THE SPECIFICATIONS AND INFORMATION REGARDING THE PRODUCTS IN THIS MANUAL ARE SUBJECT TO CHANGE WITHOUT NOTICE. ALL STATEMENTS, INFORMATION, AND RECOMMENDATIONS IN THIS MANUAL ARE BELIEVED TO BE ACCURATE BUT ARE PRESENTED WITHOUT WARRANTY OF ANY KIND, EXPRESS OR IMPLIED. USERS MUST TAKE FULL RESPONSIBILITY FOR THEIR APPLICATION OF ANY PRODUCTS.

THE SOFTWARE LICENSE AND LIMITED WARRANTY FOR THE ACCOMPANYING PRODUCT ARE SET FORTH IN THE INFORMATION PACKET THAT SHIPPED WITH THE PRODUCT AND ARE INCORPORATED HEREIN BY THIS REFERENCE. IF YOU ARE UNABLE TO LOCATE THE SOFTWARE LICENSE OR LIMITED WARRANTY, CONTACT YOUR CISCO REPRESENTATIVE FOR A COPY.

The following information is for FCC compliance of Class A devices: This equipment has been tested and found to comply with the limits for a Class A digital device, pursuant to part 15 of the FCC rules. These limits are designed to provide reasonable protection against harmful interference when the equipment is operated in a commercial environment. This equipment generates, uses, and can radiate radio-frequency energy and, if not installed and used in accordance with the instruction manual, may cause harmful interference to radio communications. Operation of this equipment in a residential area is likely to cause harmful interference, in which case users will be required to correct the interference at their own expense.

The following information is for FCC compliance of Class B devices: The equipment described in this manual generates and may radiate radio-frequency energy. If it is not installed in accordance with Cisco's installation instructions, it may cause interference with radio and television reception. This equipment has been tested and found to comply with the limits for a Class B digital device in accordance with the specifications in part 15 of the FCC rules. These specifications are designed to provide reasonable protection against such interference in a residential installation. However, there is no guarantee that interference will not occur in a particular installation.

Modifying the equipment without Cisco's written authorization may result in the equipment no longer complying with FCC requirements for Class A or Class B digital devices. In that event, your right to use the equipment may be limited by FCC regulations, and you may be required to correct any interference to radio or television communications at your own expense.

You can determine whether your equipment is causing interference by turning it off. If the interference stops, it was probably caused by the Cisco equipment or one of its peripheral devices. If the equipment causes interference to radio or television reception, try to correct the interference by using one or more of the following measures:

- Turn the television or radio antenna until the interference stops.
- Move the equipment to one side or the other of the television or radio.
- Move the equipment farther away from the television or radio.
- Plug the equipment into an outlet that is on a different circuit from the television or radio. (That is, make certain the equipment and the television or radio are on circuits controlled by different circuit breakers or fuses.)

Modifications to this product not authorized by Cisco Systems, Inc. could void the FCC approval and negate your authority to operate the product.

The Cisco implementation of TCP header compression is an adaptation of a program developed by the University of California, Berkeley (UCB) as part of UCB's public domain version of the UNIX operating system. All rights reserved. Copyright © 1981, Regents of the University of California.

NOTWITHSTANDING ANY OTHER WARRANTY HEREIN, ALL DOCUMENT FILES AND SOFTWARE OF THESE SUPPLIERS ARE PROVIDED "AS IS" WITH ALL FAULTS. CISCO AND THE ABOVE-NAMED SUPPLIERS DISCLAIM ALL WARRANTIES, EXPRESSED OR IMPLIED, INCLUDING, WITHOUT LIMITATION, THOSE OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NONINFRINGEMENT OR ARISING FROM A COURSE OF DEALING, USAGE, OR TRADE PRACTICE.

IN NO EVENT SHALL CISCO OR ITS SUPPLIERS BE LIABLE FOR ANY INDIRECT, SPECIAL, CONSEQUENTIAL, OR INCIDENTAL DAMAGES, INCLUDING, WITHOUT LIMITATION, LOST PROFITS OR LOSS OR DAMAGE TO DATA ARISING OUT OF THE USE OR INABILITY TO USE THIS MANUAL, EVEN IF CISCO OR ITS SUPPLIERS HAVE BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES.

## CONTENTS

### About this Book 2-xv

- Audience xv
- Documentation Organization xvi
- Documentation Conventions xviii
- Obtaining Documentation, Obtaining Support, and Security Guidelines xix

### Using Cisco IOS Software 3-xxi

- Understanding Command Modes 3-xxi
- Getting Help 3-xxii
  - Example: How to Find Command Options 3-xxiii
- Using the no and default Forms of Commands 3-xxv
- Filtering Output from the show and more Commands 3-xxvi
- Finding Additional Feature Support Information 3-xxvi

### Overview of ITP 1-1

- SS7oIP Technology Overview 1-1
  - Introduction to SS7oIP 1-1
  - Stream Control Transmission Protocol (RFC2960) 1-1
  - Sigtran M2PA - SS7 MTP2-User Peer-to-Peer Adaptation Layer 1-2
  - Sigtran M3UA - SS7 MTP3-User Adaptation Layer 1-2
  - Sigtran SUA - SS7 SCCP-User Adaptation Layer 1-3
- Benefits 1-4

### Overview of ITP on SAMI 2-5

- ITP Hardware Features 2-5
- ITP Software Features 2-6
  - Quality of Service 2-6
  - Global Title Translation 2-7
  - Gateway Screening 2-7
  - SS7 Load Sharing 2-7
  - Multiple Point Codes 2-7
  - Multiple Instances 2-7
  - MLR 2-8
  - MO Proxy 2-8
  - SMS Notification Proxy 2-8

|                                                               |             |
|---------------------------------------------------------------|-------------|
| Simple Network Management Protocol                            | 2-8         |
| SS7 Routing                                                   | 2-8         |
| ITP MIBs                                                      | 2-8         |
| ITP Restrictions                                              | 2-9         |
| <b>Configuring the ITP on SAMI</b>                            | <b>3-11</b> |
| Preparing to Install the ITP Software                         | 3-11        |
| Installing the ITP Software                                   | 3-12        |
| Configuration Examples of ITP on SAMI                         | 3-13        |
| Configuration Example for Basic ITP Configuration on SAMI     | 3-13        |
| Saving and Restoring ITP Configurations                       | 3-14        |
| <b>ITP Software Upgrade on the Cisco 7600 Platform</b>        | <b>4-15</b> |
| Contents                                                      | 4-15        |
| Prerequisites for Non-Disruptive Upgrade                      | 4-16        |
| Information About Non-Disruptive Upgrade                      | 4-16        |
| Performing a Non-Disruptive Upgrade                           | 4-16        |
| Preparing for Non-Disruptive Upgrade                          | 4-16        |
| What to Do Next                                               | 4-20        |
| Resetting the Standby Supervisor                              | 4-20        |
| What to Do Next                                               | 4-20        |
| Switching the Standby Supervisor to Active Role               | 4-20        |
| What to Do Next                                               | 4-21        |
| Upgrading the Software Image on FlexWAN Line Cards            | 4-21        |
| What to Do Next                                               | 4-22        |
| Upgrading the Software Image on the Standby Supervisor        | 4-22        |
| Procedure for Upgrading a Cisco 7600 to SAMI Support          | 4-24        |
| Upgrade Procedures                                            | 4-24        |
| Supported Scenarios                                           | 4-25        |
| Line cards are not changed during upgrade                     | 4-25        |
| SAMIs or other new cards will be inserted in empty slots      | 4-25        |
| One or more FlexWANs will be replaced with SAMIs or new cards | 4-25        |
| PAs within a FlexWAN will be changed                          | 4-25        |
| Roll Back to the Previous Image                               | 4-25        |
| NDU from IRE to Any Newer Image                               | 4-26        |
| <b>Configuring ITP Basic Functionality</b>                    | <b>5-27</b> |
| Contents                                                      | 5-28        |
| Enabling Secure Shell                                         | 5-28        |

|                                                                                                                               |      |
|-------------------------------------------------------------------------------------------------------------------------------|------|
| Specifying the SS7 Variant, National Option, and Network Indicator                                                            | 5-29 |
| Specifying the Point Code                                                                                                     | 5-32 |
| Specifying the Point Code Representation                                                                                      | 5-32 |
| Specifying the Primary Local Point Code                                                                                       | 5-33 |
| Specifying a Secondary Point Code                                                                                             | 5-33 |
| Specifying the Capability Point Code                                                                                          | 5-33 |
| Specifying the Interface and Encapsulation                                                                                    | 5-34 |
| Clocking on the SS7 Port Adapter and SS7 Q.703 High Speed Port Adapter                                                        | 5-35 |
| Configuring a Serial Interface and SS7 High-Speed MTP2 Encapsulation (Q.703 Annex A) on the SS7 Q.703 High Speed Port Adapter | 5-35 |
| Configuring a Serial Interface and MTP2 Encapsulation on the SS7 Port Adapter                                                 | 5-37 |
| Configuring SS7 over ATM High Speed Links (HSL)                                                                               | 5-39 |
| Configuring BITS Network Clocking                                                                                             | 5-41 |
| Configuring SS7 ATM High Speed Links with BITS Network Clocking                                                               | 5-43 |
| Configuring Local Peers                                                                                                       | 5-46 |
| Configuring Linksets                                                                                                          | 5-46 |
| Configuring Circular Route Direction (CRD)                                                                                    | 5-48 |
| Configuring CRD for the ANSI Variant                                                                                          | 5-48 |
| Configuring CRD for the ITU and ITU-like Variants                                                                             | 5-49 |
| Configuring Multiple Linksets to Adjacent Nodes                                                                               | 5-51 |
| Specifying the Cisco ITP Route Table                                                                                          | 5-52 |
| Specifying the Default Route Table                                                                                            | 5-53 |
| Loading the Route Table Contents                                                                                              | 5-53 |
| Adding Routes to the Route Table                                                                                              | 5-53 |
| Saving the Route Table                                                                                                        | 5-54 |
| Assigning Links to Linksets                                                                                                   | 5-54 |
| Traditional SS7 Links                                                                                                         | 5-54 |
| High-Speed Signaling Links                                                                                                    | 5-55 |
| SS7 Over IP Links (Peers)                                                                                                     | 5-55 |
| Shutting Down and Restarting Linksets and Links                                                                               | 5-56 |
| Configuration Example of ITP Basic Functionality                                                                              | 5-57 |

## **Probeless Monitoring** 6-67

|                                             |      |

## About this Book

---

This preface describes the audience, organization, and conventions of *IP Transfer Point*. It also lists documentation revision history, sources for obtaining related documentation, technical assistance, and additional publications and information from Cisco Systems.

### Note

---

This publication does not contain the instructions to install router. For information on installing the router, see the installation guide that came with your router.

---

This preface contains the following sections:

- [Audience, page xv](#)
- [Documentation Organization, page xvi](#)
- [Documentation Conventions, page xviii](#)
- [Obtaining Documentation, Obtaining Support, and Security Guidelines, page xix](#)

## Audience

This publication is intended for users who are responsible for configuring and maintaining the Cisco IP Transfer Point software. It is intended for users who are responsible for migrating Signaling System 7 (SS7) to the mobile wireless SS7-over-IP (SS7oIP) environment but who may not be familiar with the configuration and maintenance tasks, the relationship among tasks, or the Cisco IOS software commands necessary to perform particular tasks. This publication is also intended for those users experienced with the Cisco ITP software who need to know about new features, new configuration options, and new software characteristics in the current software release.

# Documentation Organization

This publication is organized as follows:

| Chapter                                     | Description                                                                                                                                                                                                                                                                                                                  |
|---------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| About This Book                             | This preface describes the audience, organization, and conventions of <i>IP Transfer Point</i> . It also lists documentation revision history, sources for obtaining related documentation, technical assistance, and additional publications and information from Cisco Systems.                                            |
| Using Cisco IOS Software                    | This chapter provides helpful tips for understanding and configuring the Cisco IOS software using the command-line interface (CLI). The chapter discusses command modes, show commands, and using the CLI to get command syntax help.                                                                                        |
| Overview of ITP on SAMI                     | Describes Cisco ITP on the Service and Application Module for IP (SAMI), including supported hardware, software, and MIBs.                                                                                                                                                                                                   |
| Configuring the ITP on SAMI                 | Describes the installation, configuration, upgrading, saving, and restoration of the Cisco ITP software on the SAMI.                                                                                                                                                                                                         |
| Configuring ITP Basic Functionality         | Describes the tasks and commands to configure basic Cisco ITP functionality.                                                                                                                                                                                                                                                 |
| Multiple Instances and Instance Translation | Describes the tasks and commands to configure the Multiple Instances feature to connect the Cisco ITP to different networks with specific variant and network indicators. Describes the tasks and commands to configure Instance Translation, which enables the conversion and transfer of MSUs between different instances. |
| Global Title Translation                    | Describes the tasks and commands to configure Global Title Translation (GTT), the process by which the SCCP translates a global title into the point code and subsystem number of the destination SSP where the higher-layer protocol processing occurs.                                                                     |
| M3UA and SUA Over IP Signaling Gateways     | Describes the tasks and commands to configure the Cisco ITP Signaling Gateway (ITP SG) feature which provides open-standards-based SS7 over IP solutions through the implementation of SIGTRAN MTP3-User Adaptation (M3UA) and SCCP User Adaptation (SUA) protocols.                                                         |
| Gateway Screening                           | Describes the tasks and commands to configure the Cisco ITP Gateway Screening feature (GWS) which prevents unauthorized use of the Cisco ITP and controls the flow of messages into or through the Cisco ITP.                                                                                                                |
| Multi-Layer SMS Routing and Screening       | Describes the tasks and commands to configure the Cisco ITP Multi-Layer Routing (MLR) feature which implements the routing of SMS messages based on information found in the Transaction Capability Application Part (TCAP), Mobile Application Part (MAP), and SMS layers.                                                  |

| Chapter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ITP Distributed Short Message Routing     | Describes the tasks and commands to configure the ITP to route global system for mobile (GSM) Short Message Service (SMS) messages. With the assistance of a full-featured Short Message Service Center (SMSC), DSMR can provide a cost effective way to implement a large capacity short message routing system suitable. DSMR can also significantly reduce the SMS traffic load on the legacy SMSC complex |
| Non-Stop Operation                        | Describes the tasks and commands to configure the Non-Stop Operation feature which enables the Cisco ITP to continue operation in the event of a Supervisor 720 failure.                                                                                                                                                                                                                                      |
| ITP QoS                                   | Describes the tasks and commands to configure the ITP QoS feature which provides the framework that allows end-to-end Quality of Service (QoS) for SS7 packet flow through SS7 over IP (SS7oIP) networks.                                                                                                                                                                                                     |
| SCCP Load Sharing                         | Describes the configuration options for SCCP load sharing as well as address guidelines for when to use the different methods provided.                                                                                                                                                                                                                                                                       |
| Summary Routing and ANSI Cluster Routing  | Describes the tasks and commands to configure the Summary Routing feature. This feature allows routing of MSUs to groups of DPCs by specifying one or more routes to a summary destination in the route table rather than individual route table entries for each destination.                                                                                                                                |
| Verifying, Monitoring, and Tuning the ITP | Describes how to verify proper configuration of the RPR+ feature and the Cisco ITP, monitor status and traffic, and tune the Cisco ITP.                                                                                                                                                                                                                                                                       |
| ITP Command Set: A - D                    | Command Reference describes command syntax, usage guidelines, etc., for each command.                                                                                                                                                                                                                                                                                                                         |
| ITP Command Set: E - R                    | Command Reference describes command syntax, usage guidelines, etc., for each command.                                                                                                                                                                                                                                                                                                                         |
| ITP Command Set: S - Z                    | Command Reference describes command syntax, usage guidelines, etc., for each command.                                                                                                                                                                                                                                                                                                                         |
| ITP Debug Commands                        | Debug command reference.                                                                                                                                                                                                                                                                                                                                                                                      |
| ITP System Messages                       | Describes system messages and provides recommended actions.                                                                                                                                                                                                                                                                                                                                                   |

# Documentation Conventions

This publication uses the following conventions:

| Convention              | Description                                                                                                                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>^</b> or <b>Ctrl</b> | The ^ and Ctrl symbols represent the Control key. For example, the key combination ^D or Ctrl-D means hold down the Control key while you press the D key. Keys are indicated in capital letters but are not case sensitive.   |
| <i>string</i>           | A string is a nonquoted set of characters shown in italics. For example, when setting an SNMP community string to <i>public</i> , do not use quotation marks around the string or the string will include the quotation marks. |

Command syntax descriptions use the following conventions:

| Convention     | Description                                                                                               |
|----------------|-----------------------------------------------------------------------------------------------------------|
| <b>bold</b>    | Bold text indicates commands and keywords that you enter literally as shown.                              |
| <i>italics</i> | Italic text indicates arguments for which you supply values.                                              |
| [x]            | Square brackets enclose an optional element (keyword or argument).                                        |
|                | A vertical line indicates a choice within an optional or required set of keywords or arguments.           |
| [x   y]        | Square brackets enclosing keywords or arguments separated by a vertical line indicate an optional choice. |
| {x   y}        | Braces enclosing keywords or arguments separated by a vertical line indicate a required choice.           |

Nested sets of square brackets or braces indicate optional or required choices within optional or required elements. For example:

| Convention  | Description                                                                                              |
|-------------|----------------------------------------------------------------------------------------------------------|
| [x {y   z}] | Braces and a vertical line within square brackets indicate a required choice within an optional element. |

Examples use the following conventions:

| Convention          | Description                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>screen</code> | Examples of information displayed on the screen are set in Courier font.                                                                                                                 |
| <b>bold screen</b>  | Examples of text that you must enter are set in Courier bold font.                                                                                                                       |
| < >                 | Angle brackets enclose text that is not printed to the screen, such as passwords, and are used in contexts in which the italic document convention is not available, such as ASCII text. |
| !                   | An exclamation point at the beginning of a line indicates a comment line. (Exclamation points are also displayed by the Cisco IOS software for certain processes.)                       |
| [ ]                 | Square brackets enclose default responses to system prompts.                                                                                                                             |

The following conventions are used to attract the attention of the reader:

**Caution**

Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

**Note**

Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the manual.

## Obtaining Documentation, Obtaining Support, and Security Guidelines

For information on obtaining documentation, obtaining support, providing documentation feedback, security guidelines, and also recommended aliases and general Cisco documents, see the monthly *What's New in Cisco Product Documentation*, which also lists all new and revised Cisco technical documentation, at:

<http://www.cisco.com/en/US/docs/general/whatsnew/whatsnew.html>

## Using Cisco IOS Software

---

This chapter provides helpful tips for understanding and configuring the Cisco IOS software on the ITP using the command-line interface (CLI). It contains the following sections:

- [Understanding Command Modes, page xxi](#)
- [Getting Help, page xxii](#)
- [Using the no and default Forms of Commands, page xxv](#)
- [Filtering Output from the show and more Commands, page xxvi](#)
- [Finding Additional Feature Support Information, page xxvi](#)

## Understanding Command Modes

You use the CLI to configure the Cisco IOS software that runs on the ITP. Because the CLI is divided into many different modes, the commands available to you at any given time depend on the mode that you are currently in. Entering a question mark (?) at the CLI prompt allows you to obtain a list of commands available for each command mode.

When you log in to the CLI, you are in user EXEC mode. User EXEC mode contains only a limited subset of commands. To have access to all commands, you must enter privileged EXEC mode, normally by using a password. From privileged EXEC mode you can issue any EXEC command—user or privileged mode—or you can enter global configuration mode. Most EXEC commands are one-time commands. For example, **show** commands show important status information, and **clear** commands clear counters or interfaces. The EXEC commands are not saved when the software reboots.

Configuration modes allow you to make changes to the running configuration. If you later save the running configuration to the startup configuration, these changed commands are stored when the software is rebooted. To enter specific configuration modes, you must start at global configuration mode. From global configuration mode, you can enter interface configuration mode and a variety of other modes, such as protocol-specific modes.

ROM monitor mode is a separate mode used when the Cisco IOS software cannot load properly. If a valid software image is not found when the software boots or if the configuration file is corrupted at startup, the software might enter ROM monitor mode.

Table 1 describes how to access and exit the most common command modes of the Cisco IOS software. It also shows examples of the prompts displayed for each mode. As you configure the Cisco IOS software for your ITP, you will access many other command modes, depending on the ITP features that you are configuring.

**Table 1**      **Accessing and Exiting Command Modes**

| Command Mode            | Access Method                                                                                                                                 | Prompt             | Exit Method                                                                                                                            |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| User EXEC               | Log in.                                                                                                                                       | Router>            | Use the <b>logout</b> command.                                                                                                         |
| Privileged EXEC         | From user EXEC mode, use the <b>enable</b> command.                                                                                           | Router#            | To return to user EXEC mode, use the <b>disable</b> command.                                                                           |
| Global configuration    | From privileged EXEC mode, use the <b>configure terminal</b> command.                                                                         | Router(config)#    | To return to privileged EXEC mode from global configuration mode, use the <b>exit</b> or <b>end</b> command.                           |
| Interface configuration | From global configuration mode, specify an interface using an <b>interface</b> command.                                                       | Router(config-if)# | To return to global configuration mode, use the <b>exit</b> command.<br>To return to privileged EXEC mode, use the <b>end</b> command. |
| ROM monitor             | From privileged EXEC mode, use the <b>reload</b> command. Press the <b>Break</b> key during the first 60 seconds while the system is booting. | >                  | To exit ROM monitor mode, use the <b>continue</b> command.                                                                             |

## Getting Help

Entering a question mark (?) at the CLI prompt displays a list of commands available for each command mode. You can also get a list of keywords and arguments associated with any command by using the context-sensitive help feature.

To get help specific to a command mode, a command, a keyword, or an argument, use one of the following commands:

| Command                                     | Purpose                                                                                                                  |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>help</b>                                 | Provides a brief description of the help system in any command mode.                                                     |
| <i>abbreviated-command-entry?</i>           | Provides a list of commands that begin with a particular character string. (No space between command and question mark.) |
| <i>abbreviated-command-entry&lt;Tab&gt;</i> | Completes a partial command name.                                                                                        |
| <b>?</b>                                    | Lists all commands available for a particular command mode.                                                              |
| <i>command ?</i>                            | Lists the keywords or arguments that you must enter next on the command line. (Space between command and question mark.) |

## Example: How to Find Command Options

This section provides an example of how to display syntax for a command. The syntax can consist of optional or required keywords and arguments. To display keywords and arguments for a command, enter a question mark (?) at the configuration prompt or after entering part of a command followed by a space. The Cisco IOS software displays a list and brief description of available keywords and arguments. For example, if you were in global configuration mode and wanted to see all the keywords or arguments for the **arap** command, you would type **arap ?**.

The <cr> symbol in command help output stands for “carriage return.” On older keyboards, the carriage return key is the Return key. On most modern keyboards, the carriage return key is the Enter key. The <cr> symbol at the end of command help output indicates that you have the option to press **Enter** to complete the command and that the arguments and keywords in the list preceding the <cr> symbol are optional. The <cr> symbol by itself indicates that no more arguments or keywords are available and that you must press **Enter** to complete the command.

Table 2 shows examples of how you can use the question mark (?) to assist you in entering commands. The table steps you through configuring an IP address on a serial interface.

**Table 2**      *How to Find Command Options*

| Command                                                                                                                                                                                                                                                                                                                                                 | Comment                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router> <b>enable</b><br>Password: <password><br>Router#                                                                                                                                                                                                                                                                                                | Enter the <b>enable</b> command and password to access privileged EXEC commands. You are in privileged EXEC mode when the prompt changes to Router#.                                                                                                                                                                                                                                                                                                                                                                                                              |
| Router# <b>configure terminal</b><br>Enter configuration commands, one per line. End with CNTL/Z.<br>Router(config)#                                                                                                                                                                                                                                    | Enter the <b>configure terminal</b> privileged EXEC command to enter global configuration mode. You are in global configuration mode when the prompt changes to Router(config)#.                                                                                                                                                                                                                                                                                                                                                                                  |
| Router(config)# <b>interface serial ?</b><br><0-6>      Serial interface number<br>Router(config)# <b>interface serial 4 ?</b><br>/<br>Router(config)# <b>interface serial 4/ ?</b><br><0-3>      Serial interface number<br>Router(config)# <b>interface serial 4/0 ?</b><br><cr><br>Router(config)# <b>interface serial 4/0</b><br>Router(config-if)# | <p>Enter interface configuration mode by specifying the serial interface that you want to configure using the <b>interface serial</b> global configuration command.</p> <p>Enter ? to display what you must enter next on the command line. In this example, you must enter the serial interface slot number and port number, separated by a forward slash.</p> <p>When the &lt;cr&gt; symbol is displayed, you can press <b>Enter</b> to complete the command.</p> <p>You are in interface configuration mode when the prompt changes to Router(config-if)#.</p> |

**Table 2**      **How to Find Command Options (continued)**

| Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 | Comment                                                                                                                                                                                                                                                             |

| <pre>Router(config-if)# ip address 172.16.0.1 255.255.255.0 ? secondary       Make this IP address a secondary address &lt;cr&gt; Router(config-if)# ip address 172.16.0.1 255.255.255.0</pre> | <p>Enter the IP subnet mask. This example uses the 255.255.255.0 IP subnet mask.</p> <p>Enter <b>?</b> to display what you must enter next on the command line. In this example, you can enter the <b>secondary</b> keyword, or you can press <b>Enter</b>.</p> <p>A &lt;cr&gt; is displayed; you can press <b>Enter</b> to complete the command, or you can enter another keyword.</p>                                            |
| <pre>Router(config-if)# ip address 172.16.0.1 255.255.255.0 Router(config-if)#</pre>                                                                                                           | <p>In this example, Enter is pressed to complete the command.</p>                                                                                                                                                                                                                                                                                                                                                                  |

## Using the no and default Forms of Commands

Almost every configuration command has a **no** form. In general, use the **no** form to disable a function. Use the command without the **no** keyword to reenable a disabled function or to enable a function that is disabled by default. For example, IP routing is enabled by default. To disable IP routing, use the **no ip routing** command; to reenable IP routing, use the **ip routing** command. The Cisco IOS software command reference publications provide the complete syntax for the configuration commands and describe what the **no** form of a command does.

Configuration commands can also have a **default** form, which returns the command settings to the default values. Most commands are disabled by default, so in such cases using the **default** form has the same result as using the **no** form of the command. However, some commands are enabled by default and

have variables set to certain default values. In these cases, the **default** form of the command enables the command and sets the variables to their default values. The Cisco IOS software command reference publications describe the effect of the **default** form of a command if the command functions differently than the **no** form.

## Filtering Output from the show and more Commands

You can search and filter the output of **show** and **more** commands. This functionality is useful if you need to sort through large amounts of output or if you want to exclude output that you need not see.

To use this functionality, enter a **show** or **more** command followed by the “pipe” character (`|`); one of the keywords **begin**, **include**, or **exclude**; and a regular expression on which you want to search or filter (the expression is case-sensitive):

*command* | { **begin** | **include** | **exclude** } *regular-expression*

The output matches certain lines of information in the configuration file. The following example illustrates how to use output modifiers with the **show interface** command when you want the output to include only lines in which the expression “protocol” appears:

```
Router# show interface | include protocol

FastEthernet0/0 is up, line protocol is up
Serial4/0 is up, line protocol is up
Serial4/1 is up, line protocol is up
Serial4/2 is administratively down, line protocol is down
Serial4/3 is administratively down, line protocol is down
```

## Finding Additional Feature Support Information

If you want to use a specific Cisco IOS software feature, you will need to determine in which Cisco IOS software images that feature is supported. Feature support in Cisco IOS software images is dependent on three main factors: the software version (called the “Release”), the hardware model (the “Platform” or “Series”), and the “Feature Set” (collection of specific features designed for a certain network environment). Although the Cisco IOS software documentation set documents feature support information for Release 12.4 as a whole, it does not generally provide specific hardware and feature set information.

To determine the correct combination of Release (software version), Platform (hardware version), and Feature Set needed to run a particular feature (or any combination of features), use Feature Navigator.

Feature Navigator is a web-based tool available on Cisco.com at <http://www.cisco.com/go/fn>. Feature Navigator is available only for registered users of Cisco.com. If you do not have an account or have forgotten your username or password, click Cancel at the login dialog box and follow the instructions that appear.

Software features may also have additional limitations or restrictions. For example, a minimum amount of system memory may be required. Or there may be known issues for features on certain platforms that have not yet been resolved (called “Caveats”). For the latest information about these limitations, see the release notes for the appropriate Cisco IOS software release. Release notes provide detailed installation instructions, new feature descriptions, system requirements, limitations and restrictions, caveats, and troubleshooting information for a particular software release.

## Overview of ITP

---

Cisco IP Transfer Point (ITP) is a hardware and software SS7-over-IP (SS7oIP) solution. ITP provides a highly reliable, cost effective medium for migrating Signaling System 7 (SS7), the telecommunications network signaling technology, to the mobile wireless IP environment.

By leveraging its leadership in high-end switches and routers, Cisco has created a carrier class router with a transparent SS7oIP convergence solution. Cisco ITP is managed identically to other Cisco routers and leverages the Cisco skill sets already existing within the service provider, including provisioning, management, and tools training.

Short Message Peer-to-Peer (SMPP) protocol is not supported. Some DSMR functionality is also not supported. It is recommended that commands pertaining to these features are not configured.

This chapter introduces the Signaling System 7 (SS7) protocol and Cisco ITP technology. This chapter includes the following sections:

- [SS7oIP Technology Overview, page 1](#)
- [Benefits, page 4](#)

## SS7oIP Technology Overview

### Introduction to SS7oIP

The IETF Signaling Transport (Sigtran) Working Group is a multi-vendor organization that is developing and standardizing protocols to transport SS7 over IP. The primary purpose of this working group is to address the transport of packet-based mobile/PSTN signaling over IP networks, while also accounting for functional and performance requirements of mobile/PSTN signaling. For internetworking with a mobile/PSTN network, IP networks need to transport signaling such as Q.931 or SS7 ISDN User Part (ISUP) messages. To view the IETF Sigtran standards, refer to the following URL:  
<http://www.ietf.org/html.charters/sigtran-charter.html>.

### Stream Control Transmission Protocol (RFC2960)

The Stream Control Transmission Protocol (SCTP) is a reliable transport protocol that operates on top of an unreliable connectionless packet service such as IP. It offers acknowledged error-free, non-duplicated transfer of MSUs. SCTP uses checksums and sequence numbers to detect data

corruption, loss, or duplication, and corrects loss or corruption of data with a selective retransmission mechanism. SCTP provides the function and measurements in an architecturally identical manner to MTP2. To view the SCTP standards, refer to the following URL: <http://www.ietf.org/rfc/rfc2960.txt>.

## Sigtran M2PA - SS7 MTP2-User Peer-to-Peer Adaptation Layer

M2PA is designed for peer-to-peer signaling gateway (SG) communications. The analogy in legacy networks is STP-to-STP communication. Figure 1 provides a protocol architecture diagram.

**Figure 1** M2PA Protocol Architecture

M2PA offers a protocol high availability similar to an STP. The MTP3 implementation layer in an M2PA SG is unaware of whether a link is time-division multiplexing (TDM) or IP and run equally well over either. This preserves congestion, Layer 2 failure detection, changeover, change-back, load balancing via SLS, screening, and other MTP3 features.

## Sigtran M3UA - SS7 MTP3-User Adaptation Layer

Message Transfer Part, Level 3, User Adaptation Layer protocol (M3UA) describes a transport mechanism for delivering SS7 Message Transfer Part, Level 3 (MTP3) User Part messages as well as certain MTP network management events over Stream Control Transmission Protocol (SCTP) transport to IP-based application processors or databases. The M3UA SG terminates the SS7 MTP2 and MTP3 protocol layers and delivers ISDN User Part (ISUP), Signaling Connection Control Part (SCCP) and/or any other MTP3-User protocol messages. The Application Server Process (ASP) is the IP-based instance of an application process or database such as Call Agents, Home Location Registers (HLRs), etc.

Figure 2 depicts the relationship between the legacy SS7 Service Control Point, the M3UA SG, the IP-based Application Server Process (ASP), and the protocol stacks.

**Figure 2 M3UA Signaling Gateway Protocol Stacks**

In [Figure 2](#), the legacy SS7 SCP on the far right uses MTP1, MTP2, and MTP3 for transporting SCCP and ISUP messages into the network. The SG terminates the SS7 links, translates the MTP3 messages into M3UA messages, and transports them to the ASP over SCTP/IP. M3UA at the ASP delivers SCCP and ISUP messages.

## Sigtran SUA - SS7 SCCP-User Adaptation Layer

SUA describes a transport mechanism for delivering SS7 SCCP-User Part messages and certain SCCP network management events over SCTP transport to IP-based application processors or databases. The SUA SG terminates the SS7 MTP2, MTP3, and SCCP protocol layers and delivers TCAP, RANAP and/or any other SCCP-User protocol messages. The Application Server Process (ASP) is the IP-based instance of an application process or database (e.g. HLRs, SMSCs, etc.).

[Figure 3](#) depicts the relationship between the legacy SS7 Service Control Point, the SUA SG, the IP-based Application Server Process (ASP), and the protocol stacks.

**Figure 3** *SUA Signaling Gateway Protocol Stacks*

In Figure 3, the legacy SS7 SCP on the far right uses MTP1, MTP2, and MTP3 for transporting SCCP messages into the network. The SG terminates the SS7 links, translates the SCCP messages into SUA messages, and transports them to the ASP over SCTP/IP. SUA at the ASP delivers TCAP messages.

## Benefits

The Cisco ITP Router provides the following benefits:

- Lower incremental investment from using a cost-effective IP network
- Reduced number of links
- Reduced STP ports
- Reduced processor occupancy for STP
- Support for the full suite of Cisco routing protocols and QoS technologies
- Non-intrusive, end-point devices transparent to the SS7 network
- Full set of high-end routing protocols and IP media
- Integrated SS7 and IP management using IP-based industry standard tools
- High Availability and increased link density for SS7 line cards via an SS7 Port Adapter

## Overview of ITP on SAMI

---

The Cisco IP Transfer Point (ITP) for the Cisco 7600 Series Routers is a comprehensive product for transporting Signaling System 7 (SS7) traffic over traditional time-division multiplexing (TDM) networks or advanced SS7-over-IP (SS7oIP) networks. The Cisco 7600 ITP supports traditional, advanced, and combined traditional/advanced networks.

The Cisco 7600 ITP offers the complete feature set found in traditional signaling transfer points (STPs). When operating in a TDM mode, the Cisco 7600 ITP transports SS7 traffic over traditional TDM networks. Using the standards developed by the IETF Signaling Transport (SIGTRAN) working group, in an SS7oIP mode the Cisco 7600 ITP connects to traditional SS7 nodes or IP-enabled signaling nodes and offloads this SS7 traffic to reliable IP networks, thus freeing capacity and ports on the SS7 network. The Cisco 7600 ITP also operates in mixed SS7oIP and TDM environments.

Additionally, by incorporating the SIGTRAN working group's Message Transfer Part Layer 3 (MTP3) User Adaptation Layer (M3UA) and Signaling Connection Control Part (SCCP) User Adaptation Layer (SUA) standards, Cisco ITP provides a complete signaling solution.

Cisco IOS Release 12.2(33)IR runs on the Service and Application Module for IP (SAMI), a high performance service module for the Cisco 7600 Series Router platforms.

This chapter includes the following information:

- [ITP Hardware Features, page 5](#)
- [ITP Software Features, page 6](#)
- [ITP MIBs, page 8](#)
- [ITP Restrictions, page 9](#)

## ITP Hardware Features

ITP is available on the following versions of the Cisco SAMI:

- WS-SVC-SAMI-BB-K9—Cisco Service and Application Module for IP
- WS-SVC-SAMI-BB-K9=—Cisco Service and Application Module for IP (spare)

The Cisco SAMI is a new-generation high performance Cisco IOS software application module that occupies a single slot in the Cisco 7600 Series Router platform.

With a network processor flow-distributor and six PowerPCs (PPCs), each of which can run an instance of the same Cisco IOS image, the SAMI offers a parallel architecture for Cisco software applications such as ITP.

The benefits of the SAMI architecture include:

- Increased processing power and session density
- Reduced inter-CPU data sharing
- Improved management capabilities
- Less complex to configure

SAMI is documented in the *Cisco Service and Application Module for IP User Guide for the Cisco 7600 Series Routers* available at:

[http://www.cisco.com/en/US/docs/wireless/service\\_application\\_module/sami/user/guide/overview.html](http://www.cisco.com/en/US/docs/wireless/service_application_module/sami/user/guide/overview.html)

## ITP Software Features

The ITP Release 12.2(33)IR provides the following base features and functionality.

- [Quality of Service, page 6](#)
- [Global Title Translation, page 7](#)
- [Gateway Screening, page 7](#)
- [SS7 Load Sharing, page 7](#)
- [Multiple Point Codes, page 7](#)
- [Multiple Instances, page 7](#)
- [MLR, page 8](#)
- [MO Proxy, page 8](#)
- [SMS Notification Proxy, page 8](#)
- [Simple Network Management Protocol, page 8](#)
- [SS7 Routing, page 8](#)

### Note

Additional features are added in subsequent releases and detailed in the ITP Release Notes. The Release Notes are located at:

[http://www.cisco.com/en/US/products/sw/wirelssw/ps1862/prod\\_release\\_notes\\_list.html](http://www.cisco.com/en/US/products/sw/wirelssw/ps1862/prod_release_notes_list.html)

## Quality of Service

The ITP Quality of Service (QoS) feature provides the framework that allows end-to-end QoS for SS7 packet flow through SS7 over IP (SS7oIP) networks. QoS is per SCTP association and classification is based on:

- Service indicator
- Destination Point Code, Global Title Address, M3UA/SUA routing key
- Input link set
- Service (translation type)
- Access lists
- M3UA/SUA routing key

For more information, see the [“ITP QoS” section on page 309](#).

## Global Title Translation

A global title is an application address, such as an 800 number, calling card number, or mobile subscriber identification number. Global Title Translation (GTT) is the process by which the SCCP translates a global title into the point code and subsystem number of the destination SSP where the higher-layer protocol processing occurs. ITP offers full traditional SCCP and GTT support including ANSI GTI 2, China GTI 4, and ITU GTI 2 & 4.

For more information, see the [“Global Title Translation” section on page 93](#).

## Gateway Screening

The ITP Gateway Screening feature (GWS) prevents unauthorized use of the STP and controls the flow of messages into or through the STP. GWS screens the contents of the incoming or outgoing Message Signaling Unit (MSU). At any stage during the screening process, the message can be routed to its destination, sent to MLR for application level handling or be discarded. This functionality supports combinations of the following MSU parameters: MTP3 layer, SCCP layer, and ISUP message type.

You can implement GWS in conjunction with Access Lists, Global Translation Table (GTT), and Multi-Layer Routing (MLR). GWS also allows you to configure GWS tables to drop an SCCP packet matching a set of conditions. When you drop an SCCP packet, an SCCP error return function sends a UDTs back to the source of the SCCP packet.

For more information, see the [“Gateway Screening \(GWS\)” section on page 165](#).

## SS7 Load Sharing

ITP supports MTP3 and SCCP load sharing for links, link sets, and combined link sets for any link types.

## Multiple Point Codes

ITP supports the primary, secondary, and capability point codes and UA/SUA routing keys. With the multiple instances feature, there is support for up to 256 TDM links to adjacent nodes.

## Multiple Instances

The ITP Multiple Instance feature makes it possible to connect the ITP to different networks at one time, each with specific variant and network indicator values. The ITP treats each combination of variant and network indicator as a separate instance. Each instance acts as a separate logical ITP. Each instance is a separate domain with a defined variant, network indicator, ITP point code, optional capability point code, and optional secondary point code. Each instance also has its own routing table and Global Title Translation (GTT) table. You can configure up to 8 different instances on the ITP.

The ITP Instance Translation feature enables the conversion of packets between instances of the same variant. The ITP Instance Conversion feature enables conversion between ITU and ANSI instances for point code and global title.

For more information, see the [“Multiple Instances and Instance Translation” section on page 81](#).

## MLR

MLR enables intelligent routing of SMS messages based on the application or service from which they originated or to which they are destined. SMS applications such as audience interaction services place a heavy demand on the capacity of the legacy SS7 infrastructure, as well as the SMSC servers. These applications create extremely high bursts of signaling traffic over a very short time span, which can result in denial of service and lost messages.

The MLR feature can make SMS message routing decisions based on information found at the MTP, SCCP, TCAP, and MAP-user layer based on a flexible schema including, but not limited to, OPC/DPC/SI and CdPA parameters, CgPA parameters, and any TCAP-layer operation code. For SMS-specific operation codes, such as mobile-originated/mobile-terminated (MO/MT) messages, MLR allows for routing on additional MAP-user-layer parameters such as sending short message entity (SME), destination SME, originating IMSI, and MAP-layer service center address. MLR supports IS-41 SMS message routing, next to full operation code routing for GSM.

For more information, see the [“MLR Routing and Screening” section on page 205](#).

## MO Proxy

MO Proxy enables the routing of segmented GSM MAPv2 and higher messages based on application-layer parameters by terminating the MO dialogue. This capability helps ensure that the SMS MO dialogues for a given B-address are handled by the same Short Message Service Center (SMSC).

For more information, see the [“MLR Routing and Screening” section on page 205](#).

## SMS Notification Proxy

The purpose of the IS-41 SMS Notification Proxy feature is to perform a broadcast of incoming ANSI-41 SMS Notifications to a group of SMSCs and to provide a reply to the Home Location Register (HLR) after receiving the first positive acknowledgement message from any of the SMSCs in the distribution.

## Simple Network Management Protocol

The Simple Network Management Protocol (SNMP) is an application-layer protocol that provides a message format for communication between SNMP managers and agents. The SNMP manager can be part of a Network Management System (NMS) such as CiscoWorks. For a list of SNMP MIBs, see the [“ITP MIBs” section on page 8](#).

## SS7 Routing

SS7 routing is any-to-any routing between all link types including OPC/DPC based routing using MLR.

## ITP MIBs

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB web site on Cisco.com at <http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>.

In addition to Cisco platform MIBs and other general MIBs, ITP supports the following ITP specific MIBs:

- CISCO-ITP-ACL-MIB.my
- CISCO-ITP-DSMR-MIB.my
- CISCO-ITP-DSMR-SMPP-MIB.my
- CISCO-ITP-DSMR-UCP-MIB.my
- CISCO-ITP-GACT-MIB.my
- CISCO-ITP-GRT-MIB.my
- CISCO-ITP-GSCCP-MIB.my
- CISCO-ITP-GSP-MIB.my
- CISCO-ITP-GSP2-MIB.my
- CISCO-ITP-MLR-MIB.my
- CISCO-ITP-MSU-RATES-MIB.my
- CISCO-ITP-SP-MIB.my
- CISCO-ITP-TC-MIB.my
- CISCO-ITP-XUA-MIB.my
- CISCO-BITS-CLOCK-MIB.my
- CISCO-IETF-SCTP-MIB
- CISCO-IETF-SCTP-EXT-MIB

## ITP Restrictions

- You can install up to six SAMI modules on each Cisco 7600 series router chassis.
- ITP deployments with SAMI line cards do not support IP fragmentation. Design networks deployed with SAMI line cards to eliminate fragmentation of IP packets.
- The SAMI is designed to be used with the Cisco 76XX-S chassis for high performance and better results. A non-S chassis supports the SAMI but with inherent syncing issues at high traffic loads.

## Configuring the ITP on SAMI

---

- [Preparing to Install the ITP Software, page 11](#)
- [Installing the ITP Software, page 12](#)
- [Configuration Examples of ITP on SAMI, page 13](#)
- [Saving and Restoring ITP Configurations, page 14](#)

### Note

For hardware requirements, such as power supply and environmental requirements, as well as hardware installation instructions, see the *Service and Application Module for IP User Guide*.

---

## Preparing to Install the ITP Software

Before you install the ITP, keep the following considerations in mind:

The ITP requires the Cisco 7600 Supervisor Engine 720 WS-SUP720-3B and WS-SUP720-3BXL running Cisco IOS Release 12.2(33)IRA or later. You must upgrade to this release or later before installing the Service and Application Module for IP (SAMI). For details, see the “Upgrading to a New Software Release” section in the *Release Notes for Cisco IOS Release 12.2SR for the Cisco 7600 Series Routers*.

- The software interface for the ITP is the Cisco IOS command-line interface (CLI). For more information about using the CLI and Cisco IOS command modes, see the *Cisco 7600 Series Cisco IOS Software Configuration Guide*.
- During the installation and configuration, enter all commands by either establishing a console connection with the ITP, or by Telnetting to the ITP. Enter each configuration command on a separate line.
- In any command mode, you can enter the question mark (?) at the prompt to see a list of available commands. For example:

```
Sup> ?
```

or

```
Sup(config)# ip ITP ?
```

The online help shows the default configuration values and the ranges that are available for each command.

# Installing the ITP Software

ITP configuration is done on the supervisor module. This allows the end user to configure ITP using a single command line interface instead of the several sessions required by other SAMI applications.

The SAMI does not include any external physical interfaces to receive traffic from clients and servers. Instead, it uses internal VLAN interfaces. For general SAMI commands, see the *Cisco Service and Application Module for IP User Guide for the Cisco 7600 Series Routers* available at:

[http://www.cisco.com/en/US/docs/wireless/service\\_application\\_module/sami/user/guide/overview.html](http://www.cisco.com/en/US/docs/wireless/service_application_module/sami/user/guide/overview.html)

To set up VLANs for ITP, complete the following steps:

---

## Step 1 Create a VLAN in the normal manner

```
Sup# enable
Sup# configure terminal
Sup(config)# vlan vlan-id
```

## Step 2 Program the SAMI card to have a presence on the VLANs listed in the VLAN list parameter, by entering the following commands, beginning in privileged EXEC mode:

```
Sup# enable
Sup# configure terminal
Sup(config)# svc1c multiple-vlan-interfaces
Sup(config)# svc1c module slot-number vlan-group group-number
Sup(config)# svc1c vlan-group group-number vlan-range
```

where:

- *group-number* is the number of the VLAN group that you are assigning to the SAMI.
- *vlan-range* is a list of one or more VLANs in the group, specified as follows:
  - A single number in the range 2 to 1001 or 1025 to 4094
  - A range of numbers separated by a hyphen, such as 2-5
  - Single numbers or ranges of numbers separated by commas, such as 5,7-10,13,45-100
- *slot-number* is the slot in which the SAMI is installed.

For example, to assign VLAN groups 1 and 6 to the SAMI in slot 2, enter the following commands, beginning in global configuration mode:

```
Sup# enable
Sup# configure terminal
Sup(config)# svc1c vlan-group 1 5,30,43,765
Sup(config)# svc1c vlan-group 6 6
Sup(config)# svc1c module 2 vlan-group 1,6
Sup(config)# svc1c multiple-vlan-interfaces
```

## Step 3 Create a VLAN interface and assign an IP address.

```
Sup# enable
Sup# configure terminal
Sup(config)# cs7 sami module slot-number
Sup(config)# ip address ip-address (1) netmask vlan vlan-id (1)
Sup(config)# ip address ip-address (2) netmask vlan vlan-id (2)
Sup(config)# ip route dest_ip_prefix (1) netmask gateway_ip_address (1) (Optional)
Sup(config)# ip route dest_ip_prefix (2) netmask gateway_ip_address (2) (Optional)
```

where:

- *dest-ip-prefix* is the IP address for the route.
- *netmask* is the subnet mask for the route.
- *gateway\_ip\_address* is the IP address of the gateway router (the next-hop address for this route). The gateway address must be in the same network as specified in the ip address command for a VLAN interface.

**Note**

If the optional **ip route** command is not configured, the supervisor switching hardware is used to route packets.

**Note**

Each SAMI linecard supports 96 IP Address/Mask/VLAN combinations and 96 IP static routes.

For example, to assign IP addresses to the SAMI in slot 2, enter the following commands, beginning in privileged EXEC mode:

```
Sup# enable
Sup# configure terminal
Sup(config)# cs7 sami module 2
Sup(config)# ip address 209.165.202.129 255.255.255.224 vlan 3
Sup(config)# ip address 209.165.202.131 255.255.255.224 vlan 6
```

**Step 4** To verify the ITP configuration, use the **show cs7 sami ip** command.

```
Sup# show cs7 sami ip

SAMI Module 2
IP-Address      Mask              Vlan Sup IP
-----
209.165.202.129 255.255.255.224  3  209.165.200.253
209.165.202.131 255.255.255.224  6  209.165.200.252

IP-Net          Mask              Next Hop
-----
```

## Configuration Examples of ITP on SAMI

This section includes the following examples:

- [Configuration Example for Basic ITP Configuration on SAMI, page 13](#)

### Configuration Example for Basic ITP Configuration on SAMI

In this example, the SAMI has been allocated a group of VLANs which includes the VLAN numbers from 500 to 525. Then, for one of those VLAN (500), one IP address (200.0.0.2) has been allocated to the SAMI board, and another IP address (200.0.0.1) to the VLAN as a whole. This second IP address will be hosted on the supervisor. This .1 IP address can then be used to offload Sigtran processors to one of the SAMI processors.:

```
svclc multiple-vlan-interfaces
svclc module 4 vlan-group 4
svclc vlan-group 4 500-525
!
```

```
vlan internal allocation policy ascending
vlan access-log ratelimit 2000
vlan 500-550
!
interface Vlan500
 ip address 200.0.0.1 255.255.255.0
!
cs7 sami module 4
 ip address 200.0.0.2 255.255.255.0 vlan 500
```

## Saving and Restoring ITP Configurations

To save the ITP configuration on the Supervisor Engine bootflash and slave boot flash, enter the following command in privileged EXEC mode:

```
Sup# write memory
```

For more information about saving and restoring configurations, see the *Cisco 7600 Series Cisco IOS Software Configuration Guide*.

# ITP Software Upgrade on the Cisco 7600 Platform

---

## Feature History for Non-Disruptive Upgrade

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This feature was introduced. |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

## Contents

- [Prerequisites for Non-Disruptive Upgrade, page 16](#)
- [Information About Non-Disruptive Upgrade, page 16](#)
- [Performing a Non-Disruptive Upgrade, page 16](#)
- [Procedure for Upgrading a Cisco 7600 to SAMI Support, page 24](#)

## Prerequisites for Non-Disruptive Upgrade

- Stateful Switchover (SSO) must be configured.
- Non-Stop Operation (NSO) must be configured
- The network configuration must provide link/linkset redundancy; linksets span multiple FlexWAN modules.

## Information About Non-Disruptive Upgrade

The Non-Disruptive Upgrade feature enables you to upgrade the software image on a Supervisor 720 and a FlexWAN.

## Performing a Non-Disruptive Upgrade

**Note**

Before the first upgrade switchover users must make sure that the new image is first on the standby and the old image is first on the current active.

**Note**

The CS7 configuration will be locked out once the Standby Supervisor is reset with the new image.

To perform a Non-Disruptive Upgrade you perform the tasks described in the following sections:

- [Preparing for Non-Disruptive Upgrade, page 16](#)
- [Resetting the Standby Supervisor, page 20](#)
- [Switching the Standby Supervisor to Active Role, page 20](#)
- [Upgrading the Software Image on FlexWAN Line Cards, page 21](#)
- [Upgrading the Software Image on the Standby Supervisor, page 22](#)

## Preparing for Non-Disruptive Upgrade

The steps in this task prepare for the Non-Disruptive Upgrade procedure.

We recommend that before performing the upgrade procedure, you use the **copy running-config startup-config** command to save the running configuration as the startup configuration.

We also recommend that you run the **cs7 upgrade analysis** command. This command displays the available links configured in each FlexWAN slot and reports either the destinations that might become inaccessible due to loss of all links in a linkset if the FlexWAN is upgraded or the expected utilization of remaining links on other FlexWANs due to diversion of traffic to those links, and displays a summary of the upgrade process. Sample output is shown in the command reference chapter entry for the **cs7 upgrade analysis** command.

**Note**

You can use the **show cs7** command or **show cs7 version** command at any time during the NDU process to see the status of the upgrade.

**Note**

For the purposes of this task, *oldimage* refers to the existing pre-upgrade image and *newimage* refers to the upgrade image.

**Note**

When upgrading from IRE, IRE1, or IRE2 to IRH, the SSN number must be specified along with the point code when configuring *cdpa* or *cgpa* in the PAM.

**Note**

Special characters are not allowed in the image name. Please do not use special characters when renaming image files.

## SUMMARY STEPS

1. **enable**
2. **copy running-config startup-config**
3. **cs7 upgrade analysis**
4. **mkdir slavedisk0:archive**
5. **rename slavedisk0:oldimage slavedisk0:archive/oldimage**
6. **copy tftp:newimage slavedisk0:newimage**
7. **verify /md5 slavedisk0:newimage [checksum]**
8. **boot system disk0:**
9. **show boot | include BOOT**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                                                          | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                       |
| Step 2 | <b>copy running-config startup-config</b><br><br><b>Example:</b><br>ITP# copy running-config startup-config                                                                                  | Saves the running configuration as the startup configuration.                                                                                                                                                                          |
| Step 3 | <b>cs7 upgrade analysis</b><br><br><b>Example:</b><br>ITP# cs7 upgrade analysis                                                                                                              | Shows the current software version on Supervisors and all FlexWANs and provides an analysis of each of the FlexWAN slots.<br><br>Sample output is provided in the command reference entry for the <b>cs7 upgrade analysis</b> command. |
| Step 4 | <b>mkdir slavedisk0:archive</b><br><br><b>Example:</b><br>ITP# mkdir slavedisk0:archive                                                                                                      | Creates a subdirectory named <b>archive</b> on <b>slavedisk0</b> .                                                                                                                                                                     |
| Step 5 | <b>rename slavedisk0:oldimage slavedisk0:archive/oldimage</b><br><br><b>Example:</b><br>ITP# rename slavedisk0:s72033-itpk9v-mz.122-18.IXA<br>slavedisk0:archive/s72033-itpk9v-mz.122-18.IXA | Moves existing image from <b>slavedisk0:</b> to the <b>slavedisk0:archive</b> subdirectory.<br><br>Repeat this step as necessary to move all images from <b>slavedisk0</b> to the subdirectory.                                        |
| Step 6 | <b>copy tftp:newimage slavedisk0:newimage</b><br><br><b>Example:</b><br>ITP# copy tftp:s72033-itpk9v-mz.122-18.IXB<br>slavedisk0:s72033-itpk9v-mz.122-18.IXB                                 | Copies the new image onto the disk.                                                                                                                                                                                                    |

|        | Command or Action                                                                                                                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 7 | <p><b>verify /md5 slavedisk0:newimage [checksum]</b></p> <p><b>Example:</b></p> <pre>ITP# verify /md5 slavedisk0:s72033-itypk9v-mz.122-18.IXB 740ba4eb52bcf8ffae9909938f36a955 ..... .....Done! Verified (slavedisk0:s72033-itypk9v-mz.122-18.IXB) = 740ba4eb52bcf8ffae9909938f36a955</pre> | <p>Verifies the image on the Standby Supervisor.</p> <p>Note: In the example, the <b>verify</b> command includes an optional checksum. If you include the md5 checksum in the command, the output will indicate either verification or error. If you do not include the md5 checksum the command will simply return the computed checksum which you would have to manually check against the sum published with the image.</p>    |
| Step 8 | <p><b>boot system disk0:</b></p> <p><b>Example:</b></p> <pre>ITP# boot system disk0:</pre>                                                                                                                                                                                                  | <p>Sets the location to boot from.</p> <p>Note: Remove any other boot statements. This should be the only boot statement in the running config.</p> <p>The <b>boot system disk0:</b> command will boot the first valid image file on disk0: from the list of files as seen in the output of <b>dir disk0:</b>. Make sure that the first image on disk0: is the old image and the first image on slavedisk0: is the new image.</p> |
| Step 9 | <p><b>show boot   include BOOT</b></p> <p><b>Example:</b></p> <pre>Router# show boot   include BOOT Verify that one location is listed and that standby variable matches the primary. Example:   BOOT variable = disk0:,12;   and   Standby BOOT variable = disk0:,12;</pre>                | <p>Displays output to verify that the boot variable is set to disk0:.</p>                                                                                                                                                                                                                                                                                                                                                         |

## What to Do Next

Reset the Standby Supervisor.

## Resetting the Standby Supervisor

This task resets the standby Supervisor (SUP2 in our scenario) and boots the new software that you loaded onto the standby Supervisor in the previous task. The standby Supervisor progresses to the “STANDBY HOT” state. After resetting the Standby Supervisor, you can verify the redundancy status.

### SUMMARY STEPS

1. **hw-module module *standby-sup-slot* reset**
2. **show redundancy states**
3. **show cs7 nso state**

### DETAILED STEPS

|        | Command or Action                                                                                             | Purpose                                                                                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>hw-module module <i>standby-sup-slot</i> reset</b><br><br><b>Example:</b><br>ITP# hw-module module 6 reset | Resets the specified Supervisor module.<br><br>In the example, the specified Supervisor module is the standby Supervisor (SUP2) in slot 6.                      |
| Step 2 | <b>show redundancy states</b><br><br><b>Example:</b><br>ITP# show redundancy states                           | Displays redundancy state information.<br><br>Sample output is provided in the command reference entry for the <b>show redundancy states</b> command.           |
| Step 3 | <b>show cs7 nso state</b><br><br><b>Example:</b><br>ITP# show cs7 nso state                                   | Displays Non-stop operation (NSO) state information.<br><br>Sample output is provided in the command reference entry for the <b>show cs7 nso state</b> command. |

## What to Do Next

Switch the Standby Supervisor to ACTIVE Role

## Switching the Standby Supervisor to Active Role

This task switches the role of “ACTIVE” to the Supervisor that you reset in the previous task (SUP2, which is running the new software). The previously Active Supervisor (SUP1, which is running the old software) is now in the STANDBY COLD role. After forcing the switchover, you can verify the redundancy status.

**SUMMARY STEPS**

1. **redundancy force-switchover**
2. **show redundancy states**

**DETAILED STEPS**

|        | Command or Action                                   | Purpose                                                                                   |
|--------|-----------------------------------------------------|-------------------------------------------------------------------------------------------|
| Step 1 | <b>redundancy force-switchover</b>                  | Switches the role of “ACTIVE” to the Supervisor to the current Standby Supervisor (SUP2). |
|        | <b>Example:</b><br>ITP# redundancy force-switchover | Wait for the message<br>“Standby supervisor is up. Line cards can be upgraded now.”       |
| Step 2 | <b>show redundancy states</b>                       | Displays redundancy state information.                                                    |
|        | <b>Example:</b><br>ITP# show redundancy states      |                                                                                           |

**What to Do Next**

Upgrade the software image on the FlexWAN line cards.

**Upgrading the Software Image on FlexWAN Line Cards**

In this step, the newly ACTIVE Supervisor (SUP2 in our scenario) upgrades a specified FlexWAN line card. This step can be performed only after the message “Standby supervisor is up. Line cards can be upgraded now” is returned from the redundancy force-switchover command that you performed in the previous task.

**SUMMARY STEPS**

1. **cs7 upgrade module**

**DETAILED STEPS**

|        | Command or Action                            | Purpose                                                                                                                                                                                                                     |
|--------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>cs7 upgrade module</b> <i>slotnumber</i>  | Upgrades the software on a linecard. Repeat this step for all FlexWANs.                                                                                                                                                     |
|        | <b>Example:</b><br>ITP# cs7 upgrade module 1 | This step can be performed only after the message<br>“Standby supervisor is up. Line cards can be upgraded now”<br>is returned from the <b>redundancy force-switchover</b> command that you performed in the previous task. |

## What to Do Next

Upgrade the software image on the standby Supervisor.

## Upgrading the Software Image on the Standby Supervisor

In this final step you upgrade the software image on the Standby Supervisor (SUP1 in our scenario) to the new image. The Standby Supervisor has been in the STANDBY COLD state to allow for a quick revert/reset. You will now copy the new software image to the filesystem of the new Standby Supervisor and reset the module to bring the system back to SSO mode and a STANDBY HOT state with both Supervisors now running the new software image.

### SUMMARY STEPS

1. `mkdir slavedisk0:archive`
2. `rename slavedisk0:image slavedisk0:archive/image`
3. `copy disk0:newimage slavedisk0:newimage`
4. `hw-module module standby-sup-slot reset`<sup>1</sup>
5. `show redundancy states`
6. `show cs7 nso state`

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                      | Purpose                                                                                                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>mkdir slavedisk0:archive</code><br><br><b>Example:</b><br>ITP# <code>mkdir slavedisk0:archive</code>                                                                                             | Creates a subdirectory named <b>archive</b> on slavedisk0.                                                                                                                                     |
| Step 2 | <code>rename slavedisk0:image slavedisk0:archive/image</code><br><br><b>Example:</b><br>ITP# <code>rename slavedisk0:s72033-itpk9v-mz.122-18.IXA slavedisk0:archive/s72033-itpk9v-mz.122-18.IXA</code> | Moves existing image from <b>slavedisk0</b> to the <b>slavedisk0:archive</b> subdirectory.<br><br>Repeat this step as necessary to move all images from <b>slavedisk0</b> to the subdirectory. |
| Step 3 | <code>copy disk0:newimage slavedisk0:newimage</code><br><br><b>Example:</b><br>ITP# <code>copy disk0:NEW slavedisk0:NEW</code>                                                                         | Copies the new Supervisor image onto the Standby Supervisor.                                                                                                                                   |

1. This command is documented in detail in the Cisco 7600 Series Cisco IOS Command Reference, 12.2 SX.

|        | Command or Action                                                                                      | Purpose                                                                                                                                                         |
|--------|--------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <b>hw-module module standby-sup-slot reset</b><br><br><b>Example:</b><br>ITP# hw-module module 5 reset | Resets the Standby Supervisor.<br><br>In the example, the Standby Supervisor is in slot 5.                                                                      |
| Step 5 | <b>show redundancy states</b><br><br><b>Example:</b><br>ITP# show redundancy states                    | Displays redundancy state information.<br><br>Sample output is provided in the command reference entry for the <b>show redundancy states</b> command.           |
| Step 6 | <b>show cs7 nso state</b><br><br><b>Example:</b><br>ITP# show cs7 nso state                            | Displays Non-stop operation (NSO) state information.<br><br>Sample output is provided in the command reference entry for the <b>show cs7 nso state</b> command. |

# Procedure for Upgrading a Cisco 7600 to SAMI Support

ITP requires the Cisco 7600 Supervisor Engine 720 WS-SUP720-3B and WS-SUP720-3BXL to run Cisco IOS Release 12.2(33)IR in order to support the SAMI. This upgrade procedure is designed to replace the Cisco software release 12.2(18)IX with Cisco software release ITP 12.2(33)IR. This allows a Cisco 7600 that does not support the SAMI to support the SAMI.

The software upgrade will require a reload. The upgrade should be performed during an off-peak maintenance window. This section describes upgrading a Cisco 7600 to support the SAMI:

- [Upgrade Procedures, page 24](#)
- [Supported Scenarios, page 25](#)
- [Roll Back to the Previous Image, page 25](#)
- [NDU from IRE to Any Newer Image, page 26](#)

## Upgrade Procedures

To upgrade the Cisco 7600 to support the SAMI, perform the following steps:

### Note

Back up the old image. Ensure that the only image in the root directory on disk0 and slavedisk0 is the new image.

**Step 1** Enter the following commands in privileged EXEC mode:

```
mkdir disk0:archive
mkdir slavedisk0:archive
copy tftp://new-image disk0:new-image
copy tftp://new-image slavedisk0:new-image
verify /md5 disk0:new-image CCO_posted_hash
verify /md5 slavedisk0:new-image CCO_posted_hash
rename disk0:old-image disk0:archive/old-image
rename slavedisk0:old-image slavedisk0:archive/old-image
configure terminal
boot system disk0:
end
copy running-config startup-config
show boot | inc BOOT
```

**Step 2** Verify that one location is listed and that standby variable matches the primary, for example:

```
BOOT variable = disk0:,12;
Standby BOOT variable = disk0:,12;
```

**Step 3** Save the configuration to a file on disk in case a rollback is necessary:

```
copy startup-config disk0:old-config
copy startup-config slavedisk0:old-config
reload
```

The ITP will reload with the new image. All existing configuration and hardware will be recognized and operate as normal. Any changes in hardware should be done after the reload.

## Supported Scenarios

The following are supported upgrade scenarios:

### Line cards are not changed during upgrade

Since 12.2(18)IX supports FlexWANs only, this scenario leaves the FlexWANs in their respective slots after the upgrade. It requires no action from the user.

### SAMIs or other new cards will be inserted in empty slots

Insert the SAMIs, or other new cards, one at a time into empty slots. The ITP Online Insertion and Removal (OIR) procedure will bring the new cards into an active state. Configure items for the new cards. Save the new configuration to NVRAM.

### One or more FlexWANs will be replaced with SAMIs or new cards

Remove the desired FlexWAN from its slot with OIR. If there were any links configured on this FlexWAN they will stay in the system in a 'removed' status, in case a same, or similarly configured, FlexWAN is replaced in the same slot. These links are automatically removed when a different card type is inserted. Configure items for the new cards. Save the new configuration to NVRAM. Insert a SAMI or another new card.

### PAs within a FlexWAN will be changed

Remove the desired FlexWAN from its slot. Replace port adapters in the FlexWAN as needed. The FlexWAN should then be inserted back in the same slot. Upon insertion, previously configured items pertaining to this FlexWAN are automatically removed. Items for the new PA should be configured next. Save the new configuration to NVRAM.

## Roll Back to the Previous Image

Rollback may be necessary if there are unexpected operational problems with the new image. According to the non disruptive upgrade (NDU) design, a rollback is always disruptive.

Complete the following steps to roll back the image:

```
rename disk0:new-image disk0:archive/new-image
rename slavedisk0:new-image slavedisk0:archive/new-image
rename disk0:archive/old-image disk0:old-image
rename slavedisk0:archive/old-image slavedisk0:old-image
copy startup-config disk0:new-config
copy startup-config slavedisk0:new-config
copy disk0:old-config startup-config
```

Remove any new hardware from their slots, and issue the **reload** command. The ITP will come back up running the old image.

## NDU from IRE to Any Newer Image

While performing a NDU from IRE to any newer image, upgrade the SAMI before any other FlexWAN modules because of a possible SAMI ppc crash in which M3UA SAMI associations are present.

**Note**

ITP supports an upgrade from N to N-1 and N-2 releases in which N is the latest release of ITP.

Recommended steps are as follows:

- 
- Step 1** Wait for the following message received during the upgrade process:  
`Standby supervisor is up. Line cards can be upgraded now.`
  - Step 2** Issue the **show module** command to look for the SAMI module slot-number.
  - Step 3** Issue the **cs7 upgrade module *slot-number*** command using the slot-number found in Step 2.
  - Step 4** Repeat Step 3 for any other SAMI module.
  - Step 5** Continue with other FlexWAN module upgrades as normal.

## Configuring ITP Basic Functionality

---

This chapter describes the specific tasks and commands to configure basic Cisco ITP functionality.

For information about configuring the IOS software, beyond the specific ITP configuration instructions that are included in this document, refer to the Cisco IOS Release 12.2 documentation at the following URLs:

[http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122cgcr/finter\\_c/index.htm](http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122cgcr/finter_c/index.htm)

### Note

---

Cisco ITP on the Cisco 7600 Series Routers requires that the default MAC address is used on all FlexWAN interfaces. The ITP does not support alternate MAC addresses on FlexWAN interfaces.

---

### Note

---

Cisco ITP on the Cisco 7600 Series Routers requires traffic to be transmitted and received using only FlexWAN interfaces.

---

### Note

---

Cisco ITP on the Cisco 7600 Series Routers requires specifying a numerical next hop when configuring a default route 0.0.0.0 0.0.0.0.

---

### Note

---

IP routing is enabled on the ITP by default, and must not be disabled. Disabling IP routing can result in connection errors.

---

### Note

---

You must perform ITP CLI configuration only on the active supervisor module of the Cisco 7600 Series Routers. We recommended you not perform configuration on a SAMI. Because the active supervisor module is the controller card, the configuration is synced from the supervisor to the linecards.

---

### Note

---

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

---

# Contents

This chapter discusses the following topics and describes the associated configuration tasks:

- [Enabling Secure Shell, page 14](#)
- [Specifying the SS7 Variant, National Option, and Network Indicator, page 15](#)
- [Specifying the Point Code, page 18](#)
- [Specifying the Point Code, page 18](#)
- [Specifying the Interface and Encapsulation, page 20](#)
- [Configuring Local Peers, page 32](#)
- [Configuring Linksets, page 32](#)
- [Configuring Circular Route Direction \(CRD\), page 34](#)
- [Configuring Multiple Linksets to Adjacent Nodes, page 37](#)
- [Specifying the Cisco ITP Route Table, page 38](#)
- [Assigning Links to Linksets, page 40](#)
- [Shutting Down and Restarting Linksets and Links, page 42](#)
- [Configuration Example of ITP Basic Functionality, page 43](#)

## Enabling Secure Shell

The Secure Shell (SSH) feature enables secure sessions by establishing an encrypted connection between an SSH client and an SSH server.

For information about configuring the Secure Shell feature, beyond the basic instructions below, please refer to the *Cisco IOS Release 12.4 Security Configuration Guide* at the following URL:

[http://www.cisco.com/univercd/cc/td/doc/product/software/ios124/124cg/hsec\\_c/index.htm](http://www.cisco.com/univercd/cc/td/doc/product/software/ios124/124cg/hsec_c/index.htm)

and to the *Cisco IOS Release 12.4 Security Command Reference* at the following URL:

[http://www.cisco.com/univercd/cc/td/doc/product/software/ios124/124cr/hsec\\_r/index.htm](http://www.cisco.com/univercd/cc/td/doc/product/software/ios124/124cr/hsec_r/index.htm)

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **username *username* password *password***
4. **aaa new-model**
5. **ip domain-name *domain-name***
6. **ip ssh authentication-retries *num***
7. **crypto key generate rsa modulus *size***
8. **ssh -I *userID* {*ip-address* | *hostname*}** (Enter this command from an Xterm window.)
9. **show ssh** (Enter this command from the ITP.)

|        | Command                                                                                                                | Purpose                                                                                                                                 |
|--------|------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                    | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted.                                  |
| Step 2 | <b>configure {terminal   memory   network}</b><br><br><b>Example:</b><br>ITP# configure terminal                       | Enters configuration mode, selecting the terminal option.                                                                               |
| Step 3 | <b>username username password password</b><br><br><b>Example:</b><br>ITP(config)# username admin password jo4fhe       | Specifies the username and password.                                                                                                    |
| Step 4 | <b>aaa new-model</b><br><br><b>Example:</b><br>ITP(config)# aaa new-model                                              | Enables the authentication, authorization, and accounting (AAA) access control model.                                                   |
| Step 5 | <b>ip domain-name domain-name</b><br><br><b>Example:</b><br>ITP(config)# ip domain-name cisco                          | Specifies the domain.                                                                                                                   |
| Step 6 | <b>ip ssh authentication-retries num</b><br><br><b>Example:</b><br>ITP(config)# ip ssh authentication-retries 3        | Specifies the number of attempts after which the interface is reset.                                                                    |
| Step 7 | <b>crypto key generate rsa modulus size</b><br><br><b>Example:</b><br>ITP(config)# crypto key generate rsa modulus 768 | Generates Rivest, Shamir, and Adelman (RSA) key pairs.                                                                                  |
| Step 8 | <b>ssh -I userID {ip-address   hostname}</b><br><br><b>Example:</b><br>ITP# ssh -I adminHQ HQhost                      | (Enter this EXEC command from an xterm window.)<br>Starts an encrypted session with a remote networking device,                         |
| Step 9 | <b>show ssh</b><br><br><b>Example:</b><br>ITP# show ssh                                                                | (Enter this EXEC command from the ITP)<br>Displays the status of the SSH connections. Use this command to verify your SSH connectivity. |

## Specifying the SS7 Variant, National Option, and Network Indicator

The SS7 variant specifies which variation of SS7 the router is running. The variant configured on the ITP must match the variant of the connected SS7 network.

**Note**

If you change the variant after you have completed ITP configuration, you must first remove all linksets and the local point-code. After reconfiguring the variant, you must first reconfigure the point code and then the linkset.

To specify one of these variants, perform the following steps.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **cs7 variant {ansi | itu | china | ttc}**
4. **cs7 national-options {TFR | multiple-congestion | route-set-congestion-test | combined-linkset-loadsharing}**
5. **cs7 network-indicator {international | national | reserved | spare}**
6. **cs7 [instance *instance-number*] local-sccp-addr-ind {national | international}**

|        | Command                                                                                               | Purpose                                                                                                |
|--------|-------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                   | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted. |
| Step 2 | <b>configure {terminal   memory   network}</b><br><br><b>Example:</b><br>ITP# configure terminal      | Enters configuration mode, selecting the terminal option.                                              |
| Step 3 | <b>cs7 variant {ansi   itu   china   ttc}</b><br><br><b>Example:</b><br>ITP(config)# cs7 variant ansi | Specifies which SS7 variant the router is running.                                                     |

|        | Command                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <p><b>cs7 national-options</b> {<b>TFR</b>   <b>multiple-congestion</b>   <b>signaling-route-congestion-test</b>   <b>combined-linkset-loadsharing</b>}</p> <p><b>Example:</b><br/>ITP(config)# cs7 national-options TFR</p> | <p>Specifies national options.</p> <p>The national options apply to the variants as follows:</p> <ul style="list-style-type: none"> <li>• <b>TFR</b>—ITU and China SS7 Variants</li> <li>• <b>multiple-congestion</b>—ITU and China SS7 Variants</li> <li>• <b>signaling-route-congestion-test</b>—TTC SS7 Variant</li> <li>• <b>combined-linkset-loadsharing</b>—Configures the TTC variant to use the enhanced loadsharing algorithm</li> </ul> <p><b>Note</b> All SS7 variants, except TTC, use the enhanced loadsharing algorithm for distributing messages across the available links within a linkset and combined linkset. By default, the TTC variant uses the A/B linkset selection bit that exists as part of the SLS in the MSU routing label.</p> <p><b>Note</b> Configure national option as combined-linkset-loadsharing in TTC variant to use the enhanced loadsharing algorithm at the configuration time of variant. If you do not want to use the enhanced loadsharing algorithm, do not configure national option as combined-linkset-loadsharing. If already configured, unconfigure national option and reload the router for the change to take effect.</p> |
| Step 5 | <p><b>cs7 network-indicator</b> {<b>international</b>   <b>national</b>   <b>reserved</b>   <b>spare</b>}</p> <p><b>Example:</b><br/>ITP(config)# cs7 network-indicator international</p>                                    | <p>(Optional) Specifies the network indicator.</p> <p>The network indicator on the ITP must match the network indicator in use in the rest of the SS7 network. The default is national.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 6 | <p><b>cs7</b> [<b>instance</b> <i>instance-number</i>] <b>local-sccp-addr-ind</b> {<b>national</b>   <b>international</b>}</p> <p><b>Example:</b><br/>ITP(config)# cs7 local-sccp-addr-ind international</p>                 | <p>(Optional) Customizes the setting of the national use field within SCCP management calling and called party addresses. The default value for instances configured with the ANSI variant is national ('1'b value), and the default for all other variants is international ('0'b value).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Specifying the Point Code

Each signaling point (also called an SS7 node) in the SS7 network is identified with a unique address called a point code (PC). PCs are carried in signaling messages exchanged between signaling points to identify the source and destination of each message. Operators can assign their own PCs in private SS7 networks.

### Specifying the Point Code Representation

The format of the point code can be represented according to either the ANSI, ITU, China or Japan TTC standard. The ANSI and China standard for point code representation is 24 bits partitioned into 3 components that specify network.cluster.member, with a default representation of 8.8.8. The ITU standard for point code representation is 14 bits partitioned into 3 components that specify zone.region.signaling point (sp), with a default point code representation of 3.8.3. The TTC standard for point code representation is 16 bits partitioned into 3 fields with a default representation of 5.4.7. The delimiter that will appear between each segment (when you show output of the configuration) can be either a dot or a dash. You can modify the default point code bit format and the default delimiter at any time during configuration, without prior removal of links and linksets.

You can change the partitioning of the bits to any configuration of 1, 2, or 3 components that total the 24-bit ANSI and China standard or 14-bit ITU standard. To modify the ANSI or ITU point code format, or to return to either standard's default format, use one of the following commands in global configuration mode:

| Command                                                                                                                                                                                                                                                                            | Purpose                                                                                          |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <b>cs7</b> [ <b>instance</b> <i>instance-number</i> ] <b>point-code format</b> <i>1-24</i> [ <i>1-23</i> [ <i>1-22</i> ]] [ <b>description</b> <i>string</i> ]<br><br><b>Example:</b><br>ITP(config)# cs7 instance 1 point-code format 2 6 6<br>description network cluster member | Specifies the point code representation.                                                         |
| <b>cs7 point-code format default</b><br><br><b>Example:</b><br>ITP(config)# cs7 point-code format default                                                                                                                                                                          | Resets the point-code format to the default 8.8.8 (ANSI and China), 3.8.3 (ITU), or 5.4.7 (TTC). |

The default delimiter between components of the point code is a dot. To change the delimiter to a dash, or to return to the default delimiter (dot), use one of the following commands in global configuration mode:

| Command                                                                     | Purpose                                                        |
|-----------------------------------------------------------------------------|----------------------------------------------------------------|
| <code>cs7 point-code delimiter [default   dash]</code>                      | Specifies the delimiter between bits as either dots or dashes. |
| <b>Example:</b><br><pre>ITP(config)# cs7 point-code delimiter dash</pre>    |                                                                |
| <code>cs7 point-code delimiter default</code>                               | Resets the delimiter to dots.                                  |
| <b>Example:</b><br><pre>ITP(config)# cs7 point-code delimiter default</pre> |                                                                |

## Specifying the Primary Local Point Code

### Note

You must specify the SS7 variant before you can specify the local point code.

Each Cisco ITP must have a unique local point code that is used to send management messages to adjacent signaling points. To specify the point code, use the following command in global configuration mode:

| Command                                                           | Purpose                                       |
|-------------------------------------------------------------------|-----------------------------------------------|
| <code>cs7 point-code point-code</code>                            | Specifies the primary point code for the ITP. |
| <b>Example:</b><br><pre>ITP(config)# cs7 point-code 5.100.1</pre> |                                               |

## Specifying a Secondary Point Code

If you intend to configure a second linkset between the ITP and an adjacent node, you must specify a secondary local point code. You cannot exceed a maximum of 40 secondary point codes per chassis. To specify the secondary point code, use the following command in global configuration mode:

| Command                                                             | Purpose                                       |
|---------------------------------------------------------------------|-----------------------------------------------|
| <code>cs7 secondary-pc point-code</code>                            | Specifies a secondary point code for the ITP. |
| <b>Example:</b><br><pre>ITP(config)# cs7 secondary-pc 5.100.2</pre> |                                               |

## Specifying the Capability Point Code

The ITP supports configuration of up to 200 capability point-codes (CPC) per instance. CPC configuration is optional, but recommended for certain networks. The prime example for use of a CPC is when a mated pair of ITP nodes shares the same GTT database for redundancy purposes. In this configuration, all SCCP messages are directed to a single “capable” point-code; either ITP can handle the SCCP processing. The figure below shows a mated pair of ITPs with identical capability point-codes and a common GTT database for selecting the appropriate HLR.

Figure 4 Mated Pair of ITPs With the Same Capability Point Codes

In Figure 4, each of the MSCs have two routes to the mated pair of ITPs. The MSCs can either load-share all GTT messages between the mated pair of ITPs, or use one ITP as a backup should the primary fail. All messages requiring GTT can be routed to the same destination point-code. In this case the DPC is the CPC, which is 5.100.12. The benefit of CPC usage in this case is that if a single ITP is unreachable, the MSCs are unaware of this event.

To specify the capability point code, use the following command in global configuration mode:

| Command                                                                 | Purpose                                                                                                                           |
|-------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>cs7 capability-pc point-code</code>                               | Specifies the capability point code for the ITP. ITP supports the configuration of up to 200 capability point codes per instance. |
| <b>Example:</b><br><code>ITP(config)# cs7 capability-pc 5.100.12</code> |                                                                                                                                   |

Note

The previously defined point code format must be used to enter the capability point-code.

All messages requiring GTT processing can be routed to either the local point-code or the capability point-code.

## Specifying the Interface and Encapsulation

Note

To avoid unnecessary CPU load, we recommend that you shut down interfaces that are configured but not provisioned as part of a linkset.

The following sections provide information and tasks for various interface and encapsulation configurations:

- [Clocking on the SS7 Port Adapter and SS7 Q.703 High Speed Port Adapter, page 21](#)
- [Configuring a Serial Interface and SS7 High-Speed MTP2 Encapsulation \(Q.703 Annex A\) on the SS7 Q.703 High Speed Port Adapter, page 21](#)
- [Configuring a Serial Interface and MTP2 Encapsulation on the SS7 Port Adapter, page 23](#)

- [Configuring SS7 over ATM High Speed Links \(HSL\), page 25](#)
- [Configuring BITS Network Clocking, page 27](#)
- [Configuring SS7 ATM High Speed Links with BITS Network Clocking, page 29](#)

## Clocking on the SS7 Port Adapter and SS7 Q.703 High Speed Port Adapter

Each SS7 Port Adapter in the ITP shares a clocking source for all T1s and E1s serviced on that card. The clocking options and commands are listed here and shown in the configuration tasks that follow this section:

- Clocking source is internally generated.  
**clock source internal**  
This option imposes the requirements that all devices connected to the ITP must derive their clock from the T1/E1 by which they are connected to the ITP.
- Clocking source is derived from a T1/E1 that is terminated on the card.  
**clock source line {primary | secondary priority}**  
The SS7 Port Adapter on the ITP derives its clock from an adjacent node. All other T1s or E1s on the card are clocked with this derived source. This option imposes the restrictions that all adjacent nodes connected to T1s or E1s on that card must either derive the clock from the T1/E1 to which they are connected or are derive the clock from the same source as the ITP.
- Clocking source is provided through a dedicated port on that card via BITS (a common source received via satellite and used to synchronize all clocks across a CO and between COs)  
**clock source bits {primary | secondary priority}**  
A common dedicated clock source is wired to all devices and used by each device for all T1/E1 timing.  
A controller that is configured for BITS clocking cannot be used to carry data.

### Note

It is recommended that any controller that is not used for SS7 links or BITS clocking should be shut down.

## Configuring a Serial Interface and SS7 High-Speed MTP2 Encapsulation (Q.703 Annex A) on the SS7 Q.703 High Speed Port Adapter

The SS7 Q.703 High Speed Port Adapter for the Cisco ITP (PA-MCX-4TE1-Q) is a single-width, high speed port adapter that supports enhanced Message Transfer Part Level 2 (MTP2) functions and procedures that are suitable for the operation and control of signaling links at data rates of 1.5 and 2.0 Mb. For the complete instructions for installing and configuring the SS7 Q.703 high speed port adapter, see the *SS7 Q.703 High Speed Port Adapter Installation and Configuration Guide* at the following URL:

<http://www.cisco.com/univercd/cc/td/doc/product/core/cis7507/portadp/multicha/mcx4te1q/index.htm>.

To perform the basic configuration for the SS7 Q.703 High Speed Port Adapter, you specify the card type as E1, configure the controller, configure a channel group on the port adapter to use all the time slots, and configure the interface for SS7 high-speed MTP2 encapsulation. Perform these tasks, beginning in global configuration mode:

|         | Command                                                                                                                                                                            | Purpose                                                                                                                        |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| Step 1  | <b>card type e1 slot bay</b><br><br><b>Example:</b><br>ITP(config)# card type e1 6 0                                                                                               | Configures the card type.                                                                                                      |
| Step 2  | <b>controller e1 slot/bay/port</b><br><br><b>Example:</b><br>ITP(config)# controller e1 6/0/0                                                                                      | Configures an E1 controller.                                                                                                   |
| Step 3  | <b>framing crc4</b><br><br><b>Example:</b><br>ITP(config-controller)# framing crc4                                                                                                 | Specifies the framing format for E1 controller.                                                                                |
| Step 4  | <b>linestate debounce</b><br><br><b>Example:</b><br>ITP(config-controller)# linestate debounce                                                                                     | Supresses rapid linestate transitions that may occur due to brief interruption of the framing on an E1 controller.             |
| Step 5  | <b>clock source {bits {primary   secondary priority}   internal   line {primary   secondary priority}}</b><br><br><b>Example:</b><br>ITP(config-controller)# clock source internal | Specifies the clock source as internal.                                                                                        |
| Step 6  | <b>linecode hdb3</b><br><br><b>Example:</b><br>ITP(config-controller)#                                                                                                             | Specifies high-density bipolar 3 (hdb3) as the line-code type. Valid for E1 controller only. This is the default for E1 lines. |
| Step 7  | <b>channel-group channel-number timeslots 1-31</b><br><br><b>Example:</b><br>ITP(config-controller)# channel-group 0 timeslots 1-31                                                | Configures the channel group and timeslots 1-31.<br><br><b>Note</b> High-speed MTP2 links must use timeslots 1-31 on an E1.    |
| Step 8  | <b>exit</b><br><br><b>Example:</b><br>ITP(config-controller)# exit                                                                                                                 | Exit controller configuration mode and return to global configuration mode.                                                    |
| Step 9  | ITP(config)# <b>interface serial number</b><br><br><b>Example:</b><br>ITP(config)# interface serial 6/0/0:0                                                                        | Configures a serial interface in global configuration mode and enters interface configuration mode.                            |
| Step 10 | <b>encapsulation hs-mtp2</b><br><br><b>Example:</b><br>ITP(config-if)# encapsulation hs-mtp2                                                                                       | Configures the serial interface to use SS7 high-speed MTP2 encapsulation.                                                      |

## Configuring a Serial Interface and MTP2 Encapsulation on the SS7 Port Adapter

**Note**

The ITP supports SS7 links over T1/E1 router interfaces. These are router interfaces where the CSU/DSU functionality is integrated into the port adapter. Multiple SS7 links can be configured per T1/E1 interface in this configuration.

The SS7 Port Adapter is a single-width, eight-port T1/E1 port adapter with a custom hardware-assist engine to support SS7 signaling. The SS7 Port Adapter features full channelization of up to 126 HDLC-encoded SS7 (or DS0) channels at 56 Kbps or 64 Kbps. This feature requires the SS7 Port Adapter (PA-MCX-8TE1-M=) with the controller configured for BITS clock.

For more information on the SS7 Port Adapter, refer to the SS7 guide, *SS7 Port Adapter Installation and Configuration* on Cisco.com:

<http://www.cisco.com/univercd/cc/td/doc/product/core/cis7507/portadp/multicha/mcx8te1/index.htm>

To configure a serial interface and MTP2 encapsulation for the SS7 Port Adapter, you specify the card type, configure the controller, configure a channel group on the port adapter to use all the time slots, and specify the interface for MTP2 encapsulation.

A separate channel group statement is necessary for each traditional SS7 link to be mapped to the specific T1/E1 link.

**Note**

An SS7 port adapter that is configured to be E1 cannot use port 7 timeslot 31.

**Note**

MTP2 low speed links support only 1 timeslot per serial link.

**Note**

If you use a T1/E1 card for your SS7 connectivity, each channel group statement under the controller automatically produces a serial subinterface for that channel. To complete connectivity over the T1/E1 interface, you must enable MTP2 encapsulation on those serial sub-interfaces.

The scenario for the configuration task that follows assumes a T1 interface with T1 cross over cable to an STP. The framing and linecode are set to match the STP values. For this configuration, the T1/E1 controller parameters must be set appropriately with the device on the other side of the T1/E1 link. Here, two SS7 links are being configured over the same T1 interface, one on timeslot 1 and the other on timeslot 2.

To configure the T1 interface as indicated in the above scenario, use the following commands beginning in global configuration mode:

|         | Command                                                                                                                                                                            | Purpose                                                                                                                                                           |
|---------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1  | <b>card type</b> {t1   e1} slot bay<br><br><b>Example:</b><br>ITP(config)# card type t1 1 1                                                                                        | Configures the card type.                                                                                                                                         |
| Step 2  | <b>controller</b> {t1   e1} slot/port-adapter-num/port<br><br><b>Example:</b><br>ITP(config)# controller t1 1/1/1                                                                  | Specifies the controller and enters controller configuration mode.                                                                                                |
| Step 3  | <b>linestate debounce</b><br><br><b>Example:</b><br>ITP(config-controller)# linestate debounce                                                                                     | (Optional for E1 controller configuration.)<br>Supresses rapid linestate transitions that may occur due to brief interruption of the framing on an E1 controller. |
| Step 4  | <b>variant jt1</b><br><br><b>Example:</b><br>ITP(config-controller)# variant jt1                                                                                                   | (Optional) Applies to T1 interface only. Enables Japanese variations of the standard framing formats.                                                             |
| Step 5  | <b>framing</b> {sf   esf}<br><br><b>Example:</b><br>ITP(config-controller)# framing esf                                                                                            | Specifies the framing format for T1.                                                                                                                              |
| Step 6  | <b>clock source</b> {bits {primary   secondary priority}   internal   line {primary   secondary priority}}<br><br><b>Example:</b><br>ITP(config-controller)# clock source internal | Specifies the clock source as internal.                                                                                                                           |
| Step 7  | <b>linecode</b> {ami   b8zs   hdb3}<br><br><b>Example:</b><br>ITP(config-controller)# linecode b8zs                                                                                | Specifies the line code type as B8ZS.                                                                                                                             |
| Step 8  | <b>channel-group</b> channel-group-num timeslots range<br><br><b>Example:</b><br>ITP(config-controller)# channel-group 0 timeslots 1                                               | Specifies the channel group.                                                                                                                                      |
| Step 9  | <b>channel-group</b> channel-group-num timeslots range<br><br><b>Example:</b><br>ITP(config-controller)# channel-group 1 timeslots 2                                               | Specifies the channel group.                                                                                                                                      |
| Step 10 | <b>exit</b><br><br><b>Example:</b><br>ITP(config-controller)# channel-group 1 timeslots 2                                                                                          | Exits controller configuration mode and returns to global configuration mode.                                                                                     |

|         | Command                                                                                                           | Purpose                                                                                             |
|---------|-------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Step 11 | <pre>ITP(config)# interface serial number</pre> <p><b>Example:</b></p> <pre>ITP(config)# interface serial 1</pre> | Configures a serial interface in global configuration mode and enters interface configuration mode. |
| Step 12 | <pre>ITP(config-if)# encapsulation mtp2</pre> <p><b>Example:</b></p> <pre>ITP(config)# encapsulation mtp2</pre>   | Configures the serial interface to use MTP2 encapsulation.                                          |

## Configuring SS7 over ATM High Speed Links (HSL)

### Note

ITP HSL is compliant with both ANSI per Telcordia GR-2878-CORE and ITU per Q.2100, and includes the following protocol stack components: AAL5, SSCOP, SSCF-NNI and MTP3b. On the Cisco 7301 and Cisco 7200 routers, ATM is supported on the following IMA capable port adapters: PA-A3-8T1IMA, PA-A3-8E1IMA, PA-A3-OC3-MM, PA-A3-OC3-SMI, PA-A3-OC3-SML, PA-A6-OC3-MM, PA-A6-OC3-SMI, and PA-A6-OC3-SML.

ITP ATM HSL allows high-speed SS7 connectivity over ATM links. HSL capability can replace the traditional MTP1 and MTP2 layers of the SS7 protocol stack with SAAL. The following sections describe the required tasks for configuring an ITP for ATM HSL support:

- [Enabling an ATM Interface, page 25](#) (Required)
- [Configuring a Permanent Virtual Circuit \(PVC\), page 27](#) (Required)

### Enabling an ATM Interface

To enable an ATM interface for HSL, use the following commands, beginning in global configuration mode:

|        | Command                                                                                                                            | Purpose                                                                |
|--------|------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| Step 1 | <pre>interface atm interface-number[.subinterface-number]</pre> <p><b>Example:</b></p> <pre>ITP(config)# interface atm 2/0.1</pre> | Enters the configure ATM interface or configure ATM subinterface mode. |
| Step 2 | <pre>no shutdown</pre>                                                                                                             | Enables the interface.                                                 |

## ■ Specifying the Interface and Encapsulation

|        | Command                                                                                                        | Purpose                                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| Step 3 | <b>framing esfadm</b><br>-OR-<br><b>framing crc4adm</b>                                                        | Specifies frame type (T1 only).<br>-or-<br>Specifies frame type (E1 only).                 |
|        | For OC3 use the following:<br><br><b>atm framing sdh</b><br>-OR-<br><b>atm framing sonet</b>                   | Specifies SDH framing mode (OC3 only).<br>-or-<br>Specifies SONET framing mode (OC3 only). |
|        | <b>Example:</b><br>ITP(config-if)# framing crc4adm                                                             |                                                                                            |
| Step 4 | <b>clock source {common   internal   line}</b><br><br><b>Example:</b><br>ITP(config-if)# clock source internal | (Optional) Specifies the clock source (T1/E1 only).                                        |

**Enabling an OC3 ATM Interface**

To enable an OC3 ATM interface for HSL, use the following commands, beginning in global configuration mode:

|        | Command                                                                          | Purpose                                                             |
|--------|----------------------------------------------------------------------------------|---------------------------------------------------------------------|
| Step 1 | <b>interface atm</b> <i>interface-num</i><br><br><b>Example:</b><br>ITP(config)# | Specifies an ATM interface and enters interface configuration mode. |
| Step 2 | <b>no shutdown</b><br><br><b>Example:</b><br>ITP(config-if)# no shutdown         | Enables the interface.                                              |
| Step 3 | <b>atm sonet stm-1</b><br><br><b>Example:</b><br>ITP(config-if)# atm sonet stm-1 | Specifies SDH (STM-1) framing.                                      |

## Configuring a Permanent Virtual Circuit (PVC)

You must configure a permanent virtual circuit (PVC) on the ATM interface or subinterface before you can define the interface as a link. To configure the PVC, use the following commands, beginning in interface configuration mode:

|        | Command                                          | Purpose                                                                                        |
|--------|--------------------------------------------------|------------------------------------------------------------------------------------------------|
| Step 1 | <b>atm nni</b>                                   | Selects service specific coordination function for Network Node Interface.                     |
|        | <b>Example:</b><br>ITP(config-if)# atm nni       |                                                                                                |
| Step 2 | <b>pvc</b> [name] {vpi/vci} [qsaal]              | Specifies the PVC. The default/recommended PVC number is 0/5.                                  |
|        | <b>Example:</b><br>ITP(config-if)# pvc 0/5 qsaal | <b>qsaal</b> is a signaling type PVC used to communicate between SS7 nodes.                    |
|        |                                                  | <b>Note</b> <b>ces</b> , <b>ilmi</b> , <b>smds</b> , and <b>l2transport</b> are not supported. |

### Note

Only one qsaal is permitted for each ATM interface or subinterface. To allow more qssals, you must create an additional subinterface for each additional qssal, and add these subinterfaces to the linkset.

To configure the linkset, see the [“Configuring Linksets” section on page 32](#). To specify or tune optional HSL bundling, SSCF-NNI, or SSCOP parameters, see the [“Tuning HSL Parameters” section on page 394](#) of the [“Verifying, Monitoring, and Tuning the ITP”](#) chapter.

For details about the above commands, refer to the Cisco IOS Wide-Area Networking Command Reference, Release 12.2, ATM Commands, at the following URL:

[http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122cgcr/fwan\\_r/atmcmds/index.htm](http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122cgcr/fwan_r/atmcmds/index.htm)

## Configuring BITS Network Clocking

Building Integrated Timing Supply (BITS) is a method of ensuring network synchronization. With BITS, a single master timing source supplies the clock reference for all nodes.

### Note

A controller that is configured for BITS clocking cannot be used to carry data. If BITS clocking has been set, no channel groups can be configured. If channel groups have been configured, BITS cannot be configured.

To configure BITS network clocking, use the following commands, beginning in global configuration mode:

|        | Command                                                                                                                                                                                                                                                           | Purpose                                                            |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| Step 1 | <b>controller</b> { <b>t1</b>   <b>e1</b> } <i>slot/port-adapter-num/port</i><br><br><b>Example:</b><br>ITP(config)# <b>controller t1 1/1/1</b>                                                                                                                   | Specifies the controller and enters Controller configuration mode. |
| Step 2 | <b>framing</b> { <b>sf</b>   <b>esf</b> }<br><br><b>Example:</b><br>ITP(config)# <b>framing esf</b>                                                                                                                                                               | Specifies the framing format for T1.                               |
| Step 3 | <b>clock source</b> { <b>bits</b> { <b>primary</b>   <b>secondary</b> <i>priority</i> }   <b>internal</b>   <b>line</b> { <b>primary</b>   <b>secondary</b> <i>priority</i> }}<br><br><b>Example:</b><br>ITP(config-controller)# <b>clock source bits primary</b> | Specifies the clock source as BITS primary source.                 |
| Step 4 | <b>linecode</b> { <b>ami</b>   <b>b8zs</b>   <b>hdb3</b> }<br><br><b>Example:</b><br>ITP(config-controller)# <b>linecode b8zs</b>                                                                                                                                 | Specifies the line code type as B8ZS.                              |

## Configuring SS7 ATM High Speed Links with BITS Network Clocking

If you prefer to use a common, reliable clock source over several links, you can deliver a BITS clock to the SS7 ATM high speed links. To do so, you must configure BITS clocking on the SS7 port adapter controller. Then, connect a T1 crossover cable from the SS7 port adapter controller to a T1 Inverse Multiplexing for ATM (IMA) port adapter interface. The IMA port adapter interface receives the BITS clock source for all other interfaces on that IMA port adapter. All other interfaces on the IMA port adapter accept the BITS clock by specifying **clock source common interface-number**, where *interface-number* is the IMA port adapter interface that is crossover cabled to the SS7 port adapter.

This feature requires the SS7 Port Adapter (PA-MCX-8TE1-M=) with the controller configured for BITS clock. For more information on the SS7 Port Adapter, refer to the SS7 guide, *SS7 Port Adapter Installation and Configuration* on Cisco.com:

To provide a BITS clock source to the SS7 ATM high speed links, use the following commands, beginning in global configuration mode:

|        | Command                                                                                                                                                                                           | Purpose                                                                                         |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Step 1 | <b>controller t1 slot/port-adapter-num/port</b><br><br><b>Example:</b><br>ITP(config)# <b>controller t1 2/0/0</b>                                                                                 | Specifies controller 0 on the SS7 port adapter and enters controller configuration mode.        |
| Step 2 | <b>clock source {bits {primary   secondary priority}   internal   line {primary   secondary priority}}</b><br><br><b>Example:</b><br>ITP(config-controller)# <b>clock source bits primary</b>     | Specifies controller 0 on the SS7 port adapter as the the primary source of the BITS clock.     |
| Step 3 | <b>exit</b><br><br><b>Example:</b><br>ITP(config-controller)# <b>exit</b>                                                                                                                         | Exits from controller configuration mode to global configuration mode.                          |
| Step 4 | <b>controller t1 slot/port-adapter-num/port</b><br><br><b>Example:</b><br>ITP(config)# <b>controller t1 2/0/1</b>                                                                                 | Specifies controller 1 on the SS7 port adapter and enters controller configuration mode.        |
| Step 5 | <b>clock source {bits {primary   secondary priority}   internal   line {primary   secondary priority}}</b><br><br><b>Example:</b><br>ITP(config-controller)# <b>clock source bits secondary 1</b> | Specifies controller 1 on the SS7 port adapter as the first secondary source of the BITS clock. |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>ITP(config-controller)# <b>exit</b>                                                                                                                         | Exits from controller configuration mode to global configuration mode.                          |
| Step 7 | <b>controller t1 slot/port-adapter-num/port</b><br><br><b>Example:</b><br>ITP(config)# <b>controller t1 2/0/2</b>                                                                                 | Specifies controller 2 on the SS7 port adapter and enters controller configuration mode.        |

|        | Command                                                                                                                                                                                   | Purpose                                                                                                                                                                              |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 8 | <b>clock source</b> {bits {primary   secondary priority}   internal   line {primary   secondary priority}}<br><br><b>Example:</b><br>ITP(config-controller)# <b>clock source internal</b> | Specifies controller 2 internal clocking.<br><br><b>Note</b> This controller will provide BITS clock to the high speed links via the T1 crossover cable to the SS7 ATM port adapter. |
| Step 9 | <b>exit</b><br><br><b>Example:</b><br>ITP(config-controller)# <b>exit</b>                                                                                                                 | Exits from controller configuration mode to global configuration mode.                                                                                                               |

The following task enables an ATM interface to receive BITS clocking for HSLs.

After you configure BITS clocking on the SS7 port adapter controllers and connect the primary BITS clock from the SS7 port adapter to the IMA port adapter, you configure the ATM interfaces on the IMA port adapter to receive the BITS clock.

#### Note

A T1 crossover cable delivers the BITS clock from the configured SS7 port adapter controller to this interface. This interface will relay the BITS clock to every other ATM interface that is configured with **clock source common interface-num**, where *interface-num* is the interface physically connected to the SS7 PA. Because this interface is receiving the BITS clock from the SS7 PA, it cannot be used as an SS7 link to send or receive traffic. It is reserved for receiving and distributing the BITS clock to the other interfaces on the IMA PA. Also, the clock source on this interface must be configured as **clock source line**. This is the default, so you do not need to add this command unless it was previously set to some other value. If you are not sure, the output of the **show running-config** command will indicate if the clock source for this interface is configured for a value other than line. (Default states are not shown in the show run output.)

To enable an ATM interface to receive BITS clocking for HSLs, perform the following steps, beginning in global configuration mode:

|        | Command                                                                                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <code>interface atm interface-num</code>                                                                                                                                                                                                                                                     | Specifies ATM interface 12/0/0 and enters interface configuration mode.                                                                                                                                                                                                                                                                                                                                                                         |
| Step 2 | <p><b>Example:</b></p> <pre>ITP(config)# interface atm 12/0/0</pre> <pre>no ip address no ima-group no atm ilmi-keepalive exit</pre> <p><b>Example:</b></p> <pre>ITP(config-if)# no ip address ITP(config-if)# no ima-group ITP(config-if)# no atm ilmi-keepalive ITP(config-if)# exit</pre> | <p>Disables IP addressing.</p> <p>Disables inverse multiplexing over ATM (IMA) group.</p> <p>Disables ILMI keepalives.</p> <p>Exits from interface configuration mode to global configuration mode.</p>                                                                                                                                                                                                                                         |
| Step 3 | <code>interface atm interface-num</code>                                                                                                                                                                                                                                                     | Specifies ATM interface 12/0/1 and enters interface configuration mode.                                                                                                                                                                                                                                                                                                                                                                         |
| Step 4 | <p><code>clock source {common [interface-num]   internal   line}</code></p> <p><b>Example:</b></p> <pre>ITP(config-if)# clock source common 0</pre>                                                                                                                                          | <p>Specifies that this interface will receive the common BITS clock resource.</p> <p><b>Note</b> Steps 3 - 4 can be repeated as needed to configure ATM interfaces. The ATM physically connected to the SS7 PA (in this case atm 12/0/0 will relay the BITS clock to every ATM interface that is configured with <b>clock source common interface-num</b>, where <i>interface-num</i> is the interface physically connected to the SS7 PA).</p> |

**Caution**

You cannot configure the clock source for an ATM interface when the interface is in the administratively down state. The clock source may revert to the original clock source when the interface becomes active.

**Caution**

The Cisco VWIC-2T1/E1-RAN is required for SS7 low-speed links. SS7 low-speed links are not supported using any other VWIC.

## Configuring Local Peers

A Cisco ITP peer has two end-points: a local end-point and a remote end-point. (Peer end-points are also referred to as *instances*.) A local peer is the local end-point for SS7 over IP with Stream Control Transmission Protocol (SCTP) connections<sup>1</sup>.

A local peer is identified by its local-port-number. You must configure one (and may configure up to four) local IP address for each local-peer. Cisco ITP will use one of the four local IP addresses for a primary local end-point instance and use the other three IP addresses as backups.

The M2PA/SCTP protocol can be offloaded onto a enabling management of peer links on the and freeing the CPU for MTP3 management and routing.

To configure the local peer, and, optionally, configure M2PA/SCTP offload, use the following commands, beginning in global configuration mode:

|        | Command                                                                       | Purpose                                                                                                                                     |
|--------|-------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>cs7 local-peer</b> <i>local-port-number</i> <b>offload</b> <i>slot bay</i> | Specifies the local peer and puts you in local-peer submenu.                                                                                |
|        | <b>Example:</b><br>ITP(config)# cs7 local-peer 7000                           |                                                                                                                                             |
| Step 2 | <b>local-ip</b> <i>address</i>                                                | Configures the IP address for this local peer instance. You can repeat this step to configure backup IP addresses for this local end-point. |
|        | <b>Example:</b><br>ITP(config-cs7-lp)# local-ip 172.18.44.242                 |                                                                                                                                             |

## Configuring Linksets

A link is either a serial or ATM interface or a peer (virtual link) to a remote Cisco ITP node. Multiple links are grouped into a linkset. Each link must be assigned to one linkset, and multiple links can be assigned to a linkset. Links within the same linkset must be parallel between the same nodes.

To configure a linkset you must name the linkset and specify the point code of the adjacent signaling point.

### Note

You must specify the SS7 variant and the point code before you can configure linksets.

### Note

To avoid unnecessary CPU load, we recommend that you shut down interfaces that are configured but not provisioned as part of a linkset.

### Note

Avoid manual configuration of linksets when a MTP3 restart is in progress.

1. For more information, refer to Stream Control Transmission Protocol, RFC 2690.

To specify a linkset, use the following command in global configuration mode:

| Command                                                                                                                                                                                    | Purpose                                             |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------|
| <b>cs7</b> [ <b>instance</b> <i>instance-number</i> ] <b>linkset</b> <i>ls-name adj-pc</i> [ <b>local-pc</b> <i>pc</i> ]<br><br><b>Example:</b><br>ITP(config)# cs7 linkset LINKSET1 2.2.2 | To specify a linkset and enter CS7 linkset submode. |

## Configuring Circular Route Direction (CRD)

Circular routing is when an MSU flows through an SS7 network and ends up back at the originating point code (OPC). Circular routes can quickly lead to congestion of links and degrade network performance. SS7 messages do not have time-to-live or hop counter features, which help stop circular routing in some other protocols, so another way is needed to detect and stop the problem. If the problem is not detected and stopped, a MSU can continue on indefinitely. The CRD feature detects circular routing and disables these problematic routes. These problematic routes are usually caused by an incorrect router configuration.

### Configuring CRD for the ANSI Variant

#### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no cs7 mtp3 crd**
4. **cs7 linkset**
5. **c-link-linkset**
6. **cs7 mtp3 crd**
7. **cs7 mtp3 timer**

#### DETAILED STEPS

|        | Command or Action                                                                                                                                                          | Purpose                                                                                                                                                                                                                                             |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                                        | Enables privileged EXEC mode.                                                                                                                                                                                                                       |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                                                                | Enters global configuration mode.                                                                                                                                                                                                                   |
| Step 3 | <b>no cs7 [instance <i>instance-number</i>] mtp3 crd</b><br><br><b>Example:</b><br>ITP(config)# no cs7 mtp3 crd                                                            | Turns off CRD.                                                                                                                                                                                                                                      |
| Step 4 | <b>cs7 [instance <i>instance-number</i>] linkset <i>ls-name</i> <i>adj-pc</i> [local-pc [<i>pc</i>]]</b><br><br><b>Example:</b><br>ITP(config)# cs7 linkset LINKSET1 2.2.2 | (Optional) Specifies a linkset and puts you in linkset configuration mode.<br><br><br><b>Note</b> This step is not necessary if there are no C-links in the ITP. |

|        | Command or Action                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <b>c-link-linkset</b> [ <b>secondary</b> ]<br><br><b>Example:</b><br>ITP(config-cs7-ls)# c-link-linkset                                              | (Optional) Tags a linkset as a C-link linkset.<br><br><b>secondary</b> —(Optional) C-link linkset to the connected secondary PC.<br><br><br><b>Note</b> This step is not necessary if there are no C-links in the ITP.<br><br><br><b>Note</b> CRD also controls OPC Verification. One of the checks done during OPC Verification is if an MSU with OPC equal to the mate's PC arrives on a linkset that is not the C-link linkset, then that MSU is discarded. That makes it necessary to identify the linksets as C-link linksets before the CRD feature is turned on. This step accomplishes that. |
| Step 6 | <b>exit</b><br><br><b>Example:</b><br>ITP(config-cs7-ls)# exit                                                                                       | Returns to the global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 7 | <b>cs7</b> [ <b>instance</b> <i>instance-number</i> ] <b>mtp3 crd</b><br><br><b>Example:</b><br>ITP(config)# cs7 mtp3 crd                            | Turns on CRD and OPC verification.<br><br>The default for the ANSI variant is CRD on. The default for all other variants is CRD off.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

The timer value is in the range 10000-20000 msec. The default value is 10000 msec.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Configuring CRD for the ITU and ITU-like Variants

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 national-options multiple-congestion**
4. **cs7 linkset**
5. **c-link-linkset**
6. **cs7 mtp3 crd**
7. **cs7 mtp3 timer**

## DETAILED STEPS

|        | Command or Action                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                       | Enables privileged EXEC mode.                                                                                                                                                                                                                                                                          |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                                               | Enters global configuration mode.                                                                                                                                                                                                                                                                      |
| Step 3 | <b>cs7 [instance instance-number] national-options multiple-congestion</b><br><br><b>Example:</b><br>ITP(config)#cs7 national-options multiple-congestion | Specifies the national option.<br><br>There must be support for multiple congestion levels in the network for CRD and OPC Verification to work.                                                                                                                                                        |
| Step 4 | <b>no cs7 [instance instance-number] mtp3 crd</b><br><br><b>Example:</b><br>ITP(config)# no cs7 mtp3 crd                                                  | Turns off CRD.                                                                                                                                                                                                                                                                                         |
| Step 5 | <b>cs7 [instance instance-number] linkset ls-name adj-pc [local-pc [pc]]</b><br><br><b>Example:</b><br>ITP(config)# cs7 linkset LINKSET1 2.2.2            | (Optional) Specifies a linkset and puts you in linkset configuration mode.<br><br> <b>Note</b> This step is not necessary if there are no C-links in the ITP.                                                       |
| Step 6 | <b>c-link-linkset [secondary]</b><br><br><b>Example:</b><br>ITP(config-cs7-ls)# c-link-linkset                                                            | (Optional) Tags a linkset as a C-link linkset.<br><br><b>secondary</b> —(Optional) C-link linkset to the connected secondary PC.<br><br> <b>Note</b> This step is not necessary if there are no C-links in the ITP. |
| Step 7 | <b>exit</b><br><br><b>Example:</b><br>ITP(config-cs7-ls)# exit                                                                                            | Returns to the global configuration mode.                                                                                                                                                                                                                                                              |

|        | Command or Action                                                          | Purpose                                                                                                                         |
|--------|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Step 8 | <b>cs7</b> [instance <i>instance-number</i> ] <b>mtp3 crd</b>              | Turns on CRD and OPC verification.                                                                                              |
|        | <b>Example:</b><br>ITP(config)# cs7 mtp3 crd                               | The default for the ANSI variant is CRD on. The default for all other variants is CRD off.                                      |
| Step 9 | <b>cs7</b> [instance <i>instance-number</i> ] <b>mtp3 timer tloop msec</b> | Globally configures the ITP MTP3 management timers.                                                                             |
|        | <b>Example:</b><br>ITP(config)# cs7 mtp3 timer tloop 10000                 | <b>tloop msec</b> —The loop detection timer. The timer value is in the range 10000-20000 msec. The default value is 10000 msec. |

## Configuring Multiple Linksets to Adjacent Nodes

This optional feature allows you to configure 2 linksets between the ITP and an adjacent node. Each linkset can have 16 links, so a total of 32 links can be configured between an ITP and an adjacent node. To the adjacent node, it appears that it is connected to two different ITPs. Figure 5 represents the actual network on the left and the adjacent node's view of the network on the right. Point codes 1.1.1 and 1.1.2 appear to be two separate nodes, but they are actually the same ITP.

**Figure 5** Multiple Linksets

Before you can configure multiple linksets to an adjacent node, you must add a secondary local point code to the ITP. (This was discussed in an earlier section.) If you have not already done so, configure a secondary point code using the following command in global configuration mode:

| Command                                                | Purpose                                    |
|--------------------------------------------------------|--------------------------------------------|
| <b>cs7 secondary-pc</b> <i>point-code</i>              | Specifies a second point code for the ITP. |
| <b>Example:</b><br>ITP(config)# cs7 secondary-pc 1.1.2 |                                            |

Configure two linksets between the ITP and the adjacent node, using the following commands in global configuration mode:

| Command                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cs7 linkset ls-name adjacent-point-code [local-pc primary-point-code]</code>                                              | Specifies a linkset between the adjacent point code and the ITP primary point code and enters linkset configuration mode. If the <b>[local-pc primary-point-code]</b> option is omitted, the primary local point code is used on this linkset. If the <b>[local-pc primary-point-code]</b> is specified, either primary or secondary point code can be explicitly assigned to the linkset. |
| <b>Example:</b><br>ITP(config)# cs7 linkset LINKSET1 2.2.2<br>ITP(config-cs7-ls)exit<br>ITP(config)# cs7 linkset LINKSET2 2.2.2 |                                                                                                                                                                                                                                                                                                                                                                                            |

The combination of adjacent point code and local point code must be unique. So for any adjacent point code, the user can configure two linksets - one using the primary local pc, and one using the secondary pc. An example of configuring this is:

```
cs7 linkset LINKSET1 2.2.2 local-pc 1.1.1
  link 0 serial 1/1/1:0
  ..
  link 15 serial 1/1/1:15

cs7 linkset LINKSET2 2.2.2 local-pc 1.1.2
  link 0 serial 1/1/2:0
  ..
  link 15 serial 1/1/2:15
```

The two linksets to the adjacent node are automatically entered as a combined route to the adjacent node. Traffic going to the adjacent node will be divided between the two linksets based on SLS.

Note

In ANSI, if the two linksets each have 16 links, traffic is automatically distributed across all 32 links based on SLS.  
In ITU, because there are only 16 SLS combinations, only half the links would carry traffic in the default configuration. If the traffic is SCCP unsequenced, you can configure the **cs7 distribute-sccp-unsequenced** command, and the ITP will then use all 32 links.

# Specifying the Cisco ITP Route Table

The Cisco ITP uses a route table to select the appropriate signaling path for each message, or signal unit, that it must forward. The route table maps the destination point code (DPC) of the message to an output linkset name that is used to forward the packet.

## Specifying the Default Route Table

On the Cisco ITP router, a route table named “system” is configured by default. The system route table keeps a record of routes to all adjacent signaling points. To specify the Cisco ITP route table, use this command in global configuration mode:

| Command                                                | Purpose                                                            |
|--------------------------------------------------------|--------------------------------------------------------------------|
| <b>cs7 route-table</b> <i>rt-name</i>                  | Specifies the name of the route table and enters route table mode. |
| <b>Example:</b><br>ITP(config)# cs7 route-table system |                                                                    |

### Note

You must specify **system** as the route table name (*rt-name*).

## Loading the Route Table Contents

Route table contents can be loaded from a URL where a binary version of the route table is located. To add route table contents, use this command in route table configuration mode:

| Command                                                                         | Purpose                                |
|---------------------------------------------------------------------------------|----------------------------------------|
| <b>load</b> { <b>flash</b>   <b>ftp</b>   <b>rcp</b>   <b>tftp</b> } <i>URL</i> | Loads the contents of the route table. |
| <b>Example:</b><br>ITP(config-cs7-rt)# load tftp://64.102.16.25/route.txt       |                                        |

### Note

Whenever any change is made in the routing configuration of an instance, save the routing configuration and perform any load operation for only that particular instance.

## Adding Routes to the Route Table

Additional routes can be added to the system route table. To update a Cisco ITP route table, use the **update route** command in CS7 route table configuration mode:

| Command                                                                                                                                                                                                                                  | Purpose                               |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| <b>update route</b> <i>point-code</i> [ <i>mask</i>   <i>length</i> ] <b>linkset</b> <i>ls-name</i> [ <b>priority</b> <i>priority-value</i> <sup>1</sup> ] [ <b>qos-class</b> { <i>class</i>   <b>default</b> }] [ <b>load_balance</b> ] | Updates a route in the routing table. |
| <b>Example:</b><br>ITP(config-cs7-rt)# update route 1.50.2 255.255.255 linkset nyc                                                                                                                                                       |                                       |

1. The smaller the number, the higher the priority. See the **update route** ITP Command Set entry for an example.

## Saving the Route Table

You can save an active route table into a file. The newly created file can be used with the **load** route-table sub-command to populate the route table upon ITP startup. Note that all **update route** or **remove route** route-table sub-commands are removed from the system configuration after the save is completed. This is done because those commands have been applied to the actual route-table *before* the save, and are therefore included in the saved file.

We recommend that you save the router configuration to non-volatile memory after generating a new route-table file because the configuration has changed (update/remove route commands may have been removed from the configuration).

Update/remove routes are saved in the system configuration. Therefore, to load a file from disk, it is recommended to save the current route-configuration to disk so that the current update/remove commands are not reapplied on file load.

### Note

If the routing table configuration is loaded using a file, ensure this file exists on both Active and Standby supervisor modules before reloading the ITP.

To save an active route table to a file, use the following command in privileged EXEC mode:

| Command                                                                | Purpose                         |
|------------------------------------------------------------------------|---------------------------------|
| <b>cs7 save route-table</b> <i>name url</i>                            | Save the route table to a file. |
| <b>Example:</b><br>ITP# cs7 save route-table testtable flash:testtable |                                 |

## Assigning Links to Linksets

After specifying linksets, you can assign links to the linkset. You will assign links to adjacent legacy SS7 devices as well as links to adjacent Cisco ITP peer nodes.

### Traditional SS7 Links

You must configure a link to the legacy SS7 devices. To configure an SS7 link within a linkset, make sure that the interface encapsulation is MTP2, then use the following command in linkset configuration mode:

| Command                                | Purpose                                                                         |
|----------------------------------------|---------------------------------------------------------------------------------|
| <b>link</b> <i>slc serial number</i>   | Configures an SS7 link within a linkset and enters CS7 link configuration mode. |
| <b>Example:</b><br>ITP(config-cs7-ls)# |                                                                                 |

## High-Speed Signaling Links

You must configure a link to HSL devices. To configure an HSL link within a linkset, make sure that the ATM interface has NNI selected and a QSAAL PVC defined, then use the following command in linkset configuration mode:

| Command                                                    | Purpose                                                                    |
|------------------------------------------------------------|----------------------------------------------------------------------------|
| <b>link slc atm</b> interface-number[.subinterface-number] | Configures a link to an HSL device and enters CS7 link configuration mode. |
| <b>Example:</b><br>ITP(config-cs7-ls)#                     |                                                                            |

## SS7 Over IP Links (Peers)

A Cisco ITP peer has two end-points: a local and a remote end-point.

The local end-point is identified by the local-port-number, which you specified earlier with the **cs7 local-peer** *local-port-number* command.

The remote end-point is simply the local-peer on a remote router. In the link definition shown in the following task table, the remote router's *local-port-number* is the *remote-port-number* and the (up to) four IP addresses of the remote router's local-peer are the *remote-ip-addrs*.

The **passive** keyword (which is optional) can be used to indicate that the remote router must establish the peer connection.

### Note

IP routing is automatically enabled in the ITP and should not be disabled. If IP routing has been disabled, process suspending behavior can occur in M2PA, M3UA, or SUA configurations. To re-enable IP routing if it has been disabled, use the **ip routing** command in global configuration mode.

To configure an SS7 link within a linkset, use the following command in linkset configuration mode:

| Command                                                                                                                           | Purpose                                                                                  |
|-----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| <b>link slc sctp</b> remote-ip-addr [backup-remote-ip-addr ...]<br>remote-port-num <sup>1</sup> local-port-num [ <b>passive</b> ] | Configures SS7 over IP peers for a linkset and enters Cisco CS7 link configuration mode. |
| <b>Example:</b><br>ITP(config-cs7-ls)#                                                                                            |                                                                                          |

1. remote-port-num is the local port number of the adjacent Cisco ITP peer.

There are several SCTP parameters that you can adjust, such as tuning SCTP parameters for satellite channels. Tasks and commands to tune timers and SCTP parameters are described in the [“Tuning ITP” section on page 394](#) of the “Verifying, Monitor, and Tuning ITP” chapter.

## Shutting Down and Restarting Linksets and Links

To inhibit a link, use the following commands in EXEC mode:

| Command                                                                              | Purpose                                                           |
|--------------------------------------------------------------------------------------|-------------------------------------------------------------------|
| <b>cs7 inhibit linkset link</b><br><br><b>Example:</b><br>ITP# cs7 inhibit nyc 3     | Takes a link out of service without risking loss of connectivity. |
| <b>cs7 uninhibit linkset link</b><br><br><b>Example:</b><br>ITP# cs7 uninhibit nyc 3 | Returns the link to service.                                      |

To disable or reactivate a linkset, use one of the following commands, beginning in global configuration mode:

| Command                                                                                            | Purpose                                                         |
|----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| <b>cs7 linkset ls-name point-code</b><br><br><b>Example:</b><br>ITP(config)# cs7 linkset nyc 1.1.0 | Specifies a linkset and puts you in linkset configuration mode. |
| <b>shutdown</b><br><br><b>Example:</b><br>ITP(config-cs7-ls)# shutdown                             | Disables the linkset.                                           |
| ITP(config-ls)# <b>no shutdown</b><br><br><b>Example:</b><br>ITP(config-cs7-ls)# no shutdown       | Brings the linkset back into the active state.                  |

To disable or reactivate a link, use the following commands, beginning in global configuration mode:

| Command                                                                                                          | Purpose                                                         |
|------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| <b>cs7 linkset ls-name point-code</b><br><br><b>Example:</b><br>ITP(config)# cs7 nyc 1.1.0                       | Specifies a linkset and puts you in linkset configuration mode. |
| <b>link slc</b><br>-OR-<br><b>link slc sctp remote-peer remote-instance local-instance</b><br>[ <b>passive</b> ] | Specifies a link and puts you in link configuration mode.       |
| <b>Example:</b><br>ITP(config-cs7-ls)# link 3                                                                    |                                                                 |

| Command                                            | Purpose                                     |
|----------------------------------------------------|---------------------------------------------|
| <b>shutdown</b>                                    | Disables the link.                          |
| <b>Example:</b><br>ITP(config-cs7-ls)# shutdown    |                                             |
| <b>no shutdown</b>                                 | Brings the link back into the active state. |
| <b>Example:</b><br>ITP(config-cs7-ls)# no shutdown |                                             |

## Configuration Example of ITP Basic Functionality

This configuration example describes the basic ITP functions. Four Cisco ITPs are configured. The network configuration is illustrated in [Figure 6](#).

**Figure 6** ITPs as STPs in an SS7oIP Topology

Assumptions:

All routers have redundant ethernet connectivity and therefore all SCTP associations use two IP addresses (multi-homing).

Point codes and IP addresses for ITP routers:

```
ITPA  5.100.2  172.18.44.242 117.117.117.2
ITPB  5.100.5  172.18.44.243 117.117.117.3
ITPC  5.100.4  172.18.45.1  117.117.119.4
ITPD  5.100.3  172.18.46.1  117.117.118.4
```

Point codes for SS7 SSPs:

```
SMSC  5.100.1
VMI4   5.100.6
VT02   5.100.7
VRM2   5.100.8
```

# Probeless Monitoring

With Probeless Monitoring enabled, the ITP sends packets to an external server. The packets sent to this server contain copies of any MSUs received or sent by the ITP.

### Feature History for Probeless Monitoring

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(33)IRC | This feature was introduced. |

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

**Note**

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

# Contents

- [Information About Probeless Monitoring, page 54](#)
- [How to Configure Probeless Monitoring, page 54](#)
- [Verifying the Probeless Monitoring Configuration, page 62](#)
- [Configuration Example for Probeless Monitoring, page 62](#)

# Information About Probeless Monitoring

The basics of Probeless Monitoring are shown in [Figure 7](#), where the ITP performs its normal role and Probeless Monitoring uses the IP network to send packets to a data collection server (DCS). The packets contain copies of the MSUs from the linksets and ASs of an SS7oIP network and/or copies of the MSUs from the linksets of an SS7 network. These MSU copies are encapsulated in a proprietary Probeless Monitoring protocol (PMP), which is stacked on UDP and transmitted over a non-reliable IP stream.

**Figure 7** *Probeless Monitoring*

The DCS servers are also known as DCS nodes and serve as endpoints in the IP network that carries the PMP packets. These DCS nodes may have up to two unique IP addresses and/or ports assigned. The DCS nodes make up a DCS group, which contains a maximum of eight of these DCS nodes. Sixteen DCS groups are the maximum for an ITP.

Other characteristics of Probeless Monitoring are that ITP monitors the path to the remote DCS IP address with Internet Control Message Protocol (ICMP) echo packets, and that the loadsharing algorithm among DCS nodes of a DCS group is least cost according to round-robin scheduling. The congestion avoidance algorithm is based on Java remote method invocation (RMI). You can also enable Probeless Monitoring globally or specifically for a particular linkset or application server (AS).

## How to Configure Probeless Monitoring

This section include the following tasks and information:

- [Configuring Global Probeless Monitoring, page 55](#)
- [Configuring Hold Queue and Congestion Timer, page 56](#)
- [Configuring a DCS Node, page 56](#)

- [Configuring a DCS Group, page 59](#)
- [Configuring Probeless Monitoring for a Specific Linkset, page 60](#)
- [Configuring Probeless Monitoring for a Specific AS, page 61](#)

## Configuring Global Probeless Monitoring

When global Probeless Monitoring is off (default), it disables copying at a system level and overrides all provisioned linkset and AS pmp settings. You need to manually enable Probeless Monitoring at the system level to activate all sub-tending linkset and AS pmp settings. [Table 3](#) below defines this behavior:

**Table 3** Global Probeless Monitoring Behavior for Linkset and AS PMP Settings

| CS7 PMP | Linkset/AS PMP | Result |
|---------|----------------|--------|
| On      | On             | On     |
| On      | Off            | Off    |
| Off     | On or Off      | Off    |

To enable Probeless Monitoring globally, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 pmp**

### DETAILED STEPS

|        | Command or Action                                                           | Purpose                                                                                                            |

| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal | Enters global configuration mode.                                                                                  |
| Step 3 | <b>cs7 pmp</b><br><br><b>Example:</b><br>ITP(config)# cs7 pmp               | Turns Probeless Monitoring on for all linksets and AS.                                                             |

## Configuring Hold Queue and Congestion Timer

The congestion timer is used in conjunction with the hold queue to control the congestion of PMP packets. When PMP packets in the hold queue hit the congestion onset threshold, a congestion timer with a range of 0 to 60 seconds starts. Before the timer expires, the receiving side of PMP will be disabled. When the timer expires, the congestion status is checked based on the queue length against the abate threshold.

To enable the hold queue and congestion timer, perform the following steps.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 pmp hold-queue**
4. **cs7 pmp congestion-timer**

### DETAILED STEPS

|        | Command or Action                                                                                                           | Purpose                                                                                                            |
|--------|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br>Example:<br>ITP> enable                                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br>Example:<br>ITP# configure terminal                                                        | Enters global configuration mode.                                                                                  |
| Step 3 | <b>cs7 pmp hold-queue <i>abate-threshold onset-threshold</i></b><br><br>Example:<br>ITP(config)# cs7 pmp hold-queue 256 512 | (Optional) Controls the congestion of PMP packets.                                                                 |
| Step 4 | <b>cs7 pmp congestion-timer <i>timer</i></b><br><br>Example:<br>ITP(config)# cs7 pmp congestion-timer 60                    | (Optional) Set the integer range of the PMP congestion timer.                                                      |

## Configuring a DCS Node

A DCS node represents a PMP endpoint and is uniquely identified by name, IP address, and port number. Each DCS node may contain up to two IP addresses and port combinations. You can also configure other characteristics of the DCS node, including:

- The interval between two consecutive ICMP Echo requests
- The number of times the ITP will retry the ping before marking the DCS node as unavailable
- The optional calculation of a UDP checksum sent in the PMP stream

- The encapsulation MSU data format of the egress PMP packets
- The sending of PMP packets and pings to the DCS

## Restrictions

The following list identifies restrictions to a DCS Node:

- The remote IP address must be unique for the DCS node.
- The local IP address must be reachable.
- The local/remote IP addresses can only change when the DCS is not part of any DCS group.
- You cannot delete a DCS node referenced by a DCS group.
- You need to shut down the DCS node before deleting its local/remote IP addresses.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 dcs** *name*
4. **remote-ip** *ip\_addr1* [*ip\_addr2*] *port*
5. **local-ip** *ip\_addr* *port*
6. **ping-interval** *sec*
7. **timeout-count** *count*
8. **udp-checksum**
9. **emdt** [*emdt1* | *emdt2*]
10. **shutdown**

## DETAILED STEPS

|        | Command or Action                                                       | Purpose                                                                                                             |
|--------|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br>Example:<br>ITP> enable                            | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>• Enter your password if prompted.</li></ul> |
| Step 2 | <b>configure terminal</b><br><br>Example:<br>ITP# configure terminal    | Enters global configuration mode.                                                                                   |

|         | Command or Action                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4  | <b>remote-ip</b> <i>ip_addr1</i> [ <i>ip_addr2</i> ] <i>port</i><br><br><b>Example:</b><br>ITP(config-cs7-dcs) # remote-ip 209.165.201.31 209.165.201.28 33500 | Configures an IP address(s) and a port(s) for a DCS node. <ul style="list-style-type: none"> <li><i>addr1</i>—A v4 IP address in the form xxx.xxx.xxx.xxx. It is the primary IP address used when sending PMP traffic.</li> <li><i>addr2</i>(Optional)—A v4 IP address in the form xxx.xxx.xxx.xxx. It is a redundant IP address used when the primary IP address fails.</li> <li><i>port</i>—IP address port with an integer range of 1-65535 for remote port and 1024-65535 for local port.</li> </ul> |
| Step 5  | <b>local-ip</b> <i>ip_addr</i> <i>port</i><br><br>ITP(config-cs7-dcs) # local-ip 209.165.201.28 33500                                                          | Configures a local IP address used to send PMP or UDP to DCS nodes.<br><br> <b>Note</b> Multiple DCS nodes may have the same local IP address and port combination.                                                                                                                                                                                                                                                     |
| Step 6  | <b>ping-interval</b> <i>sec</i><br><br><b>Example:</b><br>ITP(config-cs7-dcs) # ping-interval 5                                                                | (Optional) Sets the interval between pings to the DCS nodes' IP addresses. <ul style="list-style-type: none"> <li><i>sec</i>—Length of time in seconds.</li> </ul>                                                                                                                                                                                                                                                                                                                                       |
| Step 7  | <b>timeout-count</b> <i>count</i><br><br><b>Example:</b><br>ITP(config-cs7-dcs) # timeout-count 3                                                              | (Optional) Sets the number of times the ITP will retry the ping before marking the DCS node as unavailable. <ul style="list-style-type: none"> <li><i>count</i>—Number of times the ITP will retry the ping.</li> </ul>                                                                                                                                                                                                                                                                                  |
| Step 8  | <b>udp-checksum</b><br><br><b>Example:</b><br>ITP(config-cs7-dcs) # udp-checksum                                                                               | (Optional) Turns on the optional calculation of a UDP checksum sent in the PMP stream.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 9  | <b>emdt</b> [ <i>emdt1</i>   <i>emdt2</i> ]<br><br><b>Example:</b><br>ITP(config-cs7-dcs) # emdt2                                                              | (Optional) Specifies the MSU data format encapsulation of the egress PMP packets. <ul style="list-style-type: none"> <li><b>emdt1</b>—Encapsulated MSU Data Type 1, which takes advantage of an SNMP MIB to reduce the overhead of the MSU encapsulation header.</li> <li><b>emdt2</b>—(default) Encapsulated MSU Data Type 2, which includes all the context information with the MSU.</li> </ul>                                                                                                       |
| Step 10 | <b>shutdown</b><br><br><b>Example:</b><br>ITP(config-cs7-dcs) # shutdown                                                                                       | Stops sending PMP packets and pings to this DCS node. The DCS node is shut down by default.                                                                                                                                                                                                                                                                                                                                                                                                              |

## Configuring a DCS Group

A DCS group represents a group of one or more DCS nodes and contains a maximum of eight. You identify a DCS group with a unique name.

## Restrictions

The following list identifies restrictions to a DCS group:

- You cannot delete a DCS group that is referenced by a linkset or AS.
- You cannot delete a DCS node that is referenced by a DCS group.
- You cannot add more than eight DCS nodes to group.
- You cannot add a DCS node that is not configured to a DCS group.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 dcs-group *name***
4. **dcs *name cost***

## DETAILED STEPS

|        | Command or Action                                                                        | Purpose                                                                                                               |
|--------|------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br>Example:<br>ITP> enable                                             | Enables privileged EXEC mode.<br><ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br>Example:<br>ITP# configure terminal                     | Enters global configuration mode.                                                                                     |
| Step 3 | <b>cs7 dcs-group <i>name</i></b><br><br>Example:<br>ITP(config)# cs7 dcs-group dcsGroup1 | Defines a DCS group and associates a name.                                                                            |
| Step 4 | <b>[no] dcs <i>name cost</i></b><br><br>Example:<br>ITP(config)# dcs dcs1 2              | Adds or removes a DCS node to a DCS group.                                                                            |

## Configuring Probeless Monitoring for a Specific Linkset

You can assign a DCS group to a specific linkset.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7** [**instance** *instance-number*] **linkset** *ls-name* *adj-pc* [**local-pc** [*pc*]]
4. **pmp**
5. **dcs-group** *dcs-group-name* { **in** | **out** | **all** }

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br>Example:<br>ITP> enable                                                                                                                                                | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                            |
| Step 2 | <b>configure terminal</b><br><br>Example:<br>ITP# configure terminal                                                                                                                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                             |
| Step 3 | <b>cs7</b> [ <b>instance</b> <i>instance-number</i> ] <b>linkset</b> <i>ls-name</i> <i>adj-pc</i> [ <b>local-pc</b> [ <i>pc</i> ]]<br><br>Example:<br>ITP(config)# cs7 linkset vt02 5.100.7 | Specifies a linkset and enter CS7 linkset submenu.                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 4 | <b>pmp</b><br><br>Example:<br>ITP(config-cs7-ls)# pmp                                                                                                                                       | Turn on Probeless Monitoring for the linkset. Probeless Monitoring is off by default.                                                                                                                                                                                                                                                                                                                                                         |
| Step 5 | <b>dcs-group</b> <i>dcs-group-name</i> { <b>in</b>   <b>out</b>   <b>all</b> }<br><br>Example:<br>ITP(config-cs7-ls)# dcs-group group_pmp_01 all                                            | Associates a DCS group with a linkset. <ul style="list-style-type: none"> <li>• <i>dcs-group-name</i>—Identifies the name of the DCS group.</li> <li>• <b>in</b>—Specifies inbound traffic will be copied to the specified group.</li> <li>• <b>out</b>—Specifies outbound traffic will be copied to the specified group.</li> <li>• <b>all</b>—Specifies both inbound and outbound traffic will be copied to the specified group.</li> </ul> |

## Configuring Probeless Monitoring for a Specific AS

You can assign a DSC group to a specific AS.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7** [*instance instance-number*] **as** *as-name* { **m3ua** | **sua** }
4. **pmp**
5. **dcs-group** *dcs-group-name* { **in** | **out** | **all** }

### DETAILED STEPS

|        | Command or Action                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Multiple Instances and Instance Translation

---

The Multiple Instances feature makes it possible to connect Cisco ITP to different networks with specific variant and network indicators. Instance translation enables the conversion and transfer of MSUs between different instances.

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

#### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

## Information About Multiple Instances and Instance Translation

The ITP Multiple Instance feature makes it possible to connect the ITP to different networks at one time, each with specific variant and network indicator values. The ITP treats each combination of variant and network indicator as a separate “instance.” Each instance acts as a separate logical ITP. Each instance is

a separate domain with a defined variant, network indicator, ITP point code, optional capability point code, and optional secondary point code. Each instance also has its own routing table and Global Title Translation (GTT) table

You can configure up to 8 different instances on the ITP. Instances are numbered 0 to 7.

Instance translation is the conversion of packets between instances of ANSI or ITU variants.

## Understanding Virtual Linksets

A virtual linkset is a connection from one instance to another. There are two virtual linksets between any two instances in the ITP. For example, between instance X and instance Y, there are virtual linksets VirtualLSx-y and VirtualLSy-x. VirtualLSx-y appears to be a linkset in Instance x, and it will appear in Instance x's route table, for alias destinations whose true point code exists in Instance y. VirtualLSy-x appears to be a linkset in Instance y, and it will appear in Instance Y's route table, for alias destinations whose true point code exists in Instance x.

Virtual linksets are not the same as real linksets. Virtual linksets do not have queues, and are not bandwidth limited.

Virtual linkset are created automatically when a new instance is created. When an alias point code is defined, the alias point code is automatically entered in the alias instance's routing table using the virtual linkset. For example, the following command enters an alias point code in instance 5 for a real point code in instance 6:

```
cs7 instance 6 pc-conversion 3.4.5 alias-pc 5 5.6.7
```

This creates a route in instance 5 for the alias point code 5.6.7. The linkset shown in the Virtual Linkset that goes from Instance 5 to Instance 6.

```
#show cs7 5 route 5.6.7 detailed
Routing table = system5 Instance = 5
Destination      C Q P Linkset Name      Linkset Non-adj Route
-----
5.6.7/14         acces  1 VirtualLS5-6         avail  allowed avail
```

Virtual linksets are available if the destination Instance has completed MTP Restart. They are Unavailable when the destination instance is doing an MTP Restart. For example, when instance 6 is isolated or going through an MTP Restart, here is the output of show cs7 route for the alias point code.

```
#show cs7 5 route 5.6.7 detailed
Routing table = system5 Instance = 5
Destination      C Q P Linkset Name      Linkset Non-adj Route
-----
5.6.7/14         INACC  1 VirtualLS5-6         UNAVAIL allowed UNAVAIL
```

# How to Configure Multiple Instances

To enable Multiple Instances, use the following command in global configuration mode:

| Command                                   | Purpose                               |
|-------------------------------------------|---------------------------------------|
| Router(config)# <b>cs7 multi-instance</b> | Enable the Multiple Instance feature. |

For the commands that require an instance number, anything configured before Multiple Instances is turned on (such as variant, point-code, linksets, routes) is considered to be in the default instance (instance 0) once Multiple Instances is turned on.

Also, after you turn on Multiple Instances, the ITP begins displaying the instance number when it displays a point code. The ITP displays the point code, then a colon, then the instance number. For example, 1.2.3:0 means point code 1.2.3 in instance 0.

To configure an additional instance (after the default) specify the instance, the variant, and the instance network name, using the following commands in interface configuration mode:

| Command                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 instance</b> <i>instance-number</i><br><b>variant</b> { <b>ansi</b>   <b>china</b>   <b>itu</b>   <b>ttc</b> } | Identify an instance and indicate which of the SS7 variations the ITP is running on the instance. Instance numbers are used only to configure the information specific to each instance and do not need to match across devices.                                                                                                                                   |
| Router(config)# <b>cs7 instance</b> <i>instance-number</i><br><b>network-name</b> <i>network-name</i>                                 | Specify a network name for the instance<br>The network-name is used to qualify information per signaling point in related management information bases. It is used to correlate instances into the same network by network management applications. In order for instances in the same network to be properly managed they must be assigned the same network name. |

## How to Configure Instance Translation

This section include the following tasks and information:

- [Configuring Point Code Conversion, page 69](#)
- [Configuring Global Title Conversion, page 70](#)
- [Configuring Instance Conversion After Global Title Translation, page 73](#)

### Configuring Point Code Conversion

#### Note

In the case of variant conversions among ANSI/CHINA/ITU/TTC, the MSU size may change as a result of the different point codes size.

#### Note

Point code conversion is not supported for SCCP Class 2 traffic.

The ITP performs point code conversion for the following point codes:

- DPC
- OPC
- Concerned Point Code
- SCCP Called Party PC
- SCCP Calling Party PC
- SCMG Concerned PC

To configure point code conversion, use the following command in global configuration mode:

| Command                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 instance</b> <i>instance-number</i> <b>pc-conversion</b> <i>pc alias-pc alias-instance alias-pc</i> | Configures a mapping between <i>pc</i> in instance <i>instance-number</i> , and <i>alias-pc</i> in <i>alias-instance</i> . If an MSU arrives destined for <i>alias-pc</i> in instance <i>alias-instance</i> , it will be sent to instance <i>instance</i> and the DPC converted to <i>pc</i> . |

To configure default point code conversion, use the following command in global configuration mode:

| Command                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 instance</b> <i>instance-number</i> <b>pc-conversion default</b> <i>alias-instance</i> [ <b>no-route</b> ] | Allows MSUs with unknown point codes in one instance to be another instance. Enables default conversion for point codes between instance <i>orig-instance</i> and <i>dest-instance</i> . If point code conversion between the two instances is required, and the point code does not match a specified <i>pc</i> conversion, or the ITP's point code, then the point code is unchanged in the new instance and conversion still succeeds |

## Configuring Global Title Conversion

### Note

This section describes specifying changes to Global Title fields when configuring the Instance Translation feature. If you are looking for information about specifying Global Title Address (GTA) conversion mapping, see the [“Configuring Global Title Address Conversion” section on page 121](#) of the [“Global Title Translation”](#) chapter.

The following sections describe the purpose of Global Title conversion, three methods of converting the SCCP Global Title information, and how to assign a conversion table from one instance to another. These methods are optional, and can be used separately, combined, or not at all. The methods are applied to both the Calling and Called Party Addresses.

- [Overview of Global Title Conversion, page 71](#)
- [Creating a GTI Conversion Table, page 71](#)
- [Creating a Subsystem Mapping Table, page 72](#)

- [Creating a GTA Prefix Conversion Table, page 72](#)
- [Assigning a Conversion Table to an Instance, page 72](#)

## Overview of Global Title Conversion

The optional Global Title Conversion feature enables you to specify changes to SCCP Global Title fields when performing conversion between instances. Two typical scenarios for Global Title Conversion are:

GTT is required, MSUs are destined for local point-code. The result of GTT is an application group including other instance's PC or xUA AS.

- MSUs are destined for an alias point-code in a different instance.

If the Global Title Conversion feature is not configured, the MSUs going from one instance to another will have no change in the global title data. However, Calling and Called Party point codes will be converted, if they exist.

The fields that can be changed are:

- Global Title Indicator (GTI) - ANSI networks normally use GTI 2. ITU networks typically use GTI 4.
- Translation Type (TT)
- Subsystem Number (SSN)
- Global Title Address (GTA) - This field uses the existing ITP GTA prefix conversion feature.
- Encoding Scheme - This field is used if GTI is 4, does not exist for GTI 2.
- Numbering Plan - This field is used if GTI is 4, does not exist for GTI 2.
- Nature of Address - This field is used if GTI is 4, does not exist for GTI 2.

### Note

Global Title conversion is supported for SCCP UDT, XUDT, UDTs, XUDTS message types only.

## Creating a GTI Conversion Table

The GTI conversion method can be used to update the GTI, TT, SSN, Encoding Scheme (ES), Numbering Plan (NP), and Nature of Address Indicator (NAI) in an SCCP address. You name the table, and then specify sets of input parameters and output parameters. When an MSU comes in, the ITP finds the most specific match. If no match is found, the fields in the MSU are unchanged. For ANSI, GTI 2 is supported. For ITU, GTI 2 and 4 are supported.

To create a GTI Conversion Table perform the following tasks, beginning in global configuration mode:

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                          |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | Router(config)# <b>cs7 sccp gti-conversion</b> <i>tablename</i>                                                                                                                                                                                                                                                                                                                                                                                                                 | Names the GTI Conversion table and enables CS7 SCCP GTI conversion mode.                                                                                                                                                         |
| Step 2 | Router(config-cs7-sccp-gticonv)# <b>update</b> [ <b>gti-in</b> <i>gti-in</i> ] [ <b>tt-in</b> <i>tt-in</i> ] [ <b>ssn-in</b> <i>ssn-in</i> ] [ <b>es-in</b> <i>es-in</i> ] [ <b>np-in</b> <i>np-in</i> ] [ <b>nai-in</b> <i>nai-in</i> ] [ <b>gti-out</b> <i>gti-out</i> ] [ <b>tt-out</b> <i>tt-out</i> ] [ <b>ssn-out</b> <i>ssn-out</i> ] [ <b>es-out</b> <i>es-out</i> ] [ <b>np-out</b> <i>np-out</i> ] [ <b>nai-out</b> <i>nai-out</i> ] [ <b>addr-conv</b> <i>addr</i> ] | Specifies the input and output parameters for the table.<br><br>If the <b>addr-conv</b> keyword is specified, this GTT conversion takes precedence over any GTT address conversion table specified per instance conversion rule. |

## Creating a Subsystem Mapping Table

The subsystem mapping method converts a subsystem in one instance to a different subsystem in another instance. To create a subsystem mapping table, use the following command in global configuration mode:

| Command                                                                                                                   | Purpose                                                                    |
|---------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Router(config)# <b>cs7 sccp ssn-conversion</b> <i>tablename</i> <b>in-ssn</b> <i>in-ssn</i> <b>out-ssn</b> <i>out-ssn</i> | Creates a subsystem mapping table, specifying input and output SSN values. |

If no match is found in the SSN conversion table, the SSN in the MSU is unchanged. If both GTI Conversion and Subsystem Mapping are used, and a GTI conversion specifies a new subsystem for the MSU, the subsystem specified by the GTI conversion is used.

## Creating a GTA Prefix Conversion Table

The GTA prefix conversion method uses the existing ITP address-conversion feature. This feature allows for conversion of addresses that use different prefixes or codes, such as converting between E212 and E214 addressing schemes. Address conversion is an optional part of GTT conversion and will only be applied when configured.

### Note

Both the address conversion command here and the GTI conversion command described earlier, allow the user to specify a numbering plan and nature of address values. Any NP or NAI specified by address conversion overrides those specified by GTI conversion.

To define a address conversion table and enter GTT address conversion submode, use the following commands, beginning in global configuration mode:

| Command                                                                                                                                                                                                     | Purpose                                                                                                               |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 instance</b> <i>instance-number</i> <b>gtt address-conversion</b> <i>tablename</i>                                                                                                   | Specifies a GTT address conversion table name (1-12 characters) and enables CS7 GTT address conversion table submode. |
| Router(config-cs7-gtt-conv-tbl)# <b>update in-address</b> <i>input-address</i> [ <b>out-address</b> <i>output-address</i> ] [ <b>np</b> <i>newnp</i> ] [ <b>nai</b> <i>newnai</i> ] [ <b>es</b> <i>es</i> ] | Defines input and (optionally) output address entries.                                                                |

## Assigning a Conversion Table to an Instance

This task assigns gti-conversion, subsystem mapping, and address-conversion tables for conversion from one instance to another. All three conversion methods can be used, or just one or two. If no conversion methods are assigned, the GTT in the MSUs will not be changed.

To assign a conversion table for conversion, use the following commands, beginning in global configuration mode:

| Command                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 sccp instance-conversion in-instance</b> <i>instance</i><br><b>out-instance</b> <i>instance</i> | Specifies the input and output instances.                                                                                                                                                                                                                                                                                  |
| Router(config-cs7-sccp-insconv)# <b>set gti-conversion</b> <i>tablename</i>                                            | Assigns GTI conversion table to be assigned from one instance to another.                                                                                                                                                                                                                                                  |
| Router(config-cs7-sccp-insconv)# <b>set ssn-conversion</b> <i>tablename</i>                                            | Assigns subsystem mapping table to be assigned from one instance to another.                                                                                                                                                                                                                                               |
| Router(config-cs7-sccp-insconv)# <b>set address-conversion</b> <i>tablename</i>                                        | Assigns address-conversion table to be assigned from one instance to another.                                                                                                                                                                                                                                              |
| Router(config-cs7-sccp-insconv)# <b>set message-handling</b> <i>option</i>                                             | Specifies the message handling option to be used. The following are valid options:<br><br>0               no special options<br>1-7             spare values (ie unassigned)<br>9-15            additional spare values (ie unassigned)<br>no change      leave field unchanged<br>return-on-error return [x]udts on error |
| Router(config-cs7-sccp-insconv)# <b>set national-indicator</b> <i>natl-ind</i>                                         | Specifies the SCCP national indicator to be used. The following are valid options:<br><br>0               international<br>1               national<br>no change      leave field unchanged                                                                                                                                |

## Configuring Instance Conversion After Global Title Translation

To enable Instance Conversion with global title, configure an application group in an instance and then assign point codes in other instances to the application group.

The application group has an optional parameter **instance**. If you do not specify an instance, a point code that is entered has the same instance as the application group. By using the instance parameter, you can specify a point code in a different instance. The specified point code must represent a real point code, not an alias point code.

To configure instance translation with GTT use the following command in global configuration mode:

| Command                                                                                                                                                                                 | Purpose                                                         |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| Router(config)# <b>cs7 instance</b> <i>instance-number</i> <b>gtt application-group</b> <i>application-group</i>                                                                        | Configures an application group in an instance.                 |
| Router(config-cs7-gtt-app-grp)# <b>instance</b> <i>instance-number</i> { <b>pc</b> <i>pc</i><br>  <b>asname</b> <i>asname</i> } <b>ssn</b> <i>ssn cost</i> { <b>pcssn</b>   <b>gt</b> } | Assign point codes in other instances to the application group. |

The following example creates a GTT entry for instance 0 that will convert the MSU to instance 1. If the ITP receives an SCCP MSU in instance 0, destined for the ITP, route on global title with TT 250 and GTA 919, the ITP will convert the MSU to instance 1 and send the MSU to point code 1.1.1 in instance 1 if 1.1.1/10 is available.

```
Router(config)#cs7 instance 0 gtt application-group app-group0
Router(config-cs7-gtt-app-grp)#instance 1 pc 1.1.1 ssn 10 1 pcssn
Router(config-cs7-gtt-app-grp)#pc 2.2.2 ssn 20 2 pcssn
Router(config-cs7-gtt-app-grp)#exit
Router(config)#cs7 instance 0 gtt selector selector0 tt 250
Router(config-cs7-gtt-selector)#gta 919 app-grp app-group0
Router(config-cs7-gtt-selector)#
```

The following example creates a GTT entry for the converted instance 1. Instead of sending the MSU directly to point code 1.1.1, you configure the pc to match instance 1's local pc with the RI set to gt. Assuming instance 1 has a local pc of 3.3.3, the MSU performs gtt again in instance 1 and routes the MSU based on the GTT configuration of instance 1.

```
Router(config)#cs7 instance 0 gtt application-group app-group0
Router(config-cs7-gtt-app-grp)#instance 1 pc 3.3.3 1 gt
Router(config-cs7-gtt-app-grp)#exit
Router(config)#cs7 instance 0 gtt selector selector0 tt 250
Router(config-cs7-gtt-selector)#gta 910 app-grp
Router(config-cs7-gtt-selector)#
```

You can also configure an application group that contains an asname that is in a different instance. In this case, the ITP will convert the MSU to the new instance, then send the MSU to the as.

```
dancer(config)#cs7 instance 1 gtt application-group as-app1
dance(config-cs7-gtt-app-grp)#asname as-0 1 pcssn
dance(config-cs7-gtt-app-grp)#exit
dancer(config)#cs7 instance 1 gtt selector selector0 tt 10
danc(config-cs7-gtt-selector)#gta 336 app-grp as-app1
```

# Verifying the Multiple Instances Configuration

To verify the Multiple Instances configuration, use the following command in Privileged EXEC mode:

| Command                                                                                                                                              | Purpose                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| Router# <b>show cs7 virtual-linkset</b> [ <i>linkset-name</i> ] [ <b>brief</b> ]<br>[ <b>routes</b> ] [ <b>statistics</b> ]   [ <b>utilization</b> ] | Displays information about virtual linksets. |

# Configuration Example for Multiple Instance

In the following example, the Multiple Instances feature is used to configure STPs in two SS7 networks. Network 1 has variant ANSI and network indicator national. All instances in this network will have network name specified as ANSI-NAT. Network 2 has variant ANSI and network indicator international. All instances in this network will have network name specified as ANSI-INT.

**Configuration for ITP1**

```

cs7 multi-instance
cs7 instance 0 variant ANSI
cs7 instance 0 network-name ANSI-NAT
cs7 instance 0 point-code 5.5.1
cs7 instance 1 variant ANSI
cs7 instance 1 network-name ANSI-INT
cs7 instance 1 network-indicator international
cs7 instance 1 point-code 15.5.1

```

**Configuration for ITP2**

```

cs7 multi-instance
cs7 instance 0 variant ANSI
cs7 instance 0 network-name ANSI-INT
cs7 instance 0 network-indicator international
cs7 instance 0 point-code 7.3.2
cs7 instance 1 variant ANSI
cs7 instance 1 network-name ANSI-NAT
cs7 instance 1 point-code 11.6.2

```

## Configuration Examples for Instance Translation

This section includes two examples:

- [Instance Translation: Instances with the Same Variant, page 75](#)
- [Instance Translation: Conversion from ANSI to ITU, page 77](#)
- [Instance Translation: Conversion from TTC to ITU, page 77](#)

**Instance Translation: Instances with the Same Variant**

The following example configuration is illustrated in [Figure 8](#).

**Figure 8** Instance Translation Configuration Example

In the network above, SP-0 sees the ITP with PC 1-1-5, and also sees a remote SP with PC 1-1-3. SP1 sees the ITP with PC 2-2-2, and also sees a remote SP with PC 2-2-5. The CLI to configure the alias point codes is shown below:

```

ITP#configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
ITP(config)#cs7 instance 0 pc-conversion 1.1.1 alias-pc 1 2.2.5
ITP(config)#cs7 instance 1 pc-conversion 1.1.1 alias-pc 0 1.1.3

```

When SP-0 sends an MSU to SP-1, it sets:

- DPC: 1-1-3
- OPC: 1-1-1
- Network Indicator: 2

When the ITP receives the MSU, it determines that 1-1-3 in Instance 0 is an alias for 1-1-1 in Instance 1, so it converts the MSU to Instance 1. Since Instance 1 uses Network Indicator 3, the MSU's Network Indicator is changed to 3. The converted MSU has:

- DPC 1-1-1
- OPC 2-2-5
- Network Indicator: 3

If the MSU is SCCP and contains a Calling Party PC, this PC is converted using the alias PC table. If the Calling Party PC is 1-1-1, this is converted to 2-2-5

The following show command output sections show the status before and after the configuration of Instance Translation:

```

ITP#show cs7 linkset brief
lsn=SP-0          apc=1.1.1:0      state=avail      avail/links=1/1
lsn=SP-1          apc=1.1.1:1      state=avail      avail/links=1/1

```

```
ITP#show cs7 route
```

```
Routing table = system Instance = 0
```

| Destination | Prio    | Linkset Name | Route |
|-------------|---------|--------------|-------|
| 1.1.1/24    | acces 1 | SP-0         | avail |

```
Routing table = system1 Instance = 1
```

| Destination | Prio    | Linkset Name | Route |
|-------------|---------|--------------|-------|
| 1.1.1/24    | acces 1 | SP-1         | avail |

```
ITP#show cs7 route
```

```
Routing table = system Instance = 0
```

| Destination | Prio    | Linkset Name | Route |
|-------------|---------|--------------|-------|
| 1.1.1/24    | acces 1 | SP-0         | avail |
| 1.1.3/24    | acces 1 | VirtualLS0-1 | avail |

```
Routing table = system1 Instance = 1
```

| Destination | Prio    | Linkset Name | Route |
|-------------|---------|--------------|-------|
| 1.1.1/24    | acces 1 | SP-1         | avail |
| 2.2.5/24    | acces 1 | VirtualLS1-0 | avail |

```

ITP#show cs7 linkset brief
lsn=SP-0          apc=1.1.1:0      state=avail      avail/links=1/1
lsn=SP-1          apc=1.1.1:1      state=avail      avail/links=1/1

PC          ALIAS PCs

1.1.1:1     1.1.3:0

```

### Instance Translation: Conversion from ANSI to ITU

The following GTI conversion and instance conversion tables convert E.164 global title addresses from ANSI to ITU and ITU to ANSI:

```

cs7 sccp gti-conversion ANSI2ITU
  update gti-in 2 tt-in 10 gti-out 4 tt-out 0 np-out 1 nai-out 4 es-out 2
cs7 sccp gti-conversion ITU2ANSI
  update gti-in 4 tt-in 0 np-in 1 nai-in 4 gti-out 2 tt-out 10
cs7 sccp instance-conversion in-instance 0 out-instance 2
  set gti-conversion ITU2ANSI

cs7 sccp instance-conversion in-instance 2 out-instance 0
  set gti-conversion ANSI2ITU

```

Default conversion is not allowed between different variants. The following command will be rejected and will generate a console error if *instance* and *alias-instance* have different variants:

```
cs7 instance <instance> pc-conversion default <alias-instance>
```

### Instance Translation: Conversion from TTC to ITU

The following GTI conversion and instance conversion tables convert E.164 global title addresses from TTC to ITU:

```

cs7 sccp gti-conversion gti-conv0
(config-cs7-sccp-gticonv)#update in-gti 4 in-tt 0 in-ssn 6 out-gti 2 out-tt 240
(config-cs7-sccp-gticonv)#update in-gti 4 in-tt 0 in-ssn 8 out-gti 2 out-tt 10

```

For subsystem mapping, enter the following commands:

```

(config)#cs7 sccp ssn-conversion ss-conv0 in-ssn 11 out-ssn 13
(config)#cs7 sccp ssn-conversion ss-conv0 in-ssn 200 out-ssn 6

```

For address conversion, enter the following commands:

```

cs7 instance 1 gtt address-conversion gta-conv0
update in-address 919522 out-address 1919522

```

For conversion, enter the following commands:

```
cs7 sccp instance-conversion input-instance 0 output-instance 1
set gti-conversion gti-conv0
set ssr-conversion ssr ss-conv0
set address-conversion gta-conv0
```

**Note**

---

The above conversion types are optional when performing instance conversion and they can be used separately or together.

---

# Global Title Translation

A global title is an application address, such as an 800 number, calling card number, or mobile subscriber identification number. Global Title Translation (GTT) is the process by which the SCCP translates a global title into the point code and subsystem number of the destination SSP where the higher-layer protocol processing occurs.

## Feature History for Global Title Translation

| Release     | Modification                                  |
|-------------|-----------------------------------------------|
| 12.2(33)IRA | Added support for this feature.               |
| 12.2(33)IRE | Added support for the GTT next table feature. |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

## Contents

This section describes the tasks and commands for specifying Global Title Address (GTA) conversion mapping.

For information about specifying changes to Global Title fields when configuring the Instance Translation feature, see the “[Configuring Global Title Conversion](#)” section on page 70 of the “[Multiple Instances and Instance Translation](#)” chapter.

- [Verifying Global Title Translations, page 123](#)

This section describes the methods and commands for determining if GTT is performing properly.

- [Logging GTT Errors with the ITP Logging Facility, page 124](#)

This section describes the commands for logging GTT errors to a specified local or remote destination.

- [GTT Configuration Examples, page 126](#)

This section includes a full ITP configuration, including GTT.

**Note**

---

The GTT provisioning syntax and structure is based on GR-82 STP Generic Requirements - Telcordia Technologies, Issue 3 December 1999.

---

## Overview of GTT Components

A global title is an application address, such as an 800 number, calling card number, or mobile subscriber identification number. Global Title Translation (GTT) is the process by which the SCCP translates a global title into the point code and subsystem number of the destination SSP where the higher-layer protocol processing occurs.

The two forms of GTT are described in detail in the [Configuring GTT: 6 Scenarios, page 105](#):

- Intermediate GTT -- A subsequent global title is required by another node, thus the routing indicator is set to zero, indicating *route by global title (gt)*.
- Final GTT -- No subsequent global title is required by another node, thus the routing indicator is set to 1, indicating *route by point code and ssn (pcssn)*.

The main components of GTT are described in the following sections:

- [GTT Selectors, page 93](#)
- [GTT Global Title Address Entries, page 93](#)
- [GTT Application Groups, page 94](#)
- [GTT Mated Application Entries, page 95](#)

## GTT Selectors

A GTT Selector defines the parameters that select the translation table used to perform the translation of an SCCP message to its next or final destination. A GTT selector comprises a mandatory name, Translation Type (TT), and Global Title Indicator (GTI - only mandatory for ITU). In addition, an optional Numbering Plan (NP), Nature of Address Indicator (NAI), and Quality of Service (QOS) may be specified in certain cases.

GTT Selectors have 2 configuration modes:

- The global configuration mode allows configuration of new selectors or is used to enter the submode for modifying/updating an existing selector.
- The gtt selector configuration submode is used to modify certain attributes of the selector or used to update GTAs in the referenced selector.

### Rules for Creating GTT Selectors

The following rules apply when configuring a GTT Selector:

- NP and NAI can not be specified if the variant is ANSI.
- GTI can be specified only if the variant is ITU.
- NP and NAI must be specified if GTI=4.
- The selector name must be unique and from 1 to 12 characters long.

To create a GTT selector, use the following command in global configuration mode:

| Command                                                                                                                       | Purpose                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt selector</b> <i>selector-name</i> <b>tt</b> <i>tt</i> <b>gti</b> <i>gti</i><br><b>np</b> <i>np</i> | Names and configures the GTT selector and enables CS7 GTT selector submode. |

### Rules for Modifying GTT Selectors

- A selector's TT, GTI, NP and NAI cannot be modified once they have been added. A selector must be completely deleted to change these values.
- If a QoS class is entered for a selector, it must have been defined prior to being used by the selector.
- If a new name is given for the selector, it must be unique and not longer than 12 characters.

### Rules for Deleting GTT Selectors

- The selector name must exist.
- A selector cannot be deleted if it contains Global Title Address (GTA) entries.

## GTT Global Title Address Entries

A Global Title Address (GTA) entry defines the result of a translation for a particular address mask. GTA entries are configured from the CS7 GTT selector submode. The result of a translation consists of:

- A new MTP3 Destination Point Code
- A new SCCP CDPA Routing Indicator (RI)
- A new SCCP CDPA Subsystem Number (SSN)

- A new SCCP CDPA Translation Type (TT) (mutually exclusive with SSN)
- A GTT Application Group (mutually exclusive of all of the above)
- A QoS Class
- An M3UA or SUA AS name

#### Rules for Adding GTA Entries

- A solitary GTT Mated Application (MAP) entry is automatically created when the routing indicator keyword is **pcssn** and a subsystem number (*ssn*) is specified.
- There must be room to add the MAP entry if required, since there is a maximum of 10 subsystems per point code in the GTT Mated Application table including one default entry for ssn 1. (See [GTT Mated Application Entries, page 95](#).)
- The routing indicator keyword must be **gt** if a new translation type (**ntt**) is specified.
- A TT and SSN cannot both be specified.
- The PC should not be equal to the node's self PC, capability point code, or secondary PC.
- 1 to 15 digits may be specified for the GTA. (Valid range is 0 through F hexadecimal.)
- The GTA digits must be unique for the GTA Table.
- If a GTT Application group name is specified, it must already exist in the GTT Application Group table.
- If the routing indicator is pcssn, indicating final GTT, but no SSN is specified, then at least one GTT MAP entry must exist for the specified PC.

To specify a GTA, use the following commands as appropriate to your needs, in CS7 GTT selector submode:

| Command                                                                                                                                       | Purpose                                                                            |
|-----------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>gta gta app-grp app-grp</b>                                                                               | Defines a GTA that translates to a GTT application group.                          |
| Router(config-cs7-gtt-selector)# <b>gta gta asname as-name {gt   pcssn} [ssn ssn   ntt newtt   sccp-allow-pak-conv number   pam pam-name]</b> | Defines a GTA that translates to an M3UA or SUA Application Server name.           |
| Router(config-cs7-gtt-selector)# <b>gta gta pcssn pc {gt   pcssn} [ssn ssn   ntt newtt   sccp-allow-pak-conv number   pam pam-name]</b>       | Defines a GTA entry that translates to a point code and optional subsystem number. |

## GTT Application Groups

A GTT Application group is an alternative result for the explicit PC and SSN in a GTA entry. A GTT application group should be used instead of the PC/SSN result in the following cases:

- When more than 1 backup is required for a destination
- When load sharing across more than 2 destinations is required
- When load sharing for intermediate GTT destinations is required
- When a different backup is required for the same primary destination dependent on the GTA
- When a different RI value is desired dependent on the destination selected from the application group

- When a point code backup is required for an M3UA or SUA AS, or vice versa
- When performing a weighted load sharing with traffic received with the same calling party address routed to the same destination

GTT Application groups have 2 configuration modes:

- The top-mode allows configuration of new group names or is used to enter the submode for modifying/updating an group or group item.
- The submode is used to modify certain attributes of the group or used to update entries in the group.

## GTT Mated Application Entries

A GTT Mated Application (MAP) entry has two main purposes. It is used internally by the SCCP application to track point code and SSN states such as congestion and availability. In addition it is used to define backups or alternates for a particular PC/SSN combination. An entry in the GTA table that contains a PC and SSN will have a corresponding entry in the MAP table. The entry in the MAP table may be modified to work in 1 of 3 modes:

- Solitary—No alternate if PC and/or SSN is not available
- Shared—Load shared equally across the primary PC/SSN and backup PC/SSN
- Dominant—Always translate to primary PC/SSN if available, and only translate to backup if primary is unavailable

### Rules for Configuring GTT MAP Entries

The following rules apply:

- A backup point-code and subsystem must be specified if mode (multiplicity) is shared or dominant.
- A backup point-code and subsystem cannot be specified if mode (multiplicity) is solitary.
- A PC/SSN entry cannot be deleted if it is being used as a backup by another PC/SSN entry. (See [Rules For Removing GTT Configurations](#):, page 105)
- A PC/SSN entry cannot be deleted if it is referenced by an entry in the GTA table. (See [Rules For Removing GTT Configurations](#):, page 105)
- The primary and backup point-code should not be identical.
- There is a maximum of 10 subsystems per point-code allowed, including 1 default entry for SSN 1.
- The PC should not be equal to the node's self PC, capability PC, or secondary PC.

To configure a GTT MAP entry, use the following command in global configuration mode:

| Command                                                                      | Purpose                  |
|------------------------------------------------------------------------------|--------------------------|
| Router(config)# <b>cs7 gtt map</b> <i>ppc pssn [flags] mult [bpc] [bssn]</i> | Specify a GTT MAP entry. |

# Storing and Loading GTT Configuration Data

GTT configuration data is stored and loaded differently than traditional router configuration data. GTT configuration commands are not stored in non-volatile RAM (NVRAM), so commands such as **write memory** and **show running config** have no effect. Figure 10 shows the GTT data relationships on an ITP. This section describes:

- Loading a GTT Table from a Remote File Server or Flash (No existing GTT Data), page 96
- Loading a GTT Table from a Remote File Server or Flash (Existing GTT Data), page 97
- Bulk Loading/Replacing GTT Database, page 98
- Syntax and Format Rules for Creating a GTT Database Download File, page 98

**Figure 10** GTT Table Loading

In order to preserve a GTT configuration across ITP reloads, you must use the GTT Table Loading feature.

## Warning

**All GTT data will be lost during a router reboot if you do not use the GTT Table Loading procedure.**

## Loading a GTT Table from a Remote File Server or Flash (No existing GTT Data)

The steps for loading a GTT table when the ITP has no existing GTT data are as follows:

- Step 1** Determine the desired default location for the GTT file to be loaded during ITP reloads. The default location can be either Flash or a remote server. For example, if the GTT file is to be loaded from Flash, the URL would be similar to the following:

```
flash:gttdata.txt
```

If the GTT file is to be loaded from a remote server, the URL would be similar to the following:

```
tftp://64.102.16.25/gttdata.txt
```

**Step 2** Specify that the GTT file is to be loaded into RAM during subsequent ITP reloads.

| Command                                        | Purpose                                                                              |
|------------------------------------------------|--------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt load</b> <i>URL</i> | Specify the URL location from which the GTT database will be loaded upon ITP reload. |

For example, using the default location and filename flash:gttdata.txt, the command would be:

```
cs7 gtt load flash:gttdata.txt
```

**Step 3** Save the **cs7 gtt load** definition to NVRAM with a **write memory** command.

**Step 4** Configure all desired GTT data using the CLI.

**Step 5** Save the GTT data to the file specified in step 2 using the **copy** command or the **cs7 save gtt-table** privileged EXEC command as in the following example:

```
cs7 save gtt-table flash:gttdata.txt
```

**Note**

The file “cs7:gtt-tables/gtt\_default” is a machine generated file. Its format is not meant for hand editing. It is recommended the CLI or an externally provided GUI product be used to configure GTT data, rather than editing the gtt\_default file.

Steps 4 and 5 can be repeated for subsequent updates of GTT data.

**Note**

Whenever a GTT configuration is performed for an instance, you have to perform a specific save and load of the GTT configuration for this instance.

## Loading a GTT Table from a Remote File Server or Flash (Existing GTT Data)

For an existing system with GTT data, to execute the load command immediately use the following command in global configuration mode:

| Command                                                           | Purpose                                                                    |
|-------------------------------------------------------------------|----------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt load</b> <i>URL</i> [ <b>execute</b> ] | Specify the URL location of the GTT database and, optionally, load it now. |

## Bulk Loading/Replacing GTT Database

It may be desirable to replace the entire contents of a GTT database with a new database without rebooting the ITP. The **cs7 gtt load** command discussed above does not support this capability. To perform a bulk load of the entire GTT database without the need to reboot an ITP, use the following command in privileged EXEC mode:

| Command                                                                                                                        | Purpose                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Router# <b>cs7 gtt replace-db</b> <i>URL</i><br>Are you sure?<br>[confirm]<br><br>GTT table: <i>URL</i> , loaded successfully. | Replace the entire contents of a GTT database with a new database without rebooting the ITP. |

## Syntax and Format Rules for Creating a GTT Database Download File

This section describes the syntax and format of the text file used to store and load GTT information on the ITP. This information may be useful for advanced users who require the ability to generate GTT tables offline and then load the GTT Database file onto the ITP.

Since GTT data is not preserved in NVRAM, and the maximum size of GTT data can be up to 500,000 entries, a separate compressed format (comma separated) is provided to represent GTT data configured on the ITP. The text file is generated by the ITP when GTT data is saved to a file.

### Command Identifiers in a GTT Database Download File

Table 4 shows the command identifiers supported by the GTT table download format. Each line in the text file is identified with a one-character string. All command identifiers except **v** may be prefixed with a “**d**” to indicate a delete action. Otherwise the action is assumed to be an add action. A modify action occurs only when the item already exists and one or more attributes have changed. The table shows the command identifier and the action it specifies.

**Table 4** GTT Database Download File Command Identifiers

| Command Identifier | Action                                                                                                                                                                                                |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>v</b>           | Add or modify the format version of the GTT configuration file. Must be the first command in the GTT configuration file because it identifies which parameters are valid within the various commands. |
| <b>s</b>           | Add or modify GTT Selector.                                                                                                                                                                           |
| <b>ds</b>          | Delete Selector.                                                                                                                                                                                      |
| <b>g</b>           | Add or modify GTT GTA.                                                                                                                                                                                |
| <b>dg</b>          | Delete GTT GTA.                                                                                                                                                                                       |
| <b>a</b>           | Add or modify GTT Application Groups or items in the group.                                                                                                                                           |
| <b>da</b>          | Delete GTT Application Groups or items in the group.                                                                                                                                                  |
| <b>m</b>           | Add or modify GTT MAP.                                                                                                                                                                                |
| <b>dm</b>          | Delete a GTT MAP.                                                                                                                                                                                     |
| <b>c</b>           | Add or modify a Concerned Point Code List.                                                                                                                                                            |
| <b>dc</b>          | Delete a Concerned Point Code List or item in the list.                                                                                                                                               |

**Table 4** *GTT Database Download File Command Identifiers (continued)*

|           |                                               |
|-----------|-----------------------------------------------|
| <b>p</b>  | Add or modify a GTT address conversion entry. |
| <b>dp</b> | Delete a GTT address conversion entry         |

**Syntax Rules:**

- All lines must be terminated with a '\n' (unix eol).
- All tokens are comma separated.
- Each line is parsed for syntax checks and then checked for semantics.
- If a line is parsed and fails either syntax or semantic checks the download process is aborted at the point of failure.

## Parameter Values in GTT Database Download Files

This section describes the values of the parameters that you use with the command identifiers when you create a GTT database download file.

The first line in any GTT file must indicate the version and variant of the GTT file. [Table 5](#) lists the current GTT table versions by ITP software version.

**Table 5** *GTT File Version*

| ITP Software Rel | GTT Table Version |
|------------------|-------------------|
| MB4              | 1.0               |
| MB5              | 2.0               |
| MB6              | 2.0               |
| MB7              | 3.0               |
| MB8              | 3.0               |
| MB9              | 3.1               |
| MB9A             | 3.1               |
| MB10             | 4.0               |
| MB11             | 4.0               |
| MB12             | 4.0               |
| MB13             | 4.0               |
| 12.2(20)SW       | 4.1               |
| 12.2(21)SW1      | 4.2               |
| 12.2(23)SW       | 4.2               |
| 12.2(23)SW1      | 4.3               |
| 12.2(25)SW       | 4.3               |

[Table 6](#) lists the values for each parameter of the GTT commands that can be specified in a GTT database download file.

**Table 6** GTT Command Parameter Values

| Parameter                   | Valid Values                                                                             |
|-----------------------------|------------------------------------------------------------------------------------------|
| <i>version</i>              | GTT Table Version - 1.0, 2.0, 3.0, 3.1, 4.0, 4.1, 4.2, 4.3(See <a href="#">Table 5</a> ) |
| <i>variant</i>              | Variant - {ANSI, ITU, CHINA}                                                             |
| <i>selector name</i>        | Name of Selector - alphanumeric string maximum of 12 chars                               |
| <i>tt</i>                   | Translation Type - integer {0-255}                                                       |
| <i>gti</i>                  | Global Title Indicator- integer {2,4}                                                    |
| <i>np</i>                   | Numbering Plan - integer {0-15}                                                          |
| <i>nai</i>                  | Nature of Address Indicator - integer {0-127}                                            |
| <i>es</i>                   | Encoding scheme for the address conversion result {0-2}                                  |
| <i>qos</i>                  | Quality of service Class identifier {1-7}                                                |
| <i>gta</i>                  | Global Title Address Digits - numeric/hex sting 1 to 15 digits                           |
| <i>pc</i>                   | Destination point code in hex                                                            |
| <i>ri</i>                   | Routing indicator { <b>gt</b> , <b>pcssn</b> }                                           |
| <i>ssn</i>                  | Subsystem Number - integer {2-255}                                                       |
| <i>ntt</i>                  | New Translation Type - integer {0-255}                                                   |
| <i>app-grp</i>              | Application Group name - alphanumeric string maximum of 12 chars                         |
| <i>group-name</i>           | Application Group name - alphanumeric string maximum of 12 chars                         |
| <i>mult</i>                 | Multiplicity { <b>sol</b> , <b>dom</b> , <b>sha</b> , <b>cos</b> }                       |
| <i>mult.1</i>               | Multiplicity { <b>sha</b> , <b>cos</b> }                                                 |
| <i>mult.2</i>               | Multiplicity { <b>sha</b> , <b>cos</b> , <b>cgp</b> }                                    |
| <i>cost</i>                 | Cost or priority of destination {1-8}                                                    |
| <i>ppc</i>                  | Primary point code in hex                                                                |
| <i>pssn</i>                 | Primary Subsystem Number - integer {2-255}                                               |
| <i>bpc</i>                  | Backup point code in hex                                                                 |
| <i>bssn</i>                 | Backup Subsystem Number - integer {2-255}                                                |
| <i>concern pc list name</i> | Concerned Point Code List Name - alphanumeric string maximum of 12 chars.                |
| <i>rrc</i>                  | Boolean Re-Route if Congested - integer {0,1}                                            |
| <i>adj</i>                  | Boolean Adjacency indicator {0,1}                                                        |
| <i>pre-addrconv</i>         | Name of address conversion table - alphanumeric string maximum of 12 chars.              |
| <i>post-addrconv</i>        | Name of address conversion table - alphanumeric string maximum of 12 chars.              |
| <i>network-name</i>         | Network name of instance - alphanumeric string maximum of 12 chars.                      |

## Examples of Entries in a GTT Database Download File

This section provides the syntax and examples of entries in a GTT database:

### Version and Variant

To specify the version of the GTT configuration file and the variant, use the syntax appropriate to your version:

- Syntax for version 1.0 to 3.0:

**v**,*version*,*variant*

Examples:

```
v1.0,ITU
v2.0,ANSI
v3.0,CHINA
```

- Syntax for version 4.0: In version 4.0 the ITP software supports multiple variants via the use of multiple instances. Each instance is assigned a variant.

**v**,*version*,*variant*,*instance*

Example:

```
v4.0,ANSI,0
```

- Syntax for version 4.1 and 4.2

**v**,*version*,*variant*,*instance*,*network-name*

Example:

```
v4.1,ITU,0,itu-national
```

### GTT Selector

To add, modify, or delete a GTT Selector:

- Syntax:

**[d]***sselectorname*,*tt*,*gti*,*[np]*,*[nai]*,*[qos]*,*[pre-addrconv]*,*[post-addrconv]*

Examples:

```
stest,0,4,7,4,1
stestsel,0,2, , ,
sa12345672,100,4,15,127,
```

### GTT GTA

To add, modify, or delete a GTT GTA:

- Syntax for version 1.0:

**[d]***gselectorname*,*gta*,*[pc]*,*[ri]*,*[ssn]*,*[ntt]*,*[app-grp]*,*[qos]*

Examples:

```
gtest,349,1012,gt,100, , ,
gtest,828,1012,gt, ,100, ,
gtest,828258,1012,pcssn,129, , ,
gtest,8282588595,1012,pcssn,100, ,1,
gtest,919, , , , ,test,
gtest,920, , , , ,test,
gtest,980,859,pcssn,10, , ,
```

- Syntax for version 2.0 to 4.1:

**[d]***gselectorname*,*gta*,*[pc]*,*[ri]*,*[ssn]*,*[ntt]*,*[app-grp]*,*[qos]*, *[asname]*

Examples:

```
gtest,349,1012,gt,100, , ,
gtest,828,1012,gt, ,100, ,
gtest,828258,1012,pcssn,129, , ,
gtest,8282588595,1012,pcssn,100, ,1,
gtest,919, , , , ,test,
gtest,920, , , , ,test,
gtest,980,859,pcssn,10, , ,
gtest,999, , , , , ,sua_as1
```

- Syntax for version 4.2:  
Same as previous except *ssn* may be **0** when *ri* is **gt**.

### GTT Application Groups

To add, modify, or delete a GTT Application Group:

- Syntax for version 1.0:  
`[d]agroup-name,[mult.I],cost,pc,ri,[ssn]`  
Example:  
`aapp0,cost,1,1012,gt,`
- Syntax for version 2.0:  
`[d]agroup-name,[mult.I],cost,pc,ri,[ssn],[asname]`  
Example:  
`aapp0,cost,1, , , ,as0`
- Syntax for version 3.0:  
`[d]agroup-name,[mult.I],cost,pc,ri,[ssn],[asname]`  
No syntax change, but can enter local-pc in table.  
Example:  
`aapp1,sha,1,10203,pcssn, ,`
- Syntax for version 3.1:  
`[d]agroup-name,[mult.I],cost,pc,ri,[ssn],[asname]`  
No syntax change, but allows 8 items with same cost  
Example:  
`aapp1,sha,1,10203,pcssn, ,`
- Syntax for version 4.0:  
`[d]agroup-name,[mult.2],cost,pc,ri,[ssn],[asname]`  
CGPA load sharing introduced  
Example:  
`aapp1,cgp,1,20203,pcssn, ,`
- Syntax for version 4.1:  
The item in the application group can be in a different instance than the application group. The *network-name* parameter is added to indicate the instance to which the item belongs.  
`[d]agroup-name,[mult.2],cost,pc,ri,[ssn],[asname],[network-name]`

Example:

```
aapp1,cgp,1,20203,pcssn,5, ,instance1
```

- Syntax for version 4.2:

Unchanged, except *ssn* may be 0 for intermediate GTT.

Example:

```
aapp1,cos,1,10203,pcssn,5, ,instance1
```

## GTT MAP

To add, modify or delete a GTT MAP:

- Syntax for version 1.0 and 2.0

```
[d]mppc,pcssn,mult,[bpc],[bssn],[concern pc list name],[rrc],[adj]
```

- Syntax for version 3.0 to 4.2 adds support for local-pc in the MAP table.

Examples:

```
m809,10,sol,,,0,0
m859,10,sol,,,0,0
m861,10,sol,,,0,0
m1012,10,sol,,,0,0
m859,20,sha,861,20,,0,1
m859,25,dom,861,25,,1,0
```

## Concerned PC Lists

To add, modify, or delete a Concerned PC List:

- Syntax for version 1.0 to 3.0

```
[d]cconcern pc list name,pc
```

Examples:

```
clist1,809
clist1,859
clist3,1012
```

- Syntax for version 4.0

```
[d]cconcern pc list name,pc,instance
```

Example:

```
clist1,1024,1
```

## Address Conversion Tables

To add, modify, or delete an address conversion table:

- Syntax for version 1.0 to 4.2

```
[d]paddress conversion table name,[np],[nai],gta,[gta],[np],[nai]
```

- Syntax for version 4.3

```
[d]paddress conversion table name,[np],[nai],gta,[gta],[np],[nai],[es]
```

# Modifying and Verifying the GTT Selector

You can modify certain attributes of a selector in addition to using the selector for its primary purpose of updating GTAs. To modify attributes of the selector, use the following commands in the `cs7 gtt` selector submode.

To configure the default GTT entry in a GTT table to point to another GTT table (next table) in the same instance, use the following command:

| Command                                                                 | Purpose                                                       |
|-------------------------------------------------------------------------|---------------------------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>next-table</b> <i>selector-name</i> | Configures the default GTT selector to point to a next table. |

To change the name of the selector, use the following command:

| Command                                                               | Purpose                   |
|-----------------------------------------------------------------------|---------------------------|
| Router(config-cs7-gtt-selector)# <b>new-name</b> <i>selector-name</i> | Renames the GTT selector. |

After you have defined a GTA address conversion table, you can apply the table on a GTT selector basis. To specify the global title address conversion table to apply either prior to or after performing local global title translation, use either of the following commands:

| Command                                                                              | Purpose                                                                                                          |
|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>pre-gtt-address-conversion</b> <i>tablename</i>  | Specifies the global title address conversion table to apply prior to performing local global title translation. |
| Router(config-cs7-gtt-selector)# <b>post-gtt-address-conversion</b> <i>tablename</i> | Specifies the global title address conversion table to apply after performing local global title translation.    |

Since the GTT data is not stored in NVRAM, commands such as **show running config** will not display the GTT data. To display the current running configuration regarding GTT use the **show cs7 gtt config** command in privileged EXEC mode:

```
ITP# show cs7 gtt config
cs7 instance 0 gtt selector cs7test0 tt 0 gti 4 np 1 nai 3
  gta 33333 pcssn 1.5.4 gt
  gta 333  asname gg pcssn
next-table name cs7test1
cs7 instance 0 gtt selector cs7test1 tt 1 gti 4 np 1 nai 2
  gta 22222 pcssn 2.5.4 gt
  gta 222  asname mm pcssn
```

To display the CS7 GTT selectors, use the **show cs7 gtt selector** command in privileged EXEC mode:

```
ITP# show cs7 gtt selector
Selector Name   TT   GTI   NP   NAI   DFLTQOS   #GTAs
-----
c7gsp          0     4     1     3           3
itp_gtt        0     4     0     4           1
```

# Configuring GTT: 6 Scenarios

The following sections describe how to configure GTT data on the ITP for different scenarios applicable to real customer networks. The scenarios include:

- [Configuring Intermediate GTT To Route MSUs to a Single Point Code, page 105](#)
- [Configuring Intermediate GTT To Load Balance MSUs Across Two Or More Point Codes, page 107](#)
- [Configuring Final GTT To Route MSUs to a Solitary Point Code, page 110](#)
- [Configuring Final GTT To Route MSUs to a Primary and Backup Point Code and SSN \(Dominant Mode\), page 113](#)
- [Configuring Final GTT To Load Balance MSUs Across a Group of Point Codes and Subsystems, page 116](#)
- [Configuring Final GTT to an SUA AS with a Backup Point Code \(Dominant Mode\), page 118](#)

## Rules For Removing GTT Configurations:

- To delete a selector you must first delete any GTAs that reference it, using the **no gta** command. After deleting the GTAs, you can remove the selector, using the **no selector** command.
- To delete a mated application (GTT MAP), you must first delete any application groups and GTAs that reference it (using the **no cs7 gtt application-group** command and **no gta** command). You can then delete the mated application configuration using the **no cs7 gtt map** command.
- To delete a map entry that references another map entry as a backup, change all entries that reference it to “solitary” then delete the map entry with the **no cs7 gtt map** command. You cannot directly delete the map entry with backup pc/ssn using the **no cs7 gtt map** command.
- To delete an application group that is referenced by a GTA, you must first delete the GTA using the **no gta** command. After deleting the GTA, you can remove the application group with the **no cs7 gtt app-grp** command.

## Configuring Intermediate GTT To Route MSUs to a Single Point Code

This configuration describes the scenario shown in [Figure 11](#).

**Figure 11** *Intermediate GTT With One Destination*

The ITP on the left side of [Figure 11](#) is required to perform intermediate GTT for a set of digits (GTAs). There is only 1 choice for the next destination regardless of its availability. All SCCP traffic that requires GTT and that matches the configured digits is to be GTT routed to the destination PC=158.

## Provisioning the ITP

To provision the ITP, perform the following steps:

- Step 1** Determine the criteria needed to select the appropriate translation table. For ITU the most common Global Title Indicator is 4. This means a TT, NP and NAI identify the translation table. For ANSI, only the TT is required. For this example we will use TT=0, NP=1, NAI=3.

**Note** The choices of TT, NP, and NAI are application specific. Refer to the SS7 network administrator to determine the appropriate combination of TT, NP, and NAI. ITU-T Q.714 Specifications of Signaling System No. 7- Signaling Connection Control Part defines many of the well-known applications.

- Step 2** Determine if a GTT Selector matching the criteria stated above already exists:

| Command                              | Purpose                           |
|--------------------------------------|-----------------------------------|
| Router# <b>show cs7 gtt selector</b> | Display GTT selector information. |

If a matching GTT selector exists, it can be referenced by its text name. If not, a new selector must be created. For this example assume it does not exist and the name **c7gsp** will be used.

- Step 3** Determine the range of digits from the called party address (CDPA) that need to be routed to PC=158. In this example assume that any digits matching the prefix 3330810 need to be GTT routed to PC=158. All GTA digits entered on the ITP are prefix matched against the actual digits arriving in the MSU requiring GTT. When 3330810 is provisioned on the ITP it really means 3330810xxxxx... where x is any digit. The ITP currently supports prefix matching from 1 to 15 digits (1 - 9 and hex characters A - F).

## Configuring the ITP GTT Database

Once the above criteria are determined, follow these steps to configure the ITP GTT database:

- Step 1** Configure the selector:

| Command                                                                      | Purpose                                                                    |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt selector selector tt tt gti gti np np nai nai</b> | Names and configures the GTT selector and enters CS7 GTT selector submenu. |

Using the details of the example, the command would be:

```
cs7 gtt selector c7gsp tt 0 gti 4 np 1 nai 3
```

In this simple case only one translation needs to be added within the selector.

- Step 2** Configure the GTA within the selector:

| Command                                                                          | Purpose                       |
|----------------------------------------------------------------------------------|-------------------------------|
| Router(config-cs7-gtt-selector)# <b>gta gta result-type pc routing-indicator</b> | Names and configures the GTA. |

The result type is used to specify whether the GTA will be routed to a specific point code and optional SSN (pcssn) or to an application group (app-grp). In this case the result type is pcssn which allows the operator to specify a specific point code (pc=158). An SSN is not used in this example:

```
gta 3330810 pcssn 158 gt
```

The above command can be referred to as a GTA rule. The rule states that the CDPA digits matching 3330810 will be routed to a point-code and optional subsystem number (pcssn). The point-code is 158, the subsystem number in this example is not defined and the routing indicator is set to 'gt' indicating intermediate GTT. Omitting a new SSN in the rule causes the original SSN to be preserved during the translation.

**Step 3** Exit the submode and verify the data entered:

| Command                                           | Purpose                               |
|---------------------------------------------------|---------------------------------------|
| Router(config-cs7-gtt-selector)# <b>exit</b>      | Exits CS7 GTT selector submode.       |
| Router(config)# <b>exit</b>                       | Exits global configuration mode.      |
| Router# <b>show cs7 gtt gta selector [digits]</b> | Displays details about the given GTA. |

To delete a GTT configuration, follow the rules in the [“Rules For Removing GTT Configurations:”](#) section on page 105.

## Configuring Intermediate GTT To Load Balance MSUs Across Two Or More Point Codes

This configuration describes the scenario shown in [Figure 12](#).

**Figure 12** Intermediate GTT Shared Across 2 Destinations

This example is similar to the previous example except that instead of only 1 destination point-code a group of point-codes shall be used. For this example the mode (multiplicity) used to pick which point-code to choose from the group is **shared**. This means that all SCCP messages that matched the translation will be equally shared across the available destinations in the group in a round-robin fashion.

The MTP3 destination status is used to determine if the point code is available.

In [Figure 12](#) the ITP on the left side of the illustration is required to act as an intermediate translation point to the mated pair of STPs, which handle all final translations to a HLR. In this case the ITP is required to share all GTT routed traffic for a range of digits between a mated pair of STPs (PC=158 and PC=166).

## Provisioning the ITP

To provision the ITP, perform the following steps:

- 
- Step 1** Determine the criteria needed to select the appropriate translation table. For this example assume GTT selector criteria GTI=4, TT=0, NP=1, NAI=3. Also assume the appropriate selector already exists in the ITP GTT database.
  - Step 2** Define a GTT application group representing the mated pair of STPs (PC=158, PC=166) in the intermediate/shared mode.
  - Step 3** Determine the range of digits from the called party address (CDPA) that need to be routed to the application group containing PC=158 and PC=166. In this example assume that any digits matching the prefix 328 needs to be GTT routed to the application group.
- 

## Configuring the ITP GTT Database

Once the above criteria are determined the following steps may be followed to configure the ITP GTT database:

- 
- Step 1** Define a GTT application group representing the mated pair of STPs in the intermediate/shared mode:

| Command                                                            | Purpose                                                                                                            |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt application-group</b> <i>group-name</i> | Assigns an application group name and enables the CS7 GTT application-group submode for adding items to the group. |

Using the details of the example, the command would be:

```
Router(config)# cs7 gtt application-group intergroup1
```

- Step 2** Add the point-codes into the application group then exit application group submode:

| Command                                                                                          | Purpose                                                                  |
|--------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|
| Router(config-cs7-gtt-app-grp)# <b>pc</b> <i>point-code</i> <i>cost</i> <i>routing-indicator</i> | Adds a point code, cost, and routing indicator to the application group. |
| Router(config-cs7-gtt-app-grp)# <b>exit</b>                                                      | Exits CS7 GTT application-group submode.                                 |

Using the details of the example, the commands would be:

```
Router(config-cs7-gtt-app-grp)# pc 158 1 gt
Router(config-cs7-gtt-app-grp)# pc 166 2 gt
Router(config-cs7-gtt-app-grp)# exit
```

The default mode for the group is share, which does not have to be changed for this example. In shared mode, all items in an application group must be given a unique cost (1-8) as cost is a mandatory parameter. However, in the shared mode, the cost parameter is ignored and all provisioned items in the application group are shared equally. The cost can be thought of as an item number.

In the shared mode the cost can be thought of as an item number. Should the mode be changed to a “cost” mode, the method for choosing the next destination would switch from a round-robin scheme to a least cost available algorithm. (The cost is ignored when the group is share, and share is the default.) An example of using the cost mode is not shown, but can be thought of as follows:

Instead of sharing all traffic between the items in the group, pick the least cost item (1 being the least) and choose it always if available. If the least cost item is not available, choose the next least cost available item and route to it. If no items are available, drop message and initiate error and measurement procedures.

**Step 3** Enter the submode configuration for the existing selector:

| Command                                                 | Purpose                                                      |
|---------------------------------------------------------|--------------------------------------------------------------|
| Router(config)# <b>cs7 gtt selector</b> <i>selector</i> | Enables the CS7 GTT selector submode for the given selector. |

Using the details of the example, the commands would be:

```
Router(config)# cs7 gtt selector c7gsp
```

After performing the above step, the CLI enters selector submode for configuring translations options within the selector. In this simple case only one translation needs to be added within the selector.

**Step 4** Configure the GTA within the selector:

| Command                                                                    | Purpose                                              |
|----------------------------------------------------------------------------|------------------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>gta</b> <i>gta result-type app-grp</i> | Names and configures the GTA for the given selector. |

Using the details of the example, the command would be:

```
Router(config-cs7-gtt-selector)# gta 328 app-grp intergroup1
```

**Note** The application group intergroup1 may be used by as many GTT rules as needed. Avoid creating application groups with the same items in them.

The above command can be referred to as a GTA rule. The rule states that the CDPA digits matching 328 will be routed to the application group “intergroup1.” Using an application group allows destinations to be modified, added, or deleted without impacting the GTA table.

**Step 5** Exit the submode and verify the data entered:

| Command                                      | Purpose                         |
|----------------------------------------------|---------------------------------|
| Router(config-cs7-gtt-selector)# <b>exit</b> | Exits CS7 GTT selector submode. |

| Command                                                          | Purpose                                   |
|------------------------------------------------------------------|-------------------------------------------|
| Router(config)# <b>exit</b>                                      | Exits global configuration mode.          |
| Router# <b>show cs7 gtt gta selector [sgta sgta] [egta egta]</b> | Displays details about the specified GTA. |

Using the details of the example, the command and output would be:

```
Router# show cs7 gtt gta c7gsp
```

| Selector Name | TT | GTI | NP | NAI | DFLTQOS | #GTAs |             |     |        |
|---------------|----|-----|----|-----|---------|-------|-------------|-----|--------|
| c7gsp         | 0  | 4   | 1  | 3   |         | 2     |             |     |        |
| GTA           |    | PC  |    | RI  | SSN     | TT    | App-Grp     | QOS | ASname |
| 3330810       |    | 158 |    | gt  |         |       |             |     |        |
| 328           |    |     |    |     |         |       | intergroup1 |     |        |

To delete a GTT configuration, follow the rules in the [“Rules For Removing GTT Configurations:”](#) section on page 105.

## Configuring Final GTT To Route MSUs to a Solitary Point Code

This configuration describes the scenario shown in [Figure 13](#).

**Figure 13** ITP performing Final GTT to a Solitary Point Code

This example is similar to the previous example in that a solitary point-code is used. However, this example involves final GTT rather than intermediate GTT from the previous 2 examples. The main difference in intermediate vs. final GTT is the resultant routing indicator of the outgoing/translated message. The ITP also makes use of the Subsystem status when choosing the destination.

In [Figure 13](#) the ITP (PC=158) is required to perform final GTT to a HLR (PC=245/ SSN=250) for a specific range of digits from the CDPA. In this case the ITP is required to route all GTT traffic for the range of digits to an end node such as the HLR in this example.

### Provisioning the ITP

To provision the ITP, perform the following steps:

- 
- Step 1** Determine the criteria needed to select the appropriate translation table. For this example assume GTT selector criteria GTI=4, TT=0, NP=1, NAI=3. Also assume the appropriate selector already exists in the ITP GTT database.
- Step 2** Determine the range of digits from the called party address (CDPA) that need to be routed to the HLR. In this example assume that any digits matching the prefix 3335114 needs to be GTT routed to the HLR.
- Step 3** Determine if the ITP should replace the SSN in the called party with SSN=250 or the ITP should rely on the proper SSN already being set in the CDPA. In this example the ITP will implicitly replace SSN=250 in the called party regardless of any existing SSN.
- 

## Configuring the ITP GTT Database

Once the above criteria are determined the following steps may be followed to configure the ITP GTT database.

- Step 1** Enter the submode configuration for the existing selector:

| Command                                                 | Purpose                                                                                                                    |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt selector</b> <i>selector</i> | Specifies the selector name and enables CS7 GTT selector submode for configuring translations options within the selector. |

Using the details of the example, the command would be:

```
Router(config)# cs7 gtt selector c7gsp
```

After performing the above step, the CLI enters selector submode for configuring translations options within the selector. In this simple case only one translation needs to be added within the selector.

- Step 2** Configure the GTA within the selector:

| Command                                                                                                       | Purpose                                              |
|---------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>gta</b> <i>gta result-type pc routing-indicator</i> <b>ssn</b> <i>ssn</i> | Names and configures the GTA for the given selector. |

Using the details of the example, the command would be:

```
Router(config-cs7-gtt-selector)# gta 3335114 pcssn 245 pcssn ssn 250
```

The above command can be referred to as a GTA rule. The rule states that the CDPA digits matching 3335114 will be routed to a point-code and subsystem. The point-code is 245 and the SSN=250. The resultant routing indicator shall be set to **pcssn**, indicating final GTT (route on point code and subsystem). Since the SSN was specified as 250, it will override any SSN that previously existed in the called party. Conversely if the SSN was not specified in this rule, the ITP would try to route to whatever subsystem existed in the CDPA.

- Step 3** Exit the submode and use the **show cs7 gtt** commands to verify the data entered:

| Command                                      | Purpose                                     |
|----------------------------------------------|---------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>exit</b> | Exits CS7 GTT selector submode.             |
| Router(config)# <b>exit</b>                  | Exits global configuration mode.            |
| Router# <b>show cs7 gtt gta gta</b>          | Displays details about the specified GTA.   |
| Router# <b>show cs7 gtt map</b>              | Displays details about the GTT MAP entries. |

Using the details of the example, the show command and output would be:

```
Router# show cs7 gtt gta c7gsp
```

```

Selector Name   TT   GTI   NP   NAI   DFLTQOS   #GTAs
-----
c7gsp           0     4     1     3           3

```

Table 7 describes the fields in the **show cs7 gtt map** display.

**Table 7** *show cs7 gtt map Field Descriptions*

| Field    | Description                                                                                                                                                                                                                                                               |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PCC      | Primary Point Code                                                                                                                                                                                                                                                        |
| PSSN     | Primary Subsystem Number                                                                                                                                                                                                                                                  |
| Mult     | Multiplicity (load share mode)                                                                                                                                                                                                                                            |
| BPC      | Backup Point Code for Primary Point Code                                                                                                                                                                                                                                  |
| BSSN     | Backup Subsystem Number for Primary Subsystem Number                                                                                                                                                                                                                      |
| ConPCLst | Concerned point-code list name. Concerned point-code lists are created using the <b>cs7 gtt concern-pclist</b> command. All destinations in the list are notified when a subsystem status change occurs. Concerned point-code lists are optional for all GTT MAP entries. |
| RRC      | Reroute to backup if primary is congested Used to tell SCCP routing if the backup should be used when the primary is congested. Default is OFF.                                                                                                                           |
| ADJ      | Adjacency flag. Used to signify if a PC/SSN should be considered adjacent to local node in regards to SCCP management. Default is NO.                                                                                                                                     |
| Ref      | Reference Count. Indicates how many times a MAP entry is referenced by GTA or application group entries. A referenced MAP can not be removed.                                                                                                                             |

**Note**

Whenever final GTT is provisioned with an explicit subsystem from a GTA entry such as the one for GTA=3335114, a GTT MAP (Mated Application) entry is required. The ITP will automatically create a solitary MAP as needed when the GTA entry is created. The GTT MAP entry is used internally by the ITP to manage the status of a subsystem. The operator could have pre-provisioned this MAP entry prior to configuring the GTT using the **cs7 gtt map** command. For an example where the MAP is provisioned prior to the GTA see the [“Configuring Final GTT To Route MSUs to a Primary and Backup Point Code and SSN \(Dominant Mode\)” section on page 113](#). The MAP can also be used to define a mate point-code for the primary point-code. This is an alternative to using application-groups, which take up more memory.

To delete a GTT configuration, follow the rules in the [“Rules For Removing GTT Configurations:” section on page 105](#).

## Configuring Final GTT To Route MSUs to a Primary and Backup Point Code and SSN (Dominant Mode)

This configuration describes the scenario shown in [Figure 14](#)

**Figure 14** Final GTT routed to a primary and backup PC/SSN

This example is similar to the previous example in that final GTT is being performed. However, this example involves final GTT using a customized GTT MAP entry where a backup PC and SSN are also utilized.

In [Figure 14](#) the ITP (PC=158) is required to perform final GTT to a HLR (PC=245/ SSN=250) for a specific range of digits from the CDPA. Also suppose the HLR (PC=245) has a backup (PC=1003) in case of a failure. In this case the ITP is required to route all GTT traffic for a range of digits to the primary HLR if it is available. If the primary HLR becomes unavailable, the ITP is required to use the backup instead. This method of choosing the primary and backup subsystems is typically referred to as operating in the dominant mode. Backup point code support is provided only with GTT selector.

### Provisioning the ITP

To provision the ITP, perform the following steps:

- 
- Step 1** Determine the criteria needed to select the appropriate translation table. For this example assume GTT selector criteria GTI=4, TT=0, NP=1, NAI=3. Also assume the appropriate selector already exists in the ITP GTT database.
- Step 2** Determine the range of digits from the called party address (CDPA) that need to be routed to the HLR. In this example assume that any digits matching the prefix 339 needs to be GTT routed to the primary HLR (PC=245) if available or the backup HLR (PC=1003) if the primary is not available.
- Step 3** Determine if the ITP should replace the SSN in the called party with SSN=250 or the ITP should rely on the proper SSN already being set in the CDPA. In this example the ITP will implicitly replace SSN=250 in the called party regardless of any existing SSN.
- Step 4** Determine if a GTT MAP entry having the appropriate mode and backup criteria exists. For this example assume the GTT MAP entry does not exist and create it.
- 

## Configuring the ITP GTT Database

Once the above criteria are determined, follow these steps to configure the ITP GTT database:

- Step 1** Enter the GTT MAP entry:

| Command                                                                      | Purpose                           |
|------------------------------------------------------------------------------|-----------------------------------|
| Router(config)# <b>cs7 gtt map</b> <i>ppc pssn [flags] mode [bpc] [bssn]</i> | Specifies the GTT MAP definition. |

Using the details of the example, the command would be:

```
Router(config)# cs7 gtt map 245 250 rrc dom 1003 250
```

The above command can be referred to as a GTT MAP definition. The definition dictates that PC=245 and SSN=250 is a primary application backed up in the dominant mode by PC=1003 and SSN=250. The rrc flag specifies that if the primary PC/SSN becomes congested we will re-route to the standby PC/SSN.

- Step 2** Enter the submode configuration for the existing selector:

| Command                                                 | Purpose                                                                                    |
|---------------------------------------------------------|--------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt selector</b> <i>selector</i> | Enables CS7 GTT selector submode for configuring translations options within the selector. |

Using the details of the example, the command would be:

```
Router(config)# cs7 gtt selector c7gsp
```

In this simple case only one translation needs to be added within the selector.

- Step 3** Configure the GTA within the selector:

| Command                                                                                                 | Purpose                                   |
|---------------------------------------------------------------------------------------------------------|-------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>gta</b> <i>gta result-type point-code routing-indicator ssn ssn</i> | Configure the GTA for the given selector. |

Using the details of the example, the command would be:

```
Router(config-cs7-gtt-selector)# gta 339 pcssn 245 pcssn ssn 250
```

The above command can be referred to as a GTA rule. The rule states that the CDPA digits matching 339 will be routed to a point-code and subsystem. The point-code is 245 and the SSN=250. The resultant routing indicator shall be set to 'pcssn' indicating final GTT (route on point code and subsystem). Since the SSN was specifically specified as 250, it will override any SSN that previously existed in the called party. Conversely if the SSN was not specified in this rule, the ITP would try to route to whatever subsystem existed in the CDPA. Since a GTT MAP entry was pre-defined and the PC=245 / SSN=250 exists in the GTT Mated Application entity set, a backup PC/SSN shall be used in the dominant mode with the rrc flag indicating re-route to backup if primary is congested.

**Step 4** Exit the submode and verify the data entered:

| Command                                      | Purpose                                     |
|----------------------------------------------|---------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>exit</b> | Exits CS7 GTT selector submode.             |
| Router(config)# <b>exit</b>                  | Exits global configuration mode.            |
| Router# <b>show cs7 gtt gta gta</b>          | Displays details about the given GTA.       |
| Router# <b>show cs7 gtt map</b>              | Displays details about the GTT MAP entries. |

Using the details of the example, the show command and output would be:

```
Router# show cs7 gtt map
      PPC      PSSN  MULT  BPC      BSSN  ConPCLst      RRC ADJ  Ref
      245      250   dom   1003      250      on no    2
```

**Note**

You can not delete any map entry that references another MAP entry. You must first change all entries that reference it to **sol** before you can delete the entry with the **no cs7 gtt map** command. To modify a MAP entry you must replace the entire command, including all keywords and arguments.

To delete a GTT configuration, follow the rules in the [“Rules For Removing GTT Configurations:”](#) section on page 105.

## Configuring Final GTT To Load Balance MSUs Across a Group of Point Codes and Subsystems

This configuration describes the scenario shown in [Figure 15](#).

**Figure 15** *Final GTT Load Balanced Across Multiple PC/SSN Nodes*

This example is similar to the example shown in [Figure 12](#) in that an application group name is being used rather than an explicit point-code or PC/SSN. However, this example involves final GTT instead of intermediate GTT.

In [Figure 15](#) the ITP (PC=158) is required to perform final GTT to an application existing on multiple end nodes to reduce the CPU load at any given single node. In this case the ITP is required to share all GTT traffic for a range of digits between multiple end nodes (in this case 3 shall be used - maximum of 8 destinations possible).

### Provisioning the ITP

To provision the ITP, perform the following steps:

- Step 1** Define a GTT application group representing the 3 HLRs.
- Step 2** Determine the criteria needed to select the appropriate translation table. For this example assume GTT selector criteria GTI=4, TT=0, NP=1, NAI=3. Also assume the appropriate selector already exists in the ITP GTT database.
- Step 3** Determine the range of digits from the called party address (CDPA) that need to be routed to the HLR. In this example assume that any digits matching the prefix 900 needs to be GTT routed to the application group containing the 3 HLRs.
- Step 4** Determine if the ITP should replace the SSN in the called party with SSN=250 or the ITP should rely on the proper SSN already being set in the CDPA. In this example the ITP will implicitly replace SSN=250 in the called party regardless of any existing SSN.

- Step 5** Determine if GTT MAP entries for the 3 end nodes exist. For this example assume the 3 MAP entries already exist. Note: When final GTT is being performed with the use of application groups, the MAP entry is required for each PC/SSN, but the fields in the MAP entry such as the load share mode, bpc, bssn, and optional flags are ignored.

## Configuring the ITP GTT

Once the above criteria are determined, follow these steps to configure the ITP GTT database:

- Step 1** Define a GTT application group representing the 3 HLRs in the final/shared mode.

| Command                                                            | Purpose                                                                          |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt application-group</b> <i>group-name</i> | Defines the GTT application group and enables CS7 GTT application-group submode. |

Using the details of the example, the command would be:

```
Router(config)# cs7 gtt application-group finalgroup1
```

- Step 2** Add the point codes into the application group then exit the configuration submode for the application group:

| Command                                                                                                                   | Purpose                                        |
|---------------------------------------------------------------------------------------------------------------------------|------------------------------------------------|
| Router(config-cs7-gtt-app-grp)# <b>pc</b> <i>point-code</i> <b>ssn</b> <i>ssn</i> <i>cost</i><br><i>routing-indicator</i> | Adds the point codes to the application group. |
| Router(config-cs7-gtt-app-grp)# <b>exit</b>                                                                               | Exits CS7 GTT application-group submode.       |

Using the details of the example, the commands would be:

```
Router(config-cs7-gtt-app-grp)# pc 1810 ssn 250 1 pcssn
Router(config-cs7-gtt-app-grp)# pc 558 ssn 250 2 pcssn
Router(config-cs7-gtt-app-grp)# pc 678 ssn 250 3 pcssn
Router(config-cs7-gtt-app-grp)# pc 1234 ssn 2 1 gt sccp-allow-pak-conv 1
Router(config-cs7-gtt-app-grp)# exit
```

- Step 3** Enter the submode configuration for the existing selector:

| Command                                                 | Purpose                           |
|---------------------------------------------------------|-----------------------------------|
| Router(config)# <b>cs7 gtt selector</b> <i>selector</i> | Enables CS7 GTT selector submode. |

Using the details of the example, the commands would be:

```
Router(config)# cs7 gtt selector c7gsp
```

In this simple case only one translation needs to be added within the selector.

- Step 4** Configure the GTA within the selector:

| Command                                                                                 | Purpose                                    |
|-----------------------------------------------------------------------------------------|--------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>gta</b> <i>gta result-type</i><br><i>group-name</i> | Configures the GTA for the given selector. |

Using the details of the example, the commands would be:

```
Router(config-cs7-gtt-selector)# gta 900 app-grp finalgroup1
```

The above command can be referred to as a GTA rule. The rule states that the CDPA digits matching 900 will be routed to the application group “finalgroup1.”

**Step 5** Exit the submode and verify the data entered:

| Command                                       | Purpose                                            |
|-----------------------------------------------|----------------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>exit</b>  | Exits CS7 GTT selector submode.                    |
| Router(config)# <b>exit</b>                   | Exits global configuration mode.                   |
| Router# <b>show cs7 gtt application-group</b> | Displays details about the GTT application groups. |
| Router# <b>show cs7 gtt gta gta</b>           | Displays details about the given GTA.              |

Using the details of the example, the show commands and their output would be:

```
Router# show cs7 gtt application-group
Application Group Name: finalgroup1
Multiplicity           : share
Ref Count              : 1

Application Identifier  RI      Cost
-----
PC=1810 SSN=250        pcssn  1
PC=558  SSN=250        pcssn  2
PC=678  SSN=250        pcssn  3
```

To delete a GTT configuration, follow the rules in the [“Rules For Removing GTT Configurations:” section on page 105](#).

## Configuring Final GTT to an SUA AS with a Backup Point Code (Dominant Mode)

This configuration describes the scenario shown in [Figure 16](#).

**Figure 16** Final GTT to an SUA AS with a Backup PC/SSN in SS7 Network

74592

This example is similar to the previous example in that final GTT is being performed. However, this example involves final GTT directly to an SUA AS name with a backup PC and SSN located via an SS7 linkset.

In [Figure 16](#) the ITP (PC=158) is required to perform final GTT to a primary HLR (PC=158/ SSN=6) for a specific range of digits from the CDPA. The primary HLR is composed of two SUA ASPs within an SUA AS in loadsharing mode. The routing key for the AS is sharing the ITP PC (PC=158) with an SCCP subsystem of 6.

The primary HLR (PC=158) has a backup (PC=678) in case of a failure. In this case, the ITP is required to route all GTT traffic for a range of digits to the primary HLR if it is available. If the primary HLR becomes unavailable, the ITP is required to use the backup HLR. This method of choosing the primary and backup subsystems is typically referred to as operating in the dominant mode, and is handled by using an application group.

### Provisioning the ITP

To provision the ITP, perform the following steps:

- 
- Step 1** Define a GTT application group representing the two HLRs. Note that two ASPs implement the SUA HLR, but the GTT database sees only a single SUA AS.
  - Step 2** Determine the criteria needed to select the appropriate translation table. For this example assume GTT selector criteria GTI=4, TT=0, NP=1, NAI=3. Also assume the appropriate selector already exists in the ITP GTT database.
  - Step 3** Determine the range of digits from the called party address (CDPA) that need to be routed to the HLR. In this example assume that any digits matching the prefix 900 need to be GTT routed to the application group containing the 2 HLRs.
  - Step 4** Determine if the ITP should replace the SSN in the called party with SSN=6, or if the ITP should rely on the proper SSN already being set in the CDPA. In this example, the ITP will explicitly write SSN=6 in the called party regardless of any existing SSN.
  - Step 5** Determine if a GTT MAP entry exists for the SCP HLR. For this example, assume the MAP entry already exists. Note: When final GTT is being performed with the use of application groups, the MAP entry is required for each PC/SSN, but the fields in the MAP entry such as the load share mode, bpc, bssn, and optional flags are ignored.
- 

## Configuring the GTT Application Group

Once the above criteria are determined, follow these steps to configure the ITP GTT database:

- 
- Step 1** Define a GTT application group representing the 2 HLRs in the final/shared mode.

| Command                                                            | Purpose                                                                          |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt application-group</b> <i>group-name</i> | Defines the GTT application group and enables CS7 GTT application-group submode. |

Using the details of the example, the command would be:

```
Router(config)# cs7 gtt application-group finalgroup1
```

- Step 2** Add the SUA AS name, and the backup HLR point code into the application group, and then exit the configuration submode for the application group:

| Command                                                                                                                                                                                                                                                                                        | Purpose                                               |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| Router(config-cs7-gtt-app-grp)# <b>asname</b> <i>as-name</i> { <i>cost</i> [ <i>ssn ssn</i> ] { <i>gt</i> [ <i>ntt ntt</i> ]   <i>pcssn</i> } [ <i>rate-limit rate</i> ]   <i>wf</i> [ <i>ssn ssn</i> ] { <i>gt</i> [ <i>ntt ntt</i> ]   <i>pcssn</i> }} [ <i>sccp-allow-pak-conv number</i> ] | Adds an SUA or M3UA AS name to the application group. |
| Router(config-cs7-gtt-app-grp)# <b>pc</b> <i>pc</i> [ <i>ssn ssn</i> ] { <i>cost</i> { <i>gt</i> [ <i>ntt ntt</i> ]   <i>pcssn</i> } [ <i>rate-limit rate</i> ]   <i>wf</i> { <i>gt</i> [ <i>ntt ntt</i> ]   <i>pcssn</i> }} [ <i>sccp-allow-pak-conv number</i> ]                             | Adds a point code to the application group.           |
| Router(config-cs7-gtt-app-grp)# <b>exit</b>                                                                                                                                                                                                                                                    | Exits CS7 GTT application-group submode.              |

Using the details of the example, the commands would be:

```
Router(config-cs7-gtt-app-grp)# asname SUA_HLR 1 ssn 6 pcssn
Router(config-cs7-gtt-app-grp)# pc 678 ssn 6 2 pcssn
Router(config-cs7-gtt-app-grp)# pc 1234 ssn 2 1 gt sccp-allow-pak-conv 1
Router(config-cs7-gtt-app-grp)# exit
```

- Step 3** Enter the submode configuration for the existing selector:

| Command                                                 | Purpose                           |
|---------------------------------------------------------|-----------------------------------|
| Router(config)# <b>cs7 gtt selector</b> <i>selector</i> | Enables CS7 GTT selector submode. |

Using the details of the example, the commands would be:

```
Router(config)# cs7 gtt selector c7gsp
```

In this simple case only one translation needs to be added within the selector.

- Step 4** Configure the GTA within the selector:

| Command                                                                       | Purpose                                    |
|-------------------------------------------------------------------------------|--------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>gta</b> <i>gta result-type group-name</i> | Configures the GTA for the given selector. |

Using the details of the example, the commands would be:

```
Router(config-cs7-gtt-selector)# gta 900 app-grp finalgroup1
```

The above command can be referred to as a GTA rule. The rule states that the CDPA digits matching 900 will be routed to the application group “finalgroup1.”

- Step 5** Exit the submode and verify the data entered:

| Command                                       | Purpose                                            |
|-----------------------------------------------|----------------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>exit</b>  | Exits CS7 GTT selector submode.                    |
| Router(config)# <b>exit</b>                   | Exits global configuration mode.                   |
| Router# <b>show cs7 gtt application-group</b> | Displays details about the GTT application groups. |
| Router# <b>show cs7 gtt gta</b> <i>gta</i>    | Displays details about the given GTA.              |

Using the details of the example, the show commands and their output would be:

```
Router# show cs7 gtt application-group
Application Group Name: finalgroup1
Multiplicity           : cost
Ref Count              : 1
```

| Application Identifier | RI    | Cost | PCST | SST | CONGESTED | AS ST | AVAIL |
|------------------------|-------|------|------|-----|-----------|-------|-------|
| AS=SUA_HLR             | pcssn | 1    |      |     |           |       | avail |
| PC=678 SSN=6           | pcssn | 2    |      |     |           |       | avail |

To delete a GTT configuration, follow the rules in the [“Rules For Removing GTT Configurations:”](#) section on page 105.

## Configuring Global Title Address Conversion

### Note

This section describes the tasks and commands for specifying Global Title Address (GTA) conversion mapping. For information about specifying changes to Global Title fields when configuring the Instance Translation feature, see the [“Configuring Global Title Conversion”](#) section on page 70 of the [“Multiple Instances and Instance Translation”](#) chapter.

Global Title Address conversion tables are used to specify mappings such as E.212 to E.214 address conversion and E.212 to E.164 address conversion in ITU networks. Global Title Address conversion includes the following capabilities and functions:

- The address conversion process is applied to digits in the Called Party address, and is invoked when RI=GT.
- The address conversion process is separately configurable, allowing for variable length address and resultant digit string (up to a maximum of 15 digits).
- For ITU networks, the numbering plan and nature of address indicator values in the GTA may be changed.
- Global Title Address conversion tables can be stored on local or network hard media, just as the GTT entries are.
- Global Title Address conversion table updates are allowed during router operation.
- Global Title Address conversion can occur before and/or after GTT.
- Initially, conversion rules perform a best match on the defined input addresses. Upon a successful match, the input address is replaced with the resultant, or output, address. The addresses are stored in a radix tree with the input address as the key.

### Note

Since the GTT data is not stored in NVRAM, commands such as **show running config** will not display the GTT data. To display the current running configuration regarding GTT use the **show cs7 gtt config** command.

To define a address conversion table and enter GTT address conversion submode, use the following command in global configuration mode:

| Command                                                            | Purpose                                                                                                               |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 gtt address-conversion</b> <i>tablename</i> | Specifies a GTT address conversion table name (1-12 characters) and enables CS7 GTT address conversion table submode. |

To define an input address and an output address, use the following commands in CS7 GTT address conversion table submode:

| Command                                                                                                                                                                                                                                                          | Purpose                                                |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| Router(config-cs7-gtt-conv-tbl)# <b>update</b> [ <b>in-address</b> <i>in-address</i> ] [ <b>nai</b> <i>nai</i> ] [ <b>np</b> <i>np</i> ] [ <b>out-address</b> <i>out-address</i> ] [ <b>np</b> <i>np</i> ] [ <b>nai</b> <i>nai</i> ] [ <b>es</b> <i>es-val</i> ] | Defines input and (optionally) output address entries. |

To define a new numbering plan for the entire table, use the following command in CS7 GTT address conversion submode:

| Command                                                 | Purpose                                                                                 |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------|
| Router(config-cs7-gtt-conv-tbl)# <b>np</b> <i>newnp</i> | Defines the new numbering plan value for the entire table. Only valid for ITU networks. |

To define a new nature of address for the entire table (in ITU networks only), use the following command in CS7 GTT address conversion submode:

| Command                                                    | Purpose                                                                                    |
|------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| Router (config-cs7-gtt-conv-tbl)# <b>nai</b> <i>newnai</i> | Defines the new nature of address value for the entire table. Only valid for ITU networks. |

After you have defined a GTA address conversion table, you can apply the table on a GTT selector basis. To specify the global title address conversion table to apply either prior to or after performing local global title translation, use either of the following commands in CS7 GTT selector submode:

| Command                                                                              | Purpose                                                                                                          |
|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-gtt-selector)# <b>pre-gtt-address-conversion</b> <i>tablename</i>  | Specifies the global title address conversion table to apply prior to performing local global title translation. |
| Router(config-cs7-gtt-selector)# <b>post-gtt-address-conversion</b> <i>tablename</i> | Specifies the global title address conversion table to apply after performing local global title translation.    |

# Verifying Global Title Translations

After the ITP is configured with GTT data and the links come into service, you can determine if the GTT and routing are working properly. This section describes three methods for verifying GTT:

- [GTT Measurements, page 123](#)
- [SCCP Accounting, page 123](#)
- [Subsystem Status, page 124](#)

## GTT Measurements

You can display CS7 GTT measurements based on system, map, counters, selector, application-group, or line card.

To display a report for each PC/SSN combination, including the number of times it was used by a successful translation, use the following command in privileged EXEC mode:

| Command                                      | Purpose                                        |
|----------------------------------------------|------------------------------------------------|
| Router# <b>show cs7 gtt measurements map</b> | Displays a report for each PC/SSN combination. |

To display measurements kept on a Selector basis, use the following command in privileged EXEC mode:

| Command                                                             | Purpose                              |
|---------------------------------------------------------------------|--------------------------------------|
| Router# <b>show cs7 gtt measurements selector</b> <i>[selector]</i> | Displays a report for each selector. |

To display measurements for the system, use the following command in privileged EXEC mode:

| Command                                         | Purpose                   |
|-------------------------------------------------|---------------------------|
| Router# <b>show cs7 gtt measurements systot</b> | Displays a system report. |

To display measurements for the application group, use the following command in privileged EXEC mode:

| Command                                                                | Purpose                                                      |
|------------------------------------------------------------------------|--------------------------------------------------------------|
| Router# <b>show cs7 gtt measurements application-group</b> <i>name</i> | Displays GTT measurements kept on a application group basis. |

## SCCP Accounting

In addition to the GTT measurements that are kept on a system wide scale, Cisco ITP provides optionally configurable per linkset GTT accounting. In it's current implementation, GTT accounting provides a mapping between the linkset that packets come in on, the selector that they match, the GTA within that selector, and final translated point codes. This accounting is performed for successful GTT.

To display GTT accounting, use the following command in privileged EXEC mode:

| Command                                       | Purpose                                                           |
|-----------------------------------------------|-------------------------------------------------------------------|
| Router# <b>show cs7 accounting gtt-active</b> | Displays the real time status of each entry in the GTT MAP table. |

## Subsystem Status

The ITP SCCP application must process SCCP management messages to track the status of remote subsystems. A GTT MAP entry should be created for all remote subsystems the ITP will be routing to via GTT. The ITP provides a method for displaying the real time status for any remote subsystem entered in its database. To display the status of a remote subsystem use the keyword **stat** in conjunction with the **show cs7 gtt map** privileged EXEC command:

| Command                                       | Purpose                                                           |
|-----------------------------------------------|-------------------------------------------------------------------|
| Router# <b>show cs7 accounting gtt-active</b> | Displays the real time status of each entry in the GTT MAP table. |

The following sample output of the **show cs7 accounting gtt-active** command shows the real-time status of each entry in the GTT MAP table:

```
Router# show cs7 gtt map stat
PC          SSN    PCST   SST    CONGESTED
668         250    UNAVL  avail  -----
1003        250    avail  avail  -----
1008        250    avail  UNAVL  -----
2020        250    avail  avail  level 2
```

## Logging GTT Errors with the ITP Logging Facility

The ITP Logging Facility enables you to log GTT errors to a local or remote destination for post processing. The logging facility enables you to set an interval at which the log will be archived automatically or save the archive manually as you require. You can also display the current log as you require. These capabilities are shown in the following tasks. [Table 8 on page 125](#) lists and describes GTT errors.

To enable the ITP to log GTT errors, use the **cs7 log** command in global configuration mode:

| Command                                                             | Purpose                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ITP(config)# <b>cs7 log type size size</b>                          | Enables logging, specifies the logging type, and defines the maximum number of entries in the log. The valid range is 0 to 100000. When the 100000 limit is reached, new entries will overwrite existing entries, starting from the first entry. |
| <b>Example:</b><br>ITP(config)# <b>cs7 cs7 log gtt size 1000005</b> |                                                                                                                                                                                                                                                  |

To enable automatic archiving of a log to a remote or local destination, use the **cs7 log checkpoint** command in global configuration mode:

| Command                                                                              | Purpose                                                                           |
|--------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| ITP(config)# <b>cs7 log type checkpoint secs destination</b>                         | Enables archiving to a specified path and sets the archiving interval in seconds. |
| <b>Example:</b><br>ITP(config)# cs7 log gtt checkpoint 3600<br>tftp://10.1.1.2/logs/ |                                                                                   |

To save a log to a file, use the **cs7 save log** command in privileged EXEC mode:

| Command                                                                              | Purpose                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ITP(config)# <b>cs7 save log type destination</b>                                    | Detaches the current log from the active log process and saves it to a destination. New log entries that occur while the save is in progress are written to a new log file and are not lost. The logs are written in readable text format. |
| <b>Example:</b><br>ITP(config)# cs7 save log gtt<br>tftp://10.1.1.3/logs/gttlog1.txt |                                                                                                                                                                                                                                            |

To display a log, use the **show cs7 log** command in Privileged EXEC mode:

| Command                                  | Purpose                   |
|------------------------------------------|---------------------------|
| ITP# <b>show cs7 log type</b>            | Displays the current log. |
| <b>Example:</b><br>ITP# show cs7 log gtt |                           |

## GTT Error Log

Table 8 lists and describes GTT Errors:

**Table 8** GTT Error Log

| Error Text                                | Description                                                                                                                              |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| CdPA SSN does not exist in GTT MAP Table. | The ITP received an MSU requiring GTT routing for which the SSN in the called party was not configured in the ITP's GTT MAP table.       |
| Translated DPC unavailable.               | The ITP received an MSU requiring GTT routing for which the translated DPC in the ITP's GTT MAP table was marked as unavailable.         |
| Translated DPC congested.                 | The ITP received an MSU requiring GTT routing for which the translated DPC in the ITP's GTT MAP table was marked as congested.           |
| Translated SSN unavailable.               | The ITP received an MSU requiring GTT routing for which the translated DPC/SSN in the ITP's GTT MAP table was marked as SSN unavailable. |

**Table 8**      **GTT Error Log (continued)**

| Error Text                                    | Description                                                                                                                                                                 |
|-----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Translated SSN congested.                     | The ITP received an MSU requiring GTT routing for which the translated DPC/SSN in the ITP's GTT MAP table was marked as SSN congested.                                      |
| CalledP GTI not valid.                        | The ITP received an MSU requiring GTT routing for which GTI in the SCCP called party was a value other than 2 or 4. These are the only supported values for GTI on the ITP. |
| CalledP missing SSN.                          | The ITP received an MSU requiring GTT routing for which the SSN in the called party was expected, but not present.                                                          |
| Invalid GT Type.                              | The ITP received a MSU destined to a local SSN of the wrong type.                                                                                                           |
| No translation configured.                    | The ITP received an MSU requiring GTT routing for which no translation was configured in the GTT database.                                                                  |
| Invalid or unsupported message type.          | The ITP received an SCCP message with an unsupported or invalid msg type.                                                                                                   |
| Hop Counter expired.                          | The ITP received an MSU requiring GTT routing for which the hop counter was expired.                                                                                        |
| Unqualified error.                            | The ITP received an MSU requiring GTT routing which resulted in error that could not be matched to any specific error message.                                              |
| Unexpected MTP3 routing failure.              | SCCP tried to route traffic to MTP3 which resulted in an unexpected routing failure.                                                                                        |
| Could not find corresponding GTT MAP entry.   | The ITP received an MSU requiring GTT routing, but could not find a corresponding GTT MAP entry to verify PC/SSN status.                                                    |
| SCCP unavailable at translated DPC.           | The ITP received an MSU requiring GTT routing, but SCCP was marked as unavailable at remote node.                                                                           |
| No member available in GTT Application Group. | The ITP received an MSU requiring GTT routing, but no member was found available in the resultant GTT application group.                                                    |
| No matching GTT selector found.               | The ITP received an MSU requiring GTT routing, but no matching GTT selector was found in the GTT database.                                                                  |
| Network indicator mismatch.                   | SCCP received an MSU, but the network indicator field did not match the variant configured.                                                                                 |
| Instance conversion failed.                   | SCCP tried to route across instances, but instance conversion failed.                                                                                                       |

## GTT Configuration Examples

This section includes examples for the following aspects of GTT configuration:

- [ITP GTT Configuration for ITPA Example, page 128](#)
- [ITP GTT Configuration for ITPB Example, page 130](#)
- [ITP GTT Configuration for ITPC Example, page 133](#)
- [ITP GTT Configuration for ITPD Example, page 135](#)

**Figure 17** *ITPs as STPs in an SS7oIP Topology*

This configuration example includes the Global Title Translation (GTT). Four Cisco ITPs are configured. The network configuration is illustrated in [Figure 17](#).

In this example, Intermediate GTT is performed on ITPB. All GTAs matching 339 are sent to the capability point code shared by ITPC and ITPD, where Final GTT is performed.

➔ The arrow symbol indicates the configuration statements most relevant to the GTT configuration on each ITP.

Assumptions:

All routers have redundant ethernet connectivity and therefore all SCTP associations use two IP addresses (multi-homing).

Point codes and IP addresses for ITP routers:

ITPA 5.100.2 172.18.44.242 117.117.117.2

ITPB 5.100.5 172.18.44.243 117.117.117.3

```
ITPC 5.100.4 172.18.45.1 117.117.119.4
ITPD 5.100.3 172.18.46.1 117.117.118.4
```

Point codes for SS7 SSPs:

```
SMSC 5.100.1
VMI4 5.100.6
VT02 5.100.7
VRM2 5.100.8
HLR3 5.100.9
HLR4 5.100.13
```

## ITP GTT Configuration for ITPA Example

```
no service pad
service timestamps debug uptime
service timestamps log uptime
no service password-encryption
!

## ITP GTT Configuration for ITPB Example

In the following configuration example, ITPB is configured to perform ITP QoS SCCP packet classification. QoS class 1 is assigned to the GTT selector table named **c7gsp**. QoS class 2 is assigned to GTA 339. According to QoS rules of precedence, if a QoS class is assigned to a selector table and to a GTA within that selector table, the QoS class assigned to the GTA entry has precedence over the QoS class assigned to the selector table.

## M3UA and SUA SS7 Over IP Signaling Gateways

The Cisco ITP Signaling Gateway (ITP SG) feature provides open-standards-based SS7 over IP solutions through the implementation of SIGTRAN MTP3-User Adaptation (M3UA) and SCCP User Adaptation (SUA) protocols.

### Feature History for M3UA and SUA SS7 over IP Signaling Gateways

| Release     | Modification                    |
|-------------|---------------------------------|
| 12.2(33)IRA | Added support for this feature. |
| 12.2(33)IRD | Added offload support for SGMP. |

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

#### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

## Contents

- [Information About M3UA and SUA ITP Signaling Gateways, page 138](#)
- [How to Configure Signaling Gateways, page 145](#)
- [ITP Signaling Gateway Configuration Examples, page 153](#)

#### Note

Most of the commands that are shown in the configuration task sections of this chapter are described in detail in the “[ITP Command Set](#)” chapter. Some general IOS configuration commands are not included in the ITP Command Set chapter. For those commands, a footnote indicates the IOS document where more information can be found.

# Information About M3UA and SUA ITP Signaling Gateways

The Cisco ITP SG feature enables you to develop or deploy IP-based application servers without having to develop MTP layers and SCCP on the application server platform. The application server platform needs only to implement the MTP3 User Part or SCCP User Part appropriate for the application. The MTP layers and SCCP layer reside on the ITP SG.

The ITP SG is responsible for terminating and/or translating MTP/SCCP events on the SG. The translated event or the user part protocol data is sent to the application over the IP network.

SS7 network management messages are translated to M3UA, or SUA messages before being transferred to the application server. User part messages are encapsulated and transferred transparently to the application server.

The following sections provide an overview of the main components and features of the Cisco ITP SG:

## M3UA

M3UA is a client/server protocol that provides a gateway to the legacy SS7 network for IP-based applications that interface at the MTP3 layer, such as ISDN User Part (ISUP) and Signaling Connection Control Part (SCCP). For M3UA, the user part can be ISUP for call setup applications or SCCP for TCAP/MAP and RANAP applications.

M3UA describes a transport mechanism for delivering SS7 MTP3-User Part messages as well as certain MTP network management events over SCTP transport to IP-based application processors or databases. The M3UA SG terminates the SS7 MTP2 and MTP3 protocol layers and delivers ISUP, SCCP and/or any other MTP3-User protocol messages. Protocol termination and translation and user part protocol encapsulations are done by the M3UA nodal inter-working function (NIF) on the SG. The NIF is the interface between MTP3 and M3UA.

[Figure 18](#) depicts the relationship between the legacy SS7 Service Control Point (SCP), the M3UA SG, the IP-based Application Server Process (ASP), and the protocol stacks.

**Figure 18** M3UA Signaling Gateway Protocol Stacks

In Figure 18 the legacy SS7 SCP on the far right uses MTP1, MTP2, and MTP3 for transporting SCCP and ISUP messages into the network. The SG terminates the SS7 links, translates the MTP3 messages into M3UA messages, and transports them to the ASP over SCTP/IP. M3UA at the ASP delivers SCCP and ISUP messages.

## SUA

SUA is a client/server protocol that provides a gateway to the legacy SS7 network for IP-based applications that interface at the SCCP layer, such as TCAP, RANAP, etc. For SUA, the SCCP user part can be TCAP/MAP, RANAP, etc. The MTP layers and the SCCP layer reside on the SG.

SUA describes a transport mechanism for delivering SS7 SCCP-User Part messages as well as certain SCCP network management events over SCTP transport to IP-based application processors or databases. The SUA SG terminates the SS7 MTP2, MTP3, and SCCP protocol layers and delivers TCAP, RANAP and/or any other SCCP-User protocol messages. For SUA, the protocol termination and translation and user part protocol encapsulations are done by the SUA inter-working function (IWF) on the SG. The IWF is the interface between SCCP and SUA.

Figure 19 depicts the relationship between the legacy SS7 SCP, the SUA SG, the IP-based ASP, and the protocol stacks.

**Figure 19** *SUA Signaling Gateway Protocol Stacks*

In Figure 19 the legacy SS7 SCP on the far right uses MTP1, MTP2, and MTP3 for transporting SCCP messages into the network. The SG terminates the SS7 links, translates the SCCP messages into SUA messages, and transports them to the ASP over SCTP/IP. SUA at the ASP delivers TCAP messages.

# SGMP

Two signaling gateways can function as a mated pair and exchange necessary state information using the Signaling Gateway Mate Protocol (SGMP). SGMP is used to establish an association to the mated signaling gateway with an equivalent SG configuration.

The mated-pair SGs are used to loadshare and/or back up each other in failover scenarios. The mated SG can be used as a backup point code for cases when there is a failure of an association between this SG and the ASP.

When the SG mate association is active, the SG is informed of AS state changes on the mate in real time. When an AS becomes inactive, subsequent messages are rerouted to the mate if the corresponding AS on the mate is active.

When the AS on the original SG returns to active state, new messages are temporarily queued to allow in-transit messages from the mated SG to arrive at the ASP. Queued messages are released to the ASP upon expiration of an AS recovery timer.

The mated-pair SGs also exchange ASP binding information. This allows rerouted traffic that is bound to a specific ASP to continue uninterrupted even when the AS on the original SG returns to active state. The bound traffic continues to be rerouted through the SG mate to the bound ASP. The only exception is when the bound ASP becomes active on the original SG. In this case, the bound traffic begins flowing through the original SG to the same ASP, following a queueing period to allow in-transit messages to arrive at the ASP.

Mated-pair SGs must have equivalent SG configuration, including the same AS definitions. However, the local point code of each SG must be unique and must not match the local point code, the capability point code, the secondary point code, or any AS point code (DPC).

**Note**

C-Link routing takes priority over routing.

**Note**

We recommend you manage the traffic rate in order to avoid congestion and packet drop in case of ASP association failure when the AS is in the Active state.

## C-Link Backup Routing of M3UA/SUA Traffic

The C-link backup routing provides backup routing to M3UA and SUA ASs using an MTP3/M2PA linkset to a remote SG serving the same ASs over SCTP/IP. The routing is available to any ITP running a sigtran protocol (M3UA and/or SUA) and offloaded MTP3. The remote SG that is reachable through the C-link may be another ITP, or any SG serving the same ASs.

Traffic destined for an unavailable M3UA/SUA AS on the ITP is routed to the remote SG through the C-link (with some restrictions described below), provided a route to the M3UA/SUA point code was configured using the C-link. If is configured on the ITP, C-link routing takes priority.

We recommend that the M3UA/SUA AS configuration on C-link connected SGs is identical, so that traffic received through the C-link is routed to the correct ASPs.

The C-link is configured on the ITP as an MTP3/M2PA linkset and the routes to AS point codes are configured as standard mtp3 routes (with no SLS rotation). ITP configuration currently disallows configuring a route to an AS point code, or configuring an AS point code to which an MTP3 route already exists. This release supports MTP3 routes to AS point codes, with the following limitations:

- A route to an AS point code matching a local, capability, or secondary ITP point code is not allowed.
- A route to an AS point code shared by multiple AS's is not allowed.

This release also supports AS routing keys with a point code to which an MTP3 route already exists, with the following limitation:

- A routing key containing a point code to which an MTP3 route already exists is not allowed if the point code is already configured in another AS routing key.
- A routing key containing a point code already configured as a linkset adjacent point code is not allowed.

### Restrictions

The following list identifies restrictions to the basic functionality of the C-link Backup Routing feature:

- Any AS serving an ITP local, capability, or secondary point code is not supported by the C-link.
- Any AS sharing a point code with another AS is similarly unsupported. In such a configuration, a message received through the C-link may not match an active routing key even though the AS point code is available.
- ITP configurations that map GTT directly to an AS name are not supported by the C-link because the AS has no point code.
- C-link routing using cluster or summary routes is not supported.

### C-link Route Availability

Per standard MTP3 practice, route availability to the remote AS point code is controlled by TFA/TFP/TFR messages received over the C-link. In the absence of any such messages, the route is assumed to be available. The configured route using the C-link must be fully qualified.

### AS Point Code Availability

Similar to , when an AS goes locally inactive and a route to the AS point code is available, the ITP broadcasts TFR if supported by the variant, and TFA otherwise.

### ASP Bindings

No proprietary messages are exchanged through the C-link. This means that, without enabled, the ITP is unaware of ASP bindings on the remote SG and always routes messages to a locally active AS, even if a locally inactive ASP has a binding active on the remote SG.

## Application Server (AS)

An Application Server (AS) is a logical entity serving a specific Routing Key. An example of an Application Server is a virtual switch element handling all call processing for a unique range of PSTN trunks, identified by an SS7 DPC/OPC/CIC\_range. Another example is a virtual database element, handling all HLR transactions for a particular SS7 DPC/OPC/SCCP\_SSN combination. The AS implements a set of one or more unique Application Server Processes, of which one or more is normally actively processing traffic.

## Application Server Process (ASP)

An Application Server Process (ASP) is an IP-based instance of an application server, such as Call Agents, HLRs, SMSCs, etc.

An ASP may implement more than one AS.

## Point Code Assignment and Management

Special care must be taken when planning the assignment of point codes to ASes. The ITP SG feature allows point code assignment to ASes and ASPs as follows:

- An AS may be assigned the primary local point code or the secondary local point code owned by the ITP SG. The AS is sharing the point code with the ITP SG.
- An AS may be assigned a capability code or alias point code of the ITP SG. The AS is sharing the point code with the ITP SG's mated-pair.
- An AS may be assigned a unique point code not previously assigned to any of the SGs in the mated-pair.
- An ASP can be assigned a unique point code by being the only ASP in an AS that has been assigned a unique point code.

- All ASes or groups of ASes serviced by the ITP SG may share a given point code. Any group of ASes that shares the same point code is referred to as a Signaling Point Management Cluster (SPMC). Note that a M3UA AS and a SUA AS may share only one of the router's point codes (primary local, secondary local, or capability).

Assigning more than one AS the same point code can have significant affect on the ability of the ITP SG to report ASP, AS, user part, or subsystem outages or unavailability to the SS7 network.

## AS Load-sharing Support

The ITP M3UA and SUA SG features support the load-share redundancy model.

By default, the traffic-mode of the AS will be set to load-share if the first valid ASP Active message received from an ASP in the AS has the traffic mode type set to load-share. Any subsequent ASP Active message received from an ASP in the AS that does not have the traffic mode type set to load-share will be rejected.

The desire to enforce AS load-sharing is indicated by setting the traffic-mode type parameter under the AS configuration to load-share round-robin or load-share bindings. If the traffic mode type has been configured as load-share, then any ASP Active message received for an ASP in that AS containing a traffic mode parameter with the traffic mode type not set to load-share will be rejected.

The SG will perform either basic round-robin load sharing among the active ASPs in the AS or round-robin load sharing based on a load-share seed.

When basic round-robin load sharing is done, the first received MSU will be processed by the first active ASP in the list, the next MSU by the next active ASP in the list, and so on. When each ASP in the list has been sent an MSU, the distribution of subsequent MSUs will begin again with the first active ASP in the list.

A load-share seed is a parameter or a group of parameters in an MSU and is traffic-type dependent. For example, the seed could be the DPC/OPC/CIC combination, the SLS, etc. When load-sharing is based on a load-share seed all MSUs for an AS with the same seed value must be processed by the same ASP until that ASP becomes inactive. The association of a load-share seed with a specific ASP is referred to as a binding or having traffic bound to an ASP.

Binding is necessary to maintain the proper sequencing of MSUs or to ensure that all MSUs that are a part of the same transaction, procedure, or connection are processed by the same ASP. When an MSU is received the SG will first check to see if the load-share seed of the MSU has been bound to a specific ASP. If it has been bound to an ASP, the MSU will be directed to that ASP. If no binding was found, the SG will select and bind the load-share seed to an ASP from the list of active ASPs for the AS.

Default bindings are assigned sequentially to the ASP list in the AS, up to a maximum value equal to the sum of the ASP weights in the AS. The number of default bindings owned by a single ASP is equal to its weight. ASPs of weight 0 get no default bindings. When a message is received with an unbound load-share seed, it is assigned to the ASP that owns the default binding equal to  $(received\_load\_share\_seed) \bmod (total\_asp\_weight)$ . This loadshares all bound traffic according to the relative ASP weights within the AS. If the assigned ASP is inactive or congested, the binding is round-robin loadshared to another active ASP. If the owning ASP subsequently becomes active, the binding is reassigned to it, with an 800 msec queueing period to allow in-transit messages to arrive at the old ASP. If the new ASP becomes inactive during the queueing period, queued messages are processed as new bindings. When an ASP becomes inactive all bindings for that ASP are cleared.

Load sharing per traffic type is performed as follows:

- ISUP traffic: round-robin load sharing will be done with the DPC/OPC/CIC of the MSU as the load-share seed.
- SCCP class 0 traffic: basic round-robin load sharing will be done without regard to any parameters in the MSU.
- SCCP class 1 traffic: round-robin load sharing will be done with the SLS of the MSU as the load-share seed.

When an AS requires traffic to be bound to a specific ASP, ASPs in the AS may need to exchange state information to avoid transaction, procedure, or connection disruption in the event of ASP failure and subsequent traffic redistribution.

## AS Fail-over support

The ITP M3UA and SUA SG features support the over-ride or primary/back up redundancy model. By default, the traffic-mode type of an AS is specified dynamically as follows. If the traffic mode parameter under the AS was not configured, the traffic mode of the AS will be set to over-ride if the first valid ASP Active message received for an ASP in the AS indicates a traffic mode type of over-ride. Any subsequent ASP Active message received from an ASP in the AS that does not have the traffic mode type set to over-ride will be rejected.

The desire to enforce the operation of an AS in over-ride mode is indicated by configuring the traffic-mode type parameter under the AS to over-ride. If the traffic mode type has been configured as over-ride, any ASP Active received for an ASP in that AS that contains a traffic mode parameter with traffic mode type not set to over-ride will be rejected.

In the over-ride mode AS model, traffic for the AS is not load-shared. AS traffic is only sent to the active ASP in the AS. Only one ASP is active at a time. If ASP1 and ASP2 are in the same AS, and ASP1 is active when an ASP Active(over-ride) from ASP2 is received, ASP1 will be sent a NOTIFY(alternate-asp-active) message and be placed in the inactive state. ASP2 will be placed in active state and AS traffic will now be redirected to ASP2.

## SCCP Traffic Processing for M3UA

SCCP traffic to an M3UA AS PC can be sent to only one AS. If SCCP traffic must be split (for example, by SSN), then use SUA for the affected PC.

A Signaling Connection Control Part (SCCP) Management (SCMG) message for an M3UA AS PC will be routed according to normal routing key search and AS traffic mode rules. For a broadcast traffic mode AS, the SCMG message will be sent to all active ASPs in the AS. For an override traffic mode AS, the SCMG message will be sent to the active ASP. For a loadshare AS, the SCMG message will be sent to only one of the active ASPs in the AS. Broadcast or override mode is recommended if the ASPs in a loadshare AS do not share management information.

When an SCMG message is sent to one of the router's point codes (primary local, secondary local, or capability point code), the SCMG message is distributed to a M3UA AS if the AS PC is in the router's concerned point code list. In addition, the SCMG message is sent to M3UA ASes that share a point code with the router and all M3UA ASes with GTT routing keys.

## ITP SG Quality Of Service (QoS)

**Note**

ITP Quality of Service (QoS) is described fully in the “[ITP QoS](#)” chapter. If you are unfamiliar with QoS, you are advised to refer to that chapter for more detail.

## How to Configure Signaling Gateways

**Note**

IP routing is enabled on the ITP by default, and must not be disabled. Disabling IP routing can result in connection errors.

This section describes the following ITP SG configuration tasks:

- [Performing Basic ITP Configuration, page 145](#)
- [Enabling and Disabling M3UA and SUA, page 146](#)
- [Enabling SGMP, page 147](#)
- [Enabling SGMP Offloading, page 149](#)
- [Defining an Application Server Process \(ASP\), page 150](#)
- [Defining Application Servers \(AS\) and Routing Keys, page 152](#)
- [Enabling M3UA Extended User Part Unavailable \(UPU\) Operation, page 153](#)

**Note**

ITP is designed to send error messages on a per second basis. If multiple error messages are received simultaneously for which ITP has to send error messages back, ITP sends the error message for only the first packet. The rest of the messages are throttled back.

## Performing Basic ITP Configuration

**Note**

Basic ITP configuration is described fully in the “[Configuring ITP Basic Functionality](#)” chapter. If you are unfamiliar with ITP basic configuration, you are advised to refer to that chapter for more details.

This section summarizes the basic ITP configuration tasks. To accomplish the basic ITP configuration, use the following commands in global configuration mode:

|               | Command                                                                                    | Purpose                                            |
|---------------|--------------------------------------------------------------------------------------------|----------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>cs7 variant</b> {ansi   itu   china}                                    | Specifies which SS7 variant the router is running. |
| <b>Step 2</b> | Router(config)# <b>cs7 national-options</b> {TFR   multiple-congestion}                    | Specifies ITU national options.                    |
| <b>Step 3</b> | Router(config)# <b>cs7 network-indicator</b> {international   national   reserved   spare} | Specifies this network indicator.                  |
| <b>Step 4</b> | Router(config)# <b>cs7 point-code format</b> 1-24 [1-23 [1-22]] <b>description</b> string  | Specifies the point code representation.           |

|               | Command                                                          | Purpose                                                        |
|---------------|------------------------------------------------------------------|----------------------------------------------------------------|
| <b>Step 5</b> | Router(config)# <b>cs7 point-code delimiter</b> [default   dash] | Specifies the delimiter between bits as either dots or dashes. |
| <b>Step 6</b> | Router(config)# <b>cs7 capability-pc</b> point-code              | Specifies the capability point code for the ITP.               |

## Enabling and Disabling M3UA and SUA

Configuring M3UA or SUA on the ITP SG provides the definitions necessary for the ITP SG to accept connections from an ASP.

You may configure either M3UA, SUA, or both, as needed.

### Enabling M3UA

To use M3UA as a connectivity solution, you must configure the M3UA subsystem on the ITP SG.

First you must configure an M3UA local SCTP port on the ITP for inbound connections to use as their destination port. You may configure a local port number in the range 1024 to 65535. This port may not currently be configured for M2PA, SUA, or SGMP. (2905 is the well-known port for M3UA.)

After you configure an M3UA local port, you must configure at least one local IP address known to the ITP for use by M3UA.

To configure an M3UA local port number and configure a local IP address for use by M3UA, use the following commands, beginning in global configuration mode:

| Command                                                                                     | Purpose                                                                                                                                                                                         |
|---------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 m3ua</b> local-port-number [offload linecard-slot-number bay-number] | Specifies a local port for inbound connections and enters CS7 M3UA submode.                                                                                                                     |
| Router(config-cs7-m3ua)# <b>local-ip</b> ip-address                                         | Configures a local IP address for use by M3UA. The <b>local-ip</b> ip-address must be an IP address that was already configured on the linecard to which you are offloading this M3UA instance. |

### Disabling M3UA

To disable the local M3UA port, use the following command in CS7 M3UA submode:

| Command                                  | Purpose                                                                           |
|------------------------------------------|-----------------------------------------------------------------------------------|
| Router(config-cs7-m3ua)# <b>shutdown</b> | Disables this local port on the ITP SG and kills all associations with this port. |

There are several SCTP parameters that you can modify under the M3UA local instance. The tasks and commands to tune timers and SCTP parameters are described in the [“Tuning ITP” section on page 394](#) of the “Verifying, Monitor, and Tuning ITP” chapter.

### Enabling SUA

To use SUA as a connectivity solution, you must configure the SUA subsystem on the ITP SG.

First you must configure an SUA local SCTP port on the ITP for inbound connections to use as their destination port. You may configure a local port number in the range 1024 to 65535. This port may not currently be configured for M2PA, M3UA, or SGMP. (14001 is the well-known port for SUA.)

After you configure an SUA local SCTP port, you must configure at least one local IP address known to the ITP for use by SUA via the SCTP communications protocol.

To configure an SUA local port number and configure a local IP address for use by SUA, use the following commands, beginning in global configuration mode:

| Command                                                                                                           | Purpose                                                                                                                                                                                          |
|-------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 sua</b> <i>local-port-number</i> [ <b>offload</b> <i>linecard-slot-number bay-number</i> ] | Specifies a local port for inbound connections and enters CS7 SUA submode.                                                                                                                       |
| Router(config-cs7-sua)# <b>local-ip</b> <i>ip-address</i>                                                         | Configures a local IP address for use by SUA. <b>local-ip</b> <i>ip-address</i> must be an IP address that was already configured on the linecard to which you are offloading this SUA instance. |

## Disabling SUA

To disable the local SUA port, use the following command in CS7 SUA submode:

| Command                                 | Purpose                                                                           |
|-----------------------------------------|-----------------------------------------------------------------------------------|
| Router(config-cs7-sua)# <b>shutdown</b> | Disables this local port on the ITP SG and kills all associations with this port. |

There are several SCTP parameters that you can modify under the SUA local instance. The tasks and commands to tune timers and SCTP parameters are described in the [“Tuning ITP” section on page 394](#) of the “Verifying, Monitor, and Tuning ITP” chapter.

## Enabling SGMP

Two SGs can function as a mated pair and exchange necessary state information using the Signaling Gateway Mate Protocol. SGMP is used to establish an association to the mated signaling gateway with an equivalent SG configuration.

The mated-pair SGs are used to loadshare and/or back up each other in failover scenarios. The mated SG can be used as a backup point code for cases when there is a failure of an association between this SG and the ASP.

When the SG mate association is active, the SG is informed of AS state changes on the mate in real time. When an AS becomes inactive, subsequent messages are rerouted to the mate if the corresponding AS on the mate is active.

When the AS on the original SG returns to active state, new messages are temporarily queued to allow in-transit messages from the mated SG to arrive at the ASP. Queued messages are released to the ASP upon expiration of an AS recovery timer.

Mated-pair SGs must have equivalent SG configuration. However, the local point code of each SG must be unique and must not match the local point code, the capability point code, the secondary point code, or any AS point code (dpc) configured on its mate.

Configuring a QoS classification for the SG mated pair is optional.

To enable and define the link to the SG mate, use the following commands, beginning in global configuration mode:

| Command                                                          | Purpose                                                                          |
|------------------------------------------------------------------|----------------------------------------------------------------------------------|
| Router(config)# <b>cs7 sgmp</b> <i>local-port</i>                | Enables SGMP and specifies the SGMP local port.                                  |
| Router(config-cs7-sgmp)# <b>local-ip</b> <i>ip-address</i>       | Configures a local IP address for use by SGMP.                                   |
| Router(config-cs7-sgmp)# <b>exit</b>                             | Return to global configuration mode.                                             |
| Router(config)# <b>cs7 mated-sg</b> <i>mate-name remote-port</i> | Define the mated SG name and remote port number and enable CS7 mated-sg submode. |
| Router(config-cs7-mated-sg) <b>remote-ip</b> <i>remote-ip</i>    | Specify the remote IP address of the mated SG.                                   |
| Router(config-cs7-mated-sg) <b>qos-class</b> <i>class</i>        | (Optional) Defines the QoS class for the SG mated pair.                          |

Note

If you deploy ITPs in a mated-pair redundant configuration, you may optionally define a special IP-based cross link between the two ITPs. Although significant mated pair redundancy is achieved without a cross-link definition (node failures and single IP path failures do not require this definition), such a cross link increases overall availability by offering a routing path around the specific case where all IP connectivity between an ITP and ASP fails, but the mated-pair ITP has an available IP path to the ASP.

## Enabling SGMP Offloading

Cisco 7600 platforms with Cisco Service and Application Modules for IP (SAMIs) installed can offload SGMP onto any number of linecards by supporting multiple SGMP associations. Data messages are rerouted via SGMP from the ingress linecard to an egress linecard hosting an SGMP association. Even with offloading configured, SGMP control messages are still generated by the supervisor module and are sent to the supervisor module when received on an offloaded SGMP association.

SGMP offload improves reliability by removing the linecard to supervisor module path for rerouted data packets and replacing it with the same card-to-card path used for other ITP payload traffic on the Cisco 7600 platform with SAMIs installed.

### Caution

You cannot configure SGMP offload when non-offloaded SGMP is configured. If non-offload SGMP is configured, you must delete it before configuring the SGMP offload.

To enable and define the link to the SG mate and enable linecard offloading, use the following commands, beginning in global configuration mode:

|        | Command or Action                                                                                                                                                             | Purpose                                                                                                                     |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                                           | Enables privileged EXEC mode.                                                                                               |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                                                                   | Enters global configuration mode.                                                                                           |
| Step 3 | ITP(config)# <b>cs7 sgmp</b> [ <i>local-port</i> ] <b>offload</b> [ <i>slot</i> ] [ <i>bay</i> ]<br><br><b>Example:</b><br>ITP(config)# cs7 sgmp 9999 offload 2 1             | Enables SGMP, specifies the local port number for SGMP, enables SGMP offloading, and enters cs7 sgmp configuration submenu. |
| Step 4 | ITP(config-cs7-sgmp)# <b>local-ip</b> <i>ip-address</i><br><br><b>Example:</b><br>ITP(config-cs7-sgmp)# local-ip 172.18.48.79                                                 | Configures a local IP address for use by the first of the two mated SGs.                                                    |
| Step 5 | ITP(config-cs7-sgmp)# <b>exit</b><br><br><b>Example:</b><br>ITP(config-cs7-sgmp)# exit                                                                                        | Returns to global configuration.                                                                                            |
| Step 6 | ITP(config)# <b>cs7 mated-sg</b> <i>name</i> <i>remote-port</i> [ <i>local-port</i> ] [ <b>passive</b> ]<br><br><b>Example:</b><br>ITP(config)# cs7 mated-sg mated1 8888 9999 | Defines the connection to the second of the two mated SGs.                                                                  |

|                | Command or Action                                                                                                                                                                        | Purpose                                                             |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------|
| <b>Step 7</b>  | <pre>ITP(config-cs7-mated-sg) <b>remote-ip</b> remote-ip</pre> <p><b>Example:</b><br/> <pre>Router(config-cs7-mated-sg) remote-ip 172.18.48.80</pre></p>                                 | Specifies the remote IP address of the second of the two mated SGs. |
| <b>Step 8</b>  | <pre>ITP(config-cs7-sgmp) # <b>exit</b></pre> <p><b>Example:</b><br/> <pre>ITP(config-cs7-sgmp) # exit</pre></p>                                                                         | Returns to global configuration.                                    |
| <b>Step 9</b>  | <pre>ITP(config) # <b>cs7 as</b> as-name <b>sgmp</b></pre> <p><b>Example:</b><br/> <pre>ITP(config) # cs7 as sgmp_as sgmp</pre></p>                                                      | Defines an AS and enters cs7 AS submode.                            |
| <b>Step 10</b> | <pre>ITP(config-cs7-as) # <b>mated-sg</b> name remote-port [local-port] [<b>passive</b>]</pre> <p><b>Example:</b><br/> <pre>ITP(config-cs7-as) # cs7 mated-sg mated1 8888 9999</pre></p> | Defines the connection from the AS to the mated SG.                 |
| <b>Step 11</b> | <pre>ITP(config-cs7-as) # <b>routing-key</b> rcontext</pre> <p><b>Example:</b><br/> <pre>ITP(config-cs7-as) # routing key 200</pre></p>                                                  | Configures the routing key for the AS.                              |

## Examples

The following example shows an SGMP configured for offloading:

```
cs7 sgmp 9999 offload 2 1
  local-ip 172.18.48.79
cs7 mated-sg mated1 8888 9999
  remote-ip 172.18.48.80
cs7 as sgmp_as sgmp
  mated-sg mated1
  routing-key 200
```

## Defining an Application Server Process (ASP)

Each ASP connecting to the ITP SG must be represented by an ASP definition. The ASP definition allows the ITP SG to validate the ASP IP address list and port number upon establishment of the SCTP association.

The ASP definition requires an ASP name that is used for configuration and monitoring only. The ASP name may be up to 12 characters long. The first character must be alphabetic. The name must not match any reserved keyword (such as m3ua, sua, all, operational, active, statistics, bindings, or detail).

The ASP definition also requires at least one of the remote IP addresses of the ASP, the remote SCTP port number, and the local port number that indicates the M3UA or SUA subsystem.

The combination of the remote port, remote IP, and local port must be unique for each configured ASP. If a remote port of 0 is configured, the ASP will match on any remote port (provided the remote IP and local port match).

Configuring a QoS classification is optional, as is specification of SCTP association parameter values. When a QoS classification is configured for an ASP or an AS, it takes effect only on the subsequent ASP connection. The QoS can only be changed when ASP is NOT active. Use the **shutdown** and **no shutdown** commands in CS7 ASP configuration mode to shut down and then activate the ASP with the QoS change.

To define an ASP, use the following commands, beginning in global configuration mode:

| Command                                                                                               | Purpose                                                     |
|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Router(config)# <b>cs7 asp</b> <i>asp-name remote-port local-port</i><br>[ <b>m3ua</b>   <b>sua</b> ] | Configures a CS7 ASP definition and enters CS7 ASP submode. |
| Router(config-cs7-asp) # <b>remote-ip</b> <i>remote-ip</i>                                            | Specifies the remote IP address of the ASP.                 |
| Router(config-cs7-asp) # <b>qos-class</b> <i>class</i>                                                | Defines the QoS class for the ASP                           |
| Router(config-cs7-asp) # <b>match any qos-class</b> <i>class</i>                                      | Sets the match criteria.                                    |
| Router(config-cs7-asp) # <b>match si</b> <i>si qos-class class</i>                                    | Sets the serviced indicator match criteria.                 |

To block or to terminate the SCTP association with the ASP, use one of the following commands in CS7 ASP submode:

| Command                                  | Purpose                                                                                                                                                                                                                                          |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-asp) # <b>block</b>    | Allows a new SCTP association with this ASP, but doesn't let it become active. In other words, always rejects ASP-ACTIVE messages from the ASP. If block is set while the ASP is active, it is forced inactive (but the association remains up). |
| Router(config-cs7-asp) # <b>shutdown</b> | Terminates the SCTP association with this ASP. New SCTP associations will be rejected if the ASP is in shutdown mode.                                                                                                                            |

You can optionally allow the SUA ASP additional control in determining whether an SCCP UDT or XUDT message will be generated upon receiving a CLDT message. To enable the SUA to request that the SCCP layer generate an XUDT message if the ASP has provided either the IMPORTANCE or HOP\_COUNTER parameters within the CLDT message, use the following command in global configuration mode:

| Command                                                                                                | Purpose                                                                                                                                                                  |
|--------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7</b> [ <b>instance</b> <i>instance-number</i> ]<br><b>sua-allow-xudt-request</b> | Enables the SUA to request that the SCCP layer generate an XUDT message if the ASP has provided either the IMPORTANCE or HOP_COUNTER parameters within the CLDT message. |

There are several SCTP parameters that you can modify under the ASP definition. The tasks and commands to tune timers and SCTP parameters are described in the of the “Verifying, Monitor, and Tuning ITP” chapter.

## Defining Application Servers (AS) and Routing Keys

Each ASP connecting to an ITP SG must be represented in an AS definition. The AS definition is used to properly route messages to the appropriate set of ASPs handling a particular routing key.

The AS definition requires a unique AS name that will identify the AS for configuration or monitoring. The AS name may be up to 12 characters long. The first character must be alphabetic. The AS name may not match a reserved keyword (such as m3ua, sua, all, operational, active, statistics, bindings, or detail).

The AS definition must indicate whether the AS is M3UA or SUA.

The number of ASPs associated with an AS should not exceed 16.

Configuring a QoS classification for the AS is optional.

To configure an AS definition, use the following command in global configuration mode:

| Command                                                                   | Purpose                                                   |
|---------------------------------------------------------------------------|-----------------------------------------------------------|
| Router(config)# <b>cs7 as</b> <i>as-name</i> [ <b>m3ua</b>   <b>sua</b> ] | Configures a CS7 AS definition and enters CS7 AS submode. |

Each ASP connecting to an ITP must have a routing key configured for each AS definition. The routing key defines the routing parameters used to send traffic to the ASP. Within the routing key, a routing context must be defined to identify traffic sent to and from a particular ASP. The routing context must be unique for each AS defined, but there is no other significance of the value chosen when pertaining to an ASP configuration. In the routing key, the DPC should be a valid point code.

To configure the AS routing key, use the following command in CS7 AS submode:

| Command                                                                                                                                                                                                                                                                                                                                      | Purpose                     |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------|
| Router(config-cs7-as)# <b>routing-key</b> <i>rcontext</i> { <b>gtt</b>   <i>dpc</i> [ <b>opc</b> <i>pc</i> <i>pc-mask</i> ] [ <b>si</b> { <b>aal2</b>   <b>bicc</b>   <b>b-isup</b>   <b>h248</b>   <b>isup</b>   <b>sat-isup</b>   <b>sccp</b>   <b>tup</b> }] [ <b>cic</b> <i>cic-min</i> [ <i>cic-max</i> ]   [ <b>ssn</b> <i>ssn</i> ]}} | Defines the AS routing key. |

To associate the ITP AS and ASP definitions and, optionally specify weighted round-robin ASP distribution within an AS, use the following command in CS7 AS submode:

| Command                                                                           | Purpose                                 |
|-----------------------------------------------------------------------------------|-----------------------------------------|
| Router(config-cs7-as)# <b>asp</b> <i>asp-name</i> [ <b>weight</b> <i>weight</i> ] | Specifies the ASPs contained in the AS. |

You can optionally specify the traffic mode, QoS class, recovery timeout interval and burst recovery timeout interval. To configure these options, use the following commands, in CS7 AS submode:

| Command                                                                                                                                                                                                                                                                                      | Purpose                                                                                                             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-as)# <b>traffic-mode</b> {broadcast   loadshare [bindings [sls [opc-sls [opc-shift {opc-shift-number}]   cgpa-sls][redistribute-active]]   cic [redistribute-active]   [opc-sls [opc-shift {opc-shift-number}]   cgpa-sls][redistribute-active]]   roundrobin]   override} | Specifies the traffic mode of operation of the ASP within this AS. The default is loadshare bindings.               |
| Router(config-cs7-as)# <b>recovery-timeout</b> msec                                                                                                                                                                                                                                          | Specifies the recovery timeout value, in milliseconds. The valid range is 1 to 2000 msec. The default is 2000 msec. |
| Router(config-cs7-as)# <b>burst-recovery-timeout</b> msec                                                                                                                                                                                                                                    | Specifies the amount of time allowed for an association to recover from a burst of traffic caused by failover.      |
| Router(config-cs7-as)# <b>qos-class</b> class                                                                                                                                                                                                                                                | Defines the QoS class for the ASP.                                                                                  |

## Enabling M3UA Extended User Part Unavailable (UPU) Operation

By default, the ITP sends a response-mode UPU when a received message has a DPC equal to an active AS point code and meets either of the following conditions:

- The SI value in the message is not ISUP, TUP, or SCCP
- The SI defined in the active AS routing key does not match the SI value in the message.

ITP extended UPU operation allows the ITP to send UPU in the following additional cases:

- Routing key parameters defined in the active AS don't match the message.
- An AS with OPC configured and SI configured for ISUP or TUP becomes inactive.

To enable M3UA extended UPU operation for these cases, use the following command in global configuration mode:

| Command                                   | Purpose                                                                                                  |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------|
| ITP(config)# <b>cs7 m3ua extended-upu</b> | Extends M3UA UPU Operation. In all cases, UPU is rate-limited to no more than 1 per second per SI value. |

## ITP Signaling Gateway Configuration Examples

This section includes examples for the following aspects of ITP SG configuration:

- [M3UA Configuration Example, page 154](#)
- [SUA Configuration Example, page 155](#)
- [ITP Signaling Gateway: ASPs with Unique Point Codes Configuration Example, page 155](#)
- [ITP SG Mated-SG Configuration Example, page 156](#)
- [ITP SG GTT Configuration Example, page 158](#)
- [ITP SG QoS Configuration Examples, page 159](#)

Figure 20 illustrates the M3UA and SUA configuration examples that follow.

**Figure 20** ITP Signaling Gateway

## ITP SG QoS Configuration Examples

### Example 1

In Example 1 all the traffic flowing to asp1 will be classified based on the QoS class 3 since asp1 belongs to AS as1.

```

cs7 qos class 3
  qos-ip-precedence 3
!
cs7 m3ua 2905
  local-ip 7.7.7.7
!
cs7 asp asp1 2905 2905 m3ua
  remote-ip 5.5.5.5
!
cs7 as as1 m3ua
  routing 05050505 4.4.4
  asp asp1
  qos-class 3
!

```

## Example 2

In Example 2, since asp2 has been provisioned with qos-class 4, all the traffic flowing to asp2 will be classified with QoS class 4.

```
cs7 qos class 4
    qos-ip-dscp 40
!
cs7 m3ua 2905
    local-ip 7.7.7.7
!
cs7 asp asp2 2905 2905 m3ua
    remote-ip 5.5.5.6
    qos-class 4
!
cs7 as as2 m3ua
    routing 05050506 4.4.4
    asp asp1
!
```

## Example 3

In Example 3 the ISUP and SCCP ASPs are located on the same host (same IP address, but different SCTP ports). They are defined as two different ASPs. Since isup-asp belongs to isup-as and isup-as-bk ASes, the QoS with highest IP Type Of Service (TOS), i.e. qos-class 5, will be used for the traffic flowing to isup-asp. Also the traffic flowing to sccp-asp will be classified based on QoS class 3 since this ASP belongs to AS sccp-as.

```
cs7 qos class 3
    qos-ip-precedence 3
cs7 qos class 5
    qos-ip-precedence 5
!
cs7 m3ua 2905
    local-ip 7.7.7.7
!
cs7 asp isup-asp 5500 2905 m3ua
    remote-ip 6.6.6.6
cs7 asp sccp-asp 6000 2905 m3ua
    remote-ip 6.6.6.6
!
cs7 as isup-as m3ua
    routing-key 06060606 5.5.5
    asp isup-asp
    qos-class 5
!
cs7 as isup-as-bk m3ua
    routing-key 07070707 6.6.6
    asp isup-asp
    qos-class 3
!
cs7 as sccp-as m3ua
    routing-key 08080808 7.7.7
    asp sccp-asp
    qos-class 3
!
```

## Example 4

In Example 4 any traffic coming in from asp3 will be classified as having QoS class 3. Also any ISUP (si=5) traffic coming in from asp4 will be classified as having QoS class 5. The packet is classified this way so that, if needed, it would properly get routed over M2PA links, as explained in the [“Specifying QoS Routing Over M2PA Links”](#) section on page 297.

```
cs7 qos class 3
    qos-ip-precedence 3
cs7 qos class 5
    qos-ip-dscp 40
!
cs7 m3ua 2905
    local-ip 7.7.7.7
!
cs7 asp asp3 2905 2905 m3ua
    remote-ip 6.6.6.10
    match any qos-class 3
cs7 asp asp4 2905 2905 m3ua
    remote-ip 6.6.6.11
    match si 5 qos-class 5
!
```

## Gateway Screening (GWS)

The Cisco ITP Gateway Screening (GWS) feature prevents unauthorized use of the STP and controls the flow of messages into or through the STP. GWS examines the contents of the incoming or outgoing Message Signaling Unit (MSU) and either allows or rejects the MSU based on the provisioned screening. GWS can be implemented in conjunction with access lists, Global Translation Table (GTT), and Multi-Layer Routing (MLR).

GWS allows you to configure GWS tables to drop an SCCP packet based on matching a set of conditions. When you drop an SCCP packet, an SCCP error return function sends a UDTs back to the source of the SCCP packet.

### Feature History for GWS

| Release     | Modification                           |
|-------------|----------------------------------------|
| 12.4(15)SW7 | Egress traffic rate limit introduced.  |
| 12.2(33)IRA | Feature introduced.                    |
| 12.2(33)IRF | Ingress traffic rate limit introduced. |

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

#### Note

**Configuration Mode Restrictions**—Simultaneous changes to the configuration from multiple CLI sessions are not supported. At a time, only one configuration session is allowed to enter in configuration mode; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

- [Configuration Examples for GWS, page 198](#)
- [Additional References, page 202](#)

## Information About GWS

Screening rules are specified in tables and are applied to an inbound or outbound linkset or an application server (AS). If the incoming message is allowed, it is sent to MTP/SCCP/ISUP/M3UA/SUA for further processing. If the outgoing message is allowed, it is routed to the specified destination.

The following sections provide more detail about GWS:

- [GWS Tables, page 164](#)
- [GWS Table Matching Order for Incoming Packets, page 175](#)

## GWS Tables

GWS tables are identified by the type of screening to be applied.

Each GWS table consists of two types of information:

- Screening information: screening parameters
- Structural information: next screening steps

Screening rules are chained to indicate the next screening steps. The final result is either to allow the message for further routing or to discard the message.

For a given chain, only one occurrence of a screening table type is allowed. For example, if the incoming message is to be screened against an allowed OPC table and the next step is to screen against an allowed DPC table, the third step cannot be to screen against an allowed OPC table.

The next screening step in any screening table must indicate either:

- An action set defined in the configuration
- A next step table.

[Table 9](#) shows an example of an allowed screening table, in this case an allowed opc table:

**Table 9**      *Sample Allowed OPC Table*

| PC Start | PC End   | Next Screening Step Allowed |
|----------|----------|-----------------------------|
| x.x.x    | y.y.y    | table allowed-dpc1          |
| x1.x1.x1 | y1.y1.y1 | table allowed-dpc1          |
| default  |          | action-set reject-ver       |

Figure 24 shows chained screening tables that screen incoming messages based on Linkset, OPC, and SI. Figure 25 shows chained screening tables that screen incoming messages based on AS, OPC, and SI.

**Figure 24 Chained Screening Tables - MTP**

**Figure 25 Chained Screening Tables - xUA**

Table 10, Table 11, and Table 12 list valid GWS screening table types and the valid configuration commands for each type:

**Table 10** *MTP Parameters*

| Table Type   | Description                                      | Screening Commands                                                                                                                                    |
|--------------|--------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|

## GWS Table Matching Order for Incoming Packets

For information on the GWS Table Matching Order for Incoming Packets, see the [“MLR and GWS Table Matching Order for Incoming Packets”](#) section on page 241.

## How GWS Works with Access Lists

GWS can work in conjunction with existing access lists.

Access lists are defined and applied on per linkset (inbound or outbound) basis. Access lists numbered between 2700 and 2999 are used for SS7. These access lists permit or deny traffic based on parameters - OPC, DPC, SI, bit pattern, affected PC, CdPA, CgPA.

Access list and gateway screening may be applied on the same linkset. However, neither access list nor gateway screening will verify that the screening rules are consistent with each other, if both are defined on the same linkset. Access lists take precedence for both incoming and outgoing linksets. If access list and gateway screening are defined for the same linkset, both will be executed with access list rules applied before gateway screening. Gateway screening rules will be applied only if the access list allows the message for further processing. GWS processing of MLR only applies to incoming messages.

[Figure 26](#) illustrates outgoing message processing with ACL, GWS, TTMAPPING. [Figure 27](#) illustrates incoming messages and including MLR routing processing through GWS.

Figure 26 Outgoing Message Processing with ACS, GWS, TTMAPPING

**Figure 27**      **Processing of Incoming Messages**

# How to Configure GWS

This section describes how to configure GWS. You configure GWS by defining an access list and applying it to a linkset definition. GWS supports linksets, ASes, and existing screening and routing features, including access lists and Global Title Translation.

This section contains the following procedures:

- [Defining GWS Access Lists, page 179](#)
- [Defining GWS Action Sets, page 180](#)
- [Defining GWS Tables, page 182](#)
- [Defining Entries in GWS Tables, page 184](#)
- [Defining Gateway Linkset Tables, page 187](#)
- [Defining an AS Table for GWS, page 189](#)
- [Saving a GWS Table or a GWS Configuration to a Remote or Local File, page 192](#)
- [Loading a GWS Table and GWS Configuration from a Remote or Local File, page 192](#)
- [Replacing a Running GWS Configuration or Existing GWS Table with a Remote or Local File, page 194](#)
- [Validating and Auditing the Consistency of the GWS Files in the Line Card and Main Processor, page 194](#)

**Note**

GWS supports instance specific action sets in Cisco IOS software releases and later. If a user has GWS instance specific action sets configured in a supporting release, but then reverts to Cisco IOS software release or earlier, which do not support instance specific action sets, the configured instance specific action sets will be lost. Also link set tables, AS tables, and global tables that refer to the instance specific action sets will be lost.

GWS on an SS7 node allows you to permit or deny messages based on message characteristics. You can control access to or from the Cisco ITP by defining one or more access lists and then applying the access list to an inbound or outbound linkset.

Access lists filter traffic by controlling whether packets are forwarded or blocked at the router's interfaces. The router examines each packet to determine whether to forward or drop the packet, on the basis of the criteria you specified within the access lists.

If the access list is inbound, when the ITP receives a packet it checks the access list criteria statements for a match. If the packet is permitted, the ITP continues to process the packet. If the packet is denied, the ITP discards it.

If the access list is outbound, after receiving and routing a packet to the outbound interface the ITP checks the access list criteria statements for a match. If the packet is permitted, the ITP transmits the packet. If the packet is denied, the ITP discards it.

## Defining GWS Access Lists

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list**
4. **cs7 linkset**
5. **access-group**

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Purpose                                                    |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Enables privileged EXEC mode.                              |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Enters global configuration mode.                          |
| Step 3 | ITP(config)# <b>access-list</b> <i>access-list-number</i> { <b>deny</b>   <b>permit</b> } [ <b>dpc</b> <i>point-code wildcard-mask</i>   <b>opc</b> <i>point-code wildcard-mask</i>   <b>si</b> { <b>0-15</b> }   <b>pattern</b> <i>offset hex-pattern</i>   <b>aftpc</b> <i>point-code wildcard-mask</i>   <b>cdpa</b> <i>point-code wildcard-mask</i>   <b>cgpa</b> <i>point-code wildcard-mask</i>   <i>selector</i>   <b>all</b> ]<br><br><b>Example:</b><br>ITP(config)# access-list 2703 instance 0 permit dpc 0.0.6 1.1.1 opc 0.1.5 1.2.2 | Defines an access list.                                    |
| Step 4 | <b>cs7 linkset</b> <i>ls-name adj-pc</i><br>ITP(config)# cs7 linkset <i>to_morehead</i> 1.1.1                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Specifies a linkset and enters linkset configuration mode. |
| Step 5 | <b>access-group</b> { <b>2700-2999</b>   <i>name</i> } [ <b>in</b>   <b>out</b> ]<br><br><b>Example:</b><br>ITP(config-cs7-ls)# access-group 2703 in                                                                                                                                                                                                                                                                                                                                                                                             | Applies the access list to the linkset.                    |

## Defining GWS Action Sets

### SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `cs7 [instance n] gws default`
4. `[inbound] result nextStep`
5. `cs7 gws action-set`

### DETAILED STEPS

|        | Command or Action                                                                                                | Purpose                                                                                     |
|--------|------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------|
| Step 1 | <code>enable</code><br><br><b>Example:</b><br>ITP> <code>enable</code>                                           | Enables privileged EXEC mode.                                                               |
| Step 2 | <code>configure terminal</code><br><br><b>Example:</b><br>ITP# <code>configure terminal</code>                   | Enters global configuration mode.                                                           |
| Step 3 | <code>cs7 [instance n] gws default</code><br><br><b>Example:</b><br>Router(config)# <code>cs7 gws default</code> | Applies globally to all link sets, all ASs, and all local applications in the CS7 instance. |

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <pre>[inbound] result {action   table} nextStep</pre> <p><b>Example:</b><br/>Router(config-gws-default)# inbound result table nextStep</p>                                                                                                                                                                                                                                      | <p><i>nextStep</i> is either a GWS table or GWS action set. It is the same variable used in a GWS link set table or GWS AS table.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 5 | <pre>[no] cs7 [instance instance-number] gws action-set action-set-name {allow   block [sccp-error error]   mlr {ruleset rule-set-name   group result-group-name} [logging {silent   file [verbose]   console [verbose]   file [verbose] console [verbose]}}</pre> <p><b>Example:</b><br/>Router(config)# cs7 instance 0 gws action-set ACTION_SET mlr ruleset GWS_MLR_RULE</p> | <p>Configures a GWS action-set.</p> <p>When SCCP packets are dropped, the optional <b>sccp-error</b> parameter configures the block action to send a UDTs to the originator of the SCCP packet. It is also necessary for the UDT to have return-on-error set and a return cause configured to return UDTs with unqualified return cause. <a href="#">Table 14</a> lists UDTs return cause values.</p> <p><b>Note</b> GWS action sets are instance based.</p> <p><b>mlr {ruleset rule-set-name   group result-group-name}</b>—(Optional) keyword allows the screened packet to be processed for routing by MLR.</p> <p><b>Note</b> To enable MLR, perform the configuration tasks described in the following sections of the <a href="#">MLR Routing and Screening</a> chapter: “Define MLR Global Options” section on page 206, “Define the MLR Group” section on page 207, and “Defining the MLR Modify-Profile” section on page 211</p> <p><b>Note</b> The GWS action set name must not contain the : file termination character.</p> |

Table 14 UDTs Return Cause Values

| Value (hex) | Description                                                    |
|-------------|----------------------------------------------------------------|
| 0x00        | No translation for an address of such nature                   |
| 0x01        | No translation for this specific address                       |
| 0x02        | Subsystem congestion                                           |
| 0x03        | Subsystem failure                                              |
| 0x04        | Unequipped User                                                |
| 0x05        | MTP failure                                                    |
| 0x06        | Network Congestion                                             |
| 0x07        | Unqualified                                                    |
| 0x08        | Error in message transport (applicable only to XUDT and XUDTS) |
| 0x09        | Error in local processing (applicable only to XUDT and XUDTS)  |

**Table 14**      **UDTS Return Cause Values**

| Value (hex)            | Description                                                                 |
|------------------------|-----------------------------------------------------------------------------|
| 0X0A                   | Destination cannot perform reassembly (applicable only to XUDT and XUDTS)   |
| 0X0B                   | SCCP failure (only ITU)                                                     |
| 0x0C                   | SCCP Hop counter violation (applicable only to XUDT and XUDTS)              |
| 0x0D (ITU)             | Segmentation not supported                                                  |
| 0x0E (ITU)             | Segmentation failure                                                        |
| 0x0F to 0xFF (ITU)     | Spare                                                                       |
| 0x0D-0xF8, 0xFF (ANSI) | Spare                                                                       |
| 0xF9                   | Invalid ISNI routing request (applicable only to XUDT and XUDTS)            |
| 0xFA                   | Unauthorized message                                                        |
| 0xFB                   | Message incompatibility                                                     |
| 0xFC                   | Cannot perform ISNI constrained routing (applicable only to XUDT and XUDTS) |
| 0xFD                   | Redundant ISNI constrained routing (applicable only to XUDT and XUDTS)      |
| 0xFE                   | Cannot perform ISNI identification (applicable only to XUDT and XUDTS)      |

## Defining GWS Tables

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 gws table type**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Defining Entries in GWS Tables

In this task you configure the screening parameter entries valid for the gateway table type that you specified in the **cs7 gws table** command. Each table can contain one or more entries.

In table entries with range parameters for entering minimum and maximum values, the second parameter is optional for single values. For single values, start and end parameters will be the same. A wildcard indicator (\*) can be used for some ranges.

If the incoming/outgoing message parameters (based on the direction of the message) do not match any of the entries in the table, then the default rule is executed.

In compliance with GR-82-CORE Appendix C, blocked table entries have next step action-sets that block the message. The default entry in blocked tables can have table name or action-set as the next step.

Next-step tables differ depending on the table type you configured. Next step tables are listed in [Table 13](#).

**Note**

A table or action-set must be defined prior to its use in a next-step result.

**Note**

An action-set or a table cannot be deleted if it is referenced by other entries.

**Note**

The output of the **show running-config** command might show a table definition twice if it is referenced in other tables.

**Note**

The GWS table name is not case sensitive.

To configure a screening parameter entry in a GWS table, enter one or more of the following commands in gateway table configuration mode. The screening parameter commands are listed in alphabetical order and are not intended to be entered in the order shown. The table types to which they apply are listed in the **Purpose** column. The CLI prompt may differ slightly from the example, depending on the gateway table type you specified.

| Command or Action                                                                                                                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                     |

A wildcard indicator (\*) can be used for a range of translation types (TT), as shown in [Table 16](#).

**Table 16** *TT Ranges with Wildcards*

| tt-range with Wildcards | Actual tt-range |
|-------------------------|-----------------|
| tt-range *              | 0 – 255         |
| tt-range 5 10           | 5 – 10          |
| tt-range 8 *            | 8 – 255         |
| tt-range 7              | 7 – 7           |

## What to Do Next

Define a gateway linkset table or an AS table for GWS.

## Defining Gateway Linkset Tables

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7** [*instance instance-number*] **gws linkset name** *ls-name*
4. **inbound** [**logging type** {*all* | *allow* | *block* | *rate-limit* | *mlr* {**group** *group* | **ruleset** *ruleset* } [**test**] {*silent* | *file* [*verbose*] | *console* [*verbose*] | *file* [*verbose*] *console* [*verbose*]}}] **result** {**action** *action-set-name* | **table** *tablename*}
5. **outbound** [**logging type** {*all* | *allow* | *block* | *rate-limit* | *mlr* {**group** *group* | **ruleset** *ruleset* } [**test**] {*silent* | *file* [*verbose*] | *console* [*verbose*] | *file* [*verbose*] *console* [*verbose*]}}] **result** {**action** *action-set-name* | **table** *tablename*}
6. **rate-limit-timer** *timer*
7. **rate-limit rate** *rate* [**onset-threshold** *othresh* [**abate-threshold** *athresh*]][**sccp-error** *sccp-error*]
8. **exit**
9. **cs7** [*instance instance-number*] **gws linkset default**
10. **inbound** [**logging type** {*all* | *allow* | *block* | *rate-limit* | *mlr* {**group** *group* | **ruleset** *ruleset* } [**test**] {*silent* | *file* [*verbose*] | *console* [*verbose*] | *file* [*verbose*] *console* [*verbose*]}}] **result** {**action** *action-set-name* | **table** *tablename*}
11. **outbound** [**logging type** {*all* | *allow* | *block* | *rate-limit* | *mlr* {**group** *group* | **ruleset** *ruleset* } [**test**] {*silent* | *file* [*verbose*] | *console* [*verbose*] | *file* [*verbose*] *console* [*verbose*]}}] **result** {**action** *action-set-name* | **table** *tablename*}

### DETAILED STEPS

|        | Command or Action                                                                                                                                                          | Purpose                                                                                                    |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                                        | Enables privileged EXEC mode.                                                                              |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                                                                | Enters global configuration mode.                                                                          |
| Step 3 | <b>cs7</b> [ <b>instance</b> <i>instance-number</i> ] <b>gws linkset name</b> <i>ls-name</i><br><br><b>Example:</b><br>ITP(config)# cs7 instance 0 gws linkset name dallas | Defines a gateway linkset table entry for a specified linkset, and enables gws linkset configuration mode. |

|        | Command or Action                                                                                                                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                       |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <pre>inbound [logging type {all   allow   block  rate-limit   mlr {group group   ruleset ruleset } [test] {silent   file [verbose]   console [verbose]   file [verbose] console [verbose]}} result {action action-set-name   table tablename}</pre> <p><b>Example:</b><br/>ITP(config-gws-ls)# inbound result table<br/>allowed-dpc1</p> | Specifies the inbound screening result on the linkset.                                                                                                                                                                                                                                        |
| Step 5 | <pre>outbound [logging type {all   allow   block   rate-limit   mlr {group group   ruleset ruleset } [test] {silent   file [verbose]   console [verbose]   file [verbose] console [verbose]}} result {action action-set-name   table tablename}</pre> <p><b>Example:</b><br/>ITP(config-gws-ls)# outbound result action<br/>allow</p>    | Specifies the outbound screening result on the linkset.                                                                                                                                                                                                                                       |
| Step 6 | <pre>rate-limit-timer timer</pre> <p><b>Example:</b><br/>ITP(config-gws-ls)# rate-limit-timer 5</p>                                                                                                                                                                                                                                      | <p>Enables rate limiting for GWS linksets, configures the rate limit timer, and GWS linkset rate-limit-timer configuration mode.</p> <p><i>timer</i>—The length of the time period set for the Cisco ITP to count received MSUs, expressed in seconds. The range is from 1 to 60 seconds.</p> |
| Step 7 | <pre>rate-limit rate rate [onset-threshold othresh [abate-threshold athresh]][sccp-error sccp-error]</pre> <p><b>Example:</b><br/>ITP(config-gws-ls-rmt)# rate-limit rate 2000<br/>onset-threshold 80 abate-threshold 60<br/>sccp-error 3</p>                                                                                            | <p>Enables the rate limit for the traffic rate on specified linksets, for a message type.</p> <p>Rate-limiting is disabled by default.</p> <p>The default onset threshold is set to 90%. The default abate threshold is 10% lower than the onset threshold.</p>                               |
| Step 8 | <pre>exit</pre> <p><b>Example:</b><br/>ITP(config-gws-ls)# exit</p>                                                                                                                                                                                                                                                                      | Exits gateway linkset configuration mode and enables global configuration mode.                                                                                                                                                                                                               |
| Step 9 | <pre>cs7 [instance instance-number] gws linkset default</pre> <p><b>Example:</b><br/>ITP(config)# cs7 instance 0 gws linkset default</p>                                                                                                                                                                                                 | Defines the gateway linkset table default entry and enables gws linkset configuration mode.                                                                                                                                                                                                   |

|         | Command or Action                                                                                                                                                                                                                                                                                                                                       | Purpose                                   |
|---------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------|
| Step 10 | <pre>inbound [logging type {all   allow   block   rate-limit   mlr {group group   ruleset ruleset } [test] {silent   file [verbose]   console [verbose]   file [verbose] console [verbose]}} result {action action-set-name   table tablename}</pre> <p><b>Example:</b></p> <pre>ITP(config-gws-ls)# inbound result action blocked-ver</pre>            | Specifies the default inbound screening.  |
| Step 11 | <pre>outbound [[logging type {all   allow   block   rate-limit   mlr {group group   ruleset ruleset ruleset } [test] {silent   file [verbose]   console [verbose]   file [verbose] console [verbose]}} result {action action-set-name   table tablename}</pre> <p><b>Example:</b></p> <pre>ITP(config-gws-ls)# outbound result action blocked-ver</pre> | Specifies the default outbound screening. |

## What to Do Next

Define an AS table for GWS.

## Defining an AS Table for GWS

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7** [instance *instance-number*] **gws as name** *as-name*
4. **inbound** [logging type {all | allow | block | rate-limit | mlr {group *group* | ruleset *ruleset* } [test] {silent | file [verbose] | console [verbose] | file [verbose] console [verbose]}} result {action *action-set-name* | table *tablename*}
5. **outbound** [logging type {all | allow | block | rate-limit | mlr {group *group* | ruleset *ruleset* } [test] {silent | file [verbose] | console [verbose] | file [verbose] console [verbose]}} result {action *action-set-name* | table *tablename*}
6. **rate-limit-timer** *timer*
7. **rate-limit** *rate*
8. **exit**
9. **cs7** [instance *instance*] **as default**
10. **inbound** [logging type {all | allow | block | rate-limit | mlr {group *group* | ruleset *ruleset* } [test] {silent | file [verbose] | console [verbose] | file [verbose] console [verbose]}} result {action *action-set-name* | table *tablename*}

11. **outbound** [**logging type** {**all** | **allow** | **block** | **rate-limit** | **mlr** {**group** *group* | **ruleset** *ruleset* } [**test**] {**silent** | **file** [**verbose**] | **console** [**verbose**] | **file** [**verbose**] **console** [**verbose**]}}] **result** {**action** *action-set-name* | **table** *tablename*}
12. **exit**

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                            |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Enables privileged EXEC mode.                                                                                                                                                                                                                                                      |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                                                                                                                                                                                                                                                                                                                                                                                                                  | Enters global configuration mode.                                                                                                                                                                                                                                                  |
| Step 3 | <b>cs7</b> [ <b>instance</b> <i>instance-number</i> ] <b>gws as name</b> <i>as-name</i><br><br><b>Example:</b><br>ITP(config)# cs7 instance 0 gws as name as2                                                                                                                                                                                                                                                                                                                                                                | Defines an AS table for GWS and enables GWS AS configuration mode.                                                                                                                                                                                                                 |

| Step 12 | <b>exit</b><br><br><b>Example:</b><br>ITP(config)# exit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            | Exits GWS AS configuration mode and enables global configuration mode.                                                                                                                                                                               |

## What to Do Next

Perform saving, loading, or replacing GWS configurations and table tasks, as needed.

## Saving a GWS Table or a GWS Configuration to a Remote or Local File

You can save a GWS table file or a general GWS configuration file to a local or remote file system.

Cisco IOS CLI modifications to GWS configurations may take up to 15 seconds to take effect on all linecards after the last change is made. The standard Cisco IOS CLI command `copy running-config startup-config` or `write memory`, which saves the running configuration, does not automatically save the GWS table or the GWS configuration. The user needs to save this GWS information manually. The saved provisioning will load during a Cisco ITP restart or reload.

To save this GWS information manually use the following procedure:

### SUMMARY STEPS

1. **enable**
2. **cs7** [*instance-number*] **save gws-table** *table-name* *url*
3. **cs7** [*instance-number*] **save [all] gws** *url*

### DETAILED STEPS

|        | Command or Action                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Loading a GWS Table and GWS Configuration from a Remote or Local File

You can configure Cisco ITP to load all the GWS configuration, including general GWS configuration files and GWS table files, from a local or remote file. Cisco IOS CLI modifications to GWS configurations may take up to 15 seconds to take effect on all linecards after the last change is made. Cisco IOS CLI configuration is not allowed during file loading or replacement.

The load command does not initiate the restart or reload needed to trigger the actual load operation. It configures the load operation to occur when a restart or reload occurs.

Configure Cisco ITP to load a GWS configuration from a local or remote file with the following procedure:

**Note**

Loading and replacement of GWS configuration files and tables may take a significant amount of time to complete. The user is notified of completion through a console message.

**SUMMARY STEPS**

1. **enable**
2. **configure terminal**
3. **cs7 [instance *instance-number*] gws load url**

**DETAILED STEPS**

|        | Command or Action                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------|-------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                           | Enables privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                   | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 3 | <b>cs7 [instance <i>instance-number</i>] gws load url</b><br><br><b>Example:</b><br>itp(config)#cs7 gws load disk0:gws-config | <p>Loads GWS configuration, including GWS tables, from a specified remote or local file during a Cisco ITP restart or reload.</p> <p>Valid URLs are bootflash, disk0, disk1, disk2, slot0, slot1, tftp, flash, sup-bootdisk, sup-bootflash, rcp.</p> <div>  <p><b>Caution</b> Specifying a remote file for the load command is not recommended as a best practice for high availability deployments, such as the Cisco 7600.</p> </div> <div> <p><b>Note</b> If the load operation fails, the system generates an error message with the cause of the problem. Syntax errors in the loaded file cause the load operation to fail.</p> </div> |

## Replacing a Running GWS Configuration or Existing GWS Table with a Remote or Local File

This procedure replaces the running GWS configuration or existing GWS tables with a local or remote file. Cisco IOS CLI modifications to GWS configurations may take up to 15 seconds to take effect on all linecards after the last change is made. Cisco IOS CLI configuration is not allowed during file loading or replacement. Configuration file and table replacement does not take place until all entries in the new file have been read and validated.

To accomplish this, complete the following procedure:

### Caution

When replacing a running GWS configuration, the replacement configuration or table is restricted to a maximum of 1000 table entries.

### Note

Loading and replacement of GWS configuration files and tables may take a significant amount of time to complete. The user is notified of completion through a console message.

## SUMMARY STEPS

1. **enable**
2. **cs7 [instance *instance-number*] gws replace url**
3. **cs7 [instance *instance-number*] gws-table replace url**

## DETAILED STEPS

|        | Command or Action                                                                                                                    | Purpose                                                                                                                                                                                                           |
|--------|--------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>itp> enable                                                                                  | Enables privileged EXEC mode.                                                                                                                                                                                     |
| Step 2 | <b>cs7 [instance-number] gws replace url</b><br><br><b>Example:</b><br>itp(config)# cs7 gws replace disk0:gws-replace                | (Optional) Replaces the running GWS configuration with the configuration file specified by the URL.                                                                                                               |
| Step 3 | <b>cs7 [instance-number] gws-table table-name replace url</b><br><br><b>Example:</b><br>itp# cs7 gws-table replace disk0:gws-replace | (Optional) Replaces a single GWS table with the table configuration file specified by the URL.<br><br>Valid URLs are bootflash, disk0, disk1, disk2, slot0, slot1, tftp, flash, sup-bootdisk, sup-bootflash, rcp. |

## Validating and Auditing the Consistency of the GWS Files in the Line Card and Main Processor

This procedure validates and audits the consistency of the GWS configuration files and GWS table files contained in the line card and main processor. These files should sync from the line card to the main processor when the configuration of the GWS files change in the main processor. If the procedure

recognizes inconsistencies between the the GWS files in the line card and main processor, a second sync takes place. Configure Cisco ITP to validate and audit the consistency of the GWS configuration files and GWS table files contained in the line card and main processor with the following procedure:

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 audit [timer [timer-minutes]] [GWS [sync]]**

## DETAILED STEPS

|        | Command or Action                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                       |
|--------|----------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                | Enables privileged EXEC mode.                                                                                                                                                                                                                                                                                                                 |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                             |
| Step 3 | <b>cs7 audit [timer [timer-minutes]] [GWS]</b><br><br><b>Example:</b><br>itp(config)#cs7 audit GWS | Validates and audits the consistency of the GWS configuration files and GWS table files contained in the line card and main processor.<br><br><br><b>Note</b> To see the latest audit begin time, end time, and status, use the <code>show</code> command. |

# Monitoring GWS

- [Message Logging, page 195](#)
- [Verifying GWS Configuration, page 197](#)

## Message Logging

Message logging allows you to capture information about screening results. GWS supports three types of logging:

- Silent mode: Message screened without any logging
- Test mode: Screening is done, but the screening results are NOT applied. For instance, if a linkset is configured to be in test mode, and after screening, screened result is to discard the message, the message is NOT discarded, but the log is updated to indicate that the message would be discarded if the screening rules were to apply. Test mode is applicable at the linkset or AS level or global levels. Test mode does not apply to action sets.

- Non-test mode: Screening results are applied to the message. That is, if the screening result is to discard the message, the message is actually discarded.

Two types of logging are possible in test and non-test mode: File and Console. File mode has an optional verbose mode which also logs up to 40 bytes of the message that was screened along with other parameters. In file mode, as the name suggests, the log is copied to a file. In console mode, the log is printed on the terminal. Console mode also has an optional verbose mode to include up to 40 bytes of the screened message.

## SUMMARY STEPS

1. **enable**
2. **cs7 save log type destination**

## DETAILED STEPS

|        | Command or Action                                                                                                                   | Purpose                                                        |
|--------|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                 | Enables higher privilege levels, such as privileged EXEC mode. |
| Step 2 | <b>cs7 save log type destination</b><br><br><b>Example:</b><br>ITP# cs7 save log gws-test<br>tftp://10.1.1.3/logs/gws-test-log1.txt | Saves a log to a specified destination.                        |

To enable logging, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 log type {checkpoint seconds destination | size size | verbose}**

## DETAILED STEPS

|        | Command or Action                                                                                                                                | Purpose                                                        |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                              | Enables higher privilege levels, such as privileged EXEC mode. |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                                      | Enters global configuration mode.                              |
| Step 3 | <b>cs7 log type {checkpoint seconds destination   size size   verbose}</b><br><br><b>Example:</b><br>ITP(config)# cs7 log gws-nontest size 10000 | Enables logging.                                               |

## Verifying GWS Configuration

After enabling privileged exec mode, the following show commands can be used in any order to display GWS linkset, as, or table information.

## SUMMARY STEPS

1. **enable**
2. **show cs7 gws action-set** *[name]*
3. **show cs7 gws as** *[default | name as-name]*
4. **show c7 gws default**
5. **show cs7 gws linkset** *[default | name ls-name]*
6. **show cs7** *[instance number]* **gws table** *[name table-name | type table-type]* *[detail | result-summary | entry-summary]*
7. **show cs7** *[instance number]* **gws config**
8. **show cs7** *[instance number]* **gws table-config** *table-name*

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                | Purpose                                                                                                                                                 |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                                                                                                              | Enables higher privilege levels, such as privileged EXEC mode.                                                                                          |
| Step 2 | <b>show cs7 gws action-set</b> [ <i>name</i> ]<br><br><b>Example:</b><br>ITP# show cs7 gws action-set                                                                                                                                            | Displays GWS action-set information. Details include UDS configuration for block results and MLR ruleset name and/or result group name for MLR results. |
| Step 3 | <b>show cs7 gws as</b> [ <b>default</b>   <b>name</b> <i>as-name</i> ]<br><br><b>Example:</b><br>ITP# show cs7 gws as                                                                                                                            | Displays GWS AS information, including MLR routed MSUs.                                                                                                 |
| Step 4 | <b>show cs7 gws default</b><br><br><b>Example:</b><br>ITP# show cs7 gws default                                                                                                                                                                  | Displays the global (default) GWS table for an instance.                                                                                                |

| Step 7 | <b>show cs7</b> [ <i>instance number</i> ] <b>gws config</b><br><br><b>Example:</b><br>ITP# show cs7 5 gws config                                                                                                                                | Displays the whole configuration of GWS, including global action sets, linksets, global table entries, tables, and table entries.                       |
| Step 8 | <b>show cs7</b> [ <i>instance number</i> ] <b>gws table-config</b> [ <i>table-name</i> ]<br><br><b>Example:</b><br>ITP# show cs7 5 gws table-config 5                                                                                            | Displays the table entries or the entries for the specified table.                                                                                      |

## Configuration Examples for GWS

This section provides configuration examples of GWS in the following scenarios:

- [GWS Scenario: Linkset with Allowed DPC, page 199](#)
- [GWS Scenario: XUA AS with Allowed DPC, page 200](#)

- [GWS Scenario with CgPA, CdPA, page 200](#)

## GWS Scenario: Linkset with Allowed DPC

In this usage scenario, an allowed DPC table is created. The DPC table is linked to a linkset.

**Figure 28** *GWS Scenario: Linkset with Allowed DPC*

```

cs7 multi-instance
cs7 instance 0 variant ITU
cs7 instance 0 network-name INST0
cs7 instance 0 point-code 3.3.4
cs7 instance 1 variant ITU
cs7 instance 1 network-name INST1
cs7 instance 1 point-code 1.1.3

controller E1 0/0
  clock source line primary
  channel-group 0 timeslots 1

cs7 in 0 gws as default
    inbound result action-set blocked-ver
cs7 in 0 gws as default
    outbound result action-set blocked-ver

```

## GWS Scenario with CgPA, CdPA

In this usage scenario, a linkset is tied to an allowed DPC table, an allowed CgPA PC-SSN table, allowed CgPA SCCP selector, allowed SCCP message header and allowed CdPA PC-SSN tables.

**Figure 29** GWS Scenario with CgPA, CdPA

## MLR Routing and Screening

The IP Transfer Point (ITP) Multi-Layer Routing (MLR) feature implements the routing of Short Message Service (SMS) messages based on information found in the Transaction Capability Application Part (TCAP), Mobile Application Part (MAP), and SMS layers.

### Feature History for MLR

| Release     | Modification                                                  |
|-------------|---------------------------------------------------------------|
| 12.2(33)IRA | This feature was introduced.                                  |
| 12.2(33)IRC | The <b>congestion-mode defer-to-backup</b> command was added. |
| 12.2(33)IRE | The Packet Address Modification (PAM) feature was introduced. |

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

#### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

## Information About MLR Routing and Screening

Short Message Service (SMS) applications such as audience interaction services place a heavy demand on the capacity of the legacy SS7 infrastructure, as well as the SMSC servers. These applications create extremely high bursts of signaling traffic over a very short time span, which can result in denial of service and lost messages.

The ITP MLR feature enables intelligent routing of SMS messages based on the application or service from which they originated or to which they are destined. The MLR feature can make SMS message routing decisions based on information found in the TCAP, MAP, and MAP-user layers. MAP operation include all GSM-MAP (3GPP TS 29.002 version 5.9.0 Release 5) operations in MLR rules.

The valid operation-name specifications are presented in the CLI depending on the specified protocol and are listed in tables in the [“Define One or More MLR Rulesets” section on page 224](#).

For ITU TCAP and GSM-MAP, MLR supports routing on the following operations (See [Table 20](#)):

- MAP-MO-FORWARD-SM
- MAP-MT-FORWARD-SM
- SEND-ROUTING-INFO-FOR-SM
- MAP-ALERT-SERVICE-CENTRE

For ANSI TCAP and IS-41 MAP, MLR incorporates Mobile Directory Number (MDN) based SMS routing and supports routing on the following operations:

- Smdpp
- SmsRequest
- SmsNotify

ITP MLR-based screening enables the blocking of incoming SS7 traffic based on the originating SCCP cgPa and SCCP cdPa destination, including the global title address (gta). MLR screening also enables blocking on the basis of SCCP cdPa global title digits and all GSM operations. This allows the blocking of short message transactions from a specific originating global title.

## Trigger Search Order

It is possible that a message may match to more than one primary trigger since a primary trigger can be either cdPa or cgPa based. cdPa matches are attempted before cgPa matches. The lookup mechanism for GT-based primary triggers is the GTT table, while the lookup mechanism for PC/SSN based primary triggers is the GTT MAP table. Once a primary trigger is matched, the secondary triggers are searched sequentially in the order defined until a match is found.

[Table 17](#) describes the Multi-layer routing trigger types and their function.

**Table 17**      **Multi-Layer Routing Trigger Types**

| Trigger Type            | Function                                                                                                                                                                                                                                                                           |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SCCP Global Title       | The received packets arrive into SCCP with RI=GT and a specific range of global titles. The primary routing trigger for SMS MO traffic is the cdPa destination SMSC E.164 address. The originating MSC address, which is found in the cgPa, may also be used as a routing trigger. |
| SCCP Point Code and SSN | The received packets arrive into SCCP with RI=PC/SSN. For example, SMS MO traffic for which the MSC/STP has performed final GTT will arrive destined for the ITP PC and SMSC SSN.                                                                                                  |
| Global Configuration    | All traffic received will be checked for MLR, provided that a routing table is defined.                                                                                                                                                                                            |
| Combination Triggers    | A combination of two mutually exclusive SCCP cdPa and cgPa trigger types may be specified to form a trigger match. This allows packets destined to the same SMSC from different MSCs to be handled by different routing tables.                                                    |

## Destination Selection

A match in the multi-layer routing table will map to one of the following:

- A single point-code.
- An M3UA or SUA application server name. Upon selection, the message is routed to the AS which may be composed of multiple ASPs.
- A multi-layer result group. This table will provide the set of possible results along with the associated algorithm used to select among the results. This table is independent of the global title translation function, but uses PC and SSN state to route to available destinations.
- A global title address. Upon selection, the SCCP global title translation function will be invoked for the specified address. This address may then map to an application group consisting of multiple destinations.

## How to Configure MLR-Based Routing

To enable the MLR feature, perform the configuration tasks described in the following sections:

- [Define MLR Global Options, page 206](#)
- [Define the MLR Group, page 207](#)
- [Defining the MLR Modify-Profile, page 211](#)
- (optional) [Creating and Managing Address Tables, page 214](#)
- [Define One or More MLR Rulesets, page 224](#)
- [Define the MLR Triggers, page 240](#)

**Note**

Whenever the MLR configuration is changed, verify the output of the **show cs7 offload mtp3** command on the SUP to ensure the MLR configuration is in a *sync* state for the linecard.

## Define MLR Global Options

You can define an MLR option globally per instance so that it can be applied to all MLR routed results, including trigger results, rule results, and address-table results.

When the **insert-dpc-in-cdpa** option is configured, MLR can modify the cdpa pc and the calling party (cgpa) pc of an MSU. The cdpa pc is updated for MLR results of point code (pc), point code and subsystem number (pcssn), global title (gt), and asname. This option does not apply to the MLR results **block** or **continue**.

Preserving the original destination point code (dpc) in the cdpa is not possible with an MLR GT result. The SCCP always overwrites the cdpa pc with the new GT translated dpc.

When the **preserve-opc** function is configured within the global MLR options submode, the original Originating Point Code (OPC) is retained. You can configure this feature globally, or within an MLR ruleset.

**modify-failure** allows you to specify which action you want to take when an MLR packet cannot be modified. By default, the packet is discarded. MLR modification failures include exceeding the maximum MSU or address size when inserting new data, failures when attempting to modify the destination GT, and failures when executing a modify-profile.

The following steps specify how to add MLR options that are applied to all MLR result types.

### SUMMARY STEPS

| <b>Step 3</b> | <b>cs7</b> [ <b>instance</b> <i>instance-number</i> ] <b>mlr options</b><br><br><b>Example:</b><br>ITP(config)# cs7 instance 1 mlr options                               | (Optional) Specifies an MLR result option command and enables the CS7 MLR options configuration mode.                                                                                                                                                                                                                                                                                        |
| <b>Step 4</b> | <b>insert-dpc-in-cdpa</b><br><br><b>Example:</b><br>ITP(cfg-cs7-mlr-options)# insert-dpc-in-cdpa                                                                         | (Optional) Specifies that when a packet is MLR routed, the MTP dpc is inserted into the cdpa pc if the cdpa pc is null.                                                                                                                                                                                                                                                                      |
| <b>Step 5</b> | <b>preserve-opc</b><br><br><b>Example:</b><br>ITP(cfg-cs7-mlr-options)# preserve-opc                                                                                     | (Optional) Preserves the original originating point code (OPC) when an MLR result is selected in this instance.                                                                                                                                                                                                                                                                              |
| <b>Step 6</b> | <b>modify-failure</b> { <b>discard</b>   <b>resume</b>   <b>sccp-error</b> <i>sccp-error</i> }<br><br><b>Example:</b><br>ITP(cfg-cs7-mlr-options)# modify-failure resume | (Optional) <b>modify-failure</b> indicates the action to take when an MLR packet modification fails. Options include:<br><br><b>discard</b> —discard the packet (default).<br><br><b>resume</b> —resume sending original packet to original destination.<br><br><b>sccp-error</b> —send a UDTS to the originator with the configured sccp error code, if return-on-error was set in the UDT. |
| <b>Step 7</b> | <b>disable-mlr</b><br><br><b>Example:</b><br>ITP(cfg-cs7-mlr-options)# disable-mlr                                                                                       | (Optional) Disables all MLR routing for the specified instance.                                                                                                                                                                                                                                                                                                                              |

## Define the MLR Group

A multi-layer result group is a group of destination resources to process traffic that will be routed based on multi-layer information. The result group lists the appropriate destination resources and the mechanism used to select a single destination for a given packet. State information is determined for each possible destination. Only available destination are considered for routing. Note, however, that the distribution algorithms consider GT results as always available. Ensure that the proper GT configuration is in place and available for GT routing.

The MLR feature provides two result group distributions modes: weighted round-robin and dynamic B-address binding.

The **weighted round-robin** (WRR) distribution algorithm properly balances SMS workload to servers of varying capacity. Each server within a result group (application group or multi-layer result table) is assigned a server weight from 0 to 10. The value of 0 indicates that the server is a backup, and should only be used when all of the servers in the group with a non-zero weight have failed. By default congested resources are used only when all non-zero weighted servers are congested. Instead of relying only on unavailability to trigger the use of a backup server, the **congestion-mode defer-to-backup** command in CS7 mlr result configuration mode sets congestion as an additional trigger for the use of a backup server.

**Dynamic B-address binding** uses a hashing algorithm based on the message's B-address to determine which result (SMSC) a message is to be routed to for delivery. The algorithm will select the same result (SMSC) each time based on the B-address to prevent out-of-order messaging. SMSCs with greater capacity are configured as such using the result's weight parameter. The results (SMSCs) are inserted into the result group using the order parameter. If an unplanned SMSC outage occurs (in other words, if a result is unavailable), then these messages destined for the unavailable SMSC are rerouted to the remaining SMSCs. Note that an SMSC outage does not affect the mapping for available SMSCs. This algorithm handles routing of alphanumeric B-addresses, as well as numeric B-addresses.

SMS MO Proxy sms-mo messages can use MLR result groups with WRR or dest-sme-binding modes. This simplifies configuration since both SMS MO Proxy and MLR dest-sme-binding result groups must be identically configured in an SMS MO Proxy solution. To use dest-sme-binding, you must configure a ruleset.

To define the Multi-layer result group, perform the following steps.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7** [*instance instance-number*] **mlr result** *name* [**protocol** {*gsm-map* | *ansi41*}] [**mode** {*wrr* | *dest-sme-binding*}]
4. **asname** *as-name* [**order** *order*] [**weight** *weight*]
5. **gt** *addr-string* [**tt** *tt* [**gti** *gti*] [**np** *np* [**nai** *nai*]]] [**order** *order*] [**weight** *weight*]
6. **congestion-mode defer-to-backup**
7. **pc** *dest-pc* [**ssn** *ssn*] [**order** *order*] [**weight** *weight*]
8. **unavailable-routing** {*discard* | *resume*}

## DETAILED STEPS

## Defining the MLR Modify-Profile

SCCP and MAP address modification is permitted using a MLR modify-profile. For each modify profile, you must configure a unique profile name, the protocol, and the operation name. Multiple profiles can be created for each instance. Only one profile may be specified within a rule. Within a modify profile, you can specify SCCP and MAP addresses to modify. MLR currently supports modifying only the service center address (orig-smsc) and the calling party address (CgPA) for SRI-SM messages.

For the orig-smsc, you can modify the address digits, the type of number (ton), and the numbering plan (np).

For cgpa, MLR supports inserting a point code (PC) and subsystem number (SSN), as well as modifying the existing GT information, PC, and SSN. The CgPA routing indicator (RI) is unchanged during these modifications. The PC and the SSN may be inserted or modified, regardless of the RI. GT modifications, however, apply only to packets with RI=GT. If GT modifications are configured and the received packet has a CgPA with RI=SSN, then the GT modifications are simply ignored. The GT information which can be modified includes the GT address digits, the GT translation type (tt), the global title indicator (gti), the numbering plan (np), and the nature of address indicator (nai).

You can configure prefix-based address modification or a replacement address. For prefix-based address translation, you configure the number of prefix digits that will be removed from the address and the digit string that should be prefixed to the address. Specifying a "\*" for number of prefix digits indicates that

no prefix digits to be removed. Specifying a “\*” for the digit string indicates that no prefix digits are prefixed to the address string. To replace the entire address, the user should specify the maximum value for the number of prefix digits to remove. If the resulting modified address exceeds the maximum allowed number of digits, then MLR will fail the modification and discard the packet by default. The user can optionally configure the desired action for failed modifications using the modify-failure command within the MLR options submode.

The modify profile is assigned to a rule using the modify-profile rule parameter. If an MLR rule matches, then the modify profile is applied to messages which are MLR routed. Address translation is only performed if the matched rule contains a modify-profile.

To define an MLR modify profile, perform the following steps:

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 mlr modify-profile** *profile-name* *protocol* *operation-name*
4. **orig-smsc** [**prefix** {*prefix-remove-num* | \*}] {*prefix-add-digits* | \*}] [**ton** *new-ton*] [**np** *new-np*]
5. **cgpa** [**gt** [**prefix** {*prefix-remove-num* | \*} {*prefix-add-digits* | \*}] [**tt** *tt*] [**gti** {**2** | **4** *np* *np* *nai* *nai*}] ] [**pc** *pc*] [**ssn** *ssn*]

| Step 2 | <b>configure</b> { <b>terminal</b>   <b>memory</b>   <b>network</b> }<br><br><b>Example:</b><br>ITP# configure terminal                                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Step 3 | <b>cs7 mlr modify-profile</b> <i>profile-name</i> <i>protocol</i> <i>operation-name</i><br><br><b>Example:</b><br>ITP(config)# cs7 mlr modify-profile SRISM<br>gsm-map sri-sm | Defines SCCP and MAP addresses to modify in MLR routed messages.<br><ul style="list-style-type: none"><li>• <i>profile-name</i> identifies a name to be associated with a defined MLR modify-profile.</li><li>• <i>protocol</i> Specifies an application layer protocol filter.</li><li>• <i>operation-name</i> Specifies the operation for which the modify profile is valid. MLR only allows you to define a modify-profile for a sri-sm operation.</li></ul><br><b>Note</b> You can create multiple modify profiles for each instance but can specify only one profile within a rule. |

|        | Command or Action                                                                                                                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 4 | <p><b>orig-smsc</b> [<b>prefix</b> {<i>prefix-remove-num</i>   *}{<i>prefix-add-digits</i>   *}] [<b>ton</b> <i>new-ton</i>] [<b>np</b> <i>new-np</i>]</p> <p><b>Example:</b><br/> ITP(cfg-cs7-mlr-modify)# orig-smsc prefix 2 351</p> | <p>Specifies the originating service center address.</p> <ul style="list-style-type: none"> <li>• <b>prefix</b>—specifies that the prefix modification will be performed on the address.</li> <li>• <i>prefix-remove-num</i>—an integer in the range of 1 to 38 which defines the number of prefix digits to remove from the address. If no prefix digits are to be removed, then you should specify “*”.</li> <li>• <i>prefix-add-digits</i>—a string of 1 to 38 hexadecimal digits which are added to the beginning of the address. If no digits are added, then you should specify “*”. If the number of digits in the modified address exceeds 38 digits, then the address modification cannot be performed. In this failure case, the action taken is based on the configured modify-failure parameter. By default, the packet is discarded.</li> <li>• <b>ton</b>—indicates a type of number (ton) replacement.</li> <li>• <i>new-ton</i>—an integer in the range of 0 to 7 which defines the new type of number (ton) value for the modified address.</li> <li>• <b>np</b>—indicates a numbering plan (np) replacement.</li> <li>• <i>new-np</i>—an integer in the range of 0 to 15 that defines the new numbering plan (NP) value for the modified address.</li> </ul> |

| Command or Action                                                                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Step 5</b></p> <pre>cgpa [gt [prefix {prefix-remove-num   *}{prefix-add-digits   *}]] [tt tt] [gti {2   4 np np nai nai}]] [pc pc] [ssn ssn]</pre> <p><b>Example:</b></p> <pre>ITP(cfg-cs7-mlr-modify)# cgpa gt prefix 2 351</pre> | <p>Indicates that the SCCP calling party address (CgPA) needs modification.</p> <p>The CgPA routing indicator (RI) does not change during these modifications.</p> <p><b>gt</b>—indicates global title information to modify. GT modifications apply only to packets with RI=GT. If GT modifications are configured and the received packet has a CgPA with RI=SSN, then the GT modifications are ignored.</p> <p><b>prefix</b>—specifies that the prefix modification performs on the address.</p> <p><b>prefix-remove-num</b>—an integer in the range of 1 to 15 that defines the number of prefix digits to remove from the address. If no prefix digits are removed, then * should be specified.</p> <p><b>prefix-add-digits</b>—identifies a string of 1 to 15 hexadecimal digits added to the beginning of the address. The string is input in normal form (not BCD-string format). If no digits are added, then specify * in this field. If the number of digits in the modified address exceeds the 31 digits, then the modified address truncates to 31 digits. If the number of digits in the modified address is less than 1 digit, then the address modification fails, and the configured modify-failure parameter action takes place. The default modify-failure parameter action is to discard the packet.</p> <p><b>tt</b> —indicates the global title translation type (tt) for the modified CgPA. <i>tt</i> is an integer from 0 to 255 which will replace the existing tt value in the CgPA.</p> <p><b>gti</b>—identifies the global title indicator value for the modified CgPA. This value is only specified when the CS7 variant is ITU or China. <i>gti</i> is an integer value of 2 or 4.</p> <p><b>np</b>—identifies the global title numbering plan for the modified CgPA. <i>np</i> is an integer value from 0 to 15.</p> <p><b>nai</b>—identifies the global title nature of address indicator for the modified CgPA. Only specified when the gti parameter value is 4. <i>nai</i> is an integer value from 0 to 127.</p> <p><b>pc</b>—identifies the point code for the modified CgPA. <i>pc</i> is the point code in variant-specific point-code format.</p> <p><b>ssn</b>—identifies the subsystem number for the modified CgPA. <i>ssn</i> is the subsystem number in decimal format. Valid range is 2 to 255.</p> |

## Creating and Managing Address Tables

This section discusses the configuration, storage, and retrieval of address lists that can block or route SMS messages.

MLR address tables can be stored in either NVRAM on the IOS platform or in a file that typically would be stored in flash. NVRAM limitations on some platforms might restrict the number of address entries that can be stored there. In this case, the file storage option is recommended.

This section includes 3 tasks:

- [Creating and Loading an Address Table File Using the CLI, page 215](#)
- [Creating and Loading a Stored Address Table File, page 218](#)
- [Replacing an Address Table File, page 219](#)
- [Saving an MLR Configuration to a File, page 221](#)
- [Loading an MLR Configuration from a File, page 221](#)
- [Replacing a Running MLR Configuration with a File, page 222](#)
- [Validating and Auditing the Consistency of the MLR Files in the Line Card and Main Processor, page 223](#)

## Creating and Loading an Address Table File Using the CLI

In this task you use the CLI to configure address table entries that you plan to save to an external file. You then specify a location from which you will load the file of address table entries upon reboot. Finally you save the address entries to an external file.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 mlr address-table *table-name***
4. **addr *address-name* [exact] [result {*asname asname* | *block* | *continue* | *group group-name* | *gt addr-string* [tt tt gti {2 | 4 np np nai nai}]] [instance *instance-number*] pc *pc* [ssn *ssn*] | [sccp-error *error*]]]**
5. **load *URL***
6. **exit**
7. **cs7 save address-table mlr *table-name url***

### DETAILED STEPS

|        | Command or Action                              | Purpose                                                        |
|--------|------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b>                                  | Enables higher privilege levels, such as privileged EXEC mode. |
|        | <b>Example:</b><br>ITP> enable                 | Enter your password if prompted.                               |
| Step 2 | <b>configure {terminal   memory   network}</b> | Enters global configuration mode.                              |
|        | <b>Example:</b><br>ITP# configure terminal     |                                                                |

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Step 7 | <p><b>cs7 save address-table mlr</b> <i>tablename url</i></p> <p><b>Example:</b><br/> ITP#cs7 save address-table mlr addrtbl1<br/> disk0:mlraddrtbl</p> | <p>Saves the address table to an external location and file (url).<br/> Valid URLs are bootflash, disk0, disk1, disk2, slot0, slot1, tftp, flash, sup-bootdisk, sup-bootflash, rcv.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Creating and Loading a Stored Address Table File

Address tables are typically created and stored to a file using the ITP CLI. However, advanced users can also create address tables externally and then load the created address table file into the ITP. This option may be useful for integrated tooling.

To create and load a stored address table, perform the following steps.

### SUMMARY STEPS

- 1. Create a file of addresses following the format and syntax described in the above tables.
- 2. **enable**
- 3. **configure terminal**
- 4. **cs7 mlr address-table *tablename***
- 5. **load *URL***

### DETAILED STEPS

|        | Command or Action                                                                                | Purpose                                                                                                |
|--------|--------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| Step 1 | Create a file of addresses, following the format and syntax described in Tables 1 - 4.           |                                                                                                        |
| Step 2 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                              | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted. |
| Step 3 | <b>configure {terminal   memory   network}</b><br><br><b>Example:</b><br>ITP# configure terminal | Enters global configuration mode.                                                                      |

## DETAILED STEPS

|        | Command or Action                                                                  | Purpose                                                                                                     |
|--------|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                                      | Enables higher privilege levels, such as privileged EXEC mode.                                              |
|        | <b>Example:</b><br>ITP> enable                                                     | Enter your password if prompted.                                                                            |
| Step 2 | <b>cs7 address-table replace mlr <i>tablename url</i></b>                          | Replaces an existing address table with one specified in a URL.                                             |
|        | <b>Example:</b><br>ITP# cs7 address-table replace mlr addrtbl1<br>disk0:mlraddrtbl | Valid URLs are bootflash, disk0, disk1, disk2, slot0, slot1, tftp, flash, sup-bootdisk, sup-bootflash, rcp. |

## Examples

The following example shows three address tables. Two of the address tables are loaded from stored files at startup. The third address table and the addresses in the table are configured from within the configuration.

```
cs7 mlr address-table imsi-screen
load disk0:imsi-screen
!
cs7 mlr address-table orig-screen
load disk0:orig-screen
!
cs7 mlr address-table shortcodes
addr 11112 result group grp2
addr 1111 result group grp1
addr 2222 result group grp1
addr 5551212 exact result group grp3
```

## Saving an MLR Configuration to a File

You can save a general MLR configuration file to a local or remote file system. The MLR configuration for each CS7 instance will be saved to a separate file. By default, the file format text of general MLR configuration can be obtained from files under `cs7:/mlr-config/`.

Cisco IOS CLI modifications to MLR configurations may take up to 15 seconds to take effect on all linecards after the last change is made. The standard Cisco IOS CLI command `copy running-config startup-config` or `write memory`, which saves the running configuration, does not automatically save the MLR configuration. The user needs to save this MLR information manually. The saved provisioning will load during a Cisco ITP restart or reload.

To save this MLR information manually use the following procedure:

### SUMMARY STEPS

1. **enable**
2. **cs7** [*instance-number*] **save mlr** [**all**] *url*

### DETAILED STEPS

|        | Command or Action                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                              | Enables privileged EXEC mode.                                                                                                                                                                                                                                                                                                      |
| Step 2 | <b>cs7</b> [ <i>instance-number</i> ] <b>save mlr</b> [ <b>all</b> ] <i>url</i><br><br><b>Example:</b><br>itp# cs7 save mlr all disk0:mlr-config | Saves a general MLR configuration to a separate file.<br><br>Valid URLs are bootflash, disk0, disk1, disk2, slot0, slot1, tftp, flash, sup-bootdisk, sup-bootflash, rcp.<br><br><b>Note</b> If the save operation fails, the system generates an error message with the cause of the problem, which can be insufficient resources. |

## Loading an MLR Configuration from a File

You can configure Cisco ITP to load the whole MLR configuration including general MLR configuration and address tables. The load command does not initiate the restart or reload needed to trigger the actual load operation. It configures the load operation to occur when a restart or reload occurs. Cisco IOS CLI configuration is not allowed during file loading or replacement. If the MLR loading operation occurs before system configuration, it will wait until the system configuration finish.

Configure Cisco ITP to load an MLR configuration from a local or remote file with the following procedure:

#### Note

Loading and replacement of MLR configuration files may take up to 15 seconds to take effect on all linecards after the last change is made. The user is notified of completion through a console message.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7** [*instance instance-number*] **mlr load url**

## DETAILED STEPS

|        | Command or Action                                                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------|----------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                    | Enables privileged EXEC mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                            | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Step 3 | <b>cs7</b> [ <i>instance instance-number</i> ] <b>mlr load url</b><br><br><b>Example:</b><br>itp(config)#cs7 mlr load disk0:mlr-config | <p>Loads an MLR configuration file from a specified remote or local file during a Cisco ITP restart or reload.</p> <p>Valid URLs are bootflash, disk0, disk1, disk2, slot0, slot1, tftp, flash, sup-bootdisk, sup-bootflash, rcp.</p> <div>  <p><b>Caution</b> Specifying a remote file for the load command is not recommended as a best practice for high availability deployments, such as the Cisco 7600.</p> </div> <div> <p><b>Note</b> If the load operation fails, the system generates an error message with the cause of the problem. Syntax errors in the loaded file cause the load operation to fail.</p> </div> |

## Replacing a Running MLR Configuration with a File

This procedure replaces the running MLR configurations. It replaces the entire MLR configuration, including general MLR configuration and MLR address tables. Cisco ITP maintains a new configuration and an old configuration and uses the old configuration until the new configuration loads completely with no problems. Configuration file replacement does not take place until all entries in the new file have been read and validated.

Cisco IOS CLI modifications to MLR configurations may take up to 15 seconds to take effect on all linecards after the last change is made. The user is notified of completion through a console message. Cisco IOS CLI configuration is not allowed during file loading or replacement.

To accomplish this, complete the following procedure:

## SUMMARY STEPS

1. **enable**

## 2. `cs7 [instance instance-number] mlr replace url`

### DETAILED STEPS

|        | Command or Action                                        | Purpose                                                                                                                                                                                                                |
|--------|----------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                            | Enables privileged EXEC mode.                                                                                                                                                                                          |
|        | <b>Example:</b><br>ITP> enable                           |                                                                                                                                                                                                                        |
| Step 2 | <b>cs7 [instance-number] mlr replace url</b>             | (Optional) Replaces the running MLR configuration with the configuration file specified by the URL.<br><br>Valid URLs are bootflash, disk0, disk1, disk2, slot0, slot1, tftp, flash, sup-bootdisk, sup-bootflash, rcp. |
|        | <b>Example:</b><br>itp# cs7 mlr replace disk0:mlr-config |                                                                                                                                                                                                                        |

### Validating and Auditing the Consistency of the MLR Files in the Line Card and Main Processor

This procedure validates and audits the consistency of the MLR configuration files and MLR address table files contained in the line card and main processor. These files should sync from the line card to the main processor when the configuration of the MLR files change in the main processor. If the procedure recognizes inconsistencies between the the MLR files in the line card and main processor, a second sync takes place. Configure Cisco ITP to validate and audit the consistency of the MLR configuration files and MLR address table files contained in the line card and main processor with the following procedure:

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 audit [timer [timer-minutes]] [mlr [sync]]**

## DETAILED STEPS

|        | Command or Action                                                                                               | Purpose                                                                                                                                                                                                                                                                                                                                          |
|--------|-----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br><code>ITP&gt; enable</code>                                             | Enables privileged EXEC mode.                                                                                                                                                                                                                                                                                                                    |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br><code>ITP# configure terminal</code>                        | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                |
| Step 3 | <b>cs7 audit [timer [timer-minutes]] [mlr]</b><br><br><b>Example:</b><br><code>itp(config)#cs7 audit mlr</code> | Validates and audits the consistency of the MLR configuration files and MLR address table files contained in the line card and main processor.<br><br> <b>Note</b> To see the latest audit begin time, end time, and status, use the <code>show</code> command. |

## Define One or More MLR Rulesets

With this task you specify sets of rules for processing traffic that matches triggers defined in the MLR routing table.

**MLR/SMS rule-matching implementations**

If the address-table lookup finds a match and returns a result, it may only be used if no other routing parameters are defined on this rule. If more than one parameter is configured in a rule, then the result specified under the rule is used.

If an incoming message matches an SMS rule that references an MLR address-table, then any MLR address-table result is mapped to an SMS result:

- BLOCK, PC, and PCSSN results map easily from MLR to SMS.
  - For result groups, the MLR result group name is mapped to an SMS result group name.
  - If the SMS result group is not configured, then the result specified on the rule is used.
- AS and CONTINUE results are not valid in SMS. For these cases, the result specified on the rule is used. If no result is specified, the result on the rule is used (same as MLR).

If multiple rule parameters are configured for a rule, then the rule result will be used (rather than a result specified in the address table).

If the result type specified within the table is valid, it is used. Otherwise, the result in the rule is used.

For all tables, the ton and np must match before the table is accessed.

[Table 18](#) and [Table 19](#) list the GSM-MAP and GSM-MAP Version 1 operation names mapped to ITP operation names.

[Table 20](#) lists operations that allow you to route and screen based on MAP parameters and MAP-User parameters.

Valid operation-name specifications are presented in the CLI depending on the specified protocol.

**Table 18** *GSM-MAP Operation Name Mapping to ITP CLI Operation Name*

| Operation Name in GSM-MAP Specification | ITP CLI Operation Name | Opcode Value |
|-----------------------------------------|------------------------|--------------|
| activatess                              | actSS                  | 12           |

MLR can route based on any GSM operation. The operations listed in [Table 20](#) allow you to route and screen based on MAP parameters and MAP-user parameters.

[Table 20](#) lists the parameters that are valid based on the specified **rule** operation.

**Table 20** Valid Rule Parameters by Operation

|                              | alertSc | all | smdpp | sms-mo | sms-mt | smsNot | smsReq | sri-sm | updLoc |
|------------------------------|---------|-----|-------|--------|--------|--------|--------|--------|--------|

To define a multi-layer SMS ruleset, perform the following steps.

## SUMMARY STEPS

Steps 1 through 4 are required. Later steps are optional parameters, or input conditions, for the rule. Each rule and its input conditions must be completed by a result.

1. **enable**
2. **configure terminal**
3. **cs7** [*instance instance*] **mlr ruleset name** [*protocol {gsm-map | ansi-41}*]
4. **rule order** {*{gsm-map | ansi-41} operation-name [default] | all-operations*}
5. **allow-multi-message-dialogue**
6. **dest-port** *dest-port-number*
7. **dest-sme** {*\* | dest-addr*} [*dest-sme-addr-type*] [**exact**] | [**min-digits min**] | [**max-digits max**]
8. **dest-sme-table** *table-name*
9. **dest-smsc** {*\* | dest-addr*} [*addr-type*] [**exact**] | [**min-digits min**] | [**max-digits max**]
10. **match-unknown-ton-np**
11. **allow-multi-message-dialogue**
12. **orig-imsi** {*\* | imsi-address | unknown*} [**exact**] | [**min-digits min**] | [**max-digits max**]
13. **orig-imsi-table** *tablename* [**ton ton-value np np-value**]
14. **orig-sme** {*\* | orig-addr*} [*orig-sme-addr-type*] [**exact**] | [**min-digits min**] | [**max-digits max**]
15. **orig-sme-table** *tablename* [**ton ton-value np np-value**]
16. **orig-smsc** {*\* | orig-addr*} [*smc-addr-type*] [**exact**] | [**min-digits min**] | [**max-digits max**]
17. **pid** *protocol-id*

18. **preserve-opc**
19. **teleservice** *id*
20. **modify-profile** *profile-name*]
21. **result** {**gt** *addr-string* [*gt-addr-type*] | [**instance** *instance-number*] **pc** *dest\_pc* [**ssn** *ssn*] | **asname** *as-name* | **group** *result-group* | **block** [**sccp-error** *error* | **map-error** {[**default** *ecdef* [*subdef*]] [**v1** *ec1* [*sub1*]] [**v2** *ec2* [*sub2*] ] [**v3** *ec3* [*sub3*]] } | **continue** | **route**}

## DETAILED STEPS

To define an MLR ruleset, perform the following steps, beginning in global configuration mode:

|        | Command or Action                                                     | Purpose                                                        |
|--------|-----------------------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                         | Enables higher privilege levels, such as privileged EXEC mode. |
|        | <b>Example:</b><br>ITP> enable                                        | Enter your password if prompted.                               |
| Step 2 | <b>configure</b> { <b>terminal</b>   <b>memory</b>   <b>network</b> } | Enters global configuration mode.                              |
|        | <b>Example:</b><br>ITP# configure terminal                            |                                                                |

| Command or Action                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Step 3</b></p> <pre>cs7 [instance instance-number] mlr ruleset name [protocol {gsm-map   ansi-41}]</pre> <p><b>Example:</b><br/>Router(config)#cs7 mlr ruleset MLR_RULES</p> | <p>Specifies an MLR ruleset and application layer protocol filter for the ruleset.</p> <ul style="list-style-type: none"> <li>• <i>name</i> Ruleset name.</li> <li>• <b>protocol</b> (Optional) Specifies an application layer protocol filter for this ruleset. The default behavior is that all operations may be specified within the ruleset. <ul style="list-style-type: none"> <li>– <b>gsm-map</b> Uses GSM-MAP as application layer protocol filter within the ruleset. Only <b>gsm-map</b> operations may be specified within the ruleset.</li> <li>– <b>ansi41</b> Uses ANSI-41 as application layer protocol filter within this ruleset. Only <b>ansi41</b> operations may be specified within the ruleset.</li> </ul> </li> </ul> <p>Configuring the <b>cs7 mlr ruleset</b> command enables CS7 MLR ruleset configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <p><b>Step 4</b></p> <pre>rule order {{gsm-map   ansi-41} operation-name [default]   all-operations}</pre> <p><b>Example:</b><br/>ITP(cfg-cs7-mlr-set)# rule 5 gsm-map sms-mo</p>  | <p>Specifies the rules within a Multi-layer ruleset table. Specifies the attributes of an application-layer message to be matched, and the resulting behavior for handling the message. At least one rule must be specified for the ruleset to be valid. Enables the MLR ruleset-rule configuration mode.</p> <ul style="list-style-type: none"> <li>• <i>order</i> Specifies the order in which rules are searched.</li> <li>• <b>gsm-map</b> Specifies the GSM MAP protocol. Protocol specification is required only if not specified in the <b>cs7 mlr ruleset</b> command.</li> <li>• <b>ansi-41</b> Specifies the ANSI-41 protocol. Protocol specification is required only if not specified in the <b>cs7 mlr ruleset</b> command.</li> <li>• <i>operation-name</i> Specifies the operation for which the rule is valid.</li> <li>• <b>default</b> Specifies a match of any valid operation code. If you specify a protocol in MLR ruleset level, specifying <b>all-operations</b> in a rule applies only for that protocol.</li> <li>• <b>all-operations</b> Specifies the processing of messages that match the indicated operation name only.</li> </ul> <p>Configuring the <b>rule</b> command enables MLR ruleset-rule configuration mode in which you configure the input conditions of the rule.</p> |

|        | Command or Action                                                                                                     | Purpose                                                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <b>map-version</b> <i>&lt;version number&gt;</i><br><br><b>Example:</b><br>ITP(cfg-cs7-mlr-set-rule)# map-version 1 2 | Filters specific versions of a gsm-map message. <ul style="list-style-type: none"> <li><i>version number</i> Specifies the specific MAP version used to filter the gsm-map messages. Valid range is 1 through 3.</li> </ul> |
| Step 6 | <b>allow-multi-message-dialogue</b><br><br><b>Example:</b><br>ITP(cfg-cs7-mlr-set-rule)# allow-multi-message-dialogue | Specifies that all messages including multi-message dialogues match the rule. Only valid for default rules.                                                                                                                 |
| Step 7 | <b>dest-port</b> <i>dest-port-number</i><br><br><b>Example:</b><br>ITP(cfg-cs7-mlr-set-rule)# dest-port 100           | Specifies the application destination port number.<br><br><i>dest-port-number</i> Specifies the destination port number. Valid range is 0 to 65535.                                                                         |

## Step 8

| Command or Action                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dest-sme</b> { *   <i>dest-address</i> } [ <i>dest-sme-addr-type</i> ]<br>[ <b>exact</b> ]   [ <b>min-digits</b> <i>min</i> ]   [ <b>max-digits</b> <i>max</i> ] | <p>Specifies the address of the destination short message entity (SME) within an SMS operation. This parameter is part of the rule used to match this route.</p> <ul style="list-style-type: none"> <li>• <i>dest-addr</i> Specifies the destination address. Valid range is 1 to 20 hexadecimal digits.</li> <li>• <i>dest-sme-addr-type</i> (Optional) Parameters that identify attributes of the SME address being used to match a rule. The address is composed of the following keywords: <ul style="list-style-type: none"> <li>– [<b>ton</b> <i>ton</i>] The <b>ton</b> keyword specifies the type of number value associated with the SME address. The <i>ton</i> argument is an integer value in the range 0 to 7.</li> <li>– [<b>np</b> <i>np</i>] The <b>np</b> keyword specifies the numbering plan identification value associated with the SME address. The <b>np</b> keyword is not valid when defining the <b>dest-sme</b> in an <b>smsNot</b> operation. The <i>np</i> argument is an integer value in the range 0 to 15.</li> <li>– <b>min</b> Specifies that the address is a Mobile Identification Number (MIN). This keyword can be specified for the <i>sme-addr-type</i> of ANSI-41 operations.</li> <li>– <b>imsi</b> Specifies that the address is an International Mobile Subscriber Identification (IMSI) address. This keyword can be specified for the <i>sme-addr-type</i> of ANSI-41 operations.</li> </ul> </li> <li>• <b>exact</b> (Optional) Indicates that the specified <i>dest-addr</i> should be matched only of the number of digits AND the digit values exactly match as specified in <i>dest-addr</i>. If <b>exact</b> is not specified then the <i>dest-addr</i> carries an implicit "*" at the end of the string, allowing a match on the string as a prefix (range of addresses).</li> <li>• <b>min-digits</b> <i>min</i> (Optional) Specifies the minimum number of digits in the address string. The default is 1.</li> <li>• <b>max-digits</b> <i>max</i> (Optional) Specifies the maximum number of digits in the address string. The default is the length of the address string.</li> </ul> |

**Example:**

```
ITP(cfg-cs7-mlr-set-rule)# dest-sme 1111 exact
```

## Define the MLR Triggers

An MLR table comprises a list of primary triggers, which can represent either the SCCP, cgPa, or SCCP cdPa within a given message. When you define the MLR triggers, it specifies the SS7 network-layer parameters to identify traffic that requires parsing into the application layers.

Cisco ITP supports two methods of defining the MLR triggers. The integrated GWS method and the older, proprietary method. The integrated GWS method is recommended. The proprietary method is supported primarily for legacy configurations from earlier Cisco ITP releases.

This section contains the following information and procedure:

- [Define the MLR Triggers with GWS, page 240](#)
- [Information About MLR Triggers with GWS, page 240](#)
- [Define MLR Triggers with Proprietary Method, page 242](#)

### Note

The proprietary method of configuring MLR triggers using MLR tables is still supported but not recommended.

## Define the MLR Triggers with GWS

You can configure MLR triggers using the GWS infrastructure, GWS tables, and MLR variables. For information on this, you need to refer to the [Gateway Screening \(GWS\)](#) chapter. See “[Defining GWS Action Sets](#)” section on page 180 or “[Defining Entries in GWS Tables](#)” section on page 184 in .

## Information About MLR Triggers with GWS

MLR triggers and GWS are integrated. GWS determines which packets are intercepted by MLR.

## Migration of Existing MLR Trigger Configuration

MLR table and MLR trigger configurations created in MLR tables in prior releases are still supported by later releases with integrated GWS and MLR triggers. But this is primarily so users can delete the existing triggers configured prior to the integration and replace these triggers with new triggers configured in GWS. This is the best practice since the newer GWS tables are given precedence over the older MLR tables. User should also configure any new MLR triggers through GWS.

**Note**

A warning states that the MLR table command will be deprecated.

## Logging and Test Mode for MLR with GWS

GWS logging supports MLR. You enable GWS logging when you configure a link set, AS, or global table as GWS.

Test mode is a logging option. With test mode, once the GWS tables and action-sets are configured, you can test them before applying them to live traffic. If GWS rules block the packet, the test mode may create a log and allow the packet. If GWS rules send the packet to MLR routing, the test mode may create a log and operate as if there is no MLR configured. Test mode is useful when MLR triggers configured the proprietary way are migrated to GWS tables. You test the new GWS triggers before deleting the existing proprietary MLR triggers.

For more information on logging and test mode, see the [“Message Logging” section on page 195](#).

## Disabling of MLR Triggers

MLR table configuration used the global configuration command **cs7** [*instance instance-number*] **mlr table** *table-name* and also the global configuration command **trigger**. Under MLR table configuration the **no** form of these commands deletes the configured triggers. GWS configuration also supports the **no** forms of these commands. But the GWS **no** command does not delete the triggers like the MLR table configuration **no** command does. The GWS version only disables triggers and prevents the trigger lookup for that trigger instance. The GWS disabling applies to MLR triggers configured in either GWS or through MLR tables.

## MLR and GWS Table Matching Order for Incoming Packets

Cisco ITP supports local application-based table matching for GWS in addition to table matching based on a link set or AS. The sequence of conditions for table matching depends on whether the packet is received from a local application or is received from a link set or AS.

## Precedence Followed for Link Set or AS

An attempt to match the table occurs in the following sequence for any incoming packet received on a specific link set or AS:

1. If a GWS configuration exists, the GWS configuration is applied.
2. If a GWS configuration does not exist for the specific link set or AS, but a GWS default configuration exists, the default configuration is applied.
3. If neither a specific GWS configuration nor a default GWS configuration exists, but a global table exists, the global table is applied.

4. If none of the above situations apply, but MLR triggers not configured through GWS exist, these MLR triggers apply. (This step applies only to MLR. It does not apply to GWS.)
5. If none of the above situations apply, then packet is neither screened nor routed by MLR but routed normally.

## Precedence Followed for a Local Application

### Note

Local application precedence applies only to MLR. It does not apply to GWS.

An attempt to match the table occurs in the following sequence for any incoming packet received from a local application:

1. If a global table exists, the global table is applied.
2. If no global tables exist, but MLR triggers not configured through GWS exist, these MLR triggers are applied.
3. If none of the above situations apply, then packet is neither screened nor routed by MLR but routed normally.

## How MLR Using GWS Works with Access Lists

MLR configured through GWS works with access lists in the same way that GWS does. For more information, see [“How GWS Works with Access Lists” section on page 175](#)

## Define MLR Triggers with Proprietary Method

To define the MLR table with proprietary method, perform the following steps. Steps 1 - 4 are required in the order show. Steps 5 - 7 are optional; they are used to configure secondary triggers.

### Caution

Configuring MLR using the GWS infrastructure is the recommended method.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7** [*instance instance-number*] **mlr table** *name*
4. **trigger** {**mtp3** {[*dpc point-code*] [*opc point-code*] [*si indicator*]} | **cdpa** {**gt**<sup>1</sup> {**selector** | *addr-string*} [*gt-addr-type*] | **pc** *point-code* *ssn ssn*} | **cgpa** {**gt** {**selector** | *addr-string*} [*addr-type*] | **pc** *point-code* *ssn ssn*} | **default**} [**block** | **continue** | **ruleset** *ruleset-name* | **result** {**pc** *point-code* [*ssn ssn*] | **asname** *asname* | **gt** *gta* [*gt-addr-type*] | **group** *groupname*}}
5. **cdpa** {**gt** {**selector** | *addr-string*} [*gt-addr-type*] | **pc** *point-code* *ssn ssn*} [**block** | **continue** | **ruleset** *ruleset-name* | **result** {**pc** *point-code* [*ssn ssn*] | **asname** *asname* | **gt** *gta* [*gt-addr-type*] | **group** *groupname*}}
6. **cgpa** {**gt** {**selector** | *addr-string*} [*addr-type*] | **pc** *point-code* *ssn ssn*} [**block** | **continue** | **ruleset** *ruleset-name* | **result** {**pc** *point-code* [*ssn ssn*] | **asname** *asname* | **gt** *gta* [*gt-addr-type*] | **group** *groupname*}}

1. To enable a cdpa or cgpa trigger, the CS7 GTT selector and GTA entry must be defined. For more information about configuring GTT, refer to the [“Global Title Translation”](#) chapter.

7. **default** {**block** | **continue** | **ruleset** *ruleset-name* | **result** {**pc** *point-code* [**ssn** *ssn*] | **asname** *asname* | **gt** *gt* [**gt-addr-type**] | **group** *groupname*}}

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 6 | <pre>cgpa {gt {selector   addr-string} [addr-type]   pc point-code ssn ssn} {block   continue   ruleset ruleset-name   result {pc pc [ssn ssn]   asname asname   gt gta [gt-addr-type]   group groupname}}</pre> <p><b>Example:</b><br/>Router(cfg-cs7-mlr-trigger)# cGpa gt 9991116<br/>ruleset RULESET-5</p> | Within the mlr-trigger submode, the <b>cgpa</b> , <b>cdpa</b> and <b>default ruleset</b> commands are used to define combination triggers. (MTP3 may be specified as a primary trigger only.) The secondary triggers in conjunction with the trigger address constitute the combination trigger used to match a packet. If any secondary address in the trigger submode is specified, then BOTH addresses must match for the packet to be blocked or routed using the specified ruleset. The parameter keywords and values are the same as those defined for the <b>trigger</b> command. |
| Step 7 | <pre>default {block   continue   ruleset ruleset-name   result {pc pc [ssn ssn]   asname asname   gt gta [gt-addr-type]   group groupname}}</pre> <p><b>Example:</b><br/>Router(cfg-cs7-mlr-trigger)# default ruleset<br/>DEFAULT-RULES</p>                                                                    | Within the mlr-trigger submode, the <b>cgpa</b> , <b>cdpa</b> and <b>default ruleset</b> commands are used to define combination triggers. (MTP3 may be specified as a primary trigger only.) The secondary triggers in conjunction with the trigger address constitute the combination trigger used to match a packet. If any secondary address in the trigger submode is specified, then BOTH addresses must match for the packet to be blocked or routed using the specified ruleset. The parameter keywords and values are the same as those defined for the <b>trigger</b> command. |

1. To enable a cdpa or cgpa trigger, the CS7 GTT selector and GTA entry must be defined. For more information about configuring GTT, refer to the [“Global Title Translation”](#) chapter.

## How to Configure MLR-Based Screening

The following sections describe and provide example of MLR-based screening. When a message is blocked MLR discards the packet.

- [Blocking Based on SCCP cdPa and cgPa, page 244](#)
- [Blocking Based on cgPa, cdPa, and SMS MAP Operation Code, page 247](#)
- [Blocking Based on cgPa, cdPa and SMS MO/MT Routing Parameters, page 247](#)

### Blocking Based on SCCP cdPa and cgPa

This section includes the following tasks to configure blocking based on SCCP cdPa and cgPa:

- [Define GTT Entries for cdPa and cgPa digits to Screen](#)
- [Define MLR table and Blocking Based on SCCP cdPa or cgPa](#)
- [Define MLR Table and Blocking on Combination of SCCP cdPa and cgPa](#)

### Define GTT Entries for cdPa and cgPa digits to Screen

To define the GTT entries for cdPa and cgPa digits to screen, perform the following steps. Steps 1 - 3 are required in the order shown. Perform steps 4 - 6 as appropriate to your needs, to specify a GTA.

## SUMMARY STEPS

1. **enable**
2. **configure** { **terminal** | **memory** | **network** }
3. **cs7 gtt selector** *selector tt tt gti gti np np*
4. **gta gta app-grp** *app-grp*
5. **gta gta asname** *as-name* { **gt** | **pcssn** } [**ssn** *ssn*] [**ntt** *newtt*] [**qos-class** *qos*]
6. **gta gta pcssn** *pc* { **gt** | **pcssn** } [**ssn** *ssn*] [**ntt** *newtt*]

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                                                                                                              | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted.                                                                                                                             |
| Step 2 | <b>configure</b> { <b>terminal</b>   <b>memory</b>   <b>network</b> }<br><br><b>Example:</b><br>ITP# configure terminal                                                                                                                          | Enters global configuration mode.                                                                                                                                                                                                  |
| Step 3 | <b>cs7 gtt selector</b> <i>selector tt tt gti gti np np</i><br><b>nai nai</b><br><br><b>Example:</b><br>ITP(config)# cs7 gtt selector e164 tt 10 gti 2                                                                                           | Names and configures the GTT selector and enables CS7 GTT selector submode.<br><br>MLR primary GT triggers re-use the existing GTT selector table entity containing lists of GTA entries used to perform Global Title Translation. |
| Step 4 | <b>gta gta app-grp</b> <i>app-grp</i><br><br><b>Example:</b><br>ITP(config-cs7-gtt-selector)# gta 11111 app-grp GROUP1                                                                                                                           | Defines a GTA that translates to a GTT application group.                                                                                                                                                                          |
| Step 5 | <b>gta gta asname</b> <i>as-name</i> { <b>gt</b>   <b>pcssn</b> } [ <b>ssn</b> <i>ssn</i> ] [ <b>ntt</b> <i>newtt</i> ] [ <b>qos-class</b> <i>qos</i> ]<br><br><b>Example:</b><br>ITP(config-cs7-gtt-selector)# gta 22222 asname GREENASP3 pcssn | Defines a GTA that translates to an M3UA or SUA Application Server name.                                                                                                                                                           |
| Step 6 | <b>gta gta pcssn</b> <i>pc</i> { <b>gt</b>   <b>pcssn</b> } [ <b>ssn</b> <i>ssn</i> ] [ <b>ntt</b> <i>newtt</i> ]<br><br><b>Example:</b><br>ITP(config-cs7-gtt-selector)# gta 33333 pcssn 1.1.1 pcssn                                            | Defines a GTA that translates to a point code and optional subsystem number.                                                                                                                                                       |

**Example:**

```
cs7 gtt selector e164 tt 10
gta 11111 pcssn 1-1-1 pcssn
gta 22222 pcssn 2-2-2 pcssn
gta 33333 pcssn 3-3-3 pcssn
```

**Note**

The GTT mapping results will not be used if blocking triggers are configured via MLR for the cgPa and cdPa global title addresses.

## Define MLR table and Blocking Based on SCCP cdPa or cgPa

An MLR table consists of a list of primary triggers, which can represent either the SCCP cgPa or the SCCP cdPa within a given message. To block a message based on either cgPa or cdPa, specify the block keyword in lieu of a ruleset.

**Example:**

```
cs7 mlr table sms-blocking
trigger gt 11111 tt 10 block
trigger cgpa gt 22222 tt 10 block
trigger cgpa gt 33333 tt 10 block
```

When coding a mixture of primary cgPa and primary cdPa triggers, the triggers are not searched sequentially. The first primary trigger match found is used based on the following hierarchy:

1. The default trigger is defined (only trigger configured)
2. cdPa GT triggers when SCCP cdPa is RI=GT
3. cdPa PC/SSN triggers when SCCP cdPa is RI=SSN
4. cgPa GT triggers when SCCP cgPa is RI=GT
5. cgPa PC/SSN triggers when SCCP cgPa is RI=SSN

## Define MLR Table and Blocking on Combination of SCCP cdPa and cgPa

To block a message based on a combination of SCCP cdPa and cgPa, specify the combination triggers and place the block keyword at the end of the secondary trigger.

**Example:**

```
cs7 mlr table sms-blocking
trigger cdpa gt 11111 tt 10 ruleset MY_RULES
cgpa gt 22222 tt 10 block
cgpa gt 33333 tt 10 block
```

**Note**

Ruleset `MY_RULES` is a placeholder and will not be used. A packet destined for 11111 from 44444 will not match a trigger, and will be routed normally.

## Blocking Based on cgPa, cdPa, and SMS MAP Operation Code

MLR triggers must be specified, but will be configured with an associated MLR ruleset instead of the **block** keyword. When a non-blocking MLR trigger matches, the received packet is parsed through the application layer for the rule operations identified in the ruleset.

### Example:

The following example will block all SMS MO messages from 22222 to 11111, and will block all SMS MT message from 11111 to 33333. All other messages will be routed according to standard SCCP and MTP3 procedures.

```
cs7 mlr ruleset BLOCK-SMSMO gsm-map
  rule 10 sms-mo default
  result block

cs7 mlr ruleset BLOCK-SMSMT gsm-map
  rule 10 sms-mt default
  result block

cs7 mlr table sms-blocking
  trigger cdpa gt 11111 tt 10
    cgpa gt 22222 tt 10 ruleset BLOCK-SMSMO
  trigger cdpa gt 33333 tt 10
    cgpa gt 11111 tt 10 ruleset BLOCK-SMSMT
```

## Blocking Based on cgPa, cdPa and SMS MO/MT Routing Parameters

To block based on select parameters within the SMS MO or SMS MT message, specify the appropriate routing parameters within sms-mo or sms-mt operation. Rules are searched sequentially for a match.

### Example:

The following example will block all SMS MO messages from 22222 to 11111 with an origin SME (A-address) prefix of 919 and return an UDTs with return cause set as 0x07 (Unqualified), if the return on error option is set in the received UDT portion of SMS MO. It will also block all SMS MT messages from 11111 to 33333 with a destination SME (or mobile) IMSI of 238012650007149. All other messages not matching a trigger will be routed according to standard SCCP and MTP3 procedures.

```
cs7 mlr ruleset BLOCK-SMSMT gsm-map
  rule 10 sms-mt
  dest-sme 238012650007149
  result block
cs7 mlr ruleset BLOCK-SMSMO gsm-map
  rule 10 sms-mo
  orig-sme 919
  result block 7
.....
```

## Verifying and Monitoring MLR Routing

With this task you verify configuration, monitor status, and troubleshoot errors in the MLR configuration. When MLR triggers are implemented through GWS, some GWS show commands also display details about MLR, see the [“Verifying GWS Configuration” section on page 197](#) for these commands.

To display information about the MLR configuration, perform the following steps in privileged EXEC mode:

| Command                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router# <b>show cs7</b> <i>instance-number</i> <b>mlr address-table</b> <i>name table-name</i>                 | Displays the addresses matched within the table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| router# <b>show cs7</b> [ <i>instance-number</i> ] <b>mlr config</b>                                           | This command displays the whole configuration of MLR.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Router# <b>show cs7</b> <i>instance-number</i> <b>mlr dest-sme-binding</b> <i>dest-sme [result-group-name]</i> | Displays the result that will be selected from an MLR result group for the specified dest-sme address. <ul style="list-style-type: none"> <li><i>dest-sme</i> Specifies the dest-sme address whose result you wish to display. Valid dest-sme addresses are between 1 and 20 hexadecimal digits in length. Only the final 4 digits of the address are needed to determine the dest-sme-binding result. Alphanumeric dest-sme addresses can not currently be specified.</li> <li><i>result-group-name</i> (Optional) Specifies which result group to use. If the <i>result-group-name</i> is not specified, then this display will output the dest-sme-binding result for the input dest-sme for each result group in dest-sme-binding mode.</li> </ul> |
| Router# <b>show cs7</b> [ <i>instance-number</i> ] <b>mlr modify-profile</b> [ <i>profile-name</i> ]           | Displays the current modify-profiles and their statistics. The matches count indicates the number of times that the modify profile was applied to a message. Matches does not indicate success or failure of the applied modifications. The modify failures count indicates the number of times that the matching message could not be modified as specified in the modify-profile.                                                                                                                                                                                                                                                                                                                                                                    |
| Router# <b>show cs7</b> <b>mlr options</b>                                                                     | Displays specify MLR global options information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Router# <b>show cs7</b> <i>instance-number</i> <b>mlr result</b> <i>name</i>                                   | Displays the contents of all MLR result groups, or a specific named result group along with the weight and number of matches for each server result.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

To display debug messages for Multi-layer routing, use the **debug cs7 mlr** command in privileged EXEC mode.

| Command                             | Purpose                       |
|-------------------------------------|-------------------------------|
| Router# <b>debug cs7 mlr all</b>    | Enables all debugs.           |
| Router# <b>debug cs7 mlr error</b>  | Debugs error events.          |
| Router# <b>debug cs7 mlr info</b>   | Displays informational events |
| Router# <b>debug cs7 mlr packet</b> | Displays packet events.       |

## Configuration Examples of MLR

This section includes the following examples:

- [Configuration Example of Address Modification, page 257](#) [Configuration Example for MLR: ITP Receives All SMS-MO Traffic in GT-Routed Network, page 249](#)
- [Configuration Example for MLR: Legacy SMSC Retains Point Code in PC-Routed Network, page 252](#)
- [Configuration Example for MLR: MLR Distribution to MTP3-Based SMSCs, page 254](#)
- [Examples of Configuring Routing Based on Operation Types, page 256](#)
- [Example of Routing with B-Address Binding, page 257](#)

### [Configuration Example of Address Modification, page 257](#) **Configuration Example for MLR: ITP Receives All SMS-MO Traffic in GT-Routed Network**

In this example, a mated pair of ITPs is positioned between the core SS7 network STPs and both the legacy and voting SMSCs. The network configuration is illustrated in [Figure 30](#).

**Figure 30** *MLR: ITP Receives All SMS-MO Traffic in GT-Routed Network*

141723

The STPs in the network are configured to perform final GTT toward the ITP SMSC complex. In GSM, the translation will be done based on the E.164 addresses of the legacy SMSCs. In IS-41, the translation will be done using TT=12 to map the MIN to the serving MC. In either case, the GTT translations must be changed to map to the mated-ITP pair's PC for SMSC processing, 1.1.3. No GTT is performed on the ITPs.

GAIT/GHOST SMS MO messages carried over ANSI-41 arrive at ITP1 destined for the SMSC point-code 1.1.3. An SCCP cdPa trigger based on PC/SSN will signal parsing of the TCAP, MAP and SMS routing layers. There will be a trigger for GSM MAP, as well as IS-41/GHOST based on the SSNs 8 and 11, respectively. The GSM-RULES and TDMA-RULES rulesets are then referenced to determine if the destination SME address represents a voting event. Note that each ruleset uses the same dest-sme address tables for efficient best-match lookup.

If a voting event is determined, the message is routed to the selected voting SMSC, otherwise the message is routed to the legacy SMSC. Note that SMS\_Notification messages with the same destination SME pattern are routed to the same SMSC ASes. This configuration assumes that the voting SMSCs are all ASPs within the same AS using a routing-key of PC 1.1.3.

## Configuration Example for MLR: Legacy SMSC Retains Point Code in PC-Routed Network

In this example, a mated pair of ITPs is positioned between the core SS7 network STPs and both the legacy and voting SMSCs. The network configuration is illustrated in [Figure 31](#)

**Figure 31** .MLR: Legacy SMSC Retains Point Code in PC-Routed Network

GAIT/GHOST SMS MO messages carried over ANSI-41 arrive at ITP1 destined for the legacy SMSC point-code 2.1.1. An MTP3 MLR trigger based on the DPC, SI and SCCP sub-trigger of cdPa SSN will signal parsing of the TCAP, MAP and SMS routing layers. The GSM-RULES ruleset is then referenced to determine if the destination SME address represents a voting event.

IS-136 and IS-95 SMS MO messages arrive at ITP1 destined for the legacy SMSC PC 2.1.2. The TDMA-RULES ruleset is then referenced to determine if the destination SME address represents a voting event.

If a voting event is determined, the message is routed to the selected voting SMSC, otherwise the message is routed to the legacy SMSC. Note that SMS\_Notification messages with the same destination SME pattern are routed to the same SMSC ASes. This configuration assumes that the voting SMSCs are all ASPs within the same AS using a routing-key of PC 1.1.3.

## Configuration Example for MLR: MLR Distribution to MTP3-Based SMSCs

In this example, additional SMSCs are introduced in order to distribute load based on MIN. The legacy SMSC PC is 2.1.1, and is the DPC for all MO SMS messages. MTP3-based MLR triggers are used to distribute the traffic based on the destination SME address, which in this case will be a MIN. The network configuration is illustrated in [Figure 32](#).

**Figure 32**      **MLR Distribution to MTP3-Based SMSCs**

```

## Examples of Configuring Routing Based on Operation Types

The following are examples of configuring routing based on operation types.

### Example: Configure Routing Based on SMS MT Parameters

Specify one or more of the SMS MT routing parameters when defining a rule with the sms-mt operation type. Then specify the result destination for the message via the result parameter. Rules are searched sequentially for a match, and rulesets may contain a mixture of rules defining any operation type.

In the following example, all SMS MT messages destined to the MSC 11111 with a destination SME (or mobile) IMSI of 238012650007149 are routed via the MLR distribution group named CLUSTER. SMS MT messages originating from the mobile MSISDN 9193922900 are routed to pc 1-3-1. All other SMS MT messages are routed to pc 1-2-1.

```
cs7 mlr result CLUSTER
pc 1-1-1 weight 5
pc 2-2-2 weight 1
pc 3-3-3 weight 0

cs7 mlr ruleset SMSMT gsm-map
rule 10 sms-mt
dest-sme 238012650007149
result group CLUSTER
rule 20 sms-mt
orig-sme 9193922900
result pc 1-3-1
rule 30 sms-mt default
result pc 1-2-1

cs7 mlr table MT-ROUTING
trigger cdpa gt 11111 tt 10 ruleset SMSMT
```

### Example: Configure Routing Based on SRI SM Parameters

Specify one or more of the SRI SM routing parameters when defining a rule with the sri-sm operation type. Then specify the result destination for the message via the result parameter. Rules are searched sequentially for a match, and rulesets may contain a mixture of rules defining any operation type.

In the following example, all SRI-SM messages destined to the HLR 44444 with a destination SME (MSISDN) of 9191112222 are routed via the MLR distribution group 'cluster'. All other SRI-SM messages are routed to pc 1-3-1.

```
cs7 mlr result CLUSTER
pc 1-1-1 weight 5
pc 2-2-2 weight 1
pc 3-3-3 weight 0

cs7 mlr ruleset SRISM gsm-map
rule 10 sri-sm
dest-sme 9191112222
result group CLUSTER
rule 20 sri-sm default
result pc 1-3-1
```

```
cs7 mlr table SMS-BLOCKING
trigger cdpa gt 44444 tt 10 ruleset SRISM
```

## Example of Routing with B-Address Binding

### MLR with Dynamic B-Address Binding

The following example shows a configuration in which MLR uses dynamic B-address binding to select a result for a set of SMS-MO messages. The dest-sme-binding mode uses a weighted distribution algorithm which binds a set of B-addresses to the same available result.

```
cs7 instance 0 mlr result MLR-BIND mode dest-sme-binding
pc 5.5.3 order 100 weight 20
pc 1.5.6 order 200 weight 40
pc 5.5.5 order 300 weight 15
pc 5.5.6 order 400 weight 60
!
cs7 instance 0 mlr address-table MLR-ADDRS
addr 1416
addr 1800
addr 2345
addr 919
!
cs7 instance 0 mlr ruleset MLR-RULES gsm-map
rule 100 sms-mo
dest-sme-table MLR-ADDRS
result group MLR-BIND
!
cs7 instance 0 mlr table MLR-TBL
trigger default ruleset MLR-RULES
```

## Configuration Example of Address Modification

The following example illustrates how to use the MLR SRI-SM address modification enhancement. Rule 10 indicates that MLR should modify both the SCCP CgPA and MAP Service Center Address fields. The MSU is then routed by MLR toward the original SCCP CdPA, which may include a local GT translation being performed by ITP.

```
cs7 variant itu
cs7 point-code 1-1-1

cs7 gtt selector e164 tt 0 gti 4 np 1 nai 4

4
```

```
trigger cgpa gt 3977777777 tt 0 gti 4 np 1 nai 4 ruleset FROM_MMSC
```

# How to Configure Packet Address Modification (PAM)

PAM is a general purpose mechanism to modify SCCP and MTP Header addresses. It is similar to the modify-profile MLR feature, but applies to all Cisco ITP supported MSU types.

PAM can modify these packet address fields:

- Originating Point Code (OPC)
- Destination Point Code (DPC)
- Calling Party Address (CgPA)
- Called Party Address (CdPA)
- Address Modification Points

These packet address fields can be modified at the following points:

- The point of ingress after GWS screening
- The point of egress after GWS screening
- MLR modify-profile operations
- GTT operations (as part of post-GTT address conversion)

## PAM CdPA and CgPA Modifications

CdPA and CgPA modification includes support for inserting a point code (PC) and subsystem number (SSN), as well as modifying the existing GT information, PC, and SSN. The CdPA and CgPA routing indicator (RI) is unchanged during these modifications. The PC and the SSN may be inserted or modified regardless of the RI.

The GT information that can be modified includes the GT address digits, the GT translation type (tt), the global title indicator (gti), the numbering plan (np), and the nature of address indicator (nai).

**Note**

Modifications of these parameters are allowed only when RI is set to GT. Otherwise, they are ignored.

For prefix-based GT address translation, you can configure the number of prefix digits to be removed from the address and the digit string that should be prefixed to the address. Specifying a wildcard (\*) for the number of prefix digits indicates that no digits will be removed. Specifying a wildcard (\*) for the digit string indicates that no prefix digits are added to the address string. If the resulting modified address exceeds the maximum allowed number of digits, then PAM fails the modification and discards the packet by default. You can optionally configure the preferred action for failed modifications using the modify-failure command within PAM submenu.

If the number of digits in the modified address is less than 1 digit or more than 30 digits, the address modification cannot be performed. In this case, the action taken is based on the configured modify-failure option. By default, the packet is discarded if it cannot be modified as specified.

The CdPA and CgPA routing indicator (RI) is unchanged during these modifications.

**Note**

Take care when applying PAM to send traffic and response messages in the desired direction. For instance, if a UDTs packet is generated in response to UDT with routing indicator "Route on GT," GTT must be properly configured to route UDTs towards the desired node.

## PAM in GWS

PAM can operate through GWS inbound and outbound screening. Using a configured GWS rule, a PAM modify-profile can change the packet header address. After the modification by PAM, the packet can be routed out or sent to the MLR/SCCP layer according to the result of the GWS action set. To learn more about GWS action sets, see [“Defining GWS Action Sets” section on page 180](#).

## PAM in MLR

PAM can also operate through MLR functionality in a manner similar to the MLR modify profile feature. When PAM is defined in an MLR rule, the PAM can modify the packet address. To learn more about the MLR modify profile feature and MLR rules, see the [“How to Configure MLR-Based Routing” section on page 205](#).

## PAM Modify Failure

If any error occurs during the modification of packets by PAM, a modify failure behavior can be selected with the configuration of the PAM's **modify-failure** command.

## PAM Limitations

Cisco ITP supports a maximum of 100 PAM tables.

PAM does not support the following:

- Instance conversion, variant conversion, or screening on virtual linksets
- SMS rule reference PAM
- PAM in GWS for SGMP AS
- The following modifications are also not supported:
  - MTP Service Indicator (SI), Message Priority, SLS
  - M3UA network appearance
  - SUA Address Indicator
  - SCCP Routing indicator, SCCP/SUA Protocol Class

# Configuring PAM

## Note

The MLR modify-profile and PAM cannot be configured simultaneously.

To define a PAM, perform the following steps:

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 instance** *instance-number* **pam** *pam-name*
4. **cgpa** [**gt** [**prefix** {*prefix-remove-num* | \*}]{*prefix-add-digits* | \*}] [**tt** *tt*] [**gti** {2 | 4 **np** *np* **nai** *nai*}] [**pc** *pc*] [**ssn** *ssn*]
5. **cdpa** [**gt** [**prefix** {*prefix-remove-num* | \*}]{*prefix-add-digits*|\*}] [**tt** *tt*] [**gti** {2 | 4 **np** *np* **nai** *nai*}] [**pc** *pc*] [**ssn** *ssn*]
6. **dpc** *point-code*
7. **opc** *point-code*
8. **modify-failure** {**discard** | **resume** | **sccp-error** *sccp-error*}

## DETAILED STEPS

|        | Command or Action                                                                                                                     | Purpose                                                                                                                                                                                                                                                 |
|--------|---------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                   | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted.                                                                                                                                                  |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                           | Enters global configuration mode.                                                                                                                                                                                                                       |
| Step 3 | <b>cs7 instance</b> <i>instance-number</i> <b>pam</b> <i>pam-name</i><br><br><b>Example:</b><br>ITP(config)# cs7 instance 0 pam alpha | Identifies a PAM table and enters the CS7 PAM submode.<br><br><ul style="list-style-type: none"> <li><i>pam-name</i> Creates the PAM table name. The name is specified as an alpha-numeric character string with a maximum of 12 characters.</li> </ul> |

## Step 4

| Command or Action                                                                                                                                                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Step 8 | <b>modify-failure {discard   resume   sccp-error sccp-error}</b><br><br><b>Example:</b><br>modify-failure resume | Specifies the desired action when the PAM table packet modification fails. |

## Configuration Examples of PAM

The following example shows a configuration for the PAM table pam1:

```
cs7 instance 0 pam pam1
  cgpa gt prefix tt 0 pc 1.2.3 ssn 12
  cdpa gt prefix 15 123456789abcdef tt 250 gti 4 np 15 nai 127 pc 1.123.4 ssn 255\n
  opc 1.2.3
  dpc 2.3.4
  modify-failure resume
```

The following example shows how to configure a GTA pcssn entry that refers to a PAM table named pam1:

```
cs7 instance 1 gtt selector test1 tt 0 gti 2
  gta 123 pcssn 1.2.3 gt pam pam1
```

The following example shows how to configure separate GTA asname entries that refer respectively to PAM tables named pam2 and pam3:

```
cs7 instance 1 gtt selector test1 tt 0 gti 2
  gta 124 asname as1 gt pam pam2
  gta default asname as2 gt pam pam3
```

## SMS MO Proxy

---

### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

---

IP Transfer Point (ITP) supports the Short Message Service (SMS) Mobile Originator (MO) Proxy feature. SMS MO proxy facilitates the routing of SMS messages sent from a mobile subscriber to the short message service center (SMSC).

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. ## Information About SMS MO Proxy

SMS MO Proxy uses the following configuration constructs to facilitate routing of short messages:

- **route-table**  
The route table allows the specification of the types of incoming messages that will be accepted for processing and indicates which ruleset to use for a given traffic type.
- **ruleset**  
Rulesets describe a list of rules to traverse in an ordered fashion. Within each rule, checks can be made to compare the configured parameters to the message being processed. For example, origin IMSI, source address, destination address, etc. may be compared within an SMS MO rule. If a rule

matches the inbound message, the corresponding result configured within the rule submode will be executed. The rules are traversed until the message is blocked, successfully routed, or until all rules within the ruleset have been exhausted.

- **address-table**  
Address tables are referred to by rules and allow the listing of large numbers of addresses to be compared during a specific rule. Address tables can be saved and loaded from flash memory or external servers.
- **result**  
Configured within the rule submode or within an address table, a result specifies the action to be performed on messages matching the rule. The following actions are supported:
  - **result block**: A negative acknowledgement is sent to the requester.
  - **result next-rule**: Proceed to the next rule within the ruleset.
  - **result rule**: Skip to the specified rule found later in the ruleset.
  - **result pc**: Attempt to route this request to an SMSC, routing to the SMSC's point code address.
  - **result gt**: Attempt to route this request to an SMSC, routing to the SMSC's global title address.
  - **result group**: A result group table lists the set of possible routing destinations along with the associated algorithm used to select among the destinations.
  - **result obtain-orig-imsi**: Attempt to obtain the origin IMSI of the SMS MO message.
- **result groups**  
Result groups describe a system for load balancing and fail-over for various acceptable destinations for a message. Result group type SMSC is used to route messages to a group of SMSCs.

## How to Configure SMS MO Proxy

This section describes the tasks to configure SMS MO Proxy.

- [Configuring SMSC Result Groups, page 268](#)
- [Creating and Managing SMS Address Tables, page 271](#)
- [Configuring SMS Rulesets, page 278](#)
- [Defining GSM Transport Parameters, page 292](#)

## Configuring SMSC Result Groups

When routing messages to an SMSC group, the group identifies a group of resources to process traffic. The group lists the appropriate resources and the mechanism used to select a single member for a given packet. State information is determined for each possible destination. Only available destinations are considered for routing.

There are two group distributions modes available: weighted round-robin (WRR) and dynamic B-address binding.

The **weighted round-robin** (WRR) distribution algorithm properly balances SMS workload to servers of varying capacity. Each server within an SMSC group is assigned a server weight from 0 to 10. The value of 0 indicates that the server is a backup, and should only be used when all of the servers in the

group with a non-zero weight are unavailable. By default congested resources are used only when all non-zero weighted servers are congested. Instead of relying only on unavailability to trigger the use of a backup server, the **congestion-mode defer-to-backup** command in CS7 SMS group configuration mode sets congestion as an additional trigger for the use of a backup server.

**Dynamic B-address binding** uses a hashing algorithm based on the message's B-address to determine which group member (SMSC) a message is to be routed to for delivery. The algorithm will select the same group member (SMSC) each time based on the B-address to prevent out-of-order messaging. SMSCs with greater capacity are configured as such using the weight parameter. The group members (SMSCs) are inserted using the order parameter. If an unplanned SMSC outage occurs (in other words, if a group member is unavailable), then the messages destined for the unavailable SMSC are rerouted to the remaining SMSCs. Note that an SMSC outage does not affect the mapping for available SMSCs. This algorithm handles routing of alphanumeric B-addresses, as well as numeric B-addresses.

SMS MO proxy messages can use MLR result groups with WRR or dest-sme-binding modes. This simplifies configuration since both SMS MO Proxy and MLR dest-sme-binding result groups must be identically configured in an SMS MO Proxy solutions.

**Note**

Global title results in an SMS results group are always considered available. Ensure that the proper GT configuration is in place and available for GT routing.

This section includes the following task:

- [Configuring an SMSC Result Group, page 269](#)

## Configuring an SMSC Result Group

### SUMMARY STEPS

1. **enable**
2. **configure {terminal | memory | network}**
3. **cs7 sms group *name* smsc protocol {gsm-map [mode [wrr | dest-sme-binding]]}**
4. **congestion-mode defer-to-backup**
5. **pc *pc* [ssn *ssn*] order *order* [weight *weight*]**
6. **gt *addr-string* [tt *tt*] [gti *gti*] [np *np* nai *nai*] [order *order*] [weight *weight*]**

### DETAILED STEPS

|        | Command or Action                                                                                | Purpose                                                        |
|--------|--------------------------------------------------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                                                    | Enables higher privilege levels, such as privileged EXEC mode. |
|        | <b>Example:</b><br>ITP> enable                                                                   | Enter your password if prompted.                               |
| Step 2 | <b>configure {terminal   memory   network}</b><br><br><b>Example:</b><br>ITP# configure terminal | Enables global configuration mode.                             |

|        | Command or Action                                                                                                                                                                                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Examples

The following example shows the configuration of an SMSC group named SMSCGRP.

```
cs7 sms group SMSCGRP smsc
pc 3.1.2 weight 1
pc 3.1.3 weight 1
```

## Creating and Managing SMS Address Tables

This section describes the configuration, storage, and retrieval of SMS address tables, which are lists of addresses that can be used for blocking or routing SMS messages. SMS address tables are normally stored in NVRAM on the IOS platform. NVRAM limitations on some platforms might restrict the number of address entries that can be stored there. You can also save SMS address table as individual SMS address table files externally on flash or at another location specified with a URL.

Prefix based address modification is configured with the **modify** keyword and the following parameters:

- *prefix-remove-num* The number of prefix digits that will be removed from the address
- *prefix-add-digits* The digit string that will be added to the beginning of the address
- *new-ton* The type of number (TON) that will be assigned to the modified address
- *new-np* The numbering plan (NP) that will be assigned to the modified address.

A null operator, \*, can be specified for any of these parameters, and indicates that no change will be made in that parameter. For example, **modify \* 123 \* \*** specifies that no prefix digits are to be removed, the digits 123 will be added to the beginning of the address, and the TON and NP will be unmodified from their original received values.

For **orig-sme** and **dest-sme**, the **modify** keyword is specified directly on the filter. For **orig-sme-table** and **dest-sme-table**, the **modify** keyword is specified on the **addr** statement in the address table to which the filter refers, or directly on the filter within the ruleset. Modification parameters specified on the **addr** statement within a table take precedence over modification parameters specified on the rule. This allows you to create complex address translation rules if required in the network.

Once address translation is performed, subsequent rules that attempt to match on that address must be configured to match the address in its current modified form, not the original address. For example, assume the original received destination SME address is 04445555 with TON 0 and NP 1. If rule 20 performs prefix address modification of **modify 1 31 1 1**, the current working address becomes 314445555 **ton 1** and **np 1**. If further rules are coded to match the destination SME address, they will be tested against the 31444555 address, not the original 04445555 address.

It is permissible to cascade address modification rules. For example, if rule 30 performs an address modification on the destination SME address, it is permissible for a subsequent rule, such as rule 40, to also perform destination SME address modification. The resultant address will be the combination of whatever modifications rule 30 requested, followed by whatever modifications rule 40 requested. It is also permitted to modify both the origin and destination SME addresses within the same rule. However, all rule filters must match before any address modification is performed within a given rule.

This section includes the following tasks:

- [Creating and Loading an SMS Address Table Using the CLI, page 272](#)
- [Creating and Loading a Stored SMS Address Table File, page 276](#)
- [Replacing an Existing SMS Address Table File, page 277](#)

## Creating and Loading an SMS Address Table Using the CLI

In this task you use the CLI to configure address table entries that you plan to save to an external file. You then specify a location from which you will load the file of address table entries upon reboot. Finally you save the address entries to a an external file.

### SUMMARY STEPS

1. **enable**
2. **configure** {**terminal** | **memory** | **network**}
3. **cs7 sms address-table** *tablename*
4. **addr** *address* [**exact**] [**modify** {*prefix-remove-num* | \*} {*prefix-add-digits* | \*} {*new-ton* | \*} {*new-np*}}] [**result** {**block** | **next-rule** | **group** *group-name* | **pc** *dest-pc* [*ssn ssn*] | **gt** *addr-string* [**tt** *tt* **gti** {**2** | **4** np *np* nai *nai*}}]]
5. **load** *URL*
6. **exit**
7. **cs7 save address-table sms** *tablename url*

## DETAILED STEPS

|        | Command or Action                                                                                             | Purpose                                                                                                                                                                       |
|--------|---------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                           | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted.                                                                        |
| Step 2 | <b>configure {terminal   memory   network}</b><br><br><b>Example:</b><br>ITP# configure terminal              | Enables global configuration mode.                                                                                                                                            |
| Step 3 | <b>cs7 sms address-table tablename</b><br><br><b>Example:</b><br>ITP(config)# cs7 sms address-table ADDR_TBL1 | Identifies the name of the address table. This name is used to identify the address table from within SMS ruleset commands. Enables CS7 SMS address table configuration mode. |

## Step 4

| Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|        | <b>Example:</b><br><pre>ITP(config)#cs7 save address-table sms ADDRtbl1 disk0:SMSADDRtbl</pre> |                                                                 |

## Creating and Loading a Stored SMS Address Table File

Address tables are typically created and stored to a file using the ITP CLI. But you can also use address tables created externally by loading the address table file into the ITP. An external file can be created with a network management tool or by an advanced user and may be useful for integrated tooling.

To create and load a stored address table, perform the following steps.

### SUMMARY STEPS

1. Create a file of addresses following the format and syntax described in .
2. **enable**
3. **configure {terminal | memory | network}**
4. **cs7 sms address-table** *tablename*
5. **load** *URL*

### DETAILED STEPS

|        | Command or Action                                                                                                              | Purpose                                                                                                                                                                              |
|--------|--------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | Create a file of addresses, following the format and syntax described in Tables 1 - 4.                                         |                                                                                                                                                                                      |
| Step 2 | <b>enable</b><br><br><b>Example:</b><br><pre>ITP&gt; enable</pre>                                                              | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted.                                                                               |
| Step 3 | <b>configure {terminal   memory   network}</b><br><br><b>Example:</b><br><pre>ITP# configure terminal</pre>                    | Enables global configuration mode.                                                                                                                                                   |
| Step 4 | <b>cs7 sms address-table</b> <i>tablename</i><br><br><b>Example:</b><br><pre>ITP(config)# cs7 sms address-table ADDRtbl1</pre> | Identifies the name of the address table. This name is used to identify the address table from within SMS ruleset commands.<br><br>Enables CS7 SMS address table configuration mode. |

|        | Command or Action                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <p><b>load</b> <i>URL</i></p><br><br><br><br><br><br><br><br><br><br><br><br><br><br><br><br><br><br><br><br><br><br><p><b>Example:</b><br/> ITP(cfg-cs7-sms-addr-table)# load<br/> disk0:SMSADDR_TBL</p> | <p>(Optional) Specifies an address table file to load at startup.</p> <ul style="list-style-type: none"> <li>• bootflash: URL to load</li> <li>• cs7: URL to load</li> <li>• disk0: URL to load</li> <li>• disk1: URL to load</li> <li>• flash: URL to load</li> <li>• ftp: URL to load</li> <li>• null: URL to load</li> <li>• nvram: URL to load</li> <li>• rcv: URL to load</li> <li>• slavebootflash: URL to load</li> <li>• slavecdfs: URL to load</li> <li>• slavedisk0: URL to load</li> <li>• slavedisk1: URL to load</li> <li>• slavenvram: URL to load</li> <li>• slavercsf: URL to load</li> <li>• slaveslot0: URL to load</li> <li>• slaveslot1: URL to load</li> <li>• slot0: URL to load</li> <li>• slot1: URL to load</li> <li>• system: URL to load</li> <li>• tftp: URL to load</li> </ul> |

## Replacing an Existing SMS Address Table File

You can replace an existing address table. The replacement does not impact routing until the entire replacement address table is loaded successfully. If an error occurs, the old address table (if present) remains intact. Each time an address table is replaced, the corresponding **load** command is added to the running configuration and the individual addresses are removed from the running configuration.

## SUMMARY STEPS

1. **enable**
2. **cs7 address-table replace sms *tablename url***

## DETAILED STEPS

|        | Command or Action                                                                    | Purpose                                                         |
|--------|--------------------------------------------------------------------------------------|-----------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                                        | Enables higher privilege levels, such as privileged EXEC mode.  |
|        | <b>Example:</b><br>ITP> enable                                                       | Enter your password if prompted.                                |
| Step 2 | <b>cs7 address-table replace sms <i>tablename url</i></b>                            | Replaces an existing address table with one specified in a URL. |
|        | <b>Example:</b><br>ITP# cs7 address-table replace sms ADDR_TBL1<br>disk0:SMSADDR_TBL |                                                                 |

## Examples

The following example shows three address tables. Two of the address tables are loaded from stored files at startup. The third address table and the addresses in the table are configured from within the configuration.

```
cs7 sms address-table IMSI-SCREEN
  load disk0:IMSI-SCREEN
!
cs7 sms address-table ORIG-SCREEN
  load disk0:ORIG-SCREEN
!
cs7 sms address-table SHORTCODES
  addr 11112 result group GRP2
  addr 1111 result group GRP1
  addr 2222 result group GRP1
  addr 5551212 exact result group GRP3
```

## Configuring SMS Rulesets

This section describes how to configure SMS Rulesets and specify rules within the rulesets.

A ruleset is a set of ordered rules, each with an input condition and a corresponding result that occurs if all of that rule's conditions match.

You can configure multiple rules within a ruleset. Each rule has one or more input conditions, all of which must be true for the rule to be considered a match. For each rule match, the corresponding result will execute.

Rules within the ruleset will be checked sequentially until either the message is blocked, routed successfully, or until the last rule is attempted. Backup routing can be achieved by sequencing backup routing results after primary results. If routing to the primary result fails, the backup will be attempted.

The **orig-sme-table** command is valid for SMS MO rule operations. If the address-table lookup finds a match and returns a result, it may only be used if no other routing parameters are defined on this rule. If more than one parameter is configured in a rule, then the result specified under the rule is used.

- **Prefix Based Address Modification**

Prefix based address modification is configured with the **modify** keyword and the following parameters:

- *prefix-remove-num* The number of prefix digits that will be removed from the address
- *prefix-add-digits* The digit string that will be added to the beginning of the address
- *new-ton* The type of number (TON) that will be assigned to the modified address, and
- *new-np* The numbering plan (NP) that will be assigned to the modified address.

A null operator, \*, can be specified for any of these parameters, and indicates that no change will be made in that parameter. For example, `modify * 123 * *` specifies that no prefix digits are to be removed, the digits 123 will be added to the beginning of the address, and the TON and NP will be unmodified from their original received values.

For **orig-sme** and **dest-sme**, the **modify** keyword is specified directly on the filter. For **orig-sme-table** and **dest-sme-table**, the **modify** keyword is specified on the **addr** statement in the address table to which the filter refers, or directly on the filter within the ruleset. Modification parameters specified on the **addr** statement within a table take precedence over modification parameters specified on the rule. This allows you to create complex address translation rules if required in the network.

Once address translation is performed, subsequent rules that attempt to match on that address must be coded to match the address in its current modified form, not the original address. For example, assume the original received destination SME address is 04445555 with TON 0 and NP 1. If rule 20 performs prefix address modification of `modify 1 31 1 1`, the current working address becomes 314445555 ton 1 and np 1. If further rules are coded to match the destination SME address, they will be tested against the 31444555 address, not the original 04445555 address.

It is also permissible to cascade address modification rules. For example, if rule 30 performs an address translation on the destination SME address, it is permissible for a subsequent rule, such as rule 40, to also perform destination SME address translation. The resultant address will be the combination of whatever modifications rule 30 requested, followed by whatever modifications rule 40 requested. It is also permitted to modify both the origin and destination SME addresses within the same rule. However, all rule filters must match before any address modification is performed within a given rule.

For address tables, the prefix address modification may be specified on either the **addr** statement or directly on the **orig-sme-table** or **dest-sme-table** filter command. While any operation or address table lookup may refer to that **addr**, the **modify** operand will only be applied when the operation is one of the supported operations above, and the filter must be **orig-sme-table** or **dest-sme-table**. Modification parameters specified on the **addr** statement within a table will take precedence over modification parameters specified on the rule.

#### • Automatic Address Modification

Automatic address modification is used to normalize a received address into international form. Automatic address modification will typically occur at the very beginning of a ruleset processing SMS MO messages.

Automatic address modification is only supported on the destination SME address, and is only available when using the **dest-sme** rule filter for the **gsm-map sms-mo** operation.

The following hierarchical rules are used to normalize the address:

1. Automatic address modification is not applied if the address already indicates an international format (TON = 1).
2. Automatic address modification is only applied to addresses with an NP value of Unknown (0) or ISDN/E.164 (1). An NP value of Unknown is automatically converted to ISDN/E.164 (1).
3. If TON is national format (2), then the configured country code is added to the beginning of the address, and the TON is modified to international (1).

4. If TON is unknown (0) and the prefix of the address matches the configured international prefix string, then remove the international prefix and change the TON to international (1).
  5. If TON is unknown (0) and the prefix of the address matches the configured national (trunk) prefix string, then remove the national (trunk) prefix, add the configured country code string to the beginning of the address and change the TON to international (1).
  6. If TON is unknown (0) and the national prefix was not configured, then add the configured country code string to the beginning of the address and change the TON to international (1).
- **Origin SME Prefix Based Modification**

In origin SME prefix based modification, the prefix of the origin SME address is used to normalize a received destination SME address into international format. This type of address modification usually also depends on a specific number of digits being included in the destination SME address (e.g, 7-digit local number dialing in North America). The underlying premise is that the origin SME address in the message is always sent in international format, so the country code (CC) and national destination code (NDC) portions of the E.164 address can be extracted from the beginning of the received origin SME address.

Origin SME prefix based address modification is only supported on the destination SME address, and is only available when using the **dest-sme** rule filter for the **gsm-map sms-mo** operation.

The following hierarchical rules are used to normalize the address:

1. Origin SME prefix based address conversion is not applied if the destination SME address already indicates an international format (TON = 1).
2. If the prefix of the destination SME address matches the configured international prefix string, then remove the international prefix and change the TON to international (1).
3. Compare the lengths of the origin SME and destination SME addresses. If the origin SME address is longer, the difference represents the length of the CC and NDC prefix.
  - a. If the prefix of the destination SME address matches the configured national (trunk) prefix string, then remove the national (trunk) prefix from the destination SME address.
  - b. Copy the CC-NDC prefix from the origin SME address, prefix it to the destination SME address, and change the destination SME address TON to international (1).

## Prerequisites

If the ruleset specifies a result that routes the message using a group, you must have already specified the group. See the [“Configuring SMSC Result Groups” section on page 268](#).

## Restrictions

The **dest-sme-table**, **orig-imsi-table**, and **orig-sme-table** rule parameters accept either an SMS address-table name OR an MLR address-table name. This capability is primarily for customers who want the SMS-MO Proxy functionality. Therefore, SMS and MLR address table names must be unique across all instances. You may enter an MLR address-table name for an SMS rule parameter. However, MLR cannot reference SMS address-tables.

If an incoming message matches an SMS rule that references an MLR address-table, then any MLR address-table result is mapped to an SMS result:

- BLOCK, PC, and PCSSN results map easily from MLR to SMS.

- For result groups, SMS is searched first for the corresponding group name. If not found, then MLR is searched for the specified result group name. If the result group is not configured, then the result specified on the rule is used.
- AS and CONTINUE results are not valid in SMS. For these cases, the result specified on the rule is used.
- If no result is specified, the result on the rule is used.

## SUMMARY STEPS

Steps 1. through 6. are required in the order shown.

Steps 7. through 16. are optional input conditions for a rule.

Each time you enter one of the input condition commands you must specify the result. Step 17. specifies the result.

1. **enable**
2. **configure** { **terminal** | **memory** | **network** }
3. **cs7 sms ruleset** *name* [**protocol** { **gsm-map** | **ansi41** }] [**event-trace**]
4. **rule** *order operation-name*
5. **match-unknown** **ton-np**
6. **dest-port** *dest-port-number*
7. **dest-sme** { \* | *dest-address* } [**exact**] [**min-digits** *min*] [**max-digits** *max*] [**ton** *ton-value* **np** *np-value*] [**modify** { *prefix-remove-num* | \* } { *prefix-add-digits* | \* } { *new-ton* | \* } { *new-np* | \* }]
8. **dest-sme** { \* | *dest-address* } [**exact**] [**min-digits** *min*] [**max-digits** *max*] [**ton** *ton-value* **np** *np-value*] [**auto-modify** **cc** *country-code* [**int-pfx** *international-prefix*] [**nat-pfx** *national-prefix*]]
9. **dest-sme** { \* | *dest-address* } [**exact**] [**min-digits** *min*] [**max-digits** *max*] [**ton** *ton-value* **np** *np-value*] [**orig-sme-modify** [**int-pfx** *international-prefix*] [**nat-pfx** *national-prefix*]]
10. **dest-sme-table** *tablename* [**ton** *ton-value* **np** *np-value*] [**modify** { *prefix-remove-num* | \* } { *prefix-add-digits* | \* } { *new-ton* | \* } { *new-np* | \* }]
11. **dest-smsc** { \* | *dest-address* } [**exact**] [**min-digits** *min*] [**max-digits** *max*] [**ton** *ton-value* **np** *np-value*]
12. **orig-imsi** { \* | *imsi-address* | **unknown** } [**exact**] [**min-digits** *min*] [**max-digits** *max*]
13. **orig-imsi-table** *tablename* [**ton** *ton-value* **np** *np-value*]
14. **orig-sme** { \* | *address* } [**exact**] [**min-digits** *min*] [**max-digits** *max*] [**ton** *ton-value* **np** *np-value*] [**modify** { *prefix-remove-num* | \* } { *prefix-add-digits* | \* } { *new-ton* | \* } { *new-np* | \* }]
15. **orig-sme-table** *tablename* [**ton** *ton-value* **np** *np-value*] [**modify** { *prefix-remove-num* | \* } { *prefix-add-digits* | \* } { *new-ton* | \* } { *new-np* | \* }]
16. **pid** *protocol-id*
17. **result** { **block** | **next-rule** | **group** *result-group* | **gt** *addr* [**tt** *tt*] | **pc** *dest-pc* [**ssn** *ssn*] | **rule** *index* | **obtain-orig-imsi** [**next-rule**] | **validate-orig-msc** [ **exit** | **gt-mismatch** *next-rule* | **negative-reply** *next-rule* | **no** | **pc-mismatch** *next-rule* | **timeout** *next-rule* ] }

## DETAILED STEPS

|        | Command or Action                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                                                                        | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 2 | <b>configure</b> { <b>terminal</b>   <b>memory</b>   <b>network</b> }<br><br><b>Example:</b><br>ITP# configure terminal                                                                    | Enables global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Step 3 | <b>cs7 sms ruleset name</b> [ <b>protocol</b> { <b>gsm-map</b>   <b>ansi41</b> }] [ <b>event-trace</b> ]<br><br><b>Example:</b><br>ITP(config)# cs7 sms ruleset SMS-RULES protocol gsm-map | Specifies a CS7 SMS ruleset and application layer protocol filter for the ruleset. <ul style="list-style-type: none"> <li>• <b>protocol</b> Specifies an application layer protocol filter for this ruleset. The default behavior is that all operations may be specified within the ruleset.</li> <li>• <b>gsm-map</b> Uses GSM-MAP as application layer protocol filter within the ruleset. Only <b>gsm-map</b> operations may be specified within the ruleset.</li> <li>• <b>ansi41</b> Uses ANSI-41 as application layer protocol filter within this ruleset. Only <b>ansi41</b> operations may be specified within the ruleset.</li> </ul> Configuring the <b>cs7 sms ruleset</b> command enables CS7 SMS set rule configuration mode in which you can configure rules that customize the routing of messages. |
| Step 4 | <b>rule</b> <i>order operation-name</i><br><br><br><br><br><br><br><br><br><b>Example:</b><br>ITP(cfg-cs7-sms-set)# rule 10 sms-mo                                                         | Within the ruleset, specifies a rule and the order in which it is searched.<br><br><i>order</i> Specifies the order in which rules are searched. Valid numbers are 1 to 1000.<br><br><i>operation-name</i> Specifies the operation for which the rule is valid. Valid <i>operation-name</i> parameters are: <ul style="list-style-type: none"> <li>• <b>sms-mo</b> Identifies a rule that will operate on an SMS MO message. This operation is valid for the GSM MAP.</li> <li>• <b>smsNot</b> Identifies a rule that will operate on an ANSI41-MAP SMS Notification message.</li> </ul> Configuring the <b>rule</b> command enables CS7 SMS rule configuration mode in which you configure the input conditions of the rule.                                                                                       |
| Step 5 | <b>match-unknown-ton-np</b><br><br><b>Example:</b><br>ITP(cfg-cs7-sms-set-rule)# match-unknown-ton-np                                                                                      | Specifies that incoming messages containing parameters with unknown type-of-number (ton=0), or unknown numbering plan (np=0), will be a match to the corresponding rule parameter regardless of the rule's configured ton/np values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                   | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

An integer in the range from 1 to 20. If no prefix digits are to be removed, then the null operator <i>*</i> should be specified.</li> <li>• <i>preffix-add-digits</i> Specifies the digit string to add to the beginning of the address. Range of string is from 1 to 10 hexadecimal digits. If no digits are to be added, then the null operator <i>*</i> should be specified. If the added digits would cause the modified address to exceed 20 digits, then the address modification is not performed.</li> <li>• <i>new-ton</i> Specifies the type of number (TON) to assign to the modified address. An integer in the range from 0 to 15. If the TON is not to be modified in the received message, then the null operator <i>*</i> should be specified.</li> <li>• <i>new-np</i> Specifies the numbering plan (NP) to assign to the modified address. An integer in the range from 0 to 7. If the NP is not to be modified, then the null operator <i>*</i> should be specified.</li> </ul> </li> </ul> |

Specifies the translation type. Valid range is 0 to 255.</li> <li>• <b>gti</b> <i>gti</i> Specifies a global title indicator. Valid numbers are 2(primarily used in the ANSI domain) or 4 (used in the ITU domain).</li> <li>• <b>np</b> <i>np</i> Specifies a numbering plan. Valid range is 0 through 15.</li> </ul> |

| Command or Action                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Example:</b></p> <pre>ITP(cfg-cs7-sms-set-rule)# result pc 5.3.5 ssn 7</pre> | <ul style="list-style-type: none"> <li>• <b>nai</b> <i>nai</i> Specify a nature of address indicator. Required for a <i>gti</i> value of 4. Optional for a <i>gti</i> value of 2. Valid range is 0 through 127.</li> <li>• <b>next-rule</b> Indicates that message processing will continue with next rule.</li> <li>• <b>pc</b> <i>dest-pc</i> Indicates that message will be routed using a point code and specifies the destination point code.</li> <li>• <b>ssn</b> <i>ssn</i> Optional with <i>pc</i>. Specifies a subsystem number. Valid range is 2 to 255.</li> <li>• <b>rule</b> <i>index</i> Indicates that message processing will continue at a specified rule, and indicates the rule index. Valid range is 1 to 1000.</li> <li>• <b>obtain-orig-imsi</b> Indicates that if the originator's IMSI was not provided on the SMS-MO request, then SMR will attempt to obtain its IMSI.</li> <li>• If <b>next-rule</b> is specified for the <b>obtain-orig-imsi</b> result, then the next rule in the ruleset sequence will be executed regardless of whether the origin IMSI was successfully retrieved.</li> <li>• <b>result validate-orig-msc</b> Validates MO-SMS messages sent from MSC to SMSC or from SGSN to SMSC.</li> <li>• <b>exit</b> Exits from CS7 SMS result original MSC/SGSN validation configuration submode.</li> <li>• <b>gt-mismatch</b> GTA of GT based CgPA does not match the MSC/SGSN number in SRI-SM response.</li> <li>• <b>instance</b> Indicates the PC/PCSSN result in a local or other instance.</li> <li>• <b>negative-reply</b> HLR replies negative (reject, abort, cancel, error) for SRI-SM request.</li> <li>• <b>no</b> Negates a command or set its defaults.</li> <li>• <b>pc-mismatch</b> GTA generated by applying <i>msc-proxy-addr</i> on PC based CgPA does not match the MSC/SGSN number in SRI-SM response.</li> <li>• <b>timeout</b> Timeout for HLR SRI-SM response.</li> <li>• <b>next-rule</b> Message processing will continue with the next rule.</li> </ul> |

## Examples

The following example shows a ruleset named `sms-rules`. Each rule specifies an input condition and a result, and indicates the order of search.

```
cs7 sms ruleset SMS-RULES
rule 10 sms-mo
```

```

    orig-imsi unknown
    result group SMSGRP
rule 20 sms-mo
    orig-imsi-table IMSI-SCREEN
    result block
rule 30 sms-mo
    orig-sme-table ORIG-SCREEN ton 0 np 0
    result block
rule 40 sms-mo
    dest-sme-table SHORTCODES ton 0 np 0
    result next-rule
rule 50 sms-mo
    result deliver-mt
rule 60 sms-mo
    result group SMSGRP
!
!
```

## Defining GSM Transport Parameters

The definition of the GSM transport **must** precede the definition for handling inbound gsm messages configured under the **cs7 sms route-table** command. Conversely, the GSM transport may not be removed until the handling of all GSM operations is removed from the **cs7 sms route-table**.

To enable the configuration of GSM transport-specific parameters, perform the following steps:

### SUMMARY STEPS

1. **enable**
2. **configure** {**terminal** | **memory** | **network**}
3. **cs7 sms gsm-map ssn** *ssn*
4. **smc-map-version** *version*
5. **map-source-addr digits** *digits* [**tt** *tt* [**gti** *gti* **np** *np* **nai** *nai*]]
6. **invoke-timer** *seconds*

### DETAILED STEPS

|        | Command                                                               | Purpose                                                        |
|--------|-----------------------------------------------------------------------|----------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                         | Enables higher privilege levels, such as privileged EXEC mode. |
|        | <b>Example:</b><br>ITP> enable                                        | Enter your password if prompted.                               |
| Step 2 | <b>configure</b> { <b>terminal</b>   <b>memory</b>   <b>network</b> } | Enables global configuration mode.                             |
|        | <b>Example:</b><br>ITP# configure terminal                            |                                                                |

|        | Command                                                                                                                                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <b>cs7 sms gsm-map ssn <i>ssn</i></b><br><br><b>Example:</b><br>ITP(config)#cs7 sms gsm-map ssn 8                                                                              | Specifies the GSM transport for the SMS subsystem and enables the submode in which you can configure parameters specific to that transport. Valid subsystem numbers are in the range 2 to 255.<br><br>Enables cs7 sms gsm configuration mode.                                                                                                                                                                                                                                                                                                                                                                          |
| Step 4 | <b>smsc-map-version <i>version</i></b><br><br><b>Example:</b><br>ITP(cfg-sms-gsm)#smc-map-version 2                                                                            | Specifies a locally supported MAP version.<br><br>GSM MAP version valid version numbers are 2 and 3. The default is 3.<br><br><b>smsc-map-version</b> is the highest version that all SMS dialogues may use.                                                                                                                                                                                                                                                                                                                                                                                                           |
| Step 5 | <b>map-source-addr digits <i>digits</i> [tt tt [gti <i>gti</i> np <i>np</i> nai <i>nai</i>]]</b><br><br><b>Example:</b><br>ITP(cfg-sms-gsm)# map-source-addr digits 5551234567 | Specifies the source used for all GSM dialogues.<br><ul style="list-style-type: none"> <li>• <i>digits digits</i> Specifies the address digits, in the range of 1 to 15 digits.</li> <li>• <i>tt tt</i> Specifies the translation type, in the range 0 to 255.</li> <li>• <i>gti gti</i> Specifies the global title indicator. Valid numbers are 2 (primarily used in the ANSI domain) or 4 (used in the ITU domain).</li> <li>• <i>np np</i> Specifies the numbering plan. Valid range is 0 through 15.</li> <li>• <i>nai nai</i> Specifies the nature of address indicator. Valid range is 0 through 127.</li> </ul> |
| Step 6 | <b>invoke-timer <i>seconds</i></b><br><br><b>Example:</b><br>ITP(cfg-sms-gsm)# invoke-timer 20                                                                                 | Specifies a timer to supervise initiated dialogues.<br><br><i>seconds</i> Specifies the time in seconds.<br><br>The valid range is 1 to 30 seconds. The default is 10 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Configuring the SMS Route Table

The SMS route table specifies the types of traffic that will be processed and indicates which ruleset should be used for which type of traffic.

Depending on the SMS transport that you defined, perform the steps in one of the following tasks:

- [Configure GSM MAP Routing, page 294](#)
- [Monitoring SMS MO Proxy, page 297](#)

## Configure GSM MAP Routing

This section describes the steps for configuring an SMS route table if you have defined GSM transport parameters.

### SUMMARY STEPS

1. **enable**
2. **configure** {**terminal** | **memory** | **network**}
3. **cs7 sms route-table**
4. **transaction-timer** *seconds*
5. **traffic-rate-timer** *seconds*
6. **gsm-map sms-mo**
7. **proxy-error-use**
8. **ruleset** *ruleset*
9. **proxy-msg** {**copy** | **build** [**dest-smsc** *use-gt*]}
10. **msc-proxy-addr** [**use** {**international** | **national**}] [**tt** *tt*] [**gti** *gti*] [**np** *np* **nai** *nai*]

### DETAILED STEPS

|        | Command or Action                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                              |
|--------|------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                              | Enables higher privilege levels, such as privileged EXEC mode.<br><br>Enter your password if prompted.                                                                                                                                                                                                                                                                                               |
| Step 2 | <b>configure</b> { <b>terminal</b>   <b>memory</b>   <b>network</b> }                                            | Enables global configuration mode.                                                                                                                                                                                                                                                                                                                                                                   |
|        | <b>Example:</b><br>ITP# configure terminal                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 3 | <b>cs7 sms route-table</b><br><br><b>Example:</b><br>ITP(config)# cs7 sms route-table                            | Configures an SMS route table and enables CS7 SMS route table configuration mode.                                                                                                                                                                                                                                                                                                                    |
| Step 4 | <b>transaction-timer</b> <i>seconds</i><br><br><b>Example:</b><br>ITP(cfg-sms-route-table)# transaction-timer 30 | (Optional) Specifies maximum lifetime of a message transaction.<br><br>At a minimum, you must configure enough time to allow the processing of the transaction from a mobile subscriber.<br><br><ul style="list-style-type: none"> <li>• <i>seconds</i> Timer, in the range 5 to 3600 seconds. The default state of the transaction timer is disabled (no limit to the maximum lifetime).</li> </ul> |

|        | Command or Action                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------|--------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 5 | <b>traffic-rate-timer</b> <i>seconds</i><br><br><b>Example:</b><br>ITP(cfg-sms-route-table)# traffic-rate-timer 30 | (Optional) Specifies timer for traffic rate calculation interval. <ul style="list-style-type: none"> <li><i>seconds</i> Data collection interval, in seconds. Valid range is 60-3600 seconds. The default is 600 seconds.</li> </ul>                                                                                                                                                                                                                                                                                                               |
| Step 6 | <b>gsm-map</b> <b>sms-mo</b><br><br><b>Example:</b><br>ITP(cfg-sms-route-table)# gsm-map sms-mo                    | Configures GSM MAP routing and enables CS7 SMS GSM SMSMO configuration mode. Allows configuration of a ruleset to use for routing inbound gsm-map SMS messages. <ul style="list-style-type: none"> <li><b>sms-mo</b> Identifies the gsm-map operations which should be routed under this configuration. <b>sms-mo</b> is the only valid entry.</li> </ul> <div>  <b>Note</b> If no ruleset is configured the configuration will be incomplete and ignored. </div> |
| Step 7 | <b>proxy-error-use</b><br><br><b>Example:</b><br>ITP(cfg-cs7-sms-gsm-smsmo)# proxy-error-use                       | (Optional) Returns error information received from SMSC during last MO Proxy procedure.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Step 8 | <b>ruleset</b> <i>ruleset</i><br><br><b>Example:</b><br>ITP(cfg-cs7-sms-gsm-smsmo)# ruleset SMS-RULES              | Applies an SMS ruleset to the specified inbound traffic.<br><br>A ruleset must be configured for the <b>gsm-map sms-mo</b> configuration to take effect. If no ruleset is configured, the <b>gsm-map sms-mo</b> configuration will be incomplete and will be ignored.                                                                                                                                                                                                                                                                              |

|         | Command or Action                                                                                                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 9  | <p><b>proxy-msg</b> {<b>copy</b>   <b>build</b> [<b>dest-smsc use-gt</b>]}</p> <p><b>Example:</b><br/> <pre>ITP(cfg-cs7-sms-smsmo)# proxy-msg build dest-smsc use-gt</pre></p>                                                                                                          | <p>(Optional) Specifies how a proxied SMS MO message is constructed.</p> <ul style="list-style-type: none"> <li>• <b>copy</b> Specifies that the SMS MO Proxy should copy the MAP and SMS contents of the MO-Forward-SM message as received from the MSC. This is the default behavior.</li> <li>• <b>build</b> Specifies that the SMS MO Proxy should reconstruct the MO-Forward-SM MAP and SMS layers prior to deferring the message to an SMSC. The MO-Forward-SM message will be constructed using the MAP version specified in the <b>sm-sc-map-version</b> command, as specified under the GSM transport, and may contain modified parameters from the original SMS MO message. <ul style="list-style-type: none"> <li>– <b>dest-smsc use-gt</b> (Optional) Specifies that the SMS MO Proxy should build the destination SMSC address in the MAP layer according to the global title result used by the matched sms rule that is routing the message. If a global title result is not being used, or this option is not specified, then the originally specified destination SMSC address is preserved in the MAP layer.</li> </ul> </li> </ul> |
| Step 10 | <p><b>m-sc-proxy-addr</b> [<b>use</b> {<b>international</b>   <b>national</b>}] [<b>tt</b> <i>tt</i>] [<b>gti</b> <i>gti</i>] [<b>np</b> <i>np</i> <b>nai</b> <i>nai</i>]</p> <p><b>Example:</b><br/> <pre>ITP(cfg-cs7-sms-gsm-smsmo)# m-sc-proxy-addr use international tt 4</pre></p> | <p>(Optional) Specifies MAP MSC Proxy address. The msc proxy address is used to form the SCCP CgPA for a proxied MO dialogue.</p> <ul style="list-style-type: none"> <li>• <b>tt</b> <i>tt</i> (Optional) Specifies the translation type, in the range 0 to 255. If not configured, the tt from the original request is used.</li> <li>• <b>gti</b> <i>gti</i> Specifies a global title indicator. Valid numbers are 2 (primarily used in the ANSI domain) or 4 (used in the ITU domain).</li> <li>• <b>np</b> <i>np</i> In ITU domain, specifies a numbering plan. Valid range is 0 through 15.</li> <li>• <b>nai</b> <i>nai</i> In ITU domain, specifies a nature of address indicator. Required for a <i>gti</i> value of 4. Optional for a <i>gti</i> value of 2. Valid range is 0 through 127.</li> <li>• <b>use</b> Indicates setting for national use bit in the address indicator.</li> <li>• <b>international</b> Address has international scope (default for ITU/CHINA).</li> <li>• <b>national</b> Address has national scope (default for ANSI).</li> </ul>                                                                              |

## Monitoring SMS MO Proxy

This section lists the commands used to monitor SMS MO Proxy. The commands are listed in alphabetical order, but you may use them in any order, as needed.

The pipe (|) keyword is available in many of the **show cs7 sms** commands. This keyword enables the use of the regular expression argument with the **show cs7 sms** commands. The regular-expression argument allows for complex matching requirements. For more information on the regular expression argument, refer to the *Cisco IOS Configuration Fundamentals Command Reference*. Specific information begins with the **show <command>** entries found at:

[http://www.cisco.com/en/US/docs/ios/fundamentals/command/reference/cf\\_s1.html#wp1047446](http://www.cisco.com/en/US/docs/ios/fundamentals/command/reference/cf_s1.html#wp1047446)

For complete descriptions of the **show cs7 sms** commands, see “ITP Command Set: S - Z” section on page 1084.

### SUMMARY STEPS

1. **enable**
2. **show cs7 sms address-table** [**addr** *address* | **name** *name* | **prefix** *prefix* | | *regular-expression*]
3. **show cs7 sms dest-sme-binding** *dest-sme* [*result-group-name*]
4. **show cs7 sms group** [*name*]
5. **show cs7 sms gsm-map** [*ssn ssn*] [*statistics* [*detail* [**sms-mo** | **sms-mt** | **sri-sm** | ]]]
6. **show cs7 sms offload**
7. **show cs7 sms route-table** [*gsm-map* [**sms-mo** [*ssn ssn*]]]
8. **show cs7 sms ruleset** [**name** *name*] [*detail* | **result-summary** | **rule-summary**]
9. **show cs7 sms sms-mo msc-proxy-addr**
10. **show cs7 sms statistics** [*detail* | *rate*]

### DETAILED STEPS

|        | Command or Action                                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                  |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                                                                                                                                                                      | Enables higher privilege levels, such as privileged EXEC mode.                                                                                                                                                                                                                                                                                                           |
|        | <b>Example:</b><br>ITP> enable                                                                                                                                                                     | Enter your password if prompted.                                                                                                                                                                                                                                                                                                                                         |
| Step 2 | <b>show cs7 sms address-table</b> [ <b>addr</b> <i>address</i>   <b>name</b> <i>name</i>   <b>prefix</b> <i>prefix</i> ]<br><br><b>Example:</b><br>ITP# show cs7 sms address-table name SHORTCODES | Displays SMS address table information. <ul style="list-style-type: none"> <li>• <b>addr</b> <i>address</i> Display information about specified address.</li> <li>• <b>name</b> <i>address</i> Display information about named address-table.</li> <li>• <b>prefix</b> <i>prefix</i> Display information about addresses prefixed with specified digit string</li> </ul> |

|        | Command or Action                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <p><b>show cs7 sms dest-sme-binding</b> <i>dest-sme</i> [<i>result-group-name</i>]</p> <p><b>Example:</b><br/>ITP# show cs7 sms dest-sme-binding 12345</p>                                     | <p>Displays the result that will be selected from an SMS result group for the specified dest-sme address.</p> <ul style="list-style-type: none"> <li><i>dest-sme</i> Specifies the dest-sme address whose result you wish to display. Valid dest-sme addresses are between 1 and 20 hexadecimal digits in length. Only the final 4 digits of the address are needed to determine the dest-sme-binding result. Alphanumeric dest-sme addresses can not currently be specified.</li> <li><i>result-group-name</i> (Optional) Specifies which result group to use. If the <i>result-group-name</i> is not specified, then this display will output the dest-sme-binding result for the input dest-sme for each result group in dest-sme-binding mode.</li> </ul> |
| Step 4 | <p><b>show cs7 sms group</b> [<i>name</i> ]</p> <p><b>Example:</b><br/>ITP# show cs7 sms group grp1</p>                                                                                        | <p>Displays SMS group information.</p> <ul style="list-style-type: none"> <li><i>name</i> (Optional) Group name.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## ITP Non-Stop Operation (NSO)

---

The ITP Non-Stop Operation (NSO) feature is an enhancement to the ITP High Availability support on the Cisco platform. It allows the ITP running on a Cisco router to continue operation in the event of a failure.

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

#### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

---

- [Restrictions for ITP NSO, page 301](#)
- [Information About ITP NSO, page 302](#)
- [How to Configure ITP NSO, page 302](#)
- [Monitoring NSO, page 306](#)
- [Configuration Example for ITP NSO, page 307](#)

## Restrictions for ITP NSO

The ITP NSO feature is supported on the Cisco router.

If a SAMI is configured via a SUP L2 interface, packet drop on a SUP switchover could be marginally higher than normal.

# Information About ITP NSO

is a disruptive event in the SS7 and SIGTRAN networks. MTP2, M2PA and HSL links are brought down and a full MTP3 restart occurs. Any messages that were queued at the time of the switchover are lost. M3UA and SUA (collectively referred to as xUA) SCTP associations are closed.

The ITP NSO feature minimizes the disruption caused by switchover by keeping the ITP links and xUA associations active and avoiding an MTP3 restart. This is accomplished by taking advantage of the offloaded forwarding on the and synchronizing ITP state information from the Active to the Standby

## How to Configure ITP NSO

Configuring the ITP NSO feature consists of the following tasks:

- [Configuring M2PA Offload, page 302](#)
- [Configuring xUA SCTP Offload, page 303](#)
- [Configuring Stateful Switchover Redundancy Mode, page 304](#)
- [Enabling ITP NSO, page 305](#)

**Note**

On the Cisco 7600 router platform, offload is not an optional parameter for M2PA and xUA.

## Configuring M2PA Offload

All M2PA SCTP instances must be offloaded. This allows M2PA links to remain active during failure.

### M2PA Offload

M2PA Offload is an ITP feature that enables M2PA message handling to be performed.

### SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 local-peer *port-number* offload *slot-number***

## DETAILED STEPS

| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                        | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                | Enters global configuration mode.                                                                                |
| Step 3 | <b>cs7 local-peer port-number offload slot-number</b><br><br><b>Example:</b><br>Router(config)# cs7 local-peer 1024 offload 6 | Creates an M2PA SCTP instance and offloads the M2PA SCTP processing to the specified.                            |

## What to Do Next

Configure xUA SCTP Offload.

## Configuring xUA SCTP Offload

All xUA instances must be offloaded. This allows xUA ASP connections to remain active if the active fails.

### xUA SCTP Offload

M3UA and SUA use SCTP to communicate with Application Server Processes (ASPs). This feature offloads the SCTP processing for xUA ASPs.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 m3ua port-number offload slot-number**
4. **cs7 sua port-number offload slot-number**

## DETAILED STEPS

|        | Command or Action                                                                                                 | Purpose                                                                                                          |
|--------|-------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                            | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                    | Enters global configuration mode.                                                                                |
| Step 3 | <b>cs7 m3ua port-number offload slot-number</b><br><br><b>Example:</b><br>Router(config)# cs7 m3ua 1024 offload 6 | Creates an M3UA instance and enables the offload of M3UA SCTP processing to a specified.                         |
| Step 4 | <b>cs7 sua port-number offload slot-number</b><br><br><b>Example:</b><br>Router(config)# cs7 sua 2048 offload 7   | Creates an SUA instance and enables the offload of SUA SCTP processing to a specified.                           |

## What to Do Next

Configure Stateful Switchover Redundancy Mode.

## Configuring Stateful Switchover Redundancy Mode

Configuring Stateful Switchover (SSO) redundancy mode allows the ITP NSO feature to track the redundancy state of the Cisco.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
- 3.
4. **redundancy**
5. **mode sso**

## DETAILED STEPS

|        | Command or Action                                                              | Purpose                                                                                                          |

## What to Do Next

Configure ITP NSO.

## Enabling ITP NSO

Enabling ITP NSO instructs the ITP protocols on the active to synchronize the operational state to the standby.

## SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **cs7 nso**

**DETAILED STEPS**

|        | Command or Action                             | Purpose                                                                            |
|--------|-----------------------------------------------|------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b>                                 | Enables privileged EXEC mode.                                                      |
|        | <b>Example:</b><br>Router> enable             | <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b>                     | Enters global configuration mode.                                                  |
|        | <b>Example:</b><br>Router# configure terminal |                                                                                    |
| Step 3 | <b>cs7 nso</b>                                | Enables ITP NSO.                                                                   |
|        | <b>Example:</b><br>Router(config)# cs7 nso    |                                                                                    |

**What to Do Next**

You have enabled ITP NSO and saved the configuration. At this point the ITP is in NSO mode and ready for hot switchovers.

# Monitoring NSO

Use the following commands to display NSO and MTP3 offload status.

**SUMMARY STEPS**

1. **show cs7 nso**

**DETAILED STEPS**

|        | Command or Action                             | Purpose                     |
|--------|-----------------------------------------------|-----------------------------|
| Step 1 | <b>show cs7 nso</b>                           | Displays the status of NSO. |
|        | <b>Example:</b><br>Router# show cs7 nso state |                             |

## Configuration Example for ITP NSO

```
card type t1 41
cs7 variant ANSI
cs7 network-name ITP1
cs7 point-code 3.4.5

end
```

## ITP QoS

---

The ITP QoS feature provides the framework that allows end-to-end Quality of Service (QoS) for SS7 packet flow through SS7 over IP (SS7oIP) networks.

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

#### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

## Information About ITP QoS

Quality of Service (QoS) refers to the performance of packet flow through networks. The goal in a QoS-enabled environment is to enable predictable service delivery to certain traffic classes or types regardless of other traffic flowing through the network at any given time. ITP QoS provides the framework that allows end-to-end QoS for SS7 packet flow through SS7oIP networks. End-to-end QoS is the ability of the network to deliver service required by specific network traffic from one end of the network to another. In particular, QoS features ensure improved and more predictable network service by providing the following services:

- Dedicated bandwidth

- Improving loss characteristics
- Avoiding and managing network congestion
- Shaping network traffic
- Setting traffic priorities across the network

QoS enables networks to control and predictably service a variety of network applications and traffic types. SS7 networks generally achieve QoS capabilities by over-provisioning bandwidth. Conventional SS7 networks lack the ability to identify different traffic types and provide network prioritization based on these traffic types. For instance, SS7 networks cannot separate ISUP and SCCP traffic and route this traffic over specific output links.

## ITP QoS Components

ITP QoS is based on 2 components: packet classification and packet scheduling and queuing.

Packet classification provides the capability to partition network traffic into multiple priority levels or classes of service. For instance, you can configure ITP QoS to classify incoming ISUP traffic as a member of class 1 and classify incoming SCCP traffic as a member of another class. Traffic classified by ITP QoS is directed over a specified link or a set of links. Using ITP QoS packet classification, the underlying IP network can ensure that the appropriate service level is provided to each traffic type.

Packet scheduling and queuing is concerned with implementing and policing the packet priorities through the IP network. After packets are classified as members of a QoS class and marked accordingly, the scheduling and queuing component is required to provide the appropriate network priority for the different classes of traffic. Scheduling and queuing also provides congestion management, congestion avoidance, policing, and shaping. The scheduling and queuing component of ITP QoS is provided by Cisco IOS QoS. ITP QoS depends on Cisco IOS QoS services for policing packet priority based on the IP header Type of Service (ToS) byte settings. Cisco IOS provides a rich set of QoS policies such as Weighted Fair Queuing, Class-Based Weighted Fair Queuing, Random Detection, and Traffic Shaping.

## ITP QoS Functionality

ITP QoS supports the setting of the ToS byte in the IP header. The ToS byte can be set to either a 3 bit IP precedence or 6 bit Differential Services Code Point (DSCP). Identifying the QoS requirements using the ToS byte provides the core network with an efficient classification method. Each hop can then provide each packet with the required QoS. IOS QoS techniques can be applied to provide policing for packet queuing and priority.

The ITP QoS service model allows the network administrator to configure up to 8 QoS classes, numbered 0 through 7. The hierarchy within the classes is based on the network priority characteristics assigned to each QoS class. The network administrator is responsible for provisioning the network priority characteristics to each QoS class, thus establishing the QoS class hierarchy. The network priority characteristics are provisioned by assigning either an IP precedence or DSCP to a QoS class. Packets that are classified as belonging to a provisioned QoS class will have the TOS byte in the IP header set to the assigned IP precedence or DSCP.

ITP QoS designates QoS class 0 as the default class. QoS class 0 member peer links can forward two types of packets:

- Packets are not classified as members of any other provisioned QoS class
- Packets are classified as members of a provisioned QoS class, but the QoS class does not have any member peer links available.

When peer links for an unavailable QoS class becomes available, packets classified as members of that QoS class will resume forwarding using the QoS class member peer links.

Peer links within a linkset which are not assigned a QoS class are members of the default class. **ITP QoS requires at least one default class peer link member.** The default class is provisioned automatically when the first QoS class is assigned to a peer link within a linkset. The IP precedence or DSCP for QoS class 0 defaults to zero. The IP precedence or DSCP default for QoS class 0 can be modified through the command line interface configuration for QoS classes.

By configuring ITP QoS, the network administrator can assign different network priority characteristics to certain types of traffic. ITP QoS can direct selected traffic types over a specific set of QoS provisioned peer links. The network administrator identifies the peer links that are members of a QoS class. Packets that are classified as members of a given QoS class are transmitted over the QoS class peer link members. **A peer link can be a member of only one QoS class.** It is strongly recommended that a QoS class have multiple peer link members to provide alternate links in case of link failures. ITP QoS supports changeover and changeback between peer link members of the same QoS class. When a peer link member of a QoS class fails, ITP QoS attempts changeover to a peer link member of the same QoS class. If there are no peer link members of the same QoS class available, ITP QoS forwards the packets of the unavailable QoS class using the QoS class 0 peer link members. If there are no QoS class 0 peer link members available the packets are dropped. When peer links for the unavailable QoS class become available, ITP QoS performs a changeback to switch the QoS class packets from the QoS class 0 peer links back to the QoS class peer link members that became available. The changeover and changeback function is prohibited between peer link members of different QoS classes.

MTP3 management messages will use any available peer link within a linkset regardless of the QoS classes assigned to the peer links.

Upon link failure of all peer link members provisioned for a QoS class, Transfer Restricted (TFR) messages are sent to adjacent signaling points. For ITU, the ITP QoS feature enhances the ITU specification by supporting response method TFRs. When conditions are met that require the sending of ITU response method TFRs, two TFRs at 30 second intervals will be sent. The TFR transmission interval is not configurable.

Link Selection is the process of identifying the outbound link that satisfies the classification criteria and QoS class. ITP MTP3 routing incorporates packet classification and QoS capabilities in the link selection decision. When the ITP QoS feature is configured, the outbound link for classified traffic is selected based on the QoS class and slc value.

For more information about deploying Cisco IOS QoS policies, refer to the *Cisco IOS Quality of Service Solutions Configuration Guide* and the *Cisco IOS Quality of Service Solutions Command Reference*, included in the Cisco IOS Release 12.2 documentation at the following URL:  
<http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122cgcr/index.htm>

## How to Configure ITP QoS

ITP allows packets to be classified (or colored) based on DPC, GTT selector, global title address, service indicator, inbound linkset and access list. MTP3 routing then incorporates the packet classification and link QoS capabilities into the link selection decision. Once an M2PA link is selected, the provisioned QoS class is assigned to an IP precedence value (TOS field) or a Differential Services Code Point (DSCP).

ITP also provides a mechanism such that traffic flows to M3UA or SUA may be assigned to different QoS classes. ITP enables the classification of packets received from M3UA or SUA to further enhance QoS routing over M2PA links.

## Specifying Packet Classification

Fundamental to the ITP QoS feature is packet classification or “coloring.” Classification is the process of identifying the QoS class of a packet. Packet classification provides the capability to partition network traffic into multiple classes of service. ITP QoS provides the following methods for specifying packet classification:

- [Specifying Input Linkset Classification, page 290](#)
- [Specifying Access List Classification, page 291](#)
- [Specifying Service Indicator Classification, page 292](#)
- [Specifying SCCP Packet Classification, page 293](#)
- [Specifying Destination Point Code Classification, page 295](#)
- [Specifying a QoS classification for an ASP, page 296](#)
- [Specifying QoS Routing Over M2PA Links, page 297](#)

The input linkset, access list, and service indicator packet classification methods are mutually exclusive.

The sccp and destination point code packet classification methods can be used separately or in tandem.

The sccp and destination point code packet classification methods can be used in conjunction with the input linkset, access list, and service indicator classification methods.

When combinations of the classification methods are used, the following precedence order should be observed (highest to lowest):

1. Destination point code classification
2. SCCP packet classification (GTA)
3. SCCP packet classification (Selector Table)
4. Input linkset, access list and service indicator classification

### Specifying Input Linkset Classification

ITP QoS provides the capability to classify packets based on an input linkset. The network operator can classify all packets that arrive on links within a linkset to a provisioned ITP QoS class. By this method of packet classification, all incoming packets to the linkset are classified as members of the QoS class assigned by the network operator. This method of classification provides the capability to group network traffic into a single ITP QoS class regardless of the packet destination. An example where input linkset classification would be most useful is for linksets coming from an SMSC. In this case, the network administrator can be sure all MSUs are related to the short message service and give them the appropriate priority.

To permit input linkset packet classification, use the following commands, beginning in global configuration mode:

|               | Command                                                       | Purpose                                                                    |
|---------------|---------------------------------------------------------------|----------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>cs7 qos class</b> <i>class</i>             | Defines a QoS class and enters QoS class configuration mode.               |
| <b>Step 2</b> | Router(config-cs7-qos)# <b>qos-ip-precedence</b> <i>class</i> | Defines an IP precedence for the class.                                    |
| <b>Step 3</b> | Router(config-cs7-qos)# <b>exit</b>                           | Exits CS7 QoS configuration submode, and enters global configuration mode. |

|                | Command                                                        | Purpose                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 4</b>  | Router(config)# <b>cs7 linkset</b> <i>ls-name adj-pc</i>       | Specifies an input linkset and enters linkset configuration submenu.                                                                                                                                                                                                                                                                                                                              |
| <b>Step 5</b>  | Router(config-cs7-ls)# <b>match any qos-class</b> <i>class</i> | Sets the match criteria.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 6</b>  | Router(config-cs7-ls)# <b>exit</b>                             | Exits CS7 linkset mode and enters global configuration mode.                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 7</b>  | Router(config)# <b>cs7 linkset</b> <i>ls-name adj-pc</i>       | Specifies an output linkset and enters linkset configuration submenu.                                                                                                                                                                                                                                                                                                                             |
| <b>Step 8</b>  | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                  | Specifies a link in the linkset and enters link configuration mode.                                                                                                                                                                                                                                                                                                                               |
| <b>Step 9</b>  | Router(config-cs7-ls-link)# <b>qos-class</b> <i>class</i>      | Assigns QoS class to link.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 10</b> | Router(config-cs7-ls-link)# <b>exit</b>                        | Exits CS7 link configuration mode and enters linkset configuration mode.                                                                                                                                                                                                                                                                                                                          |
| <b>Step 11</b> | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                  | Specifies a link in the linkset and enters link configuration mode. ITP QoS requires that at least one link is configured with no QoS class assigned. A link with no class is a member of the default class (class 0). QoS class 0 member links forward packets that are not classified as members of any other QoS class and packets that are classified as members of an unavailable QoS class. |

## Specifying Access List Classification

Access lists provide the capability to classify packets based on message characteristics. ITP access lists allow the specification of one or more match criteria to be applied to packets. Access-list numbers 2700-2999 can be used to define ITP access lists. Access-lists allow the logical AND or logical OR between specified match elements. For example, an access list can be defined to match destination point code (dpc) and originating point code (opc). Packets that meet the defined match criteria for an ITP access list are classified as members of the ITP QoS class assigned to the access list. Each QoS class that has been assigned an access list is considered for a match. The search begins with QoS class 0 and ends with QoS class 7. The first access list match terminates the search and assigns the corresponding QoS class to the outgoing packet. Complex access list definitions can be created but require more CPU resources to determine packet matches and can increase packet latency.

Access lists assigned to ITP QoS classes do not provide screening. Packets that match an ITP access list with the deny option eliminate that access list for consideration and progress to the next access list. When there are no more access lists to consider, the packet is routed over the default class peer link members.

To permit access list packet classification, use the following commands, beginning in global configuration mode:

|         | Command                                                                                                                                                                                                                                                                                                                                                                                     | Purpose                                                                                                                                                                                                                                                                                                                                                                                           |

| Step 8  | Router(config)# <b>cs7 linkset</b> <i>ls-name adj-pc</i>                                                                                                                                                                                                                                                                                                                                    | Specifies an output linkset and enters linkset configuration mode.                                                                                                                                                                                                                                                                                                                                |
| Step 9  | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                                                                                                                                                                                                                                                                                                                                               | Specifies a link in the linkset and enters link configuration mode.                                                                                                                                                                                                                                                                                                                               |
| Step 10 | Router(config-cs7-ls-link)# <b>qos-class</b> <i>class</i>                                                                                                                                                                                                                                                                                                                                   | Assigns the QoS class to the link.                                                                                                                                                                                                                                                                                                                                                                |
| Step 11 | Router(config-cs7-ls-link)# <b>exit</b>                                                                                                                                                                                                                                                                                                                                                     | Exits CS7 link configuration mode and enters linkset configuration mode.                                                                                                                                                                                                                                                                                                                          |
| Step 12 | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                                                                                                                                                                                                                                                                                                                                               | Specifies a link in the linkset and enters link configuration mode. ITP QoS requires that at least one link is configured with no QoS class assigned. A link with no class is a member of the default class (class 0). QoS class 0 member links forward packets that are not classified as members of any other QoS class and packets that are classified as members of an unavailable QoS class. |

## Specifying Service Indicator Classification

ITP QoS provides the capability to classify packets based on the Service Indicator (SI) field. This method of classification can be used as an alternative to access-lists without the overhead associated with access-lists. This method allows a simple match criteria based on SI value. To create more complex match criteria, ITP access lists should be used. Multiple SI value match criteria can be specified per input linkset. Packets that match one of the SI match criteria are classified as a members of the corresponding QoS class. A table lookup provides fast mapping of SI values to QoS classes. An example of where QoS based on service indicator is most useful is in distinguishing ISUP from SCCP traffic. ISUP has SI value of 5 and SCCP has SI value of 3.

To permit service indicator classification, use the following commands, beginning in global configuration mode:

|                | Command                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b>  | Router(config)# <b>cs7 qos class</b> <i>class</i>                | Defines a QoS class and enters QoS class configuration mode.                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 2</b>  | Router(config-cs7-qos)# <b>qos-ip-precedence</b> <i>class</i>    | Defines an IP precedence for the class.                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 3</b>  | Router(config-cs7-qos)# <b>exit</b>                              | Exits CS7 QoS configuration submode, and enters global configuration mode.                                                                                                                                                                                                                                                                                                                        |
| <b>Step 4</b>  | Router(config)# <b>cs7 qos class</b> <i>class</i>                | Defines a QoS class and enters QoS class configuration mode.                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 5</b>  | Router(config-cs7-qos)# <b>qos-ip-precedence</b> <i>class</i>    | Defines an IP precedence for the class.                                                                                                                                                                                                                                                                                                                                                           |
| <b>Step 6</b>  | Router(config)# <b>cs7 linkset</b> <i>ls-name adj-pc</i>         | Specifies an input linkset and enters linkset configuration submode.                                                                                                                                                                                                                                                                                                                              |
| <b>Step 7</b>  | Router(config-cs7-ls)# <b>match si si qos-class</b> <i>class</i> | Sets the match criteria.                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Step 8</b>  | Router(config-cs7-ls)# <b>exit</b>                               | Exits CS7 linkset mode and enters global configuration mode.                                                                                                                                                                                                                                                                                                                                      |
| <b>Step 9</b>  | Router(config)# <b>cs7 linkset</b> <i>ls-name adj-pc</i>         | Specifies an output linkset and enters linkset configuration submode.                                                                                                                                                                                                                                                                                                                             |
| <b>Step 10</b> | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                    | Specifies a link in the linkset and enters link configuration mode.                                                                                                                                                                                                                                                                                                                               |
| <b>Step 11</b> | Router(config-cs7-ls-link)# <b>qos-class</b> <i>class</i>        | Assigns QoS class to link.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 12</b> | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                    | Specifies a link in the linkset and enters link configuration mode.                                                                                                                                                                                                                                                                                                                               |
| <b>Step 13</b> | Router(config-cs7-ls-link)# <b>qos-class</b> <i>class</i>        | Assigns QoS class to link.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Step 14</b> | Router(config-cs7-ls-link)# <b>exit</b>                          | Exits CS7 link configuration mode and enters linkset configuration mode.                                                                                                                                                                                                                                                                                                                          |
| <b>Step 15</b> | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                    | Specifies a link in the linkset and enters link configuration mode. ITP QoS requires that at least one link is configured with no QoS class assigned. A link with no class is a member of the default class (class 0). QoS class 0 member links forward packets that are not classified as members of any other QoS class and packets that are classified as members of an unavailable QoS class. |

## Specifying SCCP Packet Classification

Packets that require a Global Title Translation (GTT) can be classified on a per Global Title Address (GTA) basis or on a GTT selector table. A network administrator can assign one of the 8 ITP QoS classes to each GTA/GTA mask or selector table. During GTT processing, the QoS class associated with the GTA/GTA mask or selector table will be stored in the packet header for further processing by the ITP QoS feature.

There is a precedence order when a QoS class is assigned to both a selector table and to a GTA within that selector table. If a QoS class is assigned to a selector table and a GTA entry, the QoS class assigned to the GTA entry has precedence over the QoS class assigned to the selector table.

If the QoS class assigned to a selector table or GTA entry is not configured, the SCCP packet is routed over the default class peer link members.

To permit SCCP packet classification for a GTT selector, use the following commands, beginning in global configuration mode:

|         | Command                                                                                       | Purpose                                                                    |
|---------|-----------------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Step 1  | Router(config)# <b>cs7 qos class</b> <i>class</i>                                             | Defines a QoS class and enters QoS configuration submode.                  |
| Step 2  | Router(config-cs7-qos)# <b>qos-ip-precedence</b> <i>class</i>                                 | Defines an IP precedence for the class.                                    |
| Step 3  | Router(config-cs7-qos)# <b>exit</b>                                                           | Exits CS7 QoS configuration submode, and enters global configuration mode. |
| Step 4  | Router(config)# <b>cs7 qos class</b> <i>class</i>                                             | Defines a QoS class and enters QoS configuration submode.                  |
| Step 5  | Router(config-cs7-qos)# <b>qos-ip-precedence</b> <i>class</i>                                 | Defines an IP precedence for the class.                                    |
| Step 6  | Router(config-cs7-qos)# <b>exit</b>                                                           | Exits QoS configuration submode and enters global configuration mode.      |
| Step 7  | Router(config)# <b>cs7 gtt selector</b> <i>selector tt tt</i>                                 | Defines the selector table and enters CS7 GTT selector mode.               |
| Step 8  | Router(config-cs7-gtt-selector)# <b>qos-class</b> <i>class</i>                                | Assigns a QoS class to the selector table.                                 |
| Step 9  | Router(config-cs7-gtt-selector)# <b>gta gta qos-class</b><br><i>class pcssn pc gt ntt ntt</i> | Assigns a QoS class to the GTA entry                                       |
| Step 10 | Router(config-cs7-gtt-selector)# <b>exit</b>                                                  | Exits CS7 GTT selector mode and enters global configuration mode.          |
| Step 11 | Router(config)# <b>cs7 linkset</b> <i>ls-name adj-pc</i>                                      | Specifies an output linkset and enters linkset configuration submode.      |
| Step 12 | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                                                 | Specifies a link in the linkset and enters link configuration mode.        |
| Step 13 | Router(config-cs7-ls-link)# <b>qos-class</b> <i>class</i>                                     | Assigns QoS class to link.                                                 |
| Step 14 | Router(config-cs7-ls-link)# <b>exit</b>                                                       | Exits link configuration mode and enters linkset configuration mode.       |
| Step 15 | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                                                 | Specifies a link in the linkset and enters link configuration mode.        |
| Step 16 | Router(config-cs7-ls-link)# <b>qos-class</b> <i>class</i>                                     | Assigns the QoS class to the link.                                         |

|                | Command                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|-----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 17</b> | Router(config-cs7-ls-link)# <b>exit</b>       | Exits CS7 link configuration mode and enters linkset configuration mode.                                                                                                                                                                                                                                                                                                                          |
| <b>Step 18</b> | Router(config-cs7-ls)# <b>link</b> <i>slc</i> | Specifies a link in the linkset and enters link configuration mode. ITP QoS requires that at least one link is configured with no QoS class assigned. A link with no class is a member of the default class (class 0). QoS class 0 member links forward packets that are not classified as members of any other QoS class and packets that are classified as members of an unavailable QoS class. |

### Specifying Destination Point Code Classification

ITP QoS provides the capability to classify packets based on the destination point code (DPC). All packets destined for a given DPC will be classified as members of the QoS class that was configured with an ITP routing entry. The QoS class configured with an ITP routing entry is stored with the ITP routes in the routing table. Storing the QoS class with the routing entry provides efficient packet classification based on DPC. An example of where QoS based on point code may be used is on links coming from an MSC. Packets to SMSC and HLR will both be SCCP MSUs with service indicator 3. The DPC may be checked to determine if the MSU is for an SMSC or an HLR (after GTT if desired) and then classified accordingly.

If the QoS class assigned to a DPC is not configured, packets are routed over the default class peer link members.

To permit destination point code packet classification, use the following commands, beginning in global configuration mode:

|               | Command                                                                                                                                                                                                                                                  | Purpose                                                                           |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| <b>Step 1</b> | Router(config)# <b>cs7 qos class</b> <i>class</i>                                                                                                                                                                                                        | Defines a QoS class and enters QoS class configuration mode.                      |
| <b>Step 2</b> | Router(config-cs7-qos)# <b>qos-ip-precedence</b> <i>class</i>                                                                                                                                                                                            | Defines an IP precedence for the class.                                           |
| <b>Step 3</b> | Router(config-cs7-qos)# <b>exit</b>                                                                                                                                                                                                                      | Exits CS7 QoS configuration submode, and enters global configuration mode.        |
| <b>Step 4</b> | Router(config)# <b>cs7 route-table system</b>                                                                                                                                                                                                            | Specifies the route table and enters CS7 route table configuration submode.       |
| <b>Step 5</b> | Router(config-cs7-rt)# <b>update route point-code</b> [ <i>mask</i>   <i>length</i> ] <b>linkset</b> <i>ls-name</i> [ <b>priority</b> <i>priority-value</i> <sup>1</sup> ] [ <b>qos-class</b> { <i>class</i>   <b>default</b> }] [ <b>load_balance</b> ] | Adds QoS class to the destination point code.                                     |
| <b>Step 6</b> | Router(config-cs7-rt)# <b>exit</b>                                                                                                                                                                                                                       | Exits CS7 route table configuration submode and enters global configuration mode. |
| <b>Step 7</b> | Router(config)# <b>cs7 linkset</b> <i>ls-name adj-pc</i>                                                                                                                                                                                                 | Specifies an output linkset and enters linkset configuration submode.             |
| <b>Step 8</b> | Router(config-cs7-ls)# <b>link</b> <i>slc</i>                                                                                                                                                                                                            | Specifies a link in the linkset and enters link configuration mode.               |
| <b>Step 9</b> | Router(config-cs7-ls-link)# <b>qos-class</b> <i>class</i>                                                                                                                                                                                                | Assigns QoS class to link.                                                        |

|                | Command                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 10</b> | <code>Router(config-cs7-ls-link)# <b>exit</b></code>       | Exits CS7 link configuration mode and enters linkset configuration mode.                                                                                                                                                                                                                                                                                                                          |
| <b>Step 11</b> | <code>Router(config-cs7-ls)# <b>link</b> <i>slc</i></code> | Specifies a link in the linkset and enters link configuration mode. ITP QoS requires that at least one link is configured with no QoS class assigned. A link with no class is a member of the default class (class 0). QoS class 0 member links forward packets that are not classified as members of any other QoS class and packets that are classified as members of an unavailable QoS class. |

1. The smaller the number, the higher the priority. See the **update route** ITP Command Set entry for an example.

## Specifying a QoS classification for an ASP

QoS packet classification occurs based on both the AS/routing-key and ASP, with ASP taking precedence.

When packets are to be delivered to the AS, the ASP selection process will remain unchanged (i.e., it will not use the QoS classification as a routing key parameter).

If QoS is provisioned for the AS, the classification will be used to set the appropriate TOS using precedence or DSCP values within the IP network. However, if an ASP is selected that is currently active in more than one AS, then the highest priority QoS classification among the active ASs will be used. Setting the QoS class to the highest class ensures that the traffic is processed at the most appropriate priority compared to other IP traffic streams.

If it is desirable for QoS classification to vary based on the type of SS7 traffic, then a unique association is required between the ITP SG and ASP host for each classification type. Thus, from the ITP SG perspective, the ASP “host” will have a unique SCTP association (ASP) per AS that it implements. Each AS is then provisioned with its appropriate QoS class on the ITP SG. For example, an ASP host supporting both ISUP and SCCP traffic would set up two associations to the ITP SG. This would appear to be two different ASPs to the SG, each supporting a unique AS with a different QoS classification value.

QoS can also be provisioned for the ASP. The QoS specified under the ASP takes precedence over the QoS specified for the AS. Consider the following example:

ASP1 has QoS class 5 and this ASP belongs to AS AS1 which has QoS class 3. Since QoS for the ASP overrides the QoS for the AS, the ASP1 will have QoS class 5.

The following rules affect QoS routing over M3UA or SUA links:

- When packets are being routed to an M3UA or SUA AS and eventually delivered to an ASP, the packet might already have been classified by existing packet classification options. The AS or ASP QoS classification overrides the previously set value.
- When a QoS classification is configured for an ASP or an AS, it takes effect only on the subsequent ASP connection. The QoS can only be changed when ASP is NOT active. Use the **shutdown** and **no shutdown** commands in CS7 ASP configuration mode to shut down and then activate the ASP with the QoS change.
- When qos-class is not specified for an ASP (and any of the ASs that the ASP serves), the Type of Service (TOS) for the SCTP association of the ASP is obtained from **cs7 qos class 0**, if it's defined. Otherwise, it is set to zero (0).

To configure a QoS classification for an ASP, use the following commands, beginning in global configuration mode:

| Command                                                                                               | Purpose                                                     |
|-------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Router(config)# <b>cs7 asp</b> <i>asp-name remote-port local-port</i><br>[ <b>m3ua</b>   <b>sua</b> ] | Configures a CS7 ASP definition and enters CS7 ASP submode. |
| Router(config-cs7-asp)# <b>remote-ip</b> <i>remote-ip</i>                                             | Specifies the remote IP address of the ASP.                 |
| Router(config-cs7-asp)# <b>qos-class</b> <i>class</i>                                                 | Defines the QoS class for the ASP                           |
| Router(config-cs7-asp)# <b>match any qos-class</b> <i>class</i>                                       | Sets the match criteria.                                    |
| Router(config-cs7-asp)# <b>match si</b> <i>si qos-class class</i>                                     | Sets the serviced indicator match criteria.                 |

### Specifying QoS Routing Over M2PA Links

Packets received from M3UA or SUA must be classified with a default QoS class as a minimum requirement, to ensure that packets are not dropped by MTP3. Additionally, you may specify a QoS classification for packets received from a specific ASP.

Packets flowing from M3UA or SUA to M2PA will be subject to Topsail R2 coloring for DPC, GTT selector and GTT address, but not inbound linkset or access list. There is no single equivalent in M3UA or SUA for the inbound linkset. The ASP from which the data was received is the closest approximation to an inbound linkset. The source AS is unknown, and may not be used for this purpose.

## Verifying ITP QoS

After the ITP is configured for QoS and the links come in service, you can verify that the ITP QoS was configured properly and that the ITP QoS functionality is available.

The **show cs7 qos** commands can be used to display a summary of the QoS configuration and QoS statistics for an input linkset.

To display a summary of the QoS configuration and verify that the QoS class and packet classifications are assigned correctly, use the following command in privileged EXEC mode:

| Command                           | Purpose                                      |
|-----------------------------------|----------------------------------------------|
| Router# <b>show cs7 qos class</b> | Displays a summary of the QoS configuration. |

The following is sample output from the **show cs7 qos class** command:

```
Router# show cs7 qos class
QoS   Prec  DSCP  Acc-Grp  MatchType  Input Linkset
---   -
1      3      10      2700     any        to_newyork
2      5      10      2700     si 3       to_chicago
3      5      10      2700     si 5       to_chicago
4      4      26      2700     access-group to_atlanta
5      3      26      2700     none
6      3      26      2701     access-group to_atlanta
```

The output indicates the following packet classifications for the configured QoS classes:

QoS class 1 is configured for input linkset packet classification.

QoS class 2 and QoS class 3 are configured for service indicator packet classification.

QoS class 4 and QoS Class 6 is configured for access list packet classification.

QoS class 5 is not configured for packet classification.

To verify that traffic is being routed over the correct QoS peer link member(s), use the following command in privileged EXEC mode:

| Command                                | Purpose                           |
|----------------------------------------|-----------------------------------|
| Router# <b>show cs7 qos statistics</b> | Displays QoS link use statistics. |

The following is sample output from the **show cs7 qos statistics** command:

```
Router# show cs7 qos statistics ls-name
lsn=to_itpa      apc=3.3.3      state=avail      available/links=2/3
  SLC  QoS      MSU In    MSU Out  Drops    ByteCnt In    ByteCnt Out
  00   0        494       492     0        8965         8864
  01   2        501       493     0        9006         8947
```

The sample output shows the number of MSUs sent and received for each QoS class (which is assigned to a peer link member or members) for a specific input linkset.

When classified packets are received from an input linkset and there are no available peer link members that support the QoS class assigned to the classified packets, the packet is dropped. The ITP displays an error message and logs an access violation in the ITP access violations database. A sample of the error message displayed is shown below:

```
no QoS class 2 link available for packets, see show cs7 accounting access-violations
```

The ITP accounting access-violations database indicates the dropped packets origin and destination point codes. To display CS7 accounting details, use the following command in privileged EXEC mode:

| Command                                              | Purpose                                      |
|------------------------------------------------------|----------------------------------------------|
| Router# <b>show cs7 accounting access-violations</b> | Displays the CS7 access-violations database. |

The following is a sample output from the **show cs7 accounting access-violations** command:

```
Router# show cs7 qos statistics
Checkpoint Interval = 5 min

Linkset = 'to_newyork'
Destination   Originating   Service      Input          Output
Point Code    Point Code    Indicator    Packets        Bytes    Packets        Bytes
-----
  3.3.3        4.4.4         8           96           3824         0             0
```

The sample output shows that access violations occurred for packets destined for 3.3.3 from origin point code 4.4.4. Packets are received on the input, but zero packets are being routed to the destination point code.

# QoS Configuration Example

This section includes the following examples of ITP QoS packet classification and Cisco IOS QoS packet scheduling and queuing:

- [Service Indicator Packet Classification and Access List Classification, page 300](#)
- [SCCP Packet Classification, page 303](#)
- [Input Linkset Classification, page 305](#)
- [Destination Point Code Classification, page 307](#)
- [Cisco IOS QoS Packet Scheduling and Queuing, page 309](#)
- [ITP SG QoS Configuration Examples, page 312](#)

The network configuration is illustrated in [Figure 35](#).

→ The arrow symbol indicates the specific configuration statements that implement QoS on each ITP.

**Figure 35** ITPs as STPs in an SS7oIP Topology

### Assumptions:

All routers have redundant ethernet connectivity and therefore all SCTP associations use two IP addresses (multi-homing).

Point codes and IP addresses for ITP routers:

```
ITPA  5.100.2  172.18.44.242 117.117.117.2
ITPB  5.100.5  172.18.44.243 117.117.117.3
ITPC  5.100.4  172.18.45.1  117.117.119.4
ITPD  5.100.3  172.18.46.1  117.117.118.4
```

Point codes for SS7 SSPs:

```
SMSC  5.100.1
VMI4   5.100.6
VT02   5.100.7
VRM2   5.100.8
```

### Service Indicator Packet Classification and Access List Classification

In the following configuration example, ITPA is configured to perform ITP QoS Service Indicator packet classification and access list classification.

All packets arriving on linkset **smsc** are classified according to service indicator. Packets with si 3 are classified class 2 and are sent out on link 1 of the linkset ITPd. Packets with si 5 are classified class 1 and are sent out on link 0 of the linkset ITPd.

All ISUP packets arriving on linkset vmi4 are matched with access list 2701, classified as QoS class3 and are sent out on link 1 of linkset ITPc. All other packets arriving from linkset vmi4 are sent out on link 0 of linkset ITPc.

### SCCP Packet Classification

In the following configuration example, ITPB is configured to perform ITP QoS SCCP packet classification. QoS class 1 is assigned to the GTT selector table named **c7gsp**. QoS class 2 is assigned to GTA 339. According to QoS rules of precedence, if a QoS class is assigned to a selector table and to a GTA within that selector table, the QoS class assigned to the GTA entry has precedence over the QoS class assigned to the selector table.

### Cisco IOS QoS Packet Scheduling and Queuing

The following configuration example illustrates ITP QoS used in conjunction with Cisco IOS QoS at the edge of the IP network.

ITPA is configured to perform ITP QoS Service Indicator packet classification. All packets arriving on linkset vmi4 are classified according to service indicator. Packets with si 3 (SCCP) are classified class 2 and are sent out on link 1 of the linkset ITPd. Packets with si 5 (ISUP) are classified class 1 and are sent out on link 0 of the linkset ITPd. The ITP QoS configuration statements are highlighted in bold text. Cisco ITP QoS configuration statements are highlighted in bold italic text.

Cisco IOS Modular QoS Command-Line Interface will be used to create traffic policies and attach these policies to interfaces. A traffic policy contains a traffic class and one or more IOS QoS features. A traffic class is used to classify traffic, while the QoS features in the traffic policy determine how to treat the classified traffic. The traffic policy in this configuration allocates 50% of the available bandwidth to ISUP packets and 25% of the available bandwidth to SCCP packets during periods of congestion.

Packets classified by ITP QoS will have the ToS byte in the IP header set to the appropriate IP precedence value. Before the classified packets are transmitted, the Cisco IOS QoS traffic policy assigned to the output interface is applied to each packet. In this example, any packets with an IP precedence value of 3, will be subject to the characteristics defined for class sccp. Packets with an IP precedence value of 4 will be subject to class isup characteristics

For more information about deploying Cisco IOS QoS policies, refer to the *Cisco IOS Quality of Service Solutions Configuration Guide* and the *Cisco IOS Quality of Service Solutions Command Reference*, included in the Cisco IOS Release 12.2 documentation at the following URL:

<http://www.cisco.com/univercd/cc/td/doc/product/software/ios122/122cgcr/index.htm>

### ITP SG QoS Configuration Examples

#### Example 1

In Example 1 all the traffic flowing to asp1 will be classified based on the QoS class 3 since asp1 belongs to AS as1.

```

cs7 qos class 3
  qos-ip-precedence 3
!
cs7 m3ua 2905
  local-ip 7.7.7.7
!
cs7 asp asp1 2905 2905 m3ua
  remote-ip 5.5.5.5
!
cs7 as as1 m3ua
  routing 05050505 4.4.4
  asp asp1
  qos-class 3
!

```

#### Example 2

In Example 2, since asp2 has been provisioned with qos-class 4, all the traffic flowing to asp2 will be classified with QoS class 4.

```

cs7 qos class 4
  qos-ip-dscp 40
!
cs7 m3ua 2905
  local-ip 7.7.7.7
!
cs7 asp asp2 2905 2905 m3ua
  remote-ip 5.5.5.6
  qos-class 4
!
cs7 as as2 m3ua
  routing 05050506 4.4.4
  asp asp1
!

```

### Example 3

In Example 3, the ISUP and SCCP ASPs are located on the same host (same IP address, but different SCTP ports). They are defined as two different ASPs. Since isup-asp belongs to isup-as and isup-as-bk ASs, the QoS with highest IP Type Of Service (TOS), i.e. qos-class 5, will be used for the traffic flowing to isup-asp. Also the traffic flowing to sccp-asp will be classified based on QoS class 3 since this ASP belongs to AS sccp-as.

```

cs7 qos class 3
  qos-ip-precedence 3
cs7 qos class 5
  qos-ip-precedence 5
!
cs7 m3ua 2905
  local-ip 7.7.7.7
!
cs7 asp isup-asp 5500 2905 m3ua
  remote-ip 6.6.6.6
cs7 asp sccp-asp 6000 2905 m3ua
  remote-ip 6.6.6.6
!
cs7 as isup-as m3ua
  routing-key 06060606 5.5.5
  asp isup-asp
  qos-class 5
!
cs7 as isup-as-bk m3ua
  routing-key 07070707 6.6.6
  asp isup-asp
  qos-class 3
!
cs7 as sccp-as m3ua
  routing-key 08080808 7.7.7
  asp sccp-asp
  qos-class 3
!

```

### Example 4

In Example 4 any traffic coming in from asp3 will be classified as having QoS class 3. Also any ISUP (si=5) traffic coming in from asp4 will be classified as having QoS class 5. The packet is classified this way so that, if needed, it would properly get routed over M2PA links, as explained in the [“Specifying QoS Routing Over M2PA Links”](#) section on page 297.

```

cs7 qos class 3
  qos-ip-precedence 3
cs7 qos class 5
  qos-ip-dscp 40
!
cs7 m3ua 2905
  local-ip 7.7.7.7
!
cs7 asp asp3 2905 2905 m3ua
  remote-ip 6.6.6.10
  match any qos-class 3
cs7 asp asp4 2905 2905 m3ua
  remote-ip 6.6.6.11
  match si 5 qos-class 5

```

# Load Sharing

## Feature History for Load Sharing

| Release     | Modification                                                                                                                             |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------|
| 12.2(33)IRA | Feature introduced.                                                                                                                      |
| 12.2(33)IRC | Added the <b>sccp-class1-loadshare</b> command.                                                                                          |
| 12.2(33)IRD | <ul style="list-style-type: none"><li>Enhanced GTT application group load balancing.</li><li>Added GTT over-flow load sharing.</li></ul> |

## Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

# Information About SCCP Load Sharing

Signaling Connection Control Part (SCCP) supports routing and translation and management functions and data transfer without logical signaling connections. ITP supports SCCP Load Balancing which includes support for SCCP class 0 and class 1 traffic.

SCCP load sharing utilizing mated applications or application groups includes the following functionality:

- Load-sharing / multiplicity is configurable on a Mated-Application (MAP) or application group basis.
- Class 0 traffic can be load-shared among a maximum of two destinations based on a round-robin algorithm using a GTT MAP (multiplicity = share).
- Class 0 traffic can be load-shared among a maximum of 2 destinations based on a dominant algorithm using a GTT MAP (multiplicity = dominant).
- Class 0 traffic can be load-shared among a maximum of 64 destinations based on a round-robin algorithm using a GTT Application Group. (multiplicity = share).
- Class 0 traffic can be load-shared among a maximum of 64 destinations based on a least cost available algorithm using a GTT Application Group. (multiplicity = cost).
- Class 0 traffic can be load-shared among a maximum of 64 destinations based on a weighted round robin (WRR) algorithm using a GTT Application Group. (multiplicity = wrr).
- Class 1 traffic can be load-shared among a maximum of 2 destinations based on 1 SLS bit using a GTT MAP (multiplicity = share).
- Class 1 traffic can be load-shared among a maximum of 2 destinations on a dominant algorithm using a GTT MAP (multiplicity = dominant).
- Class 1 traffic can be load-shared among a maximum of 64 destinations based on the class 1 traffic loadshare option using a GTT Application Group. (multiplicity = share).
- Class 1 traffic can be load-shared among a maximum of 64 destinations based on a least cost available algorithm using a GTT Application Group in conjunction with the class 1 traffic loadshare option. (multiplicity = cost).
- Class 1 traffic can be load-shared among a maximum of 64 destinations based on a weighted round robin (WRR) algorithm using a GTT Application Group. (multiplicity = wrr).

## Scenarios for SCCP Load Sharing

This section describes the possible configuration options for SCCP load sharing as well as address guidelines for when to use the different methods provided. Load-sharing/multiplicity is configurable on a Mated-Application or Application group basis.

The following SS7 network elements are typical in most SS7 architectures utilizing GTT.

1. Solitary intermediate destination – The final destination of the global title is not known and only one intermediate destination is available for the next hop.
2. Solitary final destination - The final destination of the global title is known and only one choice is available.
3. Redundant intermediate destination - The final destination of the global title is not known and two or more intermediate destinations are available for the next hop.

4. Redundant final destination - The final destination of the global title is known and two or more choices are available.
5. More than one backup final or intermediate: The result may be final or intermediate depending on the availability of external nodes or the ability to load-share across up to 64 different destinations.

Scenario 1 and 2 above do not involve any load sharing and are mentioned only for completeness. In each of these cases all resultant GTT traffic is directed to the solitary destination. In case 1, only the MTP3 status determines if the destination is available. In case 2, the MTP3 point-code status as well as the SCCP subsystem status is analyzed. In either case, if the solitary destination is not available, there is no alternate, and the message is discarded.

Scenario 3: In order to configure this situation an application group must be used. There are 2 different possibilities concerning how load sharing may be configured for this group:

- a. Share mode: When this mode is configured Class 0 traffic will be shared between the two destinations if available based on a round-robin algorithm. Class 1 traffic will be shared based on the class 1 traffic loadshare option, which has an SLS default. This situation may be configured to share between up to 64 destinations for class 0 and class 1 traffic.
- b. Cost Mode: When cost mode is configured the least cost item or items (if more than one at that cost) will be used. When more than 1 item at the least cost is available, round-robin is used for class 0 traffic and the class 1 traffic loadshare option is used for class 1 traffic.

Cost Mode Example 1: Suppose an application group is defined with two items, each with its own unique cost. In this situation all traffic would use the least cost item (A) if it were available otherwise it would use item B. This is equivalent to the dominant mode described later for GTT MAPs.

**Table 21**      *Reference for Cost Mode Example 1*

| Item | Cost |
|------|------|
| A    | 1    |
| B    | 2    |

Cost Mode Example 2: Suppose an application group is defined with two items, each with the same cost. In this situation all traffic would share equally between A and B using round robin or the class 1 traffic loadshare option depending on the protocol class. This is equivalent to the share mode described earlier.

**Table 22**      *Reference for Cost Mode Example 2*

| Item | Cost |
|------|------|
| A    | 1    |
| B    | 1    |

Cost Mode Example 3: In this example, items A and B shall always be used in a share like fashion (either by round-robin or the class 1 traffic loadshare option). If both A and B, become unavailable, then items C and D are used in the same fashion. If all items A through D become unavailable, then item E must handle all the traffic.

**Table 23**      *Reference for Cost Mode Example 3*

| Item | Cost |
|------|------|
| A    | 1    |
| B    | 1    |
| C    | 2    |
| D    | 2    |
| E    | 3    |

Scenario 4: There is no difference between scenario 4 and 3 other than the resultant routing-indicator is final for this scenario instead of intermediate. The same cost and share modes may be applied if using an application group. One option not available for scenario 3, that is available for this, is the ability to use GTT MAP (Mated Application) instead of an application group. GTT Mated Applications only allow a maximum of two replicated PC/SSN combinations as the choice for the resultant GTT. These can operate in the share or dominant modes. The advantage of using a GTT MAP instead of an application group is memory savings. An application group uses more memory than utilizing a GTT MAP.

Scenario 5: There is no difference between this scenario and scenario 3 except the items in the group may have mixed values for the resultant routing indicator. The same cost and share modes may be applied. Suppose GTT is performed from the ITP to locate HLRs (item A and B). The data on A and B is replicated and traffic is shared between them, thus the equal cost 1. If a failure occurred at A or B it may be desired to direct the traffic to another pair of ITPs which will have to perform GTT again to find a different final destination since the primary final destination could not be reached. This is one reason network operators may wish to have a mixture of final and intermediate destinations in one application group utilizing cost mode sharing.

**Table 24**      *Reference for Scenario 5*

| Item             | Cost |
|------------------|------|
| A - Final        | 1    |
| B - Final        | 1    |
| C - Intermediate | 2    |
| D - Intermediate | 2    |

## Configuring SCCP Load Sharing

Cisco ITP supports several methods for distributing SCCP traffic.

This section contains the following information and procedure:

- [Configuring GTT Application Group Overflow Load Sharing for SCCP Class 0, page 319](#)
- [Configuring the MTP Overflow Load Sharing, page 323](#)
- [Configuring GTT Application Group Load Balancing for SCCP Traffic at the Global Level, page 327](#)
- [Configuring GTT Application Groups with the WRR Algorithm for Processing SCCP Class 1 Traffic, page 329](#)
- [Configuring SCCP Class 0 Load Sharing to Ignore Class and Sequencing, page 330](#)

- [Configuring SCCP Class 1 Load Sharing to Ignore Class and Sequencing, page 330](#)

## Configuring GTT Application Group Overflow Load Sharing for SCCP Class 0

This configuration allows the ITP to send a user defined amount of traffic to a primary destination. Excess traffic is then sent to a secondary destination. This distribution is more specific than those based on congestion. Overflow load sharing is especially useful for enforcing customer limitations.

### Restrictions and Considerations

- Only one rate limit entry is allowed for a GTT application group.
- You configure the rate limit entry for a specific destination in the GTT application group.
- You must configure both a primary and secondary (backup).
- You can define the primary and secondary by configuring ASs, DPCs, or any combination of an AS and DPC.
- The primary AS or DPC is defined as the one with the lowest configured cost.

### CONFIGURATION STEPS

|        | Command or Action                                                                                                          | Purpose                                                                                                            |
|--------|----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                     | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                             | Enters global configuration mode.                                                                                  |
| Step 3 | <b>cs7 gtt application-group</b> <i>group-name</i><br><br><b>Example:</b><br>Router(config)# cs7 gtt application-group abc | Defines the GTT application group and enables application-group submode.                                           |

| Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Step 4</b></p> <p><b>multiplicity</b> {<b>cost</b>   <b>share</b>   <b>cgpa</b>   <b>wrr</b>}</p> <p><b>Example:</b><br/> Router(config-cs7-gtt-app-grp)# multiplicity cost</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                | <p>Specifies a method for selecting a destination for the application group.</p> <ul style="list-style-type: none"> <li>• <b>cost</b>—Uses the destination with the least cost if that destination is available.</li> <li>• <b>share</b>—Shares equally among all destinations.</li> <li>• <b>cgpa</b>—Uses the SCCP calling party address (CGPA) field, which results in a weighted factor selection number for choosing the next destination from the available items in the application group.</li> <li>• <b>wrr</b>—Applies weighted round robin load balancing (WRR) to SCCP class 0 and SCCP class 1 traffic.</li> </ul> <p> <b>Note</b> The <b>cost</b> keyword is used for overflow load sharing configurations.</p>                                                               |
| <p><b>Step 5</b></p> <p><b>instance</b> <i>instance-number</i> <b>asname</b> <i>as-name</i> {<b>cost</b> [<b>ssn</b> <i>ssn</i>] {<b>gt</b> [<b>ntt</b> <i>ntt</i>]   <b>pcssn</b>} [<b>limit</b> <i>rate</i>]   <b>wf</b> [<b>ssn</b> <i>ssn</i>] {<b>gt</b> [<b>ntt</b> <i>ntt</i>]   <b>pcssn</b>}}</p> <p><b>Example:</b></p> <p>The primary AS use the <b>limit</b> keyword and <i>rate</i> argument to define the rate limit.</p> <p>Router(config-cs7-gtt-app-grp)# asname weekday 1 gt limit 2000</p> <p>The backup AS does not define a rate limit.</p> <p>Router(config-cs7-gtt-app-grp)# asname weekday overflow 2 gt</p> | <p>(Optional) Assigns an M3UA or SUA AS directly to a global title.</p> <p>You must configure both a primary and backup AS to take advantage of the GTT loadshare overflow feature.</p> <p>You must assign a cost to the AS to take advantage of the GTT overflow loadsharing feature. The primary destination is defined by the lower cost.</p> <ul style="list-style-type: none"> <li>• <b>cost</b>— Index value (1-64). Specifies the priority of the AS within the application group.</li> </ul> <p>Use the <b>limit</b> keyword to limit traffic rate to a specific AS in a GTT application group. The rate limit is configured only on the primary destination.</p> <ul style="list-style-type: none"> <li>• <b>limit</b>—Specifies the traffic-rate limitation.</li> <li>• <b>rate</b>—defines the rate as an integer value from 1 to 4294967296 MSU/sec.</li> </ul> |

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

The <b>limit</b> keyword is configured only on the primary destination.</p> <ul style="list-style-type: none"> <li><b>limit</b>—specifies the traffic limitation.</li> <li><i>rate</i>—defines the rate as an integer value from 1 to 4294967296 MSU/sec.</li> </ul> |
| Step 7 | <p><b>exit</b></p> <p><b>Example:</b></p> <pre>Router(config-cs7-gtt-app-grp)# exit</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Exits CS7 GTT application-group submode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Example

In the following example, the application group SMS-peak-on-weekdays has a primary DPC with a point code of 1.1.1 is limited to a rate of 2000 MSU per second. Any overflow traffic is sent to the backup DPC with a point code of 1.1.2. The primary DPC is defined by the lower cost of 1. The backup is defined by the higher cost of 2.

```
cs7 gtt application-group SMS-peak-on-weekdays
multiplicity cost
pc 1.1.1 ssn 11 1 pcssn limit 2000
pc 1.1.2 ssn 11 2 pcssn
```

In the following example, the application group SMS-peak-on-weekdays has a primary AS named weekday is limited to a rate of 2000 MSU per second. Any overflow traffic is sent to the backup AS named weekend. The primary AS is defined by the lower cost of 1. The AS is defined by the higher cost of 2.

```
cs7 gtt application-group SMS-peak-on-weekdays
multiplicity cost
asname weekday 1 gt limit 2000
asname weekend 2 gt
```

## Verifying and Monitoring

To verify the GTT SCCP overflow loadshare feature, use the following command in EXEC mode:

| Command                                                                                                                                        | Purpose                                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------|
| Router# <b>show cs7</b> { <b>instance</b> <i>instance</i> } <b>id</b> <b>rate-limit</b> { <b>pc</b> <i>pc</i>   <b>asname</b> <i>as-name</i> } | Displays the rate limit status of MTP overflow loadshare through the GTT application group . |
| Router# <b>show cs7</b> <b>instance</b> <b>id</b> <b>gtt application-group name</b> <i>application-group-name</i> <b>rate-limit</b>            | Displays the rate limit status of each line card for GTT SCCP loadshare overflow.            |

## Configuring the MTP Overflow Load Sharing

This configuration allows the ITP to send a user defined amount of traffic to an application group using MTP. The feature is instance wide and takes into account that there may be more than application group containing the same AS or DPC. It is similar to the GTT SCCP overflow loadshare feature.

### CONFIGURATION STEPS

|        | Command or Action                                                                                                           | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                      | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                              | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 3 | <b>cs7 gtt application-group</b> <i>group-name</i><br><br><b>Example:</b><br>Router(config)# cs7 gtt application-group abc  | Defines the GTT application group and enables application-group submenu.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 4 | <b>multiplicity {cost   share   cgpa   wrr}</b><br><br><b>Example:</b><br>Router(config-cs7-gtt-app-grp)# multiplicity cost | Specifies a method for selecting a destination for the application group. <ul style="list-style-type: none"> <li><b>cost</b>—Uses the destination with the least cost if that destination is available.</li> <li><b>share</b>—Shares equally among all destinations.</li> <li><b>cgpa</b>—Uses the SCCP calling party address (CGPA) field, which results in a weighted factor selection number for choosing the next destination from the available items in the application group.</li> <li><b>wrr</b>—Applies weighted round robin load balancing (WRR) to SCCP class 0 and SCCP class 1 traffic.</li> </ul> <div>  <b>Note</b> The <b>cost</b> keyword is used for overflow load sharing configurations. </div> |

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Step 8 | <p><b>cs7 instance</b> [<i>instance id</i>] <b>rate-limit</b> <i>rate</i> { <b>pc</b> [<i>ss7 pc</i>]   <b>asname</b> [<i>as-name</i>] } [<b>type</b> <b>sccp</b>]</p> <p><b>Example:</b><br/> Router(config)# cs7 instance 7 rate-limit 1000<br/> as Alpha type sccp</p> | <p>Limits traffic rate to a specified DPC or AS in MTP overflow loadshare through a GTT application group.</p> <ul style="list-style-type: none"> <li>• <b>rate-limit</b>—specifies there is a traffic-rate limitation. It limits the total traffic rate from gtt application group to this DPC or AS. The over-flow traffic will be routed to higher cost DPC or AS in the coming gtt application group. If not specified, the DPC or AS does not have a rate-limit.</li> <li>• <b>rate</b>—An integrate value from 1 to 4294967296 MSU/sec.</li> <li>• <b>type</b>—indicates which type the rate-limit would apply to. Default is sccp.</li> <li>• <b>sccp</b>— specifies that the rate limit is only applied to MAP entry instance-wide. This means the gtt application group can be limited.</li> </ul> <p> <b>Note</b> The SCCP option is the only type currently supported.</p> |
| Step 9 | <p><b>exit</b></p> <p><b>Example:</b><br/> Router(config)# exit</p>                                                                                                                                                                                                       | <p>Exits global configuration mode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Configuring GTT Application Group Load Balancing for SCCP Traffic

GTT application group load balancing allows both SCCP class 0 and SCCP class 1 traffic to be shared among multiple active destinations. You can choose one of several method for routing the traffic.

### CONFIGURATION STEPS

|        | Command or Action                                                                                                                                                                                                                                                                                                                                                            | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                                                                                                                                       | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                                                                                                                                                                               | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Step 3 | <b>cs7 gtt application-group</b> <i>group-name</i><br><br><b>Example:</b><br>Router(config)# cs7 gtt application-group abc                                                                                                                                                                                                                                                   | Defines the GTT application group and enables CS7 GTT application-group submenu.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Step 4 | <b>multiplicity</b> { <i>cost</i>   <i>share</i>   <i>cgpa</i>   <i>wrr</i> }<br><br><b>Example:</b><br>Router(config-cs7-gtt-app-grp)# multiplicity cost                                                                                                                                                                                                                    | Specifies a method for selecting a destination for the application group. <ul style="list-style-type: none"> <li><b>cost</b>—Uses the destination with the least cost if that destination is available.</li> <li><b>share</b>—Shares equally among all destinations.</li> <li><b>cgpa</b>—Uses the SCCP calling party address (CGPA) field, which results in a weighted factor selection number for choosing the next destination from the available items in the application group.</li> <li><b>wrr</b>—Applies weighted round robin load balancing (WRR) to SCCP class 0 and SCCP class 1 traffic.</li> </ul> <div>  <b>Note</b> The destination in a GTT application group uses the wf argument when the multiplicity command is configured with the cgpa or wrr keyword. </div> |
| Step 5 | <b>instance</b> <i>instance-number</i> <b>asname</b> <i>as-name</i> [ <i>cost</i> [ <i>ssn</i> <i>ssn</i> ] { <i>gt</i> [ <i>ntt</i> <i>ntt</i> ]   <i>pcssn</i> } [ <i>rate-limit</i> <i>rate</i> ]   <i>wf</i> [ <i>ssn</i> <i>ssn</i> ] { <i>gt</i> [ <i>ntt</i> <i>ntt</i> ]   <i>pcssn</i> }}<br><br><b>Example:</b><br>Router(config-cs7-gtt-app-grp)# asname as1 4 gt | (Optional) Assigns an M3UA or SUA AS directly to a global title.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|        | Command or Action                                                                                                                                                                                                                                               | Purpose                                                                                         |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Step 6 | <b>instance</b> <i>instance-number</i> <b>pc</b> <i>pc</i> [ <b>ssn</b> <i>ssn</i> ] { <i>cost</i> { <b>gt</b> [ <i>ntt</i> <i>ntt</i> ]   <b>pcssn</b> } [ <b>rate-limit</b> <i>rate</i> ]   <b>wf</b> { <b>gt</b> [ <i>ntt</i> <i>ntt</i> ]   <b>pcssn</b> }} | (Optional) Adds or changes a point code and optional subsystem number in the application group. |
|        | <b>Example:</b><br>Router(config-cs7-gtt-app-grp)# <b>pc</b> 7.7.1 3 <b>gt</b>                                                                                                                                                                                  |                                                                                                 |
| Step 7 | <b>exit</b>                                                                                                                                                                                                                                                     | Exits CS7 GTT application-group submode.                                                        |
|        | <b>Example:</b><br>Router(config)# <b>exit</b>                                                                                                                                                                                                                  |                                                                                                 |

## Example

The following example shows how to configure a GTT application group named alpha that uses the CGPA method for selecting a destination for the application group. The CGPA method uses the SCCP calling party address (CGPA) field to determine the destination.

It also configures an application group of three items. The first item is used approximately twice as many times as the other two items. These items handle equal amounts of traffic.

```
cs7 gtt application-group alpha
multiplicity cgpa
pc 1.1.1 ssn 8 50 pcssn
pc 1.1.2 ssn 8 25 pcssn
pc 1.1.3 ssn 8 25 pcssn
```

The following example shows how to configure a GTT application group named abc that uses the destination with the least cost to select a destination for the application group.

It also configures two AS names. AS1 has a cost value of four and RI set to route on GT. AS2 has a cost value of five and the RI set to route on point code and subsystem number.

```
cs7 gtt application-group abc
multiplicity cost
pc 7.7.1 3 gt
asname as1 4 gt
asname as2 5 pcssn
```

## Configuring GTT Application Group Load Balancing for SCCP Traffic at the Global Level

You can configure the loadsharing option for GTT application groups at the global level. This applies only to Class 1 traffic.

## CONFIGURATION STEPS

|        | Command                                                                                                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                           | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                                                                                   | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Step 3 | <b>cs7</b> [ <b>instance</b> <i>instance-number</i> ] <b>sccp-class1-loadshare</b> { <b>opc-sls</b> [ <b>opc-shift</b> [ <i>opc-shift-number</i> ]   <b>cgpa</b>   <b>sls</b> }<br><br><b>Example:</b><br>ITP(config)# cs7 instance 1 sccp-class1-loadshare cgpa | Configures the global loadsharing option for GTT application groups. <ul style="list-style-type: none"> <li><b>instance</b> —(Optional) Configures the secondary point code on an instance.</li> <li><b>instance-number</b>—Defines the specific instance. Valid values are from 0 to 7.</li> <li><b>opc-sls</b>—Extends SLS based ASP binding to OPC-SLS combination based binding. This command applies only to the ITU standard not the ANSI standard.</li> <li><b>cgpa</b>—Specifies the SCCP calling party address option.</li> <li><b>sls</b>—Specifies the signaling link selection (sls) based load sharing option.</li> <li><b>opc-shift</b>—(Optional) opc-shift applies only to opc-sls option. The default shift is 0. This command applies only to the ITU standard not the ANSI standard.</li> <li><b>opc-shift-number</b>— (Optional) Defines the specific instance.</li> </ul> |

## Example

The following command configure the loadsharing option for GTT application groups in loadshare/cost mode with the SCCP calling party address option:

```
cs7 instance 1 sccp-class1-loadshare cgpa
```

## Configuring GTT Application Groups with the WRR Algorithm for Processing SCCP Class 1 Traffic

You can configure the loadsharing option for GTT application groups in WRR mode with the SCCP calling party address option. It applies for Class 1 traffic for all GTT application groups with the wrr mode in that instance.

### CONFIGURATION STEPS

|        | Command                                                                                                                                                                                              | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                               | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>Router# configure terminal                                                                                                                       | Enters global configuration mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Step 3 | <b>cs7 [instance instance-number] sccp-class1-wrr {opc-sls [opc-shift [opc-shift-number]   cgpa-sls   sls   opc]}</b><br><br><b>Example:</b><br>ITP(config)# cs7 instance 1 sccp-class1-wrr cgpa-sls | Indicates the seed for the WRR algorithm when processing SCCP class 1 traffic. <ul style="list-style-type: none"> <li><b>instance</b> —(Optional) Configures the secondary point code on an instance.</li> <li><b>instance-number</b>—Defines the specific instance. Valid values are from 0 to 7.</li> <li><b>opc-sls</b>—Extends SLS based ASP binding to OPC-SLS combination based binding. This command applies only to the ITU standard not the ANSI standard.</li> <li><b>cgpa-sls</b>—Load sharing with the combination of cgpa and sls.</li> <li><b>sls</b>—Specifies the signaling link selection (sls) based load sharing option.</li> <li><b>opc</b>—Uses OPC to calculate wrr loadsharing.</li> <li><b>opc-shift</b>—(Optional) opc-shift applies only to opc-sls option. The default shift is 0. This command applies only to the ITU standard not the ANSI standard.</li> <li><b>opc-shift-number</b>— (Optional) Defines the specific instance.</li> </ul> |

### Example

```
cs7 instance 1 sccp-class1-wrr cgpa-sls
```

## Configuring SCCP Class 0 Load Sharing to Ignore Class and Sequencing

Although some high level SS7 protocols require in-sequence delivery of packets, other high level SS7 protocols, such as SCCP and TCAP, do not. When **cs7 distribute-sccp-unsequenced** is enabled, the Cisco ITP examines the packet header and determines whether or not that protocol requires in-sequence delivery. If in-sequence delivery is not required, the SLS field value is ignored and the Cisco ITP makes a round-robin selection of the link or ASP on which to forward the packet.

### PROCEDURE STEPS

|        | Command or Action                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Step 3 | <b>cs7 [instance instance-number]<br/>distribute-sccp-unsequenced</b><br><br><b>Example:</b><br>Router(config)# cs7 instance 1<br>distribute-sccp-unsequenced | Disable SCCP load sharing recognition of class and sequencing.<br><ul style="list-style-type: none"><li><b>instance</b>—Specifies an instance if multiple instances exist. If you have configured the ITP with the multi-instance command, you must use the <b>instance</b> keyword to specify the particular instance. A single instance does not require this keyword.</li><li><b>instance-number</b>—Specifies the particular instance with a valid range of 0 through 7. The default is 0.</li></ul> |

### Example

```
cs7 distribute-sccp-unsequenced

or

cs7 instance 1 distribute-sccp-unsequenced
```

## Configuring SCCP Class 1 Load Sharing to Ignore Class and Sequencing

Having SCCP recognize the class or round-robin sequencing of traffic may not benefit some networks. For example, if the majority of traffic is SCCP class 1, but there is no advantage in keeping the traffic in sequence. The **cs7 distribute-sccp-sequenced** command configures SCCP load sharing to ignore class and sequencing. Enabling this command allows an even distribution of class 1 traffic.

#### Note

SCCP class 1 sequencing is not guaranteed and could impact application behavior.

## Example

```
cs7 distribute-sccp-sequenced

or

cs7 instance 1 distribute-sccp-sequenced
```

## Configuring MTP3 Enhanced Load Sharing For ITU

The ITU standard specifies a 4-bit SLS in the MSU for link selection (SLC). This is insufficient for combined linksets made up of 17 or more links. To enable a better load distribution for the combined linksets, the user can configure the enhanced load sharing feature. The enhanced load sharing feature concatenates a 3-bit value, derived from the opc and dpc, with the 4-bit SLS and yields a 7-bit value used to select a link from a 128 entry SLS->SLC mapping table.

The user can also shift the SLS bits used for linkset and link configuration with the **sls-shift** command.

To configure the enhanced load sharing feature or to shift the SLS bits, perform the following steps:

**Note**

These configurations are only available with the ITU variant.

## CONFIGURATION STEPS

|        | Command                                                                                                                                                                                                                                  | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

# Verifying and Monitoring MTP3 Load Sharing

The SLS field in MSUs is used for load sharing. Proper load sharing in SS7 networks relies on end nodes generating all SLS values equally. In order to trouble shoot load sharing problems in the network, this command samples the SLS values for incoming or outgoing MSUs on a link or linkset, and the related show command reports the number of MSUs received for each SLS.

## SUMMARY STEPS

1. **enable**
2. **cs7 sample linkset** [*linkset-name*] [*slc*] {**in** | **out**} [**sample-time** [*sample-time-seconds*]]
3. **show cs7 sample sls**

|        | Command                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Purpose                                                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>Router> enable                                                                                                                                                                                                                                                                                                                                                                                                                                           | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul>                             |

## Inter-Carrier Accounting

Inter-Carrier Accounting enables Cisco ITP to accumulate ingress and egress traffic statistics into accounts. Each configured account can represent an operator or carrier. Inter-Carrier Accounting allows the use of ITP accounting data for Signaling Data Records (SDR) and Inter-Carrier billing.

### Feature History for Load Sharing

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(33)IRD | This feature was introduced. |
| 12.2(33)IRF | SMS accounting was added.    |

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

#### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. One configuration session is allowed to enter configuration mode; other sessions cannot enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the number of active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

## Information About Inter-Carrier Accounting

Cisco ITP generates a large amount of statistical and accounting information from its signaling network. Inter-Carrier Accounting allows the user to tailor this information for use in billing and settlement.

The process starts with manually configuring a set of accounts. An account represents a carrier, customer or operator. Select the appropriate criteria for the traffic accumulating against these accounts. For example, you might configure Inter-Carrier Accounting for the traffic on a linkset to a specific operator.

Inter-Carrier Accounting is based on MTP3, SCCP, or SMS messages. It also has data collection and backup options to help preserve the integrity of the data.

## MTP3 Accounting

MTP3 Accounting counts the bytes and message signal units (MSUs) of the signaling traffic received from, or sent to an active linkset. For each linkset in an account, there are sets of counters that increment based on the destination of the traffic.

For MTP3 Accounting, an account consists of:

- The ITP and the instance number.
- The customer number, ID, or name that indicates the identity of the adjacent network operator.
- A set of names for the linksets that connect to this specific operator.
- A direction for the accounting inspection. The direction is set as either In, Out, or Both. Specifying In or Out prevents the ITP from having to inspect the traffic in both directions.
- (Optional) A set of either destination point codes (DPCs) or originating point codes (OPCs) for this account to accumulate. Each accounting direction (In, Out, Both) could accumulate on either OPC or DPC. This allows an operator to accumulate Outgoing traffic based on OPC, or incoming based on DPC.
- (Optional) A set of service indicators to accumulate in this account.

## SCCP Accounting

SCCP Accounting counts the bytes, message signal units (MSUs) and Global Title Translation (GTT) operations performed on the received SCCP traffic, which requires onward forwarding. This process only accounts for final or intermediate traffic requiring GTT at the ITP, when the ITP functions as an SCCP relay node instead of an MTP3 relay node. SCCP messages, in which the destination point code (DPC) is not the local point code of the ITP, should use MTP3 Accounting.

For SCCP accounting, an account would consist of:

- The ITP and the instance number.
- The customer number, ID, or name that indicates the identity of the adjacent network operator.
- A set of names for the linksets that connect to this specific operator. The use of a linkset as an account variable allows the operator to turn SCCP accounting off and on.
- A direction for the accounting. The direction is set as either In, Out, or Both. In specifies ingress traffic. Out specifies egress traffic.
- A set of either:
  - OPC (In traffic) of the operator which performed GTT previously.
  - DPC (Out traffic) of the operator which has to perform GTT next.
- (Optional) A set of one of the following:
  - CgPA GTA (originating operator for In traffic)
  - CdPA GTA (destination operator for Out traffic)

- CgPA SSN (originating service for In traffic)
- CdPA SSN (destination service for Out traffic)

## SMS Traffic Accounting

Inter-Carrier Accounting also supports accounting for incoming SMS traffic. SMS accounting is based on defining an account at the SCCP level. You define and use SMS accounting in the same manner as MTP3/SCCP accounting. The account can be defined only on the inbound interface, not on the outbound interface. Account IDs configured with the type SMS help segregate the SMS traffic. No counters increment at the MTP3 or SCCP level for SMS accounts. The defined parameters operate at the MAP/IS41 layer to isolate SMS messages for this particular account and increment the SMS specific counters.

MLR routing is required for SMS traffic accounting. SMS traffic accounting is not valid when the Cisco ITP is routing SMS traffic at the SCCP or MTP3 level.

## Service Data Records

The accounting information is stored in the form of signaling data records (SDRs) formatted as plain text. These SDRs are saved onto a storage server. You can use these accumulated SDRs to generate billing information.

The SDR contains these fields:

- Date/Time of the start and end of each time interval
- SDR Version ID
- Instance ID
- Account ID / Name
- Linkset name and direction
- OPC
- SMS MSU sent/received
- SMS Bytes/Octets transmitted or received

This is an example of an SDR:

```
Start Timestamp : 2009/09/22/09:15:03.191
End Timestamp : 2009/09/22/09:16:33.183
SDR Version ID: Ver-1.0
Total Records : 10
-----
Instance : 0
Instance      : 0
Account       : sms-acc
Linkset       : m2pa_194_0_0
SCCP OPC IN   : 1.1.2
SSN           : others
SMS MSU/SMS OCTETS : 10/1380
```

## Data Collection and Backup Options

Accounting records used for billing and Inter-Carrier settlement activities need a robust mechanism to limit the loss and maintain the integrity of the accounting data. They should also generate and retain information about the collection and distribution of the data. Inter-Carrier Accounting includes these features:

- Traceable accounting records with sequence number
- Visibility to the operator of any lost data or time gaps in the accounting data
- Uploading for backup purposes and for subsequent post-processing, and distribution or collection
- Temporary backup to a flash drive
- Minimal or no accumulator data loss after a supervisor module switchover, hardware removal, or other recoverable events

## Configuring Inter-Carrier Accounting

This section contains information and procedures:

- [Configuring an MTP3 Inter-Carrier Accounting Billing Account, page 338](#)
- [Configuring an SCCP Inter-Carrier Accounting Billing Account, page 341](#)
- [Configuring Inter-Carrier Accounting Data Collection, page 345](#)
- [Saving and Loading Inter-Carrier Accounting Configurations, page 346](#)
- [Verifying and Monitoring, page 346](#)

## Configuring an MTP3 Inter-Carrier Accounting Billing Account

You can set up an Inter-Carrier Accounting billing account based on MTP3, SCCP, or a combination of both. Either account type can also be configured for SMS Traffic Accounting. The procedure shown below configures an MTP3 account.

### CONFIGURATION STEPS

|        | Command or Action                                                           | Purpose                                                                                                            |
|--------|-----------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>• Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal | Enters global configuration mode.                                                                                  |

| Command or Action                                                                                                                                                                                         | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>Step 3</b></p> <pre>cs7 [instance instance-number] linkset ls-name adj-pc [local-pc [pc]]</pre> <p><b>Example:</b><br/>ITP(config)# cs7 instance 0 linkset LINKSET_01 2.179.0</p>                   | <p>Specifies a linkset and enter cs7 linkset submode:</p> <p><i>instance-number</i>—The range is from 0 to 7. The default instance is 0.</p> <p><i>ls-name</i>—Name of the linkset. (Linkset names are case-specific.)</p> <p><i>adj-pc</i>—Point code of the adjacent signaling point.</p> <p><b>local-pc</b>—(Optional) Specifies a secondary point code, which functions as a second linkset between the ITP and the adjacent node.</p> <p><i>pc</i>—Either the ITP's primary or secondary point code. By default, it is the primary point code.</p>                                                                                                                                                                                                                                                                                                                              |
| <p><b>Step 4</b></p> <pre>link slc [name] sctp remote-ip-addr [remote-ip-addr ...] remote-port-num local-port-num</pre> <p><b>Example:</b><br/>ITP(config-cs7-ls)# link 0 sctp LINKSET_02 24879 24879</p> | <p>Configures an SS7 link:</p> <p><i>slc</i>—Signal Link Code. Range is from 0 to 15. The <i>slc</i> value uniquely identifies this link within the linkset. The <i>slc</i> value must match the value configured on the partner node for this link.</p> <p><i>name</i>—Name of the group peer on which the link physically resides. The <i>name</i> parameter is valid (and required) only if the ITP Group feature has been configured.</p> <p><b>sctp</b>—Specifies Stream Control Transmission Protocol.</p> <p><i>remote-ip-addr</i>—Remote IP address that is one of the four IP addresses configured as local IP addresses on the remote peer. At least one, and up to four, remote IP addresses can be specified.</p> <p><i>remote-port-num</i>—Remote port number (the local port number configured on the remote ITP).</p> <p><i>local-port-num</i>—Local port number.</p> |
| <p><b>Step 5</b></p> <pre>exit</pre> <p><b>Example:</b><br/>ITP(config-cs7-ls)# exit</p>                                                                                                                  | <p>Exits submode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Inter-Carrier Accounting Billing Account Configured for MTP3 Example

In the following example, an Inter-Carrier Accounting billing account is configured for MTP3:

```
cs7 instance 0 linkset LINKSET_01 2.179.0
  link 0 sctp LINKSET_02 24879 24879

cs7 instance 0 billing pc-table PCTBL_01 mtp3
  point-code 1.1.1 si 11
  point-code 1.1.2 si 12

cs7 instance 0 billing account BILL_ACCNT
  linkset LINKSET_01 inbound type mtp3 opc-table PCTBL_01
```

## Inter-Carrier Accounting Billing Account Configured for Both MTP3 and SCCP Example

In the following example, an Inter-Carrier Accounting billing account is configured for MTP3 and SCCP:

```
cs7 instance 0 linkset LINKSET_01 2.179.0
  link 0 sctp LINKSET_02 24879 24879

cs7 instance 0 linkset to_2800-10 2.149.0
  link 0 sctp 10.74.50.149 24849 24849

cs7 instance 0 billing pc-table PCTBL_01 mtp3
  point-code 1.1.1 si 11
  point-code 1.1.2 si 12

cs7 instance 0 billing pc-table PCTBL_02 sccp
  point-code 2.2.1 ssn 8 gta 12345 tt 0 gti 2
  point-code 2.2.2 ssn 8 gta 67890 tt 0 gti 4 np 4 nai 2

cs7 instance 0 billing account BILL_ACCNT
  linkset LINKSET_01 inbound type mtp3 opc-table PCTBL_01
  linkset LINKSET_02 outbound type sccp dpc-table PCTBL_02
```

## Configuring an SCCP Inter-Carrier Accounting Billing Account

This procedure configures an Inter-Carrier Accounting Billing Account using SCCP.

### CONFIGURATION STEPS

|        | Command or Action                                                           | Purpose                                                                                                          |
|--------|-----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                         | Enables privileged EXEC mode. <ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul> |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal | Enters global configuration mode.                                                                                |

|        | Command or Action                                                                                                                                                                                                                                          | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 3 | <p><b>cs7</b> [<b>instance</b> <i>instance-number</i>] <b>linkset</b> <i>ls-name</i><br/> <i>adj-pc</i> [<b>local-pc</b> <i>pc</i>]</p> <p><b>Example:</b><br/> ITP(config)# cs7 instance 0 linkset to_2800-10<br/> 2.149.0</p>                            | <p>Specifies a linkset and enter cs7 linkset submode:</p> <p><i>instance-number</i>—The range is from 0 to 7. The default is 0.</p> <p><i>ls-name</i>—Name of the linkset. (Linkset names are case-specific.)</p> <p><i>adj-pc</i>—Point code of the adjacent signaling point.</p> <p><b>local-pc</b>—(Optional) Specifies the secondary point code, which functions as a second linkset between the ITP and the adjacent node.</p> <p><i>pc</i>—Either the ITP's primary or secondary point code. By default, it is the primary point code.</p>                                                                                                                                                                                                                                                                                                                                         |
| Step 4 | <p><b>link</b> <i>slc</i> [<i>name</i>] <b>sctp</b> <i>remote-ip-addr</i><br/> [<i>remote-ip-addr</i> ...] <i>remote-port-num</i><br/> <i>local-port-num</i></p> <p><b>Example:</b><br/> ITP(config-cs7-ls)# link 0 sctp 10.74.50.149<br/> 24849 24849</p> | <p>Configures an SS7 link:</p> <p><i>slc</i>—Signal Link Code. The range is from 0 to 15. The <i>slc</i> value uniquely identifies this link within the linkset. The <i>slc</i> value must match the value configured on the partner node for this link.</p> <p><i>name</i>—Name of the group peer on which the link physically resides. The <i>name</i> parameter is valid (and required) only if the ITP Group feature has been configured.</p> <p><b>sctp</b>—Specifies Stream Control Transmission Protocol.</p> <p><i>remote-ip-addr</i>—Remote IP address that is one of the four IP addresses configured as local IP addresses on the remote peer. At least one, and up to four, remote IP addresses can be specified.</p> <p><i>remote-port-num</i>—Remote port number (the local port number configured on the remote ITP).</p> <p><i>local-port-num</i>—Local port number.</p> |
| Step 5 | <p><b>exit</b></p> <p><b>Example:</b><br/> ITP(config-cs7-ls)# exit</p>                                                                                                                                                                                    | <p>Exits submode.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Example

In this example an Inter-Carrier Accounting billing account is configured for SCCP:

```
cs7 instance 0 linkset to_2800-10 2.149.0
  link 0 sctp 10.74.50.149 24849 24849

cs7 instance 0 billing pc-table PCTBL_02 sccp
  point-code 2.2.1 ssn 8 gta 12345 tt 0 gti 2
  point-code 2.2.2 ssn 8 gta 67890 tt 0 gti 4 np 4 nai 2

cs7 instance 0 billing account BILL_ACCNT
  linkset LINKSET_02 outbound type sccp dpc-table PCTBL_02
```

In this example, an Inter-Carrier billing account is configured for SMS:

```
cs7 instance 0 billing pc-table PCTBL_01 sms_sccp
  point-code 1.11.0 ssn 3
  point-code 1.11.5 ssn 11

cs7 instance 0 billing pc-table PCTBL_02 sms_sccp

## Configuring Inter-Carrier Accounting Data Collection

You can configure several accounting data options for Inter-Carrier Accounting. This procedure details this configuration:

### CONFIGURATION STEPS

|        | Command or Action                                                                                                                               | Purpose                                                                                                                                                                                                              |
|--------|-------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                                             | Enables privileged EXEC mode.<br><ul style="list-style-type: none"><li>Enter your password if prompted.</li></ul>                                                                                                    |
| Step 2 | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                                                     | Enters global configuration mode.                                                                                                                                                                                    |
| Step 3 | <b>cs7 billing options</b><br><br><b>Example:</b><br>ITP(config)# cs7 billing options                                                           | Enables the user to configure options for the billing account and enters the billing option configuration submode.                                                                                                   |
| Step 4 | <b>rx-per-tx times</b><br><br><b>Example:</b><br>ITP(config-options-entry)# rx-per-tx 12                                                        | (Optional) Time of data collection in a data storage interval:<br><i>times</i> —Times of data collection (3-1024).                                                                                                   |
| Step 5 | <b>rx-interval seconds</b><br><br><b>Example:</b><br>ITP(config-options-entry)# rx-interval 300                                                 | (Optional) Sets interval for a time of data collection:<br><i>seconds</i> —Seconds of interval (30-86400)                                                                                                            |
| Step 6 | <b>backstore [order][url]</b><br><br><b>Example:</b><br>ITP(config-options-entry)# backstore 0<br>ftp://admin:admin@192.168.1.2/itp_billing.dat | (Optional) Sets the location and order of the back storage files:<br><br><i>order</i> —Order of trying current back storage among all back storages (0-1).<br><i>url</i> —The URL location of the back storage file. |
| Step 7 | <b>bak-file-num num</b><br><br><b>Example:</b><br>ITP(config-options-entry)# bak-file-num 2                                                     | (Optional) Sets the backup file number.<br><br><i>num</i> —backup file number in data saving destination (1-1024)                                                                                                    |
| Step 8 | <b>exit</b><br><br><b>Example:</b><br>ITP(config-options-entry)# exit                                                                           | Exits submode.                                                                                                                                                                                                       |

### Example

In this example, Inter-Carrier Accounting options are configured:

```
(config)#cs7 billing options
(config-optns-entry)# rx-per-tx 12
(config-optns-entry)# rx-interval 300
(config-optns-entry)# backstore 0 ftp://admin:admin@192.168.1.2/itp_billing.dat
(config-optns-entry)# backstore 1 disk0:itp_billing.bak
(config-optns-entry)# bak-file-num 2
```

## Saving and Loading Inter-Carrier Accounting Configurations

You can configure the saving and loading of Inter-Carrier Accounting billing configurations. This procedure details these operations:

### CONFIGURATION STEPS

|               | Command or Action                                                                                                       | Purpose                                                                                                                                                                                                                                                                    |
|---------------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | <b>enable</b><br><br><b>Example:</b><br>ITP> enable                                                                     | Enables privileged EXEC mode.<br><ul style="list-style-type: none"> <li>Enter your password if prompted.</li> </ul>                                                                                                                                                        |
| <b>Step 2</b> | <b>configure terminal</b><br><br><b>Example:</b><br>ITP# configure terminal                                             | Enters global configuration mode.                                                                                                                                                                                                                                          |
| <b>Step 3</b> | <b>cs7 save billing-cfg url</b><br><br><b>Example:</b><br>ITP(config)# cs7 save billing config<br>disk0:itp-billing.cfg | Saves the current billing configuration to a specified URL:<br><i>url</i> —The location of the saved billing configuration.                                                                                                                                                |
| <b>Step 4</b> | <b>cs7 billing load url [execute]</b><br><br><b>Example:</b><br>ITP(config)# cs7 billing load<br>disk0:itp_billing.cfg  | Loads the stored billing configuration:<br><i>url</i> —The location of the saved billing configuration.<br><b>execute</b> —Specifies that the stored billing configuration is immediately applied. The default is to apply the configuration after the next system reboot. |

### Example

In this example, the saving and loading of an Inter-Carrier Accounting billing configuration file is shown:

```
enable
cs7 save billing-cfg disk0:itp-billing.cfg
config terminal
cs7 billing load disk0:itp_billing.cfg
```

## Verifying and Monitoring

To verify Inter-Carrier Accounting billing configurations, use the following commands in EXEC mode:

| Command                                                                                                                            | Purpose                                           |
|------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| ITP# <b>show cs7 billing configuration</b> [ <b>account</b> <i>account-name</i>   <b>pc-table</b>   <b>options</b>   <b>load</b> ] | Displays the cs7 billing configuration.           |
| ITP# <b>show cs7 billing statistics</b>                                                                                            | Displays the latest collected billing statistics. |

## Summary Routing and ANSI Cluster Routing

---

The Summary Routing feature allows routing of MSUs to groups of DPCs by specifying one or more routes to a summary destination in the route table rather than individual route table entries for each destination.

### Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

#### Note

---

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

# Information About Summary Routing and ANSI Cluster Routing

The Summary Routing feature allows routing of MSUs to groups of DPCs by specifying one or more routes to a summary destination in the route table rather than individual route table entries for each destination.

Typically a route table has primary (or normal) routes and alternate routes of lower priority to fully qualified (or full PC) destinations. A fully qualified destination has all significant bits in the point code explicitly specified. Summary Routing is the capability of using partly qualified destinations in the route table, where one or more trailing bits in the point code are left unspecified, to refer collectively to all the fully qualified destinations that have any combination of bits within the unspecified portion.

This overview begins with a fictional scenario that explains how fully-qualified point codes are assigned and how partly-qualified point codes are derived. The remainder of the overview covers in greater detail the function of summary routing and the routing table.

## How Point Codes Are Used in Summary Routing

To examine how point codes are used in Summary Routing, consider the following example for a company in France we will call Voila. This example uses the ITU standard for point codes, which uses 3 bits to indicate the zone, 8 bits to indicate the region, and 3 bits to indicate the signaling point (SP).

### Assigning Point Codes

When Voila acquired its block of point codes, the zone segment was preassigned to be 5, or 101 binary. The network administrator at Voila wanted to take advantage of Summary Routing and so devised the following numbering strategy for assigning the region and SP segments of the point codes:

- In the Ile-De-France region the region segment of the point code would begin with 00 binary.
- In the Normandy region the region segment would begin with 01 binary.
- In the Brittany region, the region segment would begin with 10 binary. The SP segments would be numbered sequentially.

Focusing on Ile-De-France, we can see that numbering the region segment 00xxxxxx binary provides the range of numbers 0 through 63 decimal. Within this numbering system, the network administrator further decided to provision point codes in the city of Paris to have a region segment of 42 or 00101010 binary. SPs would be numbered sequentially.

The following table shows a partial list of point codes in the Voila network:

**Table 0-25 Sample Point Code Numbering Plan**

| Location | Device  | Point Code |
|----------|---------|------------|
| Paris    | ITP-P1  | 5.42.1     |
| Paris    | ITP-P2  | 5.42.2     |
| Paris    | MSC-P1  | 5.42.3     |
| Paris    | MSC-P2  | 5.42.4     |
| Paris    | SMSC-P1 | 5.42.5     |
| Meudon   | HLR-P1  | 5.50.1     |
| Normandy | ITP-N1  | 5.91.1     |
| Normandy | ITP-N2  | 5.91.2     |

**Table 0-25**      **Sample Point Code Numbering Plan (continued)**

| Location | Device  | Point Code |
|----------|---------|------------|
| Normandy | MSC-N1  | 5.91.3     |
| Normandy | SMSC-N2 | 5.91.4     |
| Brittany | ITP-B1  | 5.149.1    |
| Brittany | ITP-B2  | 5.149.2    |

## Specifying Summary Destinations

In our example, the Voila network administrator assigned point codes in a way that can take advantage of the Summary Routing feature. Consider the point codes assigned to the three regions in France. All point codes belonging to each of these groups have in common the first 5 bits of the point code. For example, ITP-P1 in Paris and HLR-P1 in Meudon are both assigned point codes that belong to the same region, as defined by the network administrator.

The point code for MSC-P1 in Paris is 5.42.3, shown in binary format below:

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 0 | 1 | 1 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

The point code for HLR-P1 in the Paris suburb of Meudon is 5.50.1, shown in binary format below:

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 1 | 0 | 1 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 1 |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|

The first 5 characters of the point codes are the same for both destinations and for all of the fully qualified destinations in the region. This commonality can be expressed as a partly-qualified destination with the point code and mask 5.0.0 7.192.0 (or the equivalent expression 5.0.0/5). This partly qualified destination means “consider the first 5 bits in the point code (the mask 7.192.0 and /5 both mean the first 5 bits) and include all point codes with the zone segment equal to 5 and the region segment in the range 0 (all 8 bits off = 0) through (first 2 region bits off and the remaining 6 bits on = 63).”

Examine the point codes for Normandy and Brittany, and notice that all of these point codes can be identified by the partly-qualified destinations 5.64.0/5 (Normandy) and 5.128.0/5 (Brittany). The first two bits in the region segment for Normandy are 01, so the range of numbers in the Normandy region segment will be 64 through 127. The first two bits in the region segment for Brittany are 11, so the range of numbers in the Brittany region segment will be 128 through 255.

## Summary Routes and the Routing Table

Summary routes are used primarily to reduce the number of route table entries. Summary Routing allows an easy translation of the hierarchy in the network topology into the logical organization of the route table. For example, a remote set of nodes with DPCs 1.\*.\* (where \* is a number in the appropriate range for ITU or ANSI) can be reached by creating a set of routes to 1.0.0/3 (ITU), or 1.0.0/8 (ANSI), only. There is no need to create individual routes to all the dozens of destinations 1.\*.\* that may be present in the network, particularly if all those destinations can be reached by the same set of linksets in the same order of priority. If there happens to be a member within 1.\*.\*, say 1.6.7, routes to which do not share some or all the linksets with the routes to the summary destination, then it is possible to configure routes to 1.6.7 using these different linkset(s) along with the summary routes that covers all the other point codes within 1.\*.\*. Such a configuration would be displayed as follows:

```
Router# show cs7 route detailed
Routing table = system
C=Cong Q=QoS P=Prio
Destination      C  Q  P Linkset Name      Linkset Non-adj Route
-----
1.6.7/14         acces  2  sirius             avail    allowed avail
                  3  castor             avail    allowed avail
                  4  pollux             avail    allowed avail
1.0.0/3          acces  2  polaris            avail    avail
                  3  pollux             avail    avail
```

Summary routes can coexist with fully qualified routes. In the presence of a configured full PC member, summary routes behave as alternate routes that have priority lower than that of fully qualified alternate routes.

When a route has to be selected for an outbound MSU, the route table is searched for a full point code entry matching the DPC in order of route priority. If any route to the full PC is configured and available, it is chosen for routing, otherwise the route table is searched for the next best partial match with a shorter mask length. If a summary route is configured and it is available, then this route is chosen for routing, otherwise the search continues. The search ends after mask length zero yields no route.

If a message is received for routing to an unconfigured destination Y that is a member of a summary destination and that summary destination is inaccessible, then the Response Method will be used to send a TFP concerning Y. Likewise, if the summary destination is restricted a TFR will be sent. If a route-set test message (Route Processor/RST or RSR) is received concerning a destination Y that is a member of a summary route, then a response will be sent concerning Y depending on the status of that summary route.

Routes to 0.0.0/0 are system wide default routes that behave as alternate routes to all the fully or partly qualified routes configured in the system. The linkset that goes between a mated pair of ITPs is such a default route from the perspective of each of those ITPs. There is no special external route management messages for the support of summary routes (the ANSI cluster routing case is an exception, see below).

There are no route management messages exchanged between network elements to maintain summary route status except the usual TFP, TFR, TFA, Route Processor/RST and RSR. When a TFP is received on a certain route (i.e. a certain linkset leading to an adjacent point code) concerning a point-code, say 1.6.1 in the above example, and that point-code is not configured, and there is a summary route configured and available on that linkset, route table entries are created dynamically for the concerned point-code by copying the summary routes. The concerned route is marked prohibited. Future traffic is blocked for 1.6.1 but allowed for all other members of the summary route 1.6.0/11. Route set test is started. When a TFA is received on the same route, and all the other dynamic routes to the concerned point-code have non-adjacent status available, then all the dynamic routes are removed. Dynamic routes are also created when a TFR is received, and traffic for that route is affected as for any other restricted route. Route set restricted test is started.

In the previous example if routes to the concerned point code were configured, none being the route to which the TFP/TFR pertains, and these routes are all unavailable, then a single dynamic route is created with priority value one more than the highest configured. If a route with priority 9 were to already exist then the dynamic route cannot be added. It is therefore necessary to keep the priority value of the lowest priority configured route at, say, 6 or below when a configured full point-code route is using summary routes.

Dynamic routes are also created when TFC concerning a destination is received and summary routes to that destination exist in the route table. When the Route set congestion test procedure eventually brings the destination congestion status to zero, these dynamic routes are removed.

Dynamic routes cannot be removed using the **no update route** command. There is a periodic audit of the route table that runs once a day at 3:00 a.m. to remove dynamic entries older than 12 hours. This mechanism allows dynamic routes to remain in the system between 12 and 36 hours (24 hours average). For this audit to work properly, the system time-of-day clock and time zone must be set. When the route table is saved to file, dynamic routes are not included.

## How to Configure Summary Routes

You can create a summary route by entering the **update route** command and specifying a mask length value that is less than that for a full point code. The mask length is in the range 0 through 13 for ITU, and 0 through 15, and 17 through 23 for ANSI. For ANSI, mask length 16 is for cluster routes.

To create a summary route, enter the following command, starting in global configuration mode:

| Command                                                                                                                                                                                                                                                         | Purpose                                                                          |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| Router(config)# <b>cs7 route-table system</b>                                                                                                                                                                                                                   | Specifies the name of the route table and enters route table configuration mode. |
| Router(config-cs7-rt)# <b>update route</b> <i>point-code</i> [ <i>mask</i>   <i>length</i> ] <b>linkset</b> <i>ls-name</i> [ <b>priority</b> <i>priority-value</i> <sup>1</sup> ] [ <b>qos-class</b> { <i>class</i>   <b>default</b> }] [ <b>load_balance</b> ] | Adds a summary route to the table.                                               |

1. The smaller the number, the higher the priority. See the **update route** ITP Command Set entry for an example.

For example, the following two configurations show equivalent ways to specify a summary route when the variant is **ITU**:

```
Router(config)# cs7 route-table system
Router(config-cs7-rt)# update route 1.6.0/11 linkset polaris prio 2
Router(config-cs7-rt)# update route 1.6.0/11 linkset pollux prio 3
Router(config-cs7-rt)# end
```

OR

```
Router(config)# cs7 route-table system
Router(config-cs7-rt)# update route 1.6.0 7.255.0 linkset polaris prio 2
Router(config-cs7-rt)# update route 1.6.0 7.255.0 linkset pollux prio 3
Router(config-cs7-rt)# end
```

The following two configurations show equivalent ways to specify a summary route when the variant is **ANSI**:

```
Router(config)# cs7 route-table system
Router(config-cs7-rt)# update route 1.6.0/17 linkset polaris prio 2
Router(config-cs7-rt)# update route 1.6.0/17 linkset pollux prio 3
Router(config-cs7-rt)# end
```

OR,

```
Router(config)# cs7 route-table system
Router(config-cs7-rt)# update route 1.6.0 255.255.128 linkset polaris prio 2
Router(config-cs7-rt)# update route 1.6.0 255.255.128 linkset pollux prio 3
Router(config-cs7-rt)# end
```

ITU users should set the point code format to suit their national numbering structure and hierarchy using the **cs7 point-code format** command. This will allow them to create summary destinations with mask lengths that conveniently terminate on the point-code delimiters.

A sample route table display for an ITU case with summary routes is shown below for the default format (3 bit - 8 bit - 3 bit):

```
Router# show cs7 route detailed
Routing table = system
C=Cong Q=QoS P=Prio
Destination      C  Q  P Linkset Name      Linkset Non-adj Route
-----
1.4.0/11         RESTR      2 polaris          UNAVAIL          UNAVAIL
                  3 pollux          avail            avail
1.5.1/14         INACC      1 polaris          UNAVAIL allowed UNAVAIL
1.5.3/14         acces     1 pollux          avail allowed  avail
1.6.1/14         RESTR      2 polaris          UNAVAIL allowed UNAVAIL dyn
                  3 pollux          avail PROHIB UNAVAIL dyn
1.6.3/14         RESTR      2 polaris          UNAVAIL allowed UNAVAIL dyn
                  3 pollux          avail PROHIB UNAVAIL dyn
1.6.0/11         RESTR      2 polaris          UNAVAIL          UNAVAIL
                  3 pollux          avail            avail
```

The non-adjacent status field is blank for summary routes. Since there are no route management messages exchanged for such routes, there is no non-adjacent status. The availability of a summary route is determined solely by the linkset status. Dynamic route table entries are flagged by **dyn** at the end of the line. Although all routes to 1.6.1 and 1.6.3 are unavailable, the destination status is restricted (instead of inaccessible) because these destinations are members of the summary route 1.6.0/11, one route to which is available. Routes to 1.6.0/11 are considered to be alternate routes to 1.6.1 and 1.6.3.

Use the **show cs7 route** command with the keyword **summary-routes** to display all summary routes of which the given point code is a member:

```
Router# show cs7 route 1.6.1 summary-routes detailed
Routing table = system
C=Cong Q=QoS P=Prio
Destination      C  Q  P Linkset Name      Linkset Non-adj Route
-----
1.6.1/14         RESTR      2 polaris          UNAVAIL allowed UNAVAIL dyn
                  3 pollux          avail PROHIB UNAVAIL dyn
1.6.0/11         RESTR      2 polaris          UNAVAIL allowed UNAVAIL
                  3 pollux          avail allowed  avail
```

To turn off usage of the summary routes for routing MSUs, when configured full point-code routes exist and are unavailable, use the following command in global configuration mode:

| Command                                              | Purpose                                |
|------------------------------------------------------|----------------------------------------|
| Router(config)# <b>cs7 summary-routing-exception</b> | Turns off usage of the summary routes. |

The summary routes will be used as a default. To restore the default use the **no cs7 summary-routing-exception** global configuration command.

To configure the maximum number of dynamic routes that can be created by the system, use the following command in global configuration mode:

| Command                                                     | Purpose                                                                                                                                    |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 max-dynamic-routes</b> <i>number</i> | Specifies the maximum number of dynamic routes that can be created by the system. The valid range is 100 through 1000. The default is 500. |

To restore the default use the **no cs7 max-dynamic-routes** global configuration command.

## How to Configure ANSI Cluster Routing

ANSI Cluster Routing is a special case of Summary Routing, and has associated with it a dedicated set of route management messages and procedures as specified in T1.111 and GR-82. If the variant is ANSI, a cluster route would be created by specifying a mask length of 16 or a mask of 255.255.0 using the default point-code format 8 bit - 8 bit - 8 bit. Cluster Routing and Management Diversity (CRMD) as specified in GR-82 is supported. When a route is configured to a member of a remote cluster using a direct E-link, the route is automatically assigned a priority of 1, contrary to an example in GR-82.

Cluster routes are created by specifying a mask length of 16, or mask 255.255.0:

| Command                                                                                                                                                | Purpose                                                                          |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| Router(config)# <b>cs7 route-table</b> <i>system</i>                                                                                                   | Specifies the name of the route table and enters route table configuration mode. |
| Router(config-cs7-rt)# <b>update route</b> <i>point-code</i> {[ <b>255.255.0</b>   <b>/16 linkset</b> <i>ls-name</i> <b>prio</b> <i>priority-value</i> | Specifies a cluster route.                                                       |

The following is an example of a cluster route configured using the **/16** form to specify the mask:

```
Router(config)# cs7 route-table system
Router(config-cs7-rt)# update route 1.6.0/16 linkset polaris prio 2
Router(config-cs7-rt)# update route 1.6.0/16 linkset pollux prio 3
Router(config-cs7-rt)# end
```

Cluster routes have a non-adjacent status as dictated by the last received TCP, TCR or TCA message on that route. In the output of the **show cs7 route detailed** command, this status is displayed just as for full pc routes. Exclusion list (x-list) members are flagged by **dyn** at the end of the line for the concerned route. A route table display for an ANSI case with two clusters (1.4.0 and 1.6.0) and two x-list members (1.6.1 and 1.6.3) is shown below:

Router# **show cs7 route detailed**

Routing table = system

C=Cong Q=QoS P=Prio

| Destination | C     | Q | P | Linkset Name | Linkset | Non-adj | Route       |
|-------------|-------|---|---|--------------|---------|---------|-------------|
| 1.4.0/16    | RESTR |   | 2 | polaris      | UNAVAIL | allowed | UNAVAIL     |
|             |       |   | 3 | pollux       | avail   | allowed | avail       |
| 1.5.1/24    | INACC |   | 1 | polaris      | UNAVAIL | allowed | UNAVAIL     |
| 1.5.3/24    | acces |   | 1 | pollux       | avail   | allowed | avail       |
| 1.6.1/24    | RESTR |   | 2 | polaris      | UNAVAIL | allowed | UNAVAIL dyn |
|             |       |   | 3 | pollux       | avail   | PROHIB  | UNAVAIL dyn |
| 1.6.3/24    | RESTR |   | 2 | polaris      | UNAVAIL | allowed | UNAVAIL dyn |
|             |       |   | 3 | pollux       | avail   | PROHIB  | UNAVAIL dyn |
| 1.6.0/16    | RESTR |   | 2 | polaris      | UNAVAIL | allowed | UNAVAIL     |
|             |       |   | 3 | pollux       | avail   | allowed | avail       |

If a cluster route is configured then another summary route with mask length in the range 17 - 23 should not be created. In the example above, the presence of a summary route 1.6.128/17 would cause faulty operation.

## Verifying, Monitoring, and Tuning the ITP

This chapter describes how to verify proper configuration of the ITP, monitor status and traffic, and tune the ITP. This chapter includes the following optional tasks:

- [Verifying ITP, page 357](#)
- [Monitoring ITP, page 369](#)
- [Tuning ITP, page 394](#)

### Feature History for Verifying, Monitoring, and Tuning the ITP

| Release | Modification |
|---------|--------------|
|---------|--------------|

#### Note

**Configuration Mode Restrictions:** Simultaneous changes to the configuration from multiple CLI sessions are not supported. Only one configuration session is allowed to enter in configuration mode at a time; other sessions should not enter in configuration mode. The **show line** or **show users EXEC** command may be used to determine the active user sessions on an ITP, and the **clear line EXEC** command may be used to ensure that only a single active session exists.

## Verifying ITP

After you have configured Cisco ITP, you can perform several tasks that will verify that the Cisco ITP was installed and configured properly, and that Cisco ITP functionality is available. Perform the tasks in this section to verify the Cisco ITP.

### Verify that Cisco ITP is configured on the router with the correct variant and local point code.

To confirm that the correct variant and point code are configured, use the following command in EXEC mode:

| Command                   | Purpose                     |
|---------------------------|-----------------------------|
| Router# <b>write term</b> | Displays the configuration. |

The output of the above command should include lines such as the following that show the correct variant and point code:

```
cs7 variant ITU
cs7 point-code 1.1.1
```

**Verify that required linksets to adjacent nodes are available.**

To verify that required linksets to adjacent nodes are available, use the following command in EXEC mode:

| Command                               | Purpose                           |
|---------------------------------------|-----------------------------------|
| Router# <b>show cs7 linkset brief</b> | Displays ITP linkset information. |

The possible states of a linkset are:

- **UNAVAIL** Indicates the linkset does not have any “available” links and cannot transport traffic.
- **shutdown** Indicates the linkset has been shutdown in the configuration.
- **avail** Indicates the linkset has at least one available link and can carry traffic.

The output of the above command should include lines such as the following. The state of each linkset should be “avail.”

```
Router# show cs7 linkset brief
lsn=mscl      apc=5.5.5      state=avail
lsn=mica      apc=4.4.4      state=avail
lsn=malo      apc=2.2.2      state=avail
lsn=momo      apc=3.3.3      state=avail
```

If the state of a linkset is not available it might be shutdown or UNAVAIL:

```
lsn=momo      apc=3.3.3      state=shutdown
lsn=momo      apc=3.3.3      state=UNAVAIL
```

If the linkset state is shutdown, it should be administratively restarted. If a linkset is unavailable, verify the links within the linkset (See step 4).

**Verify that all required destinations are accessible.**

To verify that all required destinations are accessible, use the following command in EXEC mode:

| Command                       | Purpose                         |
|-------------------------------|---------------------------------|
| Router# <b>show cs7 route</b> | Displays the ITP routing table. |

The above command should include output such as the following. Each destination should be “access” and the route status should be “avail.”

```
Router# show cs7 route
Routing table = system
Destination          Prio Linkset Name      Route Status
-----
2.2.2/14             acces 1   malo              avail
                      9   mica              avail
3.3.3/14             acces 1   momo              avail
                      9   mica              avail
4.4.4/14             acces 1   mica              avail
                      9   momo              avail
5.5.1/14             acces 1   msc1              avail
                      9   momo              avail
5.5.5/14             acces 1   msc1              avail
                      9   momo              avail
6.6.1/14             acces 1   mica              avail
                      9   malo              avail
6.6.6/14             acces 1   malo              avail
                      9   mica              avail
```

Routes to a destination are listed in priority order. The first route to be selected is the route with the lowest cost (listed in the Prio field). If the route with the lowest cost is available the destination is available. If the route with the lowest cost is UNAVAIL or RESTRIC and there is another available route with a higher cost, then the destination will be RESTR.

```
3.3.3/14             RESTR 1   momo              UNAVAIL
                      9   mica              avail
```

If there are no available routes, the destination will be INACC.

```
5.5.1/14             INACC 1   msc1              UNAVAIL
                      9   momo              UNAVAIL
```

If a destination is inaccessible or restricted, investigate why by verifying the affected cs7 route.

If a required destination is not shown, the route should be administratively added to the route table.

If steps 1 - 3 yield the expected results, you have verified connectivity to all the adjacent nodes and *potentially* available routes to all destinations. (*Potentially* because Cisco ITP assumes that routes are available until the node is notified that a destination is not available.)

To verify connectivity to a particular node, use the following command in EXEC mode:

| Command                                                                                                                                                                                                             | Purpose                              |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| Router# <b>ping cs7</b> [instance-number] [-opc origination-point-code] [-duration seconds] [-ni network-indicator] [-rate MSU-per-second] [-size bytes] [-sls value   round-robin] {destination-point-code   host} | Verify that you can reach ITP nodes. |

The following is typical output of the **cs7 ping** command:

```
Router# ping cs7 2.2.2
3d19h:%CS7PING-6-RTT:Test Q.755 2.2.2:MTP Traffic test rtt 16/16/16
3d19h:%CS7PING-6-STAT:Test Q.755 2.2.2:MTP Traffic test 100% successful (1/1)
3d19h:%CS7PING-6-TERM:Test Q.755 2.2.2:MTP Traffic test terminated.
```

**Verify the links within a linkset.**

To verify that all the links in a linkset are available, use the following command in EXEC mode:

| Command                         | Purpose                               |
|---------------------------------|---------------------------------------|
| Router# <b>show cs7 linkset</b> | Displays the ITP linkset information. |

The possible states of a linkset are:

- **UNAVAIL** Indicates the linkset does not have any “available” links and cannot transport traffic.
- **shutdown** Indicates the linkset has been shutdown in the configuration.
- **avail** Indicates the linkset has at least one available link and can carry traffic.

The possible states of a link are:

- **UNAVAIL** Indicates the link is not available to carry traffic. This can occur if the link is remotely or locally inhibited by a user. It can also be unavailable if MTP2/M2PA has not been able to successfully activate the link connection or the link test messages sent by MTP3 are not being acknowledged.
- **shutdown** Indicates the link has been shutdown in the configuration. A link is **shutdown** when it is shutdown at the MTP3 layer.
- **avail** Indicates the link is active and able to transport traffic.
- **FAILED** A link is **FAILED** when the link is not shutdown but is unavailable at layer2 for some reason. It is **FAILED** when the link is unavailable because the link has been inhibited or it is blocked.
- **sys-shutdown** Indicates the link has been shutdown by the system. A link may be in this state when:
  - MTP3 offload is configured and the system is performing error recovery on the FlexWAN
  - MTP3 offload has been permanently disabled on a FlexWAN by the system due to excessive errors. When MTP3 offload has been permanently disabled on a FlexWAN (by the system) all links on that FlexWAN will be in the sys-shutdown state.
  - The Service field should indicate that links are “avail.”

```

Router# show cs7 linkset
lsn=mscl          apc=5.5.5          state=avail
  SLC  Interface          Service  PeerState  Inhib
  00   199.1.1.5 4096 4096    avail    InService  -----

lsn=mica          apc=4.4.4          state=avail
  SLC  Interface          Service  PeerState  Inhib
  00   199.1.1.4 4096 4096    avail    InService  -----
  01   199.1.1.4 4097 4097    avail    InService  -----
  02   199.1.1.4 4098 4098    avail    InService  -----
  03   199.1.1.4 4099 4099    avail    InService  -----

lsn=malo          apc=2.2.2          state=avail
  SLC  Interface          Service  PeerState  Inhib
  00   199.1.1.2 4096 4096    avail    InService  -----

```

```
lsn=momo          apc=3.3.3          state=avail
SLC  Interface    Service  PeerState    Inhib
*00  Serial0/0    avail    -----    -----
*01  Serial0/1    avail    -----    -----
*02  Serial0/2    avail    -----    -----
03   Serial0/3    avail    -----    -----
```

If a link is not available it might be shutdown, FAILED or UNAVAIL....

```
*01  Serial0/1    shutdown -----    -----
*02  Serial0/2    FAILED    -----    -----
*03  Serial0/3    UNAVAIL   -----    rem
```

If the link is shutdown, it should be administratively restarted.

If a link is failed, then the link has failed at MTP2 (or M2PA in the case of SCTP links). The cause must be investigated by verifying MTP2 (or M2PA) links.

If the link is unavailable, the link is okay at the MTP2 (or M2PA) layer.

The link might be remotely inhibited or locally inhibited, or there may be a remote processor outage.

```
*03  Serial0/3    UNAVAIL   -----    loc
```

The above link was locally inhibited. The link should be administratively uninhibited.

```
*03  Serial0/3    UNAVAIL   -----    rem
```

The above link was remotely inhibited. The link should be administratively uninhibited by the SS7 node at the remote end of the link.

```
*03  Serial0/3    UNAVAIL   -----    -----
```

The above link is unavailable and is not inhibited. It is probably blocked due to remote processor outage. (i.e. The problem is at the SS7 node at the remote end of the link)

### Verify routes.

To verify routes, use the following command in EXEC mode:

| Command                              | Purpose                                    |
|--------------------------------------|--------------------------------------------|
| Router# <b>show cs7 route detail</b> | Displays details of the ITP routing table. |

The **show cs7 route detail** command should include output such as the following:

```
Router# show cs7 route detail
Routing table = system
C=Cong Q=QoS P=Prio
Destination      C  Q  P  Linkset  Name          Linkset  Non-adj  Route
-----
2.2.2/14         acces      1  malo    avail      allowed  avail
                  9  mica    avail      allowed  avail
3.3.3/14         acces      1  momo    avail      allowed  avail
                  9  mica    avail      PROHIB   UNAVAIL
4.4.4/14         acces      1  mica    avail      allowed  avail
                  9  momo    avail      RESTRIC  RESTRIC
5.5.1/14         INACC      1  msc1    avail      PROHIB   UNAVAIL
                  9  momo    avail      PROHIB   UNAVAIL
5.5.5/14         acces      1  msc1    avail      allowed  avail
                  9  momo    avail      allowed  avail
6.6.1/14         INACC      1  mica    avail      PROHIB   UNAVAIL
```

```

6.6.6/14      acces      9  malo      avail  PROHIB  UNAVAIL
                  1  malo      avail  allowed avail
                  9  mica      avail  allowed avail

```

Routes are listed in priority order. The route with the lowest cost (listed under the Prio heading) will be the first route selected to a particular destination. A route should be “avail,” the non-adj status should be “allowed” and the linkset should be “avail.”

If a route is not available, it may be restricted or unavailable. If a route is not available and the linkset is available, then the route is restricted or unavailable because it received a TFR or TFP from the adjacent SS7 node. In this case you need to verify the route in the adjacent SS7 node.

If a route is not available and the linkset is not available, verify the links within the linkset.

### Verify MTP2 links

To Verify that the link state control is “In service,” use the following command in EXEC mode:

| Command                            | Purpose                             |
|------------------------------------|-------------------------------------|
| Router# <b>show cs7 mtp2 state</b> | Displays MTP2 state machine status. |

The following is typical output of the **show cs7 mtp2 state** command:

```

Router# show cs7 mtp2 state ser 1/0/0:0
CS7 MTP2 states for interface Serial1/0/0:0
Protocol version for interface Serial1/0/0:0 is ITU-T Q.703 (1996) (White Book)

Link State Control (LSC)                = In Service
                                         ^^^^^^^^^^
Initial Alignment Control (IAC)          = Idle
Transmission Control (TXC)              = In Service
Reception Control (RC)                  = In Service
Signal Unit Error Rate Monitor (SUERM)   = Monitoring
Alignment Unit Error Rate Monitor (AERM) = Idle
Congestion (CONG)                       = Idle

Layer3 link status                      = Started
Layer3 congestion status                 = Abate

```

Other possibilities for LSC might be as follows:

```

Link State Control (LSC)                = Out of Service
or
Link State Control (LSC)                = Initial Alignment

```

If the LSC state is “Out of Service” or transitions in and out of “Initial alignment,” check the physical interface for correct cabling, clocking, etc.

To verify that the physical link is up, use the following command in EXEC mode:

| Command                       | Purpose                             |
|-------------------------------|-------------------------------------|
| Router# <b>show interface</b> | Displays MTP2 state machine status. |

The following is typical output of the **show interface** command:

```
router# show int ser 0/0
Serial0/0 is up, line protocol is up
Hardware is PowerQUICC Serial
  MTU 290 bytes, BW 1544 Kbit, DLY 20000 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation SS7 MTP2, loopback not set
  Keepalive set (10 sec)
  Last input never, output 00:00:16, output hang never
  Last clearing of "show interface" counters 3d17h
  Queueing strategy:fifo
  Output queue 0/40, 0 drops; input queue 0/75, 20654 drops
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
    20673 packets input, 62068 bytes, 0 no buffer
    Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
    10339 packets output, 113605 bytes, 0 underruns
    0 output errors, 0 collisions, 2 interface resets
    0 output buffer failures, 0 output buffers swapped out
    4 carrier transitions
  DCD=up DSR=up DTR=up RTS=up CTS=up
```

The output might indicate that the interface is administratively down:

```
Serial0/0 is administratively down, line protocol is down
```

If the interface is “administratively down,” the interface must be started administratively.

The output might indicate that the interface is down:

```
Serial0/0 is down, line protocol is down
```

If the interface is “down” check the physical cabling.

To verify that the line protocol is up and the encapsulation is MTP2, use the following command in EXEC mode:

| Command                       | Purpose                             |
|-------------------------------|-------------------------------------|
| Router# <b>show interface</b> | Displays MTP2 state machine status. |

If the encapsulation is not MTP2, it must be changed administratively.

The following is typical output of the show interface command:

```
Router# show int ser 0/0
Serial0/0 is up, line protocol is up
      ^
Hardware is PowerQUICC Serial
MTU 290 bytes, BW 1544 Kbit, DLY 20000 usec,
    reliability 255/255, txload 1/255, rxload 1/255
Encapsulation SS7 MTP2, loopback not set
^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^^
Keepalive set (10 sec)
Last input never, output 00:00:16, output hang never
Last clearing of "show interface" counters 3d17h
Queueing strategy:fifo
Output queue 0/40, 0 drops; input queue 0/75, 20654 drops
5 minute input rate 0 bits/sec, 0 packets/sec
5 minute output rate 0 bits/sec, 0 packets/sec
  20673 packets input, 62068 bytes, 0 no buffer
    Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
  10339 packets output, 113605 bytes, 0 underruns
    0 output errors, 0 collisions, 2 interface resets
    0 output buffer failures, 0 output buffers swapped out
    4 carrier transitions
DCD=up DSR=up DTR=up RTS=up CTS=up
```

The output might indicate that the line protocol is down:

```
Serial0/0 is up, line protocol is down
```

If the line protocol is down verify that the physical cabling and clocking rates are correct.

### Verify M2PA Links

To verify M2PA links, use the following command in EXEC mode:

| Command                                        | Purpose                           |
|------------------------------------------------|-----------------------------------|
| Router# <b>show cs7 linkset</b> <i>ls-name</i> | Displays ITP linkset information. |

#### Note

When an interface is already configured, do not change its IP address. Doing so can result in the crash and mismatch in the configuration of a linkset on the standby card. Memory corruption can also occur. Since the linkset already has a port configured, it will search for the old IP address and run into this issue. If you must change the IP address on a configured interface, first remove the linkset before changing the IP address.

The following is typical output of the **show cs7 linkset** command:

```
Router# show cs7 linkset mica
lsn=Router apc=4.4.4      state=UNAVAIL
  SLC  Interface          Service  PeerState  Inhib
  00   199.1.1.4 4096 4096    avail    InService  ----
      ^^^^^^^^^
  01   199.1.1.4 4097 4097    avail    InService  ----
  02   199.1.1.4 4098 4098    avail    InService  ----
  03   199.1.1.4 4099 4099    avail    InService  ----
```

If the PeerState field shows “InitialAlignment,” check that the remote peer IP address and port number are correct and that the link at the remote end is not administratively shutdown. The remote peer IP address and port number should correspond with a local peer and port number on a remote router.

```
01 199.1.1.4 4097 4098 FAILED InitialAlignment -----
```

In the above example,

- 199.1.1.4 is the remote IP address
- 4097 is the remote port
- 4098 is the local port

Also check that the local peer IP address and port number correspond to the remote peer IP address and port number in the remote router.

To obtain the local peer IP address, use the following command in EXEC mode:

| Command                                                 | Purpose                       |
|---------------------------------------------------------|-------------------------------|
| Router# <b>show cs7 m2pa local-peer</b> <i>port-num</i> | Displays ITP M2PA statistics. |

The following is typical output of the **show cs7 m2pa local-peer** command:

```
Router# show cs7 m2pa local-peer 4097
CS7 M2PA Local Peer Info for local port = 4097
Local Port           = 4097
Local IP             = 199.1.1.1
                    ^^^^^^^^^
SCTP Instance Handle = 1
Num Peers On Instance = 1
Instance Local Recv Window = 64000
Instance maxInitRetrans = 8
Instance maxInitTimeout = 1000 ms
Instance Unordered Priority = EQUAL
```

If the remote and local peers are not correct, they need to be corrected administratively.

If they are correct and the remote link is not shutdown, then verify IP connectivity.

If the peerstate is OutofService, then the link should be administratively activated.

```
lsn=mica          apc=4.4.4          state=UNAVAIL
  SLC  Interface          Service  PeerState      Inhib
*02   199.1.1.1 4098 4098      shutdown OutOfService      -----
```

### Verify GTT

Refer to the [“Verifying Global Title Translations”](#) section on page 123 in the [“Global Title Translation”](#) chapter.

### Verify IP connectivity

To verify IP connectivity ping the remote IP address, using the following command in EXEC mode:

| Command                               | Purpose              |
|---------------------------------------|----------------------|
| Router# <b>ping</b> <i>ip-address</i> | Pings an IP address. |

The following is typical output of the **ping** command:

```
Router# ping 199.1.1.4

Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 199.1.1.4, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms
```

The ping should succeed with 100% success rate and the min/avg/max round trip delays should not be excessive.

If the success rate is zero, as in the sample output that follows, there is no IP connectivity between the cs7 peers.

```
Router# ping 199.1.1.4

!Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 199.1.1.4, timeout is 2 seconds:
.....
Success rate is 0 percent (0/5)
Router#
```

For each peer, verify that the local IP peer address is associated with an active interface. Verify this using the **show ip interface brief** command. (In this case the local IP address is 199.1.1.1.)

```
Router# show ip interface brief
```

| Interface       | IP-Address    | OK? | Method | Status | Protocol |
|-----------------|---------------|-----|--------|--------|----------|
| FastEthernet0/0 | 172.18.44.176 | YES | NVRAM  | up     | up       |
| Serial0/0       | unassigned    | YES | NVRAM  | up     | down     |
| FastEthernet0/1 | 199.1.1.1     | YES | NVRAM  | up     | up       |
|                 |               |     |        | ^^ ^^  |          |
| Serial0/1       | unassigned    | YES | NVRAM  | down   | down     |
| Serial0/2       | unassigned    | YES | NVRAM  | up     | up       |
| Serial0/3       | unassigned    | YES | NVRAM  | up     | up       |

```
Router#
```

If the interface status and protocol are not “up,” take the appropriate measures to activate the interface.

If the required interface status and protocol are up, verify that there is an IP route to the remote IP address. (In this case the remote IP address is 199.1.1.4)

```
Router# show ip route
Codes:C - connected, S - static, I - IGRP, R - RIP, M - mobile, B - BGP
       D - EIGRP, EX - EIGRP external, O - OSPF, IA - OSPF inter area
       N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
       E1 - OSPF external type 1, E2 - OSPF external type 2, E - EGP
       i - IS-IS, L1 - IS-IS level-1, L2 - IS-IS level-2, ia - IS-IS inter area
       * - candidate default, U - per-user static route, o - ODR
       P - periodic downloaded static route

Gateway of last resort is not set

    172.18.0.0/25 is subnetted, 1 subnets
C       172.18.44.128 is directly connected, FastEthernet0/0
C       199.1.1.0/24 is directly connected, FastEthernet0/1
    161.44.0.0/32 is subnetted, 1 subnets
S       161.44.2.30 [1/0] via 172.18.44.129
```

The above display shows that there is an IP route to the network 199.1.1.0 via the directly connected fastethernet0/0 interface.

### Verify the State of M3UA and SUA Application Servers and Application Server Processes

The command includes keywords to filter and format the output.

- The filter options are **active**, **all** ASes (the default), **m3ua**, **name asname**, **operational**, and **sua**.
- The GTT subfilters are **include-gtt**, **exclude-gtt**, or **only-gtt**
- The format options are **brief** (the default format), **details**, **event-history**, and **statistics**.

The following is output from the **show cs7 as** command entered with no format or filter keywords. The command uses the default filter (**all**) and the default format (**brief**):

```
Router# show cs7 as
```

| AS Name | State | Routing Context |
|---------|-------|-----------------|
| asp1    | down  | 1               |
| asp2    | down  | 2               |

| AS Name | State | Routing Context | Routing Key Dpc | Si | Opc | Cic Ssn | Cic Min | Cic Max |
|---------|-------|-----------------|-----------------|----|-----|---------|---------|---------|
| as1     | down  | 111             | 2.1.1           |    |     |         |         |         |

The following is output from the **show cs7 as** command with the **binding-table** keyword. The Mate state is the status of the remote ASP. The options are: inactive/active.

```
ITP# show cs7 as binding-table
```

AS: mas2 (Total ASP Weight: 8)

| ASP          | State  | Mate State | Weight | CIC               |
|--------------|--------|------------|--------|-------------------|
| dasp2        | down   | active     | 1      | 0, 4              |
| dasp3        | active | inactive   | 0      |                   |
| dasp4        | down   | inactive   | 0      |                   |
| dasp5        | active | inactive   | 3      | 1, 2, 3, 5, 6, 7d |
| asp1         | down   | inactive   | 4      |                   |
| m3ua_s_176_0 | active | inactive   |        |                   |

The following is output from the **show cs7 as** command entered with the **name asname** filter keyword and the **detail** format keyword:

```
Router#show cs7 as name owl5 detail
```

AS name: m3ua\_s\_176\_0 State: active Type: M3UA  
RoutContext: 6700 Class2 binding: enabled  
Traf mode: loadshare bindings SLS  
Mate AS state: unknown Rerouting queue depth: 0  
Recovery tmout: 2000 ms Recovery queue depth: 0  
QOS Class: 0 Burst recovery tmout: 4000 ms  
PMP Status: N Inbound/outbound DCS group: n/a / n/a  
Routing Key:  
Dest PC: 2.1.1 Origin PC: n/a Origin PC mask: n/a  
SI: n/a CIC min: n/a CIC max: n/a  
SSN: n/a GTT: n/a

| ASP Name | AS Name | State | Type | Rmt Port | Remote IP Addr | SCTP Assoc |
|----------|---------|-------|------|----------|----------------|------------|
| asp2     | owl5    | down  | SUA  | 9022     | 172.18.57.136  |            |
| asp1     | owl5    | down  | SUA  | 9012     | 172.18.57.136  |            |
| cuba     | owl5    | down  | SUA  | 14101    | 172.18.57.90   |            |

Traffic-mode states are: override, loadshare bindings, loadshare roundrobin, broadcast, or undefined.

AS and Mate-AS states are: shutdown, down, down-rerouting, inactive, inactive-rerouting, active, or pending.

The following is output from the **show cs7 asp sua** command in the default brief format:

| ASP Name | AS Name | State | Type | Rmt Port | Remote IP Addr | SCTP |
|----------|---------|-------|------|----------|----------------|------|
| -----    | -----   | ----- | ---- | -----    | -----          | ---- |
| asp1     | asp1    | down  | SUA  | 9012     | 172.18.57.136  |      |
| asp1     | as1     | down  | SUA  | 9012     | 172.18.57.136  |      |
| asp2     | asp2    | down  | SUA  | 9022     | 172.18.57.136  |      |
| asp2     | as1     | down  | SUA  | 9022     | 172.18.57.136  |      |
| cuba     | as1     | down  | SUA  | 14101    | 172.18.57.90   |      |

ASP States are: shutdown, blocked, down, inactive, active, or active/congested.

If the ASP is down or shutdown, then the remote port and remote IP address display the configured values instead of the actual values.

The following example includes output from the **show cs7 asp** command in the **detail** format and filtering on the ASP name **asp1**. This ASP (type SUA) is down and the association state is closed. It is offloaded to the line card in slot 6.

AspVipId is an internal number used to identify the ASP.

Options for ASP state include: down/inactive/active/standby

The Mate state is the status of the remote ASP. The options are: inactive/active.

If the ASP is down or shut down, then the remote port and remote IP address display the configured values instead of the actual values.

```
ITP# show cs7 asp name asp1 detail
ASP name: asp1                               Type: SUA
Availability: enabled                         ASP id: n/a
SCTP association state: closed                 Association id: n/a
AS name: as1                                ASP state: down    Mate state: inactive
Traffic mode: ldshr rr                       Active Time: Not Active
Configured remote port: 6000                 Actual remote port: 6000
Configured remote ip addresses: 10.10.20.2
Actual remote ip addresses: n/a
Local port: 6000

# Monitoring ITP

You can perform the tasks in the following sections to monitor and maintain the Cisco ITP:

- [Configuring ITP for Event Logging to an External Server, page 369](#)
- [Enabling Simple Network Management Protocol, page 370](#)
- [Monitoring the Cisco ITP, page 372](#)

## Configuring ITP for Event Logging to an External Server

Routers send system messages to an internal logging process. The logging process controls the distribution of system messages to the various destinations, such as the console (default), terminal lines, router logging buffer, or external UNIX syslog server.

To set the severity level of the system messages to control the type of messages displayed at each of the destinations, use the following commands in global configuration mode:

| Command                                      | Purpose                                                                                                                          |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>logging console level</b> | Limits the logging of messages displayed on the console terminal to a specified level.                                           |
| Router(config)# <b>logging monitor level</b> | Limits the logging messages displayed on terminal lines other than the console line to messages at or above the specified level. |
| Router(config)# <b>logging trap level</b>    | Limits the logging of error messages sent to syslog servers to only those messages at the specified level.                       |

By default, system messages are delivered to the console. To enable messages on a terminal line, Use the following command in EXEC mode:

| Command                         | Purpose                                                                                      |
|---------------------------------|----------------------------------------------------------------------------------------------|
| Router# <b>terminal monitor</b> | Display debug command output and system error messages for the current terminal and session. |

To enable logging to a non-volatile ITP buffer and adjust the size of the buffer, use the following command in EXEC mode:

| Command                                      | Purpose                                                                                                  |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------|
| Router(config)# <b>logging buffered size</b> | Log messages to an internal buffer. The logging is circular, so newer messages overwrite older messages. |

To enable logging messages to a UNIX syslog server host, use the following command in EXEC mode:

| Command                                    | Purpose                                                                                                                                                                                                                                          |
|--------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>logging</b> <i>host</i> | Log messages to a UNIX syslog server host. The host parameter is the name or Internet address of the server. By repeating the command, you can have messages sent to multiple syslog servers. the syslog format is compatible with 4.3 BSD UNIX. |

By default, a syslog message contains the IP address of the interface it uses to leave the router. To specify that all syslog messages contain the same IP address, regardless of which interface they take to reach the syslog server, use the following command in global configuration mode:

| Command                                         | Purpose                                          |
|-------------------------------------------------|--------------------------------------------------|
| Router(config)# <b>logging source-interface</b> | Specify the source IP address of syslog packets. |

## Enabling Simple Network Management Protocol

The Simple Network Management Protocol (SNMP) is an application-layer protocol that provides a message format for communication between SNMP managers and agents. The SNMP system consists of the following three parts:

- An SNMP manager
- An SNMP agent
- A Management Information Base (MIB)

The SNMP manager can be part of a Network Management System (NMS) such as CiscoWorks. The agent and MIB reside on the router. To configure SNMP on the router, you define the relationship between the manager and the agent. For more information about SNMP, refer to “Configuring SNMP Support” in the Cisco IOS Release 12.1 *Configuration Fundamentals Configuration Guide*, Part 3, Cisco IOS System Management, at the following URL:

[http://www.cisco.com/univercd/cc/td/doc/product/software/ios121/121cgcr/fun\\_c/fcprt3/fcd301.htm](http://www.cisco.com/univercd/cc/td/doc/product/software/ios121/121cgcr/fun_c/fcprt3/fcd301.htm)

To enable SNMP traps for Cisco ITP to be sent, use the **snmp-server enable traps cs7** global configuration command.

| Command                                                                                                                                                                            | Purpose                           |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| Router(config)# <b>snmp-server enable traps cs7</b> [gw-map-state] [gw-link-congestion] [gw-link-state] [gw-link-utilization] [gw-linkset-state] [gw-route-mgmt-state] [xua-state] | Enables SNMP traps for Cisco ITP. |

When you enable CS7 traps, the default value for trap queue length (10 events) might cause traps to be lost. To avoid this situation set the trap queue length to 100 using the **snmp-server queue-length** global configuration command:

| Commands                                            | Purpose                                        |
|-----------------------------------------------------|------------------------------------------------|
| Router(config)# <b>snmp-server queue-length 100</b> | Sets the default for trap queue length to 100. |

You can control the rate of notifications for destination state changes and route state changes.

To specify the maximum number of destination state changes allowed per window, use the **cs7 snmp dest-max-window** global configuration command:

| Command                                         | Purpose                                                                                                                                                                                                                                               |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 snmp dest-max-window</b> | Sets the maximum number of destination state changes allowed per window. Valid range is 10 to 9000 changes. Default is 60. (Large values can impact the performance of the device and all notifications might not be sent to the management station.) |

The **cs7 snmp dest-max-window** command corresponds to the `cgrtDestNotifMaxPerWindow` object in the Cisco-ITP-GRT-MIB.my MIB. Destination state changes are sent in the `ciscoGrtdDestStateChange` notification.

To specify the maximum number of route management state changes allowed per window, use the **cs7 snmp mgmt-max-window** global configuration command:

| Command                                         | Purpose                                                                                                                                                                                                                                                    |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 snmp mgmt-max-window</b> | Sets the maximum number of route management state changes allowed per window. Valid range is 10 to 9000 changes. Default is 60. (Large values can impact the performance of the device and all notifications might not be sent to the management station.) |

The **cs7 snmp mgmt-max-window** command corresponds to the `cgrtMgmtNotifMaxPerWindow` object in the Cisco-ITP-GRT-MIB.my MIB. Route management state changes are sent in the `ciscoGrtdMgmtStateChange` notification.

You can control the rate of notifications for rev1 destination state changes and rev1 route state changes.

To specify the maximum number of destination state changes allowed per window, use the **cs7 snmp dest-max-r1-window** global configuration command:

| Command                                            | Purpose                                                                                                                                                                                                                                                    |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 snmp dest-max-r1-window</b> | Sets the maximum number of rev1 destination state changes allowed per window. Valid range is 10 to 9000 changes. Default is 60. (Large values can impact the performance of the device and all notifications might not be sent to the management station.) |

The **cs7 snmp dest-max-r1-window** command corresponds to the `cgrtDestNotifMaxPerWindow` object in the Cisco-ITP-GRT-MIB.my MIB. Destination state changes are sent in the `ciscoGrtDestStateChange` notification.

To specify the maximum number of rev1 route management state changes allowed per window, use the **cs7 snmp mgmt-max-r1-window** global configuration command:

| Command                                            | Purpose                                                                                                                                                                                                                                                         |
|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 snmp mgmt-max-r1-window</b> | Sets the maximum number of rev1 route management state changes allowed per window. Valid range is 10 to 9000 changes. Default is 60. (Large values can impact the performance of the device and all notifications might not be sent to the management station.) |

The **cs7 snmp mgmt-max-r1-window** command corresponds to the `cgrtMgmtNotifMaxPerWindow` object in the Cisco-ITP-GRT-MIB.my MIB. Route management state changes are sent in the `ciscoGrtMgmtStateChange` notification.

## Monitoring the Cisco ITP

This section includes information about the following tasks:

- [Monitoring CPU/Memory, page 372](#)
- [Monitoring Linksets and Links, page 373](#)
- [Monitoring MTP2 Links/Interfaces, page 375](#)
- [Monitoring M2PA Links/Interfaces, page 380](#)
- [Monitoring GTT Measurements, page 383](#)
- [Monitoring M3UA or SUA, page 384](#)
- [Monitoring AS, ASP, Mated-SG, page 385](#)
- [Monitoring Routes, page 391](#)
- [Monitoring Gateway Screening Violations, page 392](#)
- [Monitoring System Messages, page 392](#)
- [Monitoring Accounting, page 393](#)

## Monitoring CPU/Memory

### Why is this task important?

A healthy SS7oIP router needs to be running at less than 50% CPU during non fail-over conditions and must have 50% available memory to handle route table changes due to network conditions. If an SS7oIP router has a CPU and/or memory shortage, network availability is at risk. CPU and memory should be monitored via system error messages or SNMP traps alerts

### Under what circumstances should this task be performed?

System health monitoring is an ongoing process and should be automated. CiscoWorks network management application can be used to automate this task.

**What incidents or system messages should prompt the user to monitor the CPU/memory?**

When Cisco ITP attempts to allocate memory for an event for which no memory is available, the following IOS message is displayed:

```
%SYS-2-MALLOCFAIL:Memory allocation of [dec] bytes failed from [hex], pool
[chars], alignment [dec]
```

**Explanation** The requested memory allocation is not available from the specified memory pool. The current system configuration, network environment, or possibly a software error might have exhausted or fragmented the router memory.

**Action** Copy the error message exactly as it appears on the console or in the system log, call your Cisco technical support representative, and provide the representative with the gathered information.

**Should this task be part of a regular maintenance process that the user should do at regular intervals? If so, how frequently?**

Ongoing.

**What commands does the user issue?**

The **show proc cpu** command will display output such as the following:

```
CPU utilization for five seconds:0%/0%; one minute:0%; five minutes:0%
PID Runtime(ms) Invoked uSecs 5Sec 1Min 5Min TTY Process
27 0 1 0 0.00% 0.00% 0.00% 0 MTP3 Input
28 30238 70601 428 0.00% 0.01% 0.00% 0 MTP3 Mgmt
53 56 353673 0 0.00% 0.00% 0.00% 0 CS7 MTP2 timer
```

The **show proc mem** command will display output such as the following:

```
Total:26494208, Used:4829456, Free:21664752
PID TTY Allocated Freed Holding Getbufs Retbufs Process
27 0 192 0 13036 0 0 MTP3 Input
28 0 267888 276 274456 0 0 MTP3 Mgmt
53 0 20948 340 27452 0 0 CS7 MTP2 timer
```

The **show mem** command will display output such as the following:

|           | Head     | Total (b) | Used(b) | Free(b)  | Lowest (b) | Largest (b) |
|-----------|----------|-----------|---------|----------|------------|-------------|
| Processor | 80DBBB00 | 26494208  | 4829308 | 21664900 | 21615220   | 21640172    |
| I/O       | 2700000  | 26214400  | 2227876 | 23986524 | 23979088   | 23979036    |

Refer to the “Command Reference” section of this document for detailed descriptions of the show commands.

## Monitoring Linksets and Links

**Why is this task important?**

Links and linksets can change states from available to unavailable while the system is running. It is important to monitor when a linkset has become unavailable since it can indicate total or partial loss of a route to a destination node. When a link becomes unavailable, it can have a negative impact on the throughput, since there will be fewer links to carry the traffic.

**Under what circumstances should this task be performed?**

Link and linkset availability should be monitored at all times when there is traffic flowing over it.

**What incidents or system messages should prompt the user to monitor Linksets and Links?**

The user should monitor the links and linkset whenever a route or destination becomes unavailable.

**Should this task be part of a regular maintenance process that the user should do at regular intervals? If so, how frequently?**

Whenever a link or linkset becomes unavailable, error messages are displayed on the console and an SNMP trap is sent to the network management node.

**What commands does the user issue?**

To monitor all linksets, issue the **show cs7 linkset brief** command, which displays output such as the following:

```
lsn=to_2651_1      apc=0.3.3      state=UNAVAIL
lsn=to_helium      apc=0.2.2      state=avail
lsn=to_mgts_15     apc=1.1.1      state=UNAVAIL
```

The following explanations are based on the preceding output of the **show cs7 linkset brief** command.

- Linkset **to\_helium** is available and for traffic. A linkset is in available state when it has at least one available link in it. The detailed display below indicates that the linkset has several links that are available.
- Linkset **to\_2651\_1** is unavailable because it does not have any available links. Link 0 has been shutdown via configuration.
- In linkset **to\_helium**, link 5 has been locally inhibited and as such is unavailable to carry traffic.
- Link 6 has been remotely inhibited and is also unavailable to carry traffic. (If a link has been locally inhibited via the **cs7 inhibit** command, the Inhibit column will display **loc** to indicate that the link was locally inhibited. If a link is inhibited from the adjacent node, the show output will display **rem** to indicate that it was remotely inhibited.
- Linkset **to\_mgts\_15** is also not available to carry traffic because it does not have any available links.
- Link 0 has failed.

**Linkset States**

- **UNAVAIL** Indicates the linkset does not have any “available” links and cannot transport traffic.
- **shutdown** Indicates the linkset has been shutdown in the configuration.
- **avail** Indicates the linkset has at least one available link and can carry traffic.

**Link States**

- **UNAVAIL** Indicates the link is not available to carry traffic. This can occur if the link is remotely or locally inhibited by a user. It can also be unavailable if MTP2/M2PA has not been able to successfully activate the link connection or the link test messages sent by MTP3 are not being acknowledged.
- **shutdown** Indicates the link has been shutdown in the configuration. A link is **shutdown** when it is shutdown at the MTP3 layer.
- **avail** Indicates the link is active and able to transport traffic.
- **FAILED** A link is **FAILED** when the link is not shutdown but is unavailable at layer2 for some reason. It is **FAILED** when the link is unavailable because the link has been inhibited or it is blocked.

- **sys-shutdown** Indicates the link has been shutdown by the system. A link may be in this state when:
  - MTP3 offload is configured and the system is performing error recovery on the FlexWAN
  - MTP3 offload has been permanently disabled on a FlexWAN by the system due to excessive errors. When MTP3 offload has been permanently disabled on a FlexWAN (by the system) all links on that FlexWAN will be in the sys-shutdown state.

To monitor all linksets and all links in the linksets, issue the **show cs7 linkset** command. Refer to the “Command Reference” section of this document for descriptions of the show commands.

```
Router# show cs7 linkset
lsn=to_2651_1      apc=0.3.3      state=UNAVAIL
  SLC  Interface      Service  PeerState      Inhib
*00   10.10.10.5 5000 5000      shutdown OutOfService    -----

  SLC  Interface      Service  PeerState      Inhib
*00    Serial1/1/0      FAILED  -----        -----.
```

## Monitoring MTP2 Links/Interfaces

### Why is this task important?

Monitoring interfaces is useful for determining the status of MTP2/SCTP links, for providing statistical information about the performance of the interface.

### Under what circumstances should this task be performed?

If an MTP2 link goes down.

If performance on an MTP2 link is degraded.

### What incidents or system messages should prompt the user to monitor interfaces?

### Should this task be part of a regular maintenance process that the user should do at regular intervals? If so, how frequently?

Regular monitoring is not necessary for link failure problems because system messages will indicate link failure conditions. Regular monitoring to find performance problems may be necessary.

**What commands does the user issue?**

```

show interface serial
show cs7 mtp2 state serial
show cs7 mtp2 congestion serial
show cs7 mtp2 statistics serial

```

The output of the **show interface serial** command can reveal possible Link Down problems. The fields to examine are indicated with arrows in the sample output below:

```

Router# show int ser 5/0/0:0
→ Serial5/0/0:0 is up, line protocol is up
  Hardware is Multichannel T1
  MTU 290 bytes, BW 64 Kbit, DLY 20000 usec,
    reliability 255/255, txload 1/255, rxload 1/255
→ Encapsulation SS7 MTP2, crc 16, CRC 16, Data non-inverted
  Keepalive set (10 sec)
  Last input 00:00:45, output 00:00:45, output hang never
  Last clearing of "show interface" counters 00:05:39
  Queueing strategy:fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  30 second input rate 0 bits/sec, 0 packets/sec
  30 second output rate 0 bits/sec, 0 packets/sec
    139 packets input, 1270 bytes, 0 no buffer
    Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
    119 packets output, 856 bytes, 0 underruns
    0 output errors, 0 collisions, 0 interface resets
    0 output buffer failures, 0 output buffers swapped out
    1 carrier transitions no alarm present
  Timeslot(s) Used:1, subrate:64Kb/s, transmit delay is 0 flags
  Transmit queue length 43

```

The field “line protocol” should display “line protocol is up” rather than down.

The field “Encapsulation” should display “SS7 MTP2” rather than (for example) HDLC.

The output of the **show cs7 mtp2 state serial** command indicates the status of the MTP2 state machine. The fields to examine are indicated with arrows in the sample output below:

```

Router# show cs7 mtp2 state ser 5/0/0:0
CS7 MTP2 states for interface Serial5/0/0:0
Protocol version for interface Serial5/0/0:0 is ITU-T Q.703 (1996) (White Book)

→ Link State Control (LSC) = In Service
  Initial Alignment Control (IAC) = Idle
→ Transmission Control (TXC) = In Service
→ Reception Control (RC) = In Service
  Signal Unit Error Rate Monitor (SUERM) = Monitoring
  Alignment Unit Error Rate Monitor (AERM) = Idle
  Congestion (CONG) = Idle

→ Layer3 link status = Started
  Layer3 congestion status = Abate

```

The field “Link State Control (LSC)” should display “In Service.”

The field “Transmission Control (TXC)” should display “In Service.”

The field “Reception Control (RC)” should display “In Service.”

The field “Layer3 link status” should display “Started.”

The output of the **show interface serial** command can reveal possible performance problems. The fields to examine are indicated with arrows in the sample output below:

```
Router# show int ser 5/0/0:0
→ Serial5/0/0:0 is up, line protocol is up
  Hardware is Multichannel T1
  MTU 290 bytes, BW 64 Kbit, DLY 20000 usec,
→   reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation SS7 MTP2, crc 16, CRC 16, Data non-inverted
  Keepalive set (10 sec)
  Last input 00:00:45, output 00:00:45, output hang never
  Last clearing of "show interface" counters 00:05:39
  Queueing strategy:fifo
→   Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  30 second input rate 0 bits/sec, 0 packets/sec
  30 second output rate 0 bits/sec, 0 packets/sec
→   139 packets input, 1270 bytes, 0 no buffer
  Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
→   0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored, 0 abort
  119 packets output, 856 bytes, 0 underruns
  0 output errors, 0 collisions, 0 interface resets
  0 output buffer failures, 0 output buffers swapped out
  1 carrier transitions no alarm present
  Timeslot(s) Used:1, subrate:64Kb/s, transmit delay is 0 flags
  Transmit queue length 43
```

The field “line protocol” should display “line protocol is up.”

The field “reliability” displays a fraction in the range 255/255 to x/255 which indicates the percentage of reliability. The fraction should represent 100%.

The field “txload” displays a fraction in the range 1/255 to x/255 which indicates the percentage of transmit load on the link.

- Under 40% txload is optimal.
- 40%-80% txload indicates a heavily loaded link.
- Over 80%txload indicates a heavily congested link.

The field “rxload” displays a fraction in the range 1/255 to x/255 which indicates the percentage of receive load on the link.

- Under 40% rxload is optimal.
- 40%-80% rxload indicates a heavily loaded link.
- Over 80% rxload indicates a heavily congested link.

In the field “Output queue 0/40, 0 drops; input queue 0/75, 0 drops”:

- Output drops indicate local txCongestion or rxCongestion at remote.
- Input drops indicate local rxCongestion or txCongestion at remote.

The field “<number> no buffer” indicates packet drops because of buffer shortage. The number should be 0.

The field “<number> input errors, <number> CRC, <number> frame, <number> overrun, <number> ignored, <number> abort” indicates problems with interface receive. The numbers should be 0.

In the field “<number> output errors, <number> collisions, <number> interface resets” all numbers should be 0.

The field “<number> output buffer failures, <number> output buffers swapped out” indicates problems with interface transmit.

The output of the **show cs7 mtp2 congestion serial** command indicates congestion levels. The fields to examine are indicated with arrows in the sample output below:

```
Router# show cs7 mtp2 congestion ser 5/0/0:0
CS7 MTP2 congestion status for interface Serial5/0/0:0
Protocol version for interface Serial5/0/0:0 is ITU-T Q.703 (1996) (White Book)

→ Layer3 congestion status      = Abate

→ CongestionRxInd               = Abate
→ CongestionTxInd               = Abate (Level0)

CongestionTxOnset Level1       = 250 ( 50% of xmitQ maxDepth)
CongestionTxOnset Level2       = 350 ( 70% of xmitQ maxDepth)
CongestionTxOnset Level3       = 450 ( 90% of xmitQ maxDepth)
CongestionTxOnset Level4       = 500 (100% of xmitQ maxDepth)

→ XmitQ depth (max-used)        = 15
→ XmitQ depth (max-allowed)     = 500
```

The field “Layer3 congestion status” should display “Abate” (MTP3 not congested) rather than “Onset” (MTP3 congested).

The fields “CongestionRxInd” and “CongestionTxInd” indicate current congestion levels.

The field “XmitQ depth (max-used)” indicates the maximum number of packets ever waiting on the queue and indicate how congested router might have been.

The output of the **show cs7 mtp2 statistics serial** command indicate congestion levels. The fields to examine are indicated with arrows in the sample output below:

```
Router# show cs7 mtp2 statistics ser 5/0/0:0
CS7 MTP2 Statistics for interface Serial5/0/0:0
Protocol version for interface Serial5/0/0:0 is ITU-T Q.703 (1996) (White Book)

OMtimeINSV (secs)              = 756
OMtimeNotINSV (secs)           = 49

→ OMMSU_unexpectedFSN    = 0      (packets dropped)
→ OMMSU_discarded        = 0      (packets dropped)

```

The fields “OMMSU\_RE\_XMIT\_Count” and “OMMSUBytesRetransmitted” indicate retransmission on the link. Retransmission is an indication of probable congestion.

The fields “OMCongestionRxCount”, “OMCongestionTxCount”, “OMRemote\_Congestion\_C indicate congestion counts on the local or remote device.

The fields “OMunreasonableFSN\_rcvd”, “OMunreasonableBSN\_rcvd”, “OMabnormalBSN\_rcvd” and “OMabnormalFIB\_rcvd” indicate protocol errors.

The field “OMMSU\_congestionDrops” indicates the number of MSU packets dropped due to rxCongestion.

The field “OMMSU\_unexpectedFSN” indicates packets dropped due to unexpected FSN received.

The field “OMMSU\_discarded” indicates total MSU packets dropped, probably due to congestion.

## Monitoring M2PA Links/Interfaces

### Note

M2PA/SCTP links run over any interface that supports IP (serial, ethernet, fast ethernet, token ring, etc. The example used in this section is for fast ethernet.

### Why is this task important?

Monitoring interfaces is useful for determining the status of M2PA/SCTP links and for providing statistical information about the performance of the interface.

### Under what circumstances should this task be performed?

If the M2PA/SCTP links fail or if the M2PA/SCTP link performance is degraded.

### What incidents or system messages should prompt the user to issue the monitor M2PA Links/Interfaces?

### Should this task be part of a regular monitoring process that the user should do at regular intervals? If so, how frequently?

Regular monitoring is not necessary for link failure problems because system messages will indicate link failure conditions. Regular monitoring to identify performance problems may be necessary.

### What commands does the user issue?

```
show interface interface-type
show cs7 m2pa state ls-name
```

The following output of the show interface ethernet command reveals possible link down problems:

```
Router# show int faste0/1
FastEthernet0/1 is up, line protocol is up
  Hardware is AmdFE, address is 0003.e348.5f41 (bia 0003.e348.5f41)
  Internet address is 50.50.50.1/24
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 100Mb/s, 100BaseTX/FX
  ARP type:ARPA, ARP Timeout 04:00:00
  Last input 00:00:16, output 00:00:03, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy:fifo
  Output queue 0/40, 0 drops; input queue 0/75, 0 drops
  30 second input rate 0 bits/sec, 0 packets/sec
  30 second output rate 0 bits/sec, 0 packets/sec
    75799 packets input, 11049547 bytes
    Received 5616 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
    0 watchdog
    0 input packets with dribble condition detected
    155409 packets output, 15498764 bytes, 0 underruns(0/0/0)
    0 output errors, 0 collisions, 1 interface resets
    0 babbles, 0 late collision, 614 deferred
    0 lost carrier, 0 no carrier
    0 output buffer failures, 0 output buffers swapped out
```

The field “line protocol” should display “line protocol is up.”

The field “Internet address” should display a valid IP address.

```
CS7 M2PA states for Peer (50.50.50.2 :9000)
M2PA Peer State           = InService
SCTP Peer State           =SCTP_ESTABLISHED
```

```
T1 aligned/ready          = 5000 ms
T6 remote cong            = 3000 ms
```

```
Local Processor Outage    = FALSE
Remote Processor Outage   = FALSE
InService LSSU Recv'd    = TRUE
Transport Handle          = 0
```

The field “M2PA Peer State” should display “InService.”

The field “SCTP Peer State” should display “SCTP\_ESTABLISHED.”

The following output of the **show interface ethernet** command reveals possible performance problems:

```
Router# show int faste0/1
FastEthernet0/1 is up, line protocol is up
  Hardware is AmdFE, address is 0003.e348.5f41 (bia 0003.e348.5f41)
  Internet address is 50.50.50.1/24
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 100Mb/s, 100BaseTX/FX
  ARP type:ARPA, ARP Timeout 04:00:00
  Last input 00:00:10, output 00:00:09, output hang never
  Last clearing of "show interface" counters never
  Queueing strategy:fifo
  Output queue 0/40, 20 drops; input queue 0/75, 25 drops
  30 second input rate 0 bits/sec, 0 packets/sec
  30 second output rate 0 bits/sec, 0 packets/sec
  75895 packets input, 11064304 bytes
    Received 5641 broadcasts, 0 runts, 0 giants, 0 throttles
  0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
  0 watchdog
  0 input packets with dribble condition detected
  155709 packets output, 15529225 bytes, 0 underruns(0/0/0)
  0 output errors, 0 collisions, 1 interface resets
  0 babbles, 0 late collision, 0 deferred
  0 lost carrier, 0 no carrier
  0 output buffer failures, 0 output buffers swapped out
```

The field “line protocol” should display “line protocol is up.”

The field “Internet address” should display a valid IP address.

The field “reliability” displays a fraction in the range 255/255 to x/255 which indicates the percentage of reliability. The fraction should represent 100%.

The field “txload” displays a fraction in the range 1/255 to x/255 which indicates the percentage of transmit load on the link.

- Under 40% txload is optimal.
- 40%-80% txload indicates a heavily loaded link.
- Over 80%txload indicates a heavily congested link.

The field “rxload” displays a fraction in the range 1/255 to x/255 which indicates the percentage of receive load on the link.

- Under 40% rxload is optimal.
- 40%-80% rxload indicates a heavily loaded link.
- Over 80% rxload indicates a heavily congested link.

In the field “Output queue 0/40, 0 drops; input queue 0/75, 0 drops”:

- Output drops indicate local txCongestion or rxCongestion at remote.
- Input drops indicate local rxCongestion or txCongestion at remote.

The field “<number> no buffer” indicates packet drops because of buffer shortage. The number should be 0.

The field “<number> input errors, <number> CRC, <number> frame, <number> overrun, <number> ignored, <number> abort” indicates problems with interface receive. The numbers should be 0.

In the field “<number> output errors, <number> collisions, <number> interface resets” all numbers should be 0.

The field “number output buffer failures, number output buffers swapped out” indicates problems with interface transmit.

```
Router# show cs7 m2pa statistics to_duck
CS7 M2PA Peer Statistics for (50.50.50.2 :9000)
M2PA Peer State           = InService
SCTP Peer State           = SCTP_ESTABLISHED
MSU_XMIT_Count             = 98658

Total SCTP Datagrams Rcvd:    41099
Total ULP Datagrams Sent:     10877
Total ULP Datagrams Ready:    10877
Total ULP Datagrams Rcvd:     10877

```

The field “Total Data Chunks Retrans” displays the number of retransmissions that have occurred.

The field “Total Chunks Discarded” displays the number of packets that have been discarded due to duplicates.

## Monitoring GTT Measurements

You can display CS7 GTT measurements based on system, map, counters, selector, application-group, or line card.

To display a report for each PC/SSN combination, including the number of times it was used by a successful translation, use the following command in privileged EXEC mode:

| Command                                      | Purpose                                        |
|----------------------------------------------|------------------------------------------------|
| Router# <b>show cs7 gtt measurements map</b> | Displays a report for each PC/SSN combination. |

To display measurements kept on a Selector basis, use the following command in privileged EXEC mode:

| Command                                                             | Purpose                              |
|---------------------------------------------------------------------|--------------------------------------|
| Router# <b>show cs7 gtt measurements selector</b> <i>[selector]</i> | Displays a report for each selector. |

To display measurements for the system, use the following command in privileged EXEC mode:

| Command                                         | Purpose                   |
|-------------------------------------------------|---------------------------|
| Router# <b>show cs7 gtt measurements systot</b> | Displays a system report. |

To display measurements for the application group, use the following command in privileged EXEC mode:

| Command                                                        | Purpose                                                      |
|----------------------------------------------------------------|--------------------------------------------------------------|
| Router# <b>show cs7 gtt measurements app-group</b> <i>name</i> | Displays GTT measurements kept on a application group basis. |

To display measurements for the line card, use the following command in privileged EXEC mode:

| Command                                                                     | Purpose                                                                                                                                              |
|-----------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router# <b>show cs7 gtt measurements line-card</b> [ <i>line-card-num</i> ] | Displays GTT measurements kept on a line card basis. If line-card-num is not specified, all line-card measurements for all line cards are displayed. |

To reset all GTT measurements to 0, use the following command in privileged EXEC mode:

| Command                           | Purpose                           |
|-----------------------------------|-----------------------------------|
| Router# <b>clear cs7 gtt-meas</b> | Resets all GTT measurements to 0. |

## Monitoring M3UA or SUA

This section includes information about the following monitoring tasks:

- [Monitoring M3UA, page 384](#)
- [Monitoring SUA, page 384](#)
- [Monitoring Point Code Status, page 385](#)
- [Monitoring AS, page 385](#)
- [Monitoring ASP, page 387](#)
- [Monitoring and Mated SG Pairs, page 389](#)

### Monitoring M3UA

The following is sample output from the **show cs7 m3ua** command.

The “State” field should be “Active” and the number of active SUA and M3UA peers should math the number of ASPs available.

```
Router# show cs7 m3ua
Sigtran M3UA RFC number: 3332

M3UA Local port: 2905 State: active          SCTP instance handle: 5
Local ip address:                            172.18.48.39
Number of active M3UA peers:                  0
Max number of inbound streams allowed:        17
Local receive window:                        64000
Max init retransmissions:                     8
Max init timeout:                             1000 ms
Unordered priority:                           equal
SCTP defaults for new associations
Transmit queue depth:    1000          Cumulative sack timeout:    200 ms
Assoc retransmissions:   10           Path retransmissions:      4
Minimum RTO:             1000 ms      Maximum RTO:                1000 ms
Bundle status:           on           Bundle timeout:              5 ms
Keep alive status:       true          Keep alive timeout:          30000 ms
```

### Monitoring SUA

The following is sample output from the **show cs7 sua** command:

```
Router# show cs7 sua
```

```

Sigtran SUA draft version: 14

SUA Local port: 14001 State: active          SCTP instance handle: 5
Local ip address:                            172.18.48.39
Number of active SUA peers:                  0
Max number of inbound streams allowed:       17
Local receive window:                        64000
Max init retransmissions:                    8
Max init timeout:                            1000 ms
Unordered priority:                          equal
SCTP defaults for new associations
  Transmit queue depth:    1000          Cumulative sack timeout: 200 ms
  Assoc retransmissions:   10            Path retransmissions:   4
  Minimum RTO:             1000 ms       Maximum RTO:             1000 ms
  Bundle status:           on            Bundle timeout:          5 ms
  Keep alive status:        true          Keep alive timeout:      30000 ms

```

## Monitoring Point Code Status

The **show cs7 point-codes** command displays the type and status of all point codes configured as a destination point code in an M3UA or SUA routing key (default).

The **event-history** keyword displays the point code status history (default). The **ssn** keyword displays the status of all point codes configured as a DPC in an SUA routing key that also contains a valid SSN.

The following is sample output from the **show cs7 point-code** command

Router#**show cs7 point-codes**

| CS7 Point Code | Type  | Status       |
|----------------|-------|--------------|
| 1.1.2          | local | active       |
| 2.1.1          | AS    | SUA inactive |

Router#**show cs7 point-code ssn**

| SUA Point Code | SSN | Status       |
|----------------|-----|--------------|
| 5.6.7          | 3   | SUA inactive |

## Monitoring AS, ASP, Mated-SG

### Monitoring AS

The **show cs7 as** command includes keywords to filter and format the output.

- The filter options are **active**, **all** ASes (the default), **m3ua**, **name asname**, **operational**, and **sua**.
- The GTT subfilters are **include-gtt**, **exclude-gtt**, or **only-gtt**
- The format options are **brief** (the default format), **details**, **event-history**, and **statistics**.

The following is output from the **show cs7 as** command entered with no format or filter keywords. The command uses the default filter (**all**) and the default format (**brief**):

Router# **show cs7 as**

| AS Name | State | Routing Context |
|---------|-------|-----------------|
| asp1    | down  | 1               |
| asp2    | down  | 2               |

| AS Name | State | Routing Context | Routing Key Dpc | Si | Opc | Cic Ssn | Cic Min | Cic Max |
|---------|-------|-----------------|-----------------|----|-----|---------|---------|---------|
| as1     | down  | 111             | 2.1.1           |    |     |         |         |         |

The following is output from the **show cs7 as** command entered with the **name asname** filter keyword and the **detail** format keyword:

```
Router#show cs7 as name owl5 detail
AS name: m3ua_s_176_0      State: active      Type: M3UA
RoutContxt: 6700          Class2 binding: enabled
Traf mode: loadshare bindings SLS
Mate AS state: unknown  Rerouting queue depth: 0
Recovery tmout: 2000 ms  Recovery queue depth: 0
QOS Class: 0             Burst recovery tmout: 4000 ms
PMP Status: N            Inbound/outbound DCS group: n/a / n/a
Routing Key:
  Dest PC: 2.1.1          Origin PC: n/a          Origin PC mask: n/a
  SI: n/a                 CIC min: n/a           CIC max: n/a
  SSN: n/a                GTT: n/a
ASP Name    AS Name      State    Type    Rmt Port Remote IP Addr  SCTP Assoc
asp2        owl5         down     SUA     9022  172.18.57.136
asp1        owl5         down     SUA     9012  172.18.57.136
cuba        owl5         down     SUA     14101 172.18.57.90
```

Traffic-mode states are: override, loadshare bindings, loadshare roundrobin, broadcast, or undefined.

AS and Mate-AS states are: shutdown, down, down-rerouting, inactive, inactive-rerouting, active, or pending.

## Monitoring ASP

The following is output from the **show cs7 asp sua** command in the default brief format:

| ASP Name | AS Name | State | Type | Rmt Port | Remote IP Addr | SCTP |
|----------|---------|-------|------|----------|----------------|------|
| asp1     | asp1    | down  | SUA  | 9012     | 172.18.57.136  |      |
| asp1     | as1     | down  | SUA  | 9012     | 172.18.57.136  |      |
| asp2     | asp2    | down  | SUA  | 9022     | 172.18.57.136  |      |
| asp2     | as1     | down  | SUA  | 9022     | 172.18.57.136  |      |
| cuba     | as1     | down  | SUA  | 14101    | 172.18.57.90   |      |

ASP States are: shutdown, blocked, down, inactive, active, or active/congested.

If the ASP is down or shutdown, then the remote port and remote IP address display the configured values instead of the actual values.

The following is output from the **show cs7 asp** command in the detail format:

```
Router#show cs7 asp detail
ASP name: asp1                                Type: SUA
Availability: enabled                          ASP id: n/a
SCTP association state: closed                 Association id: n/a
AS name: asp1
  ASP state: down      Traf mode: n/a          Active Time: Not Active
AS name: as1
  ASP state: down      Traf mode: n/a          Active Time: Not Active
Configured remote port: 9012                  Actual remote port: n/a
Configured remote ip addresses: 172.18.57.136
Actual remote ip addresses: n/a
Local port: 14001
ASP protocol class capability: class 0, class 1
ASP interworking with SS7 networks capability: ASP
Local receive window: 64000                   Cumulative sack timeout: 200 ms
Assoc retrans: 10                             Path retrans: 4
Max init retrans: 8                           Max init RTO: 1000 ms
Minimum RTO: 1000 ms                          Maximum RTO: 1000 ms
Bundle status: on                             Bundle timeout: 5 ms
Keep alive status: true                       Keep alive timeout: 30000 ms
Unordered priority: equal                     Transmit queue depth: 20000
Unordered priority: equal                     Cleanup timeout: 0 ms
Link status T1 timeout: 0 ms                  Remote congest T6 timeout: 0 ms
SCTP congestion level: 0                      SCON congestion level: 0
Transmit queue depth: 1000
Thresholds for congestion on transmit queue
  Level 1 onset: 500                          Level 1 abate: 300
  Level 2 onset: 700                          Level 2 abate: 500
  Level 3 onset: 900                          Level 3 abate: 700
  Level 4 onset: 1000                         Level 4 abate: 900
QOS Class: 0                                  IP TOS: 0x0
Match Type: None
```

The following is sample output from the **show cs7 asp** command in the **statistics** format:

```
Router# show cs7 asp statistics

## Monitoring and Mated SG Pairs

The following is sample output from the **show cs7** command:

```

ITP# show cs7
  Local port: 14002      State: active      SCTP instance handle: 5
  Local ip address:      172.18.48.39
  Number of active peers: 0
  Max number of inbound streams allowed: 17
  Local receive window: 5555
  Max init retransmissions: 8
  Max init timeout: 1000 ms
  Unordered priority: equal
  Offload to FlexWAN: No      Slot: -1
  SCTP defaults for new associations
    Transmit queue depth: 1000      Cumulative sack timeout: 200 ms
    Assoc retransmissions: 17      Path retransmissions: 4
    Minimum RTO: 1000 ms      Maximum RTO: 1000 ms
    Bundle status: on      Bundle timeout: 5 ms
    Keep alive status: true      Keep alive timeout: 30000 ms
    Initial cwnd: 3000      Idle cwnd rate: 50
    Retrans cwnd rate: 50      Retrans cwnd mode: RFC
    FastRetrans rate: 50

```

The following is sample output from the **show cs7 mated-sg** command in the default brief format:

Options for the SG Mate state include: Inactive/Active/Shutdown

If the Mate is shutdown, then the remote port and remote IP address display the configured values instead of the actual values.

Router# **show cs7 mated-sg**

| Mate Name | State  | Passive | Remote Port | Effect Primary<br>Remote IP Addr | SCTP Assoc |
|-----------|--------|---------|-------------|----------------------------------|------------|
| bermuda   | active | no      | 14002       | 172.18.48.15                     | 0          |

The following is sample output from the **show cs7 mated-sg** command with the **detail** keyword:

Options for SG Mate state include: Inactive/Active/Shutdown

Router# **show cs7 mated-sg detail**

```

Mated SG name: bermuda                               Type:

```

## Monitoring Routes

### Why is this task important?

Monitoring routes is important because it reveals the status of all the routes in the network, and thus the ability of the network to transport messages efficiently.

### Under what circumstances should routes be monitored?

The status of routes should be monitored whenever the performance of the network is noticeably degraded. This may reveal congestion on specific routes, for example, which may indicate a need to deploy more links. In conjunction with other system messages it may reveal failures in various network components.

### What incidents or system messages should prompt the user to issue the `show cs7 route` command?

Whenever a destination accessibility status change message such as the following appears on the console:

```
00:05:51:%CS7MTP3-5-DESTSTATUS:Destination 10.5.1 is inaccessible
```

Whenever a destination is reported to be inaccessible or restricted, the **show cs7 route detailed** command will reveal what caused the destination to enter that state.

### Should this task be part of a regular monitoring process that the user should do at regular intervals? If so, how frequently?

Normally this should be performed to verify the configuration of new routes or deletion/modification of existing routes. A regular monitoring is not needed because system generated messages (such as in the example shown above) will inform the user of any abnormal operating conditions.

### What commands does the user issue?

The **show cs7 route** command displays information such as the following:

```
router# show cs7 route
Routing table = system
```

| Destination | Prio  | Linkset | Name    | Route |
|-------------|-------|---------|---------|-------|
| 1.1.1/14    | acces | 1       | bermuda | avail |
| 3.1.1/14    | acces | 5       | bermuda | avail |

```
Routing table = XUA
```

| Destination | Cong  |
|-------------|-------|
| 2.1.1/14    | INACC |

Refer to the [ITP Command Set](#) chapter of this document for detailed descriptions of the show commands.

## Monitoring Gateway Screening Violations

**Why is this task important?**

When screening is configured you can view screening activity.

**Under what circumstances should this task be performed?**

When screening is configured.

**What incidents or system messages should prompt the user to monitor gateway screening violations?**

None. Violations do not appear as system messages because of the volume of messages this might generate.

**Should this task be part of a regular monitoring process that the user should do at regular intervals? If so, how frequently?**

At user's discretion.

**What commands does the user issue?**

```
show cs7 access-lists
```

```
show cs7 accounting access-violations [checkpoint]
```

Refer to the “Command Reference” section of this document for detailed descriptions of the show commands.

## Monitoring System Messages

**Why is this task important?**

System messages are part of the ITP alert infrastructure.

**Under what circumstances should this task be performed?**

Monitoring should be automated via an external syslog server.

**What incidents or system messages should prompt the user to monitor system messages?**

Refer to the Cisco IOS Software System Error Messages documentation at the following URL:  
<http://www.cisco.com/univercd/cc/td/doc/product/software/ios121/121sup/index.htm>

**Should this task be part of a regular monitoring process that the user should do at regular intervals? If so, how frequently?**

Yes, this process should be ongoing and automated.

**What commands does the user issue?**

```
show log
```

## Monitoring Accounting

### Why is this task important?

Monitoring accounting provides information about user-specific usage.

### Under what circumstances should this task be performed?

At user's discretion.

### What incidents or system messages should prompt the user to monitor system messages?

Traffic degradation, debugging of problems.

### Should this task be part of a regular monitoring process that the user should do at regular intervals? If so, how frequently?

At user's discretion. This task can be part of ongoing statistics collection to be used for network capacity planning or traffic profiling.

### What commands does the user issue?

**accounting**

**show cs7 accounting [checkpoint]**

**show cs7 linkset statistics**

Refer to the "Command Reference" section of this document for detailed descriptions of the show commands.

## Summary of Commands to Monitor Cisco ITP

The following is a summary of commands in EXEC mode to monitor various functions of Cisco ITP.

| Command                                                                                                                                                                                                                                                                              | Purpose                           |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| Router# <b>show cs7 access-lists</b>                                                                                                                                                                                                                                                 | Displays ITP access lists.        |
| Router# <b>show cs7 accounting [access-violations] [checkpoint]</b>                                                                                                                                                                                                                  | Displays accounting details.      |
| Router# <b>show cs7 as [ binding-table   [m3ua [include-gtt   exclude-gtt   only-gtt]]   [sua [include-gtt   exclude-gtt   only-gtt]]   [all [include-gtt   exclude-gtt   only-gtt]]   [name as-name] [operational   active   all] [statistics   detail   brief   event-history]</b> | Displays CS7 AS statistics.       |
| Router# <b>show cs7 [instance-number] asp [m3ua   sua   all   name asp-name   asname as-name] [statistics [detail]   bindings   detail   event-history]</b>                                                                                                                          | Displays CS7 ASP statistics.      |
| Router# <b>show cs7 gtt {address-conversion   application-group   concern-pclist   config   consistency   gta selector   map   measurements   selector}</b>                                                                                                                          | Displays GTT statistics.          |
| Router# <b>show cs7 linkset [ls-name   routes   sls   statistics   timers   ttmap] [brief   detailed]</b>                                                                                                                                                                            | Displays ITP linkset statistics.  |
| Router# <b>show cs7 m2pa {[local-peer port-num]   [peer ls-name [slc]]   [state ls-name [slc]]   [statistics ls-name [slc]]}</b>                                                                                                                                                     | Displays ITP M2PA statistics.     |
| Router# <b>show cs7 m3ua local-port</b>                                                                                                                                                                                                                                              | Displays CS7 M3UA statistics.     |
| Router# <b>show cs7 mated-sg</b>                                                                                                                                                                                                                                                     | Displays CS7 Mated SG statistics. |

| Command                                                                                                                                 | Purpose                                                  |
|-----------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| Router# <b>show cs7 mtp2</b> [ <b>congestion</b>   <b>state</b>   <b>statistics</b>   <b>timers</b>   <b>variant</b> ] <i>interface</i> | Displays ITP MTP2 statistics.                            |
| Router# <b>show cs7 mtp3 timers</b>                                                                                                     | Displays output from MTP3 timers.                        |
| Router# <b>show cs7 ping</b> <i>point-code</i>                                                                                          | Displays output from a Cisco ITP ping test.              |
| Router# <b>show cs7 point-codes</b> [ <b>event-history</b>   <b>ssn</b> ]                                                               | Displays point codes the ITP SG is responding to.        |
| Router# <b>show cs7 qos</b> {[ <b>class</b> <i>class</i> ]   [ <b>statistics</b> <i>ls-name</i> ]}                                      | Displays QoS class information.                          |
| Router# <b>show cs7 route</b> [ <i>destination</i> ] [ <b>brief</b>   <b>detailed</b> ]                                                 | Displays the routing table.                              |
| Router# <b>show cs7</b>                                                                                                                 | Displays Signaling Gateway Mate Protocol () information. |
| Router# <b>show cs7 sua</b>                                                                                                             | Displays CS7 SUA information.                            |

## Tuning ITP

The following sections provide information about tuning the Cisco ITP:

- [Tuning HSL Parameters, page 394](#)
- [Tuning MTP3 Timers, page 397](#)
- [Tuning MTP2 Parameters, page 398](#)
- [Tuning SCTP Parameters, page 402](#)

## Tuning HSL Parameters

ITP allows you to specify bundling, SSCF-NNI, and SSCOP parameters for ATM HSL support. You can choose either or both of two configuration methods. You can configure the parameters in a CS7 profile that you apply globally to all links in a linkset. Or, you can specify or modify the parameters on a specific link.

The following sections describe both methods for specifying HSL parameters:

[Create a Profile to Support HSL, page 394](#)

[Specify HSL Parameters on a Link, page 397](#)

### Create a Profile to Support HSL

You can create a CS7 profile, specify the HSL parameters, then apply the profile to a linkset.

#### Step 1 Create a CS7 Profile

To create the profile use the following commands, beginning in global configuration mode:

| Command                                        | Purpose                                                           |
|------------------------------------------------|-------------------------------------------------------------------|
| Router(config)# <b>cs7 profile</b> <i>name</i> | Names the CS7 profile and enables CS7 profile configuration mode. |
| Router(config-cs7-profile)# <b>hsl</b>         | Enables the CS7 profile mode for configuring HSL parameters.      |

**Step 2** Specify HSL Parameters

A CS7 profile can specify values for SSCF-NNI parameters, SSCOP parameters, and bundling.

The SSCF NNI provides mapping of the services provided by SSCOP and of the SAAL to the ULP, in this case MTP3.

To configure the HSL parameters for SSCF-NNI, use the following commands in CS7 profile configuration mode:

| Command                                                              | Purpose                                                                                                                                                          |
|----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-profile-hsl)# <b>sscf-nni force-proving timer</b>  | Specify the time (in minutes) to monitor the link after proving. The range is 0 to 20 minutes. The default is 10 minutes.                                        |
| Router(config-cs7-profile-hsl)# <b>sscf-nni n1 num</b>               | Specify the number of PDUs sent during proving. The range is 5 to 180000 PDUs. The default for ITU is 1000 PDUs. The default for ANSI is 60000 PDUs.             |
| Router(config-cs7-profile-hsl)# <b>sscf-nni no-credit timer</b>      | Specify the time (in seconds) allowed with no credit. The range is 1 to 6 seconds. The default is 2 seconds.                                                     |
| Router(config-cs7-profile-hsl)# <b>sscf-nni nrp num</b>              | Specify the maximum number of retransmissions allowed during proving. The range is 1 to 10 retransmissions. The default is 1 retransmission.                     |
| Router(config-cs7-profile-hsl)# <b>sscf-nni sscop-recovery timer</b> | Specify the time (in minutes) for SSCOP recovery. The range is 30 to 1440 minutes. The default is 60 minutes.                                                    |
| Router(config-cs7-profile-hsl)# <b>sscf-nni t1 timer</b>             | Specify the time (in seconds) to reestablish connection. The range is 1 to 15 seconds. The default is 5 seconds.                                                 |
| Router(config-cs7-profile-hsl)# <b>sscf-nni t2 timer</b>             | Specify the time (in seconds) for alignment to complete. The range is 15 to 180 seconds. The default for ITU is 30 seconds. The default for ANSI is 120 seconds. |
| Router(config-cs7-profile-hsl)# <b>sscf-nni t3 timer</b>             | Specify the time (in milliseconds) to send proving packets. The range is 1 to 5000 milliseconds. The default is 1 millisecond.                                   |

The Service-Specific connection -Oriented Protocol (SSCOP) resides in the service-specific convergence sublayer (SSCS) of the ATM adaptation layer (AAL). SSCOP is used to transfer variable-length service data units (SDUs) between users of SSCOP. SSCOP provides for the recovery of lost or corrupted SDUs.

To configure the HSL parameters for SSCOP, use the following commands in CS7 profile configuration mode:

| Command                                                            | Purpose                                                                                                                                                               |
|--------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-profile-hsl)# <b>sscop cc-timer timer</b>        | Specify the time (in milliseconds) to send BGN/END/RS/ER PDU at the connection control phase. The range is 100 to 2000 milliseconds. The default is 200 milliseconds. |
| Router(config-cs7-profile-hsl)# <b>sscop idle-timer timer</b>      | Specify the time (in milliseconds) to send poll PDU at the idle phase. The range is 25 to 1000 milliseconds. The default is 100 milliseconds.                         |
| Router(config-cs7-profile-hsl)# <b>sscop keepalive-timer timer</b> | Specify the time (in milliseconds) to send poll PDU at the transient phase. The range is 25 to 500 milliseconds. The default is 100 milliseconds.                     |

| Command                                                             | Purpose                                                                                                                                                      |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-profile-hsl)# <b>sscop max-cc num</b>             | Specify the maximum number of retries for connection control operations. The range is 1 to 127 retries. The default is 4 retries.                            |
| Router(config-cs7-profile-hsl)# <b>sscop max-pd num</b>             | Specify the maximum number of Sd frames to send before sending a Poll. The range is 1 to 500 Sd frames. The default is 500 Sd frames.                        |
| Router(config-cs7-profile-hsl)# <b>sscop noResponse-timer timer</b> | Specify the time (in milliseconds) in which at least one STAT PDU must be received. The range is 200 to 2000 milliseconds. The default is 1500 milliseconds. |
| Router(config-cs7-profile-hsl)# <b>sscop poll-timer timer</b>       | Specify the times (in milliseconds) to send poll PDU at the active phase. The range is 25 to 500 milliseconds. The default is 100 milliseconds.              |
| Router(config-cs7-profile-hsl)# <b>sscop receive-window num</b>     | Specify the maximum number of Sd(p) frames our partner can send. The range is 1 to 1024 Sd(p) frames. The default is 1024 Sd(p) frames.                      |
| Router(config-cs7-profile-hsl)# <b>sscop send-window num</b>        | Specify the maximum number of Sd frames to send before waiting for acknowledgement. The range is 1 to 1024 frames. The default is 1024 frames.               |

To configure HSL bundling, use the following command in CS7 profile configuration mode:

| Command                                                  | Purpose                                                                                                                          |
|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-profile-hsl)# <b>bundling interval</b> | Specifies (in milliseconds) the HSL packet bundling interval. The range is 5 to 100 milliseconds. The default is 5 milliseconds. |

### Step 3 Apply the CS7 Profile to a Linkset

After you have created the profile, apply it to a linkset by using the following commands, beginning in CS7 profile configuration mode:

| Command                                                    | Purpose                                                                                           |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| Router(config-cs7-profile-hsl)# <b>cs7 linkset ls-name</b> | Specifies the linkset to which you will apply the profile, and enters linkset configuration mode. |
| Router(config-cs7-ls)# <b>profile name</b>                 | Applies the parameter values specified in the profile to all the links in the linkset.            |

#### Note

Whenever you change the CS7 profile, the revised profile automatically applies to the linkset.

#### Note

You can override parameter applied with the profile by configuring the specific parameter on the link.

## Specify HSL Parameters on a Link

You can specify/modify individual HSL parameters on a link, or you can specify/modify all the HSL parameters on the link. To configure parameters on a link, use any of the commands described in [Step 2 Specify HSL Parameters, page 395](#) from CS7 link configuration mode. To enable CS7 link configuration mode, use the following commands, beginning in global configuration mode:

| Command                                           | Purpose                                                                                                 |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 linkset</b> <i>ls-name</i> | Specifies the linkset to which you will apply the profile, and enters linkset configuration mode.       |
| Router(config-cs7-ls)# <b>link</b> <i>slc</i>     | Identifies the link to which you intend to apply HSL parameters, and enter CS7 link configuration mode. |

## Tuning MTP3 Timers

MTP3 timers can be defined at 3 levels, global, linkset, and link.

All global, linkset, and link specific timers can be defined at the global level. These values serve as defaults and are propagated down to the lower levels.

To globally configure MTP3 timers, Use the following command in global configuration mode:

| Command                                                 | Purpose                                                                      |
|---------------------------------------------------------|------------------------------------------------------------------------------|
| Router(config)# <b>cs7 mtp3 timer</b> <i>timer msec</i> | Configure MTP3 timers for the system, the linkset, or the link. <sup>1</sup> |

1. For details about the MTP3 timers that you can configure with this command, see the Command Reference entry for [cs7 mtp3 timer](#).

Linkset and link specific timers can be defined at the linkset level. These values serve as defaults for the linkset and all links defined within that linkset. Any values defined at the linkset level will override any global values.

To configure MTP3 timers on a linkset, use the following commands in linkset configuration mode:

| Command                                           | Purpose                                                                                                                                                                                                       |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-ls)# <b>timer</b> <i>timer msec</i> | Configure MTP3 timers for a linkset, and (optionally) for links on the linkset. For details about the MTP3 timers that you can configure with this command, see the Command Reference page for <b>timer</b> . |
| Router(config-ls)# <b>sls-shift</b> {0-3}         | Shift which SLS bits are used for link and linkset selection. Available for ITU variant only.                                                                                                                 |

Link specific timers can be defined at the link level. Timers defined at the link level will apply to the link and will override any values for that timer defined at either the linkset, or global level.

To configure MTP3 timers on a link, use the following commands in linkset configuration mode:

| Command                                                     | Purpose                                                                                                                                                        |
|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-ls-link)# <b>link-timer</b> <i>timer msec</i> | Configure MTP3 link timers. For details about the MTP3 timers that you can configure with this command, see the Command Reference page for <b>link-timer</b> . |

## Tuning MTP2 Parameters

The following sections describe the MTP2 parameters that you can tune, and describes 2 methods for specifying MTP2 parameters for a link:

- [Understanding the MTP2 Parameters, page 398](#)
- [Specifying MTP2 Parameters in a CS7 Profile, page 399](#)
- [Specifying MTP2 Parameters Individually, page 401](#)

## Understanding the MTP2 Parameters

You can customize MTP2 protocol parameters for timers, bundling, and transmit queue depth to control and influence the MTP2 behavior.

### MTP2 Timers

You can adjust the following MTP2 timers:

- T1 (alignment ready)
- T2 (not aligned)
- T3 (aligned)
- T4E (emergency proving period)
- T4N (normal proving period)
- T5 (sending SIB)
- T6 (remote congestion)
- T7 (excessive delay of acknowledgment)
- TTC timers, including
  - **ttc ta timer**: TTC Timer for sending SIE. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.
  - **ttc te timer**: TTC Timer for error monitoring. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.
  - **ttc tf timer**: TTC Timer for sending FISU. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.
  - **ttc to timer**: TTC Timer for sending SIO. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.
  - **ttc ts timer**: TTC Timer for sending SIOS. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.

### Bundling

The bundling parameter is used to set the bundling interval (an amount of time to wait for packets before sending the bundle). It is recommended that bundling be enabled for high packet rates (1000 pps or higher) with small packets (50 bytes and lower). Bundling can be less than optimal for lower data rates with small or large packets because of the transmission delay. Bundling is found to be effective for large packets at high data rates in networks with symmetrical traffic. Applications with low data rates should disable bundling if the increase in round-trip time is undesirable. It is recommended that bundling be enabled for applications sending small packets that may start with low data rates, but are capable of increasing to higher sustained data rates. The default bundling delay is 5 milliseconds.

### Transmit Queue

The tx-queue-depth parameter is used to determine the onset and abate thresholds for congestion on transmit queue. The tx-queue-depth parameter controls the number of packets allowed on the transmit queue. The tx-queue exist to absorb inevitable traffic burst. When selecting the tx-queue-depth, there will be a compromise between hitting transmit congestion thresholds causing dropped packets and transmit delays due to queuing times. Applications that are sensitive to small delays should account for transmit delays due to queuing when selecting a tx-queue-depth. During periods of SCTP link congestion, the tx-queue-depth will control the number of packets that can be queued before packets are discarded, causing application retransmissions. The default tx-queue-depth is 1000 packets for M3UA and SUA. The default tx-queue-depth is 20,000 packets for SGMP.

## Specifying MTP2 Parameters in a CS7 Profile

You can create a CS7 profile that specifies MTP2 parameters, then apply the profile to a link.

### Step 1 Create a CS7 Profile.

A CS7 profile can specify values for MTP2 timers, bundling, and transmit queue depth. To create the profile use the following commands, beginning in global configuration mode:

| Command                                                      | Purpose                                                                                                                |
|--------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 profile</b> <i>name</i>               | Names the CS7 profile and enables CS7 profile submenu.                                                                 |
| Router(config-cs7-profile)# <b>mtp2</b>                      | Enables the CS7 profile submenu for configuring MTP2 parameters.                                                       |
| Router(config-cs7-profile-mtp2)# <b>bundling</b> <i>msec</i> | Enables bundling and specifies the bundling interval (the length of time to wait for packets before sending a bundle). |

| Command                                                                                                                                                                             | Purpose                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-profile-mtp2)# <b>timer</b> { <b>t1</b>   <b>t2</b>   <b>t3</b>   <b>t4e</b>   <b>t4n</b>   <b>t5</b>   <b>t6</b>   <b>t7</b>   <b>ttc timer</b> }<br><i>msec</i> | Specifies the following MTP2 timers: <sup>1</sup> <ul style="list-style-type: none"> <li>t1 -- T1 (alignment ready)</li> <li>t2 -- T2 (not aligned)</li> <li>t3 -- T3 (aligned)</li> <li>t4e -- T4E (emergency proving period)</li> <li>t4n -- T4N (normal proving period)</li> <li>t5 -- T5 (sending SIB)</li> <li>t6 -- T6 (remote congestion)</li> <li>t7 -- T7 (excessive delay of acknowledgment)</li> <li>ttc ta timer -- TTC Timer for sending SIE. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.</li> <li>ttc te timer -- TTC Timer for error monitoring. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.</li> <li>ttc tf timer -- TTC Timer for sending FISU. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.</li> <li>ttc to timer -- TTC Timer for sending SIO. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.</li> <li>ttc ts timer -- TTC Timer for sending SIOS. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.</li> </ul> |
| Router(config-cs7-profile-mtp2)# <b>tx-queue-depth</b><br><i>msec</i>                                                                                                               | Specifies the number of packets that MTP2 will queue for transmission.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Router(config-cs7-profile-mtp2)# <b>exit</b>                                                                                                                                        | Exits the CS7 profile submode for MTP2.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Router(config-cs7-profile)# <b>exit</b>                                                                                                                                             | Exits the CS7 profile submode (returning you to global configuration mode).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

1. For detailed information about MTP2 timers, refer to the appropriate standards.

**Step 2** Apply the profile to all of the links in a linkset.

After you have created the profile, apply it to a linkset by using the following commands, beginning in global configuration mode:

| Command                                           | Purpose                                                                                                                                                                                                                   |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config)# <b>cs7 linkset</b> <i>ls-name</i> | Specifies the linkset to which you will apply the profile, and enters linkset configuration mode.                                                                                                                         |
| Router(config-cs7-ls)# <b>profile</b> <i>name</i> | Applies the parameter values specified in the profile to all the links in the linkset. (The <b>no</b> version of this command removes the profile from the linkset and resets the MTP2 parameters to the default values.) |

**Note**

Whenever you change the CS7 profile, the revised profile automatically applies to the linkset.

**Note**

You can override an MTP2 parameter applied with the profile by configuring the specific parameter on the link.

## Specifying MTP2 Parameters Individually

You can specify or change the values of MTP2 timers, bundling, and transmit queue depth individually at the link level.

To tune the MTP2 timers, use the following command in CS7 link submode:

| Command                                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-ls-link)# <b>mtp2-timer</b> {t1   t2   t3   t4e   t4n   t5   t6   t7} msec | Specifies the following MTP2 timers: <sup>1</sup> <ul style="list-style-type: none"> <li>t1 -- T1 (alignment ready)</li> <li>t2 -- T2 (not aligned)</li> <li>t3 -- T3 (aligned)</li> <li>t4e -- T4E (emergency proving period)</li> <li>t4n -- T4N (normal proving period)</li> <li>t5 -- T5 (sending SIB)</li> <li>t6 -- T6 (remote congestion)</li> <li>t7 -- T7 (excessive delay of acknowledgment)</li> </ul> |

1. For detailed information about MTP2 timers, refer to the appropriate ANSI and ITU standards.

To enable bundling of packets sent between MTP3 on the Route Processor and MTP2 on the FlexWAN, and to specify the bundling interval for the link, use the following command in CS7 link submode:

| Command                                          | Purpose                                                                                                                |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-ls-link)# <b>bundling</b> msec | Enables bundling and specifies the bundling interval (the length of time to wait for packets before sending a bundle). |

You can adjust the number of packets that can be queued for transmission before reaching a state of transmit congestion. This parameter is known as the transmit queue depth.

The values for this parameter vary depending on the type of link. For an MTP2 link, the range is 25 to 5000 packets with a default of 500 packets. For an SCTP link, the range is 100 to 20000 packets, with a default of 1000 packets.

To tune the transmit queue depth for the link, use the following command in CS7 link submode:

| Command                                                   | Purpose                                                        |
|-----------------------------------------------------------|----------------------------------------------------------------|
| Router(config-cs7-ls-link)# <b>tx-queue-depth</b> packets | Specifies the number of packets allowed on the transmit queue. |

## Tuning SCTP Parameters

The following sections describe SCTP parameters and tasks:

- [How SCTP Parameters Work, page 402](#)
- [Tuning SCTP Parameters for M2PA, page 404](#)
- [Tuning SCTP Parameters for M3UA and SUA, page 407](#)
- [Tuning SCTP Parameters for an ASP, page 408](#)
- [Tuning AS Options, page 408](#)
- [Tuning SCTP Parameters for a Mated SG, page 409](#)
- [Tuning SCTP Parameters for Satellite Channels, page 410](#)

### How SCTP Parameters Work

SCTP provides several protocol parameters that can be customized by the upper layer protocol. These protocol parameters can be customized to control and influence SCTP performance behavior. Different network designs and implementations pose their own unique performance requirements. It is not possible to provide customized protocol parameters that are suitable for all implementations. The tuning information in this section is provided as a guide for understanding what the SCTP protocol parameters are and how they affect the various SCTP algorithms.

#### Connection Establishment

The protocol parameters `assoc-retransmit`, `init-retransmit` and `init-timeout` can be customized to control connection establishment. During SCTP association initialization sometimes packet retransmissions occur. When initialization packet retransmissions occur, the timeout value is doubled for each retransmission. The first initialization packet timeout occurs after 1 second. The maximum timeout value is bound by the `init-timeout` parameter. The `init-timeout` parameter is used to control the time between initialization packet retries. As a general rule, `init-timeout` should be configured to reflect the round-trip-time for packets to traverse the network. An `init-timeout` value that is too small, can cause excessive retries of initialization packets. Large `init-timeout` values can increase connection establishment times.

The number of retries allowed for connection establishment packets is controlled by the `init-retransmit` protocol parameter. When you configure the number of retries to attempt, take into account the varying network conditions that may prevent initialization packets from traversing the network.

The defaults used by M2PA are recommendations from RFC 2960 or RFC 4960 depending upon which RFC version has been provisioned. The `init-timeout` default is 1 second. The `init-retransmit` default is set for 8. The `init-retransmit` and `init-timeout` defaults are suitable for most high-speed links. The defaults may require adjusting for slower links.

#### SCTP Multi-homing

A key feature of SCTP is multi-homing. An SCTP endpoint is considered multi-homed if more than one IP address can be used as a destination to reach that endpoint. Upon failure of the primary destination address SCTP switches to an alternate address.

In the configuration of a multi-homed endpoint, the first remote IP address specified on the peer link is defined as the primary address. If the primary address is determined to be unreachable, SCTP multi-homing switches to one of the alternate addresses specified on the peer link. SCTP will monitor the reachability of the failed destination address. Upon notification that reachability is re-established to the primary address, M2PA directs SCTP to switch back to the primary address.

The protocol parameters `path-retransmit` and `retransmit-timeout` can be customized to control how long SCTP waits before switching to an alternate address. The `path-retransmit` parameter controls the number of times that SCTP attempts to retransmit a packet before declaring the destination address unreachable. The `retransmit-timeout` parameter is used to determine whether a packet must be retransmitted. If an acknowledgement is not received by the time the retransmission timer expires, all packets that have been transmitted, but not acknowledged are retransmitted.

### Path-retransmit

The `path-retransmit` parameter is the number of packet retries before the destination address is deemed unreachable. The number of path-retransmits multiplied by the retransmission timer ultimately controls how fast an alternate address becomes the primary path for multi-homed nodes. This relationship suggests the RTO parameters and `path-retransmit` parameter should be considered together. Configuring the default RTO values and default path retransmit value of 4 allows a multi-homed node to switch to an alternate destination address within 4 seconds.

### Retransmit-timeout

The retransmission timeout (RTO) should be adjusted for round-trip delay between nodes. Preferably, the retransmission timeout should be greater than the round-trip delay between nodes. There will be a compromise between allowing a long delay, and having responsive discovery of lost frames. We can calculate a simplistic estimate of round-trip times (rtt) for various packet sizes (ignoring propagation delay and latencies in transmission equipment) using the following estimated rtt equation:

$$\text{estimated rtt} = ( (\text{packet size} * \text{bits per byte}) / \text{link speed} ) * 2$$

Assume a packet with a 20 byte IP header, 32 byte sctp header and 100 bytes of user data and a 1,544,000 bits/sec link between two nodes. Using the estimated rtt equation shown in the previous paragraph we estimate an rtt of 1.5 ms.

SCTP computes RTO values based on rtt measurements. When packet retransmission occurs, the timeout value is doubled for each retransmission, with an upper limit of `max rto`. Multi-homed nodes will have to compromise between allowing a long delay and having responsive switching to an alternate IP address. Switching to an alternate path is of primary importance for multi-homed nodes. The maximum `rto` value for multi-homed nodes should be set equal to or just slightly higher than the minimum RTO value. The number of outstanding bytes allowed decreases with each retransmission timeout. The trade-off of bounding the maximum RTO close to the minimum RTO is the frequency of retransmissions versus increasing transmit delays for packets on the transmit queue. During periods of retransmissions multi-homed nodes sends duplicate packets until the alternate address becomes the primary path. The alternate address becomes the primary when the number of retries exceed the `path-retransmit` parameter. The default value for minimum and maximum RTO is 1 second. Propagation delays and latencies vary in networks, so care should be taken when selecting an RTO value.

### Bundling

It is recommended that bundling be enabled for high packet rates (1000 pps or higher) with small packets (50 bytes and lower). Bundling can be less than optimal for lower data rates with small or large packets because of the transmission delay. Bundling is found to be effective for large packets at high data rates in networks with symmetrical traffic. The default bundling delay is 5 ms. Applications with low data rates should disable bundling if the increase in round-trip time is undesirable. It is recommended that bundling be enabled for applications sending small packets that may start with low data rates, but are capable of increasing to higher sustained data rates.

### Cumulative Selective Ack

The cumulative selective ack (cs-ack) is commonly known as “delayed ack.” The cs-ack parameter controls how long a receiver can delay before sending an acknowledgment. The ack is delayed hoping to have data going in the same direction as the ack, so the ack can “piggyback” with the data. The default of cs-ack is 200 ms. The cs-ack configured at the receiver should be less than the rto minimum value configured at the sender. When the cs-ack of the receiver is greater than the rto of the sender, unnecessary retransmissions may occur because the sender rto expires before the receiver sends the delayed acknowledgment.

### Receive Window

The size of the receive window offered by the receiver generally can affect performance. SCTP adapts its transmission rate to suit the available network capacity by using a congestion-sensitive, sliding-window flow control mechanisms described in RFC 2581. At any given instance only a certain number of bytes can be outstanding through the network. Keeping the path full of packets requires both congestion window (cwnd) and receive window (rwnd) to reach the effective size of the “pipe” represented by the so-called bandwidth-delay product. We can calculate the capacity of the pipe using the following capacity equation:

$$\text{capacity (bits)} = \text{bandwidth (bits/sec)} \times \text{round-trip-time(sec)}$$

The bandwidth-delay product can vary widely depending on the network speed and round-trip-time (rtt) between the two end points. Using the capacity equation shown in the previous paragraph, we can estimate the minimum buffer size given the bandwidth of the communication media and the round-trip time between the nodes. Assuming the nodes are connected by a 1,544,000 bits/sec T1 link with a round-trip time of 60 ms, gives an estimated minimum buffer size of 11,580 bytes. The receive-window parameter default is set for 64000 bytes. The congestion control and windowing algorithms adjust to network conditions by controlling the number of bytes that can be outstanding through the network.

### Transmit Queue

The tx-queue-depth parameter is used to determine the onset and abate thresholds for congestion on the transmit queue. The tx-queue-depth parameter controls the number of packets allowed on the transmit queue. The transmit queue exists to absorb the inevitable traffic bursts. When selecting the tx-queue-depth, there will be a compromise between hitting transmit congestion thresholds causing dropped packets and transmit delays due to queuing times. Applications that are sensitive to small delays should account for transmit delays due to queuing when selecting a tx-queue-depth. During periods of SCTP link congestion, the tx-queue-depth will control the number of packets that can be queued before packets are discarded, causing application retransmissions. The default tx-queue-depth is 1000 packets for M3UA and SUA. The default tx-queue-depth is 20,000 packets for SGMP.

#### Note

While changing the tx-queue-depth for a XUA, ensure there is no traffic on that ASP. If there is traffic on that ASP, as soon as the tx-queue-depth is changed, reset the ASP by using the **shutdown** and then the **no shutdown** commands. Resetting the ASP is required so the ASP is not stuck in congestion.

## Tuning SCTP Parameters for M2PA

To tune the SCTP parameters at the M2PA level of the Cisco ITP, use the following commands in link configuration mode:

| Command                                                                                | Purpose                                                                                                                |
|----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-ls-link)# <b>assoc-retransmit</b><br><i>max-returns</i>              | Configure the maximum number of consecutive retransmissions to a peer before the peer is considered unreachable.       |
| Router(config-cs7-ls-link)# <b>bundling</b> <i>msec</i>                                | Enables bundling and specifies the bundling interval (the length of time to wait for packets before sending a bundle). |
| Router(config-cs7-ls-link)# <b>cumulative-sack</b> <i>msec</i>                         | Configures the cumulative selective acknowledgment time-out value for the link.                                        |
| Router(config-cs7-ls-link)# <b>init-retransmit</b><br><i>max-retries</i>               | Configures the number of retransmissions for peer initialization messages.                                             |
| Router(config-cs7-ls-link)# <b>init-timeout</b> <i>msec</i>                            | Configures the maximum time-out value for retransmission initialization messages.                                      |
| Router(config-cs7-ls-link)# <b>ip-precedence</b> <i>ip-tos</i>                         | Sets the IP precedence.                                                                                                |
| Router(config-cs7-ls-link)# <b>ip-dscp</b> <i>ip-tos</i>                               | Sets the IP Differential Services Code Point.                                                                          |
| Router(config-cs7-ls-link)# <b>keepalive</b> <i>msec</i>                               | Enable a peer link keepalive interval.                                                                                 |
| Router(config-cs7-ls-link)# <b>large-msu-support</b>                                   | Allows an M2PA link to carry MSU sizes of up to 4096 bytes.                                                            |
| Router(config-cs7-ls-link)# <b>path-retransmit</b><br><i>max-retries</i>               | Configures path retransmissions on a remote peer address.                                                              |
| Router(config-cs7-ls-link)# <b>peer-timer</b> <i>timer msec</i>                        | Configures the alignment-ready timer.                                                                                  |
| Router(config-cs7-ls-link)# <b>retransmit-timeout</b> <i>rto-min</i><br><i>rto-max</i> | Configure the retransmission time-out value on a link.                                                                 |
| Router(config-cs7-ls-link)# <b>tx-queue-depth</b> <i>queue-depth</i>                   | Adjust the number of packets that M2PA will queue for transmission.                                                    |

To tune the M2PA of the ITP on a local peer, use the following command in cs7 local-peer configuration submode:

| Command                                                      | Purpose                                                                                         |
|--------------------------------------------------------------|-------------------------------------------------------------------------------------------------|
| Router(config-cs7-lp)# <b>sctp-rfc-version</b> {2960   4960} | Sets the RFC compliance to either SCTP RFC 2960 or SCTP RFC 4960. The default is SCTP RFC 2960. |

To tune the M2PA levels of the ITP on a local peer, use the following command in CS7 local-peer configuration mode:

| Command                                                  | Purpose                                   |
|----------------------------------------------------------|-------------------------------------------|
| Router(config-cs7-lp)# <b>receive-window</b> <i>size</i> | Configures the local receive window size. |

To tune the M2PA for all the links in the CS7 instance, use the following command in global configuration mode:

| Command                                                                                | Purpose                                                    |
|----------------------------------------------------------------------------------------|------------------------------------------------------------|
| Router(config)# <b>cs7 instance</b> <i>instance-number</i><br><b>large-msu-support</b> | Allows an instance to carry MSU sizes of up to 4096 bytes. |

To tune the ITP all the M2PA links in the linkset, use the following command in cs7 m2pa profile configuration mode:

| Command                                                   | Purpose                                                   |
|-----------------------------------------------------------|-----------------------------------------------------------|
| Router(config-cs7-profile-m2pa)# <b>large-msu-support</b> | Allows M2PA links to carry MSU sizes of up to 4096 bytes. |

## Tuning SCTP Parameters for M3UA and SUA

SCTP parameters that are set in the local instance are used as the defaults when an SCTP association is established. To configure SCTP parameters for M3UA or SUA local instance use the following commands in either CS7 M3UA, CS7, or CS7 SUA submode. The parameters function the same for all three modes and are shown here in CS7 M3UA mode:

| Command                                                                          | Purpose                                                                                                                                                                                                        |
|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-m3ua)# <b>assoc-retransmit</b> <i>max-returns</i>              | Specifies the maximum number of association retransmissions to be used when a new SCTP association is started with the local port. Range is 2 to 20. Default is 10.                                            |
| Router(config-cs7-m3ua)# <b>bundling</b> <i>msec</i>                             | Specifies that packet bundling is supported and configures the bundling interval to be used when a new SCTP association is started with the local port. Range is 5 to 1000 milliseconds. Default is 100.       |
| Router(config-cs7-m3ua)# <b>cumulative-sack</b> <i>msec</i>                      | Configures the cumulative selective acknowledgment time-out value to be used when a new SCTP association is started with the local port. Range is 100 to 500 milliseconds. Default is 200.                     |
| Router(config-cs7-m3ua)# <b>init-retransmit</b> <i>max-retries</i>               | Configures the maximum number of retransmissions of the peer initialization packets for the local port. Range is 2 to 20 milliseconds. Default is 8.                                                           |
| Router(config-cs7-m3ua)# <b>init-timeout</b> <i>msec</i>                         | Configures the maximum interval for the initialization packet retransmission timeout for the local port. Range is 1000 to 60000 milliseconds. Default is 1000.                                                 |
| Router(config-cs7-m3ua)# <b>keepalive</b> <i>msec</i>                            | Specifies that keepalive timer is supported and configures the keepalive interval to be used when a new SCTP association is started with the local port. Range is 300 to 30000 milliseconds. Default is 30000. |
| Router(config-cs7-m3ua)# <b>max-inbound-streams</b> <i>max-streams</i>           | Specifies the maximum number of inbound streams allowed for the local port. Range is 2 to 25. Default is 17.                                                                                                   |
| Router(config-cs7-m3ua)# <b>path-retransmit</b> <i>max-retries</i>               | Configures the maximum number of path retransmissions on a remote address used when a new SCTP association is started with the local port. Range is 2 to 10 retries. Default is 4.                             |
| Router(config-cs7-m3ua)# <b>receive-window</b> <i>recv-win</i>                   | Specifies the local receive window size for the local port. Default is 24000.                                                                                                                                  |
| Router(config-cs7-m3ua)# <b>retransmit-timeout</b> <i>rto-min</i> <i>rto-max</i> | Specifies the minimum retransmission timeout value used when a new SCTP association is started with the local port. Range is 40 to 60000 milliseconds. Default is 1000.                                        |
| Router(config-cs7-m3ua)# <b>sctp-rfc-version</b> {2960   4960}                   | Sets the RFC compliance to either SCTP RFC 2960 or SCTP RFC 4960. The default is SCTP RFC 2960.                                                                                                                |
| Router(config-cs7-m3ua)# <b>tx-queue-depth</b> <i>queue-depth</i>                | Specifies the maximum transmit queue depth for new SCTP associations established with the local port.                                                                                                          |
| Router(config-cs7-m3ua)# <b>unordered-priority</b> {equal   high}                | Specifies the priority of the unordered packets. The default is "equal."                                                                                                                                       |

## Tuning SCTP Parameters for an ASP

SCTP parameters that are set in the local instance (in CS7 M3UA or CS7 SUA submode) are used as defaults when an SCTP association is established. You can override a default SCTP parameter by specifying an SCTP parameter in the CS7 ASP submode. To specify SCTP parameters under the ASP definition, use the following commands in CS7 ASP submode:

| Command                                                                            | Purpose                                                                                                                                                                                                   |
|------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-asp)# <b>assoc-retransmit</b> <i>max-returns</i>                 | Specifies the maximum number of association retransmissions for the association. Range is 2 to 20. Default is the value specified under the local port instance.                                          |
| Router(config-cs7-asp)# <b>bundling</b> <i>msec</i>                                | Specifies that packet bundling is supported and configures the bundling interval for the association. Range is 5 to 1000 milliseconds. Default is the value specified under the local port instance.      |
| Router(config-cs7-asp)# <b>cumulative-sack</b> <i>msec</i>                         | Configures the cumulative selective acknowledgment time-out value for the association. Range is 100 to 500 milliseconds. Default is the value specified under the local port instance.                    |
| Router(config-cs7-asp)# <b>keepalive</b> <i>msec</i>                               | Specifies that keepalive timer is supported and configures the keepalive interval for the association. Range is 300 to 30000 milliseconds. Default is the value specified under the local port instance.  |
| Router(config-cs7-asp)# <b>path-retransmit</b> <i>max-retries</i>                  | Configures the maximum number of path retransmissions on a remote address for the association. Range is 2 to 10 retries. Default is the value specified under the local port instance.                    |
| Router(config-cs7-asp)# <b>retransmit-timeout</b> <i>rto-min</i><br><i>rto-max</i> | Specifies the minimum retransmission timeout value for the association. Range is 40 to 60000 milliseconds. Default is the value specified under the local port instance.                                  |
| Router(config-cs7-asp)# <b>tx-queue-depth</b> <i>queue-depth</i>                   | Determines the onset and abate thresholds for congestion on transmit queue. Specifies the maximum transmit queue depth for the association. Default is the value specified under the local port instance. |

## Tuning AS Options

To configure the QoS class, recovery timeout value, or traffic mode for an AS, use the following commands in CS7 AS submode:

| Command                                                          | Purpose                                                                                                                                              |
|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-as)# <b>burst-recovery-timeout</b> <i>msec</i> | Specifies the amount of time allowed for an association to recover from a burst of traffic caused by failover.                                       |
| Router(config-cs7-as)# <b>qos-class</b> <i>class</i>             | Specifies a QoS class for the packets sent to the ASPs in this AS. The QoS class defined under the ASP overrides the QoS class defined under the AS. |

| Command                                                                                                                                     | Purpose                                                                                                                                                                                                           |
|---------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-as)# <b>recovery-timeout</b> <i>msec</i>                                                                                  | (Optional) Specifies the recovery timeout value. Range is 0 to 2000 milliseconds. Default is 2000.                                                                                                                |
| Router(config-cs7-as)# <b>traffic-mode</b> { <b>broadcast</b>   <b>override</b>   <b>loadshare</b> [ <b>bindings</b>   <b>roundrobin</b> ]} | (Optional) Specifies the traffic mode of operation of the ASP within an AS. Used to validate the traffic mode specified on the ASP Active messages. ASPs connecting with a different traffic mode will be failed. |

## Tuning SCTP Parameters for a Mated SG

SCTP parameters that are set in the local instance (in CS7 M3UA or CS7 SUA submode) are used as defaults when an SCTP association is established. You can override a default SCTP parameter by specifying an SCTP parameter in the CS7 Mated SG submode. To specify SCTP parameters under the Mated SG definition, use the following commands in CS7 Mated SG submode:

| Command                                                                       | Purpose                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-mated-sg)# <b>assoc-retransmit</b> <i>max-returns</i>       | Specifies the maximum number of association retransmissions for the association. Range is 2 to 20. Default is the value specified under the local port instance.                                                                         |
| Router(config-cs7-mated-sg)# <b>bundling</b> <i>msec</i>                      | Specifies that packet bundling is supported and configures the bundling interval for the association. Range is 5 to 1000 milliseconds. Default is the value specified under the local port instance.                                     |
| Router(config-cs7-mated-sg)# <b>cumulative-sack</b> <i>msec</i>               | Configures the cumulative selective acknowledgment time-out value for the association. Range is 100 to 500 milliseconds. Default is the value specified under the local port instance.                                                   |
| Router(config-cs7-mated-sg)# <b>keepalive</b> <i>msec</i>                     | Specifies that keepalive timer is supported and configures the keepalive interval for the association. Range is 300 to 30000 milliseconds. Default is the value specified under the local port instance.                                 |
| Router(config-cs7-mated-sg)# <b>path-retransmit</b> <i>max-retries</i>        | Configures the maximum number of path retransmissions on a remote address for the association. Range is 2 to 10 retries. Default is the value specified under the local port instance.                                                   |
| Router(config-cs7-mated-sg)# <b>qos-class</b> <i>class</i>                    | Specifies the QoS class for the packets sent to the SG Mate.                                                                                                                                                                             |
| Router(config-cs7-mated-sg)# <b>retransmit-timeout</b> <i>rto-min rto-max</i> | Specifies the minimum retransmission timeout value for the association. Range is 40 to 60000 milliseconds. Default is the value specified under the local port instance.                                                                 |
| Router(config-cs7-mated-sg)# <b>tx-queue-depth</b> <i>queue-depth</i>         | Determines the onset and abate thresholds for congestion on transmit queue. Specifies the maximum transmit queue depth for the association. Range is 100 to 65535 packets. Default is the value specified under the local port instance. |

## Tuning SCTP Parameters for Satellite Channels

This section includes the following information about SCTP and Satellite Channels

- [Overview of SCTP and Satellite Channels, page 410](#)
- [Tuning SCTP on Satellite Channels, page 411](#)
- [Verifying SCTP Parameters on Satellite Channels, page 413](#)

### Overview of SCTP and Satellite Channels

There is an inherent delay in the delivery of a message over a satellite link due to the finite speed of light and the altitude of communication satellites. Satellite channels have several characteristics that are different from most terrestrial channels. These characteristics can degrade the performance and channel utilization of SCTP. Some of the characteristics include long delays, large delay-times-bandwidth products, and transmission errors. The delay-times-bandwidth product defines the amount of data a protocol should have outstanding at any one time to fully utilize the available channel capacity. Some satellite channels exhibit a higher bit-error rate than typical terrestrial networks. SCTP interprets all packet drops as signals of network congestion. Since SCTP cannot determine if a packet loss was due to corruption or congestion, SCTP must assume the packet loss was due to network congestion. Packet loss due to corruption can cause SCTP to reduce the amount of data that can be injected into the network. While performance of a transport protocol is not the only consideration when constructing a network containing satellite channels, SCTP congestion control algorithms have an unfavorable effect on performance and channel utilization.

SCTP employs congestion control algorithms to adjust the amount of unacknowledged data that can be injected into the network and to retransmit segments dropped by the network. The SCTP congestion control algorithms respond to packet loss as an indication of network congestion. Packet loss detected by SCTP congestion control algorithms can put the sender in slow-start with a reduced congestion window, thereby limiting the amount of data that can be transmitted. The slow-start algorithm will force the sender to wait for an acknowledgment before transmitting new data. The slow-start and congestion control algorithms can force poor utilization of the available channel bandwidth when using long delay networks.

SCTP congestion control uses two state variables to accomplish congestion control. The first variable is the congestion window (cwnd). The congestion window is an upper bound on the amount of data the sender can inject into the network before receiving an acknowledgment. The second variable is the slow-start threshold (ssthresh). The slow-start threshold variable determines which algorithm is used to increase cwnd. If cwnd is less than or equal to ssthresh, the slow-start algorithm is used to increase cwnd. If cwnd is greater than ssthresh the congestion avoidance algorithm is used to increase cwnd. There are two methods of packet loss detection (interpreted as congestion notification by the SCTP congestion controls) defined in SCTP:

- Timeout of the retransmission timer. The congestion control algorithms resets the congestion control state variables cwnd and ssthresh. The setting of the congestion control state variables have the effect of putting the sender in slow-start and assure that no more than one packet is outstanding until it receives an acknowledgment.

```
ssthresh = max (cwnd/2, 2*MTU)
cwnd    = 1*MTU
```

- Detection of gaps in received Transmission Sequence Numbers (TSNs) through Gap Ack reports in a Selective Acknowledgment (SACK). Normally a sender will wait four consecutive Gap Ack reports before reacting to the indication of packet loss. The congestion control algorithms reset the congestion control state variables cwnd and ssthresh as a result of detecting the packet loss. The setting of the congestion control variables will put the sender in slow-start with a reduced cwnd effectively limiting the amount of data the sender can transmit.

```
ssthresh = max(cwnd/2, 2*MTU)
cwnd = ssthresh
```

The SCTP congestion control algorithms generally respond unfavorably in networks that have large delays, a large delay-times-bandwidth product, and high bit-error rates. SCTP congestion control on the ITP has been enhanced to address the characteristics of satellite channels that contribute to low channel utilization of SCTP. SCTP on the ITP provides for the provisioning of four SCTP parameters that change how the SCTP congestion control algorithms responds to packet loss on satellite channels. The configuration of these parameters are shown in the [“Tuning SCTP on Satellite Channels” section on page 411](#).

#### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

## Tuning SCTP on Satellite Channels

Before you can modify the SCTP parameters, you must create a basic ITP configuration, which is described fully in the “Configuring ITP Basic Functionality” chapter. If you are unfamiliar with ITP basic configuration, you are advised to refer to that chapter for more details before continuing.

The following SCTP parameters can be provisioned to change how SCTP congestion control responds to packet loss on satellite channels:

### init-timeout

The init-timeout SCTP parameter controls the retransmission of SCTP association setup messages. The init-timeout is how long a SCTP endpoint will wait for a response to a setup message before retransmitting. The init-timeout parameter should be adjusted to for the expected round trip delays expected on the satellite channel.

### retransmit-timeout

The retransmission timeout (RTO) should be adjusted for round-trip delays. Round-trip times for some satellite channels can range from 250 ms to 500 ms. Preferably, the retransmission timeout should be greater than the round-trip delay between nodes.

### init-cwnd-size

The parameter init-cwnd-size specifies the initial window size used by the sender. If this parameter is provisioned, the window-size specified must match the receive-window size of the remote end of the SCTP association. Failure to match the init-cwnd-size to the remote receive-window will cause non deterministic congestion control behavior. This parameter should be used to overcome slow-start on satellite channels where large burst of sustainable traffic is present. Note the total sizes of the init-cwnd-size and receive-window sizes for all the SCTP associations should not exceed the amount of free memory available.

**idle-cwnd-rate**

When the endpoint does not transmit data on a given transport address, the congestion window of that transport address is decreased to  $\max(\text{cwnd}/2, 2 * \text{MTU})$  per retransmission timeout. The `idle-cwnd-rate` allows the administrator to control the rate at which the congestion window is decreased due to being idle. Using the `idle-cwnd-rate`, the congestion window is decreased to  $\max(\text{cwnd}/\text{idle-cwnd-rate}, \text{init-cwnd-size})$  per retransmission timeout.

**fast-cwnd-rate**

Normally a SCTP sender will wait four consecutive Gap Ack reports that indicates a missing packet before reacting to the indication of packet loss. On the fourth consecutive Gap Ack report, the SCTP congestion control algorithm decreases the slow-start threshold to  $\max(\text{cwnd}/2, 2 * \text{MTU})$  and reduces the congestion window equal to the slow-start threshold. The setting of the congestion control variables as described will put the sender in slow-start with a reduced cwnd effectively limiting the amount of data the sender can transmit. The `fast-cwnd-rate` parameter allows the administrator to control the rate at which the congestion window is decreased. Using the `fast-cwnd-rate` parameter the slow-start threshold variable is set to  $\max(\text{cwnd}/\text{fast-cwnd-rate}, 2 * \text{MTU})$ . The congestion window variable is set to equal to the slow-start threshold as described previously. The sender is still put in slow-start, but depending on the value of the `fast-cwnd-rate` parameter the congestion window will be reduced conservatively or aggressively. Using the `fast-cwnd-rate`, we can effectively control how the congestion control algorithm responds to packet loss on satellite channels.

**retransmit-cwnd-rate**

When a retransmission timer timeout occurs, SCTP congestion control sets slow-start threshold to  $\max(\text{cwnd}/2, 2 * \text{MTU})$  and reduces the congestion window to  $1 * \text{MTU}$ . This has the effect of putting the sender in slow-start and assure that no more than one packet is outstanding until it receives an acknowledgment. The `retransmit-cwnd-rate` parameter allows the administrator to control the rate at which the slow-start threshold is reduced and provides for the setting of the congestion window. Using the `retransmit-cwnd-rate` parameter the slow-start threshold variable is set to  $\max(\text{cwnd}/\text{retransmit-cwnd-rate}, 2 * \text{MTU})$ . The congestion window variable can be set using one of two methods. The first option for setting the congestion window variable sets the congestion window to its default of  $1 * \text{MTU}$ . The second option for setting the congestion window variable sets the congestion window equal to the slow-start threshold. Setting the congestion window equal to the slow-start threshold variable follows the same procedure for setting the congestion window variable as done for a fast-retransmit. The second option for setting the congestion window allows the congestion control algorithm to respond evenly to packet loss detected by either retransmission timer timeouts or fast-retransmits.

To specify SCTP parameters for satellite channels, use the following commands in CS7 Linkset submode:

| Command                                                          | Purpose                                                                                                                                                                           |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-ls-link)# <b>fast-cwnd-rate</b> <i>percent</i> | Specifies the rate at which the size of the SCTP congestion window will be decreased due to fast transmission. The range is 0 to 100 percent. The default is 50 percent.          |
| Router(config-cs7-ls-link)# <b>idle-cwnd-rate</b> <i>percent</i> | Specifies the rate at which the size of the SCTP congestion window will be decreased due to the association being idle. The Range is 0 to 100 percent. The default is 50 percent. |
| Router(config-cs7-ls-link)# <b>init-cwnd-size</b> <i>bytes</i>   | Specifies the size of the SCTP initial congestion window. The range is 3000 to 20971520 bytes. The default is 2 times the smallest MTU of the SCTP interface, in bytes.           |

| Command                                                                      | Purpose                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Router(config-cs7-ls-link)# <b>init-timeout</b> <i>msec</i>                  | Specifies how long a SCTP endpoint will wait for a response to a setup message before retransmitting. The init-timeout parameter should be adjusted for the round trip delays expected on the satellite channel. The range is 1000 to 60000 milliseconds. The default is 1000 milliseconds.                                                                         |
| Router(config-cs7-ls-link)# <b>retransmit-cwnd-rate</b> <i>percent</i>       | Specifies the rate at which the size of the SCTP congestion window will be decreased due to retransmission timer expiration. The range is 0 to 100 percent. The default is 50 percent.                                                                                                                                                                              |
| Router(config-cs7-ls-link)# <b>retransmit-timeout</b> <i>rto-min rto-max</i> | Specifies the retransmission timeout value. The retransmission timeout (RTO) should be adjusted for round-trip delays. Round-trip times for some satellite channels range from 250 to 500 msec. The retransmission timeout should be greater than the round-trip delay between nodes. The range is 40 through 60000 milliseconds. The default is 1000 milliseconds. |

## Verifying SCTP Parameters on Satellite Channels

To verify the SCTP congestion control parameters, use the following command in EXEC mode:

| Command                                                                                             | Purpose                                                                 |
|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| Router# <b>show cs7 m2pa sctp</b> [ <b>parameters</b>   <b>statistics</b> ]<br><i>ls-name</i> [slc] | Displays the current status and parameter values of a SCTP association. |

The following is sample output from the **show cs7 m2pa** command using the **sctp** keyword:

```
Router#show cs7 m2pa sctp

## ITP Command Set: A - D

---

This section documents new or modified commands. All other commands used with this feature are documented in the Cisco IOS Release 12.2 Command Reference publication. Short Message Peer-to-Peer (SMPP) protocol is not supported. Some DSMR functionality is also not supported. It is recommended that commands pertaining to these features are not configured.

# access-group

To enable Cisco ITP gateway screening on a linkset, use the `access-group cs7 linkset` submode command. To disable access lists on the linkset, use the `no` form of this command.

**access-group** { **2700-2999** | *name* } [**in** | **out**]

**no access-group** { **2700-2999** | *name* } [**in** | **out**]

|                           |                  |                                               |
|---------------------------|------------------|-----------------------------------------------|
| <b>Syntax Description</b> | <b>2700-2999</b> | Number of an access list.                     |
|                           | <i>name</i>      | Name of an access list.                       |
|                           | <b>in</b>        | Applies this access list to inbound packets.  |
|                           | <b>out</b>       | Applies this access list to outbound packets. |

**Defaults** None.

**Command Modes** `cs7 linkset` submode

## Command History

**Usage Guidelines** The **access-group** command assigns an ITP access list to a linkset to screen either inbound or outbound packets.

**Examples** The following example shows how to assign access list 2700 to filter inbound packets:

```
access-list 2700 permit dpc 4.100.0 0.0.255
.
.
cs7 linkset michael 10.1.1
  access-group 2700 in
```

|                         |                                       |                                                      |
|-------------------------|---------------------------------------|------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>                        | <b>Description</b>                                   |
|                         | <a href="#">access-list</a>           | Defines an access list.                              |
|                         | <a href="#">show cs7 access-lists</a> | Displays information about defined ITP access lists. |

# access-list

To define a Cisco ITP access list, use the **access-list** command in global configuration mode. To remove a Cisco SS7 access list, use the **no** form of this command.

```
access-list access-list-number [instance instance-number] [compiled] [dynamic-extended]
[rate-limit precedence | mask precedence-bitmask] {deny | permit} [dpc point-code
wildcard-mask | opc point-code wildcard-mask | si {0-15} | pattern offset hex-pattern | aftpc
point-code ss-number wildcard-mask ss-number-mask | cdpa point-code ss-number
wildcard-mask ss-number-mask | cgpa point-code ss-number wildcard-mask ss-number-mask |
```

```
selector | all] [remark line]
```

**no access-list** *access-list-number*

## Syntax Description

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access-list-number</i> | Number of an access list. The Cisco SS7 access list range is a decimal number from 2700 to 2999. The other access list ranges are:<br>1–99 IP standard access list<br>100– 999 IP extended access list<br>1100–1199 Extended 48-bit MAC address access list<br>1300–1999 IP standard access list (expanded range)<br>200–299 Protocol type-code access list<br>2000–2699 IP extended access list (expanded range)<br>700–799 48-bit MAC address access list |
| <b>instance</b>           | Indicates the specific instance, if the Multiple Instances feature is enabled.                                                                                                                                                                                                                                                                                                                                                                              |
| <i>instance-number</i>    | Instance number.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>compiled</b>           | Enables IP access-list compilation.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>dynamic-extended</b>   | Extends the dynamic ACL.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>rate-limit</b>         | Simple rate-limit access list.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>precedence</i>         | Precedence. Valid range is 0 to 7.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>mask</b>               | Uses a precedence bitmask.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>precedence-bitmask</i> | Precedence bitmask. Valid range is 0 to FF.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>deny</b>               | Denies access if the conditions are matched.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>permit</b>             | Permits access if the conditions are matched.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>dpc</b>                | Applies the access list to the destination point code.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>point-code</i>         | Point code to which the packet is being sent.                                                                                                                                                                                                                                                                                                                                                                                                               |
| <i>wildcard-mask</i>      | Specifies which bits of the point code to ignore for matching.                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>opc</b>                | Applies the access list to the origination point code.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>point-code</i>         | Point code from which the packet is being sent.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>wildcard-mask</i>      | Wildcard bits to be applied to the origination point code.                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>si</b>                 | Service indicator.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>si-value</i>           | Service indicator value. Range is 0 to 15.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>pattern</b>            | Uses pattern matching to determine access.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>offset</i>             | Decimal number indicating the number of bytes into the packet where the byte comparison should begin.                                                                                                                                                                                                                                                                                                                                                       |
| <i>hex-pattern</i>        | Hexadecimal string of digits representing a byte pattern.                                                                                                                                                                                                                                                                                                                                                                                                   |

|                       |                                                                                          |
|-----------------------|------------------------------------------------------------------------------------------|
| <b>aftpc</b>          | Applies the access list to the affected point code and SSN in SCCP management messages.  |
| <i>point-code</i>     | Affected point code in the SCCP management message.                                      |
| <i>ss-number</i>      | Subsystem number at the affected point code.                                             |
| <i>wildcard-mask</i>  | Specifies which bits of the point code to ignore for matching.                           |
| <i>ss-number-mask</i> | Specifies which bits of the subsystem number to ignore for matching.                     |
| <b>cdpa</b>           | Applies the access list to the called party address point code and SSN in SCCP messages. |
| <i>point-code</i>     | Called party point code in the SCCP message.                                             |
| <i>ss-number</i>      | Subsystem number at the point code.                                                      |
| <i>wildcard-mask</i>  | Specifies which bits of the point code to ignore for matching.                           |
| <i>ss-number-mask</i> | Specifies which bits of the subsystem number to ignore for matching.                     |
| <b>cgpa</b>           | Applies the access list to the calling party point code and SSN in SCCP messages.        |
| <i>point-code</i>     | Calling party point code in the SCCP management message.                                 |
| <i>ss-number</i>      | Subsystem number at the point code.                                                      |
| <i>wildcard-mask</i>  | Specifies which bits of the point code to ignore for matching.                           |
| <i>ss-number-mask</i> | Specifies which bits of the subsystem number to ignore for matching.                     |
| <b>selector</b>       | Called party (gti tt np nai).                                                            |
| <b>all</b>            | Permits or denies all (other) packets.                                                   |
| <b>remark line</b>    | Includes a remark.                                                                       |

**Defaults**

Any message that does not match any of the access-list entries is, by default, denied.

**Command Modes**

Global configuration

**Command History****Usage Guidelines**

The **access-list** command defines the access list. After defining the access list, you use the **access-group** command to apply the access list to a linkset.

SCCP screening screens MSUs on inbound and outbound linksets.

If the access list is inbound, when the ITP receives a packet it checks the access list criteria statements for a match. If the packet is permitted, the ITP continues to process the packet. If the packet is denied, the ITP discards it.

If the access list is outbound, after receiving and routing a packet to the outbound interface the ITP checks the access list criteria statements for a match. If the packet is permitted, the ITP transmits the packet. If the packet is denied, the ITP discards it.

The **selector** and **cgpa** keywords enable screening on the inbound linkset.

The **aftpc** and **cdpa** keywords enable screening on the outbound linkset.

## Examples

The following example shows how to define an access list for the ITP:

```
access list 2700 permit dpc 4.100.0 0.0.255
!
!
cs7 linkset tony 4.100.2
  access-group 2700 out
!
```

The following example shows how to drop all SCCP management packets with affected point code 7.5.4 and SSN 10 but permit all the rest:

```
access-list 2710 deny aftp 7.5.4 10
access-list 2710 permit all

cs7 linkset tony 4.100.2
  access-group 2710 in
```

## Related Commands

|---------------------------------------|------------------------------------------------------|
| <a href="#">access-group</a>          | Assigns an ITP access list to a linkset.             |
| <a href="#">cs7 paklog</a>            | Configures the ITP Packet Logging facility.          |
| <a href="#">show cs7 access-lists</a> | Displays information about defined ITP access lists. |

# accounting (cs7 as)

To enable accounting for M3UA payload data and SUA CLDT/CLDR packets, use the **accounting cs7 as** submode command.

If the command is issued for an M3UA AS, normal M3UA accounting is enabled. For each OPC+DPC+SI combination, normal M3UA accounting tracks the number of M3UA payload data messages sent and received.

If the command is issued for an SUA AS, normal SUA accounting is enabled. SUA normal accounting tracks the number of SUA CLDT/CLDR packets received from and sent to the AS.

To disable accounting, use the **no** form of this command.

**accounting**

**no accounting**

---

**Syntax Description** This command has no arguments or keywords.

---

**Defaults** Accounting is not enabled.

---

**Command Modes** cs7 as submode

---

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXF | This command was introduced. |
|                 | 12.4(15)SW1 |                              |
|                 | 12.2(33)IRA |                              |

---

---

**Usage Guidelines** Because accounting is enabled by default, only the **no** form of the command displays as output from the **show configuration** command.

---

**Examples** The following example shows how to enable accounting on the AS named as1:

```
cs7 as as1
gtt-accounting
```

---

## addr (cs7 mlr address-table)

To specify an MLR address within the MLR address table, use the **addr** command in cs7 mlr address-table configuration mode. To remove the definition, use the **no** form of this command.

```
addr address-name [exact] [result {asname as-name | block | continue | group group-name | gt
addr-string [tt tt gti {2 | 4 np np nai nai}}] | [instance instance-number] pc pc [ssn ssn] |
[sccp-error error]]
```

```
no addr address-name [exact] [result {asname as-name | block | continue | group group-name | gt
addr-string [tt tt gti {2 | 4 np np nai nai}}] | [instance instance-number] pc pc [ssn ssn] |
[sccp-error error]]
```

### Syntax Description

|                        |                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>address-name</i>    | Address of 1 to 20 hexadecimal digits.                                                                                                                                                                                                                                          |
| <b>exact</b>           | (Optional) Configured address must match address exactly.                                                                                                                                                                                                                       |
| <b>result</b>          | (Optional) Configures result.                                                                                                                                                                                                                                                   |
| <b>asname</b>          | (Optional) Routes message to an AS.                                                                                                                                                                                                                                             |
| <i>as-name</i>         | AS name.                                                                                                                                                                                                                                                                        |
| <b>block</b>           | (Optional) Drops message.                                                                                                                                                                                                                                                       |
| <b>continue</b>        | (Message) Continues message processing.                                                                                                                                                                                                                                         |
| <b>group</b>           | (Optional) Routes messages using an MLR or SMS result group.                                                                                                                                                                                                                    |
| <i>group-name</i>      | Group name.                                                                                                                                                                                                                                                                     |
| <b>gt</b>              | (Optional) Routes message using the SCCP global title. The specified address is placed in the SCCP Called Party Address (CdPA), the routing indicator (RI) is changed to RI=GT, and then the message is routed based on the locally provisioned global title translation table. |
| <i>addr-string</i>     | Address string of 1 to 5 hexadecimal characters. The string is input in normal form, not in BCD-string format.                                                                                                                                                                  |
| <b>tt</b>              | Specifies a translation type.                                                                                                                                                                                                                                                   |
| <i>tt</i>              | Translation type. In the Called Party field of the GTT message, the SSP sets the TT to indicate which GTT table the STP should use. The TT is a 1-byte field that usually maps to a specific service. Valid numbers range from 0 to 255.                                        |
| <b>gti</b>             | (Optional) Specifies a global title indicator. (Used only when the <b>cs7 variant</b> command specifies ITU or China.)                                                                                                                                                          |
| <i>gti</i>             | Global title indicator. Valid numbers are 2 (primarily used in the ANSI domain) or 4 (used in the ITU domain).                                                                                                                                                                  |
| <b>np</b>              | (Optional) Specifies a numbering plan. (Used only when <i>gti</i> is 4.)                                                                                                                                                                                                        |
| <i>np</i>              | Numbering plan value. Valid range is 0 to 15.                                                                                                                                                                                                                                   |
| <b>nai</b>             | (Optional) Specifies a nature of address indicator. (Used only when <i>gti</i> is 4.)                                                                                                                                                                                           |
| <i>nai</i>             | (Optional) Nature of address indicator. Valid range is 0 to 127.                                                                                                                                                                                                                |
| <b>instance</b>        | (Optional) Indicates the PC/PCSSN result in a local or other instance.                                                                                                                                                                                                          |
| <i>instance-number</i> | (Optional) Instance number. The valid range is 0 to 7. The default instance is 0.                                                                                                                                                                                               |
| <b>pc</b>              | (Optional) Routes point code message using PC.                                                                                                                                                                                                                                  |

■ **addr (cs7 mlr address-table)**

|                                |                                                                                      |
|--------------------------------|--------------------------------------------------------------------------------------|
| <i>pc</i>                      | Destination point code used to route message.                                        |
| <b>ssn</b>                     | (Optional) Specifies a subsystem number.                                             |
| <i>ssn</i>                     | Subsystem number. Valid range is 2 to 255.                                           |
| <b>sccp-error</b> <i>error</i> | Configures block results and supports configuring an sccp-error on the block result. |

**Defaults**

None.

**Command Modes**

cs7 mlr address-table configuration

**Command History**

| Release                                   | Modification                           |
|-------------------------------------------|----------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.           |
| 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | The <b>instance</b> keyword was added. |

**Examples**

The following example shows how to specify an MLR address table named TABLE1 with an MLR address of 24. The configured address must match exactly, and the result group is SMSC-GROUP1.

```
cs7 mlr address-table TABLE1
  addr 24 exact result group SMSC-GROUP1
```

The following example shows how to specify an MLR address table named TABLE1 with the result configured for a GT address:

```
cs7 instance 0 mlr address-table TABLE1
  addr 123456 result gt 8282 tt 11 gti 2
  addr 12345 result gt 4545 tt 10 gti 4 np 2 nai 1
  addr 1234
  addr 180002 exact
```

The following example shows how to configure 1 as the instance in the **addr** command:

```
cs7 instance 0 mlr address-table test
  addr 133 result instance 1 pc 3.3.3 ssn 8
```

## algorithm (cs7 mlr result)

To specify the order of the coefficients used to calculate the dest-sme hash value, where **a** represents the last MSISDN digit, use the **algorithm** command in cs7 mlr result configuration mode. To remove the definition, use the **no** form of this command.

**algorithm** [abcd | dcba]

**no algorithm** [abcd | dcba]

### Syntax Description

|             |                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>abcd</b> | Order of the coefficients used to calculate the dest-sme hash value, where <b>a</b> represents the last MSISDN digit. (This algorithm is the default.) |
| <b>dcba</b> | Changes the order of the coefficients used to calculate the dest-sme hash value from the default of abcd to dcba.                                      |

### Defaults

The default algorithm is **abcd**.

### Command Modes

cs7 mlr result configuration

### Command History

| Release      | Modification                 |
|--------------|------------------------------|
| 12.2(25)SW12 | This command was introduced. |
| 12.2(18)IXF  |                              |
| 12.4(15)SW1  |                              |

### Usage Guidelines

The **algorithm** command requires the **dest-sme-binding** keyword when you use the **cs7 mlr result** command, which enters cs7 mlr result configuration mode. Dest-sme-binding result groups default to the abcd algorithm.

### Examples

The following example shows output from the **algorithm abcd** command:

```
Router# show cs7 mlr result MLR_BIND
Result Group: MLR_BIND      Instance: 0  Unavailable-routing: discard
Protocol: gsm-map          Mode: dest-sme-binding
                           Algorithm: dcba
```

| Order | Result Type | Stat | Weight | Matches |
|-------|-------------|------|--------|---------|
| 10    | PC 4.5.4    | unav | 1      | 0       |

# algorithm (cs7 sms group)

To specify the order of the coefficients used to calculate the dest-sme hash value, where **a** represents the last MSISDN digit, use the **algorithm** command in cs7 sms group configuration mode. To remove the definition, use the **no** form of this command.

**algorithm** [abcd | dcba]

**no algorithm** [abcd | dcba]

## Syntax Description

|             |                                                                                                                                                        |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>abcd</b> | Order of the coefficients used to calculate the dest-sme hash value, where <b>a</b> represents the last MSISDN digit. (This algorithm is the default.) |
| <b>dcba</b> | Changes the order of the coefficients used to calculate the dest-sme hash value from the default of abcd to dcba.                                      |

## Defaults

The default algorithm is **abcd**.

## Command Modes

cs7 sms group configuration

## Command History

## Usage Guidelines

The **algorithm** command requires the **dest-sme-binding** keyword when you use the **cs7 sms group** command, which enters cs7 sms group mode. Dest-sme-binding result groups default to the abcd algorithm.

## Examples

The following example shows output from the **algorithm abcd** command:

```
router# show cs7 sms group SMS_BIND
```

```
Instance: 0 Group: SMS_BIND
```

```
Protocol: gsm-map
```

```
Type: smsc
```

```
Mode: dest-sme-binding
```

```
Algorithm: abcd
```

| Order | Result   | Type | Stat | Weight | Matches |
|-------|----------|------|------|--------|---------|
| 10    | PC 4.3.2 |      | unav | 10     | 0       |
| 20    | PC 4.3.3 |      | unav | 20     | 0       |
| 30    | PC 5.3.2 |      | unav | 30     | 0       |

## Related Commands

| <a href="#">cs7 sms group</a> | Enables cs7 sms group configuration mode. |

# allow-multi-message-dialogue (cs7 mlr ruleset rule)

To match segmented TCAP short messages, short messages that have the More-Messages-To-Send indicator set, and short messages concatenated at the SMS layer, use the **allow-multi-message-dialogue** command in cs7 mlr ruleset rule configuration mode. To remove the specification, use the **no** form of this command.

**allow-multi-message-dialogue**

**no allow-multi-message-dialogue**

---

**Syntax Description** This command has no arguments or keywords.

---

**Defaults** None.

---

**Command Modes** cs7 mlr ruleset rule configuration

---

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

---

---

**Usage Guidelines** If the **allow-multi-message-dialogue** command is configured, no other routing parameters can be configured within cs7 mlr ruleset rule configuration mode.

Unlike other routing commands, this command is valid in a rule defined with the **all** keyword.

The **allow-multi-message-dialogue** command is allowed for sms-mo and sms-mt operations. If specified, the following messages will match this operation:

- Empty BEGIN messages
- CONTINUE messages
- BEGIN and CONTINUE messages containing an INVOKE component with the More-Messages-to-Send indicator (sms-mt only)
- Concatenated messages

---

**Examples** The following example shows how to use the **allow-multi-message-dialogue** command:

```
cs7 mlr ruleset ruleset1
rule 10 gsm-map sms-mt
  allow-multi-message-dialogue
result group SMS1
```

| <a href="#">rule (cs7 mlr ruleset)</a> | Specifies the rules for a routing trigger within a multilayer ruleset table. |

## ansi41 (cs7 sms route-table)

To configure the routing information for received ANSI-41 messages, use the **ansi41** command in cs7 sms route-table configuration mode. To remove the definition, use the **no** form of this command.

**ansi41** *operation-name*

**no ansi41** *operation-name*

### Syntax Description

|                       |                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>operation-name</i> | Specifies the operation: <ul style="list-style-type: none"> <li>• <b>smsNot</b> identifies the input operation as the ANSI-41 SMS Notification operation.</li> </ul> |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Defaults

None.

### Command Modes

cs7 sms route-table configuration

### Command History

### Usage Guidelines

The **ansi41** command with the **smsNot** keyword enables cs7 sms ansi41 smsnot configuration mode.

### Examples

The following example shows how to configure SMS Notification proxy. The configuration specifies the input protocol as the ANSI-41 MAP layer and identifies the input operation as the ANSI-41 SMS Notification.

```
cs7 sms route-table
ansi41 smsNot
ruleset SMS-PROXY
```

### Related Commands

| Command             | Description                     |
|---------------------|---------------------------------|
| cs7 sms route-table | Configures the SMS route table. |

## asname (cs7 gtt application group)

To assign an M3UA or SUA AS directly to a global title, use the **asname** command in cs7 gtt application group submode. To remove the configuration, use the **no** form of this command.

```
[instance instance-number] asname as-name { cost [ssn ssn] { gt [ntt ntt] | pcssn } [rate-limit rate] | wf
[ssn ssn] { gt [ntt ntt] | pcssn } } [sccp-allow-pak-conv number]
```

```
no [instance instance-number] asname as-name
```

### Syntax Description

|                            |                                                                                                                                                                                                                                                                                  |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-name</i>             | Application server name. You can assign a global title translation to an M3UA or SUA AS instead of to a point code and SSN. This argument also allows the administrator to have flexibility in assigning backup point codes and alternate AS names to handle a specific service. |
| <i>cost</i>                | Index value (1 to 64) specifying the priority of PC (PC/SSN) within the application group.                                                                                                                                                                                       |
| <b>ssn</b>                 | Sets the subsystem number during the translation process.                                                                                                                                                                                                                        |
| <i>ssn</i>                 | Subsystem number.                                                                                                                                                                                                                                                                |
| <b>gt</b>                  | Sets RI to route on GT.                                                                                                                                                                                                                                                          |
| <b>ntt</b>                 | Configures a new translation type value to be set within the called party address global title selector data. The keyword is valid only when the <b>gt</b> keyword is specified.                                                                                                 |
| <i>ntt</i>                 | New translation type value in the range of 0 to 255.                                                                                                                                                                                                                             |
| <b>pcssn</b>               | Sets RI to route on point code and subsystem number.                                                                                                                                                                                                                             |
| <b>rate-limit</b>          | Specifies the traffic-rate limitation to this PC/SSN. The over-flow traffic routes to higher cost DPC/ASNAME. If not specified, the PC does not have a rate-limit.                                                                                                               |
| <i>rate</i>                | An integrate value specifying the traffic rate. Valid range is 1 to 4294967296 MSU/sec.                                                                                                                                                                                          |
| <i>wf</i>                  | Weight factor. Any items added to the group require a cost if the <b>multiplicity</b> command specifies <b>cgpa</b> or <b>wrr</b> .                                                                                                                                              |
| <b>sccp-allow-pak-conv</b> | Enables conversion of SCCP packet between XUDT/XUDTS and UDT/UDTS.                                                                                                                                                                                                               |
| <i>number</i>              | 1 specifies XUDT/XUDTS to UDT/UDTS conversion<br>2 specifies UDT/UDTS to XUDT/XUDTS conversion<br>3 specifies NO CONVERSION                                                                                                                                                      |

### Defaults

None.

### Command Modes

cs7 gtt application group submode

**Command History**

| Release                    | Modification                                                                               |
|----------------------------|--------------------------------------------------------------------------------------------|
| 12.4(15)SW9<br>12.2(33)IRI | The <b>sccp-allow-pak-conv</b> keyword was added.                                          |
| 12.2(33)IRA                | The command was introduced.                                                                |
| 12.2(33)IRD                | The <b>rate limit</b> keyword and <i>rate</i> argument were introduced.                    |
| 12.2(33)IRD                | Noted that command requires a cost if the <b>multiplicity</b> command specifies <b>wrr</b> |

**Usage Guidelines**

The **asname** command assigns an M3UA or SUA AS directly to a global title. You must configure a **cs7 as** command with the same name, and a **routing-key** subcommand of type **gtt** must be configured. Verification of the AS name is performed at execution time.

The destination in a GTT application group uses the *wf* argument when the **multiplicity** command was configured with the **cgpa** or **wrr** keyword.

**Examples**

The following example shows how to configure two AS names. AS1 has a cost value of four and RI set to route on GT. AS2 has a cost value of five and the RI set to route on point code and subsystem number.

```
cs7 gtt application-group abc
multiplicity cost
pc 7.7.1 3 gt
asname as1 4 gt
asname as2 5 pcssn
```

**Related Commands**

|-------------------------------------------|--------------------------------------------------------------------------|
| <a href="#">cs7 gtt application-group</a> | Defines a GTT application group.                                         |
| <a href="#">multiplicity</a>              | Specifies a method for selecting a destination in the application group. |

## asname (cs7 mlr result)

To specify a particular destination M3UA or SUA application server, use the **asname** command in cs7 mlr result configuration mode. To remove the definition, use the **no** form of this command.

**asname** *as-name* [**order** *order*] [**weight** *weight*][**preserve-dpc**]

**no asname** *as-name* [**order** *order*] [**weight** *weight*][**preserve-dpc**]

| Syntax Description  |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-name</i>      |  | Identifies an M3UA or SUA application server name. The name can be 1 to 12 characters long.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>order</b>        |  | Specifies the order in which the results are stored in the result group. Required for (and only present in the CLI for) results in a dest-sme-binding mode. Results in a WRR result group are not able to configure an <b>order</b> keyword.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>order</i>        |  | An integer value ranging from 1 to 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>weight</b>       |  | Specifies the weight applied to the weighted round-robin (WRR) distribution algorithm used for MLR result groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>weight</i>       |  | For dest-sme-binding mode, an integer value in the range 1 to 2147483647. The weight value should reflect the relative capacity of the result (smc). This value is used by the dynamic B-address routing algorithm to select a deterministic result (SMSC) based on the message B-address. If not configured, the default <i>weight</i> value is 1.<br><br>For WRR mode, an integer value in the range of 0 to 10. A value of 10 indicates the resource should be selected 10 times more than a resource assigned a weight of 1. A weight of 0 indicates that the resource should only be used in the event that all nonzero-weighted resources are unavailable. If multiple zero-weighted resources exist, then messages are equally distributed between them if all nonzero-weighted resources fail. If not specified, a default weight of 1 is used. |
| <b>preserve-dpc</b> |  | Instructs MLR not to alter the DPC when routing the message to the specified M3UA AS name. If the AS name is an SUA AS, then the keyword is ignored. If the message must be routed to the AS using MTP3 C-link backup routing, then the keyword is ignored.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Defaults** The default weight is 1.

**Command Modes** cs7 mlr result configuration

### Command History

**Usage Guidelines** If multiple zero-weighted resources exist, then messages are equally distributed between them if all nonzero-weighted resources fail. If not specified, a default weight of 1 is used.

This result type is not currently supported by DSMR (SMS MO Proxy).

When using the **preserve-dpc** keyword, M3UA ASPs must support receiving messages that indicate a DPC different from the one configured under the routing-key definition within the associated M3UA AS submode.

The original DPC is not preserved when messages are routed over an MTP3 C-link used for M3UA/SUA backup routing. When routing these messages, the DPC is always set to the defined AS point code.

## Examples

The following example shows how to specify a destination application server resource in the result group SMS-WEIGHTED. The application server, SMS\_AS1, is assigned a weighted round-robin (WRR) value of 10.

```
cs7 mlr result SMS-WEIGHTED
  asname SMS_AS1 weight 10
```

The following example shows how to specify a destination application server resource in the result group SMS-BINDING. The application server, SMS\_AS1, is assigned a weight value of 10 and an order of 1.

```
cs7 mlr result SMS-BINDING
  asname SMS_AS1 order 1 weight 10
```

## Related Commands

| Command                        | Description                                                                                                                                                     |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 mlr result</a> | Specifies the name of the MLR results group. The result group contains the list of resources that process traffic to be routed based on multilayer information. |

# asp

To list the ASPs contained in the AS, use the **asp** command in **cs7** as configuration mode. To remove the ASP from the AS definition, use the **no** form of this command.

**asp** *asp-name* [**weight** *weight*]

**no asp** *asp-name* [**weight** *weight*]

## Syntax Description

|                 |                                                                                                                                                                                                                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>asp-name</i> | ASP name. The name may be up to 12 characters long, and the first character must be alphabetic. The name must not match any reserved keyword (such as <b>m3ua</b> , <b>sua</b> , <b>all</b> , <b>operational</b> , <b>active</b> , <b>statistics</b> , <b>bindings</b> , or <b>detail</b> ). |
| <b>weight</b>   | Specifies the weighted round-robin ASP distribution within an AS.                                                                                                                                                                                                                            |
| <i>weight</i>   | Weight assigned to the ASP. Valid range is 0 to 10. The default weight is 1.                                                                                                                                                                                                                 |

## Defaults

The default weight is 1.

## Command Modes

cs7 as configuration

## Command History

### Usage Guidelines

You can associate multiple ASPs to an AS by specifying multiple **asp** commands. The number of ASPs associated with an AS should not exceed 16.

The ASP name must already be defined using the **cs7 asp** command before it can be associated with an AS.

The **no** form of the command deletes this ASP from the AS definition and inactivates the routing context for this ASP by generating a Notify message with this routing context.

You can assign a weight value in the range 0 to 10 to an ASP. A higher weight indicates a higher priority (similar to MLR weighted round-robin operation). If **weight** is not specified, the ASP has a default weight of 1.

In an override or broadcast AS, the **weight** keyword is unused. In a loadshare AS, an ASP of weight 0 receives packets only if all other ASPs in the AS are inactive or congested. If multiple active ASPs have a weight of 0, and no other active and uncongested ASPs are available, packets are evenly distributed to the ASPs of weight 0.

## Examples

The following example shows how to define an M3UA application server named AS1 with a routing key of 01010101 and a destination point code of 3.3.3. AS1 contains two ASPs named ASP1 and ASP2.

```
cs7 as as1 m3ua
  routing-key 01010101 3.3.3
  asp asp1
  asp asp2
```

**Related Commands**

| Command                 | Description                            |
|-------------------------|----------------------------------------|
| <a href="#">cs7 as</a>  | Defines an application server.         |
| <a href="#">cs7 asp</a> | Defines an application server process. |

## assoc-retransmit (cs7 asp)

An association retransmits packets when the sender does not receive an acknowledgement within a specified time period. To configure the maximum number of consecutive retransmissions, use the **assoc-retransmit** command in cs7 asp configuration mode. To disable the configuration, use the **no** form of this command.

**assoc-retransmit** *max-retrans*

**no assoc-retransmit** *max-retrans*

| Syntax Description | <i>max-retrans</i> | Maximum association retransmissions. Range is 2 to 20. The default is the value specified under the local M3UA or SUA instance. |
|--------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
|--------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------|

| Defaults | The default retransmission value is the value specified under the local M3UA or SUA instance. |
|----------|-----------------------------------------------------------------------------------------------|
|----------|-----------------------------------------------------------------------------------------------|

| Command Modes | cs7 asp configuration |
|---------------|-----------------------|
|---------------|-----------------------|

### Command History

| Usage Guidelines | The assoc-retransmit counter includes retransmissions of association initialization packets and retransmissions to all the destination transport addresses of the peer if it is multihomed. |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Examples | The following example shows how to set the maximum number of retransmissions to 20: |
|----------|-------------------------------------------------------------------------------------|
|----------|-------------------------------------------------------------------------------------|

```
cs7 asp ASP1 2904 2905 m3ua
  remote-ip 1.1.1.1
  assoc-retransmit 20
```

| Related Commands | Command                             | Description                                                        |
|------------------|-------------------------------------|--------------------------------------------------------------------|
|                  | <a href="#">cs7 asp</a>             | Defines an application server process and enables cs7 asp submode. |
|                  | <a href="#">show cs7 asp detail</a> | Displays ASP information.                                          |

## assoc-retransmit (cs7 link)

An association retransmits packets when the sender does not receive an acknowledgement within a specified time period. To configure the maximum number of consecutive retransmissions to a peer before the peer is considered unreachable, use the **assoc-retransmit** command in cs7 link configuration mode. When the maximum number is exceeded all transmission is stopped and the association is closed. To disable the configuration, use the **no** form of this command.

**assoc-retransmit** *max-retrans*

**no assoc-retransmit** *max-retrans*

### Syntax Description

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <i>max-retrans</i> | Maximum association retransmissions. Range is 2 to 20. |
|--------------------|--------------------------------------------------------|

### Defaults

10 retransmissions

### Command Modes

cs7 link configuration

### Command History

### Usage Guidelines

The assoc-retransmit counter includes retransmissions of association initialization packets and retransmissions to all the destination transport addresses of the peer if it is multihomed.

### Examples

The following example shows how to set the maximum number of retransmissions to 20:

```
cs7 linkset michael 10.1.1
link 0 sctp 172.18.44.147 7000 7000
  assoc-retransmit 20
```

### Related Commands

| Command                       | Description                                         |
|-------------------------------|-----------------------------------------------------|
| <a href="#">cs7 linkset</a>   | Specifies a linkset and enters cs7 linkset submode. |
| <a href="#">show cs7 m2pa</a> | Displays ITP M2PA statistics.                       |

## assoc-retransmit (cs7 m2pa profile)

An association retransmits packets when the sender does not receive an acknowledgement within a specified time period. To configure the maximum number of consecutive retransmissions to a peer before the peer is considered unreachable, use the **assoc-retransmit** command in cs7 m2pa profile configuration mode. When the maximum number is exceeded all transmission is stopped and the association is closed. To disable the configuration, use the **no** form of this command.

**assoc-retransmit** *max-retrans*

**no assoc-retransmit** *max-retrans*

### Syntax Description

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <i>max-retrans</i> | Maximum association retransmissions. Range is 2 to 20. |
|--------------------|--------------------------------------------------------|

### Defaults

10 retransmissions

### Command Modes

cs7 m2pa profile configuration

### Command History

### Usage Guidelines

The assoc-retransmit counter includes retransmissions of association initialization packets and retransmissions to all the destination transport addresses of the peer if it is multihomed.

### Examples

The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the **assoc-retransmit** command, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
 m2pa
  assoc-retransmit
.
.
.
cs7 linkset to_nyc
 profile m2parfc
```

|----------------------|---------------------------------------------|
| <a href="#">m2pa</a> | Specifies M2PA parameters in a CS7 profile. |

## assoc-retransmit (cs7 m3ua)

An association retransmits packets when the sender does not receive an acknowledgement within a specified time period. To configure the maximum number of consecutive retransmissions to be allowed when a new SCTP association is started with the local port, use the **assoc-retransmit** command in **cs7 m3ua** configuration mode. When the maximum number is exceeded all transmission is stopped and the association is closed. To disable the configuration, use the **no** form of this command.

**assoc-retransmit** *max-retrans*

**no assoc-retransmit** *max-retrans*

### Syntax Description

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <i>max-retrans</i> | Maximum association retransmissions. Range is 2 to 20. |
|--------------------|--------------------------------------------------------|

### Defaults

10 retransmissions

### Command Modes

cs7 m3ua configuration

### Command History

### Usage Guidelines

The assoc-retransmit counter includes retransmissions of association initialization packets and retransmissions to all the destination transport addresses of the peer if it is multihomed.

### Examples

The following example shows how to set the maximum number of retransmissions to 20:

```
cs7 m3ua 2905 offload
 local-ip 4.4.4.4
 assoc-retransmit 20
```

|-------------------------------|-----------------------------------------------------------------------|
| <a href="#">cs7 m3ua</a>      | Specifies the local port number for M3UA and enters cs7 m3ua submode. |
| <a href="#">show cs7 m3ua</a> | Displays M3UA node information.                                       |

## assoc-retransmit (cs7 mated-sg)

An association retransmits packets when the sender does not receive an acknowledgement within a specified time period. To configure the maximum number of association retransmissions for the association, use the **assoc-retransmit** command in **cs7 mated-sg** configuration mode. To disable the configuration, use the **no** form of this command.

**assoc-retransmit** *max-retrans*

**no assoc-retransmit** *max-retrans*

|                           |                    |                                                        |
|---------------------------|--------------------|--------------------------------------------------------|
| <b>Syntax Description</b> | <i>max-retrans</i> | Maximum association retransmissions. Range is 2 to 20. |
|---------------------------|--------------------|--------------------------------------------------------|

|                 |                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------|
| <b>Defaults</b> | The value of <i>max-retrans</i> defaults to the value specified under the local port instance. |
|-----------------|------------------------------------------------------------------------------------------------|

|                         | <a href="#">cs7 mated-sg</a>             | Specifies a connection to a mated SG and enters cs7 mated-sg submode. |
|                         | <a href="#">show cs7 mated-sg detail</a> | Displays mated-SG information.                                        |

## assoc-retransmit (cs7 sgmp)

An association retransmits packets when the sender does not receive an acknowledgement within a specified time period. To configure the maximum number of consecutive retransmissions to be allowed when a new SCTP association is started with the local port, use the **assoc-retransmit** command in **cs7 sgmp** configuration mode. When the maximum number is exceeded all transmission is stopped and the association is closed. To disable the configuration, use the **no** form of this command.

**assoc-retransmit** *max-retrans*

**no assoc-retransmit** *max-retrans*

### Syntax Description

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <i>max-retrans</i> | Maximum association retransmissions. Range is 2 to 20. |
|--------------------|--------------------------------------------------------|

### Defaults

10 retransmissions

### Command Modes

cs7 sgmp configuration

### Command History

### Usage Guidelines

The assoc-retransmit counter includes retransmissions of association initialization packets and retransmissions to all the destination transport addresses of the peer if it is multihomed.

### Examples

The following example shows how to set the maximum number of retransmissions to 20:

```
cs7 sgmp 5000
 local-ip 4.4.4.4
 assoc-retransmit 20
```

### Related Commands

## assoc-retransmit (cs7 sua)

An association retransmits packets when the sender does not receive an acknowledgement within a specified time period. To configure the maximum number of consecutive retransmissions to be allowed when a new SCTP association is started with the local port, use the **assoc-retransmit** command in cs7 sua configuration mode. When the maximum number is exceeded all transmission is stopped and the association is closed. To disable the configuration, use the **no** form of this command.

**assoc-retransmit** *max-retrans*

**no assoc-retransmit** *max-retrans*

### Syntax Description

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <i>max-retrans</i> | Maximum association retransmissions. Range is 2 to 20. |
|--------------------|--------------------------------------------------------|

### Defaults

10 retransmissions

### Command Modes

cs7 sua configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The assoc-retransmit counter includes retransmissions of association initialization packets and retransmissions to all the destination transport addresses of the peer if it is multihomed.

### Examples

The following example shows how to set the maximum number of retransmissions to 10:

```
cs7 sua 15000
local-ip 4.4.4.4
assoc-retransmit 20
```

## Related Commands

| Command | Description        |
|---------|--------------------|
| pvc     | Specifies the PVC. |

# authorize

Authorization of the IMSI must be performed by accessing the subscriber's profile stored in the HLR. This subscriber profile is obtained by initiating a MAP version 2 Restore Data operation to the HLR servicing the IMSI. To authorize the IMSI, use the **authorize** command in gsm-authent-vlr configuration mode. To disable the IMSI, use the **no** form of this command.

**authorize** {**bs** *bs-number* | **ts** *ts-number*}

**no authorize** {**bs** *bs-number* | **ts** *ts-number*}

## Syntax Description

|                  |                                                                                                                                                                                                                                                       |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>bs</b>        | Performs the subscriber authorization check against a provisioned bearer service field in the subscriber's profile.                                                                                                                                   |
| <i>bs-number</i> | A decimal coded integer in the range of 0 to 255. This value represents the decimal encoded value of the bearer service as specified in the GSM MAP specification 09.02 <sup>1</sup> . Refer to <a href="#">Table 26</a> for a list of common values. |
| <b>ts</b>        | Performs the subscriber authorization check against a provisioned teleservice field in the subscriber's profile.                                                                                                                                      |
| <i>ts-number</i> | A decimal coded integer ranging from 0 to 255. This value represents the decimal encoded value of the teleservice as specified in the GSM MAP specification (09.02). Refer to <a href="#">Table 27</a> for a list of common values.                   |

1. ETS 300 599: "Digital cellular telecommunications system (Phase 2); Mobile Application Part (MAP) specification (GSM 09.02 version 4.19.1).

## Defaults

If the **authorize** command is not specified, then no authorization check is performed. There is no default bearer service or teleservice value.

## Command Modes

gsm-authent-vlr configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

[Table 26](#) lists the bearer services defined in ETSI specification GSM 02.02 and the MAP encoded values in the MSU. ITP uses the decimal representation of the MAP encoded value.

**Table 26** *Bearer Services and Decimal MAP Values*

| Bearer Service      | GSM 02.02 Bearer Service Number | Decimal MAP Value for Configuring ITP |
|---------------------|---------------------------------|---------------------------------------|
| allBearerServices   |                                 | 0                                     |
| allDataCDA-Services |                                 | 16                                    |

**Table 26** *Bearer Services and Decimal MAP Values (continued)*

| <b>Bearer Service</b>                | <b>GSM 02.02 Bearer Service Number</b> | <b>Decimal MAP Value for Configuring ITP</b>                   |
|--------------------------------------|----------------------------------------|----------------------------------------------------------------|
| Asynchronous General Bearer Service  | 20                                     | 23                                                             |
| Asynchronous 300 bps                 | 21                                     | 17                                                             |

| plmn-specificTS-F                              |                                                   | 223                                              |

**Examples**

The following example shows how to configure bs 17 on the ITP to perform the subscriber authorization check against bearer service 21 (Asynchronous 300 bps data service), which is provisioned in the subscriber's profile on the HLR.

```
gsm-authent-vlr
  authorize bs 17
  cache-size 10000
  max-return 2
```

**Related Commands**

| <b>Command</b>  | <b>Description</b>                                                                                                      |
|-----------------|-------------------------------------------------------------------------------------------------------------------------|
| gsm-authent-vlr | Enables authent-vlr submode for provisioning parameters specific to the Process_Obtain_Authentication_Sets_VLR service. |

# bind-type (cs7 sms profile parameters)

To set the SMPP bind type parameter, use the **bind-type** command in cs7 sms profile parameters configuration mode. To return to the default bind type, use the **no** form of this command.

**bind-type** {any | receiver | transceiver | transmitter}

**no bind-type** {any | receiver | transceiver | transmitter}

## Syntax Description

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>any</b>         | Allows receipt of any SMPP bind type; sends transceiver binds. |
| <b>receiver</b>    | Receives or sends SMPP receiver binds only.                    |
| <b>transceiver</b> | Receives or sends SMPP transceiver binds only.                 |
| <b>transmitter</b> | Receives or sends SMPP transmitter binds only.                 |

## Defaults

The default bind type is **any**.

## Command Modes

cs7 sms profile parameters configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

Received SMPP binds are checked against this command and rejected if they do not match.

The **bind-type** command is valid for SMPP profiles only. It cannot be configured in UCP profiles.

# bind-type (cs7 sms session parameters)

To set the SMPP bind type parameter, use the **bind-type** command in cs7 sms session parameters configuration mode. To return to the default bind type, use the **no** form of this command.

**bind-type** {any | receiver | transceiver | transmitter}

**no bind-type** {any | receiver | transceiver | transmitter}

## Syntax Description

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>any</b>         | Allows receipt of any SMPP bind type; sends transceiver binds. |
| <b>receiver</b>    | Receives or sends SMPP receiver binds only.                    |
| <b>transceiver</b> | Receives or sends SMPP transceiver binds only.                 |
| <b>transmitter</b> | Receives or sends SMPP transmitter binds only.                 |

## Defaults

The default bind type is **any**.

## Command Modes

cs7 sms session parameters configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

Received SMPP binds are checked against this command and rejected if they do not match.

The **bind-type** command is valid for SMPP profiles only. It cannot be configured in UCP profiles.

## Related Commands

|------------------------------------------------------------|-------------------------------------|
| <a href="#">response-timer (cs7 sms session parms)</a>     | Specifies session response timer.   |
| <a href="#">send-window (cs7 sms session parms)</a>        | Specifies send window size.         |
| <a href="#">session-init-timer (cs7 sms session parms)</a> | Specifies session initiation timer. |

# block

To allow a new SCTP association to be established but prevent the ASP from going into the active state, use the **block** cs7 asp submode command. To reverse the block, use the **no** form of this command.

**block**

**no block**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** cs7 asp submode

| Command History | Release                                  | Modification                 |
|-----------------|------------------------------------------|------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

**Usage Guidelines** The **block** and **shutdown** cs7 asp submode commands differ significantly.

The **shutdown** command terminates the SCTP association with this ASP. New SCTP associations are rejected when the ASP is in shutdown mode. Each time the SCTP tries to establish the association, it fails to receive an asp-up acknowledgement.

The **block** command sends an unsolicited asp-inactive acknowledgement. However, the ITP does not terminate the SCTP association. The SCTP keeps trying until it receives an asp-active acknowledgement.

**Examples** The following example shows how to block the ASP from entering an active state:

```
cs7 asp ASP1 2904 2905 m3ua
block
```

| Related Commands | Command                            | Description                                                        |
|------------------|------------------------------------|--------------------------------------------------------------------|
|                  | <a href="#">cs7 asp</a>            | Defines an application server process and enables cs7 asp submode. |
|                  | <a href="#">show cs7 asp</a>       | Displays ASP information.                                          |
|                  | <a href="#">shutdown (cs7 asp)</a> | Terminates the SCTP association with this ASP.                     |

# broadcast

To enable the broadcast of route management messages, use the **broadcast** command in cs7 linkset configuration mode. To disable broadcasting, use the **no** form of this command.

## ANSI Variant

**broadcast** {all | txa-txr | txp}

**no broadcast** {all | txa-txr | txp}

## ITU or China Variant

**broadcast** {all | tfa | tfp}

**no broadcast** {all | tfa | tfp}

## Syntax Description

|                |                                           |
|----------------|-------------------------------------------|
| <b>all</b>     | Broadcasts all route management messages. |
| <b>tfa</b>     | Broadcasts TFA.                           |
| <b>tfp</b>     | Broadcasts TFP.                           |
| <b>txa-txr</b> | Broadcasts TFA/TCA and TFR/TCR.           |
| <b>txp</b>     | Broadcasts TFP/TCP.                       |

## Defaults

The ANSI, ITU, and China variants broadcast all route management messages.

## Command Modes

cs7 linkset configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

This command is used to manage the ITP. Whenever a destination status changes on the ITP (due to received route management messages and linkset status changes), the ITP broadcasts the new status to the adjacent nodes by sending route management messages (TFP, TFR, TFA, TCP, TCR, TCA). The adjacent nodes use these messages to update their route tables.

If a large number of messages are sent to any adjacent node, that node can become temporarily overloaded, because processing a large number of management messages can be processor intensive. The **broadcast** command allows you to regulate the broadcast of route management messages to prevent this potential overloading.

You can disable broadcast messages on a per-linkset basis. If broadcast is disabled, the adjacent nodes do not receive the new status right away. However, when the nodes attempt to route the next MSU to the concerned destination via the ITP, the ITP sends a response method TFP or TFR (if the destination status is inaccessible or restricted). If the response method is TFP, the MSU is dropped.

## Examples

### ANSI, ITU, China Variants

The following example shows how to enable the broadcast of all route management messages on linkset1:

```
cs7 linkset linkset1
  broadcast all
```

The following example shows how to disable the broadcast of all route management messages on linkset1:

```
cs7 linkset linkset1
  no broadcast all
```

### ANSI Variant

The following example shows how to enable the broadcast of TFA/TCA and TFR/TCR messages on linkset1:

```
cs7 linkset linkset1
  broadcast txa-txr
```

### ITU or China Variants

The following example shows how to enable the broadcast of TFP messages on linkset1:

```
cs7 linkset linkset1
  broadcast tfp
```

# bundling (cs7 asp)

Multiple user messages can be bundled into a single SCTP packet. To configure message bundling, use the **bundling** command in cs7 asp configuration mode. To disable bundling, use the **no** form of this command.

**bundling** *msec*

**no bundling** *msec*

## Syntax Description

|             |                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Maximum amount of time that to wait for messages for bundling. Valid range is 5 to 1000 milliseconds. The default is the value specified under the M3UA or SUA instance. |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Defaults

The waiting time defaults to the value specified under the M3UA or SUA instance.

## Command Modes

cs7 asp configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

When message bundling is enabled, packets might experience a delay before being sent. The delay is the amount of time the ITP waits for messages to be bundled. When messages are bundled, the resulting packet (including IP and SCTP headers) must be less than or equal to the MTU for the current path.

During periods of congestion, the ITP bundles messages (when possible) even if bundling is disabled. During these periods, abatement messages are bundled whenever possible, with no impact on performance.

## Examples

The following example shows how to set the bundling interval to 500 milliseconds:

```
cs7 asp ASP1 2905 2905 m3ua
  remote-ip 1.1.1.1
  bundling 500
```

## Related Commands

| <a href="#">cs7 asp</a>             | Specifies an application server process and enables cs7 asp submode. |
| <a href="#">show cs7 asp detail</a> | Displays ASP information.                                            |

## bundling (cs7 link)

Multiple user messages can be bundled into a single packet. To configure message bundling, use the **bundling** command in cs7 link configuration mode. To disable bundling, use the **no** form of this command.

**bundling** *msec*

**no bundling** *msec*

### Syntax Description

|             |                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Maximum amount of time to wait for messages for bundling. Valid range is 5 to 1000 milliseconds. The default is 5 milliseconds. |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|

### Defaults

This command is enabled.  
The default waiting time is 5 milliseconds.

### Command Modes

cs7 link configuration

### Command History

| Release     | Modification                                    |
|-------------|-------------------------------------------------|
| 12.2(18)IXA | This command was introduced to enable bundling. |
| 12.4(11)SW  |                                                 |
| 12.2(33)IRA |                                                 |

### Usage Guidelines

When message bundling is enabled, packets might experience a delay before being sent. The delay is the amount of time the ITP waits for messages to be bundled. When messages are bundled, the resulting packet (including IP and SCTP headers) must be less than or equal to the MTU for the current path.

During periods of congestion, the ITP bundles messages (when possible) even if bundling is disabled. During these periods, abatement messages are bundled whenever possible, with no impact on performance.

MTP2 parameters can also be specified in a CS7 profile.

### Examples

The following example shows how to set the bundling interval to 500 milliseconds:

```
cs7 linkset michael 10.1.1
 link 0 sctp 172.18.44.147 7000 7000
  bundling 500
```

### Related Commands

|-------------------------------|------------------------------------------------------------------------------------|
| <a href="#">cs7 linkset</a>   | Specifies a linkset and enters cs7 linkset submode.                                |
| <a href="#">cs7 profile</a>   | Defines a profile of MTP2 parameters that you can apply to all links in a linkset. |
| <a href="#">show cs7 m2pa</a> | Displays ITP M2PA statistics.                                                      |

## bundling (cs7 m2pa profile)

Multiple user messages can be bundled into a single packet. To configure message bundling, use the **bundling** command in cs7 m2pa profile configuration mode. To disable bundling, use the **no** form of this command.

**bundling** *msec*

**no bundling** *msec*

### Syntax Description

|             |                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Maximum amount of time to wait for messages for bundling. Valid range is 5 to 1000 milliseconds. The default is 5 milliseconds. |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|

### Defaults

This command is enabled.  
The default waiting time is 5 milliseconds.

### Command Modes

cs7 m2pa profile configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

When message bundling is enabled, packets might experience a delay before being sent. The delay is the amount of time the ITP waits for messages to be bundled. When messages are bundled, the resulting packet (including IP and SCTP headers) must be less than or equal to the MTU for the current path.

During periods of congestion, the ITP bundles messages (when possible) even if bundling is disabled. During these periods, abatement messages are bundled whenever possible, with no impact on performance.

MTP2 parameters can also be specified in a CS7 profile.

### Examples

The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the **bundling** command, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
  m2pa
    bundling 100
  .
  .
  .
cs7 linkset to_nyc
  profile m2parfc
```

■ bundling (cs7 m2pa profile)

## bundling (cs7 m3ua)

Multiple user messages can be bundled into a single SCTP packet. To specify whether packet bundling is supported and the bundling interval to be used when a new SCTP association is started with the local port, use the **bundling** cs7 m3ua submode command. To disable bundling, use the **no** form of this command.

**bundling** *msec*

**no bundling** *msec*

### Syntax Description

|             |                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Maximum amount of time to wait for messages for bundling. Valid range is 5 to 1000 milliseconds. The default is 5 milliseconds. |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|

### Defaults

This command is enabled.  
The default waiting time is 5 milliseconds.

### Command Modes

cs7 m3ua submode

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

When message bundling is enabled, packets might experience a delay before being sent. The delay is the amount of time the ITP waits for messages to be bundled. When messages are bundled, the resulting packet (including IP and SCTP headers) must be less than or equal to the MTU for the current path.

During periods of congestion, the ITP bundles messages (when possible) even if bundling is disabled. During these periods, abatement messages are bundled whenever possible, with no impact on performance.

### Examples

The following example shows how to set the bundling interval to 500 milliseconds:

```
cs7 m3ua 2905
 local-ip 4.4.4.4
 bundling 500
```

### Related Commands

# bundling (cs7 mated-sg)

Multiple user messages can be bundled into a single SCTP packet. To configure message bundling, use the **bundling** command in cs7 mated-sg configuration mode. To disable bundling, use the **no** form of this command.

**bundling** *msec*

**no bundling** *msec*

## Syntax Description

|             |                                                                                                                                                                    |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Maximum amount of time to wait for messages for bundling. Valid range is 5 to 1000 milliseconds. The default is the value specified under the local port instance. |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Defaults

The waiting time defaults to the value specified under the SGMP instance.

## Command Modes

cs7 mated-sg configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

When message bundling is enabled, packets might experience a delay before being sent. The delay is the amount of time the ITP waits for messages to be bundled. When messages are bundled, the resulting packet (including IP and SCTP headers) must be less than or equal to the MTU for the current path.

During periods of congestion, the ITP bundles messages (when possible) even if bundling is disabled. During these periods, abatement messages are bundled whenever possible, with no impact on performance.

## Examples

The following example shows how to set the bundling interval to 500 milliseconds:

```
cs7 mated-sg BLUE 5000
  remote-ip 5.5.5.5
  bundling 500
```

## Related Commands

## bundling (cs7 profile)

Multiple user messages can be bundled into a single packet. To configure message bundling in a CS7 profile, use the **bundling** command in cs7 profile configuration mode. To disable bundling, use the **no** form of this command.

**bundling** *msec*

**no bundling** *msec*

### Syntax Description

|             |                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Maximum amount of time to wait for messages for bundling. Valid range is 5 to 1000 milliseconds. The default is 5 milliseconds. |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|

### Defaults

This command is enabled.  
The default waiting time is 5 milliseconds.

### Command Modes

cs7 profile configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

When message bundling is enabled, packets might experience a delay before being sent. The delay is the amount of time the ITP waits for messages to be bundled. When messages are bundled, the resulting packet (including IP and SCTP headers) must be less than or equal to the MTU for the current path.

During periods of congestion, the ITP bundles messages (when possible) even if bundling is disabled. During these periods, abatement messages are bundled whenever possible, with no impact on performance.

### Examples

The following example shows how to define a profile named timers. The profile supports MTP2, configures the packet bundling, t1, and t2 settings, and applies to all the links in the linkset named itpa.

```
cs7 profile timers
 mtp2
  timer t1 15000
  timer t2 9000
.
.
.
cs7 linkset itpa
 profile timers
```

# bundling (cs7 sgmp)

Multiple user messages can be bundled into a single SCTP packet. To specify whether packet bundling is supported and the bundling interval to be used when a new SCTP association is started with the local port, use the **bundling** command in cs7 sgmp configuration mode. To disable bundling, use the **no** form of this command.

**bundling** *msec*

**no bundling** *msec*

## Syntax Description

|             |                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Maximum amount of time to wait for messages for bundling. Valid range is 5 to 1000 milliseconds. The default is 5 milliseconds. |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|

## Defaults

This command is enabled.  
The default waiting time is 5 milliseconds.

## Command Modes

cs7 sgmp configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

When message bundling is enabled, packets might experience a delay before being sent. The delay is the amount of time the ITP waits for messages to be bundled. When messages are bundled, the resulting packet (including IP and SCTP headers) must be less than or equal to the MTU for the current path.

During periods of congestion, the ITP bundles messages (when possible) even if bundling is disabled. During these periods, abatement messages are bundled whenever possible, with no impact on performance.

## Examples

The following example shows how to set the bundling interval to 500 milliseconds:

```
cs7 sgmp 5000
 local-ip 4.4.4.4
 bundling 500
```

# bundling (cs7 sua)

Multiple user messages can be bundled into a single SCTP packet. To specify whether packet bundling is supported and the bundling interval to be used when a new SCTP association is started with the local port, use the **bundling** command in cs7 sua configuration mode. To disable bundling, use the **no** form of this command.

**bundling** *msec*

**no bundling** *msec*

## Syntax Description

|             |                                                                                                                                 |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Maximum amount of time to wait for messages for bundling. Valid range is 5 to 1000 milliseconds. The default is 5 milliseconds. |
|-------------|---------------------------------------------------------------------------------------------------------------------------------|

## Defaults

This command is enabled.

The default waiting time is 5 milliseconds.

## Command Modes

cs7 sua configuration

# burst-recovery-timeout

To specify the amount of time allowed for an association to recover from a burst of traffic due to failover, use the **burst-recovery-timeout** command in `cs7` as configuration mode. To disable the configuration, use the **no** form of this command.

**burst-recovery-timeout** *msec*

**no burst-recovery-timeout** *msec*

| Syntax Description | <i>msec</i> | Recovery timeout value. The valid range is 1000 to 10000 milliseconds. The default is 4000 milliseconds. |
|--------------------|-------------|----------------------------------------------------------------------------------------------------------|
|--------------------|-------------|----------------------------------------------------------------------------------------------------------|

| Defaults | 4000 ms |
|----------|---------|
|----------|---------|

| Command Modes | cs7 as configuration |

# cache-size

To specify the total number of IMSIs for which authentication triplets are cached, use the **cache-size** command in cs7 authentic-vlr configuration mode. To disable caching, use the **no** form of this command. (Also, if the value of 0 is specified, caching is disabled.)

**cache-size** *cache-size*

**no cache-size** *cache-size*

|                           |                   |                                                                                                                                 |
|---------------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>cache-size</i> | Total number of IMSIs for which authentication triplets are cached. Valid value is a decimal number ranging from 1024 to 65535. |
|---------------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------|

|                 |                                  |
|-----------------|----------------------------------|
| <b>Defaults</b> | The default cache size is 65535. |
|-----------------|----------------------------------|

|                      |                                 |
|----------------------|---------------------------------|
| <b>Command Modes</b> | cs7 authentic-vlr configuration |
|----------------------|---------------------------------|

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

|                         |                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | A maximum of five triplets can be stored for each IMSI.                                                                   |
|                         | If you specify 0 for the cache size, caching is disabled. If you do not specify a value, the default cache size is 65535. |

|                 |                                                                 |
|-----------------|-----------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to specify a cache size of 100: |
|-----------------|-----------------------------------------------------------------|

```
gsm-authent-vlr
  cache-size 100
  max-return 2
```

| <b>Related Commands</b> | Command                         | Description                                                                                                                                  |
|-------------------------|---------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
|                         | <a href="#">ttl</a>             | Specifies the amount of elapsed time in seconds that a cached authentication triplet will be stored.                                         |
|                         | <a href="#">gsm-authent-vlr</a> | Enables authentic-vlr submode, in which you can provision parameters specific to the GSM MAP Process_Obtain_Authentication_Sets_VLR service. |
|                         | <a href="#">max-return</a>      | Specifies the maximum number of authentication triplets that may be returned to a MAPUA client for a single request.                         |

## cdpa (cs7 mlr modify-profile)

To indicate that the SCCP calling party address (cdpa) needs to be modified, use the **cdpa** command in cs7 mlr modify-profile mode. To disable modifications, use the **no** form of this command.

This command may be specified within the modify-profile for the ANSI-41 protocol or within any gsm-map operation. The cdpa routing indicator (RI) is unchanged during the modifications.

```
cdpa [gt [prefix {prefix-remove-num | *} {prefix-add-digits | *}] [tt tt] [gti {2 | 4 np np nai nai}] ]
[pc pc] [ssn ssn]
```

```
no cdpa [gt [prefix {prefix-remove-num | *} {prefix-add-digits | *}] [tt tt] [gti {2 | 4 np np nai
nai}] ] [pc pc] [ssn ssn]
```

### Syntax Description

|                          |                                                                                                                                                                                                                                                                                                                         |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>gt</b>                | Indicates global title information to modify. GT modifications apply only to packets with RI=GT. If GT modifications are configured and the received packet has a CdPA with RI=SSN, then the GT modifications are ignored.                                                                                              |
| <b>prefix</b>            | Performs prefix modification on the address.                                                                                                                                                                                                                                                                            |
| <i>prefix-remove-num</i> | An integer in the range from 1 to 15 that defines the number of prefix digits to remove from the address. If no prefix digits are to be removed, then specify a wildcard (*). Only GTAs with fewer than 15 digits can be replaced. To replace the entire address, specify that the maximum 15 digits are to be removed. |
| <i>prefix-add-digits</i> | A string of 1 to 15 hexadecimal digits to add to the beginning of the address. The string is input in normal form (not in BCD-string format). If no digits are to be added, then specify a wildcard (*) in this field.                                                                                                  |
| <b>tt</b>                | Indicates the global title translation type (tt) for the modified cdpa.                                                                                                                                                                                                                                                 |
| <i>tt</i>                | Integer from 0 to 255 that replaces the existing <i>tt</i> value in the cdpa.                                                                                                                                                                                                                                           |
| <b>gti</b>               | Identifies the global title indicator value for the modified cdpa. This value is used only when the <b>cs7 variant</b> command specifies ITU or China.                                                                                                                                                                  |
| <i>gti</i>               | Integer value of 2 or 4.                                                                                                                                                                                                                                                                                                |
| <b>np</b>                | Identifies the global title numbering plan for the modified cdpa.                                                                                                                                                                                                                                                       |
| <i>np</i>                | Integer value from 0 to 15.                                                                                                                                                                                                                                                                                             |
| <b>nai</b>               | Identifies the global title nature of address indicator for the modified cdpa. Specified only when <i>gti</i> is 4.                                                                                                                                                                                                     |
| <i>nai</i>               | Integer value from 0 to 127.                                                                                                                                                                                                                                                                                            |
| <b>pc</b>                | Indicates that the cdpa trigger being defined is RI=PC. Identifies the point code for the modified cdpa.                                                                                                                                                                                                                |
| <i>pc</i>                | Point code in variant-specific point code format.                                                                                                                                                                                                                                                                       |
| <b>ssn</b>               | Identifies the subsystem number for the modified cdpa.                                                                                                                                                                                                                                                                  |
| <i>ssn</i>               | Subsystem number in decimal. Valid range is 2 to 255.                                                                                                                                                                                                                                                                   |

---

---

**Examples**      cs7 mlr modify-profile *SRISM* gsm-map sri-sm  
                          orig-smsc prefix 2 351  
                          cdpa gt prefix 2 351

---

**Usage Guidelines**      CdPA modification includes support for inserting a point code (PC) and subsystem number (SSN), as well as modifying the existing GT information, PC, and SSN. The CdPA routing indicator (RI) is unchanged during these modifications. The PC and the SSN may be inserted or modified regardless of the RI.
**Note**

---

 GT modifications apply only to packets with RI=GT.
 

---

If GT modifications are configured and the received packet has a CdPA with RI=SSN, then the GT modifications are ignored. The GT information that can be modified includes the GT address digits, the GT translation type (tt), the global title indicator (gti), the numbering plan (np), and the nature of address indicator (nai).

For prefix-based GT address translation, you can configure the number of prefix digits to be removed from the address and the digit string that should be prefixed to the address. Specifying a wildcard (\*) for the number of prefix digits indicates that no digits will be removed. Specifying a wildcard (\*) for the digit string indicates that no prefix digits are added to the address string. If the resulting modified address exceeds the maximum allowed number of digits, then MLR fails the modification and discards the packet by default. You can optionally configure the preferred action for failed modifications using the **modify-failure** command within mlr options submode.

Operations for applying MLR message modifications are in the following order:

1. Modifications specified using global MLR options
2. Modifications specified using MLR **modify-profile** within the selected rule
3. Modifications specified using MLR **result** within the selected rule

For example, MLR modifications to the CdPA using **modify-profile** are done before the processing of the selected MLR result. If result gt was selected, then any CdPA modifications made using **modify-profile** will be overwritten with the address specified in the result gt. Use **result route** to initiate routing of the packet to the CdPA that has been modified using **modify-profile**.

If the number of digits in the modified address is less than 1 digit or more than 30 digits, the address modification cannot be performed. In this case, the action taken is based on the configured **modify-failure** option. By default, the packet is discarded if it cannot be modified as specified.

**Note**

---

 The CdPA routing indicator (RI) is unchanged during these modifications.

|                  | <a href="#">modify-failure (mlr options)</a> | Specifies the desired action when MLR packet modification fails. |

## cdpa (cs7 mlr trigger)

You can configure a secondary trigger in conjunction with the primary trigger address to create a combination trigger used to match a packet. To create a combination trigger based on the combination of the calling party and the called party, use the **cdpa** command in cs7 mlr trigger configuration mode within a calling party address trigger. To disable the specific routing trigger, use the **no** form of this command.

```
cdpa {gt addr-string [gt-addr-type] | pc point-code ssn ssn} {block | continue | ruleset
ruleset-name | result {pc pc [ssn ssn] | asname as-name | gt gta [gt-addr-type] | group
group-name}}
```

```
no cdpa {gt addr-string [gt-addr-type] | pc point-code ssn ssn} {block | continue | ruleset
ruleset-name | result {pc pc [ssn ssn] | asname as-name | gt gta [gt-addr-type] | group
group-name}}
```

| Syntax Description  |                                                                                             |                                                                                                                                                                                                                                                                                                                                       |

The PC within the SCCP CdPA is inspected first. If the PC is not present, then the OPC is used.                                                                                                                                                                          |
| <i>point-code</i>   |                                                                                             | Point code in variant-specific point code format.                                                                                                                                                                                                                                                                                     |
| <b>ssn</b>          |                                                                                             | (Optional) Routes based on PC and subsystem number.                                                                                                                                                                                                                                                                                   |
| <i>ssn</i>          |                                                                                             | Subsystem number in decimal. Valid range is 2 to 255.                                                                                                                                                                                                                                                                                 |
| <b>block</b>        |                                                                                             | Drops messages matching this trigger. This keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                                                                                                        |

|                     |                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>continue</b>     | Routes messages matching this trigger as received. This behavior is the same as if no primary trigger had been matched. This keyword is ignored if combination triggers are defined within cs7 mlr trigger mode. |
| <b>ruleset</b>      | Specifies the MLR ruleset table that should be used if this trigger is matched, and overrules the ruleset specified on the <b>trigger</b> command.                                                               |
| <i>ruleset-name</i> | Name of a defined CS7 MLR ruleset table. The name is specified as a character string with a maximum of 12 characters.                                                                                            |
| <b>result</b>       | Routes the message based on the trigger alone. Result groups with dest-sme-binding mode are not valid trigger results.                                                                                           |
| <b>pc</b>           | Routes based on point code.                                                                                                                                                                                      |
| <i>pc</i>           | Point code.                                                                                                                                                                                                      |
| <b>ssn</b>          | (Optional) Specifies the subsystem number.                                                                                                                                                                       |
| <i>ssn</i>          | Subsystem number.                                                                                                                                                                                                |
| <b>asname</b>       | Routes based on AS name.                                                                                                                                                                                         |
| <i>as-name</i>      | AS name.                                                                                                                                                                                                         |
| <b>gt</b>           | Routes based on global title.                                                                                                                                                                                    |
| <i>gta</i>          | Global title address.                                                                                                                                                                                            |
| <b>group</b>        | Routes based on result group.                                                                                                                                                                                    |
| <i>group-name</i>   | Result group name.                                                                                                                                                                                               |

**Defaults**

None.

cs7 mlr trigger configuration

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

A combination trigger uses more than one network layer address for identifying a trigger match. Within a combination trigger, one address is defined as the primary trigger and the other address is the secondary trigger.

The primary trigger must correlate with a defined GTT GTA, GTT selector, or GTT MAP entry. The GTT and GTT MAP databases are used as the lookup mechanism for primary triggers. After a primary trigger match occurs, then the list of secondary triggers (defined within the primary trigger submode) is checked. If one or more secondary triggers have been defined, the secondary triggers are sequentially searched for a match. If no match on the secondary trigger occurs, then the packet is not routed using MLR. If no secondary triggers have been defined, then MLR processing continues based on the primary trigger only.

If you configure a secondary address in cs7 mlr trigger mode, then *both* addresses must match for the packet to be blocked or routed using the specified ruleset.

The primary trigger must be for a calling party address for the **cdpa** command to be valid.

CdPA GT and CdPA GT secondary triggers do not require a matching GTT entry.

In all primary and secondary trigger definitions:

- The **pc** keyword is matched only if RI=SSN.
- The **ssn** keyword is matched only if RI=SSN.

With the configurable **result** trigger action, MLR users can route messages based on the trigger alone. If a trigger result is configured, the TCAP/MAP/SMS layers are not parsed. If a message matches a trigger with a **result** trigger action, then the message is redirected as indicated in the trigger result. Result groups with dest-sme-binding mode are not valid trigger results.

### Examples

The following example shows how to create a combination trigger based on the combination of the primary trigger (the CgPA) and the secondary trigger (the CdPA). The example applies ruleset-5 if the combination trigger is found.

```
cs7 mlr table sms-router
trigger cgpa gt 9991117770
cdpa gt 9991116 ruleset ruleset-5
```

The following example shows how to create a combination trigger based on the combination of the primary trigger (the CgPA) and the secondary trigger (the CdPA), and places the **block** keyword at the end of the secondary trigger:

```
cs7 mlr table sms-blocking
trigger cgpa gt 9991117777 tt 10
cdpa gt 9991115555 tt 10 block
```

The following example shows how to create a combination trigger based on the combination of the primary trigger (the CgPA) and the secondary trigger (the CdPA). If a message matches the trigger, the message is redirected to point code 3.3.3.

```
cs7 mlr table sms-router
trigger cgpa gt 9991117770
cdpa gt 9991116 result pc 3.3.3
```

### Related Commands

| Command                                      | Description                                                                                                           |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 mlr ruleset</a>              | Specifies sets of rules that will be used to process traffic-matching triggers defined in a multilayer routing table. |
| <a href="#">default</a>                      | Specifies the routing of packets on primary triggers when defined secondary triggers are not matched.                 |
| <a href="#">show cs7 mlr table</a>           | Displays MLR information.                                                                                             |
| <a href="#">trigger cgpa (cs7 mlr table)</a> | Specifies a primary routing trigger that is located in the SCCP calling party address field of the incoming MSU.      |

## cdpa (cs7 pam)

To configure one called party address (cdpa) entry in the PAM table, use the **cdpa** command in CS7 PAM configuration submode. To disable modifications, use the **no** form of this command.

```
cdpa [gt [prefix {prefix-remove-num | *} {prefix-add-digits | *}]] [tt tt] [gti {2 | 4 np np nai nai}] [pc pc] [ssn ssn]
```

```
no cdpa [gt [prefix {prefix-remove-num | *} {prefix-add-digits | *}]] [tt tt] [gti {2 | 4 np np nai nai}] [pc pc] [ssn ssn]
```

### Syntax Description

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>gt</b>                | Indicates global title information to modify.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>prefix</b>            | Performs prefix modification on the address.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>prefix-remove-num</i> | An integer in the range from 1 to 15 that defines the number of prefix digits to remove from the address. If no prefix digits are to be removed, then specify a wildcard (*). Only GTAs with fewer than 16 digits can be replaced.                                                                                                                                                                                                                                                            |
| <i>prefix-add-digits</i> | A string of 1 to 15 hexadecimal digits which are to be added to the beginning of the address. The string is input in normal form (not BCD-string format). If no digits are added, then "*" should be specified in this field. If the number of digits in the modified address would exceed the 30 digits, then the address modification cannot be performed. In this failure case, the action taken is based on the configured modify-failure parameter. By default, the packet is discarded. |
| <b>tt</b>                | Indicates the global title translation type (tt) for the modified CgPA.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>tt</i>                | Integer from 0 to 255 that replaces the existing <i>tt</i> value.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>gti</b>               | Identifies the global title indicator value for the modified cdpa. This value is used only when the <b>cs7 variant</b> command specifies ITU or China.                                                                                                                                                                                                                                                                                                                                        |
| <i>gti</i>               | Integer value of 2 or 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>np</b>                | Identifies the global title numbering plan.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>np</i>                | Integer value from 0 to 15.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>nai</b>               | Identifies the global title nature of address indicator for the modified cdpa. Specified only when <i>gti</i> is 4.                                                                                                                                                                                                                                                                                                                                                                           |
| <i>nai</i>               | Integer value from 0 to 127.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>pc</b>                | Identifies the point code for the modified cdpa.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>pc</i>                | Point code in variant-specific point code format.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ssn</b>               | Identifies the subsystem number for the modified cdpa.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>ssn</i>               | Subsystem number in decimal. Valid range is 2 to 255.                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Defaults

None.

### Command Modes

CS7 PAM configuration submode

**Command History**

|             |                              |
|-------------|------------------------------|
| 12.4(15)SW5 | This command was introduced. |
| 12.2(33)IRE |                              |

**Examples**

The following example shows a cdpa entry configured for the PAM table named pam1:

```
cs7 instance 0 pam pam1
  cgpa gt prefix tt 0 pc 1.2.3 ssn 12
  cdpa gt prefix 15 123456789abcdef tt 250 gti 4 np 15 nai 127 pc 1.123.4 ssn 255\n
  opc 1.2.3
  dpc 2.3.4
  modify-failure resume
```

**Usage Guidelines**

CdPA modification includes support for inserting a point code (PC) and subsystem number (SSN), as well as modifying the existing GT information, PC, and SSN. The CdPA routing indicator (RI) is unchanged during these modifications. The PC and the SSN may be inserted or modified regardless of the RI.

The GT information that can be modified includes the GT address digits, the GT translation type (tt), the global title indicator (gti), the numbering plan (np), and the nature of address indicator (nai).

For prefix-based GT address translation, you can configure the number of prefix digits to be removed from the address and the digit string that should be prefixed to the address. Specifying a wildcard (\*) for the number of prefix digits indicates that no digits will be removed. Specifying a wildcard (\*) for the digit string indicates that no prefix digits are added to the address string. If the resulting modified address exceeds the maximum allowed number of digits, then PAM fails the modification and discards the packet by default. You can optionally configure the preferred action for failed modifications using the modify-failure command within mlr options submenu.

If the number of digits in the modified address is less than 1 digit or more than 30 digits, the address modification cannot be performed. In this case, the action taken is based on the configured modify-failure option. By default, the packet is discarded if it cannot be modified as specified.

The CdPA routing indicator (RI) is unchanged during these modifications.

**Related Commands**

| Command                              | Description                                                                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 pam</a>              | Identifies a packet address modification (PAM) table and enters the CS7 PAM submenu.                                              |
| <a href="#">cgpa (cs7 pam)</a>       | Configures one cgpa entry in the PAM table.                                                                                       |
| <a href="#">opc</a>                  | Configures an opc entry in the PAM table.                                                                                         |
| <a href="#">dpc</a>                  | Configures a dpc entry in the PAM table.                                                                                          |
| <a href="#">modify-failure (pam)</a> | Specifies the desired action when the PAM table packet modification fails.                                                        |
| <a href="#">cs7 gws action-set</a>   | Defines gateway screening action sets that may include a PAM table.                                                               |
| <a href="#">gta asname</a>           | Creates or modifies a GTA entry that translates to an M3UA or SUA application server name. The GTA entry may include a PAM table. |

## cgpa (cs7 mlr modify-profile)

To indicate that the SCCP calling party address (CgPA) needs to be modified, use the **cgpa** command in global configuration mode. To disable modifications, use the **no** form of this command.

```
cgpa [gt [prefix {prefix-remove-num | *} {prefix-add-digits | *}] [tt tt] [gti {2 | 4 np np nai nai}] ] |
[pc pc] [ssn ssn]
```

```
no cgpa [gt [prefix {prefix-remove-num | *} {prefix-add-digits | *}] [tt tt] [gti {2 | 4 np np nai nai}] ] |
[pc pc] [ssn ssn]
```

### Syntax Description

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cgpa</b>              | Indicates that the SCCP calling party address (CgPA) needs to be modified. The CgPA routing indicator (RI) is unchanged during these modifications.                                                                                                                                                                                                                                                                                                                          |
| <b>gt</b>                | Indicates global title information to modify. GT modifications apply only to packets with RI=GT. If GT modifications are configured and the received packet has a CdPA with RI=SSN, then the GT modifications are ignored.                                                                                                                                                                                                                                                   |
| <b>prefix</b>            | Performs prefix modification on the address.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <i>prefix-remove-num</i> | An integer in the range of 1 to 15 that defines the number of prefix digits to remove from the address. If no prefix digits are to be removed, then specify a wildcard (*). Only GTAs with fewer than 15 digits can be replaced. To replace the entire address, specify that the maximum 15 digits are to be removed.                                                                                                                                                        |
| <i>prefix-add-digits</i> | A string of 1 to 15 hexadecimal digits to add to the beginning of the address. The string is input in normal form (not in BCD-string format). If no digits are to be added, then specify a wildcard (*) in this field. If the number of digits in the modified address exceeds 30 digits, then the address cannot be modified. In this case, the action taken is based on the configured build-failure parameter. By default, a UDTs is sent with an unqualified sccp-error. |
| <b>tt</b>                | Indicates the global title translation type (tt) for the modified CgPA.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>tt</i>                | Integer from 0 to 255 that replaces the existing <i>tt</i> value in the CgPA.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>gti</b>               | Identifies the global title indicator value for the modified CgPA. This value is used only when the <b>cs7 variant</b> command specifies ITU or China.                                                                                                                                                                                                                                                                                                                       |
| <i>gti</i>               | Integer value of 2 or 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>np</b>                | Identifies the global title numbering plan for the modified CgPA.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <i>np</i>                | Integer value from 0 to 15.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>nai</b>               | Identifies the global title nature of address indicator for the modified CgPA. Specified only when the <i>gti</i> value is 4.                                                                                                                                                                                                                                                                                                                                                |
| <i>nai</i>               | Integer value from 0 to 127.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>pc</b>                | Indicates that the CgPA trigger being defined is RI=PC. Identifies the point code for the modified CgPA.                                                                                                                                                                                                                                                                                                                                                                     |
| <i>pc</i>                | Point code in variant-specific point code format.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>ssn</b>               | Identifies the subsystem number for the modified CgPA.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>ssn</i>               | Subsystem number in decimal. Valid range is 2 to 255.                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Defaults**

None.

**Command Modes**

cs7 mlr modify-profile

**Examples**

**cs7 mlr modify-profile** *SRISM* gsm-map sri-sm  
 orig-smsc prefix 2 351  
 cgpa gt prefix 2 351

**Usage Guidelines**

This command may be specified within the modify-profile for the ANSI-41 protocol or within any gsm-map operation. The CgPA routing indicator (RI) is unchanged during the modifications.

CgPA modification includes support for inserting a point code (PC) and subsystem number (SSN), as well as modifying the existing GT information, PC, and SSN. The CgPA routing indicator (RI) is unchanged during these modifications. The PC and the SSN may be inserted or modified regardless of the RI.

**Note**

GT modifications apply only to packets with RI=GT.

If GT modifications are configured and the received packet has a CgPA with RI=SSN, then the GT modifications are ignored. The GT information that can be modified includes the GT address digits, the GT translation type (tt), the global title indicator (gti), the numbering plan (np), and the nature of address indicator (nai).

For prefix-based GT address translation, you can configure the number of prefix digits to be removed from the address and the digit string that should be prefixed to the address. Specifying a wildcard (\*) for the number of prefix digits indicates that no digits will be removed. Specifying a wildcard (\*) for the digit string indicates that no prefix digits are added to the address string. If the resulting modified address exceeds the maximum allowed number of digits, then MLR fails the modification and discards the packet by default. You can optionally configure the preferred action for failed modifications using the **modify-failure** command within mlr options submode.

Operations for applying MLR message modifications are in the following order:

1. Modifications specified using global MLR options
2. Modifications specified using MLR **modify-profile** within the selected rule
3. Modifications specified using MLR **result** within the selected rule

For example, MLR modifications to the CgPA using **modify-profile** are done before the processing of the selected MLR result. If result **gt** was selected, then any CgPA modifications made using **modify-profile** will be overwritten with the address specified in the result **gt**. Use **result route** to initiate routing of the packet to the CdPA that has been modified using **modify-profile**.

If the number of digits in the modified address is less than 1 digit or more than 30 digits, the address modification cannot be performed. In this case, the action taken is based on the configured **modify-failure** option. By default, the packet is discarded if it cannot be modified as specified.

**Note**

---

The CgPA routing indicator (RI) is unchanged during these modifications.

---

## cgpa (cs7 mlr trigger)

You can configure a secondary trigger in conjunction with the trigger address to create a combination trigger used to match a packet. To create a combination trigger based on the combination of the calling party and the called party, use the **cgpa** command in cs7 mlr trigger configuration mode within a called party address trigger. To disable the specific routing trigger, use the **no** form of this command.

```
cgpa {gt addr-string [gt-addr-type] | pc point-code ssn ssn} {block | continue | ruleset
ruleset-name | result {pc pc [ssn ssn] | asname as-name | gt gt [gt-addr-type] | group
group-name}}
```

```
no cgpa {gt addr-string [gt-addr-type] | pc point-code ssn ssn} {block | continue | ruleset

| <b>gt</b>           | Indicates that the CgPA trigger being defined is received with RI=GT.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>addr-string</i>  | Address string of 1 to 15 hexadecimal characters. The string is input in normal form, not in BCD-string format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>gt-addr-type</i> | (Optional) Identifies attributes of the global title address being used as a trigger. The parameters are variant-specific, and are identical to those parameters specified on the <b>cs7 gtt selector</b> command. If not specified, the default is the standard E.164 address type for the network variant being used.<br><br><b>tt</b> <i>tt</i> [ <b>gti</b> <i>gti</i> ] [ <b>np</b> <i>np</i> <b>nai</b> <i>nai</i> ]<br><b>tt</b> Identifies the translation type specified within the address.<br><i>tt</i> An integer value from 0 to 255.<br><b>gti</b> Identifies the global title indicator value for the specified address. This value is used only when the <b>cs7 variant</b> command specifies ITU or China.<br><i>gti</i> Integer value of 2 or 4.<br><b>np</b> Identifies the numbering plan of the specified address. Used only when the <i>gti</i> value is 4.<br><i>np</i> Integer value from 0 to 15.<br><b>nai</b> Identifies the nature of address indicator. Used only when the <i>gti</i> value is 4.<br><i>nai</i> Integer value from 0 to 127. |
| <b>pc</b>           | Matches the trigger if it contains the specified point code. The PC within the SCCP CdPA is inspected first. If the PC is not present, then the DPC in the routing label is used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>point-code</i>   | Point code in variant-specific point code format.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>ssn</b>          | (Optional) Routes based on PC and subsystem number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>ssn</i>          | Subsystem number in decimal. Valid range is 2 to 255.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>block</b>        | Drops messages matching this trigger. This keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                     |                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>continue</b>     | Routes messages matching this trigger as received. This behavior is the same as if no primary trigger had been matched. This keyword is ignored if combination triggers are defined within cs7 mlr trigger mode. |
| <b>ruleset</b>      | Specifies the MLR ruleset table that should be used if this trigger is matched, and not overruled by a secondary trigger ruleset.                                                                                |
| <i>ruleset-name</i> | Name of an already defined cs7 mlr ruleset table. The name is specified as a character string with a maximum of 12 characters.                                                                                   |
| <b>result</b>       | Routes the message based on the trigger alone. Result groups with dest-sme-binding mode are not valid trigger results.                                                                                           |
| <b>pc</b>           | Routes based on point code.                                                                                                                                                                                      |
| <i>pc</i>           | Point code.                                                                                                                                                                                                      |
| <b>ssn</b>          | (Optional) Routes based on PC and subsystem number.                                                                                                                                                              |
| <i>ssn</i>          | Subsystem number.                                                                                                                                                                                                |
| <b>asname</b>       | Routes based on AS name.                                                                                                                                                                                         |
| <i>as-name</i>      | AS name.                                                                                                                                                                                                         |
| <b>gt</b>           | Routes based on global title.                                                                                                                                                                                    |
| <i>gta</i>          | Global title address.                                                                                                                                                                                            |
| <b>group</b>        | Routes based on result group.                                                                                                                                                                                    |
| <i>group-name</i>   | Result group name.                                                                                                                                                                                               |

**Defaults**

None.

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

A combination trigger uses more than one network layer address for identifying a trigger match. Within a combination trigger, one address is defined as the primary trigger and the other address is the secondary trigger.

The primary trigger must correlate with a defined GTT GTA, GTT selector, or GTT MAP entry. The GTT and GTT MAP databases are used as the lookup mechanism for primary triggers. After a primary trigger match occurs, then the list of secondary triggers (defined within the primary trigger submode) is checked. If one or more secondary triggers have been defined, the secondary triggers are sequentially searched for a match. If no match on the secondary trigger occurs, then the packet is not routed using MLR. If no secondary triggers have been defined, then MLR processing continues based on the primary trigger only.

If you configure a secondary address in cs7 mlr trigger submode, then *both* addresses must match for the packet to be blocked or routed using the specified ruleset.

The primary trigger must be for a called party for the **cgpa** submode command to be valid.

CDPA GT and CGPA GT secondary triggers do not require a matching GTT entry.

In all primary and secondary trigger definition:

- The **pc** keyword is matched only if RI=SSN.
- The **ssn** keyword is matched only if RI=SSN.

With the configurable **result** trigger action, MLR users can route messages based on the trigger alone. If a trigger result is configured, the TCAP/MAP/SMS layers are not parsed. If a message matches a trigger with a **result** trigger action, then the message is redirected as indicated in the trigger result. Result groups with dest-sme-binding mode are not valid trigger results.

### Examples

The following example shows how to create a combination trigger based on the combination of the primary trigger (the called party, cdpa) and the secondary trigger (the calling party, cgpa). The example applies ruleset-5 if the combination trigger is found.

```
cs7 mlr table sms-router
trigger cdpa gt 9991117770
cgpa gt 9991116 ruleset ruleset-5
```

The following example shows how to create a combination trigger based on the combination of the primary trigger (the CdPA) and the secondary trigger (the CgPA), and places the **block** keyword at the end of the secondary trigger:

```
cs7 mlr table sms-blocking
trigger cdpa gt 11111 tt 10
cgpa gt 22222 tt 10 block
```

The following example shows how to create a combination trigger based on the combination of the primary trigger (the CdPA) and the secondary trigger (the CgPA). If a messages matches the trigger, the message is redirected to point code 3.3.3.

```
cs7 mlr table sms-router
trigger cdpa gt 9991117770
cgpa gt 9991116 result pc 3.3.3
```

### Related Commands

| Command                                      | Description                                                                                                           |
|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 mlr ruleset</a>              | Specifies sets of rules that will be used to process traffic-matching triggers defined in a multilayer routing table. |
| <a href="#">default</a>                      | Creates a trigger to be used if all other subtriggers are unmatched.                                                  |
| <a href="#">show cs7 mlr table</a>           | Displays multilayer SMS routing information.                                                                          |
| <a href="#">trigger cdpa (cs7 mlr table)</a> | Specifies a routing trigger that is located in the SCCP called party address field of the incoming MSU.               |

## cgpa (cs7 pam)

To configure a calling party address (cgpa) entry in the PAM table, use the **cgpa** command in CS7 PAM configuration submode. To disable modifications, use the **no** form of this command.

```
cgpa [gt [prefix {prefix-remove-num | *} {prefix-add-digits | *}] [tt tt] [gti {2 | 4 np np nai nai}] ]
[pc pc] [ssn ssn]
```

```
no cgpa [gt [prefix {prefix-remove-num | *} {prefix-add-digits | *}] [tt tt] [gti {2 | 4 np np nai nai}] ]
[pc pc] [ssn ssn]
```

### Syntax Description

|                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>gt</b>                | Indicates global title information to modify.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>prefix</b>            | Performs prefix modification on the address.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>prefix-remove-num</i> | An integer in the range from 1 to 15 that defines the number of prefix digits to remove from the address. If no prefix digits are to be removed, then specify a wildcard (*). Only GTAs with fewer than 16 digits can be replaced.                                                                                                                                                                                                                                                            |
| <i>prefix-add-digits</i> | A string of 1 to 15 hexadecimal digits which are to be added to the beginning of the address. The string is input in normal form (not BCD-string format). If no digits are added, then "*" should be specified in this field. If the number of digits in the modified address would exceed the 30 digits, then the address modification cannot be performed. In this failure case, the action taken is based on the configured modify-failure parameter. By default, the packet is discarded. |
| <b>tt</b>                | Indicates the global title translation type (tt) for the modified CgPA.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>tt</i>                | Integer from 0 to 255 that replaces the existing <i>tt</i> value.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>gti</b>               | Identifies the global title indicator value for the modified cgpa. This value is used only when the <b>cs7 variant</b> command specifies ITU or China.                                                                                                                                                                                                                                                                                                                                        |
| <i>gti</i>               | Integer value of 2 or 4.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>np</b>                | Identifies the global title numbering plan.                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>np</i>                | Integer value from 0 to 15.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>nai</b>               | Identifies the global title nature of address indicator for the modified cgpa. Specified only when <i>gti</i> is 4.                                                                                                                                                                                                                                                                                                                                                                           |
| <i>nai</i>               | Integer value from 0 to 127.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>pc</b>                | Identifies the point code for the modified cgpa.                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>pc</i>                | Point code in variant-specific point code format.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>ssn</b>               | Identifies the subsystem number for the modified cgpa.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>ssn</i>               | Subsystem number in decimal. Valid range is 2 to 255.                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### Defaults

None.

### Command Modes

CS7 PAM configuration submode

**Command History**

|             |                              |
|-------------|------------------------------|
| 12.4(15)SW5 | This command was introduced. |
| 12.2(33)IRE |                              |

**Examples**

The following example shows a cgpa entry configured for the PAM table named pam1:

```
cs7 instance 0 pam pam1
  cgpa gt prefix tt 0 pc 1.2.3 ssn 12
  cdpa gt prefix 15 123456789abcdef tt 250 gti 4 np 15 nai 127 pc 1.123.4 ssn 255\n
  opc 1.2.3
  dpc 2.3.4
  modify-failure resume
```

**Usage Guidelines**

CgPA modification includes support for inserting a point code (PC) and subsystem number (SSN), as well as modifying the existing GT information, PC, and SSN. The PC and the SSN may be inserted or modified regardless of the RI.

The GT information that can be modified includes the GT address digits, the GT translation type (tt), the global title indicator (gti), the numbering plan (np), and the nature of address indicator (nai).

For prefix-based GT address translation, one can configure the number of prefix digits to be removed from the address and the digit string that should be prefixed to the address. Specifying a wildcard (\*) for the number of prefix digits (prefix-remove-num) indicates that no digits will be removed. Specifying a wildcard (\*) for the prefix-add-digits digit string indicates that no prefix digits are added to the address string. If the resulting modified address exceeds the maximum allowed number of digits, then PAM fails the modification and discards the packet by default. You can optionally configure the preferred action for failed modifications using the modify-failure command within mlr options submenu.

If the number of digits in the modified address is less than 1 digit or more than 30 digits, the address modification cannot be performed. In this case, the action taken is based on the configured modify-failure option. By default, the packet is discarded if it cannot be modified as specified.

The CgPA routing indicator (RI) is unchanged during these modifications.

**Related Commands**

| Command                              | Description                                                                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 pam</a>              | Identifies a packet address modification (PAM) table and enters the CS7 PAM submenu.                                              |
| <a href="#">cdpa (cs7 pam)</a>       | Configures one cdpa entry in the PAM table.                                                                                       |
| <a href="#">opc</a>                  | Configures an opc entry in the PAM table.                                                                                         |
| <a href="#">dpc</a>                  | Configures a dpc entry in the PAM table.                                                                                          |
| <a href="#">modify-failure (pam)</a> | Specifies the desired action when the PAM table packet modification fails.                                                        |
| <a href="#">cs7 gws action-set</a>   | Defines gateway screening action sets that may include a PAM table.                                                               |
| <a href="#">gta asname</a>           | Creates or modifies a GTA entry that translates to an M3UA or SUA application server name. The GTA entry may include a PAM table. |

# clear cs7 accounting

To clear the ITP accounting databases, use the **clear cs7 accounting** EXEC command.

**clear cs7** [*instance-number*] **accounting** [**access-violations** | **gtt** | **unrouteable**] [**checkpoint**]

## Syntax Description

|                          |                                                                              |
|--------------------------|------------------------------------------------------------------------------|
| <i>instance-number</i>   | Instance number.                                                             |
| <b>access-violations</b> | Clears the access-violation accounting database.                             |
| <b>checkpoint</b>        | Clears all checkpointed accounting databases.                                |
| <b>gtt</b>               | Clears the GTT accounting database, including all the linksets and xUA ASes. |
| <b>unrouteable</b>       | Clears all unrouteable accounting databases.                                 |

## Defaults

None.

## Command Modes

EXEC

## Command History

## Usage Guidelines

The **clear cs7 accounting** command resets counters. It is useful in debugging because it can track new message activity.

This command can be issued either globally or on an instance.

## Examples

The following example shows how to clear the ITP access violations database:

```
clear cs7 accounting access-violations
```

|-------------------------------------|----------------------------------|
| <a href="#">show cs7 accounting</a> | Displays ITP accounting details. |
| <a href="#">clear cs7 all</a>       | Clears accounting details.       |

# clear cs7 all

To clear all accounting, statistics, and GTT measurements, use the **clear cs7 all** EXEC command.

**clear cs7** [*instance-number*] **all** [**checkpoint**]

| Syntax Description | <b>checkpoint</b>      | (Optional) Clears all data, including all checkpoint tables. |
|--------------------|------------------------|--------------------------------------------------------------|
|                    | <i>instance-number</i> | Instance number.                                             |

# clear cs7 dynamic-route

To clear a dynamic route, use the **clear cs7 dynamic-route** EXEC command.

**clear cs7** [*instance-number*] **dynamic-route** {*point-code* | **all** [*minutes*]}

|                           |                        |                                                                        |
|---------------------------|------------------------|------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>instance-number</i> | Instance number.                                                       |
|                           | <i>point-code</i>      | Clears the dynamic route with this point code.                         |
|                           | <b>all</b>             | Clears all dynamic routes.                                             |
|                           | <i>minutes</i>         | Purges only if older than specified time. Range is 0 to 20160 minutes. |

**Defaults** None.

**Command Modes** EXEC

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Usage Guidelines** This command can be issued either globally or on an instance.

**Examples** The following example shows how to clear all dynamic routes:

```
clear cs7 dynamic-route all
```

# clear cs7 gtt-gta

To clear all GTA\_MATCH counters, use the **clear cs7 gtt-gta** command in privileged EXEC mode.

**clear cs7 gtt-gta**

|                           |                                            |
|---------------------------|--------------------------------------------|
| <b>Syntax Description</b> | This command has no arguments or keywords. |
|---------------------------|--------------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                 |
|----------------------|-----------------|
| <b>Command Modes</b> | Privileged EXEC |
|----------------------|-----------------|

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.4(15)SW8    | This command was introduced. |
|                        | 12.2(33)IRH    |                              |

|                         |                                                                                                                                                                  |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | GTA-MATCH counters apply only for LC. Hence, the counters do not increment on SUP. If the command is executed on SUP, the output is zero for GTA_MATCH counters. |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                  |
|-----------------|------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to clear all GTA_MATCH counters: |
|-----------------|------------------------------------------------------------------|

```
clear cs7 gtt-gta
```

|                         |                                  |                                            |
|-------------------------|----------------------------------|--------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>                   | <b>Description</b>                         |
|                         | <a href="#">show cs7 gtt gta</a> | Displays a summary of CS7 GTT GTA entries. |

# clear cs7 gtt-meas

To reset all GTT measurements to 0, use the **clear cs7 gtt-meas** privileged EXEC command.

**clear cs7** [*instance-number*] **gtt-meas**

| <b>Syntax Description</b>                 | <i>instance-number</i> Instance number.                                                                                                                                                                       |         |              |                                           |                                                  |            |             |

# clear cs7 msu-rates

To clear the MSU traffic rate values, use the **clear cs7 msu-rates** command at the privileged EXEC mode.

**clear cs7 msu-rates** [ **peak** *slot cpu* ]

## Syntax Description

|             |                                                         |
|-------------|---------------------------------------------------------|
| <b>peak</b> | Indicates the maximum peak values for MSU traffic rate. |
| <i>slot</i> | Slot number.                                            |
| <i>cpu</i>  | Bay or processor number.                                |

## Defaults

None.

## Command Modes

privileged EXEC mode

## Command History

| Release     | Modification                           |
|-------------|----------------------------------------|
| 12.4(15)SW7 | The <b>peak</b> option was introduced. |
| 12.2(33)IRG |                                        |

## Usage Guidelines

This command resets all the counters associated with MSU traffic rate. Use the peak option to clear the maximum values of MSU traffic rate for a specified slot and CPU processor.

## Examples

The following example shows how to clear the maximum MSU traffic rate values:

```
clear cs7 msu-rates peak 1 0
```

# clear cs7 statistics

To clear statistics concerning MSU throughput on a linkset basis, use the **clear cs7 statistics** EXEC command.

**clear cs7** [*instance-number*] **statistics** [*linkset* [*link*]]

## Syntax Description

|                        |                      |
|------------------------|----------------------|
| <i>instance-number</i> | Instance number.     |
| <i>linkset</i>         | Name of the linkset. |
| <i>link</i>            | Number of the link.  |

## Defaults

None.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

This command can be issued either globally or on an instance.

The ITP statistics are helpful in debugging and analyzing MSU throughput. The **clear cs7 statistics** command can be used by a customer or TAC engineer any time a starting point is needed to see statistics counted.

The ITP keeps the following statistics: MSU In, MSU Out, LSSU In, LSSU Out, ByteCnt In, ByteCnt Out, and Drop.

You can display statistics with the **show cs7 linkset statistics** command.

## Examples

The following example shows how to reset to zero all counters for all linksets, then reset to zero all counters on the linkset named rosebud:

```
clear cs7 statistics
!resets all counts to zero for all linksets)
clear cs7 statistics rosebud
!resets all counts on the linkset rosebud to zero)
```

## Related Commands

# clear ip sctp association

An SCTP (Stream Control Transmission Protocol) association is a protocol relationship between SCTP endpoints. The relationship consists of two endpoints and the protocol state information.

To clear the errors, statistics, and monitor values for the specified SCTP association, use the **clear ip sctp association** EXEC command.

**clear ip sctp association** *assoc-id*

| Syntax Description       | <i>assoc-id</i> Association identifier. Shows the associated ID statistics for the SCTP association.                                                                                                                                                          |  |         |              |              |                              |                          |                                                                                |

| clear ip sctp statistics | Resets all SCTP global counters and clears counters for all SCTP associations.                                                                                                                                                                                |  |         |              |              |                              |                          |                                                                                |

# c-link-linkset

A C-link links connecting mated STPs. To tag a linkset as a C-link linkset, use the **c-link-linkset** **cs7** linkset configuration submode command. To disable the command, use the **no** form of this command.

**c-link-linkset** [secondary]

**no c-link-linkset** [secondary]

|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | <p>You can configure one or two C-link linksets. Two linksets comprise a primary linkset and a secondary linkset. Both linksets are treated equally; “secondary” means only that one end of the link is a secondary point code (when multiple local PCs are configured). If two C-link linksets exist and only one has been tagged, when MTP circular route detection (CRD) is configured, the links in the untagged linkset will fail. The links fail because configuring CRD also turns on OPC verification, which drops MSUs with an OPC equal to the mate's PC if they do not arrive on a C-link. The verification process also drops signaling link test messages.</p> <p>To avoid link failures, we recommend that all changes to C-link linkset configuration be made while CRD is turned off.</p> |

|                 |                                                                                                                                     |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | <p>The following example shows the configuration of the C-link linkset:</p> <pre>cs7 instance 0 linkset l1name c-link-linkset</pre> |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------|

# clock source (controller)

To set the clock source, use the **clock source** command in controller configuration mode. To restore the clock source to its default setting, use the **no** form of this command.

**clock source** { **bits** | **line** } { **primary** | **secondary** *priority* } | { **free-running** | **internal** }

**no clock source**

## Syntax Description

|                     |                                                                              |
|---------------------|------------------------------------------------------------------------------|
| <b>bits</b>         | Clocking for all nodes is derived from one designated source.                |
| <b>line</b>         | Clocking is derived from the external source to which the port is connected. |
| <b>primary</b>      | Primary source of clock.                                                     |
| <b>secondary</b>    | Secondary source of clock.                                                   |
| <i>priority</i>     | Priority of the clock source. The valid range is 1 to 8.                     |
| <b>free-running</b> | A free-running clock derived from the oscillator on the motherboard.         |
| <b>internal</b>     | Clocking is derived from the controller's internal phase-locked loop (PLL).  |

## Defaults

The default clock source is **line**.

## Command Modes

Controller configuration

## Usage Guidelines

A controller that is configured for BITS clocking cannot be used to carry data. If BITS clocking has been set, no channel groups can be configured. If channel groups have been configured, BITS cannot be configured.

## Examples

The following example shows how to specify the BITS clock source as the primary clock:

```
controller t1 4/0/7
 clock source bits primary
```

## Related Commands

| Command | Description                                        |
|---------|----------------------------------------------------|
| framing | Selects the frame type for the T1 or E1 data line. |

# clock source (interface)

To set the clock source, use the **clock source** command in interface configuration mode. To restore the clock source to its default setting, use the **no** form of this command.

**clock source** { **common** | **internal** | **line** } *interface-number*

**no clock source**

## Syntax Description

|                         |                                                                                                                               |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>common</b>           | Interface clocks its transmitted data from a common clock source.                                                             |
| <b>internal</b>         | Interface clocks its transmitted data from its internal clock.                                                                |
| <b>line</b>             | Interface clocks its transmitted data from a clock recovered from the line's receive data stream. This source is the default. |
| <i>interface-number</i> | Specific physical link or port number of the common clock source.<br>Valid range is 0 to 7.                                   |

## Defaults

The default clock source is **line**.

## Command Modes

Interface configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(11)SW  | This command was introduced. |
| 12.2(33)IRA |                              |

## Usage Guidelines

### Caution

You cannot configure the clock source for an ATM interface when the interface is in the administratively down state. The clock source may revert to the original clock source when the interface becomes active.

The **common** keyword is used as part of a configuration that provides BITS clocking to SS7 ATM high-speed links (HSL). A BITS clock is delivered, via a T1 crossover cable, *from* an SS7 port adapter controller that has been configured as the primary BITS clock *to* a T1 Inverse Multiplexing for ATM (IMA) port adapter interface. The IMA port adapter interface receives the BITS clock source for all other interfaces on that IMA port adapter. All other interfaces on the IMA port adapter accept the BITS clock by specifying **clock source common** *interface-number*, where *interface-number* is the IMA port adapter interface that is connected by a crossover cable to the SS7 port adapter.

## Examples

The following example shows how to provide BITS clocking to ATM HSLs. Controller 0 of the SS7 port adapter is configured as the primary source of the BITS clock. Controller 1 of the SS7 port adapter is configured as the secondary source. Controller 2 of the SS7 port adapter is connected to the IMA port adapter interface 0 with a T1 crossover cable and provides the BITS clock to the IMA.

**clock source (interface)**

```
controller T1 2/0/0
  clock source bits primary
  description PRIMARY BITS CLOCK RCVD

controller T1 2/0/1
  clock source bits secondary 1
  description SECONDARY BITS CLOCK RCVD

controller T1 2/0/2
  clock source internal
  description PROVIDES BITS CLOCK TO T1 ATM12/0/0
  description INTERFACE IS CONNECTED TO ATM12/0/0

interface ATM12/0/0
  no ip address
  no ima-group
  no atm ilmi-keepalive
  description RECEIVES BITS CLOCK SOURCE FOR ALL INTERFACES ON THIS IMA PA
  description INTERFACE IS CONNECTED TO T1 2/0/3

interface ATM12/0/1
  clock source common 0
  atm nni
  pvc 0/5 qsaal

interface ATM12/0/2
  clock source common 0
  atm nni
  pvc 0/5 qsaal
```

## congestion-mode defer-to-backup (cs7 mlr result)

With this command, **congestion-mode** specifies the occurrence of local congestion and **defer-to-backup** specifies the option of using a backup server.

To choose backup servers when all primary servers are unavailable or congested, use the **congestion-mode defer-to-backup** command in cs7 mlr result configuration mode. To return to the default backup server selection scheme, use the **no** form of this command.

**congestion-mode defer-to-backup**

**no congestion-mode defer-to-backup**

### Syntax Description

This command has no arguments or keywords.

### Defaults

The backup server is used when the primary server is unavailable, and the presence of congestion is not recognized as a factor.

### Command Modes

cs7 mlr result configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXH | This command was introduced. |
| 12.4(15)SW3 |                              |
| 12.2(33)IRC |                              |

### Usage Guidelines

This same command configured in SMS groups sets congestion as a factor in determining the server chosen for SMS results.

### Examples

The following example shows how to enable congestion as a factor in the MLR backup server choice:

```
cs7 instance 1 mlr result mo-proxy mode wrr
  congestion-mode defer-to-backup
  pc 1.16.0 ssn 8 weight 5
  pc 3.2.3 ssn 8 weight 0
```

### Related Commands

| Command             | Description                                    |
|---------------------|------------------------------------------------|
| cs7 mlr result      | Enters cs7 mlr result configuration mode.      |
| cs7 sms offload     | Enables SMS-MO Proxy and SMSNot Proxy offload. |
| pc (cs7 mlr result) | Specifies the destination point code.          |

# congestion-mode defer-to-backup (cs7 sms group)

With this command, **congestion-mode** specifies the occurrence of local congestion and **defer-to-backup** specifies the option of using a backup server.

To choose backup servers when all primary servers are unavailable or congested, use the **congestion-mode defer-to-backup** command in cs7 sms group configuration mode. To return to the default backup server selection scheme, use the **no** form of this command.

**congestion-mode defer-to-backup**

**no congestion-mode defer-to-backup**

## Syntax Description

This command has no arguments or keywords.

## Defaults

The backup server is used when the primary server is unavailable, and the presence of congestion is not factored into using the backup server.

## Command Modes

cs7 sms group configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXH | This command was introduced. |
| 12.4(15)SW3 |                              |
| 12.2(33)IRC |                              |

## Usage Guidelines

This same command configured in MLR result groups sets congestion as a factor in determining the server chosen for results.

## Examples

The following example shows how to enable congestion as a factor in the backup server choice:

```
cs7 sms group SMSCGRP smsc
  congestion-mode defer-to-backup
pc 1.16.0 ssn 8 weight 5
pc 3.2.3 ssn 8 weight 0
```

## Related Commands

| Command             | Description                                    |
|---------------------|------------------------------------------------|
| cs7 sms group       | Enters cs7 sms group configuration mode.       |
| cs7 sms offload     | Enables SMS-MO Proxy and SMSNot Proxy offload. |
| pc (cs7 sms result) | Specifies the destination point code.          |

## cookie-life (cs7 local peer)

To configure the valid cookie life of an SCTP association, use the **cookie-life** command in cs7 local-peer configuration submode. To return to the default congestion threshold, use the **no** form of this command.

**cookie-life** *cookie-life-milliseconds*

**no cookie-life** *cookie-life-milliseconds*

|                           |                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>cookie-life-milliseconds</i> The lifespan of the cookie used in the SCTP handshake in milliseconds (5000-120000). |
|---------------------------|----------------------------------------------------------------------------------------------------------------------|

|                 |                                  |
|-----------------|----------------------------------|
| <b>Defaults</b> | 5000 milliseconds (or 5 seconds) |
|-----------------|----------------------------------|

|                      |                                   |
|----------------------|-----------------------------------|
| <b>Command Modes</b> | cs7 local peer configuration mode |
|----------------------|-----------------------------------|

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|------------------------|----------------|------------------------------|
|                        | 12.2(33)IRE    | This command was introduced. |

|                         |                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The cookie is part of the four-step handshake procedure that occurs during the SCTP association start up. The lifespan of this cookie is an SCTP parameter. You can tune this parameter for your network with the <b>cookie-life</b> command. |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                              |
|-----------------|----------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows the valid cookie life of an SCTP association set for 20 seconds: |
|-----------------|----------------------------------------------------------------------------------------------|

```
cs7 multi-instance
cs7 instance 0 variant ANSI

## cookie-life (cs7 m3ua)

To configure the valid cookie life of an SCTP association, use the **cookie-life** command in cs7 m3ua configuration submode. To return to the default congestion threshold, use the **no** form of this command.

**cookie-life** *cookie-life-milliseconds*

**no cookie-life** *cookie-life-milliseconds*

|                           |                                 |                                                                                      |
|---------------------------|---------------------------------|--------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>cookie-life-milliseconds</i> | The lifespan of the cookie used in the SCTP handshake in milliseconds (5000-120000). |
|---------------------------|---------------------------------|--------------------------------------------------------------------------------------|

|                 |                                  |
|-----------------|----------------------------------|
| <b>Defaults</b> | 5000 milliseconds (or 5 seconds) |
|-----------------|----------------------------------|

|                      |                                |
|----------------------|--------------------------------|
| <b>Command Modes</b> | cs7 m3ua submode configuration |
|----------------------|--------------------------------|

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|------------------------|----------------|------------------------------|
|                        | 12.2(33)IRE    | This command was introduced. |

|                         |                                                                                                                                                                                                                                               |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The cookie is part of the four-step handshake procedure that occurs during the SCTP association start up. The lifespan of this cookie is an SCTP parameter. You can tune this parameter for your network with the <b>cookie-life</b> command. |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                                                    |
|-----------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows the valid cookie life of an SCTP association set for 20 seconds on the M3UA port 9000: |
|-----------------|--------------------------------------------------------------------------------------------------------------------|

```
router#show cs7 m3ua 9000
Sigtran M3UA RFC number: 4666

M3UA Local port: 9000          State: active          SCTP instance handle: 9000
Local ip address:              117.117.200.1
                               118.118.200.1
Number of active M3UA peers:   16
Max number of inbound streams allowed: 17
Local receive window:         64000
Max init retransmissions:     8
Max init timeout:              1000 ms
Unordered priority:            equal
Extended UPU support:         disabled
Handling DUPU from ASPs:      disabled
Offload to linecard:          Yes      Slot: 8 1
SCTP defaults for new associations
Transmit queue depth: 1000          Cumulative sack timeout: 200 ms
Assoc retransmissions: 10           Path retransmissions: 4
Minimum RTO: 1000 ms              Maximum RTO: 1000 ms
Bundle status: on                  Bundle timeout: 5 ms
Keep alive status: true            Keep alive timeout: 30000 ms
```

```

Initial cwnd:          3000          Idle cwnd rate:          50
Retrans cwnd rate:     50            Retrans cwnd mode:       RFC
FastRetrans cwnd rate: 50            SCTP RFC Version:        2960
Cookie Life:           20000

```

The following example shows how information on the configured cookie life is also displayed with the **show running-config** command:

```

router#show running-config
!
cs7 m3ua 9000 offload 8 1
local-ip 117.117.200.1
local-ip 118.118.200.1
cookie-life 20000
!

```

# cs7 acc-audit-timer

To configure CS7 accounting timer and cp measurement timer, use the **cs7 acc-audit-timer** command in global configuration mode. To remove the configuration, use the default value of the timer, 10 seconds.

**cs7 acc-audit-timer** *seconds*

**cs7 acc-audit-timer** 10

|                           |                |                                                    |
|---------------------------|----------------|----------------------------------------------------|
| <b>Syntax Description</b> | <i>seconds</i> | Timer value in seconds. Range is 5 to 300 seconds. |
|---------------------------|----------------|----------------------------------------------------|

|                 |                                        |  |
|-----------------|----------------------------------------|--|
| <b>Defaults</b> | The default timer value is 10 seconds. |  |
|-----------------|----------------------------------------|--|

|                      |                      |  |
|----------------------|----------------------|--|
| <b>Command Modes</b> | Global configuration |  |
|----------------------|----------------------|--|

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.4(15)SW9    | This command was introduced. |
|                        | 12.2(33)IRI    |                              |

|                         |                                                                                                                             |  |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------|--|
| <b>Usage Guidelines</b> | This command is configurable for only instance zero.                                                                        |  |
|                         | Do not use the no form of this command. To reset the timer value, issue this command with the time value of 10 seconds.     |  |
|                         | To check the value of the timer, issue the <b>show cs7 offload mtp3 detailed</b> command.                                   |  |
|                         | If configured on instances 1 to 7, there is no impact to ITP.                                                               |  |
|                         | To prevent memory depletion on the SUP, the recommended value for this timer is 20 seconds on a system loaded with 4 SAMIs. |  |

|                 |                                                                  |  |
|-----------------|------------------------------------------------------------------|--|
| <b>Examples</b> | The following example shows how to set the timer to 100 seconds: |  |
|                 | <pre>cs7 instance 0 acc-audit-timer 100</pre>                    |  |

|                         |  |  |

## cs7 accounting

To configure CS7 accounting options, use the **cs7 accounting** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 accounting** { **checkpoint-interval** *min* | **checkpoint-limit** *entries* | **global-gtt** | **global-mtp3** | **global-unrouteable** | **global-xua** | **global-virtual-linkset** | **gtt-checkpoint-interval** *gtt\_min* }

| Syntax Description            |  |                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------|--|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>min</i>                    |  | An accounting checkpoint interval. The range is 1 to 3600 minutes. The default is 5 minutes.                                                                                                                                                                                                                                                                                  |
| <i>entries</i>                |  | Maximum number of entries for all accounting tables. The range is 5000 to 1000000 entries.                                                                                                                                                                                                                                                                                    |
| <b>global-gtt</b>             |  | Enables GTT accounting on all linksets. Same effect as specifying the <b>gtt-accounting</b> command on all linksets.                                                                                                                                                                                                                                                          |
| <b>global-mtp3</b>            |  | Enables MTP3 accounting on all linksets. Same effect as specifying the <b>accounting</b> command on all linksets.                                                                                                                                                                                                                                                             |
| <b>global-xua</b>             |  | Enables xUA normal accounting on all xUA (M3UA and SUA) ASes. This setting allows counting of the M3UA payload data messages received from and sent to M3UA ASes. This setting also allows the counting of the number of CLDT/CLDR packets received from and sent to the SUA AS.                                                                                              |
| <b>global-unrouteable</b>     |  | Enables unroutable accounting on all linksets and xUA ASes.                                                                                                                                                                                                                                                                                                                   |
| <b>global-virtual-linkset</b> |  | Enables virtual linkset accounting globally, including normal MTP3 accounting, unroutable accounting, and SCCP accounting. This keyword controls the collection of all types of accounting information for virtual linksets. After it is enabled, information for traffic sent and received over virtual linksets appears in the MTP3, unroutable, and GTT accounting tables. |
| <i>gtt_min</i>                |  | GTT accounting checkpoint interval. The range is 1 to 3600 minutes. The default is 5 minutes.                                                                                                                                                                                                                                                                                 |

### Defaults

The default accounting checkpoint interval is 5 minutes.

The default GTT accounting checkpoint interval is 5 minutes.

### Command Modes

Global configuration

### Command History

### Usage Guidelines

The **global-gtt**, **global-mtp3**, and **global-unrouteable** keywords have the same effect.

### Examples

The following example shows how to set the GTT accounting checkpoint interval to 30 minutes:

```
cs7 accounting gtt-checkpoint-interval 30
```

**Related Commands**

| Command                             | Description                      |
|-------------------------------------|----------------------------------|
| <a href="#">show cs7 accounting</a> | Displays ITP accounting details. |

# cs7 address-table replace

To replace an already configured or new address table with one specified in a URL, use the **cs7 address-table replace** command in global configuration mode. To remove the line from the configuration, use the **no** form of this command.

**cs7 address-table replace** { **mlr** | **sms** } *table-name url*

**no cs7 address-table replace** { **mlr** | **sms** } *table-name url*

|                           |                   |                                                                                                                 |
|---------------------------|-------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <b>mlr</b>        | Specifies table type <b>mlr</b> .                                                                               |
|                           | <b>sms</b>        | Specifies table type <b>sms</b> .                                                                               |
|                           | <i>table-name</i> | Identifies the existing address table that is to be replaced.                                                   |
|                           | <i>url</i>        | User-assigned local or remote location representing the filename and path from which the file will be replaced. |

**Defaults** None.

**Command Modes** Global configuration

## Command History

**Usage Guidelines** The replacement does not impact routing until the entire replacement address table is loaded successfully. If an error occurs, the old address table (if present) remains intact. Each time an address table is replaced, the corresponding **load** command is added to the running configuration.

**Examples** The following command shows how to replace an SMS address table named addrtbl1 with the file at disk0:smsaddrtbl:

```
cs7 address-table replace sms addrtbl1 disk0:smsaddrtbl
```

|                         |                                              |                                        |
|-------------------------|----------------------------------------------|----------------------------------------|

|                         | <a href="#">load (cs7 sms address-table)</a> | Specifies the file to load on startup. |

# cs7 as

To define an application server (AS), use the **cs7 as** command in global configuration mode. To inactivate an AS and delete the AS definition from configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **as** *as-name* { **m3ua** | **sua** | **sgmp** }

**no** **cs7** [*instance instance-number*] **as** *as-name* { **m3ua** | **sua** | **sgmp** }

## Syntax Description

|                        |                                                                           |
|------------------------|---------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Associates an application server (AS) with a defined instance. |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.    |
| <i>as-name</i>         | A unique name that identifies an AS for configuration and monitoring.     |
| <b>m3ua</b>            | Indicates an M3UA AS.                                                     |
| <b>sua</b>             | Indicates an SUA AS.                                                      |
| <b>sgmp</b>            | Indicates an SGMP AS.                                                     |

## Defaults

None.

## Command Modes

Global configuration

## Command History

| Release     | Modification                            |
|-------------|-----------------------------------------|
| 12.2(33)IRA | This command was introduced.            |
| 12.2(33)IRD | The <b>sgmp</b> keyword was introduced. |

## Usage Guidelines

The as-name may be up to 12 characters long. The first character must be alphabetic. The AS name cannot duplicate an AS route name and cannot match the following reserved keywords: **m3ua**, **sua**, **all**, **operational**, **active**, **statistics**, **bindings**, or **detail**.

You must configure the ASPs before you configure the AS.

You must specify both a routing key and at least one ASP in as submode. An incomplete AS definition will be deleted.

You cannot delete an AS that is currently defined in an AS route. You must first remove this AS from the AS route.

This command is not instance related and cannot be specified with the **instance** keyword.

Issuing the **cs7 as** command enables cs7 as submode. In this submode for M3UA and SUA ASs, you can configure the routing key, ASP, traffic-mode AS parameters, and QoS class. You cannot modify the parameters of an active AS.

In the AS submode for SGMP, you can only configure the **cs7 mated-sg**, **shutdown**, and **routing-key rcontext** commands. SGMP is a common channel and SGMP AS configuration requires a routing-context value. The routing-context value can be any value that does not conflict with other routing-keys. Mated ITPs must use same SGMP routing key. You cannot modify the parameters of an active AS.

When an AS is not active, the ASPs associated with the AS are also not active for this routing context. This will generate a Notify message.

## Examples

The following example shows how to configure an M3UA AS named BLUE:

```
cs7 as BLUE m3ua
```

The following example shows how to configure the AS named BLUE for SUA use:

```
cs7 as BLUE sua
```

The following example shows how to configure the instance 0 AS named provence for SGMP use:

```
cs7 instance 0 as provence sgmp
```

|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">asp</a>                                     | Associates ASPs to an AS.                                                                                                                    |
| <a href="#">burst-recovery-timeout</a>                  | Specifies the amount of time allowed for an association to recover from a burst of traffic due to failover.                                  |
| <a href="#">cs7 asp</a>                                 | Defines an ASP.                                                                                                                              |
| <a href="#">cs7 m3ua</a>                                | Specifies the local port number for M3UA.                                                                                                    |
| <a href="#">cs7 mtp3 tuning rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination.                                                                   |
| <a href="#">cs7 sua</a>                                 | Specifies the local port number for SUA.                                                                                                     |
| <a href="#">qos-class (cs7 as)</a>                      | Configures a QoS class for the packets sent to the ASPs in this AS.                                                                          |
| <a href="#">recovery-timeout</a>                        | Specifies the recovery timeout value.                                                                                                        |
| <a href="#">show cs7 as</a>                             | Displays AS and routing key information.                                                                                                     |
| <a href="#">cs7 sgmp</a>                                | Enables SGMP offloading.                                                                                                                     |
| <a href="#">cs7 mated-sg</a>                            | Configure a connection to a mated SG.                                                                                                        |
| <a href="#">routing-key (cs7 as)</a>                    | Describes a set of SS7 parameters and parameter values that uniquely define the range of signaling traffic to be handled by a particular AS. |

# cs7 asp

To specify an application server process and enable cs7 asp submode, use the **cs7 asp** command in global configuration mode. To delete an ASP definition from the configuration, use the **no** form of this command.

**cs7 asp** *asp-name* *remote-port* [*local-port*] [**m3ua** | **sua**]

**no cs7 asp** *asp-name* *remote-port* [*local-port*] [**m3ua** | **sua**]

## Syntax Description

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>asp-name</i>    | A unique name that identifies an ASP for configuration and monitoring. This name may be up to 12 characters long. The first character must be alphabetic. The ASP name cannot match a reserved keyword (such as <b>m3ua</b> , <b>sua</b> , <b>all</b> , <b>operational</b> , <b>active</b> , <b>statistics</b> , <b>bindings</b> , or <b>detail</b> ).                                                                                                                                                                                                                    |
| <i>remote-port</i> | Remote port number of the ASP. Valid range is 0 to 65535. This argument is used for validation. The SCTP connection requests from the ASP must come in with this remote port number. If two ASPs are configured with the same remote IP address, then the remote port and the local port are used to differentiate between the two ASPs. If a remote port of 0 is configured, the ASP matches on any remote port (providing <i>remote-ip</i> and <i>local-port</i> match). The remote IP, remote port, and local port combination must be unique for each configured ASP. |
| <i>local-port</i>  | Local port number of the ITP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>m3ua</b>        | (Optional) Indicates an M3UA ASP. This value must match the protocol of the specified local port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>sua</b>         | (Optional) Indicates an SUA ASP. This value must match the protocol of the specified local port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Defaults

None.

## Command Modes

Global configuration

## Command History

|-------------|------------------------------|
| 12.2(33)IRA | This command was introduced. |

## Usage Guidelines

The **cs7 asp** command defines an ASP and enables cs7 asp submode. The remote IP address and remote port number combination must be unique for each configured ASP. An SCTP association for an ASP will fail if the ASP is not associated with an AS. An ASP may be associated with multiple ASes.

You can modify the remote port, local port, and protocol of a previously configured ASP. If you enter a valid remote port, local port, and protocol combination, the ASP is updated if its SCTP association is down. You cannot change both the local port and protocol of an ASP that is defined in an AS.

The **no cs7 asp** command deletes this ASP definition from the configuration. If an association is up with this ASP, you must first shut down the ASP and remove the ASP from all CS7 AS definitions before this command can be deleted from the configuration.

In cs7 asp submode, you can disable the ASP by entering the **shutdown** or **block** command. New SCTP associations are rejected when the ASP is in shutdown mode.

You cannot delete an ASP that is currently configured in an AS. You must first remove the ASP from the AS configuration.

You must specify at least one remote IP address in cs7 asp submode or the incomplete ASP definition will be deleted.

This command is not instance related and cannot be specified with the **instance** keyword.

## Examples

The following example shows how to configure an M3UA ASP named ASP1 with remote port number 5000 and local port number 5000:

```
cs7 m3ua 5000
  local-ip 1.1.1.1
!
cs7 asp ASP1 5000 5000 m3ua
  remote-ip 2.2.2.2
```

## Related Commands

|----------------------------------------------|--------------------------------------------------------------------------------------------------------|
| <a href="#">assoc-retransmit (cs7 asp)</a>   | Configures the maximum number of consecutive retransmissions for the association.                      |
| <a href="#">block</a>                        | Allows a new SCTP association to be established but prevents the ASP from going into the active state. |
| <a href="#">bundling (cs7 asp)</a>           | Specifies the maximum amount of time, in milliseconds, that SCTP will wait for messages for bundling.  |
| <a href="#">cs7 as</a>                       | Defines an application server.                                                                         |
| <a href="#">cs7 qos class</a>                | Defines a CS7 QoS class.                                                                               |
| <a href="#">cumulative-sack (cs7 asp)</a>    | Specifies the cumulative selective acknowledgment timeout value, in milliseconds.                      |
| <a href="#">keepalive (cs7 asp)</a>          | Specifies the keepalive interval, in milliseconds.                                                     |
| <a href="#">match any (cs7 asp)</a>          | Assigns a QoS class number to all inbound traffic.                                                     |
| <a href="#">match si (cs7 asp)</a>           | Assign a QoS class number to any inbound packet that has a specific service indicator.                 |
| <a href="#">path-retransmit (cs7 asp)</a>    | Specifies the maximum number of path retransmissions on a remote address for the association.          |
| <a href="#">qos-class (cs7 asp)</a>          | Defines a QoS class for the packets sent to this ASP.                                                  |
| <a href="#">remote-ip (cs7 asp)</a>          | Configures a remote IP address to associate incoming packets from an ASP to a configured ASP.          |
| <a href="#">retransmit-timeout (cs7 asp)</a> | Specifies the minimum retransmission timeout value for the association.                                |
| <a href="#">show cs7 asp</a>                 | Displays ASP information.                                                                              |
| <a href="#">shutdown (cs7 asp)</a>           | Disables an ASP without deleting the configuration.                                                    |
| <a href="#">tx-queue-depth (cs7 asp)</a>     | Specifies the maximum transmit queue depth for the association.                                        |

# cs7 audit

To validate and audit the consistency of the content in the files of the line card and main processor, including MLR or GWS configuration files, GWS table files, and MLR address table files, use the **cs7 audit** command in global configuration mode. To disable the feature, use the **no shutdown** command.

```
cs7 audit [timer [timer-minutes]] [gws[sync]][mlr[sync]]
```

```
no cs7 audit [timer [timer-minutes]] [gws[sync]][mlr[sync]]
```

## Syntax Description

|                      |                                                           |
|----------------------|-----------------------------------------------------------|
| <b>timer</b>         | Signifies the use of the audit interval timer.            |
| <i>timer-minutes</i> | Length of time between audits. The default is 60 minutes. |
| <b>gws</b>           | Enables an audit for GWS. The default is disabled.        |
| <b>mlr</b>           | Enables an audit for MLR. The default is disabled.        |
| <b>sync</b>          | Matches the SUP and LC configuration.                     |

## Defaults

This command is disabled.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXF | This command was introduced. |
| 12.4(15)SW1 |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

If the audit discovers that the line card has a different configuration from the supervisor engine, the configurations synchronize again from the supervisor to the line card.

## Examples

The following example shows how to configure a GWS audit:

```
cs7 audit gws
```

|                           | <a href="#">cs7 billing load</a>                                                                                                                                                           | Specifies the billing configuration file to load.                                  |

# cs7 billing load

To load a configuration file for a billing account, use the **cs7 billing load** command in global configuration mode. To disable the loading, use the **no** form of this command.

**cs7 billing load** *location* [**execute**]

**no cs7 billing load** *location* [**execute**]

## Syntax Description

|                 |                                                                 |
|-----------------|-----------------------------------------------------------------|
| <i>location</i> | The URL or disc location of the configuration file.             |
| <b>execute</b>  | (Optional) Immediately loads the configuration file on the ITP. |

## Defaults

The configuration file from the URL or disc location will load onto the ITP during the next system reboot.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW4 | This command was introduced. |
| 12.2(33)IRD |                              |

## Usage Guidelines

Use this command to configure the file loading URL or disc location for a cs7 billing configuration file.

## Examples

The following command shows how to load a configuration from the disc location `disk0:itp_billing`. The file loads during the next reboot of the ITP:

```
cs7 billing load disk0:itp_billing
```

| Command                              | Description                                       |
|--------------------------------------|---------------------------------------------------|
| <a href="#">cs7 billing pc-table</a> | Configures a pc-table for the billing account.    |
| <a href="#">cs7 billing options</a>  | Configures options for billing.                   |
| <a href="#">cs7 billing load</a>     | Specifies the billing configuration file to load. |

# cs7 billing options

To configure user options for the billing account and enter the billing option configuration submode, use the **cs7 billing options** command in global configuration mode. To disable the loading, use the **no** form of this command.

**cs7 billing options** {*rx-interval seconds* | *rx-per-tx times* | **backstore** *order url* | **bak-file-num** *num*}

**no cs7 billing options** {*rx-interval seconds* | *rx-per-tx times* | **backstore** *order url* | **bak-file-num** *num*}

## Syntax Description

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <i>seconds</i> | Seconds of interval for a time of data collection (30-86400).       |
| <i>times</i>   | Times of data collection in a data storage interval (3-1024).       |
| <i>order</i>   | Order of trying current back storage among all back storages (0-1). |
| <i>url</i>     | The URL location of the back storage file.                          |
| <i>num</i>     | The backup file number in the data saving destination (1-1024).     |

## Defaults

The default interval for times of data collection is 300 seconds. The default interval for a time of data collection is 5. The default backup file number in the data saving destination is 1.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW4 | This command was introduced. |
| 12.2(33)IRD |                              |

## Usage Guidelines

This command also enters the cs7 billing option configuration submode.

## Examples

The following example configure user options for the billing account and enters the cs7 billing option configuration submode. It also sets the times of data collection at a data storage interval of 12 and a data collection interval of 300 seconds:

```
(config)#cs7 billing options
(config-optns-entry)#rx-per-tx 12
(config-optns-entry)#rx-interval 300
```

## Related Commands

# cs7 billing pc-table

To configure a point code table used for billing criteria, use the **cs7 billing pc-table** command in global configuration mode. To remove the point code table, use the **no** form of this command.

**cs7** [*instance instance-number*] **billing pc-table** *pctbl\_name* {**mtp3** | **sccp** | **sms\_sccp**}

**no** **cs7** [*instance instance-number*] **billing pc-table** *pctbl\_name* {**mtp3** | **sccp** | **sms\_sccp**}

## Syntax Description

|                   |                                                              |
|-------------------|--------------------------------------------------------------|
| <i>pctbl_name</i> | Name of the pc table.                                        |
| <b>mtp3</b>       | The first of two protocols you can specify for the pc table. |
| <b>sccp</b>       | The second of two protocols you can specify for pc table.    |
| <b>sms_sccp</b>   | The third of three protocols you can specify for pc table.   |
| <i>pctbl_name</i> | Name of the pc table associated with this entry.             |

## Defaults

None.

## Command Modes

Global configuration mode

## Command History

| Release                    | Modification                                |
|----------------------------|---------------------------------------------|
| 12.4(15)SW4<br>12.2(33)IRD | This command was introduced.                |
| 12.4(15)SW6<br>12.2(33)IRF | The keyword <b>sms_sccp</b> was introduced. |

## Usage Guidelines

This command enters pc-table configuration submode, which allows you to add table entries. You can associate a pc table with one or more configured billing account entries.

## Examples

The following example shows how to configure a billing pc table named *PCTBL\_02* with the SCCP protocol on instance 0:

```
cs7 instance 0 billing pc-table PCTBL_02 sccp
```

The following example shows how to configure a billing pc table named *PCTBL\_01* with the SMS protocol on instance 0:

```
cs7 instance 0 billing pc-table PCTBL_01 sms_sccp
```

# cs7 capability-pc

To configure the capability point code for ITP and its mated node, use the **cs7 capability-pc** command in global configuration mode. To remove the capability point code, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **capability-pc** *zone.region.sp*

**no cs7** [**instance** *instance-number*] **capability-pc** *zone.region.sp*

| Syntax Description | <b>instance</b>        | (Optional) Configures the capability point code for a specified instance of the ITP and its mated node. |
|--------------------|------------------------|---------------------------------------------------------------------------------------------------------|
|                    | <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                  |
|                    | <i>zone.region.sp</i>  | Capability point code.                                                                                  |
|                    |                        |                                                                                                         |

|          |                            |
|----------|----------------------------|
| Defaults | The default instance is 0. |
|----------|----------------------------|

|               |                      |
|---------------|----------------------|
| Command Modes | Global configuration |
|---------------|----------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.4(15)SW1 | This command was introduced. |
|                 | 12.2(33)IRA |                              |

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Usage Guidelines | <p>The ITP supports configuring up to 200 capability point codes for each instance.</p> <p>A capability point code must be configured according to the existing point code format.</p> <p>The capability point code functions like an alias for a mated pair of ITPs. For example, for redundancy, a capability point code is assigned to a mated pair of ITPs that share a GTT database. In this case, all SCCP messages are directed to a single “capable” point code and either ITP can handle the processing.</p> |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|          |                                                                                                                                          |
|----------|------------------------------------------------------------------------------------------------------------------------------------------|
| Examples | <p>The following example shows excerpts from two separate ITP configurations. Both ITPs are assigned the same capability point code.</p> |
|----------|------------------------------------------------------------------------------------------------------------------------------------------|

```
hostname itpa
cs7 multi-instance
cs7 instance 0 variant itu
cs7 instance 0 point-code 5.100.2
cs7 instance 0 capability-pc 5.100.12
```

```
hostname itpb
cs7 multi-instance
cs7 instance 0 variant itu
cs7 instance 0 point-code 5.100.3
cs7 instance 0 capability-pc 5.100.12
```

# cs7 clli

A Common Language Location (CLLI) code is an 11-character standardized geographic identifier that uniquely identifies the geographic location of telecommunication equipment. To define a CLLI code for an ITP, use the **cs7 clli** command in global configuration mode. To remove the definition, use the **no** form of this command.

**cs7 clli** *line*

**no clli** *line*

| Syntax Description | <i>line</i> | A text string used to define a common language location code for the ITP. The string can be from 1 to 11 alphanumeric characters long. |
|--------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------|
|--------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------|

| Defaults | None. |
|----------|-------|
|----------|-------|

| Command Modes | Global configuration |
|---------------|----------------------|
|---------------|----------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXF | This command was introduced. |
|                 | 12.4(15)SW1 |                              |
|                 | 12.2(33)IRA |                              |

| Usage Guidelines | <p>The CLLI <i>line</i> value is included on traps that apply to the SS7 resources on the ITP. The value is also used by network management stations.</p> <p>Complete listings of geographical and geopolitical codes can be found in the BR 751-401-xxx series and BR 751-100-055, respectively.</p> <p>This command is not instance related and cannot be specified with the <b>instance</b> keyword.</p> |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Examples | <p>The following example shows how to define a common language location code for the ITP:</p> <pre>cs7 clli QSWYNJPIDS5</pre> |
|----------|-------------------------------------------------------------------------------------------------------------------------------|
|----------|-------------------------------------------------------------------------------------------------------------------------------|

| Related Commands | Command             | Description                                                        |
|------------------|---------------------|--------------------------------------------------------------------|
|                  | show running config | Displays the contents of the currently running configuration file. |

# cs7 dcs

A DCS (data collection server) node represents an endpoint that receives a proprietary probeless monitoring protocol (PMP). The protocol relies on UDP and carries copies of sent or received ITP MSUs.

To specify the name for a DCS node and enter cs7 dcs submode, use the **cs7 dcs** command in global configuration mode. To remove the name, use the **no** form of this command.

**cs7 dcs** *name*

**no cs7 dcs** *name*

| Syntax Description | <i>name</i> | Identifies a name to be associated with this DCS. The name is specified as an alphanumeric string with a maximum of 12 characters. |
|--------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------|
|--------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------|

| Defaults | None. |
|----------|-------|
|----------|-------|

| Command Modes | Global configuration |
|---------------|----------------------|
|---------------|----------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.4(15)SW3 | This command was introduced. |
|                 | 12.2(33)IRC |                              |

| Usage Guidelines | The DCS node name must be unique among all DCS endpoints. A DCS node represents a probeless monitoring protocol (PMP) endpoint and is uniquely identified by name, IP address, and port number. Each DCS node may contain up to two IP address and port combinations. |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Examples | The following example shows how to create a DCS node named dcs1: |
|----------|------------------------------------------------------------------|

# cs7 dcs-group

A DCS group is a collection of DCS nodes. To identify a name to be associated with a DCS group, use the **cs7 dcs-group** command in global configuration mode. To remove the name, use the **no** form of this command.

**cs7 dcs-group** *name*

**no cs7 dcs-group** *name*

## Syntax Description

|             |                                                                                                                                          |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <i>name</i> | Identifies a name to be associated with this DCS group. The name is specified as an alphanumeric string with a maximum of 12 characters. |
|-------------|------------------------------------------------------------------------------------------------------------------------------------------|

## Defaults

None.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Usage Guidelines

A DCS group represents a group of one or more DCS endpoints. Each DCS group may contain up to eight DCS nodes. The DCS group name must be unique among all DCS groups. You cannot delete a DCS group that is referenced by a linkset or AS.

## Examples

The following example shows how to create a DCS group named pmpGroup1:

```
cs7 pmp
cs7 pmp hold-queue 64 128
cs7 pmp congestion-timer 30
!
cs7 multi-instance
cs7 instance 0 variant ANSI
cs7 instance 0 network-name ANSI
cs7 instance 0 point-code 6.0.1

# cs7 description

To specify a description of the ITP to be used by the administrator or the network management stations, use the **cs7 description** command in global configuration mode. To remove the text string, use the **no** form of this command.

**cs7** [*instance instance-number*] **description** *line*

**no cs7** [*instance instance-number*] **description** *line*

## Syntax Description

|                        |                                                                                          |
|------------------------|------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies a description of an instance.                                       |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                   |
| <i>line</i>            | Text string description of the ITP. Length can be from 1 to 254 alphanumeric characters. |

## Defaults

The default instance is 0.

## Command Modes

Global configuration

## Command History

| Release | Modification                 |
|---------|------------------------------|
|         | This command was introduced. |

## Usage Guidelines

The **cs7 description** command provides extra data to help service the point code. This command is not instance related and cannot be specified with the **instance** keyword.

## Examples

The following examples show how to include text in a **cs7 description** command:

```
cs7 description "Houston 1.2.1 Primary contact Mike Workhard at 111-222-3456"
```

# cs7 display-name

The **cs7 display-name** command assigns a descriptive name to an ITP instance. The name is included on traps that apply to the SS7 resources on the ITP instance and is displayed with such information on the NMS.

To define a display name, use the **cs7 display-name** command in global configuration mode. To remove the definition, use the **no** form of this command.

**cs7** [*instance instance-number*] **display-name** *line*

**no cs7** [*instance instance-number*] **display-name** *line*

## Syntax Description

|                        |                                                                                                                                   |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Assigns a descriptive name to an ITP instance.                                                                         |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                                            |
| <i>line</i>            | Text string description or the ITP point code formatted as an ASCII string in dotted decimal format. Length can be 30 characters. |

## Defaults

The default value of *line* is the point code formatted as an ASCII string in the format defined by the **cs7 point-code format** command.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXF | This command was introduced. |
| 12.4(15)SW1 |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The display name is included on traps that apply to the SS7 resources on the router. The display name is included with information that is sent to the NMS.

## Examples

The following examples show how to configure the display name for the ITP:

```
cs7 display-name West-Chicago
```

```
cs7 instance 1 display-name West-Chicago
```

## Related Commands

| Command                  | Description                                                                               |
|--------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">show cs7</a> | Displays the ITP basic configuration, including the point code and capability point code. |

# cs7 distribute-sccp-sequenced

To enable the ITP to override in-sequence delivery of SSCP traffic, use the **cs7 distribute-sccp-sequenced** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **distribute-sccp-sequenced**

**no cs7** [*instance instance-number*] **distribute-sccp-sequenced**

|                           |                        |                                                                                                                                                                                                                                                                    |
|---------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <b>instance</b>        | (Optional) Specifies an instance if multiple instances exist. If you have configured the ITP with the <b>multi-instance</b> command, you must use the <b>instance</b> keyword to specify the particular instance. A single instance does not require this keyword. |
|                           | <i>instance-number</i> | (Optional) Number of the particular instance. Valid range is 0 to 7. The default instance is 0.                                                                                                                                                                    |

**Defaults** SSCP traffic is delivered in sequence.

**Command Modes** Global configuration

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        |                | This command was introduced. |

**Usage Guidelines** Although some high-level SS7 protocols require in-sequence delivery of packets, other high-level SS7 protocols, such as SCCP and TCAP, do not. When **cs7 distribute-sccp-sequenced** is enabled, the ITP overrides the in-sequence delivery of SCCP traffic.

**Examples** The following examples show how to enable the **cs7 distribute-sccp-sequenced** command:

```
cs7 distribute-sccp-sequenced
```

or

```
cs7 instance 1 distribute-sccp-sequenced
```

|                         |                                                         |                                                                                           |
|-------------------------|---------------------------------------------------------|-------------------------------------------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>                                          | <b>Description</b>                                                                        |
|                         | <a href="#">cs7 mtp3 tuning rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination.                |
|                         | <a href="#">show cs7</a>                                | Displays the ITP basic configuration, including the point code and capability point code. |

# cs7 distribute-sccp-unsequenced

To enable the ITP to determine how to forward packets when in-sequence delivery is not required, use the **cs7 distribute-sccp-unsequenced** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **distribute-sccp-unsequenced**

**no cs7** [*instance instance-number*] **distribute-sccp-unsequenced**

## Syntax Description

|                        |                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies on an instance how to forward packets when in-sequence delivery is not required. |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                |

## Defaults

Distributed links are included in round-robin selection.

## Command Modes

Global configuration

## Command History

| Release | Modification                 |
|---------|------------------------------|
|         | This command was introduced. |

## Usage Guidelines

Although some high-level SS7 protocols require in-sequence delivery of packets, other high-level SS7 protocols, such as SCCP and TCAP, do not. When **cs7 distribute-sccp-unsequenced** is enabled, the Cisco ITP examines the packet header and determines whether or not that protocol requires in-sequence delivery. If in-sequence delivery is not required, the SLS field value is ignored and the Cisco ITP makes a round-robin selection of the link or ASP on which to forward the packet.

## Examples

The following examples show how to enable the **cs7 distribute-sccp-unsequenced** command:

```
cs7 distribute-sccp-unsequenced
```

```
cs7 instance 1 distribute-sccp-unsequenced
```

## Related Commands

# cs7 fast-restart

To enable MTP3 fast restart, use the **cs7 fast-restart** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **fast-restart**

**no cs7** [*instance instance-number*] **fast-restart**

|                           |                        |                                                                        |
|---------------------------|------------------------|------------------------------------------------------------------------|
| <b>Syntax Description</b> | <b>instance</b>        | (Optional) Enables MTP3 fast restart on an instance.                   |
|                           | <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0. |

**Defaults** Fast restart is disabled.

**Command Modes** Global configuration

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        |                | This command was introduced. |

**Usage Guidelines** When an SP restarts, it normally waits to receive a TRA from each of its adjacent nodes before it marks the links available for passing user traffic. If TRAs are not received from each of the adjacent nodes, the SP eventually times out (30 seconds by default) and starts passing user traffic.

The **cs7 fast-restart** command bypasses this timeout so that the SP does not need to wait for TRAs from the adjacent nodes.

**Examples** The following examples show how to enable fast restart:

```
cs7 fast-restart
```

```
cs7 instance 2 fast-restart
```

|                         |                                                         |                                                                                           |
|-------------------------|---------------------------------------------------------|-------------------------------------------------------------------------------------------|

|                         | <a href="#">cs7 mtp3 tuning rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination.                |
|                         | <a href="#">show cs7</a>                                | Displays the ITP basic configuration, including the point code and capability point code. |

## cs7 fisu-audit-interval

To enable sending FISU messages evenly across the links and specify its time interval, use the **cs7 fisu-audit-interval** command in cs7 configuration mode. To disable this feature, use the **no** form of the command.

**cs7 fisu-audit-interval** *fisuauditinterval*

**no cs7 fisu-audit-interval** *fisuauditinterval*

|                           |                                                                                       |
|---------------------------|---------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>fisuauditinterval</i> FISU rate audit interval value in seconds. Range is 1 to 25. |
|---------------------------|---------------------------------------------------------------------------------------|

|                 |                                          |
|-----------------|------------------------------------------|
| <b>Defaults</b> | The <i>fisuauditinterval</i> value is 1. |
|-----------------|------------------------------------------|

|                      |                   |
|----------------------|-------------------|
| <b>Command Modes</b> | cs7 configuration |
|----------------------|-------------------|

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(33)IRH | This command was introduced. |

|                         |                                                                                                                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | To send the FISU messages evenly across the links configured inside the ITP on the basis of a configured time interval, use the <b>cs7 fisu-audit-interval</b> command in cs7 configuration mode. |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                   |
|-----------------|-----------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to configure a FISU audit interval of 10 seconds: |
|-----------------|-----------------------------------------------------------------------------------|

```
cs7 fisu-audit-interval 10
```

**Note**

In CS7 group, manual configuration of **cs7 instance dest-instance pc-conversion default orig-instance [no-route]** must not be done at the alternate node if it is already synced from the manager node.

# cs7 gtt address-conversion

To configure a global title address conversion table, use the **cs7 gtt address-conversion** command in global configuration mode. To remove the definition, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **gtt address-conversion** *table-name*

**no cs7** [**instance** *instance-number*] **gtt address-conversion** *table-name*

## Syntax Description

|                        |                                                                                            |
|------------------------|--------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Configures a global title address conversion table on an instance.              |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                     |
| <i>table-name</i>      | Global title address conversion table name. The table name may be 1 to 12 characters long. |

## Defaults

The default instance is 0.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(11)SW  | This command was introduced. |
| 12.2(33)IRA |                              |

## Usage Guidelines

This command specifies a GTT address conversion table name and enables cs7 gtt address conversion table submenu. The address conversion tables are used to specify mappings such as E.212 - E.214 address conversion. After you have defined a GTT address conversion table, you can apply the table on a GTT-selector basis.

## Examples

The following command shows how to specify a global title address conversion table named conv1:

```
cs7 gtt address-conversion conv1
```

The following command shows how to specify a global title address conversion table named conv1 for instance 1:

```
cs7 instance 2 gtt address-conversion conv1
```

## Related Commands

| <a href="#">update (cs7 gtt address conversion)</a>     | Adds, removes, or changes a GTT address conversion entry.                  |

# cs7 gtt application-group

To configure a GTT application group and enter the CS7 GTT application group submode, use the **cs7 gtt application-group** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **gtt application-group** *name*

**no** **cs7** [*instance instance-number*] **gtt application-group** *name*

## Syntax Description

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Configures a GTT application group on an instance.          |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0. |
| <i>name</i>            | Name of the application group.                                         |

## Defaults

The default instance is 0.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(11)SW  | This command was introduced. |
| 12.2(33)IRA |                              |

## Usage Guidelines

The application group must be defined before you can define the GTA subcommands that use it.

ITP supports performing GTT on two instances for the same MSU. For example, instance 0 can have a GTT application group that specifies the local PC of another instance and the RI set to route on the GT. If this method is used, the MSU may perform a GTT lookup in instance 0 and then translate to the local PC of instance 1. Afterward, the MSU is again translated in instance 1 to its final destination.

## Examples

The following example shows how to configure an application group named group1:

```
cs7 gtt application-group group1
```

The following example shows how to configure an application group named group1 on instance 3:

```
cs7 instance 3 gtt application-group group1
```

| <a href="#">show cs7 gtt consistency</a>       | Displays GTT point codes that do not have routes provisioned for them.  |
| <a href="#">show cs7 gtt gta</a>               | Displays CS7 GTT GTA entries.                                           |

# cs7 gtt concern-pclist

To configure a GTT concerned point code list, use the **cs7 gtt concern-pclist** command in global configuration mode. To remove a point code from an existing concerned point code list, use the **no** form of this command. To delete the concerned point code list, remove all point codes from the list.

**cs7** [**instance** *instance-number*] **gtt concern-pclist** *list-name cpc*

**no cs7** [**instance** *instance-number*] **gtt concern-pclist** *list-name cpc*

## Syntax Description

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| <i>cpc</i>             | Concerned point code, in the form <i>zone.region.sp</i> .              |
| <b>instance</b>        | (Optional) Configures a GTT concerned point code list on an instance.  |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0. |
| <i>list-name</i>       | Name of the concerned point code list.                                 |

## Defaults

The default instance is 0.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(11)SW  | This command was introduced. |
| 12.2(33)IRA |                              |

## Usage Guidelines

To create a new concerned point code list with one point code, the list name must be unique. Use the following syntax: **cs7 gtt concern-pclist** *listname cpc*

To add a new point code to an existing list, the point code specified must be unique for the list. Use the following syntax: **cs7 gtt concern-pclist** *existinglistname newcpc*

To remove a point code from an existing concerned point code list, the point code must exist. Use the following syntax: **cs7 gtt concern-pclist** *existinglistname cpc*

To delete the concerned point code list, remove all point codes from the list. You cannot delete the last point code in a list if it is referenced by a MAP entry.

## Examples

The following example shows how to create a new concerned point code list named mylist with the point code 5.100.5:

```
cs7 gtt concern-pclist mylist 5.100.5
```

The following example shows how to create a new concerned point code list on instance 2 named mylist with the point code 5.100.5:

```
cs7 instance 2 gtt concern-pclist mylist 5.100.5
```

|                  | <a href="#">show cs7 gtt map</a>                        | Displays CS7 GTT MAP entries.                                              |

# cs7 gtt load

Upon ITP reload, to specify the URL location from which the GTT database is loaded, use the **cs7 gtt load** command in global configuration mode.

**cs7** [**instance** *instance-number*] **gtt load** *url* [**execute**]

|                           |                        |                                                                                                                            |
|---------------------------|------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>url</i>             | Path and filename for the GTT load file.                                                                                   |
|                           | <b>execute</b>         | Executes the load immediately.                                                                                             |
|                           | <b>instance</b>        | (Optional) Specifies the URL location from which, on ITP reload, the GTT database for a specified instance will be loaded. |
|                           | <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                                     |

**Defaults** The default instance is 0.

**Command Modes** Global configuration

|                        |                           |                              |

## cs7 gtt map

To configure a global title mated application (MAP) entry, use the **cs7 gtt map** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **gtt map** *ppc pssn* [*flags*] *mult* [*bpc*] [*bssn*]

**no cs7 gtt map** [**instance** *instance-number*]

### Note

You cannot delete any map entry that references another map entry. You must first change all entries that reference it to **sol** before you can delete the entry with the **no cs7 gtt map** command.

### Syntax Description

|                        |                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Configures a global title mated application (MAP) entry for an instance.                                                                                                                                                                                                                                                                                                                 |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                                                                                                                                                                                                                                                                                                              |
| <i>ppc</i>             | Primary SS7 point code, in the form <i>zone.region.sp</i> .                                                                                                                                                                                                                                                                                                                                         |
| <i>pssn</i>            | Primary subsystem number.                                                                                                                                                                                                                                                                                                                                                                           |
| <i>flags</i>           | One of the following flags:<br><b>adj</b> —Marks <i>ppc/pssn</i> as adjacent.<br><b>csplist name</b> —Specifies a concerned point code list name.<br><b>rrc</b> —Reroutes if congested.                                                                                                                                                                                                             |
| <i>mult</i>            | The entry in the MAP table may be modified to work in one of three multiplicities or modes:<br><b>solitary</b> —Uses a single PC (no alternate if PC and/or SSN is not available).<br><b>share</b> —Shares load equally across the primary PC/SSN and backup PC/SSN.<br><b>dominant</b> —Always translates to primary PC/SSN if available, and only translates to backup if primary is unavailable. |
| <i>bpc</i>             | Backup point code, in the form <i>zone.region.sp</i> .                                                                                                                                                                                                                                                                                                                                              |
| <i>bssn</i>            | Backup subsystem number. Valid range is 2 to 255.                                                                                                                                                                                                                                                                                                                                                   |

## Usage Guidelines

A GTT MAP entry has two main purposes. First, the SCCP application uses it internally to track point code and SSN states such as congestion and availability. Second, it is used to define backups or alternates for a particular PC/SSN combination. An entry in the GTA table that contains a PC and SSN has a corresponding entry in the MAP table. The following rules apply to these entries:

- A backup point code and subsystem must be specified if the mode (multiplicity) is shared or dominant.
- A backup point code and subsystem cannot be specified if the mode (multiplicity) is solitary.
- A PC/SSN entry cannot be deleted if it is being used as a backup by another PC/SSN entry.
- A PC/SSN entry cannot be deleted if it is referenced by an entry in the GTA table.
- The primary and backup point codes cannot be identical.
- A maximum of 9 subsystems for each point code is allowed.
- The PC cannot be equal to the node's own PC.

When a CS7 node changes the RI of a message requiring GTT to "Route on Subsystem," SCRC must look in the GTT MAP table to see if the subsystem is available and to determine which method to use to route the message. ITU-T Q.714 section 5.1 describes the following routing modes:

- **Solitary mode**

The destination subsystem or next translation node is chosen from the one single SCCP node. When that node or its SCCP fails, the SCCP management notifies the SCCP routing control; the traffic toward the **solitary** nodes is discarded or returned if return-option is set.

- Replicated service in **dominant mode**

The next translation node or destination subsystem can be chosen from two SCCP nodes. Traffic toward a specific subdomain (characterized by ranges of global titles) is normally sent to the SCCP of a primary node. When the primary node is inaccessible, the SCCP management notifies the routing control and this traffic is routed to the SCCP of a backup node. As soon as the primary node becomes accessible again, the traffic is again routed to it.

- Replicated service in dynamically load **shared mode**

The next translation node or destination subsystem is chosen from two SCCP nodes. The traffic is dynamically distributed to the next two nodes by the traffic-sending node. The next pair of SCCP nodes receiving the traffic back up each other. If one of the nodes becomes inaccessible, the SCCP management notifies the routing control and the traffic is routed to the other one. As soon as the previously inaccessible node becomes accessible again, the traffic is dynamically distributed to those two nodes again.

In the ANSI domain, GR-82 describes the requirement to support eight different destinations, each having a relative cost, rather than supporting only a primary and secondary node.

## Examples

The following example shows how to configure a solitary mated application for instance 2 with PC=1.10.1 and SSN=20:

```
cs7 instance 2 gtt map 1.10.1 20 sol
```

The following example shows how to configure a primary mated application with PC=1.20.1 and SSN=250. The backup is PC=2.20.2 SSN=20 operating in dominant mode.

```
cs7 gtt map 1.20.1 250 dom 2.20.2 250
```

The following example shows how to configure a primary mated application with PC=1.30.1 and SSN=250. The backup is PC=2.30.2 SSN=250 operating in shared mode.

```
cs7 gtt map 1.30.1 250 share 2.30.2 250
```

| <b>Command History</b> | <b>Release</b>            | <b>Modification</b>          |
|                        | 12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

**Usage Guidelines** Use this command when it becomes necessary (for example, for maintenance purposes) to prevent GTT translated messages from being sent to a point code in the map table.

**Note** This command is not applied to xUA DPC.

**Examples** The following example shows how to set the state of the remote point code 2.3.4 in the map table to prohibited:

```
cs7 gtt map sp prohibited 2.3.4
```

The following example shows how to set the state of the remote point code 2.3.4 in the map table for instance 2 to prohibited:

```
cs7 instance 2 gtt map sp prohibited 2.3.4
```

|                         |                                                         |                                                                            |

# cs7 gtt map ss

To change the state of a subsystem in the map table, use the **cs7 gtt map ss** privileged EXEC command.

```
cs7 [instance instance-number] gtt map ss {available | prohibited | ignore-ss | accept-ss}
    point-code ssn
```

## Syntax Description

|                        |                                                                                       |
|------------------------|---------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Changes the state of a subsystem in the map table for an instance.         |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                |
| <b>accept-ss</b>       | Processes subsystem test messages received for the affected point code and subsystem. |
| <b>available</b>       | Overrides the current state of the subsystem and sets it to available.                |
| <b>ignore-ss</b>       | Ignores subsystem test messages received for the affected point code and subsystem.   |
| <b>prohibited</b>      | Overrides the current state of the subsystem and sets it to prohibited.               |
| <i>point-code</i>      | Remote SP point code.                                                                 |
| <i>ssn</i>             | Subsystem number.                                                                     |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(11)SW  | This command was introduced. |
| 12.2(33)IRA |                              |

## Usage Guidelines

When the ITP receives a subsystem prohibited message from the network, it changes the state of the subsystem to “prohibited” and starts sending subsystem test messages to the node that sent the message. It continues to send test messages until it receives a subsystem available message.

With the **cs7 gtt map ss** command, you can manually change the subsystem state to prohibited. Because you are performing a manual operation on the ITP, the ITP cannot send a subsystem test message (as it normally would) because it does not have a point code to send the message to.

**Note** This command is not applied to xUA DPC.

## Examples

The following example shows how to set the state of the remote point code 2.3.4 in the map table to prohibited:

```
cs7 gtt map ss prohibited 2.3.4 10
```

The following example shows how to set the state of the remote point code 2.3.4 in the map table to prohibited for instance 1:

```
cs7 instance 1 gtt map ss prohibited 2.3.4 10
```

# cs7 gtt replace-db

To replace the entire contents of the GTT database, use the **cs7 gtt replace-db** privileged EXEC command.

**cs7** [**instance** *instance-number*] **gtt replace-db** *url*

## Syntax Description

|                        |                                                                              |
|------------------------|------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Replaces the entire contents of the GTT database for an instance. |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.       |
| <i>url</i>             | URL of replacement contents.                                                 |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(11)SW  | This command was introduced. |
| 12.2(33)IRA |                              |

## Usage Guidelines

GTT database replacement is non-disruptive as of Cisco IOS release 12.2(18)IXA, 12.4(11)SW, and 12.2(33)IRA.

## Examples

The following example shows how to replace the GTT database with a file named gttdata.txt in flash memory:

```
cs7 gtt replace-db flash:gttdata.txt
```

The following example shows how to replace the GTT database with a file named gttdata.txt in flash memory for instance 1:

```
cs7 instance 1 gtt replace-db flash:gttdata.txt
```

## cs7 gtt selector

To create and configure a GTT selector and enter the submode for modifying the attributes of an existing selector, use the **cs7 instance gtt selector** command in global configuration mode. To delete a selector, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **gtt selector** *selector* **tt** *tt* [**gti** *gti*] [**np** *np*] [**nai** *nai*]

**no** **cs7** *instance-number* **gtt selector** *selector*

### Syntax Description

|                        |                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Creates and configures a GTT selector for an instance.                                                                                                                                                                        |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                                                                                                                                                   |
| <i>selector</i>        | Name of the GTT selector. The name must be unique and no longer than 12 characters.                                                                                                                                                      |
| <b>tt</b>              | Specifies a translation type.                                                                                                                                                                                                            |
| <i>tt</i>              | Translation type. In the Called Party field of the GTT message, the SSP sets the TT to indicate which GTT table the STP should use. The TT is a 1-byte field that usually maps to a specific service. Valid numbers range from 0 to 255. |
| <b>gti</b>             | Specifies a global title indicator.                                                                                                                                                                                                      |
| <i>gti</i>             | (Optional) Global title indicator. Valid numbers are 2 (primarily used in the ANSI domain) or 4 (used in the ITU domain).                                                                                                                |
| <b>np</b>              | Specifies a numbering plan value.                                                                                                                                                                                                        |
| <i>np</i>              | (Optional) Numbering plan value. Valid range is 0 to 15.                                                                                                                                                                                 |
| <b>nai</b>             | Specifies a nature of address indicator.                                                                                                                                                                                                 |
| <i>nai</i>             | (Optional) Nature of address indicator. Required for GTI 4. Optional for GTI 2. Valid range is 0 to 127.                                                                                                                                 |

### Defaults

The default instance is 0.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The following rules apply to creating a GTT selector:

- NP and NAI cannot be specified if the variant is ANSI.
- GTI can be specified only if the variant is ITU.
- NP and NAI must be specified if GTI=4.

- For ITU nodes, GTI must be 2 or 4.
- For ANSI nodes, GTI must be 2.

The **cs7 gtt selector** *selector* command exits global configuration mode and enters cs7 gtt selector mode. This mode is used to modify attributes of a selector or to update global title addresses (GTAs) of a selector.

### Examples

The following example shows how to configure for instance 2 a selector named itp\_gtt with tt=0, gti=4, np=1, and nai=3:

```
cs7 instance 2 gtt selector itp_gtt 0 4 1 3
```

The following example shows how to configure a selector named itp\_gtt with tt=0, gti=4, np=1, and nai=3:

```
cs7 gtt selector itp_gtt 0 4 1 3
```

## cs7 gws action-set

To define gateway screening action sets, use the **cs7 gws action-set** command in global configuration mode. To remove the specification, use the **no** form of this command.

```
cs7 [instance instance-number] gws action-set action-set-name {allow | block [sccp-error error]| mlr
{ruleset ruleset-name | group result-group-name} [logging {silent | file [verbose] | console [verbose] | file
[verbose] console [verbose]}}] [pam pam-name]
```

```
no cs7 gws action-set action-set-name
```

### Syntax Description

|                                |                                                                                                                                                                                                                                                               |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>                | (Optional) Specifies an instance.                                                                                                                                                                                                                             |
| <i>instance-number</i>         | Instance number.                                                                                                                                                                                                                                              |
| <i>action-set-name</i>         | Name of the action set. Valid names may contain no more than 12 characters.                                                                                                                                                                                   |
| <b>allow</b>                   | Allows the message for further processing.                                                                                                                                                                                                                    |
| <b>block</b>                   | Blocks (rejects) the message.                                                                                                                                                                                                                                 |
| <b>mlr</b>                     | Routes the MSU using MLR.                                                                                                                                                                                                                                     |
| <b>ruleset</b>                 | Specifies a ruleset.                                                                                                                                                                                                                                          |
| <i>ruleset-name</i>            | Name of the ruleset.                                                                                                                                                                                                                                          |
| <b>group</b>                   | Specifies a result group.                                                                                                                                                                                                                                     |
| <i>result-group-name</i>       | Name of the result group.                                                                                                                                                                                                                                     |
| <b>logging</b>                 | (Optional) Enables logging.                                                                                                                                                                                                                                   |
| <b>silent</b>                  | Screens messages without any logging.                                                                                                                                                                                                                         |
| <b>file</b>                    | Copies the log to a file.                                                                                                                                                                                                                                     |
| <b>verbose</b>                 | (Optional) Prints packets up to 40 bytes to the file or displays them on the console along with other parameters.                                                                                                                                             |
| <b>console</b>                 | Displays the log on the console.                                                                                                                                                                                                                              |
| <b>sccp-error <i>error</i></b> | Configures <b>block</b> to send a UDTS to the originator of the SCCP packet. The UDT must also have return-on-error set and a return cause configured to return UDTS with an unqualified return cause.<br><br>This keyword is used only for incoming packets. |
| <b>pam</b>                     | This keyword indicates a PAM table is part of the GWS action.                                                                                                                                                                                                 |
| <i>pam-name</i>                | Name used to specify the particular PAM table.                                                                                                                                                                                                                |

### Defaults

The default logging type is **silent**.

### Command Modes

Global configuration

### Command History

### Usage Guidelines

An action set cannot be deleted if it is referenced by other entries.  
Action sets are independent of CS7 variants.

You can configure **block** with **scep-error** in MLR rules and address table entries.

### Examples

The following example shows how to define the action sets allowed-ver and blocked-ver:

```
cs7 gws action-set allowed-ver allow
cs7 gws action-set blocked-ver block
```

The following example shows how to define GWS action sets for the PAM tables named pam1, pam2, and pam3:

```
cs7 instance 0 gws action-set action-set1 mlr group test pam pam1
cs7 instance 0 gws action-set action-set2 mlr ruleset test pam pam2
cs7 instance 0 gws action-set action-set2 allow pam pam3
```

### Related Commands

|-----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">show cs7 gws action-set</a> | Displays ITP gateway screening action-set information.                                                                            |
| <a href="#">cs7 pam</a>                 | Identifies a packet address modification (PAM) table and enters the CS7 PAM submode.                                              |
| <a href="#">cgpa (cs7 pam)</a>          | Configures one cgpa entry in the PAM table.                                                                                       |
| <a href="#">cdpa (cs7 pam)</a>          | Configures one cdpa entry in the PAM table.                                                                                       |
| <a href="#">opc</a>                     | Configures an opc entry in the PAM table.                                                                                         |
| <a href="#">dpc</a>                     | Configures a dpc entry in the PAM table.                                                                                          |
| <a href="#">modify-failure (pam)</a>    | Specifies the desired action when the PAM table packet modification fails.                                                        |
| <a href="#">gta asname</a>              | Creates or modifies a GTA entry that translates to an M3UA or SUA application server name. The GTA entry may include a PAM table. |

## cs7 gws as

To configure a GWS AS screening table, use the **cs7 gws as** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **gws as** {**name** *as-name* | **default**}

**no cs7** [**instance** *instance-number*] **gws as** {**name** *as-name* | **default**}

### Syntax Description

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| <b>instance</b>        | Specifies an instance.                                                 |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0. |
| <b>name</b>            | Specifies an AS name.                                                  |
| <i>as-name</i>         | AS name.                                                               |
| <b>default</b>         | Default screening for all ASes.                                        |

### Defaults

The default instance is 0.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The GWS AS can be defined before or after the CS7 AS is defined.

The **cs7 gws as** command enables gws as configuration mode.

### Examples

The following example shows how to configure an AS table for gateway screening. The AS name is as2.

```
cs7 instance 0 gws as name as2
  outbound result action ALLOW
!
```

The following example shows how to configure an AS table for gateway screening. The AS name is default.

```
cs7 instance 0 gws as default
  inbound logging type block file console verbose result table SIO0
  outbound result action BLOCK
!
```

|---------------------------------|--------------------------------------------------------|
| <a href="#">show cs7 gws as</a> | Displays ITP gateway screening information for the AS. |

# cs7 gws linkset

To specify a linkset table for gateway screening, use the **cs7 gws linkset** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **gws linkset** { **name** *ls-name* | **default** }

**no cs7** [*instance instance-number*] **gws linkset** { **name** *ls-name* | **default** }

## Syntax Description

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| <b>instance</b>        | Specifies an instance.                                                 |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0. |
| <b>name</b>            | Specifies a linkset.                                                   |
| <i>ls-name</i>         | Linkset name.                                                          |
| <b>default</b>         | Specifies the default screening for all linksets.                      |

## Defaults

Logging is silent.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The GWS linkset can be defined before or after the CS7 linkset is defined.  
The **cs7 gws linkset** command enables gws linkset configuration mode.

## Examples

The following example shows how to configure a GWS linkset screening table for the linkset *to\_morehead1* and specify the inbound and outbound results:

```
cs7 instance 1 gws linkset name to_morehead1
  inbound result table OPCTTC1
  outbound result action BLOCK
```

## Related Commands

| Command                              | Description                                                 |
|--------------------------------------|-------------------------------------------------------------|
| <a href="#">show cs7 gws linkset</a> | Displays ITP gateway screening information for the linkset. |

# cs7 gws replace

To replace the running GWS configuration file or existing GWS tables with ones from a local or remote file, use the **cs7 gws replace** EXEC command.

**cs7** [**instance** *instance-number*] **gws replace** *url*

## Syntax Description

|                        |                                         |
|------------------------|-----------------------------------------|
| <b>instance</b>        | (Optional) Specifies an instance.       |
| <i>instance-number</i> | Instance number.                        |
| <i>url</i>             | Location where the file is to be saved. |

## Defaults

None.

## Command Modes

EXEC

## Command History

## Usage Guidelines

Cisco ITP does not need to be reloaded to replace the running configuration.

## Examples

The following example shows how to substitute a new GWS configuration for an older configuration:

```
cs7 gws-table replace xxx disk0:gws-replace
```

## Related Commands

| Command                               | Description                                                                                                                  |
|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 gws-table replace</a> | Replaces a single GWS table with the table configuration file specified by the URL.                                          |
| <a href="#">cs7 gws load</a>          | Loads a GWS configuration, including GWS tables, from a specified remote or local file during a Cisco ITP restart or reload. |
| <a href="#">show cs7 gws table</a>    | Displays the GWS table entries.                                                                                              |

# cs7 gws-table replace

To replace a single GWS table with the table configuration file specified by the URL, use the **cs7 gws-table replace EXEC** command.

**cs7** [*instance instance-number*] **gws-table replace** *table-name url*

## Syntax Description

|                        |                                         |
|------------------------|-----------------------------------------|
| <b>instance</b>        | (Optional) Specifies an instance.       |
| <i>instance-number</i> | Instance number.                        |
| <i>table-name</i>      | Name of the new GWS table.              |
| <i>url</i>             | Location where the file is to be saved. |

## Defaults

None.

## Command Modes

EXEC

## Command History

## Usage Guidelines

Cisco ITP does not need to be reloaded to replace the GWS table.

## Examples

The following example shows how to substitute a new GWS table for an older one:

```
cs7 gws-table replace disk0:gws-replace
```

| <a href="#">show cs7 gws table</a> | Displays the GWS table entries.                                                                                              |

# cs7 gws load

To load a GWS configuration, including GWS tables, from a specified remote or local file during a Cisco ITP restart or reload, use the **cs7 gws load** command in global configuration mode.

**cs7** [**instance** *instance-number*] **gws load** [*url*]

## Syntax Description

|                        |                                     |
|------------------------|-------------------------------------|
| <b>instance</b>        | (Optional) Specifies an instance.   |
| <i>instance-number</i> | Instance number.                    |
| <i>url</i>             | Location where file is to be saved. |

## Defaults

None.

## Command Modes

Global configuration

## Command History

### Usage Guidelines

Entering the **load** command does not initiate the restart or reload needed to trigger the actual load operation. It configures the load operation to occur when a restart or reload occurs.

If the load operation fails, the system generates an error message with the probable cause of the problem. Syntax errors in the loaded file can cause the load operation to fail.

## Examples

The following example shows how to load a GWS configuration:

```
cs7 gws load disk0:gws-config
```

**Usage Guidelines**

To be deleted, a table must have no entries and must not be referenced by any other entries.

The **cs7 gws table** command enables gws table configuration mode for the table type specified.

**Examples**

The following example shows how to configure a gateway screening table named allowed-dpc-1. The table type is **dpc** and the action is **allowed**.

```
cs7 instance 0 gws table allowed-dpc-1 type dpc action allowed
```

# cs7 host

To map a hostname to a point code, use the **cs7 host** command in global configuration mode. To remove all point code mappings for a name, use the **no cs7 host hostname** form of this command. To remove only one point code from a name mapping, use the **no cs7 host hostname point-code** form of this command.

```
cs7 host hostname [additional] {point-code [point-code ...]} | {point-code:instance-number  
[point-code:instance-number...]}
```

```
no cs7 host hostname [additional] {point-code [point-code ...]} | {point-code:instance-number  
[point-code:instance-number...]}
```

## Syntax Description

|                        |                                                                                |
|------------------------|--------------------------------------------------------------------------------|
| <b>additional</b>      | Appends an additional point code.                                              |
| <i>hostname</i>        | Name of the SS7 node.                                                          |
| <i>instance-number</i> | When the multiple instances feature is enabled, specifies the instance number. |
| <i>point-code</i>      | Point code to be mapped.                                                       |

## Defaults

None.

## Command Modes

| 12.2(33)IRA |                              |

## Usage Guidelines

You can map multiple point codes to the same hostname. This feature allows a node that is part of multiple instances to have the same name in all instances. However, a point code *cannot* be mapped to multiple names.

The optional **additional** keyword must be used when assigning an additional point code to a hostname. If you do not specify **additional**, an existing mapping of point codes to the name is replaced with the new configuration.

When the multiple instance feature is enabled, include the instance number.

To display the mapping of hostnames to point codes, use the **show hosts** command. If a point code represents a node (no clusters, networks, or summarized routes) and a name for the point code is configured, the name is displayed instead of the point code. Otherwise, the numeric point code is displayed.

You can specify a name instead of a point code in the **show cs7** and **ping cs7** commands. However, configuration statements require a numeric point code.

## Examples

The following configuration includes an example of the **cs7 host** command:

```
cs7 multi-instance
cs7 instance 0 variant ITU
cs7 instance 0 point-code format 14
cs7 instance 1 variant ANSI
cs7 instance 1 network-name ansi

cs7 host red 1.1.1:1 1234:0
cs7 host green 5121:0
!
cs7 instance 0 route-table
update route 5221 16383 linkset one
update route 5121 16383 linkset one
update route 5120 16376 linkset one
update route 1234 16383 linkset one
!
cs7 instance 1 route-table
update route 1.1.1 255.255.255 linkset two
!
cs7 instance 0 linkset one 666
!
cs7 instance 1 linkset two 3.3.3
!
```

## cs7 ignore-sccp-pcconv

To configure instance conversion to ignore the SCCP point code (PC), use the **cs7 ignore-sccp-pcconv** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **ignore-sccp-pcconv** *point-code*

**no** [*instance instance-number*] **ignore-sccp-pcconv** *point-code*

|                        |                                |
|------------------------|--------------------------------|
| <i>instance-number</i> | Specifies the instance number. |
| <i>point-code</i>      | Point code to be mapped.       |

### Defaults

None.

### Command Modes

### Command History

| Release      | Modification                 |
|--------------|------------------------------|
| 12.2(18)IXH1 | This command was introduced. |
| 12.4(15)SW5  |                              |
| 12.2(33)IRE  |                              |

### Usage Guidelines

When Cisco ITP is performing instance conversion, it tries to instance convert MTP3 PC and SCCP PCs. If Cisco ITP is doing MTP3 routing, there is no info for the SCCP PC and it produces an error. This command prevents that error when the CxPA PC does not have a PC conversion item configured for it.

Without the **cs7 ignore-sccp-pcconv** command configured, the Cisco ITP blocks the traffic because it is unable to convert the SCCP layer PC. No alias is defined for the SCCP layer PC.

With the **cs7 ignore-sccp-pcconv** command configured, the Cisco ITP does not attempt to convert the SCCP layer PC to the alias PC anymore. The traffic is routed normally.

### Examples

The following command shows how to configure the Cisco ITP to ignore the PC conversion failure in SCCP layer if the packet goes from y to x.

```
cs7 instance [x] ignore-sccp-pcconv [y]
```

# cs7 inhibit

To inhibit a link, use the **cs7 inhibit** user EXEC command with the linkset name and the link number. To reverse the inhibit, use the **cs7 uninhibit** command.

**cs7 inhibit** *linkset link*

**cs7 uninhibit** *linkset link*

| 12.2(33)IRA |                              |

## Usage Guidelines

Use the **inhibit** command when you need to make or keep a signaling link unavailable to user-generated signaling traffic (for example, for maintenance). Inhibiting a link is allowed only if the action does not cause any previously accessible destinations to become inaccessible at either end of the signaling link.

A signaling traffic management command, **inhibit** does not cause any link status changes at Level 2. In particular, a signaling link that was active and in service before being inhibited will remain so, and will be able to transmit and receive maintenance and test messages.

## Examples

The following command shows how to inhibit link 0 on the linkset named tony:

```
cs7 inhibit tony 0
```

|-------------------------------------|-------------------------------------------|
| <a href="#">shutdown (cs7 link)</a> | Disables a link or linkset.               |
| <a href="#">cs7 uninhibit</a>       | Puts the link or linkset back in service. |

# cs7 large-msu-support

To configure large MSU support for all M2PA links in a CS7 instance, use the **cs7 instance large-msu-support** command in global configuration mode. To disable the support, use the **no** form of this command.

**cs7 instance** *instance-number* **large-msu-support**

**no cs7 instance** *instance-number* **large-msu-support**

## Syntax Description

|                        |                  |
|------------------------|------------------|
| <i>instance-number</i> | Instance number. |
|------------------------|------------------|

## Defaults

M2PA restricts the outgoing packet size to 273 bytes.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXH | This command was introduced. |
| 12.4(15)SW3 |                              |
| 12.2(33)IRC |                              |

## Usage Guidelines

This command allows an instance to carry MSU sizes of up to 4096 bytes instead of the default maximum of 273 bytes. SCTP segmentation and reassembly is used for the MSUs that are greater than the 1500 bytes and carried by the M2PA link, because M2PA runs over IP networks with a maximum MSU size of 1500 bytes.

## Examples

The following example shows large MSU is supported on all the M2PA links in that CS7 instance:

```
cs7 instance 0 large-msu-support
```

|-----------------------------|-----------------------------------------------------|
| <a href="#">cs7 linkset</a> | Specifies a linkset and enters cs7 linkset submode. |

# cs7 linkset

To specify a linkset and enter cs7 linkset submode, use the **cs7 linkset** command in global configuration mode. To disable the specification, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **linkset** *ls-name* *adj-pc* [**local-pc** [*pc*]]

**no cs7** [**instance** *instance-number*] **linkset** *ls-name* *adj-pc*

## Syntax Description

|                        |                                                                                                                     |
|------------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies a linkset for an instance.                                                                     |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                              |
| <i>ls-name</i>         | Name of the linkset. (Linkset names are case-specific.)                                                             |
| <i>adj-pc</i>          | Point code of the adjacent signaling point.                                                                         |
| <b>local-pc</b>        | (Optional) Specifies another point code, which functions as a second linkset between the ITP and the adjacent node. |
| <i>pc</i>              | Can be the ITP's primary or secondary point code. By default, it is the primary point code.                         |

## Defaults

The specified local pc is the ITP's primary point code.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

You must specify the SS7 variant and the point code before you can configure linksets.

When you remove a linkset from the configuration with the **no cs7 linkset** command, a few seconds elapse before the system responds. This delay ensures that all previous shutdown-related activity has completed for the linkset.

### Note

To avoid overloading the CPU, we recommend that you shut down interfaces that are configured but not provisioned as part of a linkset.

With the optional multiple linkset feature, you can configure two linksets to an adjacent node, each having 16 links, for a total of 32 links. To configure the linksets, use the optional keyword **local-pc**. This local PC must be either the ITP's primary PC (configured with the **cs7 point-code** command) or the ITP's secondary PC, configured with the **cs7 secondary-pc** command. (By default, it is the primary PC.)

When a linkset is created using the **cs7 linkset** command, a route table entry is automatically created for destination *adj-pc*. Because this entry is the direct linkset to this destination, it is assigned the highest priority of 1.

When two linksets to the adjacent node are created, they are automatically entered in the route table as a combined route to the adjacent node. Traffic going to the adjacent node is divided between the two linksets based on the signaling link selector (SLS).

When you issue the **cs7 linkset** command, you enter cs7 linkset submode. In this submode, you have access to commands that allow you to further configure linksets.

Linkset names are case-specific.

## Examples

The following example shows how to configure a single a linkset named linkset1 with an adjacent node at point code 2.2.2.:

```
cs7 linkset linkset1 2.2.2
```

The following example shows how to configure two linksets to the adjacent node 2.2.2.

Linkset1 specifies the adjacent signaling point 2.2.2 and the ITP's primary point code 1.1.1.

Linkset2 specifies the adjacent signaling point 2.2.2 and the ITP's secondary point code 1.1.2.

```
cs7 linkset linkset1 2.2.2 local-pc 1.1.1
cs7 linkset linkset2 2.2.2 local-pc 1.1.2
```

The following example shows how to configure two linksets on instance 1 to the adjacent node 2.2.2.

Linkset1 specifies the adjacent signaling point 2.2.2 and the ITP's primary point code 1.1.1.

Linkset2 specifies the adjacent signaling point 2.2.2 and the ITP's secondary point code 1.1.2.

```
cs7 instance 1 linkset linkset1 2.2.2 local-pc 1.1.1
cs7 instance 1 linkset linkset2 2.2.2 local-pc 1.1.2
```

|---------------------------------------------------------|----------------------------------------------------------------------------|
| <a href="#">cs7 mtp3 tuning rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination. |
| <a href="#">show cs7 linkset</a>                        | Displays ITP linkset information.                                          |

# cs7 local-peer

To specify the local peer and, optionally, configure M2PA/SCTP offload, use the **cs7 local-peer** command in global configuration mode. To remove the local peer from the ITP configuration, use the **no** form of this command.

**cs7 local-peer** *port-number* [**offload**] [*line-card-slot-number*] [*bay-number*]

**no local-peer** *port-number* [**offload**] [*line-card-slot-number*] [*bay-number*]

## Syntax Description

|                              |                                                               |
|------------------------------|---------------------------------------------------------------|
| <i>port-number</i>           | Port number of the local peer. Range is 1024 to 49151.        |
| <b>offload</b>               | Configures local peer for M2PA/SCTP offload onto a line card. |
| <i>line-card-slot-number</i> | Line card slot number. Valid range is 0 to 16.                |

## Defaults

None.

## Command Modes

Global configuration

## Command History

| Release                                  | Modification                                                                       |
|------------------------------------------|------------------------------------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                                                       |
| 12.2(25)IRA                              | Extended the range of the <i>bay-number</i> argument for use with SAMI processors. |

## Usage Guidelines

This command is not instance related and cannot be specified with the **instance** keyword.

When you issue the **cs7 local-peer** command, you enter cs7 local peer submode. In this submode, you can configure a local IP address for an instance.

The range for *bay-number* (3 to 8) reflects the labeling of the SAMI card processors. It is consistent with other SAMI applications, as well as the faceplate numbering for the console connections.

## Examples

The following example shows how to offload M2PA/SCTP onto the SAMI card in slot 2, processor 3:

```
cs7 local-peer 7000 offload 2 3
```

The following example shows how to specify a local peer with a local port number of 7000:

```
cs7 local-peer 7000
```

The following example shows how to offload M2PA/SCTP onto the line card in slot 2, bay 0:

```
cs7 local-peer 7000 offload 2 0
```

|                  | <a href="#">show cs7 sami ip</a>   | Displays an ITP SAMI configuration.      |

## cs7 local-sccp-addr-ind

To customize the setting of the national use field within SCCP management calling and called party addresses, use the **cs7 local-sccp-addr-ind** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **local-sccp-addr-ind** {**national** | **international**}

**no cs7** [*instance instance-number*] **local-sccp-addr-ind** {**national** | **international**}

### Syntax Description

|                        |                                                                                                                                               |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies on an instance how to set the value of the national indicator value within SCCP management calling and called addresses. |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                                                        |
| <b>national</b>        | Sets the address indicator field to '1'b to indicate national format.                                                                         |
| <b>international</b>   | Sets the address indicator field to '0'b to indicate international format.                                                                    |

### Defaults

The default value for instances configured with the ANSI variant is national ('1'b value), and the default for all other variants is international ('0'b value).

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

Bit 8 of the address indicator field within the SCCP calling and called address parameters is reserved for use by national specifications. (The ANSI variant, for example, sets this indicator to '1'b to indicate that the SCCP addresses are in a national format.) SCCP processing of the addresses is not affected by the setting of this indicator, but some STP and SCP implementations perform validity checking on the indicator.

The configuration of this command only affects the construction of SCCP management address fields.

### Examples

In the following example, the default instance (instance 0) is configured with the China variant and the address indicator field is set to national. Instance 1 is configured with the ANSI variant and the address indicator field is set to international.

```
cs7 variant china
cs7 local-sccp-addr-ind national

cs7 instance 1 ansi
cs7 instance 1 local-sccp-addr-ind international
```

# cs7 log

To enable the ITP to log events, errors, and traces, use the **cs7 log** command in global configuration mode. To disable logging, use the **no** form of this command.

**cs7 log** *type* { **checkpoint** *seconds destination* | **size** *entries* | **verbose** }

**no cs7 log** *type*

## Syntax Description

|                    |                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i>        | Specifies the type of log. Valid types are:                                                                                                                                                        |
| <b>gtt</b>         | Log related to global title translation errors.                                                                                                                                                    |
| <b>gws-nontest</b> | Enhanced gateway screening logging in nontest mode.                                                                                                                                                |
| <b>gws-test</b>    | Enhanced gateway screening logging in test mode.                                                                                                                                                   |
| <b>checkpoint</b>  | Enables automatic archiving of a log to a remote or local destination at a specified interval.                                                                                                     |
| <i>seconds</i>     | Archiving interval in seconds. The valid range is 60 to 86400 seconds.                                                                                                                             |
| <i>destination</i> | Specifies the location where the log is stored. Valid destinations are:                                                                                                                            |
| <b>cs7:</b>        | path to store log                                                                                                                                                                                  |
| <b>flash:</b>      | path to store log                                                                                                                                                                                  |
| <b>ftp:</b>        | path to store log                                                                                                                                                                                  |
| <b>null:</b>       | path to store log                                                                                                                                                                                  |
| <b>nvr:</b>        | path to store log                                                                                                                                                                                  |
| <b>nvram:</b>      | path to store log                                                                                                                                                                                  |
| <b>rcp:</b>        | path to store log                                                                                                                                                                                  |
| <b>system:</b>     | path to store log                                                                                                                                                                                  |
| <b>tftp:</b>       | path to store log                                                                                                                                                                                  |
| <b>size</b>        | Specifies the maximum number of entries in the log.                                                                                                                                                |
| <i>entries</i>     | Maximum number of entries in the log. The valid range is 0 to 100,000 entries. The default is 0. When the limit is reached, new entries overwrite existing entries, starting from the first entry. |
| <b>verbose</b>     | Enables verbose output of log entries.                                                                                                                                                             |

## Defaults

Logging is off. The default log size is 0.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

The log is saved to an internal file. The filename is created internally and comprises the log type and the timestamp indicating when the checkpoint occurred.

**Examples**

The following example shows how to archive a GWS log every hour and send the log to the destination directory tftp://10.1.1.2/logs:

```
cs7 log gws-test checkpoint 3600 tftp://10.1.1.2/logs
```

The following example shows how to specify the maximum number of entries in the circular log. When the current number of entries exceeds 10000, the first entry is overwritten.

```
cs7 log gws-test size 10000
```

The following example shows how to specify the checkpoint DIRECTORY. The filename is created automatically and contains the timestamp when the checkpoint occurred.

```
cs7 log gws-test checkpoint 10000 tftp://bizarre/rosebud/
```

**Related Commands**

| Command                      | Description               |

| <a href="#">show cs7 log</a> | Displays the current log. |

# cs7 log checkpoint

To enable automatic archiving of a log to a remote or local destination at a specified interval of time, use the **cs7 log checkpoint** command in global configuration mode. To disable the checkpoint operation, use the **no** form of this command.

**cs7 log type checkpoint secs destination**

**no cs7 log type checkpoint secs destination**

## Syntax Description

|                    |                                                   |
|--------------------|---------------------------------------------------|
| <i>type</i>        | Specifies the type of log.                        |
| <i>secs</i>        | Specifies the interval in seconds.                |
| <i>destination</i> | Path and filename of the log archive destination. |

## Defaults

Log checkpointing is off.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |

## cs7 m3ua

To specify the local port number for M3UA and enter m3ua submode, use the **cs7 m3ua** command in global configuration mode. To delete the M3UA configuration (if there are no configured M3UA ASes or ASPs), use the **no** form of this command.

**cs7 m3ua** *port-number* [**offload**] [*line-card-slot-number*] [*bay-number*]

**no m3ua** *port-number* [**offload**] [*line-card-slot-number*] [*bay-number*]

### Syntax Description

|                              |                                                                                                                            |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>port-number</i>           | Port number of the local peer. Range is 1024 to 49151. The M3UA well-known port is 2905.                                   |
| <b>offload</b>               | (Optional) Configures the local peer for M2PA/SCTP offload onto a line card. Offloading applies only to the 7600 platform. |
| <i>line-card-slot-number</i> | (Optional) Line card slot number. Valid range is 0 to 16.                                                                  |

### Defaults

None.

### Command Modes

Global configuration

### Command History

| Release                                  | Modification                                                               |
|------------------------------------------|----------------------------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                                               |
| 12.2(25)IRA                              | Extends the range of the bay-number argument for use with SAMI processors. |

### Usage Guidelines

The range for *bay-number* (3 to 8) reflects the labeling of the SAMI card processors. It is consistent with other SAMI applications, as well as the faceplate numbering for the console connections.

M3UA uses SCTP to communicate with application server processes (ASPs). The **offload** keyword enables the ITP to offload M3UA SCTP message processing to the line card. If you are configuring M3UA SCTP offload, the **local-ip** *ip-address* must be an IP address that was already configured on the line card to which you are offloading this M3UA instance. When offload is enabled, only a single IP route is allowed for each destination.

If offloaded, a specific M3UA instance can run on only one line card, but different offloaded M3UA instances can run on different line cards or on the same line card. If you offload M3UA or SUA to a line card, that line card cannot also be used for M2PA offload.

Issuing the **cs7 m3ua** command enables cs7 m3ua submode.

The **cs7 m3ua** command cannot be specified with the **instance** keyword.

The M3UA configuration must be removed before the variant or local point code can be removed.

## Examples

The following example shows how to specify a local port number of 2000 for M3UA:

```
cs7 m3ua 2000 offload 2 0
local-ip 10.10.10.7
```

The following example shows how to offload two different instances of M3UA processing to the line card in slot 5, bay 0 and another instance to the line card in slot 6, bay 0:

```
cs7 m3ua 3000 offload 5 0
local-ip 10.10.10.8
!
cs7 m3ua 3500 offload 5 0
local-ip 10.10.10.8
!
cs7 m3ua 4000 offload 6 0
local-ip 10.10.10.9
```

|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

|                         |                                                                                                                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | By default, the ITP sends response-mode UPU messages when a received message has a DPC equal to a locally managed ITP PC (including M3UA and SUA AS PCs) that is available, and the service indicator (SI) within the received message is not supported or not available. |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

With **cs7 m3ua extended-upu** configured, the ITP also sends UPU messages in the following cases. (Note that the destination M3UA AS PC must still be available.)

- If the M3UA AS goes down or becomes inactive, send UPU message to the OPC in the AS routing key with unavailability cause = inaccessible remote user.
- If the M3UA AS is inactive or down and matches a received MSU, send UPU message to the OPC in the MSU with unavailability cause = inaccessible remote user.
- If an ISUP or TUP MSU is received and matches no routing key, send UPU message to the OPC in the MSU with unavailability cause = unequipped remote user.
- If an M3UA AS with OPC configured and SI configured for ISUP or TUP becomes inactive, send UPU message to the OPC in the AS routing key.

Extended UPU is not allowed if any M3UA AS has a CIC range configured. Conversely, CIC range configuration is not allowed if extended UPU is enabled.

In all cases, UPU is rate-limited to no more than 1 per second per SI value.

|                 |                                                                        |
|-----------------|------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to enable M3UA extended UPU operation: |
|-----------------|------------------------------------------------------------------------|

```
cs7 m3ua extended-upu
```

## cs7 mated-sg

To configure a connection to a mated SG, use the **cs7 mated-sg** command in global configuration mode. To remove the mate definition from the configuration, use the **no** form of this command.

**cs7 mated-sg** *name* *remote-port* [*local-port*] [**passive**]

**no** **cs7 mated-sg** *name* *remote-port* [*local-port*] [**passive**]

|                           |                    |                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>name</i>        | Name of the mated SG. The mated-SG name is a unique name used to identify the mate for configuration and monitoring. This name may be up to 12 characters long. The first character must be alphabetic. The mate name cannot match a reserved keyword (such as <b>m3ua</b> , <b>sua</b> , <b>all</b> , <b>operational</b> , <b>active</b> , <b>statistics</b> , <b>bindings</b> , or <b>detail</b> ). |
|                           | <i>remote-port</i> | Remote port number of the mate, in the range 1024 to 65535. This argument is used for validation. The SCTP connection requests from the mate must come in with this remote port number.                                                                                                                                                                                                               |
|                           | <i>local-port</i>  | (Optional) Local port number for SGMP link offloaded to line card                                                                                                                                                                                                                                                                                                                                     |
|                           | <b>passive</b>     | (Optional) Does not attempt to initiate the connection to the mate.                                                                                                                                                                                                                                                                                                                                   |

**Defaults** None.

**Command Modes** Global configuration

|                        |                                          |                                                |

|                        | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                   |
|                        | 12.2(33)IRD                              | The <i>local-port</i> argument was introduced. |
|                        |                                          |                                                |

**Usage Guidelines** The Signaling Gateway Mate Protocol (SGMP) is used to establish an association to the mated SG with an equivalent SG configuration.

The **cs7 mated-sg** command allows you to define the mated SG and enables cs7 mated-sg configuration submode. Only one mate can be defined on a SG. The mate uses the SGMP local port.

The **no** form of the **cs7 mated-sg** command deletes the mate definition from configuration. You must remove the mate from all **cs7 asroute** definitions before this command can be deleted from the configuration.

This command is not instance related and cannot be specified with the **instance** keyword.

**Examples** The following example shows how to specify a mated SG named mate2 at remote port 5000 with the **passive** keyword:

```
cs7 mated-sg mate2 5000 passive
```

**Related Commands**

|------------------------------------------|-----------------------------------------------------------------------------|
| <a href="#">cs7 as</a>                   | Defines an AS.                                                              |
| <a href="#">cs7 sgmp</a>                 | Specifies the local port number for SGMP and enters cs7 sgmp submode.       |
| <a href="#">remote-ip (cs7 mated-sg)</a> | Configures a remote IP address to associate incoming packets from the mate. |
| <a href="#">show cs7 mated-sg</a>        | Displays mated-SG information.                                              |

# cs7 max-dynamic-routes

To specify the maximum number of dynamic routes, use the **cs7 max-dynamic routes** command in global configuration mode. To restore the default maximum number of dynamic routes, use the **no** form of this command.

**cs7 max-dynamic-routes** *number*

**no cs7 max-dynamic-routes** *number*

|                           |               |                                                                                                             |
|---------------------------|---------------|-------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>number</i> | Maximum number of dynamic routes that can be created. The range is 100 to 2000. The default number is 1000. |

# cs7 mlr address-table

To define a table of addresses to use when searching with the previously specified routing parameter, use the **cs7 mlr address-table** command in global configuration mode. To remove the definition, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **mlr address-table** *table-name*

**no** [**instance** *instance-number*] **cs7 mlr address-table** *table-name*

## Syntax Description

|                        |                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies the ITP network instance in which the MLR table is valid.                                                                                                                                  |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                                                                                                                          |
| <i>table-name</i>      | Identifies a name to be associated with this multilayer result table. The name must be unique among all multilayer routing tables. The name is specified as a character string with a maximum of 12 characters. |

## Defaults

The default instance is 0.

## Command Modes

Global configuration

## Command History

| Release    | Modification                 |
|------------|------------------------------|
| 12.2(21)SW | This command was introduced. |

## Usage Guidelines

The MLR address table contains addresses and destinations that more than one rule may reference. If a table is required in more than one instance, then it must be defined in each appropriate instance. If the instance is not specified, then the table may be used only for the default network instance, 0.

Both DSMR (SMS MO Proxy) and MLR can reference MLR address tables.

The **cs7 mlr address-table** command enables cs7 mlr address-table configuration mode.

## Examples

The following example shows how to define a table of addresses named VSMSC-ADDRS:

```
cs7 mlr address-table VSMSC-ADDRS
```

## Related Commands

| Command                                      | Description                                                  |
|----------------------------------------------|--------------------------------------------------------------|
| <a href="#">addr (cs7 mlr address-table)</a> | Specifies an MLR address within the MLR address table.       |
| <a href="#">show cs7 mlr address-table</a>   | Displays addresses matched within the CS7 MLR address table. |

# cs7 mlr load

To load an MLR configuration, including MLR tables, from a specified remote or local file during a Cisco ITP restart or reload, use the **cs7 mlr load** privileged EXEC command.

**cs7** [**instance** *instance-number*] **mlr load** *url*

## Syntax Description

|                        |                                         |
|------------------------|-----------------------------------------|
| <b>instance</b>        | (Optional) Specifies an instance.       |
| <i>instance-number</i> | Instance number.                        |
| <i>url</i>             | Location where the file is to be saved. |

## Defaults

None.

## Command Modes

Privileged EXEC

## Command History

### Usage Guidelines

Entering the **load** command does not initiate the restart or reload needed to trigger the actual load operation. It configures the load operation to occur when a restart or reload occurs.

If the load operation fails, the system generates an error message with the probable cause of the problem. Syntax errors in the loaded file can cause the load operation to fail.

## Examples

The following example shows how to load an MLR configuration:

```
cs7 mlr load disk0:mlr-config
```

## Related Commands

| Command                         | Description                                                               |
|---------------------------------|---------------------------------------------------------------------------|
| <a href="#">cs7 save mlr</a>    | Saves a general MLR configuration to a separate file.                     |
| <a href="#">cs7 mlr replace</a> | Replaces the running configuration file with a file specified by the URL. |

## cs7 mlr modify-profile

To specify an MLR modify profile, use the **cs7 mlr modify-profile** configuration command. To remove the specification, use the **no** form of this command.

A modification profile specifies SCCP and MAP address modification rules for messages that are routed by a configured set of MLR rules. For each profile, you must configure the instance, a unique profile name, the protocol, and optional operation. Multiple profiles can be created for each instance. Only one profile may be assigned to a specific rule.

MLR supports CgPA and CdPA modification for all GSM-MAP and ANSI-41 operations, provided that the protocol and operation of the associated rule and modify-profile are compatible.

```
cs7 [instance instance] mlr modify-profile profile-name {gsm-map [operation-name] | ansi-41}
```

```
no cs7 [instance instance] mlr modify-profile profile-name {gsm-map [operation-name] | ansi-41}
```

### Syntax Description

|                        |                                                                                                                                                                                                                                                                                                                                                                           |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies an instance.                                                                                                                                                                                                                                                                                                                                         |
| <i>instance-number</i> | Instance number.                                                                                                                                                                                                                                                                                                                                                          |
| <i>profile-name</i>    | Identifies a name to be associated with this MLR modify-profile. The name must be unique among all CS7 MLR modify-profiles. The name is specified as a character string with a maximum of 12 characters.                                                                                                                                                                  |
| <b>gsm-map</b>         | Modify-profile is valid for GSM MAP messages.                                                                                                                                                                                                                                                                                                                             |
| <b>ansi-41</b>         | Modify-profile is valid for ANSI-41 messages.                                                                                                                                                                                                                                                                                                                             |
| <i>operation-name</i>  | (Optional) Operation for which the modify-profile is valid. The only currently valid operation name is <b>sri-sm</b> , which indicates that the modify-profile will operate only on a GSM-MAP sendRoutingInfoForSM message. If an operation is not specified, then the profile applies to all operations using the configured protocol (for example, GSM MAP or ANSI-41). |

### Defaults

None.

### Command Modes

cs7 mlr modify-profile configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **cs7 mlr modify-profile** command enters cs7 mlr modify configuration submode.

You can create multiple modify profiles for each instance, but can specify only one profile within a rule.

MLR currently supports modifying only the service center address (orig-smsc) and the calling party address (CgPA) for SRI-SM messages.

The modify-profile is assigned to a rule using the **modify-profile rule** command. If an MLR rule matches, then the modify-profile is applied to messages that are routed using MLR. Address translation is performed only if the matched rule contains a modify-profile.

MLR modify-profile and PAM cannot be configured simultaneously.

| Related Commands | Command                                               | Description                                                                                         |
|------------------|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
|                  | <a href="#">clear cs7 accounting</a>                  | Specifies a combination trigger based on the combination of the calling party and the called party. |
|                  | <a href="#">modify-profile (cs7 mlr ruleset rule)</a> | Specifies SCCP and MAP addresses to modify in messages that are routed with MLR.                    |

# cs7 mlr options

To specify MLR global options, use the **cs7 mlr options** command in global configuration mode. To remove the definition, use the **no** form of this command.

**cs7** [*instance instance-number*] **mlr options**

**no cs7** [*instance instance-number*] **mlr options**

## Syntax Description

|                        |                                                                                                              |
|------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies the IP Transfer Point (ITP) network instance in which the MLR global options are valid. |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                       |

## Defaults

The default instance is 0.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXB | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **cs7 mlr options** command enables cs7 mlr options configuration mode.

## Examples

The following example shows how to enable global options and, when a packet is routed with MLR, insert the Message Transfer Part (MTP) destination point code (DPC) into the called party (cdpa) point code (pc) if the cdpa is null. This global option applies to the MLR-routed results **pc**, **pcssn**, **gt**, and **asname**.

```
cs7 instance 0 mlr options
  insert-dpc-in-cdpa
```

## Related Commands

| Command                                               | Description                                                                                   |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <a href="#">insert-dpc-in-cdpa</a>                    | Global option inserts DPC into the cdPA PC for packets that are routed with MLR.              |
| <a href="#">preserve-opc (cs7 mlr ruleset)</a>        | Preserves the original originating point code (OPC) when an MLR is selected in this instance. |
| <a href="#">modify-profile (cs7 mlr ruleset rule)</a> | Specifies SCCP and MAP addresses to modify in messages that are routed with MLR.              |

# cs7 mlr replace

To replace the running MLR configuration file or existing MLR tables with ones from a local or remote file, use the **cs7 mlr replace** EXEC command.

**cs7** [**instance** *instance-number*] **mlr replace** *url*

## Syntax Description

|                        |                                         |
|------------------------|-----------------------------------------|
| <b>instance</b>        | (Optional) Specifies an instance.       |
| <i>instance-number</i> | Instance number.                        |
| <i>url</i>             | Location where the file is to be saved. |

## Defaults

None.

## Command Modes

EXEC

## Command History

## Usage Guidelines

Cisco ITP does not need to be reloaded to replace the running configuration.

## Examples

The following example shows how to substitute a new MLR configuration for an older configuration:

```
cs7 mlr replace disk0:mlr-config
```

## Related Commands

| Command                      | Description                                                                                                                  |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 mlr load</a> | Replaces a single MLR table with the table configuration file specified by the URL.                                          |
| <a href="#">cs7 save mlr</a> | Loads a GWS configuration, including GWS tables, from a specified remote or local file during a Cisco ITP restart or reload. |

## cs7 mlr result

To name a multilayer result group, use the **cs7 mlr result** command in global configuration mode. The result group lists destination resources that process traffic to be routed based on multilayer information.

To delete a multilayer result group, use the **no** form of this command.

```
cs7 [instance instance-number] mlr result result-name [protocol {gsm-map | ansi41}] [mode {wrr | dest-sme-binding}]
```

```
no cs7 [instance instance-number] mlr result result-name [protocol {gsm-map | ansi41}] [mode {wrr | dest-sme-binding}]
```

| Syntax Description      |                                                                                                                                                                                                                                                                                             |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>         | (Optional) Specifies the ITP network instance in which the MLR table is valid. If a table is required in more than one instance, then it must be defined in each appropriate instance. If an instance is not specified, then the table may only be used for the default network instance 0. |
| <i>instance-number</i>  | Instance number. The valid range is 0 to 7. The default instance is 0.                                                                                                                                                                                                                      |
| <i>result-name</i>      | Identifies a name to be associated with this multilayer result table. The name must be unique among all multilayer routing tables. The name is specified as a character string with a maximum of 12 characters.                                                                             |
| <b>protocol</b>         | Used only by SMS-MO Proxy (DSMR). It is included in MLR result group configuration in case a DSMR result references an MLR result group. It is not used by MLR.                                                                                                                             |
| <b>gsm-map</b>          | Protocol used by SMS-MO Proxy (DSMR) for the results in this result group.                                                                                                                                                                                                                  |
| <b>ansi41</b>           | Protocol used by SMS-MO Proxy (DSMR) for the results in this result group. The protocol is ANSI-41/IS-41.                                                                                                                                                                                   |
| <b>mode</b>             | Algorithm used by this result group. If <b>mode</b> is not configured, then the mode defaults to WRR.                                                                                                                                                                                       |
| <b>wrr</b>              | Weighted round-robin algorithm is used by this result group to select a result.                                                                                                                                                                                                             |
| <b>dest-sme-binding</b> | Dynamic B-address binding algorithm is used by this result group to select a result. This mode uses a weighted distribution algorithm that binds a set of B-addresses to the same available result.                                                                                         |

### Defaults

The default instance is 0.

The default mode is WRR.

### Command Modes

Global configuration

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

The result group lists the appropriate destination resources and the mechanism used to select a single destination for a given packet. State information is determined for each possible destination. Only available destinations are considered for routing. Note, however, that the distribution algorithms consider GT results to be always available. Ensure that the proper GT configuration is in place and available for GT routing.

MLR provides the following result group distributions modes:

- **Weighted round-robin (WRR)**

This distribution algorithm properly balances SMS workload to servers of varying capacity. Each server within a result group (application group or multilayer result table) is assigned a server weight from 0 to 10. The value of 0 indicates that the server is a backup, and should be used only when all of the servers in the group with a nonzero weight have failed. Congested resources are used only if no available, noncongested destinations exist.

- **Dynamic B-address binding**

This mode uses a hashing algorithm based on the message's B-address to determine which result (SMSC) a message is to be routed to for delivery. The algorithm selects the same result (SMSC) each time based on the B-address to prevent out-of-order messaging. SMSCs with greater capacity are configured as such using the result's **weight** keyword. The results (SMSCs) are inserted into the result group using the **order** keyword. If an unplanned SMSC outage occurs (in other words, if a result is unavailable), then these messages destined for the unavailable SMSC are rerouted to the remaining SMSCs. Note that an SMSC outage does not affect the mapping for available SMSCs. This algorithm handles routing of alphanumeric B-addresses, as well as numeric B-addresses.

SMS MO Proxy sms-mo messages can use MLR result groups with WRR or dest-sme-binding mode. This ITP enhancement was introduced to simplify configuration because both SMS MO Proxy and MLR dest-sme-binding result groups must be identically configured in an SMS MO Proxy solution. However, DMSR does not currently support **asname** command results within an SMS result group. DMSR can reference only those MLR groups that contain no **asname** results.

**Examples**

The following example shows how to identify a multilayer result group named vas-grp:

```
cs7 mlr result vas-grp
  asname voting-as1 weight 1
  asname voting-as2 weight 1
  pc 3.3.1 weight 0
  pc 3.3.2 weight 0
  pc 3.3.3 weight 0
```

The following example shows how to identify a multilayer result group named MLR-BINDING:

```
cs7 instance 0 mlr result MLR-BINDING mode dest-sme-binding
  pc 5.5.3 order 10 weight 20
  pc 1.5.6 order 20 weight 40
  asname AS1 order 30 weight 15
  pc 5.5.6 order 40 weight 60
```

| Related Commands | Command                                                | Description                                                                                |
|------------------|--------------------------------------------------------|--------------------------------------------------------------------------------------------|
|                  | <a href="#">asname (cs7 mlr result)</a>                | Specifies a particular destination M3UA or SUA application server.                         |
|                  | <a href="#">pc (cs7 mlr result)</a>                    | Specifies the destination point code.                                                      |
|                  | <a href="#">gt (cs7 mlr result)</a>                    | Specifies an outbound global title destination from within a result group.                 |
|                  | <a href="#">response-timer (cs7 sms profile parms)</a> | Specifies the processing to perform on a packet matching the specified trigger and rule.   |
|                  | <a href="#">show cs7 mlr configuration</a>             | Displays the result to select from an SMS result group for the specified dest-sme address. |
|                  | <a href="#">show cs7 mlr result</a>                    | Specifies a multilayer result group.                                                       |

## cs7 mlr ruleset

To specify sets of rules to process traffic-matching triggers defined in a multilayer routing table, use the **cs7 mlr ruleset** command in global configuration mode. To remove the rules, provided that no defined MLR triggers are using the ruleset, use the **no** form of this command.

```
cs7 [instance instance-number] mlr ruleset result-name [protocol {gsm-map | ansi-41}]
[event-trace]
```

```
no cs7[instance instance-number] mlr ruleset result-name [protocol {gsm-map | ansi-41}]
[event-trace]
```

|                        |                                                                                                                                                                                                                                                                               |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) ITP network instance in which the MLR table is valid. If a table is required in more than one instance, then it must be defined in each appropriate instance. If an instance is not specified, then the table may only be used for the default network instance 0. |
| <i>instance-number</i> | An integer value in the range 0 to 7. The default instance is 0.                                                                                                                                                                                                              |
| <i>result-name</i>     | Identifies a name to be associated with this multilayer ruleset table. The name must be unique among all multilayer ruleset tables. The name is specified as a character string with a maximum of 12 characters.                                                              |
| <b>protocol</b>        | (Optional) Specifies an application layer protocol filter for this ruleset.                                                                                                                                                                                                   |
| <b>gsm-map</b>         | (Optional) Uses GSM MAP <sup>1</sup> as the application layer protocol filter within the ruleset. For networks with mixed application layer protocols, the filter should not be specified so that all protocol operations on the rule statement are allowed.                  |
| <b>ansi-41</b>         | Uses ANSI-41 <sup>2</sup> or IS-41 as the application layer protocol filter within the ruleset. For networks with mixed application layer protocols, the filter should not be specified so that all protocol operations on the rule statement are allowed.                    |

### Defaults

The default instance is 0.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

This command enables cs7 mlr ruleset configuration submode. The command configures rules that customize message routing. When issued, the command enters cs7 mlr set configuration submode. In this submode, the **rule** command is valid.

**Examples**

The following example shows how to create a ruleset named ruleset-5:

```
cs7 mlr ruleset ruleset-5
rule 10 sms-mo
  dest-sme 1234
  result group vas-grp
rule 20 sms-mo
  dest-sme 5678
  result group vas-grp
```

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Usage Guidelines** This command enables cs7 mlr table mode.  
In the current release, only a single multilayer routing table is allowed.

**Examples** The following example shows how to specify a CS7 MLR routing table named SMS-TABLE:

```
cs7 mlr table SMS-TABLE
trigger cdpa gt 9991117770 ruleset ruleset-5
cgpa gt 9991116 ruleset ruleset-5
```

The following example shows how to specify a CS7 MLR routing table named SMS-TABLE and that the MLR table is valid in instance 2:

```
cs7 instance 2 mlr table SMS-TABLE
```
