper 8 digits of the supplied MSID, such as 01234567 and any two digits at the remaining two places.

---

all | callid *call_id* **| imsi** *imsi_num* **| ip-address** *ip_addr* **| msid** *msid_num* **| peer-address [** *operator* **]** *peer_address* **| reverse-tunnel { on | off } | username** *user_name*

all: Displays all available information.
callid *call_id*: Displays information only for calls with the call ID specified as a 4-byte hexadecimal number.
imsi *imsi_num*: Specifies an IMSI (international mobile subscriber ID) for which information is to be displayed. The IMSI is a 15-character field which identifies the subscriber's home country and carrier.
ip-address *ip_addr*: Displays statistics for a call with the IP address specified in IPv4 dotted-decimal notation.

msid *msid_num*: Specifies a mobile subscriber ID only for which information is to be displayed. *ms_id* must be from 7 to 16 digits specified as an IMSI, MIN, or RMI.
peer-address *peer_address*: Displays statistical information for the peer IP address specified using IPv4 dotted-decimal notation.
reverse-tunnel { **on** | **off** }: Enables the display of reverse IP tunnel information.
username *user_name*: Displays user MIP call information for the username specified as an alphanumeric string of 1 through 127 characters including wildcard characters ($ and *).

---

peer-address [*operator* **]** *peer_address*

In conjunction with **mipha [summary] peer-address** keyword, indicates a range of peers is to be displayed.
peer_address must be specified using IPv4 dotted-decimal notation.
operator implies how to logically specify a range of peer-addresses and it must be one of the following:

- **<**: IP address is less than the specified *peer_address*
- **>**: IP address is greater than the specified *peer_address*
- **greater-than**: IP address is greater than the specified *peer_address*
- **less-than**: IP address is less than the specified *peer_address*

---

statistics [ha-service *ha_name* **| peer-address** *peer_address* **]**

Displays statistical information for the home agent service specified by its name (an alphanumeric string of 1 through 63 characters) or peer IP address (IPv4 notation).

---

peers ha-service *service_name* **[current-sessions { { > | greater-than }** *sessions* **[<** *sessions* **] | { < | less-than }** *sessions* **[>** *sessions* **] |** *sessions* **}] [peer-address** *address* **]**

Displays peer servers for the specified HA service.
ha-service *service_name*: Specifies the name of an existing HA service for which the associated peer servers are to be displayed as an alphanumeric string of 1 through 63 characters.
current-sessions: Displays only peer servers with current sessions meeting the following criteria:

- > | greater-than *sessions*: Displays only peer servers currently running sessions higher than the value entered in this parameter. *sessions* must be an integer from 1 to 3000000. **Note**: the keyword "**greater-than**" and the "**>**" symbol are interchangeable in this instance of the command.
- **<** *sessions*: Displays only peer servers that are currently running sessions higher than the **greater-than** parameter but less than the value entered in this parameter. *sessions* must be an integer from 1 to 3000000.
- < | less-than *sessions*: Displays only peer servers currently running sessions lower than the value entered in this parameter. *sessions* must be an integer from 1 to 3000000. **Note**: the keyword "**less-than**" and the "**<**" symbol are interchangeable in this instance of the command.
- > *sessions*: Displays only peer servers that are currently running sessions lower than the **less-than** permitter but more than the value entered in this parameter. *sessions* must be an integer from 1 to 3000000.
- *sessions*: Displays only peer servers currently running sessions that are equal to the value entered in this parameter. *sessions* must be an integer from 1 to 3000000.

peer-address *address*: Displays only peer servers matching the IP address entered in this parameter. *address* must be specified using IPv4 dotted-decimal notation and can be followed by the netmask of the address.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View MIP home agent information to support troubleshooting subscriber issues by viewing call information and filtering on the subscriber information using various methods.

Example

The following displays the call information for all mobile IP HA calls and statistics for *ha1*, respectively:

```
show mipha all

show mipha statistics ha-service ha1
```

The following commands displays call information for user *isp1user1* in full detail and in summary:

```
show mipha full username isp1user1

show mipha summary username user1
```

The following displays MIP-HA call information for calls from mobile subscribers with reverse tunneling *off* and peer address *10.2.3.4*, respectively:

```
show mipha reverse-tunnel off

show mipha peer-address 10.2.3.4
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show mipv6ha

Displays information for specified Mobile IPv6 Home Agent (MIPv6-HA) calls.

Product

PDSN, HA

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show mipv6ha [all | callid *callid* **| counters** *filter* **| full** *filter* **| ipv6-address** *ip_addr*| **statistics mipv6ha-service** *mipv6ha-service_name* **| summary** *filter* **| username** *user_name* **]**

---

all

Displays all information for MIPv6-HA calls.

---

callid *call_id*

Specifies the Call Identification number as an 8-digit hexadecimal number.

---

counters [all | callid | ipv6-address | username]

Displays the counters associated with the MIPv6-HA service. The following filters are available:

- **all**
- **callid:**
- **ipv6-address**
- **username**

---

full [all | callid | ipv6-address | username]

Displays all available information for the associated display or filter keyword.
The following filters are available:

- **all**
- **callid:**
- **ipv6-address**
- **username**

---

ipv6-address *ip_addr*

Displays information for subscribers connected via the packet control function for a specific or range of IPv6 addresses. The address must be specified using the IPv6 colon-separated notation.

- **<**: Filters output so that only information less than the specified IPv6 address value is displayed.
- **>**: Filters output so that only information greater than the specified IPv6 address value is displayed.
- **less-than**: Filters output so that only information less than the specified IPv6 address value is displayed.
- **greater-than**: Filters output so that only information greater than the specified IPv6 address value is displayed.

statistics [mipv6ha-service *mipv6ha-service_name* **]**

Displays all information collected for specific protocol since last the **restart** or **clear** command. This can be filtered according to a specified **mipv6ha-service**.

summary [all | callid | ipv6-address | username]

Displays summary information for defined sessions, based on defined parameters.
The following filters are available:

- **all**
- **callid:**
- **ipv6-address**
- **username**

username *user_name*

Displays session information for a specific username.

Usage

View MIPv6 home agent information to support troubleshooting subscriber issues by viewing call information and filtering on the subscriber information using various methods.

Example

The following displays the call information for all mobile IPv6 HA calls:

```
show mipv6ha all
```

The following command displays call information for user *mipv6hauser1* in full detail and in summary:

```
show mipv6ha full username mipv6hauser1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show mme-service

Displays configuration information for Mobility Management Entity (MME) services on this system.

Product

MME

Privilege

Inspector

Syntax

show mme-service { all | name *svc_name* **} [| { grep** *grep_options* **| more }]**

all

Displays configuration information for all MME services configured on this system.

name *service_name*

Displays configuration information for an existing MME service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to view configuration information for MME services on this system.

Example

The following command displays service statistics for the MME service named *mme1*:

```
show mme-service name mme1
```

Important: Output descriptions for these commands are available in the *Statistics and Counters Reference*.

show mme-service db record

Displays the Mobile Management Entity (MME) database records for MME sessions grouped in session instances on this system and filtered with IMSI or GUTI as criteria.

Product

MME

Privilege

Inspector

Syntax

show mme-service db record { all | call-id *call_id* **| guti plmn** *plmn_id* **group-id** *mme_grp_id* **code** *mme_code* **m-tmsi** *mtmsi_value*| **imsi** *imsi_identifier*

all

Displays all database records of a session instance used for MME service.

call-id *call_id*

Displays database records filtered by the call ID specified as an 8-digit hexadecimal number

guti plmn *plmn_id* **group-id** *mme_grp_id* **code** *mme_code* **m-tmsi** *mtmsi_value*

Displays database records filtered by the Globally Unique Temporary Identifier (GUTI). The GUTI is constructed from the GUMMEI and the M-TMSI.
The GUMMEI is constructed from the public land mobile network (PLMN) ID [MMC and MNC] and the MME Group ID (MMEGI). Within the MME, the mobile is identified by the M-TMSI.
A GUTI has: 1) a unique identity for the MME which allocated the GUTI; and 2) the unique identity of the UE within the MME that allocated the GUTI.
The MME Identifier (MMEI) is constructed from an MME Group ID (MMEGI) and an MME Code (MMEC).

imsi *imsi_identifier*

Displays database records filtered by International Mobile Subscriber Identity (IMSI).
imsi_identifier is a 15-character IMSI field which identifies the subscriber's home country and carrier. Wildcard characters $ and * are allowed. The * wildcard matches multiple characters and the $ wildcard matches a single character. If you do not want the wildcard characters interpreted as a wildcard enclose them in single quotes (‘). For example; ‘$’.

Usage

Use this command to view database records for all or a particular instance of session manager for MME services on this system with IMSI or GUTI as a filter criteria.

Example

The following command displays the summary database records of a session instance for a subscriber having IMSI as *123455432112345* in the MME service:

```
show mme-service db record imsi 123455432112345
```

Important: Output descriptions for these commands are available in the *Statistics and Counters Reference*.

show mme-service db statistics

This command displays the Mobile Management Entity (MME) database statistics for all or specific MME sessions on this system.

Product

MME

Privilege

Inspector

Syntax

show mme-service db statistics [instance *smgr_instance* **]**

instance *smgr_instance*

Displays MME database statistics for a specific instance of a session manager running the MME service. *smgr_instance* is an instance ID specified as an integer from 0 through 4294967295. If an instance is not specified, summary statistics are displayed.

Usage

Use this command to view database statistics for all or a particular instance of session manager for MME services on this system.

Example

The following command displays summary database statistics for the MME service running on a system:

```
show mme-service db statistics
```

Important: Output descriptions for these commands are available in the *Statistics and Counters Reference*.

show mme-service enodeb-association

Displays configuration information for an eNodeB association within an MME service.

Product

MME

Privilege

Inspector

Syntax

show mme-service enodeb-association [summary | full] [all | | ipsec | mme-service-name *mme_svc_name* **| peer-address** *peer_ip_address* **| peer-id** *peer_identifier* **] [| { grep** *grep_options* **| more }]**

---

summary

Displays summarized output for this command.

---

full

Displays detailed output for this command.

---

all

Displays information of all eNodeBs associated with MME services on this system.

---

ipsec

Displays information of all IPSec enabled eNodeBs associated with MME services on this system.

---

mme-service-name *mme_svc_name*

Displays summarized or detailed configuration information for eNodeBs associated with an existing MME service specified as an alphanumeric string of 1 through 63 characters.

---

peer-address *peer_ip_address*

Displays summarized or detailed configuration information of eNodeBs associated with an existing MME peer IP address configured with an MME service and expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

---

peer-id *peer_identifier*

Displays summarized or detailed configuration information for eNodeBs associated with a an existing MME peer ID configured with an MME service and specified as an integer from 1 through 4294967295.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to view configuration information of eNodeBs associated with an MME service on this system.

Example

The following command displays detailed service statistics for associated eNodeBs within the MME service named *mme1*:

```
show mme-service enodeb-association full mme-service-name mme1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show mme-service session

Displays session information for Mobile Management Entity (MME) service(s) running on a peer or local system.

Product

MME

Privilege

Inspector

Syntax

show mme-service session [summary | full | counters] [all | callid *call_identifier* **| imei** *imei_id* **| imsi** *imsi_id* **| ipsec | mme-service** *service_name* **| msisdn** *number* **| pdn-address** *pdn_ip_address* **| s1-peer** *s1_peer_ip_address* **| s11-peer** *s11_peer_ip_address* **| vlr-name** *vlr_name* **| ue-ecm-state { connected | idle }] [| { grep** *grep_options* **| more }]**

summary

Displays summarized output for this command.

full

Displays detailed output for this command.

counters

Displays all counters for related events and messages for an MME session running on a system.

all

Displays information for all MME sessions running on this system.

callid *call_identifier*

Displays summarized or detailed configuration information for an MME session filtered by a call identifier within an MME service configured on this system.
call_identifier must be an existing call identity in 8-digit hexadecimal format running in an MME service on this system.

imei *imei_id*

Displays summarized or detailed configuration information about MME sessions running and filtered by an International Mobile Equipment Identification (IMEI) number within an MME service configured on this system.
imei_id must be an existing IMEI in an existing MME service on the system. *imei_id* must contain an 8-digit TAC (Type Allocation Code) and a 6-digit SNR (Serial Number).

imsi *imsi_id*

Displays summarized or detailed configuration information about MME sessions running and filtered by an International Mobile Subscriber Identity (IMSI) number within an MME service configured on the system.
imsi_id must be an existing IMSI in an existing MME service on the system. *imsi_id* is a 15-character IMSI field which identifies the subscriber's home country and carrier.

Wildcard characters $ and * are allowed. The * wildcard matches multiple characters and the $ wildcard matches a single character. If you do not want the wildcard characters interpreted as a wildcard enclose them in single quotes (‘). For example; ‘$’.

ipsec

Displays information for all IPSec enabled sessions using MME services on the system.

mme-service *service_name*

Displays summarized or detailed configuration information about MME sessions running and filtered by an MME service name configured on the system.
service_name must be a configured MME service on the system, expressed as an alphanumeric string of 1 through 63 characters.

msisdn *number*

Displays summarized or detailed configuration information about MME sessions running and filtered by a Mobile Station International ISDN Number.
number must be a combination of the CC (Country Code) and National (significant) mobile number, not exceeding 15 digits.

pdn-address *pdn_ip_address*

Displays summarized or detailed configuration information about MME sessions running and filtered by the IP address of a connected PDN(s) within an MME service configured on this system.
pdn_ip_address must be a configured IP address of a PDN expressed in IPv4 dotted-decimal or IPv6 colon-separated notation within an existing MME service on the system.

s1-peer *s1_peer_ip_address*

Displays summarized or detailed configuration information of MME sessions running and filtered by the IP address of a peer connected through an S1 interface within an MME service configured on this system.
s1_peer_ip_address must be a configured IP address of a peer on S1 interface expressed in IPv4 dotted-decimal or IPv6 colon-separated notation within an existing MME service on this system.

s11-peer *s11_peer_ip_address*

Displays summarized or detailed configuration information of MME sessions running and filtered by IP address of a peer connected through S11 interface with an MME service configured on this system.
s11_peer_ip_address must be a configured IP address of a peer on S11 interface expressed in IPv4 dotted-decimal or IPv6 colon-separated notation within an existing MME service on this system.

vlr-name *vlr_name*

Displays summarized or detailed configuration information of MME sessions running and filtered by Visitor Location Register (VLR) name.
vlr_name must be an alphanumeric string of 1 through 63 characters.

ue-ecm-state { connected | idle }

Displays summarized or detailed configuration information about MME sessions running and filtered by the UE’s EPS Connected Management (ECM) state.
connected: Specifies that summarized or detailed configuration information about MME sessions is to be displayed based on the UE ECM state of “connected”.

idle: Specifies that summarized or detailed configuration information about MME sessions is to be displayed based on the UE ECM state of "idle".

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to view information for MME sessions within MME services on this system.

Example

The following command displays detailed session statistics for an MME service running on this system:

```
show mme-service session full
```

Important: Output descriptions for these commands are available in the *Statistics and Counters Reference*.

The following command displays detailed session counters for an MME service running on this system:

```
show mme-service session counters
```

show mme-service statistics

This command displays the service statistics of an MME service specified by various criteria.

Product

MME

Privilege

Security Administrator, Administrator

Syntax

show mme-service statistics [sctp [mme-service *mme_svc_name* **] | s1ap [mme-service** *mme_svc_name* **| peer-id** *peer_identifier* **] | [emm-only | esm-only] [mme-service** *mme_svc_name* **| peer-id** *peer_identifier*] **| handover] [verbose] [| { grep** *grep_options* **| more }]**

emm-only

Filters the output of EPS mobility management (EMM) related statistics by an MME service name or peer MME identifier.

esm-only

Filters the output of EMM related statistics by MME service name or peer MME identifier.

s1ap

Filters the output of S1-AP statistics by MME service name of peer MME identifier.

sctp

Filters the output of SCTP statistics by MME service name of peer MME identifier.

mme-service *mme_svc_name*

Filters the output of all MME service statistics (such as EMM, ESM, SCTP, S1-AP, and SCTP) by MME service name.

peer-id *peer_identifier*

Filters the output of all MME service statistics (such as EMM, ESM, SCTP, S1-AP, and SCTP) by MME peer identifier.

handover

Filters the output of all handover statistics (such as Intra-MME, EUTRAN<->EUTRAN via S10, EUTRAN<->UTRAN via GnGp, EUTRAN<->GERAN via GnGp, and EUTRAN<->UTRAN via S3) by an MME service.

verbose

Displays comprehensive information for a specific argument or set of arguments.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

This command is used to display the statistical information of an MME service based on various filter criteria as a local MME service or a peer MME related to EMM, ESM, SCTP, S1-AP, and SCTP.

Example

The following command displays the service session statistics of all MME service on a system related to all; such as EMM, ESM, SCTP, S1-AP, and SCTP:

```
show mme-service statistics
```

Important: Output descriptions for these commands are available in the *Statistics and Counters Reference*.

The following command displays the service session statistics of all MME services on a system related to S1-AP:

```
show mme-service statistics s1ap
```

The following command displays the service session statistics of all MME services on a system related to EMM only:

```
show mme-service statistics emm-only
```

show mpls ldp

Displays the Multiprotocol Label Switching (MPLS) Label Distribution Protocol (LDP) information.

Product

GGSN

Privilege

Security Administrator, Administrator

Syntax

```
show mpls ldp { bindings { ldp-id IPv4_add | local [ ldp-id | local | prefix | remote ] |
prefix IPv4_addr | remote } | discovery | neighbor { detail | ldp-id } }
```

bindings

Displays the MPLS LDP label bindings.

ldp-id

Displays label values for a specific peer LDP ID.

local

Displays locally assigned label values.

prefix

Displays label values for a specific prefix.

remote

Displays remotely assigned label values.

discovery

Displays the MPLS LDP discovery information.

neighbor

Displays the MPLS LDP peer information.

detail

Displays the MPLS LDP peer information in details. The displayed information includes, Local LDP ID, Peer LDP ID, Transport address, State (for example, Established), Role (for example, Active), Uptime, Keepalive negotiated hold time, Proposed Local/Peer, Remaining Keepalive hold time, and Address advertised.

Usage

This command displays statistical information for an MPLS Label Distribution Protocol configuration. The information includes Prefix, LDP ID, Label, Nexthop, and Egress_if_index for all MPLS LDP Bindings configurations.

Example

The following command displays information about MPLS LDP protocol related configurations:

```
show mpls ldp discovery neighbor ldp-id 10.2.3.4 detail bindings ldp-id
31.32.33.34 prefix 192.168.102.232 local remote
```

The following command displays the MPLS LDP discovery information, including, LDP Peer IDs, Hold time (in seconds), Proposed Local/Peer, and Remaining (time in seconds):

```
show mpls ldp discovery
```

The following command displays the remotely assigned label values in the MPLS LDP binding configuration:

```
show mpls ldp bindings remote
```

Important: Output descriptions for these commands are available in the *Statistics and Counters Reference*.

show mseg-config

Displays Mobile Services Edge Gateway (MSEG) configuration information.

Important: This command is not supported in this release. For more information please contact your Cisco account representative.

Product

MSEG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show mseg-config all [| { grep *grep_options* **| more }]**

all

Displays all available MSEG configuration information.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to view MSEG configuration information.

show mseg-service

Displays Mobile Services Edge Gateway (MSEG) service configuration information.

Important: This command is not supported in this release. For more information please contact your Cisco account representative.

Product

MSEG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show mseg-service { all | name *mseg_service_name* **} [| { grep** *grep_options* **| more }]**

all

Displays configuration information for all MSEG services.

name *mseg_service_name*

Displays configuration information for the specified MSEG service.
mseg_service_name must be the name of a configured MSEG service, expressed as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to view MSEG service configuration information.

Example

The following command displays configuration information for the MSEG service named *standard*:

```
show mseg-service name standard
```

show multicast-sessions

Displays information for multicast sessions defined by the specified keywords.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show multicast-sessions [*command_keyword* **] [** *filter_keywords* **] [| { grep** *grep_options* **| more }**

command_keyword

The following keywords are base commands that each have a distinct display output. Only one keyword can entered on the command line.

debug-info { callid *id* **| flowid** *id* **}**

Displays internal call troubleshooting information for multicast sessions defined by the specified keywords.
callid *id:* Displays subscriber information for the call specified as an 8-digit hexadecimal number.
flowid *id:* Displays information for a specific BCMCS flow, defined by The flow ID as a hexadecimal number.

full

Displays all available multicast session information. The following filter keywords are valid for this command: active, all, callid, card-num, dormant, flowid, flowid-type, mcast-address, pcf, pdsn-service, grep, more

summary

Only displays a summary of multicast session information. The following commands are valid for this command: active, all, callid, card-num, dormant, flowid, flowid-type, mcast-address, pcf, pdsn-service, grep, more

filter_keywords

The following keywords are filters that modify or filter the output of the Command Keywords. Not all filters are available for all Command Keywords. Multiple Filter Keywords can be entered on a command line. When multiple Filter Keywords are specified, the output conforms to all of the Filter Keywords specifications.

active

Only displays information for multicast sessions that are currently active.

all

If no keywords are specified before **all**, information for all multicast sessions is displayed. If keywords are specified before **all**, all information is displayed with no further options being allowed.

callid *id*

Displays multicast session information for the call specified by *id*. The call must be specified as an 8-digit hexadecimal number.

card-num *card_num*

The slot number of the processing card by which the subscriber session is processed. *card_num* is a slot number from 1 through 7 or 10 through 16.

dormant

Shows information for subscriber sessions that are dormant (not transmitting or receiving data).

flowid *id*

Displays information for a specific BCMCS flow, defined by *id*. The flow ID must be a hexadecimal number.

flowid-type [flow | program]

Displays information for multicast sessions according to the type of flow.
flow: Shows all multicast sessions for the flow ID type "flow".
program: Shows all multicast sessions for the flow ID type "program".

mcast-address *ipv4_address*

Show multicast sessions for a specific multicast address. Must be followed by the IP address of an interface, using IPv4 dotted-decimal notation.

pcf *ipv4_address*

Displays information for multicast sessions connected via the packet control function, defined by *ipv4_address*. The address must be specified using IPv4 dotted-decimal notation.

pdsn-service *svc_name*

Displays information for multicast session connected to the packet data service *svc_name*.The packet data service must have been previously configured and expressed as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
Please refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter for details on the usage of **grep** and **more**.

Usage

Use this command to view information about multicast sessions.
The output of this command may be considered for part of a periodic system auditing program by verifying active and dormant sessions.

Example

The following command displays the all broadcast-multicast sessions active in a context/system:

```
show multicast-sessions all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show network-requested-pdp-context

Displays information for the specified network-requested packet data protocol (PDP) context.

Product

GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show network-requested-pdp-context imsi *imsi_value*

imsi *imsi_value*

Specifies that information will be displayed for a particular International Mobile Subscriber Identity (IMSI). *imsi_value* is an integer from 1 to 15 digits.

Usage

USe this command to display information pertaining to network-requested PDP contexts.

Example

The following command displays network-requested PDP context information for a subscriber with an IMSI of *123456789*:

```
show network-requested-pdp-context imsi 123456789
```

show network-service-entity

Displays information regarding the network service entities (NSEs) in the network.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show network-service-entity { consolidated-status | fr-config [ peer-nsei nsei] | ip-
config [ nsvl { all | instance value } ] }
```

consolidated-status

Displays Network Service Virtual Connection (NSVC) status information for all network service entities in the network. This keyword is particularly useful for troubleshooting.

fr-config [peer-nsei *nsei*]

Displays network service configurations for NSEs using Frame Relay configurations.
peer-nsei *nsei* limits the display to a specific peer NSE identified as an integer from 0 through 65535.

ip-config [nsvl { all | instance *value* }

Displays network service configurations for NSEs using IP configurations.
Including the **nsvl** keyword limits the display to all or a single (instance 0 to 3) of a network service virtual link.

Usage

Use this command to display NSE information pertaining to the NSVCs of the NSEs in the networks or NSEs configured for Frame Relay or IP.

Example

The following command displays the status of all the NSVCs for all the NSEs in the network.

```
show network-service-entity consolidated-status
```

show npu error-counters

Displays packet error counters.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show npu error-counters [| { grep *grep_options* **| more }]**

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View network timing protocol information to troubleshooting system clock issues by displaying the associations and status of the local NTP client.

Example

The following displays the NPU information.

show npu error-countersshow npu error-counters |grep *qwe*

show npu utilization

Displays NPU information utilization.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show npu utilization table [| { grep *grep_options* **| more }]**

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View network timing protocol information to troubleshooting system clock issues by displaying the associations and status of the local NTP client.

Example

The following displays the NPU information.

show npu utilization table

show npu utilization table | grep *qwe*

show ntp

Displays the network timing protocol (NTP) associations and status.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ntp { associations | status } [address *ip_address* **] [| { grep** *grep_options* **| more }]**

associations

Displays the current NTP server associations and related statistics.

status

Displays the client permeates configured and the synchronization status.

address *ip_address*

Specifies the IP address of an NTP server/client in the current context in IPv4 dotted-decimal notation.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View network timing protocol information to troubleshooting system clock issues by displaying the associations and status of the local NTP client.

Example

The following displays the NTP associations and status, respectively.

```
show ntp associationsshow ntp status
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show nw-reachability server

Displays the configuration of network reachability servers for the current context.

Product

HA

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show nw-reachability server { all | name server_name }
```

all

Displays configuration information for all network reachability servers in the current context.

name *server_name*

Displays configuration information for an existing network reachability server specified as an alphanumeric string of 1 through 15 characters.

Usage

Use this command to display configuration information on network reachability servers configured in the current context.

Example

The following command displays information on all network reachability servers in the current context:

```
show nw-reachability server all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show operator-policy

Displays the information configured for an operator policy.

Product

MME, S-GW, SGSN

Privilege

Inspector

Syntax

show operator-policy { all | full { all | name *op_policy_name* **} | name** *op_policy_name* **} [| { grep** *grep_options* **| more }]**

---

all

Displays a list of all operator policies configured on the system.

---

full { all | name *op_policy_name* **}**

full:Displays a full set of available information for the specified operator policy (policies).
all: Displays a full set of available information for all operator policies configured on the system.
name *op_policy_name*: Displays a full set of available information for an existing operator policy specified as an alphanumeric string of 1 through 64 characters.

---

name *op_policy_name*

Displays a full set of available information for an existing operator policy specified as an alphanumeric string of 1 through 64 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for operator policies configured on the system. Operator policies are configured through the Global Configuration Mode and in the Operator Policy Configuration Mode. For more information regarding operator policy commands, refer to the *Operator Policy Configuration Mode Commands* chapter.

Example

The following command displays all available information for an operator policy named *policy-5*:

```
show operator-policy full name policy-5
```

show orbem

Displays information and statistics for the Object Request Broker Element Manager (ORBEM) interface in the current context.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show orbem { client { id *client_name* **| table } | event-notif-service filters | session { id** *session_name* **| table } | status } [| { grep** *grep_options* **| more }]**

---

client { id *client_name* **| table }**

Indicates the Common Object Request Broker Architecture (CORBA) client information is to be displayed. The keyword **table** is used to output to the display information on all configured clients. The keyword **id** is used to specify a specific client for which information is to be displayed specified as *client_name*.
client_name must refer to an existing client which is found using the **table** keyword option.

---

event-notif-service filters

Displays information pertaining to filters configured for the ORB Notification Service.

---

session { id *session_name* **| table }**

Indicates session information is to be displayed. The keyword **table** is used to output to the display information on all configured clients. The keyword **id** is used to specify a specific session for which information is to be displayed specified as *session_name*.
session_name must refer to an existing session which is found using the **table** keyword option.

---

status

Indicates that the ORBEM server status information is to be displayed.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Display current sessions when ORBEM system response may appear sluggish. This command is also useful in periodic verification of the server status.

Example

The following commands will display the information for all clients.

```
show orbem client table
```

The following commands display the information for the *clientName* and *sessionID*, respectively:

show orbem client id *clientName*

show orbem session id *sessionId*

The following command displays the ORBEM server status:

show orbem status

The following command displays the information for all sessions:

show orbem session table

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show patch-progress

Displays the status of the on-going software patch installation.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show patch-progress
```

Usage

Use this command to show the status of an on-going software patch installation.

Important: Software Patch Upgrades are not supported in this release.

show pcc-af service

Displays the statistical and configuration information of configured Policy and Charging Control- Application Function (PCC-AF) services configured in a context.

Product

IPCF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show pcc-af service [statistics] { all | name *pcc_af_svc_name* **| summary } [| { grep** *grep_options* **| more }]**

all

all: displays information for all configured PCC-AF services.

name *pcc_af_svc_name*

Displays information only for an existing PCC-AF service specified as an alphanumeric string of 1 through 79 characters

statistics

Displays the statistical information for a specific service or all PCC-AF services configured in a context.

summary

Displays the summarized output of this command.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display the statistical and configuration information of configured PCC-AF services configured in a context.
Display can further be filtered for specific PCC-AF service name or summarized output of the command.

Example

The following command displays the information for the PCC-AF service named *pccApp1* in summarized output:

```
show pcc-af service name pccApp1 summary
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pcc-af session

Displays the active/dormant session information about Policy and Charging Control- Application Function (PCC-AF) service instances configured and running on this system based on different filter criteria.

Product

IPCF

Privilege

Inspector

Syntax

show pcc-af sessions [full | summary] [all] [apn | call-id *call_id* **| ip-address** *pcc_af_ip_address* **| service** *pcc_af_svc_name* **| sipuri** *sip_uri* **]] [| { grep** *grep_options* **| more }]**

full

Displays the full information of specific registered IP Connectivity Access Network (IP-CAN) session(s) on a PCC-AF service instance running on system. Display can be filtered based on given filtering criteria.

summary

Displays summarized information for specific registered IP-CAN session(s) on a PCC-AF service instance running on system. Display can be filtered based on given filtering criteria.

all

Displays summarized or full information for all registered IP-CAN session(s) on a PCC-AF service instance running on system. Display can be filtered based on given filtering criteria.

apn *apn_name*

Displays information for PCC-AF service sessions connected via an existing APN at the Policy and Charging Enforcement Function (PCEF).

ip-address *pcc_af_ip_address*

Filters the display of full or summarized session statistics for IP-CAN session(s) based on the IP address of a registered PCC-AF server on a PCC-AF service instance.
pcc_af_ip_address is an IP address expressed in IPv4 dotted-decimal or IPv6 colon-separated notation.

call-id *call_id*

Filters the display of full or summarized session statistics for IP-CAN session(s) based on the registered call ID on a PCC-AF service instance for the IP-CAN session subscriber in 8-digit hexadecimal format.

pcc-af-service *pcc_af_svc_name*

Filters the display of session statistics for a registered IP-CAN session(s) based on an existing PCC-AF service name specified as an alphanumeric string of 1 through 63 characters.

sipuri *sip_uri*

Displays summarized or full information for IP-CAN session(s) based on the SIP-URI on a PCC-AF service instance.
sip_uri is the Session Initiation Protocol (SIP) addressing schema to call another person. It resembles an e-mail address and is written in the SIP URI format as *sip:x@y:Port* format, where *x*=Username and *y*=host (domain or IP)

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to view the session statistics of all or specific registered IP-CAN session(s) or in selected part of user session for PCC-AF services configured and running on this system.

Example

The following command displays the summarized session statistics for all registered IP-CAN sessions on the PCC-AF service named *pccAF1*:

```
show pcc-af sessions summary all service pccAF1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pcc-policy service

Displays the statistical and configuration information of configured PCC-Policy services configured in a context.

Product

IPCF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show pcc-policy service [statistics] { all | name *pcc_plcy_svc_name* **| summary } [| { grep** *grep_options* **| more }]**

---

all

all: displays information for all configured PCC-Policy services.

---

name *pcc_plcy_svc_name*

Displays information for an existing PCC-Policy service specified as an alphanumeric string of 1 through 79 characters.

---

statistics

Displays statistical information for a specific or all PCC-Policy services configured in a context.

---

summary

Displays summarized output for this command.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display the statistical and configuration information of configured PCC-Policy services configured in a context.
Display can further be filtered for specific PCC-Policy service name or summarized output of the command.

Example

The following command displays the information for the PCC-Policy service named *pcc_policy1* in summarized output:

```
show pcc-policy service name pcc_policy1 summary
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pcc-policy session

Displays active/dormant session information about PCC-Policy service instances configured and running on this system based on different filter criteria.

Product

IPCF

Privilege

Inspector

Syntax

show pcc-policy sessions [full | summary] [all] [apn | call-id *call_id* **| imsi** *imsi_id* **| ip-address** *pcc_pcef_ip_address* **| service** *pcc_plcy_svc_name* **]] [| { grep** *grep_options* **| more }]**

full

Displays full information for a specific registered IP Connectivity Access Network (IP-CAN) session(s) on a PCC-Policy service instance running on system. Display can be filtered based on given filtering criteria.

summary

Displays summarized information for a specific registered IP-CAN session(s) on a PCC-Policy service instance running on system. Display can be filtered based on given filtering criteria.

all

Displays summarized or full information for all registered IP-CAN session(s) on a PCC-Policy service instance running on system. Display can be filtered based on given filtering criteria.

apn *apn_name*

Displays information for PCC-Policy service sessions connected via an existing APN on the PCEF.

imsi *imsi_id*

Displays summarized or full information for IP-CAN session(s) based on the International Mobile Subscriber Identity (IMSI) of a subscriber in a PCC-Policy service instance.
imsi_id is the IMSI and must be a 15-character field which identifies the subscriber's home country and carrier.

ip-address *pcc_pcef_ip_address*

Filters the display of full or summarized session statistics for IP-CAN session(s) based on the IP address of the registered PCEF node specified in IPv4 dotted-decimal or IPv6 colon-separated notation.

call-id *call_id*

Filters the display of full or summarized session statistics display for an IP-CAN session(s) based on the registered call ID in a PCC-Policy service instance.
call_id must be an existing call identifier in the IP-CAN session subscriber expressed in 8-digit hexadecimal format.

pcc-policy-service *pcc_plcy_svc_name*

Filters the display of session statistics for registered IP-CAN session(s) based on an existing PCC-Policy service name specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to view the session statistics for all or a specific registered IP-CAN session(s) for PCC-Policy services configured and running on this system.

Example

The following command displays summarized session statistics for all registered IP-CAN sessions on the PCC-Policy service named *pccPolicy1*:

```
show pcc-policy sessions summary all service pccPolicy1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pcc-service

Displays the configuration information for Policy and Charging Control (PCC) services configured in a context.

Product

IPCF

Privilege

Security Administrator Operator, Inspector

Syntax

show pcc-service { summary | all | service-name *pcc_svc_name* **} [| { grep** *grep_options* **| more }]**

all

all: displays information for all configured PCC services.

service-name *pcc_svc_name*

Displays information for an existing PCC service specified as an alphanumeric string of 1 through 79 characters.

summary

Displays the summarized output of this command.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display statistical and configuration information for configured PCC services in a context.
Display can further be filtered for a specific PCC- service name.

Example

The following command displays the information for the PCC service named *pcc_svc1*:

```
show pcc-service service-name pcc_svc1 summary
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pcc-service session

Displays active/dormant session information about Policy and Charging Control (PCC) service instances configured and running on this system based on different filter criteria.

Product

IPCF

Privilege

Inspector

Syntax

show pcc-service sessions [full | summary] [all] [call-id *call_id* **| instance** *instance_id* **| service-name** *pcc_svc_name* **]] [| { grep** *grep_options* **| more }]**

full

Displays full information for a specific registered IP Connectivity Access Network (IP-CAN) session(s) in a PCC service instance running on system. Display can be filtered based on given filtering criteria.

summary

Displays summarized information for a specific registered IP-CAN session(s) in a PCC service instance running on system. Display can be filtered based on given filtering criteria.

all

Displays summarized or full information for all registered IP-CAN sessions on a PCC service instance running on system. Display can be filtered based on given filtering criteria.

instance *instance_id*

Displays summarized or full information for an IP-CAN session(s) based on the PCC service instance identifier on an IPCF/PCRF node specified as an integer from 1 through 512.

service-name *pcc_svc_name*

Filters the display of session statistics display of registered IP-CAN session(s) based on an existing PCC service name specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to view session statistics for all or a specific registered IP-CAN session(s) in PCC services configured and running on this system.

Example

The following command displays summarized session statistics for all registered IP-CAN sessions in the PCC service named *pccsvc1*:

```
show pcc-service sessions summary service-name pccsvc1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pcc-service statistics

Displays the statistical information for Policy and Charging Control (PCC) services configured in a context.

Product

IPCF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show pcc-service statistics { all | service-name *pcc_svc_name* **[profile-name** *pcc_profile_name* **] } [| { grep** *grep_options* **| more }]**

all

Displays statistical information for all configured PCC services on a system.

service-name *pcc_svc_name*

Displays information for an existing PCC service specified as an alphanumeric string of 1 to 79 characters. It can be further filtered by the PCC profile name used in an IP-CAN session.

profile-name *pcc_profile_name*

Displays information for an existing PCC profile in an IP-CAN session.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display the statistical information for PCC services configured in a context.
Display can further be filtered for a specific Profile name used in a session.

Example

The following command displays the information for the PCC service named *pcc_svc1* using PCC profile named *pcc_profile_default*:

```
show pcc-service statistics service-name pcc_svc1 profile-name
pcc_profile_default
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pcc-sp-endpoint

Displays statistical and configuration information for a configured PCC Sp-Endpoint instance in a context.

Product

IPCF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show pcc-sp-endpoint [statistics] [all | name *sp_endpt_name* **] [| { grep** *grep_options* **| more }]**

all

Displays statistical information for all configured PCC Sp-Endpoint instances on a system.

name *sp_endpt_name*

Displays information for an existing PCC Sp-Endpoint instance specified as an alphanumeric string of 1 through 79 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display statistical information for a configured PCC Sp-Endpoint instance in a context. Display can further be filtered for a specific PCC Sp-Endpoint instance used in a session.

Example

The following command displays statistical information for the PCC Sp-Endpoint instance named *Sp_Intf1*:

```
show pcc-sp-endpoint statistics name Sp_Intf1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pcc-sp-endpoint connection

Displays statistical and configuration information for an Sp interface connection in a PCC Sp-Endpoint instance.

Product

IPCF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show pcc-sp-endpoint connection [ all | name sp_endpt_name [ peer sp_peer_name ] ] [ | { grep grep_options | more } ]
```

all

Displays statistical information for all configured PCC Sp-Endpoint instances on a system.

name *sp_endpt_name*

Displays information for an existing PCC Sp-Endpoint instance specified as an alphanumeric string of 1 through 79 characters. It can further be filtered with an Sp Endpoint peer (SSC/SPR) name used for the IP Connectivity Access Network (IP-CAN) session.

peer *ssc_name*

Displays information only for the PCC Sp-Endpoint instance within an existing Subscriber Service Controller/Subscriber Profile Repository (SSC/SPR) as a peer for an IP-CAN session.
ssc_name is the name of the SSC/SPR node used by the Sp Endpoint interface.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display statistical information for Sp interface connections in PCC Sp-Endpoint instances.
Display can further be filtered for a specific peer name (SSC/SPR).

Example

The following command displays the Sp interface connection related statistical information for the PCC Sp-Endpoint instance named *Sp_Intf1* using peer name *SSC1*:

```
show pcc-endpoint connection name Sp_Intf1 peer SSC1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pdg-service

Displays configuration information about Packet Data Interworking Function (PDIF) services configured on the system.

Product

PDG/TTG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show pdg-service { all | name *service_name* **}**

all

Displays information for all configured Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) services.

name *service_name*

Displays information only for an existing PDG service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display information for PDG services.

Example

The following command displays available information for all active PDG services:

```
show pdg-service all
```

show pdg-service statistics

Displays statistics for the Packet Data Gateway/Tunnel Termination Gateway (PDG/TTG) since the last **restart** or **clear** command. The output includes the number of each type of Extensible Authentication Protocol (EAP) messages.

Product

PDG/TTG

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show pdg-service statistics [name *service_name* **| peer-address** *ipv4_address* **]**

name *service_name*

Displays statistics for an existing PDG service specified an alphanumeric string of 1 through 63 characters.

peer-address *ipv4_address*

Displays statistics for a specific subscriber with the WLAN IP address specified in IPv4 dotted-decimal notation.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display PDG service statistics.

Example

The following command displays statistics for all active PDG services:

```
show pdg-service statistics
```

show pdif-service

Displays configuration information about Packet Data Interworking Function (PDIF) services configured on the system.

Product

PDIF

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show pdif service { all [counters] | name *name* **[counters] | statistics [name** *name* **| peer-address** *address* **] } [| { grep** *grep_options* **| more }]**

all [counters]

Displays configuration information and statistical counters for all PDIF services in the system.

name *name* **[counters]**

Displays configuration information and statistical counters for an existing PDIF service specified as an alphanumeric string of 1 through 63 characters.

statistics [name *name* **| peer-address** *address* **]**

name *name*: Displays service statistics for a an existing PDIF service specified as an alphanumeric string of 1 through 63 characters.
peer-address *address*: Displays service statistics for a peer server IP address specified in IPv4 dotted-decimal notation.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display configuration information and statistics about PDIF services on the system.

Example

The following example displays configuration information about a PDIF service named *pdif23*:

```
show pdif service name pdif23
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show pdsn-service

Displays information for configured packet data services in the current context.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show pdsn-service { all | name pdsn_name } [ pcf-status [ address ip_address | filter [
all | icmp-monitored | no-calls | summary | up ] ] ] [ | { grep grep_options | more } ]
```

all | name *pdsn_name*

all: Displays information for all configured packet data services.
name *pdsn_name*: Displays information only for an existing PDSN service specified as an alphanumeric string of 1 through 79 characters.

pcf-status [address *ip_address* **| filter [all | icmp-monitored | no-calls | summary | up]]**

pcf-status: Displays summary information for all Packet Control Functions (PCFs).
address *ip_address:* Only lists information for the PCF with the IP address specified in IPv4 dotted-decimal notation.
filter: Filters the output so only the specified information is displayed. If a filter is specified with no keywords, summary information for all PCFs is displayed.

- **all**: Displays information for all the PCFs
- **icmp-monitored**: Displays information only for PCFs which are ICMP monitored
- **no-calls**: Displays information only for PCFs which have no active sessions
- **summary**: Displays only a summary of the status of the PCFs
- **up**: Displays information only for PCFs which are alive

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Show the PDSN service information for standard system monitoring or troubleshooting.

Example

The following will display the information for all configured services and *sampleService*, respectively:

```
show pdsn-service all

show pdsn-service name sampleService
```

show pgw-service

Displays configuration information for PDN Gateway (P-GW) services on this system.

Product

P-GW

Privilege

Inspector

Syntax

```
show pgw-service { all | name service_name | statistics { all | name service_name } [
verbose ] } [ | { grep grep_options | more } ]
```

all

Displays configuration information for all P-GW services configured on this system.

name *service_name*

Displays configuration information for an existing P-GW service specified as an alphanumeric string of 1 through 63 characters.

statistics { all | name *service_name* **} [verbose]**

Displays P-GW service statistics.
all: Displays statistics for all P-GW services on the system.
name *service_name*: Displays statistics for an existing P-GW service specified as an alphanumeric string of 1 through 63 characters.
If **verbose** is also specified, the information is displayed in more detail.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to view configuration information for P-GW services on this system.

Example

The following command displays service statistics for the P-GW service named *pgw1*:

```
show pgw-service name pgw1
```

show port

Displays information on configured parameters and operational statistics for physical and logical ports in the system.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show port { datalink counters [*slot/port* **] | info [** *slot/port* **] [vlan** *vlan_id* **] | npu counters [** *slot/port* **[tagged | untagged | vlan** *tag_id* **]] | table | utilization table } [| { grep** *grep_options* **| more }]**

---

datalink counters *slot/port*

Displays the information for all data links or only the one specified by the slot/port location of a previously configured port.

---

info [*slot/port* **] [vlan** *vlan_id* **]**

Displays detailed information for all ports within the chassis or only the one specified by slot/port location of a previously configured port.
vlan *vlan_id*: Displays detailed information about all Virtual Local Area Networks (VLANs) in the port/slot. If the optional vlan_id is not specified, this keyword displays port information for all VLANs in the slot/port location.

---

npu counters [*slot/port* **[tagged | untagged | vlan** *tag_id* **]] | bound | unbound]**

Displays the information for Network Processing Unit (NPU) ports. The information for all ports is output or only the one specified by the lsot/port location of a previously configured port.
tagged: Display statistics for all tagged packets.
untagged: Display statistics for all untagged packets.
vlan *tag_id*: Display NPU counters for a previously configured VLAN ID.
bound: Displays individual and cumulative NPU port counters for the bound ports within the current context. If the command is invoked in the local context, all of the bound ports for all contexts and cumulative counter values for all contexts are displayed.
unbound: Displays individual and cumulative NPU port counters for all unbound ports within system.

---

table

Displays information for all physical ports on rear-installed cards with physical interfaces.

---

utilization table

Shows average port utilization in Mbps. The output is a table that lists the current utilization average, a 5-minute average, and a 15-minute average, for all enabled ports.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.

For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Display port information for troubleshooting of network communications by viewing statistics and configuration information for physical ports.

Example

The following displays detailed information for port 1 in slot 17:

```
show port info 17/1show port table
```

The following displays information for the data link port 33/1:

```
show port datalink counters 33/1
```

```
show port npu counters 33/1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show power

Displays information about the power on/off status of individual cards and the operating status of installed power filter units.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show power [all | chassis | *card_num* **] [| { grep** *grep_options* **| more }]**

all | chassis | *card_num* **]**

all: Displays power on/off state for all cards in the chassis.
chassis: Displays the operating status of installed power filter units. This is the default setting.
card_num: Displays the power on/off state for a single card specified an integer from 1 through 48.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

View power source information to quickly check the power for all cards within a chassis.

Important: On some platforms, only **show power** is supported with no other keywords or variables.

Example

The following displays power supply status for the chassis:

```
show power
```

The following command displays the power status for all slots:

```
show power all
```

show ppp

Displays the point-to-point protocol (PPP) information, detailed or summarized, for one or all connections by the use of filtering options.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show ppp { [counters | full | summary] { all | callid *call_id* **| imsi** *id* **| msid** *ms_id* **| username** *user_name* **} | statistics [pcf-address [** *pcf_ip_addr* **| all] | pdsn-service** *pdsn_name* **] } [| { grep** *grep_options* **| more }]**

counters | full | summary

Filters the output for the level and type of information with the options described below.
counters: Displays PPP statistics.
full: Displays all available information.
summary: Displays only a summary of available information.

all | callid *call_id* **| imsi** *imsi_id* **| msid** *ms_id* **| username** *user_name* **}]**

all: Displays all available information.
callid *call_id*: Displays PPP information only for the call ID specified as a 4-digit hexadecimal number.
imsi *id*: Displays PPP information only for the subscriber with the specified IMSI (International Mobile Subscriber Identity). *id* is a 15-digit field which identifies the subscriber's home country and carrier.
msid *ms_id*: Displays information for a mobile subscriber ID specified as 7 to 16 digits for an IMSI, MIN, or RMI.
username *user_name*: Displays user PPP information for the specified username.

statistics [pcf-address [*pcf_ip_addr* **| all] | pdsn-service** *pdsn_name* **]**

Displays statistics for all packet data services.
pcf-address [*pcf_ip_addr* **| all**] : Displays statistics only for the time the session is connected to the specified PCF (Packet Control Function) or for all PCFs. *pcf_ip_addr* must be specified using IPv4 dotted-decimal notation.
pdsn-service *pdsn_name*: Display statistics only for an existing PDSN service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

View Point-to-Point Protocol information to support troubleshooting subscriber connections by viewing information on PPP connections for a specific subscriber.

Example

The following displays the PPP summary for all connections.

```
show ppp summary all
```

The following outputs the point-to-point detailed information for the user *user1*.

```
show ppp full username user1
```

The following command displays the standard information for the call with ID *FF0E11CD*.

```
show ppp callid ff0e11cd
```

The following command displays the PPP statistics for *pdsn1*.

```
show ppp statistics pdsn-service pdsn1
```

The following command provides summarized information for the PPP statistics.

```
show ppp
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show prepaid 3gpp2

Displays prepaid accounting information for all services or only the service specified.

Product

PDSN, GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show prepaid 3gpp2 statistics all [| { grep *grep_options* **| more }]**

show prepaid 3gpp2 statistics { ggsn-service | ha-service | lns-service | pdsn-service { all | name *service_name* **} [| { grep** *grep_options* **| more }]**

show prepaid 3gpp2 statistics per-service-summary } [| { grep *grep_options* **| more }]**

all

Displays prepaid statistics for all services.

ggsn-service

Displays statistics for GGSN service(s).

ha-service

Displays statistics for HA service(s).

lns-service

Displays statistics for LNS service(s).

pdsn-service

Displays statistics for PDSN service(s).

{ all | name *service_name* **}**

all: Displays statistics for all services of the specified type.
name *service_name*: Displays statistics for an existing service specified an alphanumeric string of 1 through 63 characters.

per-service-summary

Displays prepaid statistics per service summary for all services.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter in the *Command Line Interface Reference*.

Usage

Displays Pre-paid statistics for a particular named service or for all services.

Example

To display statistics for a PDSN service named *PDSN1*, enter the following command:

```
show prepaid 3gpp2 statistics pdsn-service name PDSN1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show prepaid wimax

This command displays prepaid WiMAX accounting information for all services or only the service specified.

Product

ASN-GW

Privilege

Inspector

Syntax

show prepaid wimax statistics { all | asngw-service { all | name *service_name* **} | ha-service { all | name** *service_name* **} | per-service-summary } [| { s** *grep_options* **| more }]**

all

This keyword displays prepaid statistics for all services.

asngw-service

Displays prepaid statistics for Access Service Network-Gateway (ASN-GW) service(s).

ha-service

Displays prepaid accounting statistics for Home Agent (HA) service(s).

{ all | name *service_name* **}**

all: Displays statistics for all services of the specified type.
name *service_name*: Displays statistics for an existing service specified as an alphanumeric string of 1 through 63 characters.

per-service-summary

Displays prepaid statistics per service summary for all services.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display prepaid WiMAX accounting statistics for named service or for all services.

Example

The following command displays prepaid WiMAX accounting statistics for an ASN-GW service named *asn1*:

```
show prepaid wimax statistics asngw-service name asn1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show profile-id-qci-mapping

Displays QoS Class Identifier-Radio Access Network (QCI-RAN) mapping tables configured on this system.

Product

HSGW

Privilege

Inspector

Syntax

show profile-id-qci-mapping table { all | name *table_name* **} [| { grep** *grep_options* **| more }]**

all

Displays information for all QCI-RAN mapping tables configured on this system.

name *table_name*

Displays information for an existing QCI-RAN table specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of **grep** and **more**, refer to the *Regulating a Command's Output* section in the *Command Line Interface Overview* chapter.

Usage

Use this command to display the contents of a specific QCI-RAN mapping table or all mapping tables configured on this system.

Example

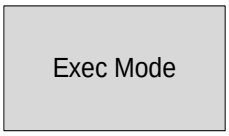
The following command displays the contents of a QCI-RAN mapping table named *table1*:

```
show profile-id-qci-mapping table name table1
```

Chapter 118
Exec Mode Show Commands (Q-S)

This chapter includes the commands **qci-qos-mapping** through **show system uptime**.

The Exec Mode is the initial entry point into the command line interface system. Exec mode **show** commands are useful in troubleshooting and basic system monitoring.



show qci-qos-mapping

Displays QoS Class Identifier-Quality of Service (QCI-QoS) mapping tables configured on this system.

Product

HSGW, P-GW, S-GW

Privilege

Inspector

Syntax

show qci-qos-mapping table { all | name *table_name* } [| { *grep_options* **| more** }]

all

Displays information for all QCI-QoS mapping tables configured on this system.

name *table_name*

Displays information for an existing QCI-QoS mapping table specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display the contents of a specific QCI-QoS mapping table or all mapping tables configured on this system.

Example

The following command displays the contents of a QCI-QoS mapping table named *table1*:

```
show qci-qos-mapping table name table1
```

show qos npu inter-subscriber traffic

Displays configuration information pertaining to Network Processing Unit (NPU) QoS priority queue bandwidth allocation and sharing.

Product

GGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show inter-subscriber traffic { bandwidth | bandwidth-sharing }
```

bandwidth

Displays NPU QoS priority queue bandwidth allocation configuration information.

bandwidth-sharing

Displays NPU QoS priority queue bandwidth sharing configuration information.

Usage

Use this command to verify configuration information and for troubleshooting.
When the bandwidth keyword is used, the output is a table showing the configuration status, the priority queue, and the bandwidth allocation per DSCP.
When the bandwidth-sharing keyword is used, the output of is a table displaying the bandwidth sharing configuration per processing card slot/CP number.
For additional information on the NPU QoS functionality, refer to the *System Administration Guide*.

Important: This functionality is not supported for use with the PDSN at this time.

show radius

Displays and statistic information for RADIUS accounting and/or authentication.

Product

PDSN, HA, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show radius { accounting servers | authentication servers } [detail] [admin-status { enabled | disabled }] [| { grep *grep_options* **| more }] [radius group** *group_name* **[detail] [| { grep** *grep_options* **| more }]]**

accounting servers

Lists information for configured accounting servers and their current state.

authentication servers

Lists information for configured authentication servers and their current state.

[detail]

Displays historical state information for configured servers of the specified type.

admin-status { enabled | disabled }

Displays information for accounting and/or authentication servers with an administrative status of "enabled" or "disabled".

radius group *group_name*

Displays the authentication/authorization RADIUS server group information for an existing server group specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Display the RADIUS server information as part of periodic monitoring of the health of the system.

Example

The following displays the information on configured accounting servers:

```
show radius accounting server
```

The following command displays detailed information for RADIUS accounting servers:

```
show radius accounting servers detail
```

The following command displays detailed information for RADIUS server group *star1* used for authentication:

```
show radius authentication servers radius group star1 detail
```

The following command displays detailed information for RADIUS server group *star1* used for accounting:

```
show radius accounting servers radius group star1 detail
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show radius charging servers

This command displays the RADIUS authentication and accounting servers or server group that are configured for use by charging services.

Product

PDSN, HA, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show radius charging servers [radius group *group_name* **] [| { grep** *grep_options* **| more }]**

radius group *group_name* **all**

Displays all RADIUS counter information for an existing server group configured for use by charging services. *group_name* is specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display information about RADIUS servers or server group configured for use by Charging Services.

Example

The following command displays RADIUS servers configured for Charging Services:

```
show radius charging servers
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show radius client

DIsplays information about the RADIUS client configured on the system.

Product

PDSN, HA, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show radius client status [| { grep *grep_options* **| more }]**

status

Displays a status summary for the RADIUS client.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Configuring the RADIUS protocol on the system enables RADIUS client functionality. This command is displays information pertaining to the status of the client.

Example

The following command displays detailed information pertaining to the system's RADIUS client:

```
show radius client status
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show radius counters

Displays RADIUS server and statistic information for accounting and/or authentication.

Product

PDSN, HA, GGSN, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show radius counters { all | radius group *group_name* **all | server** *ip_address* **[port** *number* **] | summary [all-contexts [verbose]] } [| { grep** *grep_options* **| more }]**

---

counters { all | server *ip_address* **[port** *number* **] }**

all: Displays statistics for all servers.
server *ip_address*: Displays statistics for the server specified by its IPv4 address.
port *number*: Displays statistics for a port on the server specified as an integer from 0 through 65535.

---

radius group *group_name* **all**

Displays all RADIUS counter information for an existing server group specified as an alphanumeric string of 1 through 63 characters.
all: Displays statistics for all servers.

---

summary [all-contexts [verbose]]

Displays a summary of RADIUS statistics for all the RADIUS servers configured in a specific context.
all-contexts: Displays a summary of RADIUS statistics for all RADIUS servers configured in all context. If **verbose** is also specified, the information is displayed in more detail.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Display the RADIUS server information as part of periodic monitoring of the health of the system.

Example

The following command displays detailed information pertaining to the RADIUS server group *star1* with in current context:

```
show radius counters radius group star1 all
```

The following displays the statistics for the server with IP address *10.2.3.4*, then just port *7777*, followed by **all** services.

```
show radius counters server 10.2.3.4
```

```
show radius counters server 10.2.3.4 port 7777

show radius counters all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show resources

Displays the resource information by CPU or session.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show resources { cpu | npu | session } [ | { grep grep_options | more } ]
```

cpu | npu | session

cpu: Displays resource information by CPU.
npu: Displays resource information by network processing unit (NPU).
session: Displays resource information by session.

| { grep *grep_options* | more }

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View resource utilization as part of troubleshooting systems which appear sluggish or are having excessive connection timeouts or other connection issues.

Example

The following display the resource information by CPU and session, respectively.

```
show resources cpu

show resources session
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show rohc counters

Displays RObust Header Compression (ROHC) counters for all active calls.

Product

PDSN, HSGW, ASN-GW

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show rohc counters [all | callid *call_id* **| imsi** *imsi_num* **| ip-address** *ip_addr* **| msid** *msid_num* **| username** *user_name* **] [| { grep** *grep_options* **| more }]**

all

Displays all information.

callid *call_id*

Displays the information only for the call ID specified as a 4-byte hexadecimal number.

imsi *imsi_num*

Displays information for the specified IMSI (International Mobile Subscriber Identity). The IMSI is an up to 15-digit field which identifies the subscriber's home country and carrier: 3 digits of Mobile Country Code (MCC), 2 or 3 digits of Mobile Network Code (MNC), followed by the Mobile Subscriber Identification Number MSIN. Example: 123-45-678910234. May also be entered as 12345678910234.

ip-address *ip_addr*

Displays information only for the mobile subscriber IP address specified in IPv4 dotted-decimal or IPv6 colon-separated notation.

msid *msid_num*

Displays information only for a mobile subscriber ID from 7 to 16 digits for an IMSI, MIN, or RMI.

username *user_name*

Displays radio-packet (R-P) interface information only for a specified username.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display ROHC counters for all active calls.

Example

The following command displays ROHC counters for all active calls:

```
show rohc counters all
```

show rohc statistics

Displays statistics and counters for RObust Header Compression (ROHC) IP header compression.

Product

PDSN, HSGW, and ASN-GW.

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show rohc statistics [ pdsn-service pdsnsvc_name ] [ asngw-service asngwsvc name ] [
hsgw-service hsgwsvc_name ] [ | { grep grep_options | more } ]
```

Important: Keywords available for this command are license-driven. For example, if a PDSN license is loaded, the **pdsn-service** option is visible.

pdsn-service *pdsnsvc_name*

Displays ROHC statistics and counters for the an existing PDSN service specified as an alphanumeric string of 1 through 63 characters.

asngw-service *asngwsvc_name*

Displays ROHC statistics and counters for an existing ASN-GW service specified as an alphanumeric string of 1 through 63 characters.

hsgw-service *hsgwsvc_name*

Displays ROHC statistics and counters for an existing HSGW service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display ROHC statistics for all services or for a specific ASN-GW, PDSN, or HSGW.

Example

The following command displays ROHC statistics for the PDSN service named pdsn1:

```
show rohc statistics pdsn-service pdsn1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show route-map

Displays entries for all route maps or a specific route map.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show route-map [name *route-map name* **] [| { grep** *grep_options* **| more }]**

name *route-map name*

Displays information for a route-map specified as an alphanumeric string of 1 through 79 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to see the rules configured in all route-maps for the current context.

Example

The following command displays the route-map information for prefix list *Prefix100*:

```
show route-map Prefix100
```

Refer to the **match** and **set** command descriptions in the *Route-map Configuration Mode Commands* chapter for descriptions of the various entries listed.

show rp

Displays radio-packet (R-P) interface statistics using the filtering options specified.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show rp [counters | full | summary] { all | callid *call_id* **| msid** *ms_id* **| peer-address** *peer_ip_address* **| username** *user_name* **} [| { grep** *grep_options* **| more }]**

counters | full | summary

Provides an optional modifier to the output for the desired level and type of information.
counters: Displays R-P protocol statistics.
full: Displays all available information.
summary: Displays only a summary of available information.
These options are not available in conjunction with the keywords **statistics** or **service-option statistics**.

all | callid *call_id* **| msid** *ms_id* **| peer-address** *peer_ip_address* **| username** *user_name*

all: Displays all R-P information.
callid *call_id*: Displays only the information for the call ID specified as a 4-digit hexadecimal number.
msid *ms_id*: Displays information only for a mobile subscriber ID specified by 7 to 16 digits for an IMSI, MIN, or RMI.
peer-address *peer_ip_address*: Displays R-P information for the peer IP address of the PCF specified in IPv4 dotted-decimal notation.
username *user_name*: Displays R-P information for the specified username.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View the R-P interface statistics for the current context.

Example

The following displays the summary for all connections.

```
show rp summary all
```

The following outputs the R-P interface detailed information for the user *isp1user1*.

```
show rp full username isp1user1
```

The following command displays the standard information for the call with ID *FF0E11CD*.

```
show rp callid ff0e11cd
```

The following displays the statistics summary for the R-P facility.

```
show rp
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show rp service-option

Displays the radio-packet (R-P) service option statistics using the filtering options specified.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show rp service-option statistics [number *svc_option_num* **| pdsn-service** *pdsn_name* **] [| { grep** *grep_options* **| more }]**

---

number *svc_option_num* **| pdsn-service** *pdsn_name*

Default: display statistics for all service option numbers and associated packet data services.
number *svc_option_num*: Displays statistics for the specified service option number.
pdsn-service *pdsn_name*: Displays statistics for the specified packet data service.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View the R-P service option statistics for the current context.

Example

The following displays the statistics for all service options.

```
show rp service-option statistics
```

The following displays the statistics for service option *5*.

```
show rp service-option statistics number 5
```

The following command displays the statistics for all service options in collected for the packet data service *sampleService*.

```
show rp service-option statistics pdsn-service sampleService
```

show rp statistics

Displays the radio-packet (R-P) protocol statistics using the filtering options specified.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show rp statistics [ hsgw-service hsgw-name | pcf-summary [  wf1 ] | pdsn-service
pdsn_name | peer-address { peer_address | all } ] [ include-bcmcs ] [ verbose ] [ | {
grep grep_options | more } ]
```

hsgw-service *hsgw_name*

Specifies an eHRPD Serving Gate Way service followed by the name of an HSGW service specified as an alphanumeric string of 1 through 63 characters.

pcf-summary [wf1]

Displays a session summary of Packet Control Function (PCF) statistics.

The **wf1** option displays PCF statistics in wide-format number 1.

pdsn-service *pdsn_name*

Displays the statistics information for the pdsn-service specified as an alphanumeric string of 1 through 63 characters.

peer-address { *peer_address* | all }

- *peer_address*: Displays statistics only for the peer specified by its IP address in IPv4 dotted-decimal notation.
- **all**: Displays statistics for all peers.

verbose

Displays more detailed statistics.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View the R-P statistics for the current context.

Example

The following displays all collected R-P statistics.

```
show rp statistics
```

The following displays the R-P statistics associated with the peer address *10.2.3.4*.

```
show rp statistics peer-address 10.2.3.4
```

The following command displays the R-P statistics for the packet data service *PCFnet*.

```
show rp statistics pdsn-service PCFnet
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show rsvp counters

Displays Resource Reservation Protocol (RSVP) counters using the filtering options specified.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show rsvp counters [all | callid *call_id* **| msid** *ms_id* **| username** *user_name* **]**

all | callid *call_id* **| msid** *ms_id* **| username** *user_name*

all: Displays all RSVP information.
callid *call_id*: Displays information only for the call ID specified as a 4-digit hexadecimal number.
msid *ms_id*: Displays information for a mobile subscriber ID specified a string of 7 to 16 digits for an IMSI, MIN, or RMI.
username *user_name*: Displays RSVP information only for the specified username.

Usage

View the RSVP counters for the current context.

Example

The following displays all collected RSVP counters.

```
show rsvp counters all
```

show rsvp statistics

Displays Resource Reservation Protocol (RSVP) statistics using the filtering options specified.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show rsvp counters [pdsn-service *service* **| sessmgr instance** *instance* **]**

pdsn-service *service* **| sessmgr instance** *instance*

pdsn-service *service*: Displays statistics for the service specified as an alphanumeric string of 1 through 63 characters.
sessmgr instance *instance*: Displays statistics for the specified session manager instance.

Usage

View the RSVP statistics for the current context.

Example

The following displays collected RSVP statistics for a *sampleService*.

```
show rsvp statistics pdsn-service sampleService
```

show sccp-network

Displays SS7 Signaling Connection Control Part (SCCP) network configuration and status information.

Product

SGSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show sccp-network { *ntwk_index* | all } [status [all | dpc]]

ntwk_index

Displays configuration and status information for the SSCP network configuration with the network index specified as an integer from 1 through 12.

all

Displays all available configuration and status information for all SSCP networks.

status all

Displays all status information for specified SCCP networks.

status dpc

Displays status information for the device in the SCCP network identified by the destination point-code (DPC).

Usage

Use this command to display global SCCP statistics or to display SCCP statistics for a specified service or network.

Example

The following command displays global SCCP statistics:

```
show sccp-network all
```

The following command displays information for an SCCP network configuration with the network index of *1*:

```
show sccp-network 1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show sccp statistics

Displays SS7 Signaling Connection Control Part (SCCP) statistics for services that use the SCCP protocol.

Product

SGSN

Privilege

Inspector

Syntax

show sccp statistics [iups-service *iups_srvc_name* **| map-service** *map_srvc_name* **| sccp-network** *ntwk_index* **[dpc** *dpc* **[ssn** *ssn* **] | global-title-translation { address-map instance** *add_map_inst* **| association instance** *assoc_inst* **} [sessmgr instance** *sessmgr_inst* **]] [| { grep** *grep_options* **| more }]**

iups-service *iups_srvc_name*

Displays SCCP protocol statistics for an existing IuPS service in the current context specified as an alphanumeric string of 1 through 63 characters.

map-service *map_srvc_name*

Displays SCCP protocol statistics for the an existing Mobile Application Part (MAP) service in the current context specified as an alphanumeric string of 1 through 63 characters.

sccp-network *ntwk_index*

Displays SCCP protocol statistics for the SSCP network configuration with a network index specified as an integer from 1 through 12.
The following filters can be added to fine tune the display of SCCP network statistics:

- **dpc** *dpc*: Enter a standard pointcode address to limit the display of SCCP network statistics to those for the identified DPC.
- **ssn** *ssn*: Enter an integer from 1 to 255 to limit the display of SCCP network statistics to those for the identified subsystem number.
- **global-title-translation address-map instance** *add_map_inst*: Enter an integer from 1 to 4096 to limit the display of SCCP network statistics to those for the identified GTT address-map.
- **global-title-translation association instance** *assoc_inst*: Enter an integer from 1 to 16 to limit the display of SCCP network statistics to those for the identified GTT association.
- **sessmgr instance** *sessmgr_inst*: Enter an integer from 1 to 384 to limit the display of SCCP network statistics to those for the identified session manager.

Usage

Use this command to display global SCCP statistics or to display SCCP statistics for a specified service or SCCP network.

Example

The following command displays global SCCP statistics:

```
show sccp statistics
```

The following command displays SCCP statistics for the IuPS service named *iups-serv1*:

```
show sccp statistics iups-service iups-serv1
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show sctp-param-template

Displays configuration information for Stream Control Transmission Protocol (SCTP) parameter templates configured on this system.

Product

MME

Privilege

Inspector

Syntax

show sctp-param-template { all | name *template_name* **} [| { grep** *grep_options* **| more }]**

all

Displays configuration information for all SCTP parameter templates configured on this system.

name *template_name*

Displays configuration information for an existing SCTP parameter template specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to view configuration information for SCTP parameter templates on this system.

Example

The following command displays configured parameters for an SCTP parameter template named *sctp_pt3*:

```
show sctp-param-template name sctp_pt3
```

show session counters historical

Displays historical information for session-related counters based on data collected in bulk statistics.

Product

All

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

```
show session counters historical { all | arrived | callops | connected | disconnected |
failed | handoff | rejected | renewal } [ all-intervals | cumulative | graph |
incremental | recent-intervals | table ]
```

all

Displays data for all counters either as a single, wide table or multiple graphs.

arrived

Displays only data for “total calls arrived” counters. This is based on the “sess-ttlarrived” statistic in the system schema.

callops

Displays data for all call operations. This is a calculated value based on the following formula:
(arrived + rejected + disconnected + failed + handoffs + renewals)

connected

Displays only data for “total calls connected” counters. This is based on the “sess-ttlconnected” statistic in the system schema.

disconnected

Displays only data for “total calls disconnected” counters. This is based on the “sess-ttldisconn” statistic in the system schema.

failed

Displays only data for “total calls failed” counters. This is based on the “sess-ttlfailed” statistic in the system schema.

handoff

Displays only data for “total handoffs” counters. This is based on the “sess-ttlhandoff” statistic in the system schema.

rejected

Displays only data for “total calls rejected” counters. This is based on the “sess-ttlrejected” statistic in the system schema.

renewal

Displays only data for "total renewal" counters. This is based on the "sess-ttlrenewal" statistic in the system schema.

Output Options

The following output options are available for this command:

- **all-intervals**Displays all available historical information from all samples. This this filter is used by default.
- **cumulative**Displays total data for all samples up to and including the last one. In this view, values increase over time.
- **graph**Displays data in graphical form.
- **incremental**Displays data changes for each specific sample. The data for each sample is the amount of change since the previous sample. This filter is used by default.
- **recent-intervals**Displays historical information for only recent samples.
- **table**Displays data in tabular form. This is the default view.

Usage

This command provides the ability to track key session-related statistic information over time. This information can be used as part of system performance monitoring and capacity planning.

Important: The information provided in the output of this command requires that bulk statistics functionary be enabled on the system. Refer to the *System Administration Guide* for more information on configuring and enabling bulk statistics support.

The output of this command displays historical data collected at various sample intervals. The interval length is 15 minutes and is not user-configurable. Up to 192 samples (two days' worth of data) are maintained.

Important: Data collection is "best-effort" over these intervals. Data is preserved on system management card switchovers. As with all counters, certain session failures can cause inaccuracies with counters, including counters which appear to go backwards.

Each sample is identified by a timestamp that displays the approximate time the data was gathered. the timestamp is in the format YYYY:MM:DD:hh:mm:ss.
Data acquired during the sample may be marked with an "S" appended to the end of the timestamp or to the counter value. The "S" indicates that the data is suspect (potentially bad). Occurrences of this result from events like changes to the real time clock, which can cause an interval to be an atypical length. Instances of suspect data should be rare. Additionally, there may be occasions in which a sample may be marked as "invalid". "invalid" identifies bad data, a situation that could result when the polling has not run long enough, or because of an unexpected error retrieving data.
Since baseline values must be obtained prior to collecting interval samples, the first interval of data will not be available until up to twice the interval period.

Example

The following command displays cumulative total calls arrived information for the most recent intervals and displays the output in graphical format:

```
show session counters historical arrived recent-intervals cummulative
graph
```

The following command displays historical data for all counters for all intervals and displays the output in tabular format:

```
show session counters historical all
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show session counters pcf-summary

Displays the Packet Control Function (PCF) summary which include the number of calls, call types, and Tx/Rx packets/octets statistics.

Product

PDSN

Privilege

Security Administrator, Administrator, Operator, Inspector

Syntax

show session counters pcf-summary [call-types | data | wf1 [pcf *pcf_address* **| [| { grep** *grep_options* **| more }]]]**

call-types

Displays the number of calls and the types of calls.

data

Displays the number of successful calls and Tx/Rx packets/octets statistics.

pcf *pcf_address*

Displays the given PCF summary for a particular address.

wf1

Displays the PCF summary in a single very wide line.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display a summary of all PCFs.

Example

```
show session counters pcf-summary
```

show session disconnect-reasons

Displays a list of the reasons for call disconnects and the number of calls disconnected for each reason.

Product

All

Privilege

Security Administrator, Administrator, Inspector, Operator

Syntax

show session disconnect-reasons [gprs-only | sgsn-only | mme-only | verbose] [| { grep *grep_options* **| more }]]**

gprs-only

Only supported on the SGSN.
This keyword limits the display to session disconnect reasons for the SGSN's 2G MM and PDP context disconnects.

sgsn-only

Only supported on the SGSN.
Displays session disconnect reasons for the SGSN's 3G MM and PDP context disconnects.

mme-only

Displays session disconnect reasons for MME call disconnects.

verbose

List all disconnect reasons even if the values are zero (0).

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display a list of the reasons why calls were disconnected.

Example

To view session disconnect statistics, enter the following command:

```
show session disconnect-reasons
```

To view a list of the disconnect reasons with verbose output, enter the following command:

```
show session disconnect-reasons verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show session duration

Displays session duration information for the current context filtered by the options specified.

Product

All

Privilege

Security Administrator, Administrator, Inspector, Operator

Syntax

show session duration [*session_filter* **] [| { grep** *grep_options* **| more }]**

session_filter

Specifies the name of the entity whose session duration information is to be filtered and displayed. This options are:

- **asn-peer-address** *ip_address*: Displays session information for the ASN GW peer whose IP address is specified in IPv4 dotted-decimal notation.
- **asngw-service** *service_name*: Displays session information for the specified ASN-GW service.
- **asnpc-peer-address** *ip_address*: Displays session information for the Access Service Network Paging Controller (ASN PC) peer whose IP address is specified in IPv4 dotted-decimal notation.
- **asnpc-service** *service_name*: Displays session information for the specified ASN PC service.
- **apn** *apn_name*: Displays session information for an existing Access Point Name (APN) specified as an alphanumeric string of 1 through 63 characters that is case sensitive.
- **cscf-service** *service_name*:Displays session information for an existing Call Session Control Function (CSCF) service specified as an alphanumeric string of 1 through 63 characters.

Important: Displays information for in-progress CSCF SIP calls only. Registrations are not considered calls.

- **dhcp-server** *dhcp_address*: Displays session information for the Dynamic Host Configuration Protocol (DHCP) server specified by its IP address in IPv4 dotted-decimal notation.
- **fa** *fa_address*: Displays session information for the foreign agent (FA) whose IP address is specified in IPv4 dotted-decimal notation.
- **fa-service** *fa_name*: Displays session information for the named foreign agent service.
- **ggsn-service** *ggsn_name*: Displays session information for an existing GGSN service specified as an alphanumeric string of 1 through 63 characters that is case sensitive.
- **gprs-only**: Limits the display to the session information for the SGSN's 2G MM and PDP contexts.
- **ha** *ha_address*: Displays session information for the home agent specified by its IP address in IPv4 dotted-decimal notation.
- **ha-service** *ha_name*: Displays session information for the named home agent (HA) service.
- **hnbgw-only**: Displays session information for the HNB-GW service related sessions instances (such as HNB, IuPS, IuCS).
- **hsgw-service** *service_name*: Displays session information for an existing HSGW service specified as an alphanumeric string of 1 through 63 characters.

- **lma-service** *service_name*: Displays session information for an existing Local Mobility Anchor (LMA) service specified as an alphanumeric string of 1 through 63 characters.
- **mme-service** *service_name*: Displays session information for an existing Mobility Management Entity (MME) service specified as an alphanumeric string of 1 through 63 characters.
- **mag-service** *service_name*: Displays session information for an existing Mobile Access Gateway (MAG) service specified as an alphanumeric string of 1 through 63 characters.
- **pcf** *pcf_address*: Displays session information for the packet control function specified by its IP address in IPv4 dotted-decimal notation.
- **pdsn-service** *pdsn_name*:Displays session information for the named packet data service.

Important: If no PCF address or PDSN service is specified, the session information for all sessions is displayed.

- **sgsn-address** *sgsn-address*: Displays session information for the SGSN specified by its IP address in IPv4 dotted-decimal notation.
- **sgsn-only**: Limits the display to the session information for the SGSN's 3G MM and PDP contexts.
- **sgw-service** *service_name*: Displays session information for an existing S-GW service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View the session information to troubleshoot subscriber problems and for general monitoring for orphaned sessions.

Example

The following commands display the duration for the session connected to the packet control function with address *10.2.3.4*, packet data service *sampleService*, and for all sessions, respectively.

```
show session duration pcf 10.2.3.4

show session duration pdsn-service sampleService

show session duration
```

show session-event-record

Displays session event module statistics and file space usage information.

Product

S-GW

Privilege

Operator

Syntax

```
show session-event-record { file-space-usage | statistics }
```

file-space-usage

Displays session event module file storage limits and capacities.

statistics

Displays session event module statistics regarding the handling and transfer of event records to an external collection server.

Usage

View the session event information to troubleshoot handling and transfer problems and for general monitoring for file storage use.

Example

The following command displays the file storage limit and use for all event modules on the system:

```
show session-event-record file-space-usage
```

show session progress

Displays session progress information for the current context filtered by the options specified.

Product

All

Privilege

Security Administrator, Administrator, Inspector, Operator

Syntax

show session progress [asn-peer-address *ip_address* **| asngw-service** *service_name* **| asnpc-service** *service_name* **| asnpc-peer-address** *ip_address* **| apn** *apn_name* **| cscf-service** *service_name* **| dhcp-server** *dhcp_address* **| fa** *fa_address* **| fa-service** *fa_name* **| ggsn-service** *ggsn_name* **| ha** *ha_adress* **| ha-service** *ha_name* **| hsgw-servie** *service_name* **| lma-service** *service_name* **| mag-service** *service_name* **| mme-address** *mme_address* **| mseg-service** *mseg_service_name* **| pcf { ** *pcf_address* **| all } | pdsn-service** *pdsn_name* **| pdsnclosedrp-service | pgw-address** *ip_address* **| sgsn-address** *sgsn_address* **| sgw-service** *service_name* **] [| { grep** *grep_options* **| more }]**

---

progress [asn-peer-address *ip_address* **| asngw-service** *service_name* **| asnpc-service** *service_name* **| asnpc-peer-address** *ip_address* **| apn** *apn_name* **| cscf-service** *service_name* **| dhcp-server** *dhcp_address* **| fa** *fa_address* **| fa-service** *fa_name* **| ggsn-service** *ggsn_name* **| ha** *ha_adress* **| ha-service** *ha_name* **| hsgw-servie** *service_name* **| lma-service** *service_name* **| mag-service** *service_name* **| mme-address** *mme_address* **| mseg-service** *mseg_service_name***| pcf { ** *pcf_address* **| all } | pdsn-service** *pdsn_name* **| pdsnclosedrp-service | pgw-address** *ip_address* **| sgsn-address** *sgsn_address* **| sgw-service** *service_name* **]**

progress: indicates session progress information is to be displayed.

- **asn-peer-address** *ip_address*: Displays session information for the Access Service network-Gateway (ASN-GW) peer specified by its IP address in IPv4 dotted-decimal notation.
- **asngw-service** *service_name*: Displays session information for the named ASN-GW service.
- **asnpc-service** *service_name*: Displays session information for the named Access Service Network Paging Controller (ASN PC) service.
- **asnpc-peer-address** *ip_address*: Displays session information for the ASN PC peer specified by its IP address in iIPv4 dotted-decimal notation.
- **apn** *apn_name*: Displays session information for an existing Access Point Name (APN) specified as an alphanumeric string of 1 through 63 characters that is case sensitive.
- **cscf-service** *service_name*: Displays session information for an existing Call Session Control Function (CSCF) service specified as an alphanumeric string of 1 through 63 characters.

Important: Displays information for in-progress CSCF SIP calls only. Registrations are not considered calls.

- **dhcp-server** *dhcp_address*: Displays session information for the Dynamic Host Configuration Protocol (DHCP) server specified by its IP address in IPv4 dotted-decimal notation.
- **fa** *fa_address*: Displays session information for the foreign agent (FA) whose IP address is specified in IPv4 dotted-decimal notation.

- **fa-service** *fa_name*: Displays session information for the named foreign agent service.
- **ggsn-service** *ggsn_name*: Displays session information for an existing GGSN service specified as an alphanumeric string of 1 through 63 characters that is case sensitive.
- **gprs-only**: Limits the display to the session information for the SGSN's 2G MM and PDP contexts.
- **ha** *ha_address*: Displays session information for the home agent specified by its IP address in IPv4 dotted-decimal notation.
- **ha-service** *ha_name*: Displays session information for the named home agent (HA) service.
- **hnbgw-only**: Displays session information for the HNB-GW service related sessions instances (such as HNB, IuPS, IuCS).
- **hsgw-service** *service_name*: Displays session information for an existing HSGW service specified as an alphanumeric string of 1 through 63 characters.
- **lma-service** *service_name*: Displays session information for an existing Local Mobility Anchor (LMA) service specified as an alphanumeric string of 1 through 63 characters.
- **mme-service** *service_name*: Displays session information for an existing Mobility Management Entity (MME) service specified as an alphanumeric string of 1 through 63 characters.
- **mag-service** *service_name*: Displays session information for an existing Mobile Access Gateway (MAG) service specified as an alphanumeric string of 1 through 63 characters.
- **pcf** *pcf_address*: Displays session information for the packet control function specified by its IP address in IPv4 dotted-decimal notation.
- **pdsn-service** *pdsn_name*:Displays session information for the named packet data service.

Important: If no PCF address or PDSN service is specified, the session information for all sessions is displayed.

- **pgw-address** *ip_address*: Displays session progress information for the P-GW specified by its IP address in IPv4 dotted-decimal notation.
- **sgsn-address** *sgsn-address*: Displays session information for the SGSN specified by its IP address in IPv4 dotted-decimal notation.
- **sgw-service** *service_name*: Displays session progress information for an existing S-GW service specified as an alphanumeric string of 1 through 63 characters.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View the session information to troubleshooting subscriber problems and for general monitoring for orphaned sessions.

Example

The following commands display the status information for the session connected to the packet control function with address *10.2.3.4*, packet data service *sampleService*, and for all sessions, respectively.

```
show session progress pcf 10.2.3.4
```

```
show session progress pdsn-service sampleService

show session progress
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show session recovery status

Displays session recovery status information for the current context filtered by the options specified.

Product

All

Privilege

Security Administrator, Administrator, Inspector, Operator

Syntax

show session recovery status [verbose] [| { grep *grep_options* **| more }]**

recovery status

Displays the current status of the system's ability to recover from a hardware or software fault that requires the recovery of home agent-based Mobile IP session(s).

verbose

Includes per-CPU Session Recovery status.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View the session information for troubleshooting subscriber problems and for general monitoring for orphaned sessions.

Example

To display the session recovery status information, enter the following command:

```
show session recovery status
```

Adding the optional verbose keyword to this command provides more details.

```
show session recovery status verbose
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show session setuptime

Displays session setup time information for all sessions or sessions associated with the specified Access Gateway (AGW).

Product

PDSN, HNB-GW, SGSN

Privilege

Operator

Syntax

show session setuptime [hnbgw-only | pcf *pcf_address* **| gprs-only | sgsn-address** *sgsn_address***| sgsn-only] [| { grep** *grep_options* **| more }]**

[hnbgw-only | mme-only | pcf pcf_address | gprs-only | sgsn-address *sgsn_address* **| sgsn-only]**

Displays the call setup times aggregated into basic ranges of time.

- **hnbgw-only**: Filters and displays the call setup information for HNB-GW calls only.
- **pcf** *pcf_address*: displays call setup data for the packet control function whose IP address is specified as *pcf_address*. *pcf_address* must be specified using IPv4 dotted-decimal notation. The call setup times for all PCFs is displayed when no specified PCF is specified.
- **gprs-only**: Displays 2G call setup data for the for the SGSN for the MM and PDP contexts.
- **sgsn-address** *sgsn_address***:** Displays call setup times for the specified SGSN. *sgsn_address* is the IP address of the SGSN and must be expressed in IPv4 dotted-decimal notation. This keyword is used by the GGSN.
- **sgsn-only**: Displays 3G call setup data for the for the SGSN for the MM and PDP contexts.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View the session information to troubleshooting subscriber problems and for general monitoring for orphaned sessions.
When no keywords are specified, the information shown is cumulative for all sessions that have been facilitated by the system.

Example

The following command shows setup time statistics for all sessions from the PCF at IP address *192.168.10.3*:

```
show session setuptime pcf 192.168.10.3
```

show session subsystem

Displays session information for system subsystems. If no keywords are specified, information for all subsystems is displayed.

Product

All

Privilege

Security Administrator, Administrator, Inspector, Operator

Syntax

show session subsystem [full | facility *facility* **[all | instance** *id* **]] [verbose] [| { grep** *grep_options* **| more }]**

[full | facility *facility* **[all | instance** *id* **]]**

- **full**: Indicates that a full statistics summary of all subsystems is to be displayed.
- **facility** *facility*: Specifies the facility for which subsystem statistics is to be displayed where *facility* is specified as one of:
  - **a11mgr**: A11 Manager
  - **aaamgr**: Accounting and Authentication Manager
  - **aaaproxy**: AAA Proxy Manager
  - **asngwmgr**: ASN Gateway Manager
  - **asnpcmgr**: ASN Paging/Location-Registry Manager
  - **cscfmgr**: SIP CSCF Manager
  - **dgmbmgr**: Diameter Gmb Application Manager
  - **diamproxy**: Diameter Proxy Application Manager
  - **egtpegmgr**: EGTP Egress Demux Manager
  - **egtpinmgr**: EGTP Ingress Demux Manager
  - **famgr**: Foreign Agent Manager
  - **gtpumgr**: GTPUMGR Demux Manager
  - **gtpcmgr**: GTPC Manager
  - **hamgr**: Home Agent Manager
  - **hnbmgr**: HNBGW HNB Manager
  - **imsimgr**: SGSN IMSI Manager
  - **ipsgmgr**: IP Services Gateway Manager
  - **l2tpdemux**: L2TP Demux Manager
  - **l2tpmgr**: L2TP Manager
  - **linkmgr**: SGSN/SS7 Master Manager
  - **magmgr**: Mobile Access Gateway Manager
  - **megadiammgr**: Mega Diameter Manager

- **mmedemux**: MME Demux Manager logging facility
- **mmemgr**: MME Manager logging facility
- **mmgr**: SGSN/SS7 Master Manager
- **phsgwmgr**: PHS Gateway Manager
- **phspcmgr**: PHS Paging Controller Manager
- **sessmgr**: Session Manager
- **sgtpcmgr**: SGSN GTPC Manager

- **all | instance** *id*: the keyword **all** indicates all instances of the specified facility are to be displayed whereas the keyword **instance** specifies a specific instance for which information is to be displayed where *id* must be specified as an integer from 0 through 4294967295. If all or instance is not specified summary statistics are displayed.

verbose

Displays everything the **show session subsystem** command displays with the exception that the Setup Time statistics are reported in 100 millisecond increments from 100 ms up to 9600 ms.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

View the session information to troubleshooting subscriber problems and for general monitoring for orphaned sessions.
If this command is entered with no keywords, the information displayed is cumulative for all sessions facilitated by the system.

Example

The following commands display the statistics information summarized for all sessions, then for the *famgr* facility (all sessions), and finally only for the session ID *127589* for the *hamgr* subsystem.

```
show session subsystem full

show session subsystem facility famgr all

show session subsystem facility hamgr instance 127589
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show session trace

Displays status and statistics for the session trace application.

Product

GGSN, MME, P-GW, S-GW

Privilege

Inspector

Syntax

show session trace { statistics | subscriber network-element { ggsn | mme | pgw | sgw } trace-ref *value* **| tce-address** *ip_address* **tce-index** *num* **| tce-summary | trace-summary } [| { grep** *grep_options* **| more }]**

statistics

Displays summary statistics for the session trace subsystem.

subscriber network-element { ggsn | mme | pgw | sgw } trace-ref *value*

Displays status and statistics for a specified session trace using the network element type; GGSN, MME, P-GW, and S-GW, and a valid trace reference of 12 characters.

tce-address *ip_address* **tce-index** *num*

Displays status and statistics for an existing Trace Collection Entity (TCE) connection specified by its IP address in IPv4 dotted-decimal or IPv6 colon-separated notation.
tce-index *num*: Specifies a TCE index of the trace collection entity as an integer from 0 through 7.

tce-summary

Displays a summary of all active TCE connections.

trace-summary

Displays a summary of all active session traces.

| { grep *grep_options* **| more }**

Pipes (sends) the output of the command to the command specified. You must specify a command to which the output will be sent.
For details on the usage of the **grep** and **more** commands, refer to the *Regulating a Command's Output* section of the *Command Line Interface Overview* chapter.

Usage

Use this command to display status and statistics for the session trace application.

Example

The following command displays status and statistics for a subscriber session trace on a P-GW with a trace reference of *32223398765*:

```
show session trace subscriber network-element pgw trace-ref 32223398765
```

The following command displays status and statistics for a subscriber session trace on an MME with a trace reference of *32221234567*:

```
show session trace subscriber network-element mme trace-ref 32223398765
```

The following command displays status and statistics for a subscriber session trace on an GGSN with a trace reference of *1203398765*:

```
show session trace subscriber network-element ggsn trace-ref 1203398765
```

Important: Output descriptions for commands are available in the *Statistics and Counters Reference*.

show sgs-service

Displays information and statistics about Visitor Location Register (VLR) SGs interface services configured on this system.

Product

MME

Privilege

Inspector

Syntax

show sgs-service { all | name *name* **| statistics { all | name** *name* **} | vlr-status [service-name** *name* **] [vlr-name** *name* **] [full]**

all

Displays information about all SGs interface services configured on this system.

---

name *name*

Displays information about an existing SGs service specified as an alphanumeric string of 1 through 63 characters.

---

statistics { all | name *name* **}**

Displays statistics for SGs services configured on this system.
all: Displays statistics for all SGs services configured on this system.
name *name*: Displays statistics for an existing SGs service specified as an alphanumeric string of 1 through 63 characters.

---

vlr-status [service-name *name* **] [vlr-name** *name* **] [full]**

Displays status information about VLRs configured in SGs services on this system.
service-name *name*: Displays names and states of VLRs configured in an existing SGs service specified as an alphanumeric string of 1 through 63 characters.
vlr-name *name*: Displays the name and state of an existing VLR configured in SGs services on this system and specified as an alphanumeric string of 1 through 63 characters.
full: Displays additional information about VLRs configured in SGs services on this system. Additional information includes ports, addresses and peer IDs.

Usage

Use this command to display information and statistics about SGs services configured on this system.

Example

The following command displays statistics for an SGs service named *sgs3*:

```
show sgs-service name sgs3
```

The following command displays VLR status information for a configured VLR named *vlr-main*:

```
show sgs-service vlr-status vlr-name vlr-main
```

show sgsn-operator-policy

This command has been deprecated. Refer to the **show operator-policy** command.

show sgsn

Displays session manager (SessMGR) statistics specific to the SGSN service.

Product

SGSN

Privilege

Inspector

Syntax

show sgsn sessmgr { all | instance *smgr_inst* **}**

all

Displays all SessMGR statistics specific to the system's SGSN services.

instance *smgr_inst*

Displays the statistics for a session manager instance of the SGSN service specified as an integer between 1 and 10000000.

Usage

Use this command to display information for SGSN services.

Example

The following command displays SGSN SessMGR statistics for all SGSN services on the system:

```
show sgsn sessmgr all
```

show sgsn-fast-path

Displays information related to SGSN fast-path.

Product

SGSN

Privilege

Inspector

Syntax

```
show sgsn-fast-path statistics [ all | smgr-instance smgr_inst ] [ | { grep grep_options
| more } ]
```

all

Displays fast-path statistics for all session managers.

smgr-instance *smgr_inst*

Displays the fast-path statistics for a session manager instance specified as an integer between 1 and 65535.
