|                  | <a href="#">rule (cs7 mlr ruleset)</a>       | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode.                                                                |
|                  | <a href="#">show cs7 mlr ruleset</a>         | Displays information about the CS7 MLR ruleset.                                                                                                                                                 |
|                  | <a href="#">trigger cdpa (cs7 mlr table)</a> | Specifies the routing key, or trigger, for a multilayer SMS routing table and indicates that the routing trigger is located in the SCCP called party address (CdPA) field of the incoming MSU.  |
|                  | <a href="#">trigger cgpa (cs7 mlr table)</a> | Specifies the routing key, or trigger, for a multilayer SMS routing table and indicates that the routing trigger is located in the SCCP calling party address (CdPA) field of the incoming MSU. |

# cs7 msu-rates notification-interval

To configure a notification interval for MSU rate notifications, use the **cs7 msu-rates notification-interval** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 msu-rates notification-interval** *seconds*

**no cs7 msu-rates notification-interval** *seconds*

| Syntax Description                              | <i>seconds</i> Interval for notifications. Range is from 60 to 3600 seconds. The default is 900 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |         |              |                                               |                                                                     |                                                 |                                                                                                      |                                              |                                                                                                  |                                    |                                                      |

# cs7 msu-rates sample-interval

To configure the interval over which MSU rates are calculated, use the **cs7 msu-rates sample-interval** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 msu-rates sample-interval** *seconds*

**no cs7 msu-rates sample-interval** *seconds*

|                           |                |                                                                           |
|---------------------------|----------------|---------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>seconds</i> | Sample interval. Range is from 1 to 60 seconds. The default is 5 seconds. |
|---------------------------|----------------|---------------------------------------------------------------------------|

|                 |           |
|-----------------|-----------|
| <b>Defaults</b> | 5 seconds |
|-----------------|-----------|

|                         | <a href="#">cs7 msu-rates threshold-default</a>     | Configures the global MSU rate threshold ranges and defaults for all processors in the ITP platform. |
|                         | <a href="#">cs7 msu-rates threshold-proc</a>        | Configures MSU rate threshold ranges for a specific processor, overriding the global thresholds.     |
|                         | <a href="#">show cs7 msu-rates</a>                  | Displays information about configured SS7 MSU rates.                                                 |

## cs7 msu-rates threshold-default

To configure the global MSU rate threshold defaults for all processors on the ITP platform, use the **cs7 msu-rates threshold-default** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 msu-rates threshold-default** *acceptable warning overloaded*

**no cs7 msu-rates threshold-default** *acceptable warning overloaded*

### Syntax Description

|                   |                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>acceptable</i> | Threshold value, in MSUs per second, that indicates an acceptable rate of traffic. This value must be less than both the <i>warning</i> and <i>overloaded</i> values. Range is from 100 to 999999.                                    |
| <i>warning</i>    | Threshold value, in MSUs per second, that indicates a rate of traffic that may impact the device. This value must be greater than the <i>acceptable</i> value and less than the <i>overloaded</i> value. Range is from 100 to 999999. |
| <i>overloaded</i> | Threshold value, in MSUs per second, that indicates a rate of traffic that impacts operation of the device. This value must be greater than both the <i>acceptable</i> and <i>warning</i> values. Range is from 100 to 999999.        |

### Defaults

This command establishes the default MSU rate threshold values for all processors on the platform.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

Use the **cs7 msu-rates threshold-default** command to establish global thresholds for the acceptable, warning, and overloaded MSU rates of traffic for all processors in the ITP platform. After you establish these global thresholds, you can override them on specific processors with the **cs7 msu-rates threshold-proc** command.

### Examples

The examples in this section are intended only to describe the command parameters. They do not represent recommended configurations.

In the following example for a Cisco 7513 ITP platform, the first line defines global thresholds for acceptable, warning, and overloaded MSU rates for all FlexWANs in the ITP platform. Lines 4 and 5 set the threshold values for the Route Processors.

```
cs7 msu-rates threshold-default 2000 3000 6000
cs7 msu-rates sample-interval 1
cs7 msu-rates notification-interval 60
```

```
cs7 msu-rates threshold-proc 6 5000 6000 12000
cs7 msu-rates threshold-proc 7 5000 6000 12000
snmp-server enable traps cs7 msu-rates
```

**Related Commands**

| Command                                             | Description                                                                                      |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <a href="#">cs7 msu-rates notification-interval</a> | Configures the notification interval used to prevent excessive generation of notifications.      |
| <a href="#">cs7 msu-rates sample-interval</a>       | Configures the sample interval over which MSU rates are calculated.                              |
| <a href="#">cs7 msu-rates threshold-proc</a>        | Configures MSU rate threshold ranges for a specific processor, overriding the global thresholds. |
| <a href="#">show cs7 msu-rates</a>                  | Displays information about configured SS7 MSU rates.                                             |

## cs7 msu-rates threshold-proc

To override previously defined global MSU rate thresholds and configure the MSU rate thresholds for a specific processor, use the **cs7 msu-rates threshold-proc** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 msu-rates threshold-proc** [*slot* [*bay*]] *acceptable* *warning* *overloaded*

**no cs7 msu-rates threshold-proc** [*slot* [*bay*]] *acceptable* *warning* *overloaded*

| Syntax Description |                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>slot</i>        | (Optional) Slot that contains the processor. This keyword applies only to those ITP platforms that support multiple processors.                                                                                                                                 |
| <i>bay</i>         | (Optional) Bay that contains the processor. This keyword applies only to those ITP platforms that support multiple processors.                                                                                                                                  |
| <i>acceptable</i>  | Threshold value in MSUs per second that defines, for the specified processor, an acceptable rate of traffic. This value must be less than both the <i>warning</i> and <i>overloaded</i> values. Range is from 100 to 999999.                                    |
| <i>warning</i>     | Threshold value in MSUs per second that defines, for the specified processor, a rate of traffic that may impact the device. This value must be greater than the <i>acceptable</i> value and less than the <i>overloaded</i> value. Range is from 100 to 999999. |
| <i>overloaded</i>  | Threshold value in MSUs per second that defines, for the specified processor, a rate of traffic that impacts operation of the device. This value must be greater than both the <i>acceptable</i> and <i>warning</i> values. Range is from 100 to 999999.        |

**Defaults** The default MSU rate threshold values were globally configured for all processors on the platform with the **cs7 msu-rate threshold-default** command. The **cs7 msu-rate threshold-proc** command overrides those defaults for specified processors.

**Command Modes** Global configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** You use the **cs7 msu-rates threshold-proc** command to override, for a specified processor, the global thresholds that you previously defined for all processors with the **cs7 msu-rates threshold-default** command. The **cs7 msu-rates threshold-proc** command defines the threshold MSU rates for acceptable, warning, and overloaded rates of traffic on a specific processor in the ITP.

## Examples

The examples in this section are intended only to describe the command parameters. They do not represent recommended configurations.

In the following example for a Cisco 7513 ITP platform, the first line defines global thresholds for acceptable, warning, and overloaded MSU rates for all FlexWANs in the ITP platform. Lines 4 and 5 set the threshold values for the Route Processors.

```
cs7 msu-rates threshold-default 2000 3000 6000
cs7 msu-rates sample-interval 1
cs7 msu-rates notification-interval 60
cs7 msu-rates threshold-proc 6 5000 6000 12000
cs7 msu-rates threshold-proc 7 5000 6000 12000
snmp-server enable traps cs7 msu-rates
```

| <a href="#">cs7 msu-rates threshold-default</a>     | Configures the global MSU rate threshold ranges and defaults for all processors in the ITP platform. |
| <a href="#">show cs7 msu-rates</a>                  | Displays information about configured SS7 MSU rates.                                                 |

# cs7 mtp3 crd

Circular route detection occurs when an MSU flows through an SS7 network and traverses a path that takes it back to the originating point code. CRD recognizes the behavior and disables the route.

To turn on circular route detection, use the **cs7 mtp3 crd** command in global configuration mode. To turn off the feature, use the **no** form of this command.

**cs7 mtp3 crd**

**no cs7 mtp3 crd**

## Syntax Description

This command has no arguments or keywords.

## Defaults

For the ANSI variant, CRD is on. For all other variants, CRD is off.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXG | This command was introduced. |
| 12.4(15)SW2 |                              |
| 12.2(33)IRB |                              |

## Usage Guidelines

The following restrictions apply to this command:

- If the ITP has a mate and one or more C-link linksets are already configured, then these linksets must be identified in the configuration for correct operation of OPC verification.
- Because both CRD and OPC verification are on by default for ANSI, you must turn off CRD before making any changes to a C-link linkset configuration.
- The CRD default for all other variants is off, but if CRD is turned on in the configuration, you need to turn it off before changing the C-link linkset configuration.
- If CRD is on for either ANSI or another variant, then C-links may fail due to dropped link test messages.

For ITU and similar variant national options, you must configure multiple congestion levels before enabling CRD.

## Examples

The following example shows how to enable CRD:

```
cs7 mtp3 crd
```

**Related Commands**

| Command                        | Description                                                           |
|--------------------------------|-----------------------------------------------------------------------|
| <a href="#">show cs7 route</a> | Displays the ITP routing table.                                       |
| <a href="#">cs7 mtp3 timer</a> | Configures MTP3 management timers including the loop detection timer. |

## cs7 mtp3 event-history

To specify the maximum number of events to store in memory, use the **cs7 mtp3 event-history** command in global configuration mode. To return to the default number of events to store (512), use the **no** form of this command.

**cs7** [**instance** *instance-number*] **mtp3 event-history** *number*

**no cs7** [**instance** *instance-number*] **mtp3 event-history**

| Syntax Description | instance        | (Optional) Specifies the maximum number of events to store in memory for an instance.                                                                                                   |
|--------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | instance-number | Instance number. The valid range is 0 to 7. The default instance is 0.                                                                                                                  |
|                    | number          | Maximum number of events to log in memory. Valid range is 0 to 5000. The default number is 512.<br><br>Setting the number to 0 removes all saved events and discontinues event logging. |

**Defaults** 512 events are logged.

**Command Modes** Global configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** Because events are continuously logged in round-robin fashion, new events will overwrite the old ones when the maximum value is reached.

**Examples** The following example shows how to set the maximum number of events to be logged at 1024:

```
cs7 mtp3 event history 1024
```

The following example shows how to set the maximum number of events to be logged to 1024 for instance 2:

```
cs7 instance 2 mtp3 event history 1024
```

| Related Commands | Command                                                 | Description                                                                                            |
|------------------|---------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
|                  | <a href="#">cs7 mtp3 tuning rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination.                             |
|                  | <a href="#">show cs7 mtp3 event-history</a>             | Displays logged events exchanged among the three MTP components (traffic, link, and route management). |

## cs7 mtp3 timer

To configure the ITP MTP3 management timers globally, use the **cs7 mtp3 timer** command in global configuration mode. To reset a timer to its default value, use the **no** form of this command.

```
cs7 [instance instance-number] mtp3 timer {retry msec | slt-t1 msec | slt-t2 msec | t01 msec | t02 msec | t03 msec | t04 msec | t05 msec | t6 msec | t8 msec | t10 msec | t11 msec | t12 msec | t13 msec | t14 msec | t15 msec | t16 msec | t17 msec | t18 msec | t19 msec | t20 msec | t21 msec | t22 msec | t23 msec | t24 msec | t25 msec | t26 msec | t28 msec | t29 msec | t30 msec | t32 msec | tc msec} | loop msec
```

```
no cs7 [instance instance-number] mtp3 timer {retry | slt-t1 | slt-t2 | t01 | t02 | t03 | t04 | t05 | t6 | t8 | t10 | t11 | t12 | t13 | t14 | t15 | t16 | t17 | t18 | t19 | t20 | t21 | t22 | t23 | t24 | t25 | t26 | t28 | t29 | t30 | t32 | tc msec} | loop msec
```

### Note

Ranges are defined by ANSI, ITU, or TTC. MTP3 timer values for the China variant are the same as ITU. When used, the MTP3 timer values for TTC match ITU.

### Syntax Description

|                        |                                                                                                                                                                                              |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Configures the ITP MTP3 management timers globally on an instance.                                                                                                                |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.                                                                                                                                       |
| <b>retry msec</b>      | (ANSI, ITU) Link activation retry timer.<br>(ANSI, ITU) Range of <i>msec</i> is 60000 to 90000 milliseconds.<br>Default is 60000 milliseconds.                                               |
| <b>slt-t1 msec</b>     | (ANSI, ITU) Link test acknowledgment timer.<br>(ANSI, ITU) ITU Range of <i>msec</i> is 4000 to 12000 milliseconds.<br>Default is 8000 milliseconds.                                          |
| <b>slt-t2 msec</b>     | (ANSI, ITU) Interval timer for sending test messages.<br>(ANSI, ITU) Range of <i>msec</i> is 30000 to 90000 milliseconds.<br>(ANSI, ITU) Default is 60000 milliseconds.                      |
| <b>t01 msec</b>        | (ANSI, ITU, TTC) Delays to avoid message missequencing.<br>(ANSI, ITU, TTC) Range of <i>msec</i> is 500 to 1200 milliseconds.<br>(ANSI, ITU, TTC) Default is 800 milliseconds.               |
| <b>t02 msec</b>        | (ANSI, ITU, TTC) Waits for changeover acknowledgment.<br>(ANSI, ITU, TTC) Range of <i>msec</i> is 700 to 2000 milliseconds.<br>(ANSI, ITU, TTC) Default is 1400 milliseconds.                |
| <b>t03 msec</b>        | (ANSI, ITU, TTC) Delays to avoid missequencing in changeback.<br>(ANSI, ITU, TTC) Range of <i>msec</i> is 500 to 1200 milliseconds.<br>(ANSI, ITU, TTC) Default is 800 milliseconds.         |
| <b>t04 msec</b>        | (ANSI, ITU, TTC) Waits for changeback acknowledgment (first attempt).<br>(ANSI, ITU, TTC) Range of <i>msec</i> is 500 to 1200 milliseconds.<br>(ANSI, ITU, TTC) Default is 800 milliseconds. |
| <b>t05 msec</b>        | (ANSI, ITU) Waits for changeback acknowledgment (second attempt).<br>(ANSI, ITU) Range of <i>msec</i> is 500 to 1200 milliseconds.<br>(ANSI, ITU) Default is 800 milliseconds.               |

**Usage Guidelines**

MTP3 timers can be defined at three levels: global, linkset, and link.

All global-, linkset-, and link-specific timers can be defined at the global level. These values serve as defaults and are propagated down to the lower levels.

All linkset- and link-specific timers can be defined at the linkset level. These values serve as defaults for the linkset and all links defined within that linkset. Any values defined here override any global values.

All timers defined at the link level apply to the link and override any values for that timer defined at either the linkset or global level.

**Examples**

The following example shows how to set the ITP MTP3 T6 timer to 1000 milliseconds:

```
cs7 mtp3 timer t6 1000
```

The following example shows how to set the ITP MTP3 T6 timer to 1000 milliseconds:

```
cs7 mtp3 timer t6 1000
```

# cs7 mtp3 tuning

To specify MTP3 performance tuning parameters, use the **cs7 mtp3 tuning** command in global configuration mode. To return to the default MTP3 tuning parameters, use the **no** form of this command.

**cs7 mtp3 tuning** {**buffered-packet-threshold** *bufferedPaks* | **rx-congestion-threshold** *queuedPaks*}

**no cs7 mtp3 tuning** {**buffered-packet-threshold** *bufferedPaks* | **rx-congestion-threshold** *queuedPaks*}

|                           |                                                      |                                                                                                                                                                                                                |
|---------------------------|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <b>buffered-packet-threshold</b> <i>bufferedPaks</i> | Number of packets buffered at MTP3 for changeover/changeback after which packets begin being dropped. The range is 1000 to 80000 buffered packets per ITP. The default is 20000 buffered packets for each ITP. |
|                           | <b>rx-congestion-threshold</b> <i>queuedPaks</i>     | Percentage of the maximum number of packets on the MTP3 link's interface input queue at which the link is declared to be congested. The range is 0 to 100. The default percentage is 50.                       |

## Defaults

The default buffered-packet threshold is 20000 packets for each ITP.

## Command Modes

## cs7 mtp3 tuning rx-congestion-threshold

To specify the value of the rx-queue-depth, use the **cs7 mtp3 tuning rx-congestion-threshold** command in global configuration mode. To return to the default rx-queue-depth, use the **no** form of this command.

**cs7 mtp3 tuning rx-congestion-threshold** {mtp2-link | mtp2-hsl-link | m2pa-link | atm-hsl-link}  
*rx-queue-depth*

### Syntax Description

|                       |                                                                                                                                        |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <i>rx-queue-depth</i> | The configurable number of packets that the congestion onset threshold and the congestion abatement threshold are based on (20-20000). |
| <b>mtp2-link</b>      | Specifies the rx-queue-depth is for all serial links.                                                                                  |
| <b>mtp2-hsl-link</b>  | Specifies the rx-queue-depth is for all Q.703 links.                                                                                   |
| <b>m2pa-link</b>      | Specifies the rx-queue-depth is for all M2PA links.                                                                                    |
| <b>atm-hsl-link</b>   | Specifies the rx-queue-depth is for all ATM HSL links.                                                                                 |

### Defaults

The defaults for the *rx-queue-depth* are listed below:

|             |              |
|-------------|--------------|
| serial link | 500 packets  |
| Q.703       | 5000 packets |
| M2PA        | 1000 packets |
| ATM HSL     | 1000 packets |

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW5 | This command was introduced. |
| 12.2(33)IRE |                              |

### Usage Guidelines

The congestion onset threshold is defined as 50% of the rx-queue-depth, and the congestion abate threshold is defined as 30% of the rx-queue-depth.

### Examples

You can display information on the following link types with the **show-running config** command:

The following example shows the *rx-queue-depth* configured at 10,000 for a serial link:

```
cs7 mtp3 tuning rx-congestion-threshold mtp2-link 10000
```

The following example shows the *rx-queue-depth* configured at 10,000 for a Q.703 link:

```
cs7 mtp3 tuning rx-congestion-threshold mtp2-hsl-link 10000
```

The following example shows the *rx-queue-depth* configured at 10,000 for a M2PA link:

```
cs7 mtp3 tuning rx-congestion-threshold m2pa-link 10000
```

The following example shows the *rx-queue-depth* configured at 10,000 for an ATM HSL link:

```
cs7 mtp3 tuning rx-congestion-threshold atm-hsl-link 10000
```

# cs7 multi-instance

To enable multiple instances of a variant and network indicator combination, use the **cs7 multi-instance** command in global configuration mode. To disable multiple instances, use the **no** form of this command.

**cs7 multi-instance**

**no cs7 multi-instance**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

Use the **cs7 multi-instance** command to enable multiple variants and network indicator combinations to run concurrently on one ITP. Up to eight instances can be configured.

The multiple instance feature cannot be enabled until the default instance is first assigned a variant.

## Examples

The following example shows how to enable the configuration of multiple variant and network indicator “instances”:

```
cs7 multi-instance
```

# cs7 national-options

To configure national options, use the **cs7 national-options** command in global configuration mode. To remove national options, use the **no** form of this command.

**cs7** [*instance instance-number*] **national-options** { **tfr** | **multiple-congestion** | **route-set-congestion-test** | **combined-linkset-loadsharing** }

**no cs7** [*instance instance-number*] **national-options**

## Syntax Description

|                                     |                                                                                                              |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------|
| <b>instance</b>                     | (Optional) Configures national options on an instance.                                                       |
| <i>instance-number</i>              | Instance number. An integer value in the range 0 to 7.                                                       |
| <b>tfr</b>                          | (Applies to ITU and China SS7 variants.)<br>Sends Transfer Restricted Messages.                              |
| <b>multiple-congestion</b>          | (Applies to ITU and China SS7 variants.)<br>Uses multiple congestion levels.                                 |
| <b>route-set-congestion-test</b>    | (Applies to TTC SS7 variant.)<br>Enables route set congestion test (RSCT).                                   |
| <b>combined-linkset-loadsharing</b> | (Applies to TTC SS7 variant.)<br>Allows ITPs with the TTC variant to use the enhanced loadsharing algorithm. |

## Defaults

None.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The national options apply to the variants as follows:

- **TFR:** ITU and China SS7 variants
- **multiple-congestion:** ITU and China SS7 variants
- **route-set-congestion-test:** TTC SS7 variant
- **combined-linkset-loadsharing:** TTC SS7 variant

Before Release 12.2(25)SW1, all SS7 variants used an enhanced loadsharing algorithm for distributing messages across the available links within a linkset and combined linkset. (This algorithm allows for efficient load balancing when an unequal number of available links exists in the two linksets that comprise the combined linkset.) In Release 12.2(25)SW1, the TTC variant reverted to using the A/B

linkset selection bit that exists as part of the SLS in the MSU routing label. To allow ITPs configured with the TTC variant to use the enhanced loadsharing algorithm, specify the **combined-linkset-loadsharing** keyword.

To display national options, use the **show running config** command.

Refer to Q.704 section 11.2.4 for multiple-congestion, and Q.704 section 13.4 for TFR.

### Examples

The following example shows how to configure the national options to send transfer restricted messages:

```
cs7 national-options TFR
```

| <a href="#">show cs7 mtp2</a>                           | Displays ITP MTP2 status.                                                  |

# cs7 network-indicator

To configure the network indicator, use the **cs7 network-indicator** command in global configuration mode. To return to the default, use the **no** form of this command.

**cs7** [*instance instance-number*] **network-indicator** {**international** | **national** | **reserved** | **spare**}

**no cs7** [*instance instance-number*] **network-indicator**

## Syntax Description

|                        |                                                             |
|------------------------|-------------------------------------------------------------|
| <b>instance</b>        | (Optional) Configures the network indicator on an instance. |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.      |
| <b>international</b>   | International network.                                      |
| <b>national</b>        | National network.                                           |
| <b>reserved</b>        | Reserved for national use.                                  |
| <b>spare</b>           | Reserved for international use.                             |

## Defaults

National network

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example shows how to configure the network indicator to international:

```
cs7 network-indicator international
```

The following example shows how to configure the network indicator to international on instance 3:

```
cs7 instance 3 network-indicator international
```

## Related Commands

| <a href="#">mtp2-timer</a>                              | Configures MTP2 encapsulation timers.                                      |
| <a href="#">show cs7 mtp2</a>                           | Displays ITP MTP2 status.                                                  |

# cs7 network-name

To specify a network name for a signaling point, use the **cs7 network-name** command in global configuration mode. To remove the name, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **network-name** *network-name*

**no cs7** [**instance** *instance-number*] **network-name** *network-name*

## Syntax Description

|                        |                                                                           |
|------------------------|---------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies a network name for a signaling point on an instance. |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.                    |
| <i>network-name</i>    | Network name. Valid names are text strings up to 19 characters long.      |

## Defaults

None.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The network name allows network management to group signaling points by network. The network name is not required for instance 0. For all other instances, the name must be specified after the variant and before all other commands for the instance.

## Examples

The following example shows how to specify the network name hr:

```
cs7 network-name hr
```

The following example shows how to specify the network name hr for instance 2:

```
cs7 instance 2 network-name hr
```

## Related Commands

| Command                                                 | Description                                                                |
|---------------------------------------------------------|----------------------------------------------------------------------------|
| <a href="#">cs7 mtp3 tuning rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination. |

# cs7 nso

To enable ITP Nonstop Operation (NSO), use the **cs7 nso** command in global configuration mode. To disable ITP NSO, use the **no** form of this command.

**cs7 nso**

**no cs7 nso**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** Global configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |
|                 |             |                              |

**Usage Guidelines** Issuing the **no cs7 nso** command reloads the standby Route Processor, if it is present. Reloading occurs because the ITP protocols on the standby Route Processor must revert to the state required for RPR+ operation. This state is the default for ITP if the redundancy mode is SSO and NSO is not configured.

**Examples** The following example shows how to enable NSO:

```
cs7 nso
```

| Related Commands | Command                      | Description               |
|------------------|------------------------------|---------------------------|
|                  | <a href="#">show cs7 nso</a> | Displays NSO information. |

# cs7 offload mtp3

To enable MTP3 offload (line card to line card forwarding of MSUs), use the **cs7 offload mtp3** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 offload mtp3**

**no cs7 offload mtp3**

## Syntax Description

This command has no arguments or keywords.

## Defaults

MTP3 offload is disabled.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **cs7 offload mtp3** command activates MTP3 offload on all line cards.

MTP3 offload and the Instance Translation feature are mutually exclusive. MTP3 offload cannot be enabled if the Instance Translation feature has been configured, and the Instance Translation feature cannot be enabled if MTP3 offload has been configured.

The **cs7 offload mtp3** command takes effect when the ITP is reloaded.

## Examples

The following example shows how to enable the ITP to forward MSUs between line cards without involving the Route Processor:

```
cs7 offload mtp3
```

## Related Commands

| Command                  | Description                                                                    |
|--------------------------|--------------------------------------------------------------------------------|
| <a href="#">show cs7</a> | Displays the ITP basic configuration and indicates if MTP3 offload is enabled. |

# cs7 offload mtp3 restart

To enable the ITP software to reload IOS microcode on a line card on which MTP3 offload has been permanently disabled by the MTP3 offload feature (due to excessive errors), use the **cs7 offload mtp3 restart** privileged EXEC command. Because the command can only be issued for a physical slot, it reloads both bays (CPUs) on the FlexWAN.

## cs7 offload mtp3 slot restart

| <b>Syntax Description</b>                                                                          | <i>slot</i> Line card slot number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |         |             |                                  |                                                                |

# cs7 paklog

To configure the ITP Packet Logging facility, use the **cs7 paklog** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 paklog** *dest-ip* **dest-port** *dest-port* [**severity** *severity*] [**facility** *facility*] [**src-port** *src-port*] [**hostname** *hostname*]

**no cs7 paklog** *dest-ip* **dest-port** *dest-port* [**severity** *severity*] [**facility** *facility*] [**src-port** *src-port*] [**hostname** *hostname*]

## Syntax Description

|                                   |                                                                                                                                                                                         |
|-----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dest-ip</i>                    | Destination IP address of the syslog receiving host.                                                                                                                                    |
| <b>dest-port</b> <i>dest-port</i> | Indicates the destination IP port of the remote syslog receiving port. Valid range is port number 1 to 65535.                                                                           |
| <b>severity</b> <i>severity</i>   | (Optional) Specifies the severity of the message. Valid range is 0 to 7. If no severity is specified, the default is severity level 7, debug level severity.                            |
| <b>facility</b> <i>facility</i>   | (Optional) Specifies the facility for the message. Valid range is 0 to 23. If no facility is specified, the default facility is 16, "local use 0."                                      |
| <b>src-port</b> <i>src-port</i>   | (Optional) Specifies the source IP port of the UDP syslog message. Valid range is port number 1 to 65535. If no source IP port is specified, the default source port 10000 is assigned. |
| <b>hostname</b> <i>hostname</i>   | (Optional) Specifies a hostname to be sent in the syslog message. If no hostname is specified, the local ITP host name is assigned.                                                     |

## Defaults

If no severity is specified, the default is severity level 7, debug level severity.  
 If no facility is specified, the default facility is 16, "local use 0."  
 If no source IP port is specified, the default source port 10000 is assigned.  
 If no hostname is specified, the local ITP host name is assigned.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The ITP Packet Logging facility uses the BSD Syslog protocol (RFC 3164) to send selected MSUs to a user-selected monitoring tool via the UDP connectionless protocol (RFC 768). Cisco does not provide monitoring tools specifically for receiving and decoding messages sent by the facility. You must obtain a suitable tool for receiving syslog messages.

Under normal conditions, using the ITP Packet Logging facility does not impact system performance. However, if packet logging is configured incorrectly, system performance can be diminished during periods of high traffic.

### Examples

The following example shows how to specify a CS7 access list. The access list permits packets to be logged, specifies the destination IP address and port number of the host that will receive the packets, and specifies the source IP port of the UDP syslog message.

```
cs7 paklog 64.102.85.109 dest-port 514

access-list 2700 instance 0 permit all

debug cs7 mtp3 paklog 2700
```

### Related Commands

| Command                     | Description                      |
|-----------------------------|----------------------------------|
| <a href="#">access-list</a> | Defines a Cisco ITP access list. |

# cs7 pam

To identify a packet address modification (PAM) table and enter the CS7 PAM submode, use the **cs7 instance pam** command in global configuration mode. To remove the identify of the PAM table, use the **no** form of this command.

**cs7 instance** *instance-number* **pam** *pam-name*

**no cs7 instance** *instance-number* **pam** *pam-name*

## Syntax Description

|                 |                                                                                                                                    |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>pam</b>      | The keyword that indicates a PAM table identity is being set.                                                                      |
| <i>pam-name</i> | The identifying name of the PAM table. The name is specified as an alpha-numeric character string with a maximum of 12 characters. |

## Defaults

None.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW5 | This command was introduced. |
| 12.2(33)IRE |                              |

## Usage Guidelines

MLR modify-profile and PAM cannot be configured simultaneously.

## Examples

The following example shows a PAM table named alpha in instance 1:

```
cs7 instance 1 pam alpha
```

|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cgpa (cs7 pam)</a>       | Configures one cgpa entry in the PAM table.                                                                                       |
| <a href="#">cdpa (cs7 pam)</a>       | Configures one cdpa entry in the PAM table.                                                                                       |
| <a href="#">opc</a>                  | Configures an opc entry in the PAM table.                                                                                         |
| <a href="#">dpc</a>                  | Configures a dpc entry in the PAM table.                                                                                          |
| <a href="#">modify-failure (pam)</a> | Specifies the desired action when the PAM table packet modification fails.                                                        |
| <a href="#">cs7 gws action-set</a>   | Defines gateway screening action sets that may include a PAM table.                                                               |
| <a href="#">gta asname</a>           | Creates or modifies a GTA entry that translates to an M3UA or SUA application server name. The GTA entry may include a PAM table. |

## cs7 pc-conversion

To configure instance translation, use the **cs7 instance pc-conversion** command in global configuration mode. To remove the instance translation virtual link, use the **no** form of this command.

**cs7 instance** *instance-number* **pc-conversion** *pc* **alias-pc** *alias-instance* *alias-pc*

**no cs7 instance** *instance-number* **pc-conversion** *pc* **alias-pc** *alias-instance* *alias-pc*

### Syntax Description

|                        |                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------|
| <i>instance-number</i> | Instance number of the real point code. The valid range is 0 to 7.                              |
| <i>pc</i>              | CS7 point code. This point code must already exist in the instance's routing table.             |
| <b>alias-pc</b>        | Maps the alias point code to the real point code.                                               |
| <i>alias-instance</i>  | Instance number of the alias point code. The valid range is 0 to 7.                             |
| <i>alias-pc</i>        | Alias point code. This point code must not already exist in the alias instance's routing table. |

### Defaults

None.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

Instance translation is the conversion of packets between two instances on the ITP, which creates a virtual link between the instance of the real point code and the instance of the alias point code.

This command configures a mapping between *pc* in instance *instance-number* and *alias-pc* in *alias-instance*. If an MSU arrives destined for *alias-pc* in instance *alias-instance*, the ITP sends it to instance *instance* and converts the DPC to *pc*.

### Examples

The following example shows how to map the alias point code to the real point code:

```
cs7 instance 0 pc-conversion 1.1.1 alias-pc 1 2.2.5
cs7 instance 1 pc-conversion 1.1.1 alias-pc 0 1.1.3
```

### Related Commands

| Command                                  | Description                                                                                          |
|------------------------------------------|------------------------------------------------------------------------------------------------------|
| <a href="#">show cs7 virtual-linkset</a> | Displays information about virtual linksets, including link utilization and associated measurements. |
| <a href="#">show cs7 pc-conversion</a>   | Displays the status of the instance translation.                                                     |

## cs7 pc-conversion default

Default conversion sends any MSUs with unknown point codes (PCs) in one instance to another instance. Also, any PCs in the MSU that require conversion but do not have an alias point code assigned to them are unchanged in the new instance.

To configure the default conversion, use the **cs7 instance pc-conversion default** command in global configuration mode. To disable default conversion, use the **no** form of this command.

**cs7 instance** *dest-instance* **pc-conversion default** *orig-instance* [**no-route**]

**no cs7 instance** *dest-instance* **pc-conversion default** *orig-instance* [**no-route**]

### Syntax Description

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dest-instance</i> | Indicates the instance where the MSUs are sent. Valid range is 0 to 7.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>orig-instance</i> | Indicates the instance where the MSUs originate. Valid range is 0 to 7.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>no-route</b>      | <p>Allows messages to be converted to the new instance without conversion statements being configured for the source point code addressing.</p> <p>If this keyword is specified, unknown point codes are not sent to another instance. However, any PCs in MSUs that require conversion but do not have an alias point code assigned are unchanged in the new instance. This design helps prevent alias point codes for the source point code (OPC or CGPA PC) being entered when an MSU is converted to a new instance.</p> <p>Because this keyword does not enter a summary route between instances, fewer restrictions apply to its use.</p> |

### Defaults

Any MSUs with unknown point codes in one instance are sent to another instance.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

This command performs the following actions:

- Enters a summary route for mask length 0 in *orig-instance* that goes over the virtual linkset to *dest-instance*. Any MSUs routed in *orig-instance* that do not match other routes are sent to *dest-instance*. The command does not enter this summary route if the **no-route** keyword is specified.
- Enters a default conversion for point codes between *orig-instance* and *dest-instance*. If point code conversion between the two instances is required, and the point code does not match a specified PC conversion or the ITP's point code, then the point code is unchanged in the new instance and conversion still succeeds.

If you configure default conversion from instance 0 to instance 1, you must configure explicit conversion from instance 1 to instance 0 if you want destinations in instance 0 to allow traffic to be routed from instance 1 to instance 0.

If you configure default routing from one instance to another, we recommend that you also use the **cs7 instance summary-routing-exception** command. For example, instance 0 has a full point code entry for 4.4.4 and has default conversion configured from instance 0 to instance 1:

- If summary-routing-exception is not configured, when 4.4.4 becomes unavailable, the ITP sends MSUs destined for 4.4.4 to instance 1.
- If summary-routing-exception is configured for instance 0, when 4.4.4 becomes unavailable, the ITP sends TFPs for 4.4.4 and does *not* try to route MSUs destined for 4.4.4 to instance 1.

## Examples

The following example shows how to send MSUs with unknown point codes in instance 0 to instance 1:

```
cs7 instance 1 pc-conversion default 0
```

The following example shows how to enable the **no-route** keyword for a default conversion. With the **no-route** keyword, you can specify more than one instance for the default conversion.

```
cs7 instance 0 pc-conversion default 1 no-route
cs7 instance 0 pc-conversion default 2 no-route
```

## Related Commands

|-----------------------------------------------|----------------------------------------------------------------------------------------------|
| <a href="#">cs7 summary-routing-exception</a> | Disables the use of summary/cluster routes (for the purpose of routing MSU) for an instance. |
| <a href="#">show cs7 pc-conversion</a>        | Displays the status of the instance translation.                                             |

# cs7 pmp

The probeless monitoring protocol (PMP) is a proprietary ITP UDP protocol that allows copying sent or received ITP MSUs and sending them to a data collection server (DCS).

To turn probeless monitoring on for all linksets and ASes, use the **cs7 pmp** command in global configuration mode. To turn off probeless monitoring, use the **no** form of this command.

**cs7 pmp**

**no cs7 pmp**

## Syntax Description

This command has no arguments or keywords.

## Defaults

Probeless monitoring is off.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Usage Guidelines

When this command is off (the default), it disables copying at a system level and overrides all provisioned linkset and AS PMP settings. You need to manually enable probeless monitoring at the system level to activate all subtending linkset and AS PMP settings. Table 8 defines this behavior.

**Table 28** Global Probeless Monitoring Behavior for Linkset and AS PMP Settings

| CS7 PMP | Linkset/AS PMP | Result |
|---------|----------------|--------|
| On      | On             | On     |
| On      | Off            | Off    |
| Off     | On or Off      | Off    |

## Examples

The following example shows a configuration with the **cs7 pmp** command turned on globally:

```
no ip cef
no ip finger
no ip domain-lookup
!
cs7 variant itu
cs7 point-code 5.100.4
cs7 capability-pc 5.100.14
cs7 pmp
```

| Related Commands | Command            | Description                                          |
|------------------|--------------------|------------------------------------------------------|
|                  | cs7 dcs-group      | Identifies a name to be associated with a DCS group. |
|                  | cs7 pmp hold-queue | Sets the integer range of PMP hold queue thresholds. |
|                  | show cs7 pmp       | Displays errors and information about the PMP.       |
|                  | show cs7 dcs-group | Displays information about the DCS group.            |
|                  | show cs7 dcs       | Displays information about the DCS node.             |

# cs7 pmp congestion-timer

To set the integer range of the PMP congestion timer, use the **cs7 pmp congestion-timer** command in global configuration mode. To remove this configuration and restore the default threshold, use the **no** form of this command.

**cs7 pmp congestion-timer** *timer*

**no cs7 pmp congestion-timer** *timer*

## Syntax Description

|              |                                                                                            |
|--------------|--------------------------------------------------------------------------------------------|
| <i>timer</i> | Value of the congestion timer. The valid range is 0 to 60 seconds. The default value is 0. |
|--------------|--------------------------------------------------------------------------------------------|

## Defaults

The default congestion timer is 0.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Usage Guidelines

This command is used with the **cs7 pmp hold-queue command** to control the congestion of PMP packets. The ending of PMP congestion is delayed based on a configurable timer ranging from 0 to 60 seconds. When PMP packets in the hold queue hit the congestion onset threshold, ITP starts a congestion timer. Before the timer expires, the receiving side of the PMP is disabled. When the timer expires, the congestion status is checked based on the queue length against the abate threshold.

## Examples

The following configuration excerpt provides an example of the **cs7 pmp congestion-timer** command turned on globally with a *timer* value of 60 seconds:

```
cs7 pmp congestion-timer 60
```

## Related Commands

# cs7 pmp hold-queue

To set the integer range of PMP hold queue thresholds, use the **cs7 pmp hold-queue** command in global configuration mode. To remove this configuration and restore the default thresholds, use the **no** form of this command.

**cs7 pmp hold-queue** *abate-threshold onset-threshold*

**no cs7 pmp hold-queue** *abate-threshold onset-threshold*

## Syntax Description

|                        |                                                                                        |
|------------------------|----------------------------------------------------------------------------------------|
| <i>abate-threshold</i> | Value of the abate threshold. The valid range is 64 to 256. The default value is 128.  |
| <i>onset-threshold</i> | Value of the onset threshold. The valid range is 128 to 512. The default value is 256. |

## Defaults

The default abate threshold is 128 and the default onset threshold is 256.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Usage Guidelines

This command is used to control the congestion of PMP packets. When PMP packets in the hold queue hit the congestion onset threshold, ITP starts a congestion timer. Before the timer expires, the receiving side of the PMP is disabled. When the timer expires, the congestion status is checked based on the queue length against the abate threshold.

## Examples

The following configuration excerpt provides an example of the **cs7 pmp hold-queue** command turned on globally with an *abate-threshold* value of 256 and an *onset-threshold* value of 512:

```
cs7 pmp hold-queue 256 512
```

| cs7 pmp                  | Turns probeless monitoring on for all linksets and ASes. |
| cs7 pmp congestion-timer | Sets the integer range of the PMP congestion timer.      |
| cs7 ds-group             | Identifies a name to be associated with a DCS group.     |
| cs7 ds                   | Identifies a name to be associated with a DCS node.      |

# cs7 point-code

Each ITP must have a unique local point code that is used to send management messages to adjacent signaling points. To assign a local point code, use the **cs7 point-code** command in global configuration mode. To remove the point code from the instance configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **point-code** *point-code*

**no cs7** [*instance instance-number*] **point-code** *point-code*

## Syntax Description

|                        |                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Assigns a local point code to an instance.                                                                                    |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.                                                                                   |
| <i>point-code</i>      | Local point code for this router.<br>The ANSI point code range is 0.0.0 to 255.255.255.<br>The ITU point code range is 0.0.0 to 7.255.7. |

## Defaults

None.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

You must specify the SS7 variant before you can specify the local point code.

You must remove all M3UA, SUA, and linkset configurations before you can remove the local point code.

## Examples

The following example shows how to set the local point code to 10.44.254:

```
cs7 point-code 10.44.254
```

The following example shows how to set the local point code for instance 1 to 10.44.254:

```
cs7 instance 1 point-code 10.44.254
```

|------------------------------------------|------------------------------------------|
| <a href="#">cs7 point-code delimiter</a> | Specifies the point code delimiter.      |
| <a href="#">cs7 point-code format</a>    | Modifies the standard point code format. |

# cs7 point-code delimiter

The delimiter that separates the network, cluster, and member components of a point code can be either a dot (.) or a dash (-). To specify the point code delimiter, use the **cs7 point-code delimiter** command in global configuration mode. To return to the default delimiter (dot), use the **default** keyword.

**cs7** [*instance instance-number*] **point-code delimiter** { **dash** | **default** }

**no cs7** [*instance instance-number*] **point-code delimiter** { **dash** | **default** }

## Syntax Description

|                        |                                                                |
|------------------------|----------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies the point code delimiter for an instance. |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.         |
| <b>dash</b>            | Specifies a dash (-) as the point code delimiter.              |
| <b>default</b>         | Returns the delimiter to the default dot (.).                  |

## Defaults

The default point code delimiter is a dot (.).

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

You can modify the default point code bit format and the default delimiter at any time during configuration, without first removing links and linksets.

## Examples

The following example shows how to set the local point code delimiter to dash:

```
cs7 point-code delimiter dash
```

The following example shows how to set the local point code delimiter to dash for instance 2:

```
cs7 instance 2 point-code delimiter dash
```

| <a href="#">cs7 mtp3 tuning rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination. |

## cs7 point-code format

The format of point codes can be represented according to the ANSI or ITU standard. To modify either standard on an instance, use the **cs7 point-code format** command in global configuration mode. To return to either standard's default, use the **no** form of this command with the **default** keyword.

**cs7** [**instance** *instance-number*] **point-code format** { *l-24* [*l-23* [*l-22*]] } [**description** *string*]  
[**default**]

**no cs7** [**instance** *instance-number*] **point-code format** { *l-24* [*l-23* [*l-22*]] } [**description** *string*]  
**default**

### Syntax Description

|                        |                                                                 |
|------------------------|-----------------------------------------------------------------|
| <b>instance</b>        | (Optional) Modifies the point code format on an instance.       |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.          |
| <i>l-24</i>            | Number of bits used for the first component of the point code.  |
| <i>l-23</i>            | Number of bits used for the second component of the point code. |
| <i>l-22</i>            | Number of bits used for the third component of the point code.  |
| <b>description</b>     | Text description follows.                                       |
| <i>string</i>          | Text description.                                               |
| <b>default</b>         | Uses the default format.                                        |

### Defaults

The ANSI standard for point code representation is 24 bits partitioned into three segments (for network, cluster, and member), with a default representation of 8.8.8.

The ITU standard for point code representation is 14 bits partitioned into three segments (for network, cluster, and member), with a default representation of 3.8.3.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

Before modifying the point code format, you must first specify which standard SS7 variant the ITP is running. To do so, use the [cs7 variant](#) global configuration command.

You can modify the default point code bit format and the default delimiter at any time during configuration, without first removing links and linksets.

### Examples

The following example shows how to set the format for the ITU standard to 2.6.6:

```
cs7 point-code format 2 6 6 description network cluster member
```

The following example shows how to set the format for the ITU standard to 2.6.6 on instance 1:

```
cs7 instance 1 point-code format 2 6 6 description network cluster member
```

| <a href="#">cs7 mtp3 tuning rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination. |
| <a href="#">cs7 variant</a>                             | Indicates which of the SS7 variations (ANSI or ITU) the router is running. |

# cs7 profile

To define a profile that you can apply to all links in a linkset, use the **cs7 profile** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 profile** *name*

**no cs7 profile** *name*

## Syntax Description

|             |               |
|-------------|---------------|
| <i>name</i> | Profile name. |
|-------------|---------------|

## Defaults

None.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **cs7 profile** command enables cs7 profile configuration mode.

This command is not instance related and cannot be specified with the **instance** keyword.

## Examples

The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, configures peer-timer and hold-transport settings, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
 m2pa
  peer-timer t01 15000
  peer-timer t2 9000
  hold-transport
```

```
cs7 linkset to_nyc
 profile timers
```

The following example shows how to define a profile named timers. The profile supports MTP2, configures the t1 and t2 settings, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile timers
 mtp2
  timer t1 15000
  timer t2 9000
```

```
cs7 linkset to_nyc
 profile timers
```

The following example shows how to define a profile named SAAL. The profile supports HSL, specifies the packet bundling interval and SSCF NNI timers, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile SAAL
 hsl
  bundling 10
  sscf-nni t1 10
  sscf-nni t2 150
  sscf-nni t3 100
.
.
cs7 linkset to_nyc
 profile SAAL
```

**Related Commands**

| Command                       | Description                                                       |
|-------------------------------|-------------------------------------------------------------------|
| <a href="#">show cs7 mtp2</a> | Displays ITP MTP2 status.                                         |
| <a href="#">hsl</a>           | Configures CS7 link profile parameters for HSL.                   |
| <a href="#">m2pa</a>          | Configures CS7 link profile parameters for M2PA.                  |
| <a href="#">mtp2-timer</a>    | Configures CS7 link profile parameters for MTP2.                  |
| <a href="#">variant jt1</a>   | Specifies which of the SS7 variations the CS7 profile is running. |

# cs7 prompt enhanced

To configure the command line interface (CLI) prompt to display the current linkset (and, where applicable, the current link) when you are in linkset configuration mode, use the **cs7 prompt enhanced** command in global configuration mode. To return to the default prompt, use the **no** form of this command.

**cs7 prompt enhanced**

**no cs7 prompt enhanced**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** Global configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** The **cs7 prompt enhanced** command is an optional global configuration command that changes the prompt in linkset configuration mode to display the linkset (and, where applicable, the link) that is currently being configured. This command can help avoid the possibility of inadvertently shutting down the wrong linkset or link.

**Examples** The following example shows how to configure the CLI prompt to display the current linkset:

```
cs7 prompt enhanced
```

# cs7 rate-limit

To specify the traffic rate limit to apply instance wide to all application groups that share a specific DPC or AS, use the **cs7 rate limit** command in privileged EXEC command.

```
cs7 [instance instance-number] rate-limit rate {pc pc | asname as-name} [type {sccp | mtp}]
```

```
no cs7 [instance instance id] rate-limit rate {pc pc | asname as-name}
```

| Syntax Description     |                                                                                                                                               |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies the rate limit instance.                                                                                                 |
| <i>instance-number</i> | The valid range is 0 to 7. The default instance is 0.                                                                                         |
| <b>rate-limit</b>      | Specifies the traffic-rate limitation.                                                                                                        |
| <i>rate</i>            | An integrate value from 1 to 4294967296 MSU/sec.                                                                                              |
| <b>pc</b>              | Indicates that the application groups are determined by a shared DPC.                                                                         |
| <b>asname</b>          | Indicates that the application groups are determined by a shared AS.                                                                          |
| <b>type</b>            | (Optional) This optional parameter indicates which type applies to the rate-limit. If type is not configured, then the type defaults to sccp. |
| <b>sccp</b>            | Indicates that the rate limit is only applied to MAP entry instance-wide. This can limit a gtt application group.                             |

**Defaults** The default type is SCCP.

**Command Modes** Global configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.4(15)SW4 | This command was introduced. |
|                 | 12.2(33)IRD |                              |

**Usage Guidelines** This command applies instance wide to all application groups that share a specific DPC or AS. These GTT application group will automatically have the configured rate limit applied.

**Examples** The following example applies rate limiting to all of the existing GTT application group that are contained in instance 7 and that include AS Alpha as part of the GTT application group. The rate limit is set at 1000 MSUs per second:

```
cs7 instance 7 rate-limit 1000 as Alpha type sccp
```

| <a href="#">cs7 rate-limit</a>                     | Limits traffic rate to a specified DPC/AS in an MTP over-flow load-share that uses a GTT application group. Adds or changes a point code and optional subsystem number in the application group |
| <a href="#">pc (cs7 gtt application group)</a>     | Adds or changes a point code and optional subsystem number in the application group.                                                                                                            |
| <a href="#">asname (cs7 gtt application group)</a> | Assigns an M3UA or SUA AS directly to a global title.                                                                                                                                           |

## cs7 remote-congestion-msgs

To allow remote congestion status console messages, use the **cs7 remote-congestion-msgs** command in global configuration mode. To suppress the messages, use the **no** form of this command.

**cs7** [*instance instance-number*] **remote-congestion-msgs**

**no cs7** [*instance instance-number*] **remote-congestion-msgs**

### Syntax Description

|                        |                                                        |
|------------------------|--------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies a QoS class for an instance.      |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7. |

### Defaults

Remote congestion status messages are allowed.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Examples

The following example shows how to enable remote congestion status console messages:

```
cs7 remote-congestion-msgs
```

The following example shows how to enable remote congestion status console messages on instance 1:

```
cs7 instance 1 remote-congestion-msgs
```

## cs7 route-mgmt-sls

To change the way route management signaling link selector (SLS) values are assigned on an instance, use the **cs7 route-mgmt-sls** command in global configuration mode. To return to the default selection method (round-robin), use the **no** form of this command.

**cs7** [*instance instance-number*] **route-mgmt-sls** {**destination** | **round-robin** | **value** *number*}

**no** **cs7** [*instance instance-number*] **route-mgmt-sls**

### Syntax Description

|                        |                                                                                                                                                             |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Changes the way route management signaling link selector (SLS) values are assigned on an instance                                                |
| <i>instance-number</i> | Instance number. The valid range is 0 to 7. The default instance is 0.                                                                                      |
| <b>destination</b>     | Assigns route management SLS values based on the concerned point code destination.                                                                          |
| <b>round-robin</b>     | Assigns route management SLS values using the round-robin method. Route management messages are distributed evenly over the available links in the linkset. |
| <b>value</b>           | Assigns route management SLS values to a static value. Route management messages are distributed over the same link within a linkset.                       |
| <i>number</i>          | Value in the range 0 to 255 (ANSI) or 1 to 15 (ITU).                                                                                                        |

### Defaults

Route management SLS values are assigned using the round-robin method.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

When the ITP originates route management messages, it assigns an SLS value that is used by route management to distribute messages over multiple links in a linkset. When the SLS is assigned using the round-robin method, the route management messages are distributed over the available links in the linkset. This method results in the most efficient use of the available links.

Some SS7 nodes require all route management messages to have an SLS value of zero. If the ITP is connected to an adjacent node with this requirement, use the **cs7 instance route-mgmt-sls value** *number* command. Configuring this command to use a specific value causes route management messages to use the same link within a linkset. This method is not necessarily the most efficient use of the available links in a linkset, but it ensures that route management messages arrive at the adjacent node in the order they were sent.

Alternatively, the ITP has the ability to distribute route management message SLS values based on the concerned point code destination address in the route management message. This method allows the ITP to make more efficient use of the available links in the linkset, while preserving the order of route management messages to an adjacent node.

### Examples

The following command shows how to specify an SLS value of zero for route management messages:

```
cs7 route-mgmt-sls value 0
```

The following command shows how to specify an SLS value of zero for route management messages that originate at instance 2:

```
cs7 instance 2 route-mgmt-sls value 0
```

| <a href="#">cs7 multi-instance</a> | Enables multiple instances of a variant and network indicator combination. |

# cs7 route-table

To specify the ITP route table, use the **cs7 route-table** command in global configuration mode. To remove the route table, use the **no** form of this command.

**cs7** [*instance instance-number*] **route-table** *rt-name*

**no cs7** [*instance instance-number*] **route-table** *rt-name*

## Syntax Description

|                        |                                                           |
|------------------------|-----------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies the ITP route table for an instance. |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.    |
| <i>rt-name</i>         | Route table name.                                         |

## Defaults

A route table named **system** is configured.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

A route table for an instance is identified by its route table name. The ITP configures a route table named **system** by default and uses the table to keep routes to all adjacent signaling points. Additional routes can be added to the route table.

Issuing the **cs7 route-table** command enables cs7 route table configuration mode. From this mode, you can update the route table.

### Note

You must specify **system** as the route table name (*rt-name*).

## Examples

The following example shows how to create a route table:

```
cs7 route-table system
```

The following example shows how to create a route table for instance 1:

```
cs7 instance 1 route-table system
```

# cs7 save address-table

To save an address table to a specified location and file, use the **cs7 save address-table** privileged EXEC command. To remove the line from the configuration, use the **no** form of this command.

**cs7 save address-table** { **mlr** | **sms** } *table-name url*

**no cs7 save address-table** { **mlr** | **sms** } *table-name url*

|                    |                   |                                                                                                                     |
|--------------------|-------------------|---------------------------------------------------------------------------------------------------------------------|
| Syntax Description | <b>mlr</b>        | Specifies the type of table is <b>mlr</b> .                                                                         |
|                    | <b>sms</b>        | Specifies the type of table is <b>sms</b> .                                                                         |
|                    | <i>table-name</i> | Identifies the existing address table that is to be replaced.                                                       |
|                    | <i>url</i>        | The user-assigned local or remote location representing the filename and path from which the file will be replaced. |

|          |       |
|----------|-------|
| Defaults | None. |
|----------|-------|

|               |                 |
|---------------|-----------------|
| Command Modes | Privileged EXEC |
|---------------|-----------------|

|                 |                |                              |
|-----------------|----------------|------------------------------|
| Command History | <b>Release</b> | <b>Modification</b>          |
|                 | 12.2(18)IXA    | This command was introduced. |
|                 | 12.4(11)SW     |                              |
|                 | 12.2(33)IRA    |                              |

|                  |                                                                                                                                                                                                                                                                                                                   |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Usage Guidelines | SMS address tables can be stored in either NVRAM on the Cisco IOS platform or in a file that is typically stored in flash memory. NVRAM limitations on some platforms might restrict the number of address entries that can be stored there. In this case, the file storage option ( <i>url</i> ) is recommended. |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|          |                                                                                                                                                                           |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Examples | The following command shows how to save an SMS address table named addrtbl1 to disk0:smsaddrtbl:<br><br><code>cs7 save address-table sms addrtbl1 disk0:smsaddrtbl</code> |

|                    | 12.2(18)IXA                                                                                                                                           | This command was introduced.                                                                |
|                    | 12.4(11)SW                                                                                                                                            |                                                                                             |
|                    | 12.2(33)IRA                                                                                                                                           |                                                                                             |
| Usage Guidelines   | GTT data is not saved with the <b>write memory</b> command. You must use the <b>cs7 save gtt-table</b> command.                                       |                                                                                             |
| Examples           | The following example shows how to save the GTT table to a file named gttdata.txt in flash memory:<br><pre>cs7 save gtt-table flash:gttdata.txt</pre> |                                                                                             |
| Related Commands   | Command                                                                                                                                               | Description                                                                                 |
|                    | <a href="#">cs7 gtt load</a>                                                                                                                          | Specifies the location from which the GTT database is reloaded when the ITP router reboots. |

## cs7 save gws

To save the CS7 GWS configuration to a file, use the **cs7 save gws** privileged EXEC command.

**cs7** [**instance** *instance-number*] **save gws** *url*

### Syntax Description

|                        |                                                  |
|------------------------|--------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies the instance.               |
| <i>instance-number</i> | Instance number. Valid values range from 0 to 7. |
| <i>url</i>             | Location where the file is to be saved.          |

### Defaults

The default location of general GWS configuration files is cs7:gws-config.

### Command Modes

Privileged EXEC

### Command History

### Usage Guidelines

GWS configuration information is not saved with the standard Cisco IOS CLI **copy running-config startup-config** or **write memory** command. You must use the **cs7 save gws** command.

After the GWS configuration is saved to the file, any existing GWS configuration statements in the running configuration file are saved to the specified file and removed from the running configuration. To save subsequent changes made to the GWS configuration with the Cisco IOS CLI, you must again use the **cs7 save gws** command.

### Examples

The following example shows how to save a GWS configuration to a file named gws-config:

```
cs7 save gws disk0:gws-config
```

### Related Commands

| Command                               | Description                                                                                                                       |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 gws-table replace</a> | Replaces a single GWS table with the table configuration file specified by the URL.                                               |
| <a href="#">cs7 gws replace</a>       | Replaces the running GWS configuration file or existing GWS tables with ones from a local or remote file.                         |
| <a href="#">show cs7 gws config</a>   | Displays the whole configuration of GWS, including global action sets, linksets, global table entries, tables, and table entries. |

# cs7 save gws-table

To save the CS7 GWS table to a file, use the **cs7 save gws-table** privileged EXEC command.

**cs7** [*instance instance-number*] **save gws-table** *table-name url*

## Syntax Description

|                        |                                                                    |
|------------------------|--------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies an instance.                                  |
| <i>instance-number</i> | Instance number. Valid values range from 0 to 7.                   |
| <i>table-name</i>      | Table name. Valid names may not exceed 12 alphanumeric characters. |
| <i>url</i>             | Location where the file is to be saved.                            |

## Defaults

The default location of general GWS configuration files is cs7:gws-config. For GWS table files, it is cs7:gws-tables.

## Command Modes

Privileged EXEC

## Command History

### Usage Guidelines

GWS table information is not saved with the standard Cisco IOS CLI **copy running-config startup-config** or **write memory** command. You must use the **cs7 save gws-table** command.

After the GWS table is saved to the file, any existing GWS configuration statements in the running configuration file are saved to the specified file and removed from the running configuration. To save subsequent changes made to the GWS configuration with the Cisco IOS CLI, you must again use the **cs7 save gws-table** command.

## Examples

The following example shows how to save the GWS table to a file named gws-dpc0:

```
cs7 save gws-table dpc0 disk0:gws-dpc0
```

## Related Commands

|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 gws-table replace</a> | Replaces a single GWS table with the table configuration file specified by the URL.                                               |
| <a href="#">cs7 gws replace</a>       | Replaces the running GWS configuration file or existing GWS tables with ones from a local or remote file.                         |
| <a href="#">show cs7 gws config</a>   | Displays the whole configuration of GWS, including global action sets, linksets, global table entries, tables, and table entries. |
| <a href="#">show cs7 gws table</a>    | Displays the GWS table configuration.                                                                                             |

# cs7 save log

To save a log to a file, use the **cs7 save log** privileged EXEC command.

**cs7 save log** *type destination*

| Syntax Description | <i>type</i>        | Specifies the type of log. Valid types are:                               |
|--------------------|--------------------|---------------------------------------------------------------------------|
|                    | gtt                | Errors related to global title translation                                |
|                    | gws-nontest        | Enhanced gateway screening logs in nontest mode                           |
|                    | gws-test           | Enhanced gateway screening logs in test mode                              |
|                    | <i>destination</i> | Path and filename of the log archive destination. Valid destinations are: |
|                    | cs7:               | URL to saved table                                                        |
|                    | flash:             | URL to saved table                                                        |
|                    | ftp:               | URL to saved table                                                        |
|                    | null:              | URL to saved table                                                        |
|                    | nvr:               | URL to saved table                                                        |
|                    | rcp:               | URL to saved table                                                        |
|                    | system:            | URL to saved table                                                        |
|                    | tftp:              | URL to saved table                                                        |

**Defaults** None.

**Command Modes** Privileged EXEC

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** Saved logs are written in readable text format.  
New log entries that occur while the save is in progress are written to a new log file and are not lost.

**Examples** The following example shows how to detach the current log from the active log process and save it to tftp://10.1.1.3/logs/gttlog1.txt:

```
cs7 save log gtt tftp://10.1.1.3/logs/gttlog1.txt
```

The following example shows how to detach the current log from the active log process and save it to tftp://10.1.1.3/logs/gws-test-log.txt:

```
cs7 save log gws-test tftp://10.1.1.3/logs/gws-test-log1.txt
```

**Related Commands**

| Command                      | Description                                        |
|------------------------------|----------------------------------------------------|
| <a href="#">cs7 log</a>      | Enables the ITP to log events, errors, and traces. |
| <a href="#">show cs7 log</a> | Displays the current log.                          |

# cs7 save mlr

To save the CS7 MLR configuration to a file, use the **cs7 save mlr** privileged EXEC command.

**cs7** [**instance** *instance-number*] **save mlr** [**all**] *url*

## Syntax Description

|                        |                                                  |
|------------------------|--------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies an instance.                |
| <i>instance-number</i> | Instance number. Valid values range from 0 to 7. |
| <i>url</i>             | Location where the file is to be saved.          |

## Defaults

The default location of general MLR configuration files is cs7:mlr.

## Command Modes

Privileged EXEC

## Command History

### Usage Guidelines

MLR configuration information is not saved with the standard Cisco IOS CLI **copy running-config startup-config** or **write memory** command. You must use the **cs7 save mlr** command.

After the MLR configuration is saved to the file, any existing MLR configuration statements in the running configuration file are saved to the specified file and removed from the running configuration. To save subsequent changes made to the MLR configuration with the Cisco IOS CLI, you must again use the **cs7 save mlr** command.

## Examples

The following example shows how to save an MLR configuration to a file named mlr-config:

```
cs7 save mlr all disk0:mlr-config
```

## Related Commands

|---------------------------------|---------------------------------------------------------------------------|
| <a href="#">cs7 mlr load</a>    | Loads an MLR file.                                                        |
| <a href="#">cs7 mlr replace</a> | Replaces the running configuration file with a file specified by the URL. |

# cs7 save route-table

To save the CS7 route table to a file, use the **cs7 save route-table** privileged EXEC command.

**cs7 save route-table** *rt-name url*

|                    |                |                                         |
|--------------------|----------------|-----------------------------------------|
| Syntax Description | <i>rt-name</i> | Route table name.                       |
|                    | <i>url</i>     | Location where the file is to be saved. |

|          |       |
|----------|-------|
| Defaults | None. |
|----------|-------|

|               |                 |
|---------------|-----------------|
| Command Modes | Privileged EXEC |
|---------------|-----------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

|                  |                                                                                                                                                                                        |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Usage Guidelines | Use this command to save an active route table into a file. The newly created file can be used with the <b>load</b> route-table subcommand to populate the route table on ITP startup. |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

**Note**

All **update route** or **remove route** route-table commands are removed from the system configuration after the save is completed. The commands are removed because they have been applied to the actual route table *before* the save and therefore are included in the saved file.

We recommend that you save the router configuration to nonvolatile memory (NVRAM) after generating a new route-table file because the configuration has changed (update/remove route commands may have been removed from the configuration).

|          |                                                                                        |
|----------|----------------------------------------------------------------------------------------|
| Examples | The following example shows how to save a route table named testtable to flash memory: |
|----------|----------------------------------------------------------------------------------------|

```
cs7 save route-table testtable flash:testtable
```

|                  | <a href="#">update route (route-table)</a> | Updates a route.                       |

## cs7 sccp-allow-pak-conv

To configure the conversion option at instance level between XUDT/XUDTS and UDT/UDTS, use the **cs7 sccp-allow-pak-conv** command in global configuration mode. To remove the configuration, use the no form of this command.

**cs7** [**instance** *instance-number*] **sccp-allow-pak-conv** *number*

**no cs7** [**instance** *instance-number*] **sccp-allow-pak-conv** *number*

|                           |                                      |                                                                                                    |
|---------------------------|--------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>instance-number</i>               | Defines the specific instance. Valid values range from 0 to 7.                                     |
|                           | <i>number</i>                        | 1 specifies XUDT/XUDTS to UDT/UDTS conversion while 2 specifies UDT/UDTS to XUDT/XUDTS conversion. |
| <b>Defaults</b>           | None.                                |                                                                                                    |

|                           |                                      |                                                                                                    |

## cs7 sccp-class1-loadshare

To configure the loadsharing option for GTT application groups in loadshare/cost mode, use the **cs7 sccp-class1-loadshare** command in global configuration mode. To remove the configuration, use the no form of this command.

```
cs7 [instance instance-number] sccp-class1-loadshare {opc-sls [opc-shift [opc-shift-number] |
cgpa | sls}
```

```
no cs7 [instance instance-number] sccp-class1-loadshare {opc-sls [opc-shift [opc-shift-number] |
cgpa | sls}
```

| Syntax Description      |                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>         | (Optional) Configures the secondary point code on an instance.                                                                           |
| <i>instance-number</i>  | (Optional) Defines the specific instance. Valid values range from 0 to 7.                                                                |
| <b>opc-sls</b>          | Extends SLS based ASP binding to OPC-SLS combination based binding. This command applies only to the ITU standard not the ANSI standard. |
| <b>cgpa</b>             | Specifies the SCCP calling party address option.                                                                                         |
| <b>sls</b>              | Specifies the SLS based load sharing option.                                                                                             |
| <b>opc-shift</b>        | (Optional) Shifts the OPC bits that are used.                                                                                            |
| <i>opc-shift-number</i> | Number of OPC bits that are shifted.                                                                                                     |

**Defaults** SLS based loadsharing applies. The default is 0 for the *opc-shift-number* argument.

**Command Modes** Global configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXH | This command was introduced. |
|                 | 12.4(15)SW3 |                              |
|                 | 12.2(33)IRC |                              |

**Usage Guidelines** The command applies to Class 1 traffic for all GTT application groups instances configured with loadsharing.

**Examples** The following command configure the loadsharing option for GTT application groups in loadshare/cost mode with the SCCP calling party address option:

```
cs7 instance 1 sccp-class1-loadshare cgpa
```

| Related Commands | Command                                            | Description                                                                          |
|------------------|----------------------------------------------------|--------------------------------------------------------------------------------------|
|                  | <a href="#">multiplicity</a>                       | Specifies a method for selecting a destination in the application group.             |
|                  | <a href="#">asname (cs7 gtt application group)</a> | Assigns an M3UA or SUA AS directly to a global title.                                |
|                  | <a href="#">pc (cs7 gtt application group)</a>     | Adds or changes a point code and optional subsystem number in the application group. |

## cs7 sccp-class1-wrr

To configure the WRR option for GTT application groups, use the **cs7 sccp-class1-wrr** command in global configuration mode. To remove the configuration, use the no form of this command.

```
cs7 [instance instance-number] sccp-class1-wrr {opc-sls [opc-shift [opc-shift-number] | cgpa-sls | sls]}
```

```
no cs7 [instance instance-number] sccp-class1-wrr {opc-sls [opc-shift [opc-shift-number] | cgpa-sls | sls]}
```

| Syntax Description      |                                                                           |
|-------------------------|---------------------------------------------------------------------------|
| <b>instance</b>         | (Optional) Configures the secondary point code on an instance.            |
| <i>instance-number</i>  | (Optional) Defines the specific instance. Valid values range from 0 to 7. |
| <b>opc-sls</b>          | Applies the command to the ITU standard, but not to the ANSI standard.    |
| <b>opc-shift</b>        | (Optional) Shifts the OPC bits that are used.                             |
| <i>opc-shift-number</i> | Number of OPC bits that are shifted.                                      |
| <b>cgpa-sls</b>         | Specifies loadsharing based on a combination of CGPA and SLS.             |
| <b>sls</b>              | Specifies the SLS based load sharing option.                              |

**Defaults** SLS based loadsharing applies. The default is 0 for the *opc-shift-number* argument.

**Command Modes** Global configuration mode

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.4(15)SW4 | This command was introduced. |
|                 | 12.2(33)IRD |                              |

**Usage Guidelines** The command applies to class 1 traffic for all GTT application groups with WRR in that instance.

**Examples** The following command configure the loadsharing option for GTT application groups in WRR mode with the SCCP calling party address option:

```
cs7 instance 1 sccp-class1-wrr cgpa-sls
```

| Related Commands | Command                                            | Description                                                                          |
|------------------|----------------------------------------------------|--------------------------------------------------------------------------------------|
|                  | <a href="#">multiplicity</a>                       | Specifies a method for selecting a destination in the application group.             |
|                  | <a href="#">asname (cs7 gtt application group)</a> | Assigns an M3UA or SUA AS directly to a global title.                                |
|                  | <a href="#">pc (cs7 gtt application group)</a>     | Adds or changes a point code and optional subsystem number in the application group. |

# cs7 sccp gti-conversion

To configure an SCCP GTI conversion table, use the **cs7 sccp gti-conversion** command in global configuration mode. To remove the definition, use the **no** form of this command.

**cs7 sccp gti-conversion** *table-name*

**no cs7 sccp gti-conversion** *table-name*

|                           |                   |                                                                                |
|---------------------------|-------------------|--------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>table-name</i> | SCCP GTI conversion table name. The table name may be 1 to 12 characters long. |
|---------------------------|-------------------|--------------------------------------------------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |

|-------------------------|---------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | This command names the GTI conversion table and enables cs7 sccp gti conversion mode. |
|-------------------------|---------------------------------------------------------------------------------------|

|                 |                                                                                                                                        |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following command shows how to specify an SCCP GTI conversion table named gti-conv1:<br><code>cs7 sccp gti-conversion conv1</code> |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------|

|                         |                                                  |                                                        |
|-------------------------|--------------------------------------------------|--------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>                                   | <b>Description</b>                                     |
|                         | <a href="#">show cs7 sccp gti-conversion</a>     | Displays CS7 GTI conversion tables.                    |
|                         | <a href="#">update (cs7 sccp gti conversion)</a> | Creates or updates an SCCP GTI conversion table entry. |

## cs7 sccp instance-conversion

To configure or update an SCCP instance conversion entry, use the **cs7 sccp instance-conversion** command in global configuration mode. To remove the definition, use the **no** form of this command.

**cs7 sccp instance-conversion in-instance** *instance* **out-instance** *instance*

**no cs7 sccp instance-conversion in-instance** *instance* **out-instance** *instance*

### Syntax Description

|                     |                                              |
|---------------------|----------------------------------------------|
| <b>in-instance</b>  | Specifies an input instance for conversion.  |
| <i>instance</i>     | Input instance number.                       |
| <b>out-instance</b> | Specifies an output instance for conversion. |
| <i>instance</i>     | Output instance number.                      |

### Defaults

If no conversion methods are assigned, the GTTs in the MSUs do not change.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

When you configure an SCCP instance conversion entry, you can assign GTI conversion, subsystem mapping, and address conversion tables from one instance to another. You can use one, two, or all three conversion methods. If no conversion methods are assigned, the GTTs in the MSUs do not change.

You can also set message-handling options and specify a national indicator.

### Examples

The following example shows how to configure an SCCP instance conversion entry. The entry sets gti-conversion, subsystem mapping, and address conversion tables from instance 0 to instance 1.

```
cs7 sccp instance-conversion in-instance 0 out-instance 1
  set gti-conversion gtitable
  set ssn-conversion ssntable
  set address-conversion gtaddresstable
```

| <a href="#">show cs7 sccp gti-conversion</a>      | Displays the SCCP GTI conversion table.                                                 |
| <a href="#">show cs7 sccp instance-conversion</a> | Displays the SCCP instance conversion table.                                            |
| <a href="#">show cs7 sccp ssn-conversion</a>      | Displays the SCCP SSN conversion table.                                                 |

# cs7 sccp ssn-conversion

To create a subsystem mapping table, use the **cs7 sccp ssn-conversion** command in global configuration mode. To delete the table, use the **no** form of this command.

**cs7 sccp ssn-conversion** *table-name* **in-ssn** *in-ssn* **out-ssn** *out-ssn*

**no cs7 sccp ssn-conversion** *table-name* **in-ssn** *in-ssn* **out-ssn** *out-ssn*

|                           |                   |                                                                      |
|---------------------------|-------------------|----------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>table-name</i> | Subsystem table name. The table name may be 1 to 12 characters long. |
|                           | <b>in-ssn</b>     | Input SSN.                                                           |
|                           | <i>in-ssn</i>     | Valid range 0 to 255.                                                |
|                           | <b>out-ssn</b>    | Output SSN.                                                          |
|                           | <i>out-ssn</i>    | Valid range 0 to 255.                                                |

**Defaults** None.

**Command Modes** Global configuration

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|------------------------|----------------|------------------------------|
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Usage Guidelines** This command creates a subsystem mapping table that specifies input and output SSN values. If the ITP does not find a match in the SSN conversion table, the SSN in the MSU does not change.

If both GTI conversion and subsystem mapping are used, and a GTI conversion specifies a new subsystem for the MSU, the ITP uses the subsystem specified by the GTI conversion, not the subsystem from the SSN conversion table.

**Examples** The following example shows how to create a subsystem mapping table named ss-conv0:

```
cs7 sccp ssn-conversion ss-conv0 in-ssn 11 out-ssn 13
cs7 sccp ssn-conversion ss-conv0 in-ssn 200 out-ssn 6
```

## cs7 sctp crc-type

To create a subsystem mapping table, use the **cs7 sccp ssn-conversion** command in global configuration mode. To delete the table, use the **no** form of this command.

**cs7 sccp ssn-conversion** *table-name* **in-ssn** *in-ssn* **out-ssn** *out-ssn*

**no cs7 sccp ssn-conversion** *table-name* **in-ssn** *in-ssn* **out-ssn** *out-ssn*

| Syntax Description | <i>table-name</i> | Subsystem table name. The table name may be 1 to 12 characters long. |
|--------------------|-------------------|----------------------------------------------------------------------|
|                    | <b>in-ssn</b>     | Input SSN.                                                           |
|                    | <i>in-ssn</i>     | Valid range 0 to 255.                                                |
|                    | <b>out-ssn</b>    | Output SSN.                                                          |
|                    | <i>out-ssn</i>    | Valid range 0 to 255.                                                |

**Defaults** None.

**Command Modes** Global configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** This command creates a subsystem mapping table that specifies input and output SSN values. If the ITP does not find a match in the SSN conversion table, the SSN in the MSU does not change.

If both GTI conversion and subsystem mapping are used, and a GTI conversion specifies a new subsystem for the MSU, the ITP uses the subsystem specified by the GTI conversion, not the subsystem from the SSN conversion table.

**Examples** The following example shows how to create a subsystem mapping table named ss-conv0:

```
cs7 sccp ssn-conversion ss-conv0 in-ssn 11 out-ssn 13
cs7 sccp ssn-conversion ss-conv0 in-ssn 200 out-ssn 6
```

# cs7 secondary-pc

To configure secondary point codes, use the **cs7 secondary-pc** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **secondary-pc** *zone.region.sp*

**no** [**instance** *instance-number*] **secondary-pc** *zone.region.sp*

## Syntax Description

|                        |                                                                     |
|------------------------|---------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Configures the secondary point code (PC) on an instance. |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.              |
| <i>zone.region.sp</i>  | Secondary PC identifier.                                            |

## Defaults

None.

## Command Modes

Global configuration

## Command History

| Release                                  | Modification                                                     |
|------------------------------------------|------------------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                                     |
| 12.4(15)SW4<br>12.2(33)IRD               | The ability to configure 40 secondary PCs per chassis was added. |

## Usage Guidelines

This command is used to configure multiple linksets between the ITP and an adjacent node. To the adjacent node, the ITP appears to be two different nodes: one with the PC configured using the **cs7 point-code** command and one with the PC configured using the **cs7 secondary-pc** command. You may configure a maximum of 40 secondary PCs per chassis.

## Examples

The following example shows how to configure a primary, secondary, and capability point code:

```
cs7 point-code 1.1.1
cs7 secondary-pc 1.1.2
cs7 capability-pc 1.1.3
```

## cs7 sgmp

To specify the local port number for SGMP and enter cs7 sgmp submode, use the **cs7 sgmp** command in global configuration mode. To delete the SGMP configuration, if no mated SG is configured, use the **no** form of this command.

```
cs7 sgmp local_port [offload] [slot] [bay]
```

```
no cs7 sgmp local_port [offload] [slot] [bay]
```

### Syntax Description

|                   |                                                                                                                                                                                                                 |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>local_port</i> | The local port number is a number in the range 1024 to 65535. Only one SGMP local port may be specified. The local port number may not be the same as the configured local port numbers for M2PA, M3UA, or SUA. |
| <b>offloading</b> | Enables SGMP offload.                                                                                                                                                                                           |
| <i>slot</i>       | Linecard slot number.                                                                                                                                                                                           |
| <i>bay</i>        | Linecard bay number containing the processor.                                                                                                                                                                   |

### Defaults

None.

### Command Modes

Global configuration

### Command History

| Release                                  | Modification                               |
|------------------------------------------|--------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.               |
| 12.2(33)IRD                              | The <b>offload</b> keyword was introduced. |

### Usage Guidelines

Two SGs can function as a mated pair and exchange necessary state information using the Signaling Gateway Mate Protocol (SGMP). SGMP is used to establish an association to the mated-signaling gateway (with equivalent SG configuration).

The mated-pair SGs are used to loadshare and/or back up each other. The mated SG can be used as a backup point code if an association between this SG and the ASP has failed.

Mated-pair SGs must have equivalent SG configuration, including the same AS and AS route routing-key definitions. However, the local point code of each SG must be unique and must not match the local point code, the capability point code, the secondary point code, any AS point code (DPC), or any AS route point code configured on its mate.

When the SG mate association is active, the SG is informed of AS state changes on the mate in real time. When an AS becomes inactive, subsequent messages are rerouted to the mate if the corresponding AS on the mate is active.

When the AS on the original SG returns to active state, new messages are temporarily queued to allow in-transit messages from the mated SG to arrive at the ASP. Queued messages are released to the ASP when an AS recovery timer expires.

This command is not instance related and cannot be specified with the **instance** keyword.

You cannot configure SGMP offload when non-offloaded SGMP is configured. If non-offload SGMP is configured, you must delete it before configuring the SGMP offload.

---

**Examples**

The following example shows how to specify the local port number 5000 for SGMP:

```
cs7 sgmp 5000
```

The following example shows how to specify the local port number 999, SGMP offload, line card slot number 2, and line card bay number 1 :

```
cs7 sgmp 9999 offload 2 1
```

---

**Related Commands**

| Command                         | Description                                                              |

| <a href="#">cs7 mated-sg</a>    | Specifies the mated SG.                                                  |
| <a href="#">local-ip (cs7 )</a> | Configures up to four local IP addresses that will receive SGMP packets. |
| <a href="#">show cs7 sgmp</a>   | Displays SGMP information.                                               |

## cs7 sls-shift

When the variant is ITU, to shift which signaling link selection (SLS) bits are used for link and linkset selection, use the **cs7 sls-shift** command in global configuration mode. To disable the specification, use the **no** form of this command.

**cs7** [*instance instance-number*] **sls-shift** {**0-3**}

**no cs7** [*instance instance-number*] **sls-shift**

### Syntax Description

|                        |                                                                                                                                                       |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>        | Shifts SLS bits on an instance.                                                                                                                       |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.                                                                                                |
| <b>0-3</b>             | Indicates a range, from least significant bit (0) to most significant bit (3) of the SLS, to be used for linkset selection within a combined linkset. |

### Defaults

The default bit is 0 (the equivalent of the **no sls-shift** command).

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

This command is for MTP3 users (SUA/M3UA) who do not have an inbound linkset. The command works the same way as the linkset-specific **sls-shift** command.

This command is valid only when the variant is ITU. It affects MSUs received on the linkset, and changes which bit in the SLS is used for linkset selection. ITU, unlike ANSI, does not perform SLS rotation. If all nodes in the network use the same bit for linkset selection, traffic does not balance evenly.

### Examples

The following example shows how to use the most significant bit (3) for linkset selection:

```
cs7 sls-shift 3
```

# cs7 sms ansi41

To enable the configuration of ANSI-41 transport-specific parameters, use the **cs7 sms ansi41 EXEC** command. To remove the configuration, use the **no** form of this command.

**cs7 sms ansi41 ssn** *ssn*

**no cs7 sms ansi41 ssn** *ssn*

## Syntax Description

|            |                                                      |
|------------|------------------------------------------------------|
| <b>ssn</b> | Specifies the subsystem number.                      |
| <i>ssn</i> | Subsystem number. Valid numbers range from 2 to 255. |

## Defaults

None.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **cs7 sms ansi41** command allows ANSI-41 transport-specific parameters to be modified independent of the received inbound message.

Only one SMS transport (that is, GSM MAP or ANSI-41 MAP) may be defined. The definition of the ANSI-41 transport *must* precede the definition for handling inbound ANSI-41 messages configured with the **cs7 sms route-table** command. Conversely, the ANSI-41 transport may not be removed until the handling of all ANSI-41 operations is removed from the CS7 SMS route table.

The **cs7 sms ansi41** command enables cs7 sms ansi41 configuration mode.

## Examples

The following example shows how to specify the address for all sourced ANSI-41 dialogs:

```
cs7 sms ansi41 ssn 11
map-source-addr digits 9191111111
```

## Related Commands

# cs7 sms gsm-map

To enable the configuration of GSM transport-specific parameters, use the **cs7 sms gsm-map** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 sms gsm-map ssn** *ssn*

**no cs7 sms gsm-map ssn** *ssn*

## Syntax Description

|            |                                                      |
|------------|------------------------------------------------------|
| <b>ssn</b> | Specifies the subsystem number.                      |
| <i>ssn</i> | Subsystem number. Valid numbers range from 2 to 255. |

## Defaults

None.

## Command Modes

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The optional **cs7 sms gsm-map** command allows for the configuration of parameters that are specific to the GSM transport being used by the SMS subsystem.

Only one SMS transport (that is, GSM MAP or ANSI41 MAP) may be defined. The definition of the GSM transport *must* precede the definition for handling inbound GSM messages configured with the **cs7 sms route-table** command. Conversely, the GSM transport may not be removed until the handling of all GSM operations is removed from the CS7 SMS route table.

The **cs7 sms gsm-map** command enables cs7 sms gsm configuration mode.

## Examples

The following example shows how to specify GSM transport for ssn 8:

```
cs7 sms gsm-map ssn 8
  invoke-times 30
  map-source-address digits 9991117771
  gprs-delivery prefer-Saxon
```

| <a href="#">sm-sc-map-version (cs7 sms gsm map transport)</a> | Specifies a locally supported MAP version.                                      |

Both Flexwan and SAMI processors distribute messages to a set of configured processors by WRR. of one for the offload CPU of two for the offload CPU, of one for the offload CPU,

# cs7 sms ruleset

To configure an SMS ruleset, use the **cs7 sms ruleset** command in global configuration mode. To disable the ruleset, use the **no** form of this command.

**cs7 sms ruleset** *name* [**protocol** {**gsm-map** | **ansi41**}] [**event-trace**]

**no cs7 sms ruleset** *name*

## Syntax Description

|                    |                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>name</i>        | SMS ruleset name.                                                                                                                                            |
| <b>protocol</b>    | (Optional) Specifies an application layer protocol filter for this ruleset. The default behavior is that all operations may be specified within the ruleset. |
| <b>gsm-map</b>     | (Optional) Uses GSM-MAP as the application layer protocol filter within this ruleset. Only <b>gsm-map</b> operations may be specified within the ruleset.    |
| <b>ansi41</b>      | (Optional) Uses ANSI-41 as the application layer protocol filter within this ruleset. Only <b>ansi41</b> operations may be specified within the ruleset.     |
| <b>event-trace</b> | Indicates that this ruleset is used for call tracing.                                                                                                        |

## Defaults

For the **protocol** keyword, all operations may be specified within the ruleset.

## Command Modes

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **cs7 sms ruleset** command enables cs7 sms set rule configuration mode, in which you can configure rules that customize the routing of SMS messages.

## Examples

The following example shows how to specify a ruleset named SMS-RULES:

```
cs7 sms ruleset SMS-RULES
```

```

## cs7 sua

To specify the local port number for SUA and enter cs7 sua submode, use the **cs7 sua** command in global configuration mode. To delete the SUA configuration (if there are no SUA ASs or ASPs), use the **no** form of this command.

**cs7 sua** *port-number* [**offload**] [*line-card-slot-number*] [*bay-number*]

**no cs7 sua** *port-number* [**offload**] [*line-card-slot-number*] [*bay-number*]

### Syntax Description

|                              |                                                                                                                                                                                                         |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>port-number</i>           | Indicates the local port number in the range 1024 to 65535. This port number may not be the same as the configured local port numbers for M2PA, M3UA, or SGMP. The SUA well-known port number is 14001. |
| <b>offload</b>               | (Optional) Enables the ITP to perform SUA SCTP message processing on the line card. Offloading is restricted to the 7600 platform.                                                                      |
| <i>line-card-slot-number</i> | (Optional) Line card slot number. Valid range is 0 to 16.                                                                                                                                               |

### Defaults

None.

### Command Modes

Global configuration

### Command History

| Release                                  | Modification                                                                       |
|------------------------------------------|------------------------------------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                                                       |
| 12.2(18)IXA<br>12.2(33)IRA               | The <b>offload</b> keyword was added, enabling the xUA SCTP Offload feature.       |
| 12.2(33)IRA                              | Extended the range of the <i>bay-number</i> argument for use with SAMI processors. |

### Usage Guidelines

The range for *bay-number* (3 to 8) reflects the labeling of the SAMI card processors. It is consistent with other SAMI applications, as well as the faceplate numbering for the console connections.

SUA uses SCTP to communicate with application server processes (ASPs). The **offload** keyword enables the ITP to offload SUA SCTP message processing to the line card. If you are configuring SUA SCTP offload, the **local-ip** *ip-address* must be an IP address that was already configured on the line card to which you are offloading this SUA instance. When offload is enabled, only a single IP route is allowed for each destination.

If offloaded, a specific SUA instance can run on only one line card, but different offloaded SUA instances can run on the same line card or on different line cards. If you offload M3UA or SUA to a line card, that line card cannot also be used for M2PA offload.

Issuing the **cs7 sua** command enables cs7 sua submode.

The **cs7 sua** command cannot be specified with the **instance** keyword.

The SUA configuration must be removed before the variant or local point code can be removed.

### Examples

The following example shows how to specify a local port number of 5000 for SUA:

```
cs7 sua 5000 offload 5 0
local-ip 10.10.10.4
```

The following example shows how to offload two different instances of SUA SCTP message processing to the line card in slot 5, bay 0 and another instance to the line card in slot 6, bay 0:

```
cs7 sua 6000 offload 5 0
local-ip 10.10.10.5
!
cs7 sua 6500 offload 5 0
local-ip 10.10.10.5
!
cs7 sua 7000 offload 6 0
local-ip 10.10.10.6
```

### Related Commands

| Command                            | Description                                                             |
|------------------------------------|-------------------------------------------------------------------------|
| <a href="#">local-ip (CS7 SUA)</a> | Configures up to four local IP addresses that will receive SUA packets. |
| <a href="#">show cs7 asp</a>       | Displays ASP information.                                               |
| <a href="#">show cs7 sua</a>       | Displays SUA node information.                                          |

## cs7 sua-allow-xudt-request

To allow the SUA ASP additional control in determining whether an SCCP UDT or XUDT message will be generated, use the **cs7 sua-allow-xudt-request** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7** [*instance instance-number*] **sua-allow-xudt-request**

**no cs7** [*instance instance-number*] **sua-allow-xudt-request**

### Syntax Description

|                        |                                                        |
|------------------------|--------------------------------------------------------|
| <b>instance</b>        | (Optional) Specifies an instance.                      |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7. |

### Defaults

If this command is *not* used, XUDT SCCP messages are generated only when segmentation of an SCCP message is performed by the ASP.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **cs7 sua-allow-xudt-request** command allows the SUA ASP additional control in determining whether an SCCP UDT or XUDT message will be generated after receiving a CLDT message. When the command is specified, SUA requests the SCCP layer to generate an XUDT message if the ASP has provided either the IMPORTANCE or HOP\_COUNTER parameter within the CLDT message.

### Examples

The following example shows how to enable the SUA to request the SCCP layer to generate an XUDT message if the ASP has provided either the IMPORTANCE or HOP\_COUNTER parameter within the CLDT message:

```
cs7 instance 2 sua-allow-xudt-request
```

# cs7 summary-routing-exception

To turn off the use of summary/cluster routes (for the purpose of routing MSUs) for a configured full point code member, use the **cs7 summary-routing-exception** command in global configuration mode. To restore the default (allow the use of summary routes), use the **no** form of this command.

**cs7** [*instance instance-number*] **summary-routing-exception**

**no cs7** [*instance instance-number*] **summary-routing-exception**

## Syntax Description

|                        |                                                                        |
|------------------------|------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Turns off the use of summary/cluster routes on an instance. |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.                 |

## Defaults

The summary routing exception feature is disabled.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **cs7 summary-routing-exception** command controls whether the summary route or the ANSI cluster route is used when the full point code route is not available. If the command is enabled, the summary route is *not* used. The ITP drops the MSU and sends a TFP.

This feature is useful for customers who want to split destinations between routes. For example, most destinations that are covered by a summary route will route on a certain group of linksets, but one or more of the destinations within that summary route will route on different linksets.

The feature only affects MSUs that are routed for a destination for which a set of full point code routes is configured.

## Examples

The following example shows how to turn off the use of summary routes:

```
cs7 summary-routing-exception
```

## Related Commands

# cs7 tcap tid-timer

To set the minimum expiration time for TCAP transactions, use the **cs7 tcap tid-timer** command in global configuration mode. To reestablish the default timer value of 60 minutes, use the **no** form of this command.

**cs7 tcap tid-timer** *minutes*

**no cs7 cs7 tcap tid-timer**

|                           |                |                                                                                                         |
|---------------------------|----------------|---------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>minutes</i> | Time before TCAP may cancel a transaction. Valid range is 0 to 1440 minutes. The default is 60 minutes. |
|---------------------------|----------------|---------------------------------------------------------------------------------------------------------|

|                 |            |
|-----------------|------------|
| <b>Defaults</b> | 60 minutes |
|-----------------|------------|

|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

|                 |                                                                                                          |
|-----------------|----------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to set the minimum expiration time for TCAP transactions to 120 minutes: |
|-----------------|----------------------------------------------------------------------------------------------------------|

```
cs7 tcap tid-timer 120
```

|                         |                               |                                |
|-------------------------|-------------------------------|--------------------------------|
| <b>Related Commands</b> | <b>Command</b>                | <b>Description</b>             |
|                         | <a href="#">show cs7 tcap</a> | Displays CS7 TCAP information. |

# cs7 tcap variant

To specify the variant for the TCAP layer, use the **cs7 tcap variant** command in global configuration mode. To remove the specification from the configuration, use the **no** form of this command.

**cs7 tcap variant {ansi | itu}**

**no cs7 tcap variant {ansi | itu}**

## Syntax Description

|             |                                                                                                                                                                                                                       |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ansi</b> | TCAP layer uses the ANSI T1.114 variant. The ANSI T1.114 variant is required for proper ITP support of the ANSI-41 SMS Notification Proxy feature.                                                                    |
| <b>itu</b>  | TCAP layer uses the ITU/ETSI Q.77x variant. The ITU/ETSI Q.77x variant is required for proper ITP support of GSM MAP-based application features such as SIM Authentication, MMSC Gateway, GSM SMS MO Proxy, and DSMR. |

## Defaults

If the **cs7 tcap variant** command is not configured, ITU/ETSI is the default variant.

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

Configuration changes made to the TCAP variant on a running system do not take effect until the ITP is reloaded with the saved configuration.

## Examples

The following example shows how to enable the ANSI T1.114 variant:

```
cs7 tcap variant ansi
```

## Related Commands

| Command                            | Description                                                  |
|------------------------------------|--------------------------------------------------------------|
| <a href="#">cs7 tcap tid-timer</a> | Specifies the minimum expiration time for TCAP transactions. |

# cs7 tfc-pacing-ratio

To adjust the transfer control (TFC) pacing ratio to comply with the ANSI specification of one TFC for every dropped message signal unit (MSU), use the **cs7 tfc-pacing-ratio** command in global configuration mode. To reestablish the ITP default TFC pacing ratio (eight MSUs dropped for outbound link congestion for each TFC generated), use the **no** form of this command.

**cs7** [*instance instance-number*] **tfc-pacing-ratio** *count*

**no cs7** [*instance instance-number*] **tfc-pacing-ratio**

|                           |                        |                                                                            |
|---------------------------|------------------------|----------------------------------------------------------------------------|
| <b>Syntax Description</b> | <b>instance</b>        | (Optional) Adjusts the transfer control (TFC) pacing ratio on an instance. |
|                           | <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.                     |
|                           | <i>count</i>           | Valid range is 1 to 16. The default is 8.                                  |

**Defaults** 8 MSUs

**Command Modes** Global configuration

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Usage Guidelines** The **cs7 tfc-pacing-ratio** command controls the ratio of TFC MSUs sent in response to received MSUs being dropped due to outbound link congestion. The ANSI standard is a 1-to-1 ratio. To prevent congestion in the reverse direction, the ITP default configuration sets a ratio of 1 TFC for each 8 dropped MSUs.

**Examples** The following example shows how to send TFCs in a 1-to-1 ratio (TFC MSUs sent in response to MSUs dropped due to outbound congestion):

```
cs7 tfc-pacing-ratio 1
```

|                         |                                                         |                                                                            |
|-------------------------|---------------------------------------------------------|----------------------------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>                                          | <b>Description</b>                                                         |
|                         | <a href="#">cs7 mtp3 tuning rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination. |

# cs7 uninhibit

To prevent the risk of losing connectivity by shutting down the last link in a linkset, use the **cs7 inhibit** user EXEC command with the linkset name and the link number. To reverse the inhibit, use the **cs7 uninhibit** command.

**cs7 uninhibit** *linkset link*

| Syntax Description | <i>linkset</i> | Linkset name. |
|--------------------|----------------|---------------|
|                    | <i>link</i>    | Link.         |

| Defaults | None. |
|----------|-------|
|----------|-------|

| Command Modes | User EXEC |
|---------------|-----------|
|---------------|-----------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Usage Guidelines | The <b>cs7 inhibit</b> command prevents you from taking the last link in a linkset out of service. If you use the <b>shutdown</b> command to shut down the last link in a linkset, you could lose connectivity. The <b>cs7 inhibit</b> command first verifies whether a link is the last link in the linkset. The command allows you to either add linksets or reduce your bandwidth in the linksets by taking links out of service. |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Examples | The following command shows how to uninhibit link 0 on the linkset named tony:<br><br><code>cs7 uninhibit tony 0</code> |
|----------|-------------------------------------------------------------------------------------------------------------------------|
|----------|-------------------------------------------------------------------------------------------------------------------------|

| Related Commands | Command                                | Description                 |
|------------------|----------------------------------------|-----------------------------|
|                  | <a href="#">shutdown (cs7 link)</a>    | Disables a link or linkset. |
|                  | <a href="#">cs7 ignore-sccp-pcconv</a> | Inhibits a link.            |

# cs7 upgrade analysis

To display the available links configured in each line card slot, a list of the destinations that might become inaccessible when the line card is upgraded, and a step-by-step description of the software upgrade process, use the **cs7 upgrade analysis** privileged EXEC command.

## cs7 upgrade analysis

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** Privileged EXEC

| Command History | Release                                  | Modification                 |
|-----------------|------------------------------------------|------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

**Examples** The following example includes output from the **cs7 upgrade analysis** command:

```
ITP#cs7 upgrade analysis

          CS7 Version
          -----
          Major      Minor
Sup          1         1
Peer Sup     1         1
LC 1         1         1
LC 2         1         1

UPGRADE ANALYSIS FOR SLOT 1
-----

1. Linkset Name           : miramalo
   Available links (SLC)  : 0, 3

   Expected utilization of links on other slots (percent):
       Link      Rcvd      Sent
       1         7         7
   .

Step 4: Upgrade to new image on standby SUP
-----
Enter 'delete slavedisk0:old-image'
Enter 'copy disk0:new-image slavedisk0:new-image'
Enter 'hw-module module <standby sup> reset'
This will complete the upgrade process.
Verify that both SUPs are in SSO mode by entering
'show redundancy states'
```

# cs7 util-abate

To set the integer range utilization threshold, use the **cs7 util-abate** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 util-abate** *percent*

**no util-abate** *percent*

## Syntax Description

|                |                                                                                                      |
|----------------|------------------------------------------------------------------------------------------------------|
| <i>percent</i> | Integer range utilization threshold as a percentage. The range is 0 to 40 percent. The default is 0. |
|----------------|------------------------------------------------------------------------------------------------------|

## Defaults

0 percent

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The abate delta reduces the number of cItpSpLinkRcvdUtilChange and cItpSpLinkSentUtilChange notifications generated when a link's utilization fluctuates around the specified threshold. The delta lowers the falling threshold so that a significant difference exists between the rising and falling thresholds. For example, if the threshold is set to 45 percent (using **cs7 util-threshold 45**) and the abate delta is set to 10 percent, then rising notifications are generated at 45 percent and falling notifications are generated at 35 percent.

This command is not instance related and cannot be specified with the **instance** keyword.

## Examples

The following example shows how to set the utilization threshold to 30 percent:

```
cs7 util-abate 30
```

## Related Commands

| Command                            | Description                                          |

# cs7 util-sample-interval

To set the sample interval for link utilization, use the **cs7 util-sample-interval** command in global configuration mode. To remove the configuration, use the **no** form of this command.

**cs7 util-sample-interval** *seconds*

**no cs7 util-sample-interval** *seconds*

## Syntax Description

|                |                                                                                                   |
|----------------|---------------------------------------------------------------------------------------------------|
| <i>seconds</i> | Integer range utilization threshold. The range is 60 to 3600 seconds. The default is 300 seconds. |
|----------------|---------------------------------------------------------------------------------------------------|

## Defaults

300 seconds

## Command Modes

Global configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **cs7 util-sample-interval** command specifies the duration of the sample interval. Shorter intervals allow network management systems to quickly see increases in traffic. However, shorter intervals might produce notifications that do not represent sustained link utilization problems. Longer intervals are less likely to produce false link utilization notifications, but require more time to detect link utilization problems.

This command is not instance related and cannot be specified with the **instance** keyword.

## Examples

The following example shows how to set the sample interval for link utilization to 60 seconds:

```
cs7 util-sample-interval 60
```

## cs7 variant

To indicate which of the SS7 variations the ITP is running, use the **cs7 variant** command in global configuration mode. To remove the specification from the configuration, use the **no** form of this command.

**cs7** [**instance** *instance-number*] **variant** {**ansi** | **china** | **itu** | **ttc**}

**no cs7** [**instance** *instance-number*] **variant** {**ansi** | **china** | **itu** | **ttc**}

### Syntax Description

|                        |                                                                                        |
|------------------------|----------------------------------------------------------------------------------------|
| <b>instance</b>        | (Optional) Indicates which of the SS7 variations the ITP is running on an instance.    |
| <i>instance-number</i> | Instance number. An integer value in the range 0 to 7.                                 |
| <b>ansi</b>            | American National Standards Institute (ANSI) SS7 protocol variant.                     |
| <b>china</b>           | China SS7 protocol variant.                                                            |
| <b>itu</b>             | International Telecommunications Union (ITU) SS7 protocol variant.                     |
| <b>ttc</b>             | Japan Telecommunication Technology Committee (TTC) SS7 protocol variant, based on ITU. |

### Defaults

None.

### Command Modes

Global configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

In the current release of Cisco ITP, the ANSI, CHINA, ITU, and TTC SS7 protocol variants are supported.

Cisco ITP supports the following Japan TTC standards added to the CCITT recommendations:

- Priority Indicator (PRI) field, used to transmit SUs with priority in the network.
- Generic transmission timing of SUs, including 4 new timers:
  - TA timer for sending SIE (default=20 ms)
  - TF timer for sending FISU (default=20 ms)
  - TO timer for sending SIO (default=20 ms)
  - TS timer for sending SIOS (default=20 ms)
- Outstanding number of MSUs transmittable without confirmation: MTP2/TTC uses the TTC default of 40.

- FIB and BIB comparison. If FIB or receive SU differs from BIB of last transmitted SU, the received SU is discarded.
- Negative Acknowledgement: Negative acknowledgement is transmitted by receiving a repeated MSU.
- Monitoring Timing: TTC defines SU error detection on Te timer. ITP implements the timer in the disabled state.

When you change a variant, you must remove all configurations that are specific to ITP. Remove the following ITP configuration statements in the following order:

- links
- linksets
- route table
- access list
- encapsulation on serial links (removes all MTP2 timers)
- AS route
- AS
- ASPs
- M3UA and SUA
- point code
- variant

### Examples

The following example shows how to use the ANSI variant of SS7:

```
cs7 variant ansi
```

---

**Usage Guidelines**

In this mode, the priority of an incoming MSU is compared to the congestion level of the AS. If the priority of the MSU is lower than the AS congestion level, the MSU is dropped and counted. If TFC/SCON reporting is enabled, a TFC or SCON with the AS specific congestion level is sent to the originator of the MSU.

Because many ASes can share an AS PC, an especially busy AS can skew the congestion level for an AS PC, resulting in MSUs for ASes at lower congestion levels to be dropped. Operating in this mode can help reduce the potential of a very busy AS forcing MSU drops for other ASes that share the same PC.

In the default AS PC congestion level operation, the priority of an incoming MSU is compared to the congestion level of the AS PC for the AS. If the priority of the MSU is lower than the AS PC congestion level, the MSU is dropped and counted. If TFC/SCON reporting is enabled, a TFC or SCON with the AS PC congestion level is sent to the originator of the MSU.

---

**Examples** The following example shows how to base M3UA/SUA congestion on the AS congestion level:

```
cs7 xua-as-based-congestion
```

# cs7 xua-daud-inactive

To allow ASP association establishment interworking, use the **cs7 xua-dad-inactive** command in global configuration mode. To remove the statement from the configuration, use the **no** form of this command.

**cs7 xua-daud-inactive**

**no cs7 xua-daud-inactive**

|                           |                                            |
|---------------------------|--------------------------------------------|
| <b>Syntax Description</b> | This command has no arguments or keywords. |
|---------------------------|--------------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                      |

|----------------------|----------------------|

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXH    | This command was introduced. |
|                        | 12.2(33)IRC    |                              |
|                        | 12.4(15)SW3    |                              |

|                         |                                                                                                                                                              |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | Third-party equipment may send DAUD messages to the Cisco ITP prior to the Cisco ITP sending ASPAC_ACK message. The Cisco ITP will return the error message: |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|

Unexpected Message

Configuring the command **cs7 xua-daud-inactive** on the Cisco ITP will prevent the Cisco ITP from issuing this error message when receiving the DAUD message.

This command relates to the **RFC 3332 4.3.4.3**. section (**ASP Active Procedures**), which states:

*The ASP SHOULD NOT send Data or SSNM messages for the related Routing Context(s) before receiving an ASP Active Ack message, or it will risk message loss.*

|                 |                                                                                      |
|-----------------|--------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to allow ASP association establishment interworking: |
|-----------------|--------------------------------------------------------------------------------------|

```
cs7 xua-daud-inactive
```

## cs7 xua-err-diag-fmt

To modify the format of the diagnostic info parameter in outbound M3UA and SUA ERR messages, use the **cs7 xua-err-diag-fmt** command in global configuration mode. To remove the statement from the configuration, use the **no** form of this command.

**cs7 xua-err-diag-fmt {msg-only | id-offset-msg}**

**no cs7 xua-err-diag-fmt {msg-only | id-offset-msg}**

|                           |                      |                                                                                                                                                                                             |
|---------------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <b>id-offset-msg</b> | Sets the diagnostic info parameter in outbound ERR messages to contain the received offending message preceded by the 4-byte err identifier and offset fields. This keyword is the default. |
|                           | <b>msg-only</b>      | Sets the diagnostic info parameter in outbound ERR messages to contain only the received offending message (4-byte err identifier and offset fields are left out).                          |

**Defaults** The **id-offset-msg** keyword

**Command Modes** Global configuration

| <b>Command History</b> | <b>Release</b>                            | <b>Modification</b>          |
|------------------------|-------------------------------------------|------------------------------|
|                        | 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | This command was introduced. |

**Usage Guidelines** Normally, the ITP inserts four bytes of additional information in front of returned error messages to help determine the cause of the error. Some implementations may try to examine this returned payload. These implementations require that the returned error contains only the original returned message. In that case, the four bytes of additional information inserted by the ITP may interfere with the examination of the payload. You can then use the **msg-only** keyword, which will eliminate the addition of the four bytes and allow a normal examination of the payload.

**Examples** The following example shows how to configure the **msg-only** keyword:

```
cs7 xua-err-diag-fmt msg-only
```

# cs7 xua-errorHandling

To enable the XUA error handling feature, use the **cs7 xua-errorHandling** command in global configuration mode. To disable this feature, use the **no** form of this command.

**cs7 xua-errorHandling**

**no cs7 xua-errorHandling**

**Syntax Description** This command has no arguments or keywords.

**Defaults** By default this feature is not enabled.

**Command Modes** Global configuration

| Command History | Release                    | Modification                 |
|-----------------|----------------------------|------------------------------|
|                 | 12.2(33)IRH<br>12.4(15)SW8 | This command was introduced. |

**Usage Guidelines** Enable the XUA error handling feature by using this command. To configure the counter, interval, and error codes, use the **counter** and **enable** commands in the **cs7 xua-errHandling** command submode.

**Examples** The following example shows how to enable XUA error handling:

```
ITP (config)# cs7 xua-errHandling

ITP(config-cs7-xua-errHandling)# ?
counter      Set the counter and interval
enable       Enable the Error types
no           Negate a command or set its defaults

ITP(config-cs7-xua-errHandling)# counter ?
<1-100>      set counter value, default is 5

ITP(config-cs7-xua-errHandling)# counter 20 interval ?
<5-600>      set interval value in seconds, default is 5 sec

ITP(config-cs7-xua-errHandling)# counter 20 interval 20

ITP(config-cs7-xua-errHandling)# enable ?
ALL          Enable all error codes, it is default action

|-----------------|-------------------------------------------------------------------------------------------------------------|

## cs7 xua-tfc-allowed

To allow TFCs and SCONs to be sent when congestion is detected for MSUs, use the **cs7 xua-tfc-allowed** command in global configuration mode.

By default, the ITP has TFC and SCON reporting disabled. When congestion is detected for an incoming MSU, the MSU is dropped and counted, but a TFC or SCON is not sent.

To remove the statement from the configuration, use the **no** form of this command.

**cs7 xua-tfc-allowed**

**no cs7 xua-tfc-allowed**

**Examples** The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the **cumulative-sack** command, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
  m2pa
    cumulative-sack 300
.
.
.
cs7 linkset to_nyc
  profile m2parfc
```

|                         |                      |                                             |

|                         | <a href="#">cs7 sua</a>      | Specifies the local port number for SUA and enters cs7 sua submode. |
|                         | <a href="#">show cs7 sua</a> | Displays SUA information.                                           |

# cdcs

To add or remove a DCS endpoint to or from a DCS group, use the **cdcs** command in `cs7 dcs-group` configuration mode. To disable the configuration, use the **no** form of this command.

**cdcs** *name cost*

**no dcs** *name cost*

## Syntax Description

|             |                                                                                                                                                                   |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cdcs</b> | Endpoint that receives a proprietary probeless monitoring protocol (PMP).                                                                                         |
| <i>name</i> | Identifies the name of the DCS node that is added or removed from the DCS group. The name is specified as an alphanumeric string with a maximum of 12 characters. |
| <i>cost</i> | Defines which DCS node to use first if more than one DCS node is available in this DCS group. An integer with a value of 0 or 1.                                  |

## Defaults

None.

## Command Modes

`cs7 dcs-group` configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Usage Guidelines

The following rules and restrictions apply when configuring the **cdcs** command:

- You cannot delete a DCS group that is referenced by a linkset or AS.
- You cannot delete a DCS node that is referenced by a DCS group.
- You cannot add more than eight DCS nodes to a group.
- You cannot add a DCS node that is not configured to a DCS group.

## Examples

The following example shows how to configure the DCS node with the name `cdcs4` and a cost of 0:

```
cs7 dcs-group dcs-group2
  dcs cdcs4 cost 0
```

| show cs7 dcs       | Displays information about the DCS node.       |

# dcs-group

To associate a DCS group with a linkset or AS, use the **dcs-group** command in cs7 linkset or cs7 as configuration submode. To remove the DCS group, use the **no** form of this command.

**dcs-group** *dcs-group-name* { **in** | **out** | **all** }

**no dcs-group** { **in** | **out** | **all** }

## Syntax Description

|                                     |                                                                                                                                                                                              |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>dcs-group-name</i>               | Identifies the name of the DCS group that is added or removed to or from the top mode of the linkset or AS. The name is specified as an alphanumeric string with a maximum of 12 characters. |
| <b>in</b>   <b>out</b>   <b>all</b> | Specifies the direction of the traffic that is copied to the specified group.                                                                                                                |

## Defaults

None.

## Command Modes

cs7 linkset or cs7 as configuration submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Usage Guidelines

This command assigns existing DCS groups to monitor the inbound, outbound, or both-side traffic of a linkset or AS. The direction can be set to **all** only when no DCS group is yet assigned to the linkset or AS.

## Examples

The following example shows how to use cs7 linkset configuration mode to configure the DCS group named group\_pmp\_01 with a direction of **all**:

```
cs7 instance 0 linkset to_balance_0 0.1.1
dcs-group group_pmp_01 all
cs7 instance 6 linkset to_halley_6 6.3.3
dcs-group group_pmp_02 in
dcs-group group_pmp_01 out
```

## Related Commands

| Command            | Description                                              |
|--------------------|----------------------------------------------------------|
| cs7 dcs-group      | Identifies a name to be associated with a DCS group.     |

| show cs7 dcs       | Displays information about the DCS node.  |

# default

To create a default secondary trigger, use the **default** command in cs7 mlr trigger configuration mode within a primary address trigger. To disable the specific routing trigger, use the **no** form of this command.

```
default { block | continue | ruleset ruleset-name | result { pc pc [ssn ssn] | asname as-name | gt gta [gt-addr-type] | group group-name } }
```

```
no default { block | continue | ruleset ruleset-name | result { pc pc [ssn ssn] | asname as-name | gt gta [gt-addr-type] | group group-name } }
```

## Syntax Description

|                     |                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>block</b>        | Drops messages matching this trigger. The <b>block</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                                                                                                                                   |
| <b>continue</b>     | Routes messages matching this trigger as received. This behavior is the same as if no primary trigger had been matched. The <b>continue</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                                              |
| <b>ruleset</b>      | Specifies the MLR ruleset table that should be used if this trigger is matched, and not overruled by a secondary trigger ruleset.                                                                                                                                                                                                                                            |
| <i>ruleset-name</i> | Name of an already defined CS7 MLR ruleset table. The name is specified as a character string with a maximum of 12 characters.                                                                                                                                                                                                                                               |
| <b>result</b>       | (Optional) Allows MLR users to route messages based on the trigger alone. If a trigger result is configured, the TCAP/MAP/SMS layers are not parsed. If a message matches a trigger with a result trigger action, then the message is redirected as indicated in the trigger result.<br><b>Note:</b> Result groups with dest-sme-binding mode are not valid trigger results. |
| <b>pc</b>           | Routes based on point code.                                                                                                                                                                                                                                                                                                                                                  |
| <i>pc</i>           | Point code.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ssn</b>          | (Optional) Routes based on PC and subsystem number.                                                                                                                                                                                                                                                                                                                          |
| <i>ssn</i>          | Subsystem number.                                                                                                                                                                                                                                                                                                                                                            |
| <b>asname</b>       | Routes based on AS name.                                                                                                                                                                                                                                                                                                                                                     |
| <i>as-name</i>      | AS name.                                                                                                                                                                                                                                                                                                                                                                     |

| <i>gta</i>          | Global title address.                                                                                                                                                                                                                                                                                                                                                        |
| <b>group</b>        | Routes based on result group.                                                                                                                                                                                                                                                                                                                                                |
| <i>group-name</i>   | Result group name.                                                                                                                                                                                                                                                                                                                                                           |

## Defaults

None.

## Command Modes

cs7 mlr trigger configuration

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

A combination trigger uses more than one network layer address for identifying a trigger match. One address is defined as the primary trigger and the other as the secondary trigger.

If you configure a secondary address in trigger submode, then *both* addresses must match for the packet to be routed using the specified ruleset.

With the definition of the secondary triggers configured as an *and* function with the primary trigger, a default secondary trigger handles packet routing on the primary trigger only when one or more other secondary triggers are defined.

The **default** command is used only if all other subtriggers are unmatched. If **default** is not specified, then packets not matching a combination trigger are routed according to standard SCCP or MTP3 procedures.

**Examples**

The following example shows how to define three secondary triggers based on the origin of the SMS message. All messages *not* originating from one of the secondary triggers are routed based on the default secondary trigger.

```
cs7 mlr table sms_table
trigger cdpa gt 9193334444 ruleset default_rules
cgpa gt 1111111 ruleset msc1_rules
cgpa gt 2222222 ruleset msc2_rules
cgpa gt 3333333 ruleset msc3_rules
!
default ruleset default_rules
```

**Related Commands**

|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 mlr ruleset</a>              | Specifies sets of rules that will be used to process traffic matching triggers defined in a multilayer routing table. |
| <a href="#">show cs7 mlr table</a>           | Displays multilayer SMS routing information.                                                                          |
| <a href="#">trigger cdpa (cs7 mlr table)</a> | Specifies a routing trigger that is located in the SCCP called party address field of the incoming MSU.               |
| <a href="#">trigger cgpa (cs7 mlr table)</a> | Specifies a routing trigger that is located in the SCCP calling party address field of the incoming MSU.              |

# default result

To specify the default screening result, use the **default result** command in gateway screening table configuration mode.

**default result** {**action** *action-set-name* | **table** *table-name*}

**no default**

## Syntax Description

|                        |                                                                         |
|------------------------|-------------------------------------------------------------------------|
| <b>action</b>          | Screens by action set by default.                                       |
| <i>action-set-name</i> | Action-set name. Valid names may not exceed 12 alphanumeric characters. |
| <b>table</b>           | Screens by table by default.                                            |
| <i>table-name</i>      | Table name. Valid names may not exceed 12 alphanumeric characters.      |

## Defaults

None.

## Command Modes

Gateway screening table configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

Results defined as a screening step action can be either an action set or the next screening table name. The **default result** command is used in all screening tables, including gateway link set tables and AS tables.

## Examples

The following example shows how to define the allowed DPC table and specify the default result as an action:

```
cs7 instance 6 gws table OPC6 type opc action allowed
default result action ALLOW
```

The following example shows how to define the allowed cgpa-pc-ssn table and specify the default result as a chained table:

```
cs7 instance 0 gws table PCSSN1 type cgpa-pc-ssn action allowed
default result table SEL1
```

|                    | <a href="#">rule (cs7 mlr ruleset)</a>                                                                                                                                     | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode. |

## dest-sme (cs7 mlr ruleset rule)

To specify the address of the destination short message entity (SME), use the **dest-sme** command in cs7 mlr ruleset rule configuration mode. To remove the specification, use the **no** form of this command.

**dest-sme** { \* | *dest-addr* } [**exact**] [**min-digits** *min*] [**max-digits** *max*] [*dest-sme-addr-type*]

**no dest-sme** { \* | *dest-addr* } [**exact**] [**min-digits** *min*] [**max-digits** *max*] [*dest-sme-addr-type*]

### Syntax Description

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>*</b>                  | Matches all address values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>dest-addr</i>          | <p>When the rule operation is <b>sms-mo</b>, the <i>dest-addr</i> is an address string of 1 to 20 hexadecimal characters.</p> <p>When the rule operation is <b>sri-sm</b>, <i>dest-addr</i> is an address string of 1 to 16 hexadecimal characters.</p> <p>The string is not input in BCD-String format, but in normal form. The string always carries an implicit wildcard (*) at the end of the string, allowing only the prefix of a range of addresses to be specified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>dest-sme-addr-type</i> | <p>(Optional) Parameters that identify attributes of the SME address being used to match a rule. The address is composed of the following keywords:</p> <ul style="list-style-type: none"> <li>• <b>[ton ton]</b> The <b>ton</b> keyword specifies the type of number value associated with the SME address. The <i>ton</i> argument is an integer value in the range 0 to 7.</li> <li>• <b>[np np]</b> The <b>np</b> keyword specifies the numbering plan identification value associated with the SME address. The <b>np</b> keyword is not valid when defining the <b>dest-sme</b> in an <b>smsNot</b> operation. The <i>np</i> argument is an integer value in the range 0 to 15.</li> <li>• <b>min</b> Specifies that the address is a Mobile Identification Number (MIN). This keyword can be specified for the <i>sme-addr-type</i> of ANSI-41 operations.</li> <li>• <b>imsi</b> Specifies that the address is an International Mobile Subscriber Identification (IMSI) address. This keyword can be specified for the <i>sme-addr-type</i> of ANSI-41 operations.</li> </ul> |
| <b>exact</b>              | Indicates that the previously specified <i>dest-addr</i> should be matched only if the number of digits <i>and</i> the digit values match exactly as specified in <i>dest-addr</i> . If <b>exact</b> is not specified, then <i>dest-addr</i> carries an implicit wildcard (*) at the end of the string, allowing a match on the string as a prefix (range of addresses).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>min-digits</b>         | (Optional) Specifies the minimum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>min</i>                | Minimum number of digits in the address string. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>max-digits</b>         | (Optional) Specifies the maximum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <i>max</i>                | Maximum number of digits in the address string. The default is the length of the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Command Modes** cs7 mlr ruleset rule configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** **MLR/SMS rule-matching implementations before ITP release 12.2(25)SW3**  
In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter noa value.
- If an incoming message contains a parameter with noa unknown, then MLR matches that message to a rule for the corresponding parameter, regardless of the rule parameter noa specification.

#### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then MLR matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

The **dest-sme** command allows you to specify the address of the destination SME within an SMS operation. This parameter is part of the rule used to match this route.

For the **sms-mo** operation, **dest-sme** identifies the SM-TP-DA field within the SMS user information field.

For the **sms-mt** operation, **dest-sme** identifies the IMSI contained in the SM-RP-DA field within the GSM MAP layer.

For the **sri-sm** operation, **dest-sme** identifies the destination MSISDN address within the GSM MAP layer.

Table 20 shows the uses of the **dest-sme** command based on the rule operation.

**Table 29 Dest-SME by Operation**

|               | Length in hex | No <i>dest-sme-addr-type</i>            | <i>dest-sme-addr-type</i> specified |
|---------------|---------------|-----------------------------------------|-------------------------------------|
| <b>sms-mo</b> | 1–20          | Defaults to digit string matching only. | specific np/ton                     |
| <b>sms-mt</b> | 1–20          | Defaults to digit string matching only. | specific np/ton                     |

**Table 29**      **Dest-SME by Operation**

|                | Length in hex | No <i>dest-sme-addr-type</i>                                                                                                                                      | <i>dest-sme-addr-type</i> specified                                                                                                                                                |
|----------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>sri-sm</b>  | 1–16          | Defaults to digit string matching only.                                                                                                                           | Specific np/ton                                                                                                                                                                    |
| <b>alertsc</b> | 1–16          | Defaults to digit string matching only.                                                                                                                           | Specific np/ton                                                                                                                                                                    |
| <b>smdpp</b>   | 1–20          | Priority digit string matching based on the following order:<br>SMS_OriginalDestinationAddress<br>SMS_DestinationAddress<br>MIN<br>IMSI<br>SCCP CdPA (RI=GT only) | min = MIN parameter only<br>imsi = IMSI parameter only<br>np/ton = Full address matching based on the parameter order:<br>SMS_OriginalDestinationAddress<br>SMS_DestinationAddress |
| <b>smsReq</b>  | 1–20          | Priority digit string matching based on the following order:<br>MobileDirectoryNumber<br>MIN<br>IMSI<br>SCCP CdPA (RI=GT only)                                    | min = MIN parameter only<br>imsi = IMSI parameter only<br>np/ton = MobileDirectoryNumber parameter only                                                                            |
| <b>smsNot</b>  | 1–20          | Priority digit string matching based on the following order:<br>MobileDirectoryNumber<br>MIN<br>IMSI                                                              | min = MIN parameter only<br>imsi = IMSI parameter only<br>np/ton = MobileDirectoryNumber parameter only                                                                            |

**Examples**

The following example shows how to specify the address of the destination SME:

```
cs7 mlr ruleset ruleset1
rule 10 sms-mo
dest-sme 1234
```

**Related Commands**

| Command                                                     | Description                                                                                                                             |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">match-unknown-ton-np (cs7 mlr ruleset rule)</a> | Specifies that messages with unknown TON/NP will match the corresponding address parameters regardless of the rule's configured TON/NP. |
| <a href="#">rule (cs7 mlr ruleset)</a>                      | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode.        |

## dest-sme (cs7 sms set rule)

To specify a destination short message entity (SME), use the **dest-sme** command in cs7 sms set rule configuration mode. To remove the configuration, use the **no** form of this command.

**dest-sme** { \* | *dest-address* } [**exact**] | [**min-digits** *min*] | [**max-digits** *max*] [*dest-sme-addr-type*]

**no dest-sme** { \* | *dest-address* } [**exact**] | [**min-digits** *min*] | [**max-digits** *max*] [*dest-sme-addr-type*]

|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *                         | Matches all address values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>dest-address</i>       | Address of 1 to 20 hexadecimal digits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>dest-sme-addr-type</i> | (Optional) Parameters that identify attributes of the SME address being used to match a rule. The address is composed of the following keywords: <ul style="list-style-type: none"> <li>[<b>ton</b> <i>ton</i>] The <b>ton</b> keyword specifies type of number value associated with the SME address. The <i>ton</i> argument is an integer value in the range 0 to 7.</li> <li>[<b>np</b> <i>np</i>] The <b>np</b> keyword specifies the numbering plan identification value associated with the SME address. The <b>np</b> keyword is not valid when defining the <b>dest-sme</b> in an <b>smsNot</b> operation. The <i>np</i> argument is an integer value in the range 0 to 15.</li> </ul> |
| <b>exact</b>              | (Optional) Configured address must match dest-sme exactly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>min-digits</b>         | (Optional) Specifies the minimum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>min</i>                | Minimum number of digits in the address string. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>max-digits</b>         | (Optional) Specifies the maximum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <i>max</i>                | Maximum number of digits in the address string. The default is the length of the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Defaults** See Syntax Description.

**Command Modes** cs7 sms set rule configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** **MLR/SMS rule-matching implementations before ITP release 12.2(25)SW3**  
 In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter noa value.
- If an incoming message contains a parameter with noa unknown, then SMS matches that message to a rule for the corresponding parameter, regardless of the rule parameter noa specification.

### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then SMS matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

### Examples

The following example shows how to specify an SMS ruleset named SMS-RULES. The ruleset specifies a rule index of 20 and a destination SME matching all addresses.

```
cs7 sms ruleset SMS-RULES
rule 20 sms-mo
  dest-sme *
  result next-rule
```

|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 sms ruleset</a>                         | Specifies a ruleset.                                                                                                                            |
| <a href="#">dest-sme (cs7 mlr ruleset rule)</a>         | Specifies an application destination port number.                                                                                               |
| <a href="#">dest-sme-table (cs7 sms set rule)</a>       | Specifies an SMS table of destination SME addresses.                                                                                            |
| <a href="#">dest-smsc (cs7 sms set rule)</a>            | Specifies a destination SMSC.                                                                                                                   |
| <a href="#">match-unknown-ton-np (cs7 sms set rule)</a> | Specifies that messages with unknown TON/NP will be a match to the corresponding address parameters regardless of the rule's configured TON/NP. |
| <a href="#">orig-imsi (cs7 sms set rule)</a>            | Specifies an origin IMSI.                                                                                                                       |
| <a href="#">orig-imsi-table (cs7 sms set rule)</a>      | Specifies an SMS table of origin IMSI addresses (address-table).                                                                                |
| <a href="#">orig-sme (cs7 sms set rule)</a>             | Specifies an origin short message entity (SME).                                                                                                 |
| <a href="#">orig-sme-table (cs7 sms set rule)</a>       | Specifies an SMS table of origin SME addresses (address-table).                                                                                 |
| <a href="#">pid (cs7 sms set rule)</a>                  | Specifies a protocol identifier (TP-PID).                                                                                                       |
| <a href="#">result (cs7 sms set rule)</a>               | Specifies a result.                                                                                                                             |
| <a href="#">ruleset (cs7 sms ansi41 smsnot)</a>         | Specifies a rule within a ruleset.                                                                                                              |

## dest-sme-table (cs7 mlr ruleset rule)

To configure an MLR table of destination SME addresses, use the **dest-sme-table** command in cs7 mlr ruleset rule configuration mode. To remove the specification, use the **no** form of this command.

**dest-sme-table** *table-name* [*dest-sme-addr-type*]

**no dest-sme-table**

| Syntax Description        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** **MLR/SMS rule-matching implementations before ITP release 12.2(25)SW3**

In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter noa value.

- If an incoming message contains a parameter with noa unknown, then MLR matches that message to a rule for the corresponding parameter, regardless of the rule parameter noa specification.

### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then MLR matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

### Examples

The following example shows how to specify an address of the destination SME:

```
cs7 mlr ruleset ruleset1
rule 10 sms-mt
dest-sme-table 2
```

## dest-sme-table (cs7 sms set rule)

To specify an SMS table of destination SME addresses (address-table), use the **dest-sme-table** command in **cs7 sms set rule** configuration mode. To remove the configuration, use the **no** form of this command.

**dest-sme-table** *table-name* [*dest-sme-addr-type*]

**no dest-sme-table**

| Syntax Description | <i>table-name</i>         | Address table name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | <i>dest-sme-addr-type</i> | (Optional) Parameters that identify attributes of the SME address being used to match a rule for the <b>sms-mo</b> and <b>sri-sm</b> operation types. The address is composed of the following keywords: <ul style="list-style-type: none"> <li>• <b>[ton ton]</b> The <b>ton</b> keyword specifies type of number value associated with the SME address. The <i>ton</i> argument is an integer value in the range 0 to 7.</li> <li>• <b>[np np]</b> The <b>np</b> keyword specifies the numbering plan identification value associated with the SME address. ### Usage Guidelines

#### MLR/SMS rule-matching implementations before ITP release 12.2(25)SW3

In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter noa value.
- If an incoming message contains a parameter with noa unknown, then SMS matches that message to a rule for the corresponding parameter, regardless of the rule parameter noa specification.

#### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then SMS matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

The **dest-sme-table**, **orig-imsi-table**, and **orig-sme-table** commands accept either an SMS address table name *or* an MLR address table name. This ability is primarily for customers who want the SMS-MO Proxy functionality. The address table names are unique between DSMR and MLR. You may enter an MLR address table name for an SMS rule parameter. However, MLR cannot reference SMS address tables.

If an incoming message matches an SMS rule that references an MLR address table, then any MLR address table result is mapped to an SMS result:

- BLOCK, PC, and PCSSN results map easily from MLR to SMS.
  - For result groups, the MLR result group name is mapped to an SMS result group name.
  - If the SMS result group is not configured, then the result specified on the rule is used.
- AS and CONTINUE results are not valid in SMS. For these cases, the result specified on the rule is used. If no result is specified, the result on the rule is used (same as MLR).

If multiple rule parameters are configured for a rule, then the rule result is used (rather than a result specified in the address table).

If the result type specified within the table is valid, it is used. Otherwise, the result in the rule is used.

For all tables, the **ton** and **np** must match before the table is accessed.

## Examples

The following example shows how to specify an SMS ruleset named SMS-RULES. The ruleset specifies a rule index of 20 and an SMS table of destination SME addresses named SHORTLIST.

```
cs7 sms ruleset SMS-RULES
rule 20 sms-mo
  dest-sme-table SHORTLIST
  result block
```

## dest-smsc (cs7 mlr ruleset rule)

To specify the destination service center address, use the **dest-smsc** command in cs7 mlr ruleset rule configuration mode. To remove the specification, use the **no** form of this command.

**dest-smsc** { \* | *address* } [**exact**] | [**min-digits** *min*] | [**max-digits** *max*] [*addr-type*]

**no dest-smsc**

| Syntax Description |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *                  | Matches all addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>address</i>     | Address of 1 to 20 hexadecimal digits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>addr-type</i>   | (Optional) Parameters that identify attributes of the SMSC address being used to match a rule. The address is composed of the following keywords: <ul style="list-style-type: none"> <li>• <b>[ton <i>ton</i>]</b> The <b>ton</b> keyword specifies the type of number value associated with the SMSC address.<br/>The <i>ton</i> argument is an integer value in the range 0 to 7.</li> <li>• <b>[np <i>np</i>]</b> The <b>np</b> keyword specifies the numbering plan identification value associated with the SMSC address.<br/>The <i>np</i> argument is an integer value in the range 0 to 15.</li> </ul> |
| <b>exact</b>       | (Optional) Configured address must match dest-smc exactly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>min-digits</b>  | (Optional) Specifies the minimum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>min</i>         | Minimum number of digits in the address string. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>max-digits</b>  | (Optional) Specifies the maximum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>max</i>         | Maximum number of digits in the address string. The default is the length of the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Defaults** See Syntax Description.

**Command Modes** cs7 mlr ruleset rule configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** **MLR/SMS rule-matching implementations before ITP release 12.2(25)SW3**  
In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter noa value.
- If an incoming message contains a parameter with noa unknown, then MLR matches that message to a rule for the corresponding parameter, regardless of the rule parameter noa specification.

### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then MLR matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

If intermediate GTT is used toward the ITP SMS routers, then the CdPA routing trigger already contains the destination SMSC address and does not need to be specified on the rule.

### Examples

The following example shows how to specify the destination service center address:

```
cs7 mlr ruleset ruleset1
rule 20 sms-mo
dest-smsc 1234
```

### Related Commands

| Command                                                     | Description                                                                                                                             |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">match-unknown-ton-np (cs7 mlr ruleset rule)</a> | Specifies that messages with unknown TON/NP will match the corresponding address parameters regardless of the rule's configured TON/NP. |
| <a href="#">rule (cs7 mlr ruleset)</a>                      | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode.        |

## dest-smsc (cs7 sms set rule)

To specify a destination short message entity, use the **dest-sme** command in cs7 sms set rule configuration mode. To remove the configuration, use the **no** form of this command.

**dest-smsc** { \* | *address* } [**exact**] | [**min-digits** *min*] | [**max-digits** *max*] [*addr-type*]

**no dest-smsc**

### Syntax Description

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>*</b>          | Matches all addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>address</i>    | Address of 1 to 20 hexadecimal digits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>addr-type</i>  | (Optional) Parameters that identify attributes of the SMSC address being used to match a rule. The address is composed of the following keywords: <ul style="list-style-type: none"> <li><b>[ton <i>ton</i>]</b> The <b>ton</b> keyword specifies the type of number value associated with the SMSC address.<br/>The <i>ton</i> argument is an integer value in the range 0 to 7.</li> <li><b>[np <i>np</i>]</b> The <b>np</b> keyword specifies the numbering plan identification value associated with the SMSC address.<br/>The <i>np</i> argument is an integer value in the range 0 to 15.</li> </ul> |
| <b>exact</b>      | (Optional) Configured address must match dest-sme exactly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>min-digits</b> | (Optional) Specifies the minimum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>min</i>        | Minimum number of digits in the address string. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>max-digits</b> | (Optional) Specifies the maximum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <i>max</i>        | Maximum number of digits in the address string. The default is the length of the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### Defaults

See Syntax Description.

### Command Modes

cs7 sms set rule configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

#### MLR/SMS rule-matching implementations before ITP release 12.2(25)SW3

In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter noa value.
- If an incoming message contains a parameter with noa unknown, then SMS matches that message to a rule for the corresponding parameter, regardless of the rule parameter **noa** specification.

### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then SMS matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

### Examples

The following example shows how to specify an SMS ruleset named SMS-RULES. The ruleset specifies a rule index of 20 and a destination SMSC matching all addresses.

```
cs7 sms ruleset SMS-RULES
rule 20 sms-mo
dest-smsc *
result block
```

### Related Commands

| Command                                                 | Description                                                                                                                             |
|---------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 sms ruleset</a>                         | Specifies a ruleset.                                                                                                                    |
| <a href="#">dest-sme (cs7 mlr ruleset rule)</a>         | Specifies an application destination port number.                                                                                       |
| <a href="#">dest-sme (cs7 sms set rule)</a>             | Specifies a destination short message entity (SME).                                                                                     |
| <a href="#">dest-sme-table (cs7 sms set rule)</a>       | Specifies an SMS table of destination SME addresses.                                                                                    |
| <a href="#">match-unknown-ton-np (cs7 sms set rule)</a> | Specifies that messages with unknown TON/NP will match the corresponding address parameters regardless of the rule's configured TON/NP. |
| <a href="#">orig-imsi (cs7 sms set rule)</a>            | Specifies an origin IMSI.                                                                                                               |
| <a href="#">orig-imsi-table (cs7 sms set rule)</a>      | Specifies an SMS table of origin IMSI addresses (address-table).                                                                        |
| <a href="#">orig-sme (cs7 sms set rule)</a>             | Specifies an origin SME.                                                                                                                |
| <a href="#">orig-sme-table (cs7 sms set rule)</a>       | Specifies an SMS table of origin SME addresses (address-table).                                                                         |
| <a href="#">pid (cs7 sms set rule)</a>                  | Specifies a protocol identifier (TP-PID).                                                                                               |
| <a href="#">result (cs7 sms set rule)</a>               | Specifies a result.                                                                                                                     |
| <a href="#">ruleset (cs7 sms ansi41 smsnot)</a>         | Specifies a rule within a ruleset.                                                                                                      |

# digits

To configure an MSC address in an SMS MSC table that indicates time zone information for an MSC relative to the ITP, use the **digits** command in `cs7 sms msc table` configuration mode. To remove the specification, use the **no** form of this command.

**digits** *address* **time-offset** { **add** | **subtract** } *time-difference*

**no digits** *address* **time-offset** { **add** | **subtract** } *time-difference*

## Syntax Description

|                        |                                                                                                                                                                                  |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>address</i>         | Full or partial prefix MSC E.164 address. All MSCs with E.164 addresses that include the coded prefix assume the traits configured for this MSC table entry.                     |
| <b>time-offset</b>     | Specifies that the MSC is in a different time zone from the ITP.                                                                                                                 |
| <b>add</b>             | Specifies that time is added to the ITP local time to match the MSC local time.                                                                                                  |
| <b>subtract</b>        | Specifies that time is subtracted from the ITP local time to match the MSC local time.                                                                                           |
| <i>time-difference</i> | Time offset to be applied to ITP local time to match MSC local time. Valid format is <i>hh:mm</i> where <i>hh</i> is the number of hours and <i>mm</i> is the number of minutes. |

## Defaults

If an MSC table is not configured, all messages to mobile destinations are delivered with delivery times indicating the local time of the ITP, regardless of the time zone of the message destination.

## Command Modes

`cs7 sms msc table` configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The SMS MSC table stores information pertaining to MSCs with which the ITP communicates. The table stores information that indicates the time zone information for each MSC relative to the ITP.

If you configure an MSC table, short messages are delivered with delivery times indicated in the MSC's local time, which is typically also the local time of the receiver of the message.

If an MSC table is not configured, by default all messages to mobile destinations are delivered with delivery times indicating the local time of the ITP, regardless of whether the destination is in the same time zone as the ITP or not.

**Examples**

The following example shows how to specify SMS MSC addresses in an SMS MSC table:

```
cs7 sms msc-table
digits 19199332252 time-offset subtract 01:00
digits 1505 time-offset subtract 01:00
```

|-----------------|--------------------------------------------------------------------------------------------|
| cs7 sms offload | Enables cs7 sms msc table configuration mode, in which you can configure an SMS MSC table. |

# display-name (cs7 link)

To define a text string to be included on traps related to the link, use the **display-name** command in cs7 link configuration mode. To remove the text string, use the **no** form of this command.

**display-name** *line*

**no display-name** *line*

## Syntax Description

|             |                                                                    |
|-------------|--------------------------------------------------------------------|
| <i>line</i> | Text string description for the link. Length can be 30 characters. |
|-------------|--------------------------------------------------------------------|

## Defaults

The default value of *line* is a formatted string containing the linkset name and the ITP point code.

## Command Modes

cs7 link configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example shows how to configure the display name for the link:

```
cs7 linkset to_doc
link 0
display-name link0
```

## Related Commands

|------------------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">cs7 linkset</a>        | Specifies a linkset and enters cs7 linkset submode.                                       |
| <a href="#">link (cs7 linkset)</a> | Specifies a link and enters cs7 link submode.                                             |
| <a href="#">show cs7</a>           | Displays the ITP basic configuration, including the point code and capability point code. |

## display-name (cs7 linkset)

To define a text string to be included on traps related to the linkset, use the **display-name** command in cs7 linkset configuration mode. To remove the text string, use the **no** form of this command.

**display-name** *line*

**no display-name** *line*

### Syntax Description

|             |                                                                       |
|-------------|-----------------------------------------------------------------------|
| <i>line</i> | Text string description for the linkset. Length can be 30 characters. |
|-------------|-----------------------------------------------------------------------|

### Defaults

The default value of *line* is a formatted string containing the linkset name.

### Command Modes

cs7 linkset configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |

|-----------------------------|-------------------------------------------------------------------------------------------|
| <a href="#">cs7 linkset</a> | Specifies a linkset and enters cs7 linkset submode.                                       |
| <a href="#">show cs7</a>    | Displays the ITP basic configuration, including the point code and capability point code. |

# distribute-sccp-sequenced-negate

To negate the instance level setting of evenly distributing class1 SCCP non-segmented messages in an application group, use the **distribute-sccp-sequenced-negate** command in cs7 gtt application group submode. To return to the instance level setting, use the **no** form of this command.

**distribute-sccp-sequenced-negate**

**no distribute-sccp-sequenced-negate**

## Defaults

None.

## Command Modes

cs7 gtt application group submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW5 | This command was introduced. |
| 12.2(33)IRE |                              |

## Usage Guidelines

The **distribute-sccp-sequenced-negate** command in application group submode can override the instance level setting of in-sequence or out-of-sequence delivery for that specific application group.

The following table explains the ITP behavior for the different configuration combinations:

| Instance Level 0 Configuration              | Application Group Alpha Configuration |                                                                                                                                    |
|---------------------------------------------|---------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| cs7 instance 0<br>distribute-sccp-sequenced | distribute-sccp-sequenced<br>-negate  |                                                                                                                                    |
| not configured                              | not configured                        | Default in-sequence delivery for all the application groups in instance 0.                                                         |
| not configured                              | configured                            | In-sequence delivery for all the application groups in the instance 0 except out-of-sequence delivery for application group Alpha. |
| configured                                  | not configured                        | Out-of-sequence delivery for all the application groups in instance 0.                                                             |
| configured                                  | configured                            | Out-of-sequence delivery for all the application groups in the instance 0 except in-sequence delivery for application group Alpha. |

**Examples**

The following example shows the **distribute-sccp-sequenced-negate** command in application group submode overriding the instance level **distribute-sccp-sequenced** command for application group alpha:

```
cs7 instance 0 distribute-sccp-sequenced
cs7 instance 0 gtt application-group alpha
multiplicity share
distribute-sccp-sequenced-negate
pc 1671 1 pcssn
pc 1672 1 pcssn
pc 1741 1 pcssn
pc 1740 1 pcssn
```

|----------------------------------------------------|--------------------------------------------------------------------------------------|
| <a href="#">cs7 gtt application-group</a>          | Specifies a GTT application group.                                                   |
| <a href="#">cs7 gtt map</a>                        | Configures a Global Title Mated Application (MAP) entry.                             |
| <a href="#">cs7 distribute-sccp-sequenced</a>      | Configures class 1 SCCP messages to use round-robin loadsharing.                     |
| <a href="#">pc (cs7 gtt application group)</a>     | Adds or changes a point code and optional subsystem number in the application group. |
| <a href="#">asname (cs7 gtt application group)</a> | Assigns an M3UA or SUA AS directly to a global title                                 |
| <a href="#">cs7 sccp-class1-wrr</a>                | Configures the WRR option for GTT application groups.                                |

# dpc

To configure a destination point code (DPC) entry in the PAM table, use the **dpc** command in CS7 PAM configuration submode. To remove the specification, use the **no** form of this command.

**dpc** *point-code*

**no dpc** *point-code*

|                           |                   |                                                    |
|---------------------------|-------------------|----------------------------------------------------|
| <b>Syntax Description</b> | <i>point-code</i> | The signaling point code in the point code format. |
|---------------------------|-------------------|----------------------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                               |
|----------------------|-------------------------------|
| <b>Command Modes</b> | CS7 PAM configuration submode |
|----------------------|-------------------------------|

| Command History | Release                    | Modification                 |
|-----------------|----------------------------|------------------------------|
|                 | 12.4(15)SW5<br>12.2(33)IRE | This command was introduced. |

## egress-rate-lmt-timer (config-gws-as)

To enable the rate limit feature on egress traffic of a given AS and set its associated timer, use the **egress-rate-lmt-timer** command in gws as configuration mode. To disable the rate limit feature on egress traffic of a given AS, use the **no** form of this command.

**egress-rate-lmt-timer** *timer*

**no egress-rate-lmt-timer**

|                           |                                                                    |
|---------------------------|--------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>timer</i> Integer value, in seconds. The range is from 1 to 60. |
|---------------------------|--------------------------------------------------------------------|

|                 |          |
|-----------------|----------|
| <b>Defaults</b> | Disabled |
|-----------------|----------|

|                      |                                      |
|----------------------|--------------------------------------|

|----------------------|--------------------------------------|

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(33)IRG | This command was introduced. |
|                        | 12.4(15)SW7 |                              |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The rate limit feature screens outgoing MSUs for the configured time period ( <i>timer</i> value) and during this time period discards outbound MSUs that exceed the configured <b>rate-limit rate</b> value. To disable the rate limit feature on egress traffic of a given AS, remove the configuration. First, remove the <b>rate-limit rate</b> command in the egress-rate-lmt-timer configuration submode. Then, use the <b>no</b> form of the <b>egress-rate-lmt-timer</b> command. |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                    |
|-----------------|------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to configure an outbound rate limit and its timer: |
|-----------------|------------------------------------------------------------------------------------|

```
cs7 instance 0 gws as name as-1
  outbound result action-set as1
  egress-rate-lmt-timer 5
    rate-limit rate 2000 onset-threshold 80 abate-threshold 60
```

| <b>Related Commands</b> | Command                         | Description                                            |
|-------------------------|---------------------------------|--------------------------------------------------------|
|                         | <a href="#">show cs7 gws as</a> | Displays ITP gateway screening information for the AS. |

## egress-rate-lmt-timer (config-gws-ls)

To enable the rate limit feature on egress traffic of a given linkset and set its associated timer, use the **egress-rate-lmt-timer** command in gws linkset configuration mode. To disable the rate limit feature on egress traffic of a given linkset, use the **no** form of this command.

**egress-rate-lmt-timer** *timer*

**no egress-rate-lmt-timer**

| Syntax Description | <i>timer</i> | Integer value, in seconds. The range is from 1 to 60. |
|--------------------|--------------|-------------------------------------------------------|
|--------------------|--------------|-------------------------------------------------------|

| Defaults | Disabled |
|----------|----------|
|----------|----------|

| Command Modes | gws linkset configuration (config-gws-ls) |
|---------------|-------------------------------------------|
|---------------|-------------------------------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(33)IRG | This command was introduced. |
|                 | 12.4(15)SW7 |                              |

| Usage Guidelines | The rate limit feature screens outgoing MSUs for the configured time period ( <i>timer</i> value) and during this time period discards outbound MSUs that exceed the configured <b>rate-limit rate</b> value. To disable the rate limit feature on egress traffic of a given linkset, remove the configuration. First, remove the <b>rate-limit rate</b> command in the egress-rate-lmt-timer configuration submode. Then, use the <b>no</b> form of the <b>egress-rate-lmt-timer</b> command. |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Examples | The following example shows how to configure an outbound rate-limit and its timer: |
|----------|------------------------------------------------------------------------------------|
|----------|------------------------------------------------------------------------------------|

```
cs7 instance 0 gws linkset name ls-1
outbound result action as1
egress-rate-lmt-timer 5
rate-limit rate 2000 onset-threshold 80 abate-threshold 60
```

# emdt

To specify the MSU data format encapsulation of the egress PMP packets, use the **emdt** **cs7 dcs** configuration submode command. To revert to the default encapsulation, use the **no** form of this command.

**emdt** [**emdt1** | **emdt2**]

**no emdt**

## Syntax Description

|              |                                                                                                                                                     |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>emdt1</b> | Encapsulated MSU Data Type 1. Takes advantage of an SNMP MIB to reduce the overhead of the MSU encapsulation header. This data type is the default. |
| <b>emdt2</b> | Encapsulated MSU Data Type 2. Includes all the context information with the MSU.                                                                    |

## Defaults

The default data type is emdt1.

## Command Modes

cs7 dcs configuration submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Usage Guidelines

As with emdt1, emdt2 sends one or more MSUs together to the data collection server (DCS) node. The difference between emdt1 and emdt2 is that emdt2 includes all the context information together with the MSU. Including this information causes emdt2 to take up more encapsulation space than emdt1.

## Examples

The following example shows how to configure emdt2 on the DCS node:

```
edmt emdt2
```

## enable-ussd ussd-tree-type (cs7 mlr options)

To enable the USSD feature and set the USSD transaction timeout value, use the **enable-ussd ussd-tree-type** command in the cs7 mlr options submode. To disable the USSD feature, use the **no** form of this command.

**enable-ussd ussd-tree-type** *type* [**ussd-timer** *timer*]

**no enable-ussd**

|                           |                       |                                                                            |
|---------------------------|-----------------------|----------------------------------------------------------------------------|
| <b>Syntax Description</b> | <b>ussd-tree-type</b> | Indicates the key used for USSD transaction tree.                          |
|                           | <i>type</i>           | 1. Based on tid                                                            |
|                           |                       | 2. Based on combination of opc and tid                                     |
|                           | <b>ussd-timer</b>     | Indicates the USSD transaction timeout value.                              |
|                           | <i>timer</i>          | Integer value, in seconds. The range is from 1 to 180. The default is 120. |

**Defaults** Disabled.

**Command Modes** cs7 mlr options submode

| <b>Command History</b> | <b>Release</b>             | <b>Modification</b>          |
|------------------------|----------------------------|------------------------------|
|                        | 12.4(15)SW7<br>12.2(33)IRG | This command was introduced. |

**Usage Guidelines** This command enables the USSD feature and establishes the USSD transaction timeout value to time out inactive USSD transactions.

A mobileUSSD MLR ruleset should be applied for both mobileInitiated USSD requests and their corresponding response messages. The purpose of applying a mobileUSSD rule on the response messages is to perform USSD processing on response messages. Only the request messages are routed based on the result of the mobileUSSD MLR rule. The response messages are not routed based on the result of the mobileUSSD MLR rule. The response messages are routed at SCCP/MTP3.

**Examples** The following example shows how to route mobile-initiated GSM-MAP messages containing USSD string \*123\*/# to DPC 1234:

```
cs7 ins 0 mlr options
  enable ussd-tree-type 2 ussd-timer 180
```

```
cs7 ins 0 mlr ruleset abc
  rule 1 gsm-map mobileUSSD
  ussd-string 123
  result pc 1234
```

```
cs7 instance 0 gws action-set ussd_action mlr ruleset abc
cs7 instance 0 gws linkset name from_msc
    inbound result action ussd_action
cs7 instance 0 gws linkset name from_ussd
    inbound result action ussd_action
```

The following example shows how to filter mobile-initiated GSM-MAP messages containing USSD string \*123\*/#:

```
cs7 ins 0 mlr options
    enable ussd-tree-type 2 ussd-timer 180

cs7 ins 0 mlr ruleset abc
    rule 1 gsm-map mobileUSSD
        ussd-string 123
        result block
```

|                         | <a href="#">hs-mtp2-timer (cs7 link)</a> | Specifies high-speed MTP2 timers for a link.                             |

# encapsulation mtp2

To specify MTP2 encapsulation, use the **encapsulation mtp2** command in interface configuration mode. To turn off MTP2 encapsulation for the interface and return to the default HDLC encapsulation, use the **no** form of this command.

**encapsulation mtp2**

**no encapsulation mtp2**

**Syntax Description** This command has no arguments or keywords.

**Defaults** The default encapsulation is HDLC.

**Command Modes** Interface configuration

| Command History | Release                                                | Modification                 |
|-----------------|--------------------------------------------------------|------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA<br>12.4(11)SW | This command was introduced. |

**Usage Guidelines** The **encapsulation mtp2** command allows the interface to recognize SS7/MTP2 protocol packets and implements the MTP2 protocol on that interface. Traditional SS7 links use serial interfaces. You must configure ITP router interfaces to use MTP2 encapsulation.

**Examples** The following example shows how to configure serial interface 0 to use MTP2 encapsulation:

```
interface serial0/0
 no ip address
 encapsulation mtp2
```

|                  | <a href="#">mtp2-timer</a> | Tunes MTP2 encapsulation timers. |

# exclude-concatSM-from-multiMsgDialogue

To allow SMS-MO messages that are concatenated at the SMS layer to be routed directly with MLR, use the **exclude-concatSM-from-multiMsgDialogue** command in cs7 mlr options configuration mode. To remove the feature, use the **no** form of this command.

**exclude-concatSM-from-multiMsgDialogue**

**no exclude-concatSM-from-multiMsgDialogue**

---

**Syntax Description** This command has no keywords or arguments.

---

**Defaults** This command is disabled.

---

**Command Modes** cs7 mlr options configuration

---

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXG | This command was introduced. |
|                 | 12.4(15)SW2 |                              |
|                 | 12.2(33)IRB |                              |

---

---

**Usage Guidelines** You must meet at least one of the following conditions to use the **exclude-concatSM-from-multiMsgDialogue** command:

- The MSC ensures that generated concatenated SMs do not trigger TCAP/MAP segmentation.
- The MLR and SMS-MO Proxy rules for handling the last message in the SMS concatenation chain are identical, and configuration ensures that the same SMSC will receive all messages in the chain.
- The receiving SMSC complex does not require all messages in a concatenated message chain to be sent to the same SMSC.

Table 31 shows whether SMS layer segmented data sent within a TCAP begin message and with an invoke component will match the MLR rule.

**Table 30** *Effect of exclude-concatSM-from-multiMsgDialogue on MLR Rule Matching*

|                                                                                   | <b>exclude-concatSM-from-multiMsgDialogue</b> | <b>no exclude-concatSM-from-multiMsgDialogue</b> |
|-----------------------------------------------------------------------------------|-----------------------------------------------|--------------------------------------------------|
| rule 10 gsm-map sms-mo<br>multi-message-dialogue<br>result pc 7.7.2               |                                               | Match rule                                       |
| rule 10 gsm-map sms-mo<br>orig-sme *<br>result pc 7.7.1                           | Match rule                                    |                                                  |
| rule 10 gsm-map sms-mo default<br>allow-multi-message-dialogue<br>result pc 7.7.1 | Match rule                                    | Match rule                                       |
| rule 10 gsm-map sms-mo default result<br>pc 7.7.1                                 | Match rule                                    |                                                  |

As for the multi-message-dialogue (MMD), the following messages are not affected by this command and route using MO-Proxy.

- Segmented Begin without component
- Begin with MMS (more message to send)
- Segmented Continue without component
- Segmented Continue with component

## Examples

The following example shows how to set up all incoming messages from a link (LINK0) to trigger the MLR\_RULE. However, because **exclude-concatSM-from-multiMsgDialogue** has been configured, both concatenated messages and non-MMD messages will hit rule 30 and be routed to pc 7.7.1.

```
cs7 mlr options
exclude-concatSM-from-multiMsgDialogue
!
cs7 mlr ruleset MLR_RULE
rule 15 gsm-map sms-mo
multi-message-dialogue
result pc 7.7.2
rule 30 gsm-map sms-mo
orig-sme *
result pc 7.7.1
!
cs7 gws action-set ACTION1 mlr ruleset MLR_RULE
cs7 gws linkset name LINK0
inbound result action ACTION1
```

# execute-on all show cs7 offload instance

To display the current status, counters, and events maintained by the cs7 offload feature, use the **execute-on all show cs7 offload instance** EXEC command.

**execute-on** {*flex-wan-number* | **all-flex**} **all show cs7 offload instance**

## Syntax Description

|                        |                                                    |
|------------------------|----------------------------------------------------|
| <i>flex-wan-number</i> | Designates the output is from a specified FlexWan. |
| <b>all-flex</b>        | Designates the output is from all FlexWans.        |
| <b>offload</b>         | The transfer of data operations.                   |

## Defaults

None.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

For the Cisco ITP Supervisor Module, the user enters the command **execute-on** {*flex-wan-number* | **all-flex**} **all show cs7 offload instance**. The similar **show cs7 offload instance** command is used for a Cisco ITP FlexWan.

## Examples

The following output excerpt includes some of the most significant output fields for the **show cs7 offload instance** command. [Table 31](#) defines these output fields.

```
ITP# show cs7 offload instance

Instance 1
Point Code          235-33-0:1
SS7 Variant         ANSI

Dropped MSUs:
-----

opc verification drops 0
no_rt_handle
current interval      0    total 6

```

**Table 31** Significant Output Fields for the **show cs7 offload** command

| Field                    | Description                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bufferedPak_drops        | Cisco ITP has capability to buffer packets at link level equal to bufferPak_threshold per instance. If the packets to be buffered exceed this threshold for an instance, ITP drops these packets and increase this counter. |
| bufferedPak_flushes      | When the link or route is removed, then Cisco ITP flushes the packets if any are already buffered for that link/route. This counter is increased for every packet flushed.                                                  |
| tfc_attempt_drops        | Increases to count number of times TFC was dropped.                                                                                                                                                                         |
| tfc_attempt_count        | Increases to count number of times TFC was send.                                                                                                                                                                            |
| loop_detected_drops      | Increases for packets drop due to loop detection by ITP.                                                                                                                                                                    |
| in_acl_drop              | Increases for the packet dropped due to inbound ACL/GWS.                                                                                                                                                                    |
| dcs7_route_pak_fail      | Increases when the routing of the packet is unsuccessful because no link is available in a linkset.                                                                                                                         |
| no_route_link            | Increases when current route is not available due to the non-availabilty of the links in a linkset.                                                                                                                         |
| out_acl_drop             | Increases for the outbound packet dropped due to ACL/GWS.                                                                                                                                                                   |
| alias_route_pak_fail     | Increases when the routing to the alias pc failed.                                                                                                                                                                          |
| no_olink_err             | Increases when the outgoing link is not                                                                                                                                                                                     |
| invalid_pak_size_drops   | Increases when the sizeof mtp3 packet received at ITP is invalid.                                                                                                                                                           |
| circ rt detection drops  | Increases when MSUs dropped due to CRD                                                                                                                                                                                      |
| mgmt_pak_drops           | Increases when MGMT paks drop                                                                                                                                                                                               |
| opc verification drops   | Increase for packet drop due to opc verification failed when CRD is enabled.                                                                                                                                                |
| no_rt_handle/Count/total | Increases when there is no route info for the destination.                                                                                                                                                                  |

# fast-cwnd-rate (cs7 asp)

To configure the rate at which the SCTP congestion window size is reduced due to a fast retransmission, use the **fast-cwnd-rate** command in cs7 asp configuration mode. To disable the configuration, use the **no** form of this command.

**fast-cwnd-rate** *percent*

**no fast-cwnd-rate** *percent*

|                           |                |                                                                                                                                                       |
|---------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>percent</i> | Rate at which the size of the SCTP congestion window is decreased due to a fast retransmission. Range is 0 to 100 percent. The default is 50 percent. |
|---------------------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                 |
|-----------------|---------------------------------|
| <b>Defaults</b> | The default rate is 50 percent. |
|-----------------|---------------------------------|

|                      |                       |

|-----------------|------------------------------------------|------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

|                         |                                                                                                                                                                                       |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The <b>fast-cwnd-rate</b> command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to a fast retransmission on the SCTP association. |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

|                 |                                                                                       |
|-----------------|---------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to set the fast congestion window rate to 60 percent: |
|-----------------|---------------------------------------------------------------------------------------|

```
cs7 asp ASP1 2905 2905 m3ua
remote-ip 1.1.1
fast-cwnd-rate 60
```

|---------------|------------------------|
|---------------|------------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Usage Guidelines | The <b>fast-cwnd-rate</b> command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to a fast retransmission on the SCTP association. |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

| Examples | The following example shows how to set the fast congestion window rate to 60 percent: |
|----------|---------------------------------------------------------------------------------------|
|----------|---------------------------------------------------------------------------------------|

```
cs7 linkset michael 10.1.1
 link 0 sctp 172.18.44.147 7000 7000

 fast-cwnd-rate 60
```

## fast-cwnd-rate (cs7 mated-sg)

To configure the rate at which the SCTP congestion window size is reduced due to a fast retransmission, use the **fast-cwnd-rate** command in cs7 mated-sg configuration mode. To disable the configuration, use the **no** form of this command.

**fast-cwnd-rate** *percent*

**no fast-cwnd-rate** *percent*

### Syntax Description

|                |                                                                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>percent</i> | Rate at which the size of the SCTP congestion window is decreased due to a fast retransmission. Range is 0 to 100 percent. The default is 50 percent. |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|

### Defaults

The default rate is 50 percent.

### Command Modes

cs7 mated-sg configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **fast-cwnd-rate** command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to a fast retransmission on the SCTP association.

#### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

### Examples

The following example shows how to set the fast congestion window rate to 60 percent:

```
cs7 mated-sg BLUE 5000
remote-ip 5.5.5.5
fast-cwnd-rate 60
```

## fast-cwnd-rate (cs7 sua)

To configure the rate at which the SCTP congestion window size is reduced due to a fast retransmission, use the **fast-cwnd-rate** command in cs7 sua configuration mode. To disable the configuration, use the **no** form of this command.

**fast-cwnd-rate** *percent*

**no fast-cwnd-rate** *percent*

### Syntax Description

|                |                                                                                                                                                       |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>percent</i> | Rate at which the size of the SCTP congestion window is decreased due to a fast retransmission. Range is 0 to 100 percent. The default is 50 percent. |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|

### Defaults

The default rate is 50 percent.

### Command Modes

cs7 sua configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **fast-cwnd-rate** command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to a fast retransmission on the SCTP association.

#### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

### Examples

The following example shows how to set the fast congestion window rate to 60 percent:

```
cs7 sua 15000 offload 2 0
local-ip 4.4.4.4
fast-cwnd-rate 60
```

| <i>nai</i>         | Integer in the range 0 to 127.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>order</b>       | Specifies the order in which the results are stored in the result group. Required for (and present only in the CLI for) results in dest-sme-binding mode. Results in a wrp result group are not able to configure an <b>order</b> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>order</i>       | Integer in the range 1 to 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>weight</b>      | (Optional) Specifies the load-balancing weight.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>weight</i>      | For dest-sme-binding mode, an integer value in the range 1 to 2147483647. The weight value should reflect the relative capacity of the result (SMSC). This value is used by the dynamic B-address routing algorithm to select a deterministic result (SMSC) based on the message B-address. If not configured, the default <i>weight</i> value is 1.<br><br>For wrp mode, an integer value in the range 0 to 10. A value of 10 indicates the resource should be selected 10 times more than a resource assigned a weight of 1. A weight of 0 indicates that the resource should be used only when all nonzero-weighted resources are unavailable. If multiple zero-weighted resources exist, then messages are equally distributed between them if all nonzero-weighted resources fail. If not specified, a default weight of 1 is used. |

### Defaults

The default weight value is 1.

### Command Modes

cs7 mlr result configuration

■ **gt (cs7 mlr result)****Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

The **gt** result is always considered to be available and uncongested. The network global title translation function then assumes all further load-balancing, congestion, and distribution decisions for the message. This behavior is true for both wrp mode and dest-sme-binding mode.

**Examples**

The following example shows how to configure an SMS result group named POSTPAY with several optional parameters specified:

```
cs7 mlr result POSTPAY
gt 11111111 tt 0 gti 4 np 1 nai 4 weight 1
```

**Related Commands**

|--------------------------------------|---------------------------------|
| <a href="#">cs7 mlr result-group</a> | Configures an SMS result group. |

# gta app-grp

To create or modify a GTA entry that translates a GTA to a GTT application group, use the **gta app-grp** command in **cs7 gtt selector** configuration mode. To delete a GTA entry, use the **no** form of this command.

```
gta { gta | default } app-grp app-grp [pam pam-name]
```

```
no gta { gta | default }
```

## Syntax Description

|                 |                                                                                                |
|-----------------|------------------------------------------------------------------------------------------------|
| <i>gta</i>      | Global Title Address. Valid values are hexadecimal numbers in the range of 1 to 15 characters. |
| <b>default</b>  | Specifies the default translation to use if no specific GTAs match.                            |
| <b>app-grp</b>  | Result type specifying that GTA translates to a GTT application group.                         |
| <i>app-grp</i>  | Name of application group.                                                                     |
| <b>pam</b>      | This keyword indicates a PAM table is part of the GTA entry.                                   |
| <i>pam-name</i> | Name used to specify the particular PAM table.                                                 |

## Defaults

None.

## Command Modes

cs7 gtt selector configuration

| Release                                  | Modification                                         |
|------------------------------------------|------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                         |
| 12.4(15)SW5<br>12.2(33)IRE               | The ability to include the PAM table was introduced. |

## Usage Guidelines

If load sharing is required for the intermediate GTT, then the result of the GTT must use a GTT application group.

## Examples

The following example shows how to translate gta 919363 to the application group named group1:

```
cs7 gtt selector selector1 tt 250 gti 2
gta 919363 app-grp group1
```

### Usage Guidelines

The **gta asname** command allows you to assign a global title translation to an M3UA or SUA AS, instead of to a point code and SSN. By specifying the AS name, backup systems solely reside underneath the AS specified with the **cs7 as** command.

### Examples

The following example shows how to configure a GTA entry that translates to an SUA AS named GREENASP3:

```
cs7 as GREENASP3 sua
  routing-key 3 gtt
  asp ASP3
.
.
.
cs7 gtt selector E164SEL 14
  gta 1123456789001 asname GREENASP3 pcssn
```

The following example shows how to configure separate GTA asname entries that refer respectively to PAM tables named pam2 and pam3:

```
cs7 instance 1 gtt selector test1 tt 0 gti 2
  gta 123 pcssn 1.2.3 gt pam pam1
  gta 124 asname as1 gt pam pam2
  gta default asname as2 gt pam pam3
```

|--------------------------------------|------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 as</a>               | Specifies an application server and enables cs7 as submode.                                          |
| <a href="#">cs7 gtt selector</a>     | Specifies a GTT selector.                                                                            |
| <a href="#">cs7 m3ua</a>             | Specifies the local port number for M3UA and enters cs7 m3ua submode.                                |
| <a href="#">cs7 sua</a>              | Specifies the local port number for SUA and enters cs7 sua submode.                                  |
| <a href="#">show cs7 gtt gta</a>     | Displays CS7 GTT GTA entries.                                                                        |
| <a href="#">cs7 pam</a>              | Identifies a packet address modification (PAM) table and enters the CS7 PAM submode.                 |
| <a href="#">cgpa (cs7 pam)</a>       | Configures one cgpa entry in the PAM table.                                                          |
| <a href="#">cdpa (cs7 pam)</a>       | Configures one cdpa entry in the PAM table.                                                          |
| <a href="#">opc</a>                  | Configures an opc entry in the PAM table.                                                            |
| <a href="#">dpc</a>                  | Configures a dpc entry in the PAM table.                                                             |
| <a href="#">gta pcssn</a>            | Creates or modifies a GTA entry that translates a GTA to a point code and optional subsystem number. |
| <a href="#">modify-failure (pam)</a> | Specifies the desired action when the PAM table packet modification fails.                           |
| <a href="#">cs7 gws action-set</a>   | Defines gateway screening action sets that may include a PAM table.                                  |

## gta pcssn

To create or modify a GTA entry that translates a GTA to a point code and optional subsystem number, use the **gta pcssn** command in cs7 gtt selector configuration mode. To delete a GTA entry, use the **no** form of this command.

```
gta { gta | default } pcssn pc { gt | pcssn } [ntt ntt | ssn ssn | sccp-allow-pak-conv number | pam pam-name]
```

```
no gta { gta | default }
```

| Syntax Description         |                                                                                                                             |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <i>gta</i>                 | Global Title Address. Valid values are hexadecimal numbers in the range of 1 to 15 characters.                              |
| <b>default</b>             | Specifies the default translation to use if no specific GTAs match.                                                         |
| <b>pcssn</b>               | Result type specifying that GTA translates to a point code and optional subsystem number.                                   |
| <i>pc</i>                  | Point code, in the form zone.region.sp.                                                                                     |
| <b>gt</b>                  | Sets the routing indicator (RI) to Route on Global Title                                                                    |
| <b>pcssn</b>               | Sets the RI to Route on Point Code and Subsystem Number.                                                                    |
| <b>ntt</b>                 | Specifies a new translation type.                                                                                           |
| <i>ntt</i>                 | New translation type, in the range 0 to 255.                                                                                |
| <b>ssn</b>                 | Specifies a subsystem number.                                                                                               |
| <i>ssn</i>                 | Subsystem number, in the range 2 to 255.                                                                                    |
| <b>sccp-allow-pak-conv</b> | Enables conversion of SCCP packet between XUDT/XUDTS and UDT/UDTS.                                                          |
| <i>number</i>              | 1 specifies XUDT/XUDTS to UDT/UDTS conversion<br>2 specifies UDT/UDTS to XUDT/XUDTS conversion<br>3 specifies NO CONVERSION |
| <b>pam</b>                 | This keyword indicates a PAM table is part of the GTA entry.                                                                |
| <i>pam-name</i>            | Name used to specify the particular PAM table.                                                                              |

**Defaults** None.

**Command Modes** cs7 gtt selector configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Release                    | Modification                                         |
|----------------------------|------------------------------------------------------|
| 12.4(15)SW5<br>12.2(33)IRE | The ability to include the PAM table was introduced. |
| 12.4(15)SW9<br>12.2(33)IRI | The <b>sccp-allow-pak-conv</b> keyword was added.    |

**Usage Guidelines**

You must configure at least one subsystem for the point code. Otherwise, the command fails.

**Examples**

The following example shows how to add GTA entry 1111 translating to point code 1.2.3 and set the routing indicator to route on the global title:

```
gta 1111 pcssn 1.2.3 gt
```

The following example shows how to modify GTA entry 1111 translating to point code 1.2.3 and set the routing indicator to route on the point code and subsystem number:

```
gta 1111 pcssn 1.2.3 pcssn
```

The following example shows how to delete GTA entry 1111:

```
no gta 1111
```

The following example shows how to configure a GTA pcssn entry that refers to a PAM table named pam2:

```
cs7 instance 1 gtt selector test1 tt 0 gti 2
gta 123 pcssn 1.2.3 gt pam pam1
gta 124 asname as1 gt pam pam2
gta default asname as2 gt pam pam3
```

# gta-prefix

To specify a partial or a prefix match of the global title address, use the **gta-prefix** command in gws table configuration mode. To remove the specification, use the **no** form of this command.

```
gta-prefix { gta-pref [exact] | * } [min-digits min-digits] [max-digits max-digits] result { action
action-set | table table-name }
```

```
no gta-prefix { gta-pref | * }
```

## Syntax Description

|                   |                                                                           |
|-------------------|---------------------------------------------------------------------------|
| <i>gta-pref</i>   | Partial or prefix digits of the global title addresses.                   |
| <b>exact</b>      | Screens for the exact match.                                              |
| *                 | Wildcard. (See the Usage Guidelines section.)                             |
| <b>min-digits</b> | Screens against the minimum number of digits of the global title address. |
| <i>min-digits</i> | Minimum number of digits.                                                 |
| <b>max-digits</b> | Screens against the maximum number of digits of the global title address. |
| <i>max-digits</i> | Maximum number of digits.                                                 |
| <b>result</b>     | Specifies the next step.                                                  |
| <b>action</b>     | Specifies that the next step is an action set.                            |
| <i>action-set</i> | Action set name. Valid names may not exceed 12 alphanumeric characters.   |
| <b>table</b>      | Specifies that the next step is a table.                                  |
| <i>table-name</i> | Name of the next step table.                                              |

## Command Default

None.

## Command Modes

gws table configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **gta-prefix** command is valid in the following table types: cgpa-gta-prefix, cdpa-gta-prefix.

The GTA prefix table is typically the next step for CgPA PC-SSN or CdPA PC-SSN screening, pre-GTT and post-GTT respectively. The table is used for partial or prefix matching of the global title address. If **min-digits** and **max-digits** are specified, every screening is verified against the minimum and maximum number of digits in the GTA. If the optional keyword **exact** is specified, the GTA is checked for the exact match. When a wildcard (\*) is specified along with **min-digits** and/or **max-digits**, the GTA is checked for the minimum and/or maximum number of digits in the GTA.

---

**Examples**

In the following example, the second line screens for the partial prefix 455 and specifies the next step as the action set ALLOW. The third line screens for the partial prefix 556677 and specifies the next step as the action set BLOCK.

```
cs7 instance 2 gws table PGTA222 type cgpa-gta-prefix action allowed
gta-prefix 455 result action ALLOW
gta-prefix 556677 max-digits 10 result action BLOCK
```

---

**Related Commands**

| Command                       | Description                           |
|-------------------------------|---------------------------------------|
| <a href="#">cs7 gws table</a> | Configures a gateway screening table. |

# gta qos-class

To set the QoS class for a global title address, use the **gta qos-class** command in cs7 gtt selector configuration mode. To remove the configuration, use the **no** form of this command.

```
gta { gta | default } qos-class qos-class { app-grp app-grp | asname as-name | pcssn pc [{ gt | pcssn }  
{ ntt ntt } | { ssn ssn } ] }
```

```
no gta { gta | default } qos-class
```

## Syntax Description

|                  |                                                                                                |
|------------------|------------------------------------------------------------------------------------------------|
| <i>gta</i>       | Global Title Address. Valid values are hexadecimal numbers in the range of 1 to 15 characters. |
| <b>default</b>   | Specifies the default translation to use if no specific GTAs match.                            |
| <i>qos-class</i> | QoS class. Valid range is 0 to 7.                                                              |
| <b>app-grp</b>   | GTA translated to a GTT application group.                                                     |
| <i>app-grp</i>   | Name of the application group.                                                                 |
| <b>asname</b>    | Result type specifying that GTA translates to an M3UA or SUA application server name.          |
| <i>as-name</i>   | Name of the M3UA or SUA application server.                                                    |
| <b>pcssn</b>     | GTA translated to a point code and optional subsystem number.                                  |
| <i>pc</i>        | Point code in the form zone.region.sp.                                                         |
| <b>gt</b>        | Sets the routing indicator to “route on global title.”                                         |
| <b>ntt</b>       | Specifies a new translation type.                                                              |
| <i>ntt</i>       | New translation type. Valid range is 0 to 255.                                                 |
| <b>pcssn</b>     | Sets the routing indicator to “route on point code and subsystem number.”                      |
| <b>ssn</b>       | Specifies a subsystem number.                                                                  |
| <i>ssn</i>       | Subsystem number. Valid range is 2 to 255.                                                     |

## Defaults

None.

## Command Modes

cs7 gtt selector configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

If the QoS class entered for a GTA is not defined, SCCP packets for the GTA are routed over the default class peer link members.

---

**Examples**

The following example shows how to configure a QoS class 3 for the GTA 1324:

```
cs7 gtt selector c7gsp tt 3 gti 2
gta 1324 qos-class 3 pcssn 2.2.2 gt ssn 2
```

---

**Related Commands**

| Command                       | Description                     |
|-------------------------------|---------------------------------|
| <a href="#">cs7 qos class</a> | Defines a QoS class.            |
| <a href="#">show cs7 qos</a>  | Displays QoS class information. |

# gta-start

To specify a GTA range, use the **gta-start** command in gws digit-screening table configuration mode. To remove the specification, use the **no** form of this command.

**gta-start** *start-gta* [**gta-end** *end-gta*] **result** {**action** *action-set* | **table** *table-name*}

**no gta-start** *start-gta* [**gta-end** *end-gta*]

| Syntax Description |  |                                                                         |
|--------------------|--|-------------------------------------------------------------------------|
| <i>start-gta</i>   |  | Starting GTA, in the range of 1 to 15 hexadecimal digits.               |
| <b>gta-end</b>     |  | Specifies an ending GTA.                                                |
| <i>end-gta</i>     |  | Ending GTA, in the range of 1 to 15 hexadecimal digits.                 |
| <b>result</b>      |  | Specifies the next step.                                                |
| <b>action</b>      |  | Specifies that the next step is an action set.                          |
| <i>action-set</i>  |  | Action set name. Valid names may not exceed 12 alphanumeric characters. |
| <b>table</b>       |  | Specifies that the next step is a table.                                |
| <i>table-name</i>  |  | Name of the next step table.                                            |

**Defaults** None.

**Command Modes** gws digit-screening table configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** The **gta-start** command is valid in the following table types: cdpa-gta-range, cgpa-gta-range.

**Examples** The following example shows how to specify a set of GTA ranges and the next step for each range:

```
cs7 instance 0 gws table GTA1 type cgpa-gta-range action allowed
gta-start 4500 gta-end 5000 result action ALLOW
gta-start 34555 result action action ALLOW
gta-start 3922000 gta-end 3924000 result action ALLOW
```

|                  | <a href="#">cs7 gws table</a> | Configures a gateway screening table. |

## gtt-accounting (as)

To enable GTT accounting for an xUA AS, use the **gtt-accounting** *cs7* as submode command.

To disable accounting for an xUA AS, use the **no** form of this command.

**gtt-accounting**

**no gtt-accounting**

### Syntax Description

This command has no arguments or keywords.

### Defaults

This command is disabled.

### Command Modes

*cs7* as submode

### Related Commands

### Usage Guidelines

GTT accounting is performed after a successful GTT packet is received from the AS.

For an M3UA AS, GTT accounting is performed on a payload data message. For an SUA AS, GTT accounting is performed on a CLDT message where the routing indicator is GT.

### Examples

The following example shows how to enable GTT accounting:

```
gtt-accounting
```

|------------------------|-------------------------------------|
| <a href="#">cs7 as</a> | Defines an application server (AS). |

# gtt-accounting (linkset)

To enable GTT accounting on a linkset, use the **gtt-accounting** command in cs7 linkset configuration mode. To disable GTT accounting on a linkset, use the **no** form of this command.

**gtt-accounting**

**no gtt-accounting**

**Syntax Description** This command has no arguments or keywords.

**Defaults** This command is disabled.

**Command Modes** cs7 linkset configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |

# hold-transport (cs7 link)

To specify that the SCTP association will stay up when the link is shut down, use the **hold-transport** command in cs7 link configuration mode. To specify to take down the association when the link is shut down, use the **no** form of this command.

**hold-transport**

**no hold-transport**

---

**Syntax Description** This command has no arguments or keywords.

---

**Defaults** The default is to leave the link up.

---

**Command Modes** cs7 link configuration

---

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |

# hs-mtp2

To configure CS7 link profile parameters for high-speed MTP2, use the **hs-mtp2** cs7 profile submode command. To disable the settings, use the **no** form of this command.

**hs-mtp2**

**no hs-mtp2**

**Syntax Description** This command has no arguments or keywords.

**Defaults** This command is disabled.

**Command Modes** cs7 profile submode

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Examples** The following example shows how to define a profile named TIMERS. The profile supports high-speed MTP2, configures the t1 and t2 settings, and applies to all the links in the linkset named ITP\_A.

```
cs7 profile TIMERS
  hs-mtp2
    timer t1 100
    timer t2 10
  .
  .
  .
cs7 linkset ITP_A
  profile TIMERS
```

| Related Commands | Command                                              | Description                                                          |

## hs-mtp2-timer (cs7 link)

To configure high-speed MTP2 encapsulation timers on a link, use the **hs-mtp2-timer** command in cs7 link configuration mode. To reset the timers, use the **no** form of this command.

**hs-mtp2-timer** {**t1** msec | **t2** msec | **t3** msec | **t4e** msec | **t4n** msec | **t5** msec | **t6** msec | **t7** msec | **t8** msec}

**no hs-mtp2-timer** {**t1** msec | **t2** msec | **t3** msec | **t4e** msec | **t4n** msec | **t5** msec | **t6** msec | **t7** msec | **t8** msec}

| Syntax Description |                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>t1</b>          | Alignment ready timer.<br>ANSI range: 165 to 200 seconds. Default 170 seconds.<br>ITU range 25 to 350 seconds. Default 300 seconds.                                                |
| <b>t2</b>          | Not aligned timer.<br>ANSI range 5 to 14 seconds. Default 11.5 seconds.<br>ITU range 5 to 150 seconds. Default 5 seconds.                                                          |
| <b>t3</b>          | Aligned timer.<br>ANSI range 5 to 14 seconds. Default 11.5 seconds.<br>ITU range 1 to 2 seconds. Default 1.5 seconds.                                                              |
| <b>t4e</b>         | Emergency proving period timer.<br>ANSI range: 4.5 to 5.5 seconds. Default 5 seconds.<br>ITU range: 400 to 600 milliseconds. Default 500 milliseconds.                             |
| <b>t4n</b>         | Normal proving period timer.<br>ANSI range: 27 to 33 seconds. Default 30 seconds.<br>ITU range: 3 to 70 seconds. Default 30 seconds.                                               |
| <b>t5</b>          | Sending SIB timer.<br>ANSI range: 80 to 120 milliseconds. Default 100 milliseconds.<br>ITU range: 80 to 120 milliseconds. Default 100 milliseconds.                                |
| <b>t6</b>          | Remote congestion timer.<br>ANSI range: 1 to 6 seconds. Default 1 second.<br>ITU range 3 to 6 seconds. Default 3 seconds.                                                          |
| <b>t7</b>          | Excessive delay of acknowledgment timer.<br>ANSI range: 500 to 2000 milliseconds. Default 1000 milliseconds.<br>ITU range: 500 to 2000 milliseconds. Default is 1000 milliseconds. |
| <b>t8</b>          | Interval timer for errored interval monitor.<br>ANSI range: 80 to 120 milliseconds. Default 100 milliseconds.<br>ITU range: 80 to 120 milliseconds. Default 100 milliseconds.      |

### Defaults

T1: ANSI = 170 seconds; ITU = 300 seconds

T2: ANSI = 11.5 seconds; ITU = 5 seconds

T3: ANSI = 11.5 seconds; ITU = 1.5 seconds

T4E: ANSI = 5 seconds; ITU = 500 milliseconds

T4N: ANSI = 30 seconds; ITU = 30 seconds

T5: ANSI = 100 milliseconds; ITU = 100 milliseconds

T6: ANSI = 1 second; ITU = 3 seconds

T7: ANSI = 1000 milliseconds; ITU = 1000 seconds

T8: ANSI = 100 milliseconds; ITU = 100 milliseconds

### Command Modes

cs7 link configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

High-speed MTP2 parameters can also be specified in cs7 profile configuration mode.

### Examples

The following example shows how to specify timers for link 0 of linkset TO\_NYC:

```
cs7 linkset TO_NYC 3.3.3
 link 0 Serial4/1/0:0
   hs-mtp2-timer t1 100
   hs-mtp2-timer t2 10
```

# hsl

To configure CS7 link profile parameters for HSL (high-speed linking), use the **hsl** command in cs7 profile configuration mode. To disable the settings, use the **no** form of this command.

**hsl**

**no hsl**

**Syntax Description** This command has no arguments or keywords.

**Defaults** This command is disabled.

**Command Modes** cs7 profile configuration

| Command History | Release                                  | Modification                 |
|-----------------|------------------------------------------|------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

**Examples** The following example shows how to define a profile named SAAL. The profile supports HSL, specifies the packet bundling interval and SSCF NNI timers, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile SAAL
 hsl
  bundling 10
  sscf-nni t1 10
  sscf-nni t2 150
  sscf-nni t3 100
.
.
cs7 linkset to_nyc
 profile SAAL
```

| Related Commands | Command                     | Description                                                         |
|------------------|-----------------------------|---------------------------------------------------------------------|
|                  | <a href="#">cs7 profile</a> | Defines a profile that you can apply to all the links in a linkset. |
|                  | <a href="#">variant jtl</a> | Specifies which of the SS7 variations the CS7 profile is running.   |

## idle-cwnd-rate (cs7 asp)

To configure the rate at which the SCTP congestion window size is reduced due to idle time, use the **idle-cwnd-rate** command in **cs7 asp** configuration mode. To disable the configuration, use the **no** form of this command.

**idle-cwnd-rate** *percent*

**no idle-cwnd-rate** *percent*

### Syntax Description

|                |                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>percent</i> | Rate at which the size of the SCTP congestion window is decreased due to an idle association. Range is 0 to 100 percent. The default is 50 percent. |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|

### Defaults

The default rate is 50 percent.

### Command Modes

cs7 asp configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **idle-cwnd-rate** command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to the SCTP association being idle. The SCTP congestion window does not decrease below the initial congestion window size, regardless of the rate and the length of idle time.

#### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

### Examples

The following example shows how to set the idle congestion window rate to 60 percent:

```
cs7 asp ASP1 2905 2905 m3ua
  remote-ip 1.1.1
  idle-cwnd-rate 60
```

### Related Commands

|                 |                                 |
|-----------------|---------------------------------|
| <b>Defaults</b> | The default rate is 50 percent. |
|-----------------|---------------------------------|

|                      |                            |
|----------------------|----------------------------|
| <b>Command Modes</b> | cs7 mated-sg configuration |
|----------------------|----------------------------|

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

|                         |                                                                                                                                                                                                                                                                                                                    |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The <b>idle-cwnd-rate</b> command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to the SCTP association being idle. The SCTP congestion window does not decrease below the initial congestion window size, regardless of the rate and the length of idle time. |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

|                 |                                                                                       |
|-----------------|---------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to set the idle congestion window rate to 60 percent: |
|-----------------|---------------------------------------------------------------------------------------|

```
cs7 mated-sg BLUE 5000
remote-ip 5.5.5.5
idle-cwnd-rate 60
```

## idle-cwnd-rate (cs7 )

To configure the rate at which the SCTP congestion window size is reduced due to idle time, use the **idle-cwnd-rate** command in **cs7** configuration mode. To disable the configuration, use the **no** form of this command.

**idle-cwnd-rate** *percent*

**no idle-cwnd-rate** *percent*

### Syntax Description

|                |                                                                                                                                                     |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>percent</i> | Rate at which the size of the SCTP congestion window is decreased due to an idle association. Range is 0 to 100 percent. The default is 50 percent. |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|

### Defaults

The default rate is 50 percent.

### Command Modes

**cs7** configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **idle-cwnd-rate** command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to the SCTP association being idle. The SCTP congestion window does not decrease below the initial congestion window size, regardless of the rate and the length of idle time.

#### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

### Examples

The following example shows how to set the idle congestion window rate to 60 percent:

```
cs7 5000
 local-ip 4.4.4.4
 idle-cwnd-rate 60
```

# inbound (config-gws-as)

To configure screening of inbound messages, use the **inbound** command in gws as configuration mode. To remove the configuration, use the **no** form of this command.

**inbound** [**logging type** { **allow** | **block** | **rate-limit** | **both** } { **silent** | **file** [**verbose**] | **console** [**verbose**] | **file** [**verbose**] **console** [**verbose**]}] **result** { **action** *action-set-name* | **table** *table-name* }

**no inbound**

## Syntax Description

|                        |                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------|
| <b>logging</b>         | (Optional) Enables logging.                                                                    |
| <b>type</b>            | Specifies the logging type.                                                                    |
| <b>allow</b>           | Messages allowed for further processing.                                                       |
| <b>block</b>           | Messages blocked.                                                                              |
| <b>both</b>            | Allowed and blocked messages.                                                                  |
| <b>rate-limit</b>      | Logs the number of MSUs discarded due to a configured rate limit.                              |
| <b>silent</b>          | Messages are screened without logging.                                                         |
| <b>file</b>            | Log is copied to a file.                                                                       |
| <b>verbose</b>         | (Optional) The packet (up to 40 bytes) is printed to the file and/or displayed on the console. |
| <b>console</b>         | Log is displayed on the console.                                                               |
| <b>result</b>          | Specifies the next step.                                                                       |
| <b>action</b>          | Specifies that the next step is an action set.                                                 |
| <i>action-set-name</i> | Action set name. Valid names may not exceed 12 alphanumeric characters.                        |
| <b>table</b>           | Specifies that the next step is a table.                                                       |
| <i>table-name</i>      | Name of the next step table.                                                                   |

## Defaults

The default screening is silent.

## Command Modes

gws as configuration

## Command History

| Release                                  | Modification                             |
|------------------------------------------|------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.             |

## Examples

The following example shows how to configure inbound and outbound default screening for all ASes:

```
cs7 instance 0 gws as default
```

```
inbound logging type block file console verbose result table SIO0
outbound result action BLOCK
```

# inbound (config-gws-ls)

To configure screening of inbound messages, use the **inbound** command in gws linkset configuration mode. To remove the configuration, use the **no** form of this command.

**inbound** [**logging type** { **allow** | **block** | **rate-limit** | **both** } { **silent** | **file** [**verbose**] | **console** [**verbose**] | **file** [**verbose**] **console** [**verbose**]}] **result** { **action** *action-set-name* | **table** *table-name* }

**no inbound**

## Syntax Description

|                        |                                                                                                |
|------------------------|------------------------------------------------------------------------------------------------|
| <b>logging</b>         | (Optional) Enables logging.                                                                    |
| <b>type</b>            | Specifies the logging type.                                                                    |
| <b>allow</b>           | Messages allowed for further processing.                                                       |
| <b>block</b>           | Messages blocked.                                                                              |
| <b>rate-limit</b>      | Logs the number of MSUs discarded due to a configured rate limit.                              |
| <b>both</b>            | Allowed and blocked messages.                                                                  |
| <b>silent</b>          | Messages are screened without logging.                                                         |
| <b>file</b>            | Log is copied to a file.                                                                       |
| <b>verbose</b>         | (Optional) The packet (up to 40 bytes) is printed to the file and/or displayed on the console. |
| <b>console</b>         | Log is displayed on the console.                                                               |
| <b>result</b>          | Specifies the next step.                                                                       |
| <b>action</b>          | Specifies that the next step is an action set.                                                 |
| <i>action-set-name</i> | Action set name. Valid names may not exceed 12 alphanumeric characters.                        |
| <b>table</b>           | Specifies that the next step is a table.                                                       |
| <i>table-name</i>      | Name of the next step table.                                                                   |

## Defaults

The default screening is silent.

## Command Modes

gws linkset configuration

## Command History

# init-cwnd-size (cs7 asp)

To configure the SCTP initial congestion window size, use the **init-cwnd-size** command in cs7 asp configuration mode. To disable the configuration, use the **no** form of this command.

**init-cwnd-size** *window-size*

**no init-cwnd-size** *window-size*

## Syntax Description

|                    |                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>window-size</i> | Size in bytes of the SCTP initial congestion window size. Range is 3000 to 20971520 bytes. The default is two times the smallest MTU of the SCTP interfaces (in bytes). |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Defaults

The default window size is two times the smallest MTU of the SCTP interfaces (in bytes).

## Command Modes

cs7 asp configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **init-cwnd-size** command allows the administrator to configure an initial congestion window size for an SCTP association.

If this command is provisioned, the window size specified must match the receive window size of the remote end of the SCTP association. If the initial window size does not match the receive window size, congestion control behavior will be unpredictable.

### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

## Examples

The following example shows how to set the initial congestion window size to 5000 bytes:

```
cs7 asp ASP1 2905 2905 m3ua
  remote-ip 1.1.1
  init-cwnd-size 5000
```

## Usage Guidelines

The **init-cwnd-size** command allows the administrator to configure an initial congestion window size for an SCTP association.

### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

## Examples

The following example shows how to set the initial congestion window size to 5000 bytes:

```
cs7 5000
 local-ip 4.4.4.4
 init-cwnd-size 5000
```

|---------------------------------------|-------------------------------------------|
| <a href="#">receive-window (cs7 )</a> | Configures the local receive window size. |

# init-cwnd-size (cs7 sua)

To configure the SCTP initial congestion window size, use the **init-cwnd-size** command in cs7 sua configuration mode. To disable the configuration, use the **no** form of this command.

**init-cwnd-size** *window-size*

**no init-cwnd-size** *window-size*

## Syntax Description

|                    |                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>window-size</i> | Size in bytes of the SCTP initial congestion window size. Range is 3000 to 20971520 bytes. The default is two times the smallest MTU of the SCTP interfaces (in bytes). |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Defaults

The default window size is two times the smallest MTU of the SCTP interfaces (in bytes).

## Command Modes

cs7 sua configuration

## init-retransmit (cs7 m2pa profile)

To configure the number of retransmissions for peer initialization messages, use the **init-retransmit** command in cs7 m2pa profile configuration mode. To disable the configuration, use the **no** form of this command.

**init-retransmit** *max-retries*

**no init-retransmit** *max-retries*

|                           |                    |                                                                                                  |
|---------------------------|--------------------|--------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>max-retries</i> | Maximum number of initialization packet retries. The range is 2 to 20. The default is 8 retries. |
|---------------------------|--------------------|--------------------------------------------------------------------------------------------------|

|                 |           |
|-----------------|-----------|
| <b>Defaults</b> | 8 retries |

**Examples** The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the **init-retransmit** command, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
  m2pa
    init-retransmit 10
  .
  .
  .
cs7 linkset to_nyc
  profile m2parfc
```

|                    | show cs7 sgmp                                                                                                                                                        | Displays statistics.                                        |

# init-timeout (cs7 sua)

To configure the maximum interval for the init packet retransmission timeout value, use the **init-timeout** cs7 sua submode command. To disable the configuration, use the **no** form of this command.

**init-timeout** *msec*

**no init-timeout** *msec*

| Syntax Description | <i>msec</i> | Timeout value in milliseconds. Range is 1000 to 60000 milliseconds. The default is 1000 milliseconds. |
|--------------------|-------------|-------------------------------------------------------------------------------------------------------|
|--------------------|-------------|-------------------------------------------------------------------------------------------------------|

| Defaults | 1000 milliseconds |
|----------|-------------------|
|----------|-------------------|

| Command Modes | cs7 sua submode |
|---------------|-----------------|
|---------------|-----------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Examples** The following example shows how to set the timeout value for retransmission of association setup messages to 2000 milliseconds:

```
cs7 sua 15000
local-ip 4.4.4.4
init-timeout 2000
```

|------------------|------------------------------|---------------------------------------------------------------------|
|                  | <a href="#">cs7 sua</a>      | Specifies the local port number for SUA and enters cs7 sua submode. |
|                  | <a href="#">show cs7 sua</a> | Displays SUA statistics.                                            |

# insert-dpc-in-cdpa

To enable a global multilayer routing (MLR) option to insert a destination point code (dpc) into the called party (cdpa) point code (pc) for packets that are routed with MLR, use the **insert-dpc-in-cdpa** command in cs7 options configuration mode. To remove the specification, use the **no** form of this command.

**insert-dpc-in-cdpa**

**no insert-dpc-in-cdpa**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** cs7 options configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXB | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **insert-dpc-in-cdpa** command is a cdpa modification enhancement. When this option is configured and a packet is routed with MLR, the MTP dpc is inserted into the cdPa pc if the cdPa pc is null. This MLR option is configured globally per instance, so that it can be applied to all MLR-routed results, including trigger results, rule results, and address-table results. The cdpa pc is updated for MLR results of pc, point code and subsystem number (pcssn), global title (gt), and asname. This option does not apply to the MLR results **block** or **continue**.

MLR can modify the cdPa pc and the calling party (cgpa) pc of an MSU. MLR verifies that the modified MSU fits in 273 bytes. A “Failed to insert data into MSU” statistic is displayed in the MLR global statistics if the MSU is not modified. In the failed cases, the packet is still routed with MLR but without the updated Signaling Connection Control party (SCCP) addresses.

Preserving the original dpc in the cdpa is not possible with an MLR GT result. The SCCP always overwrites the cdpa pc with the new GT translated dpc.

## Examples

The following example shows how to enable global options and specifies that, when a packet is routed with MLR, the MTP dpc is inserted into the cdpa pc if the cdpa is null:

```
cs7 instance 0 mlr options
insert-dpc-in-cdpa
```

## ip-dscp (cs7 m2pa profile)

To set the differentiated services code point (DSCP) bits in the IP header ToS byte, use the **ip-dscp** cs7 m2pa profile submode command. To set the DSCP setting to the default of zero, use the **no** form of this command.

**ip-dscp** *ip-tos*

**no ip-dscp**

|                           |               |                                                                              |
|---------------------------|---------------|------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>ip-tos</i> | IP DSCP setting, in decimal notation. Range is 5000 to 63. The default is 0. |
|---------------------------|---------------|------------------------------------------------------------------------------|

|                 |                          |
|-----------------|--------------------------|
| <b>Defaults</b> | The IP ToS default is 0. |
|-----------------|--------------------------|

|                      |                          |
|----------------------|--------------------------|
| <b>Command Modes</b> | cs7 m2pa profile submode |
|----------------------|--------------------------|

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

|                         |                                                                                                                   |
|-------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The IP DSCP configured on the peer link overrides any IP ToS setting assigned to the peer link using a QoS class. |
|-------------------------|-------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                                                                                                                                   |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the <b>ip-dscp</b> command, and applies to all the links in the linkset named to_nyc. |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
cs7 profile m2parfc
  m2pa
    ip-dscp 56
  .
  .
  .
cs7 linkset to_nyc
  profile m2parfc
```

# isup-msg-type

To specify an ISUP message type, use the **isup-msg-type** command in cs7 gws isup message table configuration mode. To remove the specification, use the **no** form of this command.

**isup-msg-type** *isup-msg-type* **result** {**action** *action-set-name* | **table** *table-name*}

**no isup-msg-type** *isup-msg-type*

## Syntax Description

|                      |                                                                                                 |
|----------------------|-------------------------------------------------------------------------------------------------|
| <i>isup-msg-type</i> | ISUP message types are listed in <a href="#">Table 28</a> in the Usage Guidelines.              |
| <b>result</b>        | Specifies the next step.                                                                        |
| <b>action</b>        | Action set name.                                                                                |
| <i>action-set</i>    | Name of the action set in the next step. Valid names may not exceed 12 alphanumeric characters. |
| <b>table</b>         | Specifies that the next step is a table.                                                        |
| <i>table-name</i>    | Name of the table in the next step.                                                             |

## Defaults

None.

## Command Modes

cs7 gws isup message table configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

[Table 32](#) lists the ISUP message types.

**Table 32** *ISUP Message Types*

|      |                 |                 |                 |
|------|-----------------|-----------------|-----------------|
| ACM  | ANM             | APM (ITU only)  | BLA             |
| BLO  | CCR             | CFN             | CGB             |
| CGBA | CGU             | CGUA            | CRG             |
| CON  | COT             | CPG             | CQM             |
| CQR  | CVR (ANSI only) | CVT (ANSI only) | EXM (ANSI only) |
| FAC  | FAA (ITU only)  | FRJ (ITU only)  | FAR (ITU only)  |
| FOT  | IDR (ITU only)  | IRS (ITU only)  | INF             |
| INR  | GRA             | GRS             | IAM             |
| LPA  | LOP (ITU only)  | NRM (ITU only)  | OLM (ITU only)  |
| PAM  | PRI (ITU only)  | REL             | RES             |

**Table 32** *ISUP Message Types (continued)*

|                |                |                |                |
|----------------|----------------|----------------|----------------|
| RLC            | RSC            | SUS            | SGM (ITU only) |
| SAM (ITU only) | SDN (ITU only) | UBA            | UBL            |
| UCIC           | UPA (ITU only) | UPT (ITU only) | USR            |

**Examples**

The following example shows how to specify three ISUP message types and the next step for each type:

```
cs7 instance 0 gws table ISUP0 type isup-msg-type action allow
default result action ALLOW
isup-msg-type SAM result action ALLOW
isup-msg-type ANM result action ALLOW
isup-msg-type REL result action ALLOW
```

**Related Commands**

| Command                       | Description                           |
|-------------------------------|---------------------------------------|
| <a href="#">cs7 gws table</a> | Configures a gateway screening table. |

# keepalive (cs7 asp)

To specify if a keepalive timer is supported, and to specify the keepalive interval for the association, use the **keepalive** cs7 asp submode command. To disable the keepalive, use the **no** form of this command.

**keepalive** *msec*

**no keepalive** *msec*

| Syntax Description | <i>msec</i> | Keepalive interval, in milliseconds. The range is 300 to 30000 milliseconds. The default is the value specified under the local instance. |
|--------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------|
|--------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------|

| Defaults | Keepalive is enabled.<br>The keepalive interval defaults to the value specified under the local instance. |
|----------|-----------------------------------------------------------------------------------------------------------|
|----------|-----------------------------------------------------------------------------------------------------------|

| Command Modes | cs7 asp submode |
|---------------|-----------------|
|---------------|-----------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Examples | The following example shows how to set the keepalive value to 1000 milliseconds: |
|----------|----------------------------------------------------------------------------------|
|----------|----------------------------------------------------------------------------------|

```
cs7 asp ASP1 2904 2905 m3ua
  remote-ip 1.1.1.1
  keepalive 1000
```

| Related Commands | Command                      | Description                                                                |
|------------------|------------------------------|----------------------------------------------------------------------------|
|                  | <a href="#">cs7 asp</a>      | Specifies an application server process (ASP) and enables cs7 asp submode. |
|                  | <a href="#">show cs7 asp</a> | Displays ASP statistics.                                                   |

# keepalive (cs7 link)

To enable a peer link keepalive interval, use the **keepalive** cs7 link submode command. To disable the keepalive interval, use the **no** form of this command.

**keepalive** *msec*

**no keepalive** *msec*

| Syntax Description | <i>msec</i> | Keepalive interval, in milliseconds. The range is 300 to 30000 milliseconds. The default interval is 30000 milliseconds. |
|--------------------|-------------|--------------------------------------------------------------------------------------------------------------------------|
|--------------------|-------------|--------------------------------------------------------------------------------------------------------------------------|

| Defaults | Keepalive is enabled.<br>The default keepalive interval is 30000 milliseconds. |
|----------|--------------------------------------------------------------------------------|
|----------|--------------------------------------------------------------------------------|

| Command Modes | cs7 link submode |
|---------------|------------------|
|---------------|------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Examples | The following example shows how to set the keepalive value to 1000 milliseconds: |
|----------|----------------------------------------------------------------------------------|
|----------|----------------------------------------------------------------------------------|

```
cs7 linkset michael 10.1.1
 link 0 sctp 172.18.44.147 7000 7000
  keepalive 1000
```

| Related Commands | Command                            | Description                                         |
|------------------|------------------------------------|-----------------------------------------------------|
|                  | <a href="#">cs7 linkset</a>        | Specifies a linkset and enters cs7 linkset submode. |
|                  | <a href="#">link (cs7 linkset)</a> | Specifies a link and enters cs7 link submode.       |
|                  | <a href="#">show cs7 m2pa</a>      | Displays M2PA statistics.                           |

## keepalive (cs7 m2pa profile)

To enable a peer link keepalive interval, use the **keepalive** cs7 m2pa profile configuration command. To disable the keepalive interval, use the **no** form of this command.

**keepalive** *msec*

**no keepalive** *msec*

### Syntax Description

|             |                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Keepalive interval, in milliseconds. The range is 300 to 30000 milliseconds. The default interval is 30000 milliseconds. |
|-------------|--------------------------------------------------------------------------------------------------------------------------|

### Defaults

Keepalive is enabled.

The default keepalive interval is 30000 milliseconds.

### Command Modes

cs7 m2pa profile configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Examples

The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the **keepalive** command, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
  m2pa
  keepalive 1000
.
.
.
cs7 linkset to_nyc
  profile m2parfc
```

### Related Commands

| Command              | Description                                 |
|----------------------|---------------------------------------------|
| <a href="#">m2pa</a> | Specifies M2PA parameters in a CS7 profile. |

## keepalive (cs7 m3ua)

To specify a keepalive interval to be used when a new SCTP association is started with the local port, use the **keepalive** cs7 m3ua submode command. To disable the keepalive interval, use the **no** form of this command.

**keepalive** *msec*

**no keepalive** *msec*

### Syntax Description

|             |                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>msec</i> | Keepalive interval, in milliseconds. The range is 300 to 30000 milliseconds. The default interval is 30000 milliseconds. |
|-------------|--------------------------------------------------------------------------------------------------------------------------|

### Defaults

Keepalive is enabled.

The default keepalive interval is 30000 milliseconds.

### Command Modes

cs7 m3ua submode

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Examples

The following example shows how to set the keepalive value to 1000 milliseconds:

```
cs7 m3ua 2905
 local-ip 4.4.4.4
 keepalive 1000
```

### Related Commands

# large-msu-support (cs7 link submode)

To configure large MSU support for an M2PA link, use the **large-msu-support** cs7 link submode command. To disable the support, use the **no** form of this command.

**large-msu-support**

**no large-msu-support**

**Syntax Description** This command has no arguments or keywords.

**Defaults** M2PA restricts the size of the outgoing packet to 273 bytes.

**Command Modes** cs7 link submode

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXH | This command was introduced. |
|                 | 12.4(15)SW3 |                              |
|                 | 12.2(33)IRC |                              |

**Usage Guidelines** This command allows an M2PA link to carry MSU sizes of up to 4096 bytes instead of the default maximum of 273 bytes. SCTP segmentation and reassembly is used for MSUs that are larger than 1500 bytes and carried by the M2PA link, because M2PA runs over IP networks with a maximum MSU size of 1500 bytes.

**Examples** The following example shows how to configure large MSU support on a M2PA link:

```
cs7 instance 0 linkset alaska 1-4-4
link 0
large-msu-support
```

| Related Commands | Command            | Description                   |
|------------------|--------------------|-------------------------------|
|                  | show cs7 m2pa peer | Displays ITP M2PA statistics. |

# large-msu-support (cs7 m2pa profile)

To configure large MSU support for all M2PA links in a linkset, use the **large-msu-support** command in cs7 m2pa profile configuration mode. To disable the support, use the **no** form of this command.

**large-msu-support**

**no large-msu-support**

## Syntax Description

This command has no arguments or keywords.

## Defaults

M2PA restricts the size of the outgoing packet to 273 bytes.

## Command Modes

cs7 m2pa profile configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXH | This command was introduced. |
| 12.4(15)SW3 |                              |
| 12.2(33)IRC |                              |

## Usage Guidelines

This command allows an M2PA link to carry MSU sizes of up to 4096 bytes instead of the default maximum of 273 bytes. SCTP segmentation and reassembly is used for MSUs that are larger than 1500 bytes and carried by the M2PA links, because M2PA runs over IP networks with a maximum MSU size of 1500 bytes.

## Examples

The following example shows how to configure large MSU support in an M2PA profile:

```
cs7 instance 0 linkset alaska0 1-4-4
profile alpha
m2pa
    large-msu-support
```

## Related Commands

| Command                            | Description                                 |
|------------------------------------|---------------------------------------------|
| <a href="#">m2pa</a>               | Specifies M2PA parameters in a CS7 profile. |

# linestate debounce

To suppress rapid linestate transitions that may occur due to brief interruption of the framing on an E1 line, use the **linestate debounce** command in controller configuration mode. To disable linestate debounce, use the **no** form of this command.

**linestate debounce**

**no linestate debounce**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** Controller configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXB | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** Enabling linestate debounce changes the behavior for an individual E1 line such that a Loss of Frame (LOF) condition must persist or subside for approximately 100 milliseconds before the ITP software is notified of the linestate change.

**Examples** The following example shows how to enable linestate bounce:

```
controller e1 4/0/0
  linestate bounce
```

| Related Commands | Command    | Description             |

|                  | controller | Specifies a controller. |

## link (cs7 linkset)

To configure an SS7 link, use the **link** command in cs7 linkset submode command. To remove a link from a linkset, use the **no** form of this command. A link must be shut down before it can be removed from a linkset.

### Serial or T1/E1 TDM SS7 link

**link** *slc* [*name*] **serial** *interface-number*[:*timeslot*]

**no link** *slc* [*name*] **serial** *slot*[/*bay*] [:*timeslot*]

### M2PA SS7 over IP link

**link** *slc* [*name*] **sctp** *remote-ip-addr* [*remote-ip-addr* ...] *remote-port-num* *local-port-num* [**passive** | **draft2**]

**no link** *slc* [*name*] **sctp** *remote-ip-addr* [*remote-ip-addr* ...] *remote-port-num* *local-port-num* [**passive** | **draft2**]

### ATM HSL SS7 link

**link** *slc* [*name*] **atm** *interface-number* [.*subinterface number*]

#### Syntax Description

|                            |                                                                                                                                                                                                          |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>atm</b>                 | ATM interface.                                                                                                                                                                                           |
| <i>slc</i>                 | Signal Link Code. Valid range is 0 to 15. The <i>slc</i> value uniquely identifies this link within the linkset. The <i>slc</i> value must match the value configured on the partner node for this link. |
| <i>name</i>                | Name of the group peer on which the link physically resides. The <i>name</i> parameter is valid (and required) only if the ITP Group feature has been configured.                                        |
| <b>serial</b>              | Serial interface.                                                                                                                                                                                        |
| <i>interface-number</i>    | Interface identifier using slot, bay, and port notation, as required for the chassis in use (for example, 3/0, 1/1/0).                                                                                   |
| <b>sctp</b>                | Stream Control Transmission Protocol.                                                                                                                                                                    |
| <i>remote-ip-addr</i>      | Remote IP address that is one of the four IP addresses configured as local IP addresses on the remote peer. At least one, and up to four, remote IP addresses can be specified.                          |
| <i>remote-port-num</i>     | Remote port number (the local port number configured on the remote ITP).                                                                                                                                 |
| <i>local-port-num</i>      | Local port number.                                                                                                                                                                                       |
| <b>passive</b>             | Indicates that the remote ITP must establish the peer connection.                                                                                                                                        |
| <b>draft2</b>              | Specifies a peer link that permanently uses the M2PA draft2 protocol.                                                                                                                                    |
| <b>link</b>                | CS7 link definition.                                                                                                                                                                                     |
| <i>subinterface number</i> | (Optional) Specifies a subinterface number. A period (.) must be used to separate the interface number from the subinterface number (for example, 2/0.1).                                                |
| <i>:timeslot</i>           | Channel group number.                                                                                                                                                                                    |

**Defaults**

The 12.2(25)SW3 software assumes that the protocol of choice is the M2PA RFC version. However, if an endpoint using the pre-RFC M2PA protocol (draft2) communicates with the ITP, then the 12.2(25)SW3 software switches to the M2PA draft2 protocol.

**Command Modes**

cs7 linkset submode

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

The SLC must be the same at both ends of the signaling link to align.

When you issue the **link** command you enter cs7 linkset submode. In cs7 linkset submode, you have access to commands that allow you to further configure links.

When a link is removed from configuration using the **no** form of the command, the issuing user experiences a delayed response of a few seconds. The delay ensures that all previous shutdown-related activity has completed for the link.

**Release 12.2(25)SW3 M2PA Version Migration Strategy**

In Release 12.2(25)SW3, ITP supports both the current version of M2PA (draft2) and the RFC version. The migration strategy for upgrading from an earlier release to Release 12.2(25)SW3 is as follows:

The ITP detects and uses the protocol that is being used by the peer endpoint. If an endpoint using the M2PA draft2 protocol communicates with the ITP, then the 12.2(25)SW3 software switches to the M2PA draft2 protocol. If an endpoint using the M2PA RFC protocol communicates with the ITP, then the 12.2(25)SW3 software uses the M2PA RFC protocol. This strategy provides the flexibility to upgrade some ITPs in your network to 12.2(25)SW3 and not upgrade other ITPs. M2PA links will work without any configuration changes.

You also have the option to define a link to be a permanent M2PA draft2 link by specifying the draft2 keyword in the link statement. A link configured as such would always expect the remote endpoint to use the M2PA draft2 protocol. If the endpoint does not communicate using M2PA draft2 protocol then the M2PA link will not come up.

**Examples**

The following example shows how to configure links 0 and 1 to a legacy SS7 device. The names smith and jones are the group peers on which each link resides (indicating that the ITP Group feature has been enabled).

```
cs7 linkset black 5.100.1
 link 0 smith serial1/0/0:0
 link 1 jones serial2/0/0:0
```

The following example shows how to assign link 0 to the ITP linkset named white and how to assign the SCTP peers (remote instance at IP address 172.18.44.147 port 7000 and local instance at port 7000). The link is defined as a permanent M2PA draft2 link.

```
cs7 linkset white 10.1.1
 link 0 sctp 172.18.44.147 7000 7000 draft2
```

The following example shows how to assign link 0 to the ITP linkset named white and assign the SCTP peers (remote instance at IP address 172.18.44.147 port 7000 and local instance at port 7000). In Release 12.2(25)SW3, the ITP assumes that the protocol of choice is the M2PA RFC version.

```
cs7 linkset white 10.1.1
link 0 sctp 172.18.44.147 7000 7000
```

**Related Commands**

| Command                            | Description                   |
|------------------------------------|-------------------------------|
| <a href="#">cs7 linkset</a>        | Specifies a linkset.          |
| <a href="#">encapsulation mtp2</a> | Specifies MTP2 encapsulation. |

## linkset (cs7 billing account configuration submode)

To configure a criteria entry of a billing account, use the **linkset** command in the cs7 billing account configuration submode. To remove the criteria, use the **no** form of this command.

```
linkset linkset_name {inbound | outbound} [ type {mtp3 | sccp | sms_sccp} ] {opc-table | dpc-table} pctbl_name
```

```
no linkset linkset_name {inbound | outbound} [ type {mtp3 | sccp | sms_sccp} ] {opc-table | dpc-table} pctbl_name
```

### Syntax Description

|                     |                                                                   |
|---------------------|-------------------------------------------------------------------|
| <i>linkset_name</i> | Name of the criteria entry.                                       |
| <b>inbound</b>      | Messages on inbound interfaces are used for accounting criteria.  |
| <b>outbound</b>     | Messages on outbound interfaces are used for accounting criteria. |
| <b>mtp3</b>         | Protocol type for accounting criteria.                            |
| <b>sccp</b>         | Protocol type for accounting criteria.                            |
| <b>sms_sccp</b>     | Protocol type for accounting criteria.                            |
| <b>opc-table</b>    | Point-code specified for the pc-table. Ingress point code (OPC).  |
| <b>dpc-table</b>    | Point-code specified for the pc-table. Egress point code (DPC).   |
| <i>pctbl_name</i>   | Name of the pc table associated with this entry.                  |

### Defaults

None.

### Command Modes

cs7 billing account configuration submode

### Command History

| Release                    | Modification                                |
|----------------------------|---------------------------------------------|
| 12.4(15)SW4<br>12.2(33)IRD | This command was introduced.                |
| 12.4(15)SW6<br>12.2(33)IRF | The keyword <b>sms_sccp</b> was introduced. |

### Usage Guidelines

This command specifies an entry of accounting criteria in a billing account.

If you are configuring the cs7 billing account for the SMS protocol, the criteria can only be defined on the inbound interface.

For SMS account IDs, no counters are incremented at the MTP3 or SCCP level. The defined parameters operate at the MAP/IS41 layer to isolate SMS messages for this particular account and increment the relevant counters.

## Examples

The following example shows entering the cs7 billing account configuration submode to configure a criteria entry of a billing account with a linkset named **Linkset\_01**, an inbound traffic direction, an mtp3 protocol type, an OPC, and a pc table name of PCTBL\_01 :

```
cs7 instance 0 billing account BILL_ACCNT
  linkset LINKSET_01 inbound type mtp3 opc-table PCTBL_01
```

The following example shows entering the cs7 billing account configuration submode to configure a criteria entry of a billing account with a linkset named **hsl\_tg13\_FW1**, an inbound traffic direction, an sms protocol type, an OPC, and a pc table name of PCTBL\_01 :

```
cs7 instance 0 billing account BILL_ACCNT-AT-1
  linkset hsl_tg13_FW1 inbound type sms_sccp opc-table PCTBL_01
```

## Related Commands

| Command                              | Description                                       |
|--------------------------------------|---------------------------------------------------|
| <a href="#">cs7 billing pc-table</a> | Configures a pc-table for the billing account.    |
| <a href="#">cs7 billing options</a>  | Configures options for billing.                   |
| <a href="#">cs7 billing account</a>  | Configures a billing account.                     |
| <a href="#">cs7 billing load</a>     | Specifies the billing configuration file to load. |

# link-test

Link testing is performed by sending an SLTM message and verifying the acknowledgement (SLTA) from the adjacent node. Link testing is performed on serial and peer links. To enable link testing, use the **link-test** cs7 link submode command. To disable link testing, use the **no** form of this command.

**link-test**

**no link-test**

## Syntax Description

This command has no arguments or keywords.

## Defaults

This command is enabled by default and tests the links every 30 seconds.

A link test is run automatically when the link first comes into service.

## Command Modes

cs7 link submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

By default, a link test is run when the link first comes into service, and periodically while the link is in service. If the link test fails, the link is taken out of service.

The slt-t2 timer determines the interval for sending signaling link test messages.

The slt-t1 timer determines the interval to wait for the signaling link test acknowledgement.

If an SLTA is not received in the specified interval, a second SLTM is sent. If an SLTA is not received for the second SLTM, then the link restoration and activation procedure is initiated.

The **no link-test** command disables the link test. The **link-test** command reenables link testing.

## Examples

The following example shows how to disable link testing:

```
cs7 linkset michael 10.1.1
link 0 sctp 172.18.44.147 7000 7000
no link-test
```

## Related Commands

| Command                            | Description             |
|------------------------------------|-------------------------|
| <a href="#">cs7 mtp3 timer</a>     | Configures MTP3 timers. |
| <a href="#">link (cs7 linkset)</a> | Specifies a link.       |

# link-timer

To configure the ITP MTP3 management timers that control the link, use the **link-timer** cs7 link submode command. To reset a timer to its default value, use the **no** form of this command.

```
link-timer {retry msec | slt-t1 msec | slt-t2 msec | t01 msec | t02 msec | t03 msec | t04 msec | t05 msec | t12 msec | t13 msec | t14 msec | t17 msec | t19 msec | t20 msec | t21 msec | t22 msec | t23 msec | t24 msec | t25 msec | t32 msec}
```

```
no link-timer {retry | slt-t1 | slt-t2 | t01 | t02 | t03 | t04 | t05 | t12 | t13 | t14 | t17 | t19 | t20 | t21 | t22 | t23 | t24 | t32}
```

## Note

Ranges are defined by ANSI or ITU.

## Syntax Description

|                    |                                                                                                                                                                        |

cs7 link submode

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

MTP3 timers can be defined at three levels: global, linkset, and link.

All global, linkset, and link specific timers can be defined at the global level. These values serve as defaults and are propagated down to the lower levels.

All linkset and link specific timers can be defined at the linkset level. These values serve as defaults for the linkset and all links defined within that linkset. Any values defined here override any global values.

All timers defined at the link level apply to the link and override any values for that timer defined at either the linkset or global level.

### Examples

The following example shows how to set the ITP MTP3 T1 timer to 1000 milliseconds for link 0 of linkset1:

```
cs7 linkset linkset1
  link 0
    link-timer t01 1000
```

### Related Commands

|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 linkset</a>          | Specifies a linkset and enters cs7 linkset submode.                                                                                                                       |
| <a href="#">link (cs7 linkset)</a>   | Specifies a link and enters cs7 link submode.                                                                                                                             |
| <a href="#">cs7 mtp3 timer</a>       | Configures all global, linkset, and link specific timers.                                                                                                                 |
| <a href="#">show cs7 linkset</a>     | Used with the <b>timer</b> keyword, displays all timers for a linkset and indicates at which level the timers were defined. Displays all the link timers for the linkset. |
| <a href="#">show cs7 mtp3 timers</a> | Displays all global timers, and all linkset and link timers that have been defined at the global level.                                                                   |
| <a href="#">timer (cs7 linkset)</a>  | Configures timers for a linkset (and, optionally, timers for links on the linkset).                                                                                       |

## load (cs7 route table)

Route table contents can be loaded from a URL that locates a binary version of the route table. To load route table contents, use the **load** command in cs7 route table configuration mode. To remove the **load** command from the configuration, use the **no** form of this command.

```
load { flash | ftp | rcp | tftp } url
```

```
no load { flash | ftp | rcp | tftp } url
```

| Syntax Description | { flash   ftp   rcp   tftp } | Device where the route table is stored.        |
|--------------------|------------------------------|------------------------------------------------|
|                    | url                          | Path and filename of the route table contents. |

|          |       |
|----------|-------|
| Defaults | None. |
|----------|-------|

|               |                               |
|---------------|-------------------------------|
| Command Modes | cs7 route table configuration |
|---------------|-------------------------------|

| Command History | Release                                  | Modification                 |
|-----------------|------------------------------------------|------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

**Usage Guidelines**

The **load** command enters the (new) routing table immediately. When reloading the router, the **load** command is executed before any update route.

Removing the **load** command from the configuration does not empty the routing table, but no table is loaded when the next router reload occurs.

Use this command to load an MTP3 route table upon ITP startup. At startup the ITP loads the route table specified by *url* from a local flash file system or from a remote file system using TFTP/FTP/RCP. After the route table is loaded, all **update route** or **remove route** commands are applied to the previously loaded route table.

If you use the **load** command while the ITP is operational the current (actual/active) route table is replaced with the one specified by *url* and the configured update/remove route commands are reapplied.

|          |                                                                                    |
|----------|------------------------------------------------------------------------------------|
| Examples | The following example shows how to load a file named route.txt from a TFTP server: |
|----------|------------------------------------------------------------------------------------|

```
load tftp://64.102.16.25/route.txt
```

| <a href="#">show cs7 route</a>             | Displays the ITP routing table. |
| <a href="#">update route (route-table)</a> | Updates a route.                |

## local-ip (cs7 dcs)

To configure a local IP address for an instance used to send PMP to DCS nodes, use the **local-ip** cs7 dcs configuration submode command. To remove the configuration, use the **no** form of this command.

**local-ip** *addr port*

**no local-ip** *addr port*

|                           |             |                                                                                                |
|---------------------------|-------------|------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>addr</i> | An IPv4 address in the form xxx.xxx.xxx.xxx. It is the source IP address for PMP data packets. |
|                           | <i>port</i> | Source IP address port with an integer range of 1024 to 49151.                                 |

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                               |
|----------------------|-------------------------------|
| <b>Command Modes</b> | cs7 dcs configuration submode |
|----------------------|-------------------------------|

| <b>Command History</b> | Release                    | Modification                 |
|------------------------|----------------------------|------------------------------|
|                        | 12.4(15)SW3<br>12.2(33)IRC | This command was introduced. |

|                         |                                                                                                                                                                           |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | You must shut down the DCS node before deleting a local IP address on that node. You can only modify the local IP address when the DCS node is not part of any DCS group. |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to configure a local IP address with 209.165.201.30 as the address and 3033 as the port on the CS7 DCS node named dcs1: |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|

```
cs7 dcs dcs1
  remote-ip 209.165.201.31 209.165.201.28 33500
  local-ip 209.165.201.30 33500
  ping-interval 5
  timeout-count 3
  udp-checksum
```

### Related Commands

| Command History    | Release                                                                                                                                                                                                                                 | Modification                                                |
|                    | 12.2(18)IXA                                                                                                                                                                                                                             | This command was introduced.                                |
|                    | 12.4(11)SW                                                                                                                                                                                                                              |                                                             |
|                    | 12.2(33)IRA                                                                                                                                                                                                                             |                                                             |
| Usage Guidelines   | You must configure one (and may configure up to four) local IP addresses for each local peer. Cisco ITP uses one of the four local IP addresses for a primary local endpoint instance and uses the other three IP addresses as backups. |                                                             |
| Examples           | The following example shows how to assign IP address 172.18.44.254 to the local peer at port 7000:<br><pre>cs7 local-peer 7000   local-ip 172.18.44.254</pre>                                                                           |                                                             |
| Related Commands   | Command                                                                                                                                                                                                                                 | Description                                                 |
|                    | cs7 local-peer                                                                                                                                                                                                                          | Specifies the local peer and enters cs7 local peer submode. |

## local-ip (cs7 m3ua)

To configure a local IP address for an instance, use the **local-ip** cs7 m3ua submode command. To remove the configuration, use the **no** form of this command.

**local-ip** *addr*

**no local-ip** *addr*

|                           |             |             |

|------------------|--------------------------|---------------------------|
|                  | <a href="#">cs7 sgmp</a> | Specifies the local peer. |

## local-ip (cs7 sua)

To configure a local IP address for an instance, use the **local-ip** cs7 sua submode command. To remove the configuration, use the **no** form of this command.

**local-ip** *addr*

**no local-ip** *addr*

| Syntax Description | <i>addr</i> | Local IP address. |
|--------------------|-------------|-------------------|
|--------------------|-------------|-------------------|

| Defaults | None. |
|----------|-------|
|----------|-------|

| Command Modes | cs7 sua submode |
|---------------|-----------------|
|---------------|-----------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Usage Guidelines | <p>You must configure one (and may configure up to four) local IP addresses that will receive packets for the configured local port. You can configure multiple IP addresses for SCTP multihoming by specifying additional <b>local-ip</b> commands. The local port will receive packets only from an IP address that was configured.</p> |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

The local IP address associated with an instance can be added only on the first visit to the instance submode, or when the instance submode is shut down. The local IP address associated with an instance can be removed only when the instance is shut down.

| Examples | <p>The following example shows how to assign IP address 4.4.4.4 to the local peer at port 15000:</p> <pre>cs7 sua 15000  local-ip 4.4.4.4</pre> |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------|

| Related Commands | Command                 | Description                                                         |
|------------------|-------------------------|---------------------------------------------------------------------|
|                  | <a href="#">cs7 sua</a> | Specifies the local port number for SUA and enters cs7 sua submode. |

# m2pa

To specify M2PA parameters in a CS7 profile, use the **m2pa** command in cs7 profile configuration mode. To remove the specification, use the **no** form of this command.

**m2pa**

**no m2pa**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** cs7 profile configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |
|                 |             |                              |

**Examples** The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the **hold-transport** command, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
  m2pa
  hold-transport
.
.
.
cs7 linkset to_nyc
  profile m2parfc
```

|------------------|---------------------------------------------------|-----------------------------------------------------------------------------------------------------|
|                  | assoc-retransmit                                  | Configures association retransmissions.                                                             |
|                  | <a href="#">bundling (cs7 link)</a>               | Enables and configures message bundling.                                                            |
|                  | cumulative-sack                                   | Configures cumulative selective ack timeout.                                                        |
|                  | fast-cwnd-rate                                    | Specifies the rate at which the SCTP congestion window size decreases due to a fast retransmission. |
|                  | <a href="#">hold-transport (cs7 m2pa profile)</a> | Specifies that the SCTP association will stay up when the link is shut down.                        |
|                  | idle-cwnd-rate                                    | Specifies the rate at which the SCTP congestion window size decreases due to idle destination.      |
|                  | init-cwnd-size                                    | Specifies the initial SCTP congestion window size.                                                  |

| Command                   | Description                                                                                                     |
|---------------------------|-----------------------------------------------------------------------------------------------------------------|
| init-retransmit           | Specifies the number of retransmissions for peer initialization packets.                                        |
| init-timeout              | Specifies the maximum interval for the init packet retransmission timeout value.                                |
| ip-dscp                   | Specifies the differentiated services code point bits in the IP header ToS byte.                                |
| ip-precedence             | Configures IP precedence.                                                                                       |
| keepalive                 | Enables peer link keepalives.                                                                                   |
| path-retransmit           | Configures path retransmissions on the remote-peer address.                                                     |
| peer-timer                | Specifies the CS7 peer link timer.                                                                              |
| qos-class                 | Configures the QoS class.                                                                                       |
| retransmit-cwnd-rate      | Configures the rate at which the SCTP congestion window size is reduced due to retransmission timer expiration. |
| retransmit-timeout        | Specifies the minimum retransmission timeout value for the association.                                         |
| tx-queue-depth (cs7 link) | Configures the MTP2 transmit queue depth.                                                                       |

# map-version

To filter specific versions of a gsm-map message, use the **map-version** command in cs7 mlr ruleset rule configuration mode. To remove the configuration, use the **no** form of this command.

**map-version** *version-number*

**no map-version**

## Syntax Description

|                       |                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------|
| <i>version-number</i> | Specifies the specific MAP version used to filter the gsm-map messages. Valid range is 1 to 3. |
|-----------------------|------------------------------------------------------------------------------------------------|

## Defaults

Matches all map-versions.

## Command Modes

cs7 mlr ruleset rule configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXG | This command was introduced. |
| 12.4(15)SW2 |                              |
| 12.2(33)IRB |                              |

## Usage Guidelines

You can configure the MAP version with multiple version values in one command line by separating the versions with a space. This command may be applied to any gsm-map operations that support multiple map-versions.

This command will fail if either:

- You reconfigure the map-version without removing the original configuration.
- You configure the map-version while multi-message-dialogue or allow-multi-message-dialogue is configured.

## Examples

The following example shows how to specify map-version 1 and map-version 2 as the filter:

```
cs7 instance 0 mlr ruleset sms-rs1
rule 1 gsm-map sms-mo
map-version 1 2
```

## Related Commands

| Command                                | Description                                                                                                                      |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">rule (cs7 mlr ruleset)</a> | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode. |

# match access-group

To enable access list packet classification on a linkset, use the **match access-group** cs7 linkset submode command. To remove the configuration, use the **no** form of this command.

**match access-group**

**no match access-group**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** cs7 linkset submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

This command should be used on input linksets with legacy SS7 links. The **match access-group** command enables the mapping of CS7 access list match criteria to the access list applied to the QoS classes.

## Examples

The following example shows how to enable access list packet classification. Incoming packets with service indicator 3 (SCCP) will be assigned QoS class 5.

```
access list 2701 permit si 3

cs7 qos class 5
  qos-ip-precedence 3
  qos-access-group 2701

cs7 linkset to-washington 3.3.3
  match access-group
```

| <b>Syntax Description</b> | <b>qos-class</b>       | Specifies a QoS class.                                                                               |
|                           | <i>class</i>           | QoS class ID. Valid range is 1 to 7.                                                                 |
|                           | <i>instance-number</i> | Required if multiple instances are configured. The valid range is 0 to 7. The default instance is 0. |

**Defaults** Matches all map-versions.

**Command Modes** cs7 asp submode

|                        |                                          |                              |
|------------------------|------------------------------------------|------------------------------|
| <b>Command History</b> | <b>Release</b>                           | <b>Modification</b>          |
|                        | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

**Examples** The following example shows how to assign QoS class 4 to all incoming packets from ASP1:

```
cs7 asp ASP1
match any qos-class 4
```

|                         |                               |                                                                            |
|-------------------------|-------------------------------|----------------------------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>                | <b>Description</b>                                                         |
|                         | <a href="#">cs7 asp</a>       | Specifies an application server process (ASP) and enables cs7 asp submode. |
|                         | <a href="#">cs7 qos class</a> | Specifies a QoS class.                                                     |

## match any (cs7 linkset)

To enable input packet classification on a linkset, use the **match any** cs7 linkset submode command. To remove the configuration, use the **no** form of this command.

**match any qos-class** *class*

**no match any qos-class** *class*

### Syntax Description

|                  |                                      |
|------------------|--------------------------------------|
| <b>qos-class</b> | Specifies a QoS class.               |
| <i>class</i>     | QoS class ID. Valid range is 1 to 7. |

### Defaults

None.

### Command Modes

cs7 linkset submode

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

This command should be used on input linksets with legacy SS7 links.

### Examples

The following example shows how to configure input linkset packet classification and assign QoS class 4 to the incoming packets:

```
cs7 linkset to-washington 3.3.3
 match any qos-class 4
```

### Related Commands

| Command                       | Description            |
|-------------------------------|------------------------|
| <a href="#">cs7 qos class</a> | Specifies a QoS class. |

## match si (cs7 asp)

To assign a QoS class number to any inbound packet that has a specific service indicator, use the **match si** command in cs7 asp configuration mode. To remove the configuration, use the **no** form of this command.

**match si** *si* **qos-class** *class* [*instance-number*]

**no match si** *si* **qos-class** *class* [*instance-number*]

|                           |                        |                                                                                                      |
|---------------------------|------------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>si</i>              | Service indicator. Valid range is 0 to 15.                                                           |
|                           | <b>qos-class</b>       | Specifies a QoS class.                                                                               |
|                           | <i>class</i>           | QoS class ID. Valid range is 1 to 7.                                                                 |
|                           | <i>instance-number</i> | Required if multiple instances are configured. The valid range is 0 to 7. The default instance is 0. |

|                 |                            |
|-----------------|----------------------------|
| <b>Defaults</b> | The default instance is 0. |

## match si (cs7 linkset)

To enable service indicator packet classification on a linkset, use the **match si** command in cs7 linkset configuration mode. To remove the configuration, use the **no** form of this command.

**match si** *si* **qos-class** *class*

**no match si** *si* **qos-class** *class*

### Syntax Description

|                  |                                            |
|------------------|--------------------------------------------|
| <i>si</i>        | Service indicator. Valid range is 0 to 15. |
| <b>qos-class</b> | Specifies a QoS class.                     |
| <i>class</i>     | QoS class ID. Valid range is 1 to 7.       |

### Defaults

None.

### Command Modes

cs7 linkset configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

This command should be used on input linksets with legacy SS7 links.

### Examples

The following example shows how to configure service indicator packet classification. Service indicator 5 (ISUP) packets are assigned QoS class 3.

```
cs7 linkset to-washington 3.3.3
 match si 5 qos-class 3
```

### Related Commands

| Command                       | Description            |
|-------------------------------|------------------------|
| <a href="#">cs7 qos class</a> | Specifies a QoS class. |

## match-unknown-ton-np (cs7 mlr ruleset rule)

To match incoming messages to the corresponding rule parameter regardless of the rule's configured ton/np values, use the **match-unknown-ton-np** command in cs7 mlr ruleset rule configuration mode. Incoming messages containing parameters with an unknown type-of-number (ton=0) or an unknown numbering plan (np=0) will match the rule parameter. To remove the specification, use the **no** form of this command.

**match-unknown-ton-np**

**no match-unknown-ton-np**

|                           |                                            |
|---------------------------|--------------------------------------------|
| <b>Syntax Description</b> | This command has no arguments or keywords. |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | <p>The <b>match-unknown-ton-np</b> command applies to address parameters (such as dest-sme, orig-sme, dest-smsc, and orig-smsc) within the rule.</p> <p>Use of the <b>match-unknown-ton-np</b> command is related to the evolution of ITP configuration for matching rule parameter nature-of-address (noa) values—also known as type-of-number (ton) values—and rule parameter numbering plan (np) values with the noa/ton/np values in corresponding parameters of incoming messages. With regard to unknown noa/np values, one effect of the <b>match-unknown-ton-np</b> command is to preserve the pre-12.2(25)SW3 noa/np matching rules.</p> |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

In ITP releases earlier than release 12.2(25)SW3 no configuration matched a rule parameter of type noa 0 (unknown noa) to *only* those messages that had an unknown noa value in the corresponding parameter. With release 12.2(25)SW3, that type of match can be configured. The following usage guidelines describe the rule-matching implementation through 12.2(25)SW2, the implementation changes in 12.2(25)SW3, and the configuration changes that are automatically generated in a software update to release 12.2(25)SW3.

### MLR/SMS rule-matching implementations before ITP release 12.2(25)SW3

In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter's noa value.

- If an incoming message contains a parameter with noa unknown, then MLR matches that message to a rule for the corresponding parameter, regardless of the rule parameter's noa specification.

### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then MLR matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

### Updating from a pre-12.2(25)SW3 release

To maintain consistent MLR/SMS functionality when you update from a pre-12.2(25)SW3 release, MLR/SMS configurations are automatically updated (NVgened) as follows:

- In the pre-12.2(25)SW3 release, a rule parameter configured with **noa 0 np 0** means match that rule to incoming messages containing the corresponding address parameter, regardless of the address *noa* or *np* value. Therefore, in an updated configuration, no **ton/np** specification is NVgened because the behavior is the same as if **ton** and **np** are not used at all in the matching algorithm. The update also does not need to NVgen the **match-unknown-ton-np** command for this rule.
- In the pre-12.2(25)SW3 release, if a rule parameter is configured with any **noa noa np np** values other than the default value 0, then the new configuration will NVgen the equivalent **ton/np** values for the rule parameter. In addition, the update will NVgen the **match-unknown-ton-np** command for the rule because the pre-12.2(25)SW3 MLR action is to match that rule to incoming messages containing unknown ton and np values in the corresponding parameters.

## Examples

The following example shows the changes that are NVgened in a configuration that is updated from a pre-12.2(25)SW3 release to release 12.2(25)SW or later:

### 12.2(25)SW2

```
cs7 mlr ruleset ruleset1
rule 100 sms-mo
  dest-sme 9192 noa 0 np 0
  result as AS1
rule 200 sms-mo
  dest-sme 91934 noa 1 np 0
  result as AS2
```

### NVgened Configuration Update to 12.2(25)SW3

```
cs7 mlr ruleset ruleset1
rule 100 sms-mo
  dest-sme 9192
  result as AS1
rule 200 sms-mo
  match-unknown-ton-np
  dest-sme 91934 ton 1
  result as AS2
```

|                  | <a href="#">dest-smsc (cs7 mlr ruleset rule)</a>      | Specifies a destination service center address.                                                  |
|                  | <a href="#">orig-sme (cs7 mlr ruleset rule)</a>       | Specifies the address of the origin SME within an MLR operation.                                 |
|                  | <a href="#">orig-sme-table (cs7 mlr ruleset rule)</a> | Specifies a table of origin SME addresses to be used to find the desired routing destination.    |
|                  | <a href="#">rule (cs7 mlr ruleset)</a>                | Specifies a rule and the order in which the table is searched within a multilayer ruleset table. |

## match-unknown-ton-np (cs7 sms set rule)

To match incoming messages to the corresponding rule parameter regardless of the rule's configured ton/np values, use the **match-unknown-ton-np** command in cs7 sms set rule configuration mode. Incoming messages containing parameters with an unknown type-of-number (ton=0) or an unknown numbering plan (np=0) will match the rule parameter. To remove the specification, use the **no** form of this command.

**match-unknown-ton-np**

**no match-unknown-ton-np**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** cs7 sms set rule configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** The **match-unknown-ton-np** command applies to address parameters (such as dest-sme, orig-sme, dest-smsc, and ogig-smsc) within the rule.

Use of the **match-unknown-ton-np** command is related to the evolution of ITP configuration for matching rule parameter nature-of-address (noa) values—also known as type-of-number (ton) values—and rule parameter numbering plan (np) values with the noa/ton/np values in corresponding parameters of incoming messages. With regard to unknown noa/np values, one effect of the **match-unknown-ton-np** command is to preserve the pre-12.2(25)SW3 noa/np matching rules.

In ITP releases earlier than release 12.2(25)SW3 no configuration matched a rule parameter of type noa 0 (unknown noa) to *only* those messages that had an unknown noa value in the corresponding parameter. With release 12.2(25)SW3, that type of match can be configured. The following usage guidelines describe the rule-matching implementation through 12.2(25)SW2, the implementation changes in 12.2(25)SW3, and the configuration changes that are automatically generated in a software update to release 12.2(25)SW3.

### MLR/SMS rule-matching implementations before ITP release 12.2(25)SW3

In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter's noa value.

- If an incoming message contains a parameter with noa unknown, then SMS matches that message to a rule for the corresponding parameter, regardless of the rule parameter's noa specification.

### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then SMS matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

### Updating from a pre-12.2(25)SW3 release

To maintain consistent MLR/SMS functionality when you update from a pre-12.2(25)SW3 release, MLR/SMS configurations are automatically updated (NVgened) as follows:

- In the pre-12.2(25)SW3 release, a rule parameter configured with **noa 0 np 0** means match that rule to incoming messages containing the corresponding address parameter, regardless of the address *noa* or *np* value. Therefore, in an updated configuration, no **ton/np** specification is NVgened because the behavior is the same as if **ton** and **np** are not used at all in the matching algorithm. The update also does not need to NVgen the **match-unknown-ton-np** command for this rule.
- In the pre-12.2(25)SW3 release, if a rule parameter is configured with any **noa noa np np** other than the default value 0, then the new configuration will NVgen the equivalent **ton/np** values for the rule parameter. In addition, the update will NVgen the **match-unknown-ton-np** command for the rule because the pre-12.2(25)SW3 SMS action is to match that rule to incoming messages containing unknown ton and np values in the corresponding parameters.

## Examples

The following example shows the changes that are NVgened in a configuration that is updated from a pre-12.2(25)SW3 release to release 12.2(25)SW or later:

### 12.2(25)SW2

```
cs7 sms ruleset ruleset1
rule 100 sms-mo
  dest-sme 9192 noa 0 np 0
  result as AS1
rule 200 sms-mo
  dest-sme 91934 noa 1 np 0
  result as AS2
```

### NVgened Configuration Update to 12.2(25)SW3

```
cs7 sms ruleset ruleset1
rule 100 sms-mo
  dest-sme 9192
  result as AS1
rule 200 sms-mo
  match-unknown-ton-np
  dest-sme 91934 ton 1
  result as AS2
```

## max-inbound-streams (cs7 m3ua)

To configure the maximum number of inbound streams allowed for the local port, use the **max-inbound-streams** cs7 m3ua submode command. To remove the configuration, use the **no** form of this command.

**max-inbound-streams** *max-streams*

**no max-inbound-streams** *max-streams*

| Syntax Description | <i>max-streams</i> | The maximum number of inbound streams allowed for the local port. The range is 2 to 25. The default is 17 streams. |
|--------------------|--------------------|--------------------------------------------------------------------------------------------------------------------|
|--------------------|--------------------|--------------------------------------------------------------------------------------------------------------------|

| Defaults | 17 streams |
|----------|------------|
|----------|------------|

| Command Modes | cs7 m3ua submode |
|---------------|------------------|
|---------------|------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Examples | The following command shows how to allow a maximum of 10 streams on the local port: |
|----------|-------------------------------------------------------------------------------------|
|----------|-------------------------------------------------------------------------------------|

```
cs7 m3ua 2905
 local-ip 4.4.4.4
 max-inbound-streams 10
```

| Related Commands | Command                       | Description                                                           |
|------------------|-------------------------------|-----------------------------------------------------------------------|
|                  | <a href="#">cs7 m3ua</a>      | Specifies the local port number for M3UA and enters cs7 m3ua submode. |
|                  | <a href="#">show cs7 m3ua</a> | Displays M3UA statistics.                                             |

# max-inbound-streams (cs7 )

To configure the maximum number of inbound streams allowed for the local port, use the **max-inbound-streams** *cs7* submode command. To remove the configuration, use the **no** form of this command.

**max-inbound-streams** *max-streams*

**no max-inbound-streams** *max-streams*

|                    |                                                                                                                                                   |                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Syntax Description | <i>max-streams</i><br>The maximum number of inbound streams allowed for the local port. The range is 2 to 25. The default is 17 streams.          |                                                             |
| Defaults           | 17 streams                                                                                                                                        |                                                             |

| Related Commands   | Command                                                                                                                                           | Description                                                 |
|                    | cs7 sgmp                                                                                                                                          | Specifies the local port number for and enters cs7 submode. |
|                    | show cs7 sgmp                                                                                                                                     | Displays statistics.                                        |

## max-inbound-streams (cs7 sua)

To configure the maximum number of inbound streams allowed for the local port, use the **max-inbound-streams** cs7 sua submode command. To remove the configuration, use the **no** form of this command.

**max-inbound-streams** *max-streams*

**no max-inbound-streams** *max-streams*

|                           |                    |                                                                                                                    |
|---------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>max-streams</i> | The maximum number of inbound streams allowed for the local port. The range is 2 to 25. The default is 17 streams. |
|---------------------------|--------------------|--------------------------------------------------------------------------------------------------------------------|

|                 |            |
|-----------------|------------|
| <b>Defaults</b> | 17 streams |
|-----------------|------------|

|                      |                 |
|----------------------|-----------------|
| <b>Command Modes</b> | cs7 sua submode |
|----------------------|-----------------|

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Examples** The following command shows how to allow a maximum of 10 streams on the local port:

```
cs7 sua 15000
 local-ip 4.4.4.4
 max-inbound-streams 10
```

|                         |                              |                                                                     |
|-------------------------|------------------------------|---------------------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>               | <b>Description</b>                                                  |
|                         | <a href="#">cs7 sua</a>      | Specifies the local port number for SUA and enters cs7 sua submode. |
|                         | <a href="#">show cs7 sua</a> | Displays SUA statistics.                                            |

## modify-failure (mlr options)

To specify the desired action when MLR packet modification fails, use the **modify-failure** command in `cs7 mlr options` configuration mode. To remove the specification, use the **no** form of this command.

**modify-failure** { **discard** | **resume** | **sccp-error** *sccp-error* }

**no modify-failure** { **discard** | **resume** | **sccp-error** *sccp-error* }

### Syntax Description

|                   |                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------|
| <b>discard</b>    | Discards packet (default).                                                                                |
| <b>resume</b>     | Resumes sending the original packet to the original destination.                                          |
| <b>sccp-error</b> | Sends a UDTS to the originator with the configured SCCP error code if return-on-error was set in the UDT. |
| <i>sccp-error</i> | SCCP UDTS return cause values.                                                                            |

### Defaults

The packet is discarded.

### Command Modes

`cs7 mlr options` configuration

### Related Commands

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **modify-failure** command allows you to specify which action should be taken when an MLR packet cannot be modified. By default, the packet is discarded. MLR modification failures include exceeding the maximum MSU or address size when inserting new data, failures when attempting to modify the destination GT, and failures when executing a **modify-profile** command.

### Examples

The following example shows how to specify the **modify-profile** command:

```
cs7 mlr options
  modify-failure sccp-error 7
```

# modify-failure (pam)

To specify the desired action when the PAM table packet modification fails, use the **modify-failure** command in CS7 PAM configuration submode. To remove the specification, use the **no** form of this command.

**modify-failure** { **discard** | **resume** | **sccp-error** *sccp-error* }

**no modify-failure** { **discard** | **resume** | **sccp-error** *sccp-error* }

## Syntax Description

|                   |                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------|
| <b>discard</b>    | Discards packet (default).                                                                                |
| <b>resume</b>     | Resumes sending the original packet to the original destination.                                          |
| <b>sccp-error</b> | Sends a UDTS to the originator with the configured SCCP error code if return-on-error was set in the UDT. |
| <i>sccp-error</i> | SCCP UDTS return cause values.                                                                            |

## Defaults

The packet is discarded.

## Command Modes

CS7 PAM configuration submode

## Related Commands

| 12.4(15)SW5<br>12.2(33)IRE | This command was introduced. |

## Usage Guidelines

The **modify-failure** command allows you to specify which action should be taken when an error occurs during a packet modification.

## Examples

The following example shows how to configure a PAM table with the **modify-failure** command to resume sending the original packet to the original destination:

```
cs7 instance 0 pam alpha
  cipa gt prefix tt 0 pc 1.2.3 ssn 12
  cipa gt prefix 15 123456789abcdef tt 250 gti 4 np 15 nai 127 pc 1.123.4 ssn 255\n
1.2.3
dpc 2.3.4
modify-failure resume
```

## Related Commands

|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 pam</a>            | Identifies a packet address modification (PAM) table and enters the CS7 PAM submode.                                              |
| <a href="#">cgpa (cs7 pam)</a>     | Configures one cgpa entry in the PAM table.                                                                                       |
| <a href="#">cdpa (cs7 pam)</a>     | Configures one cdpa entry in the PAM table.                                                                                       |
| <a href="#">dpc</a>                | Configures a dpc entry in the PAM table.                                                                                          |
| <a href="#">cs7 gws action-set</a> | Defines gateway screening action sets that may include a PAM table.                                                               |
| <a href="#">gta asname</a>         | Creates or modifies a GTA entry that translates to an M3UA or SUA application server name. The GTA entry may include a PAM table. |

## modify-profile (cs7 mlr ruleset rule)

To specify SCCP and MAP addresses to modify in messages that are routed using MLR, use the **modify-profile** command in cs7 mlr ruleset rule configuration submode. Only one modification profile may be specified in a rule.

To disable the settings, use the **no** form of this command.

**modify-profile** [*profile-name*]

**no modify-profile** [*profile-name*]

|                           | 12.2(18)IXE                                                                                                                                                                                                                                          | The configuration submode was introduced.                                                                                                      |
| <b>Usage Guidelines</b>   | The protocol and operation of the associated rule and modification profile must be compatible for the modification to occur. This command is not valid for the all-operations rule operation type and protocol has not been defined for the ruleset. |                                                                                                                                                |

**Examples** The following uses the **modify-profile** command:

```
cs7 mlr modify-profile SRISM gsm-map sri-sm
  orig-smsc prefix 2 351
  cgpa gt prefix 2 351

cs7 mlr ruleset FROM_MMSC
  rule 10 gsm-map sri-sm default
    orig-smsc 397777777
    modify-profile SRISM
    result route
```

 `modify-profile (cs7 mlr ruleset rule)`

## msc-proxy-addr (cs7 sms smsmo)

To enable the SMS MO Proxy feature and specify a MAP MSC Proxy address, use the **msc-proxy-addr** command in cs7 sms smsmo configuration mode. To remove the address, use the **no** form of this command.

**msc-proxy-addr** [**use** {**international** | **national**}] **tt** *tt* **gti** *gti* [**np** *np* **nai** *nai*]

**no msc-proxy-addr**

| Syntax Description   |  |                                                                                                                                     |
|----------------------|--|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>tt</b>            |  | Configure the translation type.                                                                                                     |
| <i>tt</i>            |  | Translation type, in the range 0 to 255.                                                                                            |
| <b>gti</b>           |  | Specifies a global title indicator.                                                                                                 |
| <i>gti</i>           |  | Global title indicator. Valid numbers are 2 (primarily used in the ANSI domain) or 4 (used in the ITU domain).                      |
| <b>np</b>            |  | In ITU domain, specifies a numbering plan.                                                                                          |
| <i>np</i>            |  | Numbering plan. Valid range is 0 to 15.                                                                                             |
| <b>nai</b>           |  | In ITU domain, specifies a nature of address indicator. Required for a <i>gti</i> value of 4. Optional for a <i>gti</i> value of 2. |
| <i>nai</i>           |  | Nature of address indicator. Valid range is 0 to 127.                                                                               |
| <b>use</b>           |  | Indicates setting for national use bit in the address indicator.                                                                    |
| <b>international</b> |  | Address has international scope (default for ITU/CHINA).                                                                            |
| <b>national</b>      |  | Address has national scope (default for ANSI).                                                                                      |

**Defaults** None.

**Command Modes** cs7 sms smsmo configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |

**Usage Guidelines**

The **msc-proxy-addr** command specifies how servicing MSC addresses are translated in the proxied dialog toward the SMSC.

The **msc-proxy-addr** command specifies a MAP MSC Proxy address. The address is used to form the SCCP CgPA for a proxied MO dialog.

The **msc-proxy-addr** command enables cs7 sms smsso msc proxy configuration mode.

---

**Examples**

The following example shows how to configure an SMS route table and how to specify a CDR service, GSM MAP routing, and a MAP MSC Proxy address:

```
cs7 sms route-table
cdr-service
gsm-map sms-mo
msc-proxy-addr use international tt 4
```

|                 |                                                                                                                                                                                         |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to define a profile named timers. The profile supports MTP2, configures the t1 and t2 settings, and applies to all the links in the linkset named itpa. |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
cs7 profile timers
 mtp2
  timer t1 45000
  timer t2 9000
.
.
.
cs7 linkset itpa
 profile timers
```

|                         |                             |                                                                     |
|-------------------------|-----------------------------|---------------------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>              | <b>Description</b>                                                  |
|                         | <a href="#">cs7 profile</a> | Defines a profile that you can apply to all the links in a linkset. |
|                         | <a href="#">variant jt1</a> | Configures a CS7 link profile variant.                              |

# mtp2-timer

Traditional SS7 links use serial interfaces. ITP interfaces are configured to use encapsulation MTP2. You can tune several MTP2 timers.

To tune MTP2 encapsulation timers, use the **mtp2-timer** cs7 link submode command with one of the timers. To reset the timers, use the **no** form of this command.

```
mtp2-timer {t1 msec | t2 msec | t3 msec | t4e msec | t4n msec | t5 msec | t6 msec | t7 msec | ttc timer msec}
```

```
no mtp2-timer {t1 msec | t2 msec | t3 msec | t4e msec | t4n msec | t5 msec | t6 msec | t7 msec | ttc timer msec}
```

## Note

Ranges are ANSI or ITU defined.

## Syntax Description

|            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>t1</b>  | Alignment ready timer. ANSI default is 13000 milliseconds. ITU default is 40000 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>t2</b>  | Not aligned timer. ANSI default is 11500 milliseconds. ITU default is 5000 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>t3</b>  | Aligned timer. ANSI default is 11500 milliseconds. ITU default is 1500 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>t4e</b> | Emergency proving period timer. ANSI default is 600 milliseconds. ITU default is 500 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>t4n</b> | Normal proving period timer. ANSI default is 2300 milliseconds. ITU default is 8200 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>t5</b>  | Sending SIB timer. ANSI default is 80 milliseconds. ITU default is 100 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>t6</b>  | Remote congestion timer. ANSI default is 1000 milliseconds. ITU default is 3000 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>t7</b>  | Excessive delay of acknowledgment timer. ANSI default is 1000 milliseconds. ITU default is 1000 milliseconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>ttc</b> | <p><b>ttc ta msec</b>: TTC timer for sending SIE. Valid range is 10 to 250 milliseconds. Default is 20 milliseconds.</p> <p><b>ttc te msec</b>: TTC timer for error monitoring. **Command Modes** cs7 link submode

| Command History | Release     | Modification                                                               |
|-----------------|-------------|----------------------------------------------------------------------------|
|                 | 12.2(18)IXA | This command replaced the <b>cs7 mtp2</b> interface configuration command. |
|                 | 12.4(11)SW  |                                                                            |
|                 | 12.2(33)IRA |                                                                            |

**Usage Guidelines** MTP2 parameters can also be specified in a CS7 profile.

**Examples** The following example shows how to set the T1 timer for 25000 milliseconds:

```

cs7 linkset ITP2 6.100.5
 link 0 serial0/0:0
  mtp2-timer t1 25000

```

The following example shows how to set the TTC te timer for 100 milliseconds:

```

cs7 linkset ITP2 6.100.5
 link 0 sctp 192.68.1.2 7000 7000
  mtp2-timer ttc te 100

```

|                  | <a href="#">show cs7 mtp2</a>             | Displays ITP MTP2 status.                                                              |
|                  | <a href="#">tx-queue-depth (cs7 link)</a> | Configures the MTP2 transmit queue depth.                                              |

# mtp2-timer ttc enable

The MTP/TTC variant allows configuration of TTC Signal Unit (SU) transmission timer values. To enable the use of MTP2 TTC timers, use the **mtp2-timer ttc enable** cs7 link submode command with one of the timers. To disable the timers, use the **no** form of this command.

**mtp2-timer ttc enable**

**no mtp2-timer ttc enable**

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

|                         |                                                                          |
|-------------------------|--------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | After enabling the use of MTP2 TTC timers, you can set the timer values. |
|-------------------------|--------------------------------------------------------------------------|

|                 |                                                                  |
|-----------------|------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to enable the use of TTC timers: |
|-----------------|------------------------------------------------------------------|

```
cs7 linkset ITP2 6.100.5
link 0 serial0/0:0
mtp2-timer ttc enable
```

|                         |                               |                                  |
|-------------------------|-------------------------------|----------------------------------|
| <b>Related Commands</b> | <b>Command</b>                | <b>Description</b>               |
|                         | <a href="#">mtp2-timer</a>    | Tunes MTP2 encapsulation timers. |
|                         | <a href="#">show cs7 mtp2</a> | Displays ITP MTP2 status.        |

# multiplicity

To specify a method for selecting a destination in the application group, use the **multiplicity** in **cs7 gtt** application group submode. To restore the default multiplicity (share), use the **no** form of this command.

**multiplicity {cost | share | cgpa | wrr}**

**no multiplicity**

|                           |              |                                                                                                                                                                                            |
|---------------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <b>cost</b>  | Uses the destination with the least cost if available.                                                                                                                                     |
|                           | <b>share</b> | Shares equally among all destinations.                                                                                                                                                     |
|                           | <b>cgpa</b>  | Uses the SCCP calling party address (CGPA) field, which results in a weighted factor selection number for choosing the next destination from the available items in the application group. |
|                           | <b>wrr</b>   | Applies weighted round robin load balancing (WRR) to SCCP class 0 and SCCP class 1 traffic.                                                                                                |

**Defaults** The default multiplicity is to share.

**Command Modes** cs7 gtt application group submode

|                        |                                          |                                        |
|------------------------|------------------------------------------|----------------------------------------|
| <b>Command History</b> | <b>Release</b>                           | <b>Modification</b>                    |
|                        | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.           |
|                        | 12.4(15)SW4<br>12.2(33)IRD               | The keyword <b>wrr</b> was introduced. |

**Examples** The following example shows how to configure an application group of three items. The first item is used approximately twice as many times as the other two items. These items handle equal amounts of traffic.

```
cs7 gtt application-group group1
multiplicity cgpa
pc 1.1.1 ssn 8 50 pcssn
pc 1.1.2 ssn 8 25 pcssn
pc 1.1.3 ssn 8 25 pcssn
```

|                         |                                                |                                                                                      |

| <b>Related Commands</b> | <b>Command</b>                                 | <b>Description</b>                                                                   |
|                         | <a href="#">cs7 gtt application-group</a>      | Specifies a GTT application group.                                                   |
|                         | <a href="#">cs7 gtt map</a>                    | Configures a Global Title Mated Application (MAP) entry.                             |
|                         | <a href="#">pc (cs7 gtt application group)</a> | Adds or changes a point code and optional subsystem number in the application group. |

■ multiplicity

| Command                                            | Description                                           |
|----------------------------------------------------|-------------------------------------------------------|
| <a href="#">asname (cs7 gtt application group)</a> | Assigns an M3UA or SUA AS directly to a global title  |
| <a href="#">cs7 sccp-class1-wrr</a>                | Configures the WRR option for GTT application groups. |

# nai

To specify a new nature of address (na) to be applied for the whole GTT address conversion table, use the **nai** *cs7* gtt address conversion submode command. To disable the configuration, use the **no** form of this command.

**nai** *nai*

**no** **nai**

## Syntax Description

|            |                                                 |
|------------|-------------------------------------------------|
| <i>nai</i> | Nature of address value. The range is 0 to 127. |
|------------|-------------------------------------------------|

## Defaults

None.

## Command Modes

*cs7* gtt address conversion submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example shows how to convert the *nai* value to 4 for all addresses that are converted:

```
cs7 gtt address-conversion e212e214
nai 4
```

## Related Commands

# network-appearance

To define the value used in the network appearance parameter in M3UA and SUA messages, use the **network-appearance** command in cs7 as configuration mode. To remove the definition and use the actual instance number instead, use the **no** form of this command.

**network-appearance** *number*

**no network-appearance** *number*

|                           |               |                                                                                                               |
|---------------------------|---------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>number</i> | A value in the range 1 to 4294967295 to be used in the network appearance parameter in M3UA and SUA messages. |
|---------------------------|---------------|---------------------------------------------------------------------------------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                      |
|----------------------|----------------------|
| <b>Command Modes</b> | cs7 as configuration |
|----------------------|----------------------|

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

|                         |                                                                                                                                                                                                                       |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | If <b>network-appearance</b> is not configured, the actual instance number is used instead. If <b>network-appearance</b> is already configured on another AS, it is valid only if the other AS has the same instance. |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

When you configure a network appearance value, the value must be unique among all instances of ITP. ITP cannot share a network appearance value between instances. If you try to configure a network appearance value between 1 and 7 inside an AS, and that value instance is already configured, ITP displays a warning indicating that network appearance is reserved for that instance. For example, if you configure a network appearance value of 3 on instance 1, while instance 3 is already configured on ITP, ITP displays a warning that network appearance value of 3 is reserved for instance 3.

|                 |                                                                                    |
|-----------------|------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to define the network appearance parameter as 100: |
|-----------------|------------------------------------------------------------------------------------|

```
network-appearance 100
```

|                         | <a href="#">cs7 mtp3 tuning</a><br><a href="#">rx-congestion-threshold</a> | Enables multiple instances of a variant and network indicator combination. |

# new-name

To rename an existing GTT selector, use the **new-name** `cs7 gtt selector submode` command. To disable the configuration, use the **no** form of this command.

**new-name** *selector-name*

**no new-name**

## Syntax Description

|                      |                                |
|----------------------|--------------------------------|
| <i>selector-name</i> | New name for the GTT selector. |
|----------------------|--------------------------------|

## Defaults

None.

## Command Modes

cs7 gtt selector submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

Since the GTT data is not stored in NVRAM, commands such as **show running config** will not display the GTT data. To display the current running configuration regarding GTT use the **show cs7 gtt config** command.

## Examples

The following example shows how to rename the existing GTT selector to test1:

```
new-name test1
```

## Related Commands

| Command                             | Description                                                                                     |
|-------------------------------------|-------------------------------------------------------------------------------------------------|
| <a href="#">cs7 gtt selector</a>    | Configures a new GTT selector or enters the submode for modifying the attributes of a selector. |
| <a href="#">show cs7 gtt config</a> | Displays the running configuration of GTT.                                                      |

# next-table

To add a next table entry to an existing GTT selector, use the **next-table** *cs7* gtt selector submode command. To disable the configuration, use the **no** form of this command.

**next-table** *selector-name* [**ntt** *ntt*]

**no next-table** *selector-name* [**ntt** *ntt*]

## Syntax Description

|                      |                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>next-table</b>    | Configures a next table for the default GTT selector.                                                                                            |
| <i>selector-name</i> | Name of the GTT selector that the master table points to as the next table. The name is specified as a character string from 1 to 12 characters. |
| <b>ntt</b>           | Specifies the value of the TT which will be modified in the MSU when it is forwarded to the next ITP instance.                                   |
| <i>ntt</i>           | The value of the TT. The range is between 0 and 255.                                                                                             |

## Defaults

None.

## Command Modes

*cs7* gtt selector submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW5 | This command was introduced. |
| 12.2(33)IRE |                              |

## Usage Guidelines

This command configures the default GTT entry in a GTT table to point to another GTT table (next table). The next table needs to be in the same instance or have the same NI and SS7 variants. Multiple tables can refer to a single next table. The next table is also accessible directly for GTT operations.

Since the GTT data is not stored in NVRAM, commands such as **show running config** will not display the GTT data. To display the current running configuration regarding GTT use the **show cs7 gtt config** command.

## Examples

The following example shows how to configure the GTT selector named alpha as the next table:

```
next-table alpha
```

## Related Commands

## orig-imsi (cs7 mlr ruleset rule)

| Command                              | Description                                                                                                                       |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 pam</a>              | Identifies a packet address modification (PAM) table and enters the CS7 PAM submode.                                              |
| <a href="#">cgpa (cs7 pam)</a>       | Configures a cgpa entry in the PAM table.                                                                                         |
| <a href="#">cdpa (cs7 pam)</a>       | Configures a cdpa entry in the PAM table.                                                                                         |
| <a href="#">dpc</a>                  | Configures a dpc entry in the PAM table.                                                                                          |
| <a href="#">modify-failure (pam)</a> | Specifies the desired action when the PAM table packet modification fails.                                                        |
| <a href="#">cs7 gws action-set</a>   | Defines gateway screening action sets that may include a PAM table.                                                               |
| <a href="#">gta asname</a>           | Creates or modifies a GTA entry that translates to an M3UA or SUA application server name. The GTA entry may include a PAM table. |

To specify an origin IMSI, use the **orig-imsi** command in cs7 mlr ruleset rule configuration mode. To remove the configuration, use the **no** form of this command.

**orig-imsi** { \* | *imsi-addr* | **unknown** } [**exact**] [**min-digits** *min*] [**max-digits** *max*]

**no orig-imsi**

### Syntax Description

|                   |                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------|
| <i>imsi-addr</i>  | IMSI address up to 16 hexadecimal digits.                                                        |
| <b>unknown</b>    | Unknown origin IMSI.                                                                             |
| <b>exact</b>      | Configured address must match origin IMSI exactly.                                               |
| <b>min-digits</b> | (Optional) Specifies the minimum number of digits in the address string.                         |
| <i>min</i>        | Minimum number of digits in the address string. The default is 1.                                |
| <b>max-digits</b> | (Optional) Specifies the maximum number of digits in the address string.                         |
| <i>max</i>        | Maximum number of digits in the address string. The default is the length of the address string. |

### Defaults

The maximum number of digits in the address string is 1.

### Command Modes

cs7 mlr ruleset rule configuration

### Command History

| Release                                   | Modification                               |
|-------------------------------------------|--------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.               |
| 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | This command supports UpdateLocation MSUs. |

**Usage Guidelines**

In release 12.2(18)IXG 12.4(15)SW1 and later, this command supports UpdateLocation MSUs. This support helps identify specific subscribers by the originator IMSI and block specific fraudulent activity.

**Examples**

The following example shows how to specify a ruleset named ruleset1, a rule index of 20, and an origin IMSI address of 1111:

```
cs7 sms ruleset1
rule 20 sms-mo
  orig-imsi 1111
  result group grp1
```

The following example shows how to block the origin IMSI address of 861381234567:

```
rule 4 updLocation
orig-imsi 861381234567
result block
```

**Related Commands**

| Command                                | Description                                                                                                                      |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">rule (cs7 mlr ruleset)</a> | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode. |

## orig-imsi (cs7 sms set rule)

To specify an origin IMSI, use the **orig-imsi** command in cs7 sms set rule configuration mode. To remove the configuration, use the **no** form of this command.

**orig-imsi** { \* | *imsi-addr* | **unknown** } [**exact**] [**min-digits** *min*] [**max-digits** *max*]

**no orig-imsi**

### Syntax Description

|                   |                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------|
| <i>imsi-addr</i>  | IMSI address up to 16 hexadecimal digits.                                                        |
| <b>unknown</b>    | Unknown origin IMSI.                                                                             |
| <b>exact</b>      | Configured address must match origin IMSI exactly.                                               |
| <b>min-digits</b> | (Optional) Specifies the minimum number of digits in the address string.                         |
| <i>min</i>        | Minimum number of digits in the address string. The default is 1.                                |
| <b>max-digits</b> | (Optional) Specifies the maximum number of digits in the address string.                         |
| <i>max</i>        | Maximum number of digits in the address string. The default is the length of the address string. |

### Defaults

The maximum number of digits in the address string is 1.

### Command Modes

cs7 sms set rule configuration

### Command History

| Release                                   | Modification                                                                                      |
|-------------------------------------------|---------------------------------------------------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.                                                                      |
| 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | The <b>orig-imsi</b> and <b>orig-imsi-table</b> commands became valid under the updLoc operation. |

### Examples

The following example shows how to specify an SMS ruleset named SMS-RULES, a rule index of 20, and an origin IMSI address of 1111:

```
cs7 sms ruleset SMS-RULES
rule 20 sms-mo
  orig-imsi 1111
result group smsgrp
```

|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.                                                                           |
|                 | 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | The <b>orig-imsi</b> and <b>orig-imsi-table</b> rule commands became valid under the updLoc operation. |

**Usage Guidelines** This command supports UpdateLocation MSUs. This support helps identify specific subscribers by the originator IMSI and block specific fraudulent activity.

The **dest-sme-table**, **orig-imsi-table**, and **orig-sme-table** rule commands accept either an SMS address table name *or* an MLR address table name. This ability is primarily for customers who want the SMS-MO Proxy functionality. The address table names are unique between DSMR and MLR. You can enter an MLR address table name for an SMS rule parameter. However, MLR cannot reference SMS address tables.

If an incoming message matches an SMS rule that references an MLR address table, then any MLR address table result is mapped to an SMS result:

- BLOCK, PC, and PCSSN results map from MLR to SMS.
  - For result groups, the MLR result group name is mapped to an SMS result group name.
  - If the SMS result group is not configured, then the result specified on the rule is used.
- AS and CONTINUE results are not valid in SMS. For these cases, the result specified on the rule is used. If no result is specified, the result on the rule is used (the same as with MLR).

If multiple rule parameters are configured for a rule, then the rule result will be used (rather than a result specified in the address table).

If the result type specified within the table is valid, it is used. Otherwise, the result in the rule is used.

For all tables, the noa and np values must match before the table is accessed.

### Examples

The following example shows how to specify an MLR ruleset named ruleset1, a rule index of 20, and an SMS table of origin IMSI addresses named SHORTLIST:

```
cs7 mlr ruleset ruleset1
rule 20 sms-mo
  orig-imsi-table SHORTLIST
  result block
```

The following example shows how to block the origin IMSI table named test:

```
rule 5 updLocation
orig-imsi-table test
result block
```

|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">rule (cs7 mlr ruleset)</a> | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode. |

## orig-imsi-table (cs7 sms set rule)

To specify an SMS table of origin IMSI addresses, use the **orig-imsi-table** command in cs7 sms set rule configuration mode. To remove the configuration, use the **no** form of this command.

**orig-imsi-table** *table-name* [**noa** *noa-value* **np** *np-value*]

**no orig-imsi-table** *table-name*

### Syntax Description

|                   |                                                  |
|-------------------|--------------------------------------------------|
| <i>table-name</i> | Address table name.                              |
| <b>noa</b>        | Specifies a nature of address.                   |
| <i>noa-value</i>  | Valid range is 0 to 7.                           |
| <b>np</b>         | Specifies a numbering plan identification value. |
| <i>np-value</i>   | Valid range is 0 to 15.                          |

### Defaults

None.

### Command Modes

cs7 sms set rule configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **dest-sme-table**, **orig-imsi-table**, and **orig-sme-table** rule commands accept either an SMS address table name *or* an MLR address table name. This ability is primarily for customers who want the SMS-MO Proxy functionality. The address table names are unique between FDA and MLR. You can enter an MLR address table name for an SMS rule parameter. However, MLR cannot reference SMS address tables.

If an incoming message matches an SMS rule that references an MLR address table, then any MLR address table result is mapped to an SMS result:

- BLOCK, PC, and PCSSN results map from MLR to SMS.
  - For result groups, the MLR result group name is mapped to an SMS result group name.
  - If the SMS result group is not configured, then the result specified on the rule is used.
- AS and CONTINUE results are not valid in SMS. For these cases, the result specified on the rule is used. If no result is specified, the result on the rule is used (the same as with MLR).

If multiple rule parameters are configured for a rule, then the rule result will be used (rather than a result specified in the address table).

If the result type specified within the table is valid, it is used. Otherwise, the result in the rule is used.

For all tables, the noa and np values must match before the table is accessed.

---

**Examples**

The following example shows how to specify an SMS ruleset named SMS-RULES, a rule index of 20, and an SMS table of origin IMSI addresses named SHORTLIST:

```
cs7 sms ruleset SMS-RULES
rule 20 sms-mo
  orig-imsi-table SHORTLIST
  result block
```

## orig-sme (cs7 mlr ruleset rule)

| Command                                           | Description                                                                         |
|---------------------------------------------------|-------------------------------------------------------------------------------------|
| <a href="#">cgpa (cs7 mlr trigger)</a>            | Tests the availability of the CDR service queue as the input condition of the rule. |
| <a href="#">cs7 sms ruleset</a>                   | Specifies a ruleset.                                                                |
| <a href="#">dest-sme (cs7 mlr ruleset rule)</a>   | Specifies an application destination port number.                                   |
| <a href="#">dest-sme (cs7 mlr ruleset rule)</a>   | Specifies a destination short message entity (SME).                                 |
| <a href="#">dest-sme-table (cs7 sms set rule)</a> | Specifies an SMS table of destination SME addresses.                                |
| <a href="#">dest-smsc (cs7 sms set rule)</a>      | Specifies a destination SMSC.                                                       |
| <a href="#">orig-imsi (cs7 sms set rule)</a>      | Specifies an origin IMSI.                                                           |
| <a href="#">orig-sme (cs7 sms set rule)</a>       | Specifies an origin SME.                                                            |
| <a href="#">orig-sme-table (cs7 sms set rule)</a> | Specifies an SMS table of origin SME addresses (address-table).                     |
| <a href="#">pid (cs7 sms set rule)</a>            | Specifies a protocol identifier (TP-PID).                                           |
| <a href="#">result (cs7 sms set rule)</a>         | Specifies a result.                                                                 |
| <a href="#">ruleset (cs7 sms ansi41 smsnot)</a>   | Specifies a rule within a ruleset.                                                  |

To specify the address of the origin short message entity (SME) within an SMS operation, use the **orig-sme** command in cs7 mlr ruleset rule configuration mode. To remove the specification, use the **no** form of this command.

**orig-sme** {*\** | *address*} [**exact**] [**min-digits** *min*] [**max-digits** *max*] [*orig-sme-addr-type*]

**no orig-sme**

### Syntax Description

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>*</b>          | Matches all addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>address</i>    | <p>When the rule operation is <b>sms-mo</b>, <i>address</i> is an address string of 1 to 20 hexadecimal characters.</p> <p>When the rule operation is <b>sms-mt</b>, <i>address</i> is an address string of 1 to 16 hexadecimal characters.</p> <p>The string is not input in BCD-String format, but in normal form. The string always carries an implicit wildcard (*) at the end of the string, allowing only the prefix of a range of addresses to be specified.</p> |
| <b>exact</b>      | (Optional) The previously specified <i>address</i> should be matched only if the number of digits and the digit values match exactly. If <b>exact</b> is not specified, <i>address</i> carries an implicit wildcard (*) at the end of the string, allowing a match on the string as a prefix (range of addresses).                                                                                                                                                      |
| <b>min-digits</b> | (Optional) Specifies the minimum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>min</i>        | Minimum number of digits in the address string. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>max-digits</b> | (Optional) Specifies the maximum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>max</i>                | Maximum number of digits in the address string. The default is the length of the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>orig-sme-addr-type</i> | <p>(Optional) Parameters that identify attributes of the SME address being used to match a rule. <i>orig-sme-addr-type</i> is composed of the following keywords:</p> <ul style="list-style-type: none"> <li>• [<b>ton</b> <i>ton</i>] The <b>ton</b> keyword specifies the type of number value associated with the SME address. The <i>ton</i> argument is an integer value in the range 0 to 7.</li> <li>• [<b>np</b> <i>np</i>] The <b>np</b> keyword specifies the numbering plan identification value associated with the SME address. The <i>np</i> argument is an integer value in the range 0 to 15.</li> </ul> |

**Defaults**

The maximum number of digits in the address string is 1.

**Command Modes**

cs7 mlr ruleset rule configuration

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines****MLR/SMS rule-matching implementations earlier than ITP release 12.2(25)SW3**

In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter *noa* value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter's *noa* value.
- If an incoming message contains a parameter with *noa* unknown, then MLR matches that message to a rule for the corresponding parameter, regardless of the rule parameter's *noa* specification.

**MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3**

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (*ton/np*) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then MLR matches that rule to only those incoming messages containing the exact *ton/np* value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the *ton/np* value received.

For the **sms-mo** operation, **orig-sme** identifies from the SM-RP-OA field within the GSM MAP layer.

For the **sms-mt** operation, **orig-sme** identifies the SM-TP-OA field within the SMS user information field.

**Table 33**      **Orig-SME by Operation**

|               | Length in hex digits | No <i>orig-sme-addr-type</i>                                                                                                                                      | <i>orig-sme-addr-type</i> specified                                                                                                                                                |
|---------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>sms-mo</b> | 1–20                 | Defaults to digit string matching only.                                                                                                                           | specific np/ton                                                                                                                                                                    |
| <b>sms-mt</b> | 1–20                 | Defaults to digit string matching only.                                                                                                                           | specific np/ton                                                                                                                                                                    |
| <b>smdpp</b>  | 1–20                 | Priority digit string matching based on the following order:<br>SMS_OriginalOriginationAddress<br>SMS_OriginationAddress<br>MIN<br>IMSI<br>SCCP CgPA (RI=GT only) | min = MIN parameter only<br>imsi = IMSI parameter only<br>np/ton = full address matching based on the parameter order:<br>SMS_OriginalOriginationAddress<br>SMS_OriginationAddress |

### Examples

The following example shows how to specify the address of the origin SME:

```
cs7 mlr ruleset ruleset1
rule 10 sms-mo
  dest-sme 1234
  orig sme 60920025
  result gt 9991117777
```

| Command                                                     | Description                                                                                                                                       |
|-------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">match-unknown-ton-np (cs7 mlr ruleset rule)</a> | Specifies that messages with unknown ton/np values match the corresponding address parameters, regardless of the rule's configured ton/np values. |
| <a href="#">rule (cs7 mlr ruleset)</a>                      | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode.                  |

## orig-sme (cs7 sms set rule)

To specify an origin short message entity (SME), use the **orig-sme** command in cs7 sms set rule configuration mode. To remove the configuration, use the **no** form of this command.

**orig-sme** { \* | *address* } [**exact**] | [**min-digits** *min*] | [**max-digits** *max*] [*orig-sme-addr-type*]

**no orig-sme**

| Syntax Description        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| *                         | Matches all addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>address</i>            | SMSC Address or MSISDN, 1 to 16 hexadecimal digits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>exact</b>              | Configured address must match orig-imsi exactly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>min-digits</b>         | (Optional) Specifies the minimum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>min</i>                | Minimum number of digits in the address string. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>max-digits</b>         | (Optional) Specifies the maximum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>max</i>                | Maximum number of digits in the address string. The default is the length of the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>orig-sme-addr-type</i> | (Optional) Parameters that identify attributes of the SME address being used to match a rule. The <i>orig-sme-addr-type</i> is composed of the following keywords: <ul style="list-style-type: none"> <li>[<b>ton</b> <i>ton</i>] The <b>ton</b> keyword specifies the type of number value associated with the SME address.<br/>The <i>ton</i> argument is an integer value in the range 0 to 7.</li> <li>[<b>np</b> <i>np</i>] The <b>np</b> keyword specifies the numbering plan identification value associated with the SME address.<br/>The <i>np</i> argument is an integer value in the range 0 to 15.</li> </ul> |

**Defaults** None.

**Command Modes** cs7 sms set rule configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** **MLR/SMS rule-matching implementations earlier than ITP release 12.2(25)SW3**  
 In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter's noa value.
- If an incoming message contains a parameter with noa unknown, then SMS matches that message to a rule for the corresponding parameter, regardless of the rule parameter noa specification.

### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then SMS matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

### Examples

The following example shows how to specify an SMS ruleset named SMS-RULES, a rule index of 20, and an origin SME matching all addresses:

```
cs7 sms ruleset SMS-RULES
rule 20 sms-mo
  orig-sme *
  result block
```

| <a href="#">result (cs7 sms set rule)</a>       | Specifies a result.                |
| <a href="#">ruleset (cs7 sms ansi41 smsnot)</a> | Specifies a rule within a ruleset. |

## orig-sme-table (cs7 mlr ruleset rule)

To specify a table of origin SME addresses that will be used to find the desired routing destination, use the **orig-sme-table** command in cs7 mlr ruleset rule configuration mode. To remove the configuration, use the **no** form of this command.

**orig-sme-table** *table-name* [**ton** *ton-value*] [**np** *np-value*]

**no orig-sme-table** *table-name* [**ton** *ton-value*] [**np** *np-value*]

### Syntax Description

|                   |                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>table-name</i> | Identifies the name of a previously defined MLR address table to be used when searching with the <b>orig-sme-table</b> routing command. The name is specified as a character string with a maximum of 12 characters. |
| <b>ton</b>        | Specifies a type of number.                                                                                                                                                                                          |
| <i>ton-value</i>  | Valid range is 0 to 7.                                                                                                                                                                                               |
| <b>np</b>         | Specifies a numbering plan identification value.                                                                                                                                                                     |
| <i>np-value</i>   | Valid range is 0 to 15.                                                                                                                                                                                              |

### Defaults

None.

### Command Modes

cs7 mlr ruleset rule configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

#### MLR/SMS rule-matching implementations earlier than ITP release 12.2(25)SW3

In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter's noa value.
- If an incoming message contains a parameter with noa unknown, then MLR matches that message to a rule for the corresponding parameter, regardless of the rule parameter's noa specification.

#### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.

- If **ton/np** is specified on a rule parameter, then MLR matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.
- If **ton/np** is not specified on a rule parameter, then MLR matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

The **orig-sme-table** command is valid for smdpp, sms-mo, and sms-mt rule operations. If the address-table lookup finds a match and returns a result, it may only be used if no other routing parameters are defined on this rule. If more than one parameter is configured in a rule, then the result specified under the rule is used.

The **dest-sme-table**, **orig-imsi-table**, and **orig-sme-table** rule commands accept either an SMS address table name *or* an MLR address table name. This ability is primarily for customers who want the SMS-MO Proxy functionality. The address table names are unique between FDA and MLR. You can enter an MLR address table name for an SMS rule parameter. However, MLR cannot reference SMS address tables.

If an incoming message matches an SMS rule that references an MLR address table, then any MLR address table result is mapped to an SMS result:

- BLOCK, PC, and PCSSN results map from MLR to SMS.
  - For result groups, the MLR result group name is mapped to an SMS result group name.
  - If the SMS result group is not configured, then the result specified on the rule is used.
- AS and CONTINUE results are not valid in SMS. For these cases, the result specified on the rule is used. If no result is specified, the result on the rule is used (the same as with MLR).

If multiple rule parameters are configured for a rule, then the rule result will be used (rather than a result specified in the address table).

If the result type specified within the table is valid, it is used. Otherwise, the result in the rule is used.

For all tables, the ton and np must match before the table is accessed.

## Examples

The following example shows how to specify an SMS ruleset named ruleset1, a rule index of 20, and a table of origin SME addresses named tbl1:

```
cs7 mlr ruleset ruleset1
rule 20 sms-mo
  orig-sme-table tbl1
  result block
```

## Related Commands

| Command                                                     | Description                                                                                                                                     |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">match-unknown-ton-np (cs7 mlr ruleset rule)</a> | Specifies that messages with unknown TON/NP will be a match to the corresponding address parameters regardless of the rule's configured TON/NP. |
| <a href="#">rule (cs7 mlr ruleset)</a>                      | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode.                |

## orig-sme-table (cs7 sms set rule)

To specify an SMS table of origin SME addresses, use the **orig-sme-table** command in cs7 sms set rule configuration mode. To remove the configuration, use the **no** form of this command.

**orig-sme-table** *table-name* [**ton** *ton-value*] [**np** *np-value*]

**no orig-sme-table** *table-name* [**ton** *ton-value*] [**np** *np-value*]

### Syntax Description

|                   |                                                  |
|-------------------|--------------------------------------------------|
| <i>table-name</i> | Address table name.                              |
| <b>ton</b>        | Specifies a type of number.                      |
| <i>ton-value</i>  | Valid range is 0 to 7.                           |
| <b>np</b>         | Specifies a numbering plan identification value. |
| <i>np-value</i>   | Valid range is 0 to 15.                          |

### Defaults

None.

### Command Modes

cs7 sms set rule configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

#### MLR/SMS rule-matching implementations earlier than ITP release 12.2(25)SW3

In ITP releases earlier than 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter noa value with an incoming message as follows:

- If **noa 0** (noa unknown) is specified in a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the corresponding parameter's noa value.
- If an incoming message contains a parameter with noa unknown, then SMS matches that message to a rule for the corresponding parameter, regardless of the rule parameter's noa specification.

#### MLR/SMS rule-matching implementations in ITP release 12.2(25)SW3

Starting with ITP release 12.2(25)SW3, MLR/SMS configuration allows matching of a rule parameter type of number/numbering plan (ton/np) value with an incoming message as follows:

- A new **ton** keyword replaces the **noa** keyword. The keywords **ton** and **np** are optional and mutually independent.
- If **ton/np** is specified on a rule parameter, then SMS matches that rule to only those incoming messages containing the exact ton/np value in the corresponding parameter.

- If **ton/np** is not specified on a rule parameter, then SMS matches that rule to incoming messages containing the corresponding parameter, regardless of the ton/np value received.

The **dest-sme-table**, **orig-imsi-table**, and **orig-sme-table** rule commands accept either an SMS address table name *or* an MLR address table name. This ability is primarily for customers who want the SMS-MO Proxy functionality. The address table names are unique between DSMR and MLR. You can enter an MLR address table name for an SMS rule parameter. However, MLR cannot reference SMS address tables.

If an incoming message matches an SMS rule that references an MLR address table, then any MLR address table result is mapped to an SMS result:

- BLOCK, PC, and PCSSN results map from MLR to SMS.
  - For result groups, the MLR result group name is mapped to an SMS result group name.
  - If the SMS result group is not configured, then the result specified on the rule is used.
- AS and CONTINUE results are not valid in SMS. For these cases, the result specified on the rule is used. If no result is specified, the result on the rule is used (the same as with MLR).

If multiple rule parameters are configured for a rule, then the rule result will be used (rather than a result specified in the address table).

If the result type specified within the table is valid, it is used. Otherwise, the result in the rule is used.

For all tables, the ton and np must match before the table is accessed.

## Examples

The following example shows how to specify an SMS ruleset named SMS-RULES, a rule index of 20, and an SMS table of origin SME addresses named BLACKLIST:

```
cs7 sms ruleset SMS-RULES
rule 20 sms-mo
  orig-sme-table BLACKLIST
  result block
```

| <a href="#">ruleset (cs7 sms ansi41 smsnot)</a> | Specifies a rule within a ruleset.        |

## orig-smsc (cs7 mlr ruleset rule)

To specify the originating service center address, use the **orig-smsc** command in cs7 mlr ruleset rule configuration mode. To remove the specification, use the **no** form of this command.

```
orig-smsc { * | address } [exact] | [min-digits min] | [max-digits max] [addr-type]
```

```
no orig-smsc
```

### Syntax Description

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>*</b>          | Matches all addresses.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>address</i>    | Address of 1 to 20 hexadecimal digits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>addr-type</i>  | (Optional) Parameters that identify attributes of the SMSC address being used to match a rule. If not specified, the address defaults to an SMSC address string specifying an E.164/telephony address with international scope. <i>addr-type</i> is composed of the following keywords: <ul style="list-style-type: none"> <li>The <b>noa</b> keyword specifies the nature of address value associated with the SMSC address. Messages received with an unknown (0) value will match any nonzero noa value specified.</li> <li>The <i>noa</i> argument is an integer value in the range 0 to 7.</li> <li>The <b>np</b> keyword specifies the numbering plan identification value associated with the SMSC address. Messages received with an unknown (0) value will match any nonzero np value specified.</li> <li>The <i>np</i> argument is an integer value in the range 0 to 15.</li> </ul> |
| <b>exact</b>      | (Optional) Configured address must match dest-sme exactly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>min-digits</b> | (Optional) Specifies the minimum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>min</i>        | Minimum number of digits in the address string. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>max-digits</b> | (Optional) Specifies the maximum number of digits in the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>max</i>        | Maximum number of digits in the address string. The default is the length of the address string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### Defaults

If not specified, the *addr-type* address defaults to an E.164/telephony address with international scope. The maximum number of digits in the address string is 1.

### Command Modes

cs7 mlr ruleset rule configuration

### Command History

| Release    | Modification                 |
|------------|------------------------------|
| 12.2(18)SW | This command was introduced. |

### Usage Guidelines

The **orig-smsc** command is used to specify the address of the originating service center (SM-RP-OA field within GSM) within an SMS-MT operation. This parameter is part of the rule used to match this route.

**Note**

The originating SMSC address might also be present in the SCCP CgPA. If so, the routing trigger might already contain the destination SMSC address; the address need not be specified on the rule.

For the **sri-sm** operation, **orig-smsc** matches the originating service center address found within the GSM MAP layer.

**Examples**

The following example shows how to specify the originating service center address:

```
cs7 mlr ruleset ruleset1
rule 20 sms-mt
  orig-smsc 1111
result block
```

|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">rule (cs7 mlr ruleset)</a> | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode. |

## orig-smsc (cs7 mlr modify-profile)

To modify the originating service center address, use the **orig-smsc** command in cs7 mlr modify-profile configuration mode. To remove the specification, use the **no** form of this command.

**orig-smsc** [**prefix** {*prefix-remove-num* | \*}]{*prefix-add-digits* | \*}] [**ton** *new-ton*] [**np** *new-np*]

**no orig-smsc** [**prefix** {*prefix-remove-num* | \*}]{*prefix-add-digits* | \*}] [**ton** *new-ton*] [**np** *new-np*]

| Syntax Description       |  |                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------|--|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>prefix</b>            |  | Specifies that prefix modification is to be performed on the address.                                                                                                                                                                                                                                                                                                                                               |
| <i>prefix-remove-num</i> |  | An integer in the range of 1 to 38 that defines the number of prefix digits to remove from the address. If no prefix digits are to be removed, then the asterisk (*) should be specified. To replace the entire address, specify that all of the digits are to be removed.                                                                                                                                          |
| <i>prefix-add-digits</i> |  | A string of 1 to 38 hexadecimal digits to add to the beginning of the address. If no digits are added, then the asterisk (*) should be specified in this field. If the number of digits in the modified address exceeds 38 digits, then the address modification cannot be performed. In this case, the action taken is based on the configured <b>modify-failure</b> command. By default, the packet is discarded. |
| <b>ton</b>               |  | Indicates a type of number (ton) replacement.                                                                                                                                                                                                                                                                                                                                                                       |
| <i>new-ton</i>           |  | An integer in the range of 0 to 7 that defines the new type of number (ton) value for the modified address.                                                                                                                                                                                                                                                                                                         |
| <b>np</b>                |  | Indicates a numbering plan (np) replacement.                                                                                                                                                                                                                                                                                                                                                                        |
| <i>new-np</i>            |  | An integer in the range of 0 to 15 that defines the new numbering plan (np) value for the modified address.                                                                                                                                                                                                                                                                                                         |

**Command Modes** cs7 mlr modify-profile configuration

**Command History**

|             |                              |
|-------------|------------------------------|
| 12.2(18)IXC | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines** Using **orig-smsc**, you can modify the address digits, the type of number (ton), and the numbering plan (np).

You can configure prefix-based address modification or a replacement address. For prefix-based address translation, you configure the number of prefix digits that will be removed from the address and the digit string that should be prefixed to the address. Specifying an asterisk (\*) for the number of prefix digits indicates that no prefix digits should be removed. Specifying an asterisk (\*) for the digit string indicates that no prefix digits are prefixed to the address string. To replace the entire address, you should specify the maximum value for the number of prefix digits to remove. If the resulting modified address exceeds the maximum allowed number of digits, then MLR does not modify the packet and discards it by default. You can optionally configure the desired action for failed modifications using the **modify-failure** command within the MLR options submenu.

---

**Examples**

The following example shows how to modify the originating service center address:

```
cs7 mlr modify-profile SRISM gsm-map sri-sm
  orig-smsc prefix 2 351
  cgpa gt prefix 2 351
```

---

| <a href="#">modify-failure (mlr options)</a> | Specifies the desired action when MLR packet modification fails. |

## outbound (config-gws-as)

To configure a screening of outbound messages, use the **outbound** command in gws as configuration mode. To remove the configuration, use the **no** form of this command.

```
outbound [logging type {allow | block | rate-limit | both} {silent | file [verbose] | console
[verbose] | file [verbose] console [verbose]} result {action action-set-name | table
table-name}
```

```
no outbound
```

| Syntax Description     |                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------|
| <b>logging</b>         | (Optional) Enables logging.                                                                     |
| <b>type</b>            | Specifies logging type.                                                                         |
| <b>allow</b>           | Messages allowed for further processing.                                                        |
| <b>block</b>           | Messages blocked.                                                                               |
| <b>rate-limit</b>      | Logs the number of MSUs discarded because of a configured rate limit.                           |
| <b>both</b>            | Allowed and blocked messages.                                                                   |
| <b>silent</b>          | Messages are screened without logging.                                                          |
| <b>file</b>            | Log is copied to a file.                                                                        |
| <b>verbose</b>         | (Optional) The packet (up to 40 bytes) is printed to the file and/or displayed on the console.  |
| <b>console</b>         | Log is displayed on the console.                                                                |
| <b>result</b>          | Specifies the next step.                                                                        |
| <b>action</b>          | Specifies that the next step is an action set.                                                  |
| <i>action-set-name</i> | Name of the action set in the next step. Valid names may not exceed 12 alphanumeric characters. |
| <b>table</b>           | Specifies that the next step is a table.                                                        |
| <i>table-name</i>      | Name of the table in the next step.                                                             |

**Defaults** The default screening is silent.

**Command Modes** gws as configuration

| Command History | Release                                  | Modification                             |
|-----------------|------------------------------------------|------------------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.             |
|                 | 12.2(33)IRG<br>12.4(15)SW7               | The <b>rate-limit</b> keyword was added. |

---

**Examples**

The following example shows how to configure outbound screening on an AS named as2:

```
cs7 instance 0 gws as name as2
outbound result action ALLOW
```

The following example shows how to configure inbound and outbound default screening for all ASes:

```
cs7 instance 0 gws as default
inbound logging type block file console verbose result table SIO0
outbound result action BLOCK
```

---

## outbound (config-gws-ls)

To configure screening of outbound messages, use the **outbound** command in gws linkset configuration mode. To remove the configuration, use the **no** form of this command.

```
outbound [logging type {allow | block | rate-limit | both} {silent | file [verbose] | console
[verbose] | file [verbose] console [verbose]}] result {action action-set-name | table
table-name}
```

```
no outbound
```

| Syntax Description     |                                                                                                 |
|------------------------|-------------------------------------------------------------------------------------------------|
| <b>logging</b>         | (Optional) Enables logging.                                                                     |
| <b>type</b>            | Specifies logging type.                                                                         |
| <b>allow</b>           | Messages allowed for further processing.                                                        |
| <b>block</b>           | Messages blocked.                                                                               |
| <b>rate-limit</b>      | Logs the number of MSUs discarded because of a configured rate limit.                           |
| <b>both</b>            | Allowed and blocked messages.                                                                   |
| <b>silent</b>          | Messages are screened without logging.                                                          |
| <b>file</b>            | Log is copied to a file.                                                                        |
| <b>verbose</b>         | (Optional) The packet (up to 40 bytes) is printed to the file and/or displayed on the console.  |
| <b>console</b>         | Log is displayed on the console.                                                                |
| <b>result</b>          | Specifies the next step.                                                                        |
| <b>action</b>          | Specifies that the next step is an action set.                                                  |
| <i>action-set-name</i> | Name of the action set in the next step. Valid names may not exceed 12 alphanumeric characters. |
| <b>table</b>           | Specifies that the next step is a table.                                                        |
| <i>table-name</i>      | Name of the table in the next step.                                                             |

**Defaults** The default screening is silent.

**Command Modes** gws linkset configuration

| Command History | Release                                  | Modification                             |

# pam (cs7 mlr ruleset rule)

To configure a reference to an existing PAM table for an MLR ruleset rule, use the **pam** command in the cs7 mlr ruleset rule configuration mode. To remove the configuration, use the **no** form of this command.

**pam** *pam-name*

**no pam** *pam-name*

|                           |                 |                                                         |
|---------------------------|-----------------|---------------------------------------------------------|
| <b>Syntax Description</b> | <b>pam</b>      | The keyword indicating a PAM table is being referenced. |
|                           | <i>pam-name</i> | The identifying name of an existing PAM table.          |

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

**Examples** Using the **show cs7 mlr config** command, the following example shows the configuration of a reference to the PAM table beta under the MLR ruleset alpha.

```
cs7 instance 0 mlr ruleset alpha
 rule 1 gsm-map sms-mo default
   pam beta
```

Using the **show cs7 mlr ruleset** command, the following example also displays the PAM table beta under the MLR ruleset alpha.

```

Name:      alpha      Instance:0  Protocol: n/a
Rule       Operation   Protocol  Matches   pam
-----
1    sms-mo           gsm-map      0    beta
```

|                         |                                |                                                              |

| <a href="#">dpc</a>                  | Configures a destination point code entry in the PAM table.                                                                       |
| <a href="#">modify-failure (pam)</a> | Specifies the desired action when the PAM table packet modification fails.                                                        |
| <a href="#">cs7 gws action-set</a>   | Defines gateway screening action sets that may include a PAM table.                                                               |
| <a href="#">gta asname</a>           | Creates or modifies a GTA entry that translates to an M3UA or SUA application server name. The GTA entry may include a PAM table. |

## path-retransmit (cs7 asp)

To configure the maximum number of path retransmissions on a remote address for the association, use the **path-retransmit** *cs7 asp* submode command. To disable the configuration, use the **no** form of this command.

**path-retransmit** *max-retries*

**no path-retransmit** *max-retries*

|                           |                    |                                                                                                                                                                                                                        |
|---------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>max-retries</i> | Maximum number of packet and keepalive retries before the corresponding destination address is marked inactive. The range is 2 to 10 retries. The default number is the value specified under the local port instance. |
|---------------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                     |
|-----------------|-------------------------------------------------------------------------------------|
| <b>Defaults</b> | The maximum number of retries is the value specified under the local port instance. |
|-----------------|-------------------------------------------------------------------------------------|

|                      |                 |

## path-retransmit (cs7 link)

To configure path retransmissions on a remote peer address, use the **path-retransmit** cs7 link submode command. To disable the configuration, use the **no** form of this command.

**path-retransmit** *max-retries*

**no path-retransmit** *max-retries*

| Syntax Description            | <i>max-retries</i> Maximum number of packet and keepalive retries before the corresponding destination address is marked inactive. The range is 2 to 10 retries. The default is 4 retries.                                                                                                                                                                                                                                                                                                                                                                                                             |  |         |              |                               |                              |            |             |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--|---------|--------------|-------------------------------|------------------------------|------------|-------------|
| Defaults                      | 4 retries                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |  |         |              |                               |                              |            |             |

| Usage Guidelines              | <p>The <b>path-retransmit</b> command specifies the number of packet retries before the destination address is deemed unreachable. The number of path-retransmits multiplied by the retransmission timer ultimately controls how fast an alternate address becomes the primary path for multihomed nodes. This relationship suggests the RTO parameters and the <b>path-retransmit</b> command should be considered together. Configuring the default RTO values and a default path retransmit value of 4 allows a multihomed node to switch to an alternate destination address within 4 seconds.</p> |  |         |              |                               |                              |            |             |

## path-retransmit (cs7 m2pa profile)

To configure path retransmissions on a remote peer address, use the **path-retransmit** cs7 m2pa profile command. To disable the configuration, use the **no** form of this command.

**path-retransmit** *max-retries*

**no path-retransmit** *max-retries*

| Syntax Description | <i>max-retries</i> | Maximum number of packet and keepalive retries before the corresponding destination address is marked inactive. The range is 2 to 10 retries. The default is 4 retries. |
|--------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|--------------------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Defaults | 4 retries |
|----------|-----------|
|----------|-----------|

| Command Modes | cs7 m2pa profile configuration |
|---------------|--------------------------------|
|---------------|--------------------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Usage Guidelines | <p>The <b>path-retransmit</b> command specifies the number of packet retries before the destination address is deemed unreachable. The number of path-retransmits multiplied by the retransmission timer ultimately controls how fast an alternate address becomes the primary path for multihomed nodes. This relationship suggests the RTO parameters and the <b>path-retransmit</b> command should be considered together. Configuring the default RTO values and a default path retransmit value of 4 allows a multihomed node to switch to an alternate destination address within 4 seconds.</p> |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Examples | <p>The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the <b>path-retransmit</b> command, and applies to all the links in the linkset named to_nyc.</p> |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
cs7 profile m2parfc
  m2pa
    path-retransmit 10
  .
.
.
cs7 linkset to_nyc
  profile m2parfc
```

|------------------|----------------------|---------------------------------------------|
|                  | <a href="#">m2pa</a> | Specifies M2PA parameters in a CS7 profile. |

## path-retransmit (cs7 m3ua)

To configure the maximum number of path retransmissions on a remote ASP/ mated-SG address to be used when a new SCTP association is started with the local port, use the **path-retransmit** cs7 m3ua submode command. To disable the configuration, use the **no** form of this command.

**path-retransmit** *max-retries*

**no path-retransmit** *max-retries*

|                           |                    |                                                                                         |
|---------------------------|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>max-retries</i> | Maximum number of path retries. The range is 2 to 10 retries. The default is 4 retries. |
|---------------------------|--------------------|-----------------------------------------------------------------------------------------|

|                 |           |
|-----------------|-----------|
| <b>Defaults</b> | 4 retries |
|-----------------|-----------|

|                      |                  |
|----------------------|------------------|
| <b>Command Modes</b> | cs7 m3ua submode |
|----------------------|------------------|

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Examples** The following example shows how to set the number of path retransmit retries to 10:

```
cs7 m3ua 2905
 local-ip 4.4.4.4
 path-retransmit 10
```

|                         |                          |                                                                        |
|-------------------------|--------------------------|------------------------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>           | <b>Description</b>                                                     |
|                         | <a href="#">cs7 m3ua</a> | Specifies the local port number for M3UA and enables cs7 m3ua submode. |

## path-retransmit (cs7 mated-sg)

To configure the maximum number of path retransmissions on a remote address for the association, use the **path-retransmit** *cs7 mated-sg* submode command. To disable the configuration, use the **no** form of this command.

**path-retransmit** *max-retries*

**no path-retransmit** *max-retries*

| Syntax Description | <i>max-retries</i> | Maximum number of packet and keepalive retries before the corresponding destination address is marked inactive. The range is 2 to 10 retries. The default is the value specified under the local port instance. |
|--------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|--------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Defaults | The default maximum number of retries is the value specified under the local port instance. |
|----------|---------------------------------------------------------------------------------------------|
|----------|---------------------------------------------------------------------------------------------|

| Command Modes | cs7 mated-sg submode |
|---------------|----------------------|
|---------------|----------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Examples | The following example shows how to set the number of path retransmit retries to 10: |
|----------|-------------------------------------------------------------------------------------|
|----------|-------------------------------------------------------------------------------------|

```
cs7 mated-sg BLUE 2905
  path-retransmit 10
```

| Related Commands | Command                           | Description                                                             |
|------------------|-----------------------------------|-------------------------------------------------------------------------|
|                  | <a href="#">cs7 mated-sg</a>      | Configures a connection to a mated SG and enables cs7 mated-sg submode. |

|                 |           |
|-----------------|-----------|
| <b>Defaults</b> | 4 retries |
|-----------------|-----------|

|                      |                 |
|----------------------|-----------------|
| <b>Command Modes</b> | cs7 sua submode |
|----------------------|-----------------|

| Command History | Release                                  | Modification                 |
|-----------------|------------------------------------------|------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

**Examples** The following example shows how to set the number of path retransmit retries to 10:

```
cs7 sua 15000
local-ip 4.4.4.4
path-retransmit 10
```

## pc (cs7 gtt application group)

To add or change a point code and optional subsystem number in the application group, use the **pc** command in cs7 gtt application group submode. To remove the point code and optional subsystem number, use the **no** form of this command.

```
[instance instance-number] pc pc [ssn ssn] {cost {gt [ntt ntt] | pcssn} [rate-limit rate] | wf {gt [ntt ntt] | pcssn}} [sccp-allow-pak-conv number]
```

```
no [instance instance-number] pc pc [ssn ssn]
```

### Syntax Description

|                            |                                                                                                                                                                                  |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>            | Specifies an instance.                                                                                                                                                           |
| <i>instance-number</i>     | Instance number.                                                                                                                                                                 |
| <i>pc</i>                  | Point code, in the form zone.region.sp. The specified point code must represent a real point code, not an alias point code.                                                      |
| <b>ssn</b>                 | Specifies a subsystem number.                                                                                                                                                    |
| <i>ssn</i>                 | Subsystem number. Valid range is 2 to 255.                                                                                                                                       |
| <i>cost</i>                | Index value (1–64) specifying the priority of the AS name within the application group.                                                                                          |
| <b>gt</b>                  | Sets the routing indicator to route on the global title.                                                                                                                         |
| <b>ntt</b>                 | Configures a new translation type value to be set within the called party address global title selector data. The keyword is valid only when the <b>gt</b> keyword is specified. |
| <i>ntt</i>                 | New translation type value in the range 0 to 255.                                                                                                                                |
| <b>pcssn</b>               | Sets the routing indicator to route on the point code and subsystem number.                                                                                                      |
| <b>rate-limit</b>          | Specifies the traffic-rate limitation to this PC/SSN. The over-flow traffic will be routed to higher cost DPC/ASNAME. If not specified, the PC does not have a rate-limit.       |
| <i>rate</i>                | An integrate value specifying the traffic rate. Valid range is 1 to 4294967296 MSU/sec.                                                                                          |
| <i>wf</i>                  | Weighing factor. Any items added to the group require a cost if the destination for the <b>multiplicity</b> command is specified as <b>cgpa</b> or <b>wrr</b> .                  |
| <b>sccp-allow-pak-conv</b> | Enables conversion of SCCP packet between XUDT/XUDTS and UDT/UDTS.                                                                                                               |
| <i>number</i>              | 1 specifies XUDT/XUDTS to UDT/UDTS conversion<br>2 specifies UDT/UDTS to XUDT/XUDTS conversion<br>3 specifies NO CONVERSION                                                      |

### Defaults

None.

### Command Modes

cs7 gtt application group submode

| Command History | Release                                  | Modification                                                            |
|-----------------|------------------------------------------|-------------------------------------------------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                                            |
|                 | 12.4(15)SW4<br>12.2(33)IRD               | The <b>rate limit</b> keyword and <i>rate</i> argument were introduced. |
|                 | 12.4(15)SW9<br>12.2(33)IRI               | The <b>sccp-allow-pak-conv</b> keyword was added.                       |

### Usage Guidelines

The destination in a GTT application group uses the *wf* argument when the **multiplicity** command is configured with the **cgpa** or **wrr** keyword.

The rate-limit parameter is only valid for multiplicity cost mode.

### Examples

The following example shows how to specify point code 2.2.2, subsystem number 3, with a cost of 4. The routing indicator is set to route on the point code and subsystem number.

```
pc 1.2.3 ssn 3 4 pcssn
```

|-------------------------------------------|--------------------------------------------------------------------------|
| <a href="#">cs7 gtt application-group</a> | Specifies a GTT application group.                                       |
| <a href="#">multiplicity</a>              | Specifies a method for selecting a destination in the application group. |

## pc (cs7 mlr result)

To specify the destination point code, use the **pc** command in cs7 mlr result configuration mode. To remove the specification, use the **no** form of this command.

**[instance instance] pc dest-pc [ssn ssn] [order order] [weight weight]**

**no [instance instance] pc dest-pc [ssn ssn] [order order] [weight weight]**

| Syntax Description |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>    | (Optional) Indicates the PC/PCSSN result in local or other instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>instance</i>    | (Optional) Instance number. The valid range is 0 to 7. The default instance is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>dest-pc</i>     | A destination point code in variant-specific point-code format. The specified point code must represent a real point code, not an alias point code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ssn</b>         | (Optional) Specifies a subsystem number to be used along with the point code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>ssn</i>         | Subsystem number. Valid range is 2 to 255.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>order</b>       | Specifies the order in which the results are stored in the result group. Required for (and only present in the CLI for) results in a dest-sme-binding mode. Results in a wrp result group are not able to configure an <b>order</b> parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <i>order</i>       | An integer value in the range of 1 to 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>weight</b>      | (Optional) Specifies the load-balancing weight.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <i>weight</i>      | For dest-sme-binding mode, an integer value in the range 1 to 2147483647. The weight value should reflect the relative capacity of the result (smc). This value is used by the dynamic B-address routing algorithm to select a deterministic result (SMSC) based on the message B-address. If not configured, the default <i>weight</i> value is 1.<br><br>For wrp mode, an integer value in the range of 0 to 10. A value of 10 indicates the resource should be selected 10 times more than a resource assigned a weight of 1. A weight of 0 indicates that the resource should only be used in the event that all nonzero-weighted resources are unavailable. If multiple zero-weighted resources exist, then messages are equally distributed between them if all nonzero-weighted resources fail. If not specified, a default weight of 1 is used. |

### Defaults

The default load-balancing weight is 1 and the default instance is 0.

### Command Modes

cs7 mlr result configuration

| Command History | Release                                   | Modification                           |
|-----------------|-------------------------------------------|----------------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.           |
|                 | 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | The <b>instance</b> keyword was added. |

### Usage Guidelines

If multiple zero-weighted resources exist, then messages are equally distributed between them if all nonzero-weighted resources fail. If not specified, a default weight of 1 is used.

### Examples

The following example shows how to specify three resources in the result group SMS-WEIGHTED. The three resources are identified by point codes and assigned weighted round-robin (WRR) values.

```
cs7 mlr result SMS-WEIGHTED
  pc 3.3.2 weight 1
  pc 3.3.1 weight 2
  pc 3.3.3 weight 5
```

The following example shows how to specify the instance number as 1:

```
cs7 instance 0 mlr result ttt
instance 1 pc 1.11.1 ssn 11
```

### Related Commands

| Command                             | Description                                                                                                                                                    |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 mlr result</a>      | Specifies the name of the MLR result group. The result group contains the list of resources that process traffic to be routed based on multilayer information. |
| <a href="#">show cs7 mlr result</a> | Displays multilayer SMS routing result information.                                                                                                            |

# pc-range

To specify a point code range entry in a pc table, use the **pc-range** command in gateway screening table configuration mode. To delete a point code entry, use the **no** form of this command.

**pc-range** *pc-start* [*pc-end*] **result** { **action** *action-set-name* | **table** *table-name* }

**no pc-range** *pc-start* [*pc-end*]

## Syntax Description

|                        |                                                                         |
|------------------------|-------------------------------------------------------------------------|
| <i>pc-start</i>        | Starting pc in the range.                                               |
| <i>pc-end</i>          | (Optional) Ending pc in the range.                                      |
| <b>result</b>          | Specifies the next step.                                                |
| <b>action</b>          | Screens the result by action set.                                       |
| <i>action-set-name</i> | Action set name. Valid names may not exceed 12 alphanumeric characters. |
| <b>table</b>           | Screens the result by table.                                            |
| <i>table-name</i>      | Table name. Valid names may not exceed 12 alphanumeric characters.      |

## Defaults

None.

## Command Modes

gateway screening table configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **pc-range** command is valid for the following table types: aff-dest, dpc, opc.  
Wildcards can be used. Refer to [Table 13 on page 205](#).

## Examples

The following example shows how to specify a **pc-range** entry for the OPC1 table:

```
cs7 instance 0 gws table OPC1 type opc action allowed
pc-range 6.6.6 result table PCSSN1
```

## pc-range ssn

To specify a point code range entry in a pc-ssn table, use the **pc-range ssn** command in gateway screening table configuration mode. To delete a point code, use the **no** form of this command.

**pc-range** *pc-start* [*pc-end*] **ssn** *ssn* **result** { **action-set** *action-set-name* | **table** *table-name* }

**no pc-range ssn** *pc-start* [*pc-end*] **ssn** *ssn*

| Syntax Description     |  |                                                                         |
|------------------------|--|-------------------------------------------------------------------------|
| <i>pc-start</i>        |  | Starting pc in the range.                                               |
| <i>pc-end</i>          |  | (Optional) Ending pc in the range.                                      |
| <b>ssn</b>             |  | Specifies the subsystem number.                                         |
| <i>ssn</i>             |  | Subsystem number. Valid range is 1 to 255.                              |
| <b>result</b>          |  | Specifies the next step.                                                |
| <b>action</b>          |  | Screens the result by action set.                                       |
| <i>action-set-name</i> |  | Action set name. Valid names may not exceed 12 alphanumeric characters. |
| <b>table</b>           |  | Screens the result by table.                                            |
| <i>table-name</i>      |  | Table name. Valid names may not exceed 12 alphanumeric characters.      |

| Defaults | None. |

## peer-timer (cs7 link)

To set the peer timer, use the **peer-timer** command in cs7 link configuration mode. To disable the timer, use the **no** form of this command.

**peer-timer** {*lssu msec* | **t01 msec** | **t2 msec** | **t3 msec** | **t4e msec** | **t4n msec** | **t06 msec** | **t7 msec**}

**no peer-timer** {*lssu msec* | **t01 msec** | **t2 msec** | **t3 msec** | **t4e msec** | **t4n msec** | **t06 msec** | **t7 msec**}

| Syntax Description |  |                                                                                                                                                                                                                |
|--------------------|--|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>lssu</b>        |  | LSSU rate timer, the rate at which link status messages are sent. The range is 500 to 30000 milliseconds. The default is 5000 milliseconds. Applies to M2PA RFC links only.                                    |
| <b>t01 msec</b>    |  | Alignment ready timer. The range is 500 to 60000 milliseconds. The default is 5000 milliseconds if the link is defined as M2PA draft2, and 45000 milliseconds if the link is defined as an M2PA RFC link.      |
| <b>t2</b>          |  | Not aligned timer. The range is 500 to 150000 milliseconds. The default is 60000 milliseconds. Applies to M2PA RFC links only.                                                                                 |
| <b>t3</b>          |  | Aligned timer. The range is 500 to 60000 milliseconds. The default is 2000 milliseconds. Applies to M2PA RFC links only.                                                                                       |
| <b>t4e</b>         |  | Emergency proving period timer, the rate at which the emergency proving link status messages are sent. The range is 100 to 5000 milliseconds. The default is 500 milliseconds. Applies to M2PA RFC links only. |
| <b>t4n</b>         |  | Normal proving period timer, the rate at which the normal proving link status messages are sent. The range is 500 to 60000 milliseconds. The default is 8000 milliseconds. Applies to M2PA RFC links only.     |
| <b>t06</b>         |  | Remote congestion timer. The range is 500 to 12000 milliseconds. The default is 4000 milliseconds.                                                                                                             |
| <b>t7</b>          |  | Excessive delay of acknowledgment timer. The range is 0 to 30000 milliseconds. The default is 0 milliseconds. Applies to M2PA RFC links only.                                                                  |

**Defaults** See Syntax Description.

**Command Modes** cs7 link configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Examples** The following example shows how to set the t06 timer to 2000 milliseconds for link 0 in the linkset named to\_nyc:

```
cs7 linkset to_nyc 10.1.1
link 0 sctp 172.18.44.147 7000 7000
peer-timer t06 2000
```

#### Related Commands

|------------------------------------|-----------------------------------------------------------------|
| <a href="#">cs7 profile</a>        | Specifies a set of parameters that can be applied to a linkset. |
| <a href="#">link (cs7 linkset)</a> | Specifies a link.                                               |
| <a href="#">show cs7 m2pa</a>      | Displays M2PA statistics.                                       |

## peer-timer (cs7 m2pa profile)

To set the peer timer, use the **peer-timer** command in cs7 m2pa profile configuration mode. To disable the timer, use the **no** form of this command.

**peer-timer** {*lssu msec* | **t01 msec** | **t2 msec** | **t3 msec** | **t4e msec** | **t4n msec** | **t06 msec** | **t7 msec**}

**no peer-timer** {*lssu msec* | **t01 msec** | **t2 msec** | **t3 msec** | **t4e msec** | **t4n msec** | **t06 msec** | **t7 msec**}

| Syntax Description |  |                                                                                                                                                                                                                |
|--------------------|--|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>lssu</b>        |  | LSSU rate timer, the rate at which link status messages are sent. The range is 500 to 30000 milliseconds. The default is 5000 milliseconds. Applies to M2PA RFC links only.                                    |
| <b>t01 msec</b>    |  | Alignment ready timer. The range is 500 to 60000 milliseconds. The default is 5000 milliseconds if the link is defined as M2PA draft2, and 45000 milliseconds if the link is defined as an M2PA RFC link.      |
| <b>t2</b>          |  | Not aligned timer. The range is 500 to 150000 milliseconds. The default is 60000 milliseconds. Applies to M2PA RFC links only.                                                                                 |
| <b>t3</b>          |  | Aligned timer. The range is 500 to 60000 milliseconds. The default is 2000 milliseconds. Applies to M2PA RFC links only.                                                                                       |
| <b>t4e</b>         |  | Emergency proving period timer, the rate at which the emergency proving link status messages are sent. The range is 100 to 5000 milliseconds. The default is 500 milliseconds. Applies to M2PA RFC links only. |
| <b>t4n</b>         |  | Normal proving period timer, the rate at which the normal proving link status messages are sent. The range is 500 to 60000 milliseconds. The default is 8000 milliseconds. Applies to M2PA RFC links only.     |
| <b>t06</b>         |  | Remote congestion timer. The range is 500 to 12000 milliseconds. The default is 4000 milliseconds.                                                                                                             |
| <b>t7</b>          |  | Excessive delay of acknowledgment timer. The range is 0 to 30000 milliseconds. The default is 0 milliseconds. Applies to M2PA RFC links only.                                                                  |

**Defaults** See Syntax Description.

**Command Modes** cs7 m2pa profile configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Examples** The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, configures **peer-timer** settings and **hold-transport** settings, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
  m2pa
    peer-timer t1 15000
    peer-timer t2 9000
  .
  .
  .
cs7 linkset to_nyc
  profile m2parfc
```

## pid (cs7 mlr ruleset rule)

To specify a particular protocol identifier (PID) value for an SMS-MO or SMS-MT rule, use the **pid** command in cs7 mlr ruleset rule configuration mode. To remove the specification, use the **no** form of this command.

**pid** *protocol-id*

**no pid** *protocol-id*

|                    |                                                                                                                                                                                                                |                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Syntax Description | <i>protocol-id</i> An integer in the range 0 to 255.                                                                                                                                                           |                                                                                                                                  |
| Defaults           | None.                                                                                                                                                                                                          |                                                                                                                                  |

|                    | <a href="#">rule (cs7 mlr ruleset)</a>                                                                                                                                                                         | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration mode. |

## pid (cs7 sms set rule)

To specify a protocol identifier (TP-PID), use the **pid** command in cs7 sms set rule configuration mode. To remove the configuration, use the **no** form of this command.

**pid** *pid-value*

**no pid**

|                           |                  |                                                             |
|---------------------------|------------------|-------------------------------------------------------------|
| <b>Syntax Description</b> | <i>pid-value</i> | Protocol identifier integer value. Valid range is 0 to 255. |
|---------------------------|------------------|-------------------------------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                                |

|                         | <a href="#">cgpa (cs7 mlr trigger)</a>             | Tests the availability of the CDR service queue as the input condition of the rule. |
|                         | <a href="#">cs7 sms ruleset</a>                    | Specifies a ruleset.                                                                |
|                         | <a href="#">dest-sme (cs7 mlr ruleset rule)</a>    | Specifies an application destination port number.                                   |
|                         | <a href="#">dest-sme (cs7 sms set rule)</a>        | Specifies a destination short message entity (SME).                                 |
|                         | <a href="#">dest-sme-table (cs7 sms set rule)</a>  | Specifies an SMS table of destination SME addresses.                                |
|                         | <a href="#">dest-smsc (cs7 sms set rule)</a>       | Specifies a destination SMSC.                                                       |
|                         | <a href="#">orig-imsi (cs7 sms set rule)</a>       | Specifies an origin IMSI.                                                           |
|                         | <a href="#">orig-imsi-table (cs7 sms set rule)</a> | Specifies an SMS table of origin IMSI addresses (address-table).                    |
|                         | <a href="#">orig-sme (cs7 sms set rule)</a>        | Specifies an origin SME.                                                            |

| Command                                           | Description                                                     |
|---------------------------------------------------|-----------------------------------------------------------------|
| <a href="#">orig-sme-table (cs7 sms set rule)</a> | Specifies an SMS table of origin SME addresses (address-table). |
| <a href="#">result (cs7 sms set rule)</a>         | Specifies a result.                                             |
| <a href="#">ruleset (cs7 sms ansi41 smsnot)</a>   | Specifies a rule within a ruleset.                              |

# ping cs7

To verify that you can reach ITP nodes, use the **ping cs7** EXEC command. To stop the ping, use the **ping cs7** command with the **stop** keyword.

**ping cs7** [*instance-number*] [**-opc** *origination-point-code*] [**-duration** *seconds*] [**-ni** *network-indicator*] [**-rate** *MSU-per-second*] [**-size** *bytes*] [**-sls** *value* | **round-robin**] {*destination-point-code* | *host*}

**ping cs7** [*instance-number*] **stop** *destination-point-code*

## Syntax Description

|                               |                                                                                                                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance-number</i>        | (Optional) ITP instance.                                                                                                                                                     |
| <b>-opc</b>                   | (Optional) Specifies the secondary pc or the capability pc as the originating pc of the ping. If <b>-opc</b> is not specified, the primary pc is the default originating pc. |
| <i>origination-point-code</i> | Originating point code. You can specify a secondary pc or a capability pc.                                                                                                   |
| <b>-duration</b>              | (Optional) Specifies a ping test duration, in seconds.                                                                                                                       |
| <i>seconds</i>                | Duration of the ping, in seconds. The default is 1 second.                                                                                                                   |
| <b>-ni</b>                    | (Optional) Specifies a network indicator.                                                                                                                                    |
| <i>network-indicator</i>      | The network indicator. The default is 2.                                                                                                                                     |
| <b>-rate</b>                  | (Optional) Specifies a ping message rate in MSU per second.                                                                                                                  |
| <i>MSU-per-second</i>         | MSU per second.                                                                                                                                                              |
| <b>-size</b>                  | (Optional) Specifies a test message size, in bytes.                                                                                                                          |
| <i>bytes</i>                  | Ping test message size. The default size is 40 bytes.                                                                                                                        |
| <b>-sls</b>                   | (Optional) Signaling link selector.                                                                                                                                          |
| <i>value</i>                  | Signaling link selector value. Valid numbers are 1 to 15. The default is 0.                                                                                                  |
| <b>round-robin</b>            | Performs the ping in round-robin order.                                                                                                                                      |
| <i>destination-point-code</i> | The point code.                                                                                                                                                              |
| <i>host</i>                   | The hostname.                                                                                                                                                                |
| <b>stop</b>                   | Stops the ping.                                                                                                                                                              |

## Defaults

The primary point code is the default originating point code. The default of the duration of the ping is 1 second. The network indicator default is 2. The signaling link selector default value is 0.

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example shows how to start a 10-second ping to point code 10.44.156:

```
Router# ping cs7 -duration 10 10.44.156
%CS7PING-6-RTT:Q.755 Test 10.44.156:MTP Traffic test rtt 200/200/200
%CS7PING-6-TERM:Q.755 Test 10.44.156:MTP Traffic test terminated
```

The following example shows how to start a ping from the secondary point code 10.10.10 to 10.44.156:

```
ping cs7 -opc 10.10.10 10.44.156
```

The following example shows how to stop a ping to point code 10.44.156:

```
ping cs7 stop 10.44.156
```

#### Related Commands

| Command                          | Description                       |
|----------------------------------|-----------------------------------|
| <a href="#">cs7 host</a>         | Displays the hostname.            |
| <a href="#">show cs7 linkset</a> | Displays linkset information.     |
| <a href="#">show cs7 ping</a>    | Displays output from a ping test. |

# ping-interval

To set the interval between two consecutive ICMP Echo requests, use the **ping-interval** cs7 dcs submode command. To stop the ping, use the **no** form of this command.

**ping-interval** *sec*

**no ping-interval** *sec*

|                           |            |                                                                                                                                                                                             |
|---------------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>sec</i> | (Optional) Length of time in seconds that defines the interval between pings to the DCS nodes' IP addresses. The time interval range is 0 to 30 seconds. The default interval is 5 seconds. |
|---------------------------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |           |
|-----------------|-----------|
| <b>Defaults</b> | 5 seconds |

|                        | 12.4(15)SW3    |                              |
|                        | 12.2(33)IRC    |                              |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | <p>The source address of ICMP packets is based on the determination by the router. Normally, the source address of ICMP packets is the address of the closest interface to the destination address. This behavior conforms to the selection of source addresses when the customer issues ping commands with the CLI.</p> <p>A <i>sec</i> value of 0 indicates no ping is sent, and that the DCS is shown as always available.</p> |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                                                                          |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | <p>The following example shows how to configure a ping interval of 5 seconds between the remote IP address and the local IP address:</p> |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|

```
cs7 dcs dcs5
 remote-ip 209.165.201.29 209.165.201.28 3033
 local-ip 1209.165.20127 3033
 ping-interval 5
 timeout-count 3
 udp-checksum
```

|                         |                   |                                                      |

|--------------------|-------------------------------------------------------|
| cs7 pmp hold-queue | Sets the integer range of a PMP hold queue threshold. |
| cs 7 dcs           | Identifies a name to be associated with a DCS node.   |
| show cs7 pmp       | Displays errors and information about the PMP.        |
| show cs7 dcs-group | Displays information about the DCS group.             |
| show cs7 dcs       | Displays information about the DCS node.              |

# plan-capacity-rcvd

To configure link receive planning capacity, use the **plan-capacity-rcvd** *cs7* link submode command. To remove the configuration, use the **no** form of this command.

**plan-capacity-rcvd** *bps*

**no plan-capacity-rcvd** *bps*

|                           |            |                                                                        |
|---------------------------|------------|------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>bps</i> | Planned capacity in bits per second. The range is 56000 to 2147483647. |
|---------------------------|------------|------------------------------------------------------------------------|

|                 |                                                                                                              |
|-----------------|--------------------------------------------------------------------------------------------------------------|
| <b>Defaults</b> | For links based on Serial or ATM (HSL) technologies, the planned capacity is the physical speed of the link. |
|-----------------|--------------------------------------------------------------------------------------------------------------|

|                      |                         |

# plan-capacity-send

To configure the link send planning capacity, use the **plan-capacity-send** cs7 link submode command. To remove the configuration, use the **no** form of this command.

**plan-capacity-send** *bps*

**no plan-capacity-send** *bps*

## Syntax Description

|            |                                                                        |
|------------|------------------------------------------------------------------------|
| <i>bps</i> | Planned capacity in bits per second. The range is 56000 to 2147483647. |
|------------|------------------------------------------------------------------------|

## Defaults

For links based on Serial or ATM (HSL) technologies, the planned capacity is the physical speed of the link.

## Command Modes

cs7 link submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

Planned capacity is the maximum amount of expected data to be transmitted on a link. This value is expressed in bits per second. For links based on Serial or ATM (HSL) technologies, the planned capacity is the physical speed of the link. You do not need to specify a planned capacity for these types of links. When a planned capacity is not specified for these types of links, the ifSpeed (from the IF-MIB) is used as the planned capacity.

In the case of SCTP/IP-based links, you cannot directly determine the expected amount of traffic. The design of the IP cloud must consider the traffic from all SS7 links and allocate resources accordingly. To monitor link utilization on these types of links, a planned capacity must be specified.

## Examples

The following example shows how to set the send planning capacity on link 0 to 56000 bps:

```
cs7 linkset michael 10.1.1
link 0 sctp 172.18.44.147 7000 7000
plan-capacity-send 56000
```

## pmp (cs7 as)

The probeless monitoring protocol is a proprietary ITP UDP protocol that allows copying sent or received ITP MSUs and then sending them to a data collection server (DCS). To turn on probeless monitoring for an AS, use the **pmp** cs7 as submode command. To turn probeless monitoring off, use the **no** form of this command.

**pmp**

**no pmp**

|                           |                                            |
|---------------------------|--------------------------------------------|
| <b>Syntax Description</b> | This command has no arguments or keywords. |
|---------------------------|--------------------------------------------|

|                 |                              |
|-----------------|------------------------------|
| <b>Defaults</b> | Probeless monitoring is off. |
|-----------------|------------------------------|

|                      |                |
|----------------------|----------------|
| <b>Command Modes</b> | cs7 as submode |
|----------------------|----------------|

|                        |                            |                              |
|------------------------|----------------------------|------------------------------|
| <b>Command History</b> | <b>Release</b>             | <b>Modification</b>          |
|                        | 12.4(15)SW3<br>12.2(33)IRC | This command was introduced. |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | When probeless monitoring is turned on for an AS, you still have to specify the DCS group under cs7 as submode. When probeless monitoring is turned off at the global configuration level, it overrides the probeless monitoring setting for the AS. When the global probeless monitoring option is on, the probeless monitoring setting for a particular AS governs whether probeless monitoring is on or off for that AS. |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                           |
|-----------------|-----------------------------------------------------------|
| <b>Examples</b> | The following example shows how to turn PMP on for an AS: |
|-----------------|-----------------------------------------------------------|

```
cs7 instance 4 as as1 m3ua
  pmp
  routing-key 2333 444
  asp asp1
  contextid 2
  asp asp2
  contextid 3
  dcs-group dcs-group1 inbound
  dcs-group dcs-group2 outbound
```

|                         |                   |                                                      |
|-------------------------|-------------------|------------------------------------------------------|
| <b>Related Commands</b> | <b>Command</b>    | <b>Description</b>                                   |
|                         | pmp (cs7 linkset) | Turns probeless monitoring on for a linkset.         |
|                         | cs7 dcs-group     | Identifies a name to be associated with a DCS group. |

| Command            | Description                                           |
|--------------------|-------------------------------------------------------|
| cs7 pmp hold-queue | Sets the integer range of a PMP hold queue threshold. |
| cs 7 dcs           | Identifies a name to be associated with a DCS node.   |
| show cs7 pmp       | Displays errors and information about the PMP.        |
| show cs7 dcs-group | Displays information about the DCS group.             |
| show cs7 dcs       | Displays information about the DCS node.              |

## pmp (cs7 linkset)

The probeless monitoring protocol is a proprietary ITP UDP protocol that allows copying sent or received ITP MSUs and then sending them to a data collection server (DCS). To turn on probeless monitoring for a linkset, use the **pmp** cs7 linkset submode command. To turn probeless monitoring off, use the **no** form of this command.

**pmp**

**no pmp**

**Syntax Description** This command has no arguments or keywords.

**Defaults** Probeless monitoring is off.

**Command Modes** cs7 linkset submode

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.4(15)SW3 | This command was introduced. |
|                 | 12.2(33)IRC |                              |

**Usage Guidelines** When probeless monitoring is turned on for a linkset, you still have to specify the DCS group under cs7 linkset submode. When probeless monitoring is turned off at the global configuration level, it overrides the probeless monitoring setting for the linkset. When the global probeless monitoring option is on, the probeless monitoring setting for a particular linkset governs whether probeless monitoring is on or off for that linkset.

**Examples** The following example shows how to turn PMP on for a linkset:

```
cs7 instance 0 linkset tojupiter 2.54.0
 accounting
  pmp
  gtt-accounting
 dcs-group polystar all
 link 0 setp 10.0.90.30 2905 2905
 contextid 1
```

| <a href="#">cs7 billing options</a>            | Configures options for billing.                   |
| <a href="#">cs7 billing load</a>               | Specifies the billing configuration file to load. |

## point-code (sccp)

To configure the billing pc-table entry when the pc-table type is SCCP, use the **point-code** command in billing pc-table submenu. To remove the configuration, use the **no** form of this command.

**point-code** *point-code* [**ssn** *ssn-number*] [**gta** *gta-number* **tt** *tt-number* **gti** *gti-number*] [**np** *np-number*] [**nai** *nai-number*]

**no point-code** *point-code* [**ssn** *ssn-number*] [**gta** *gta-number* **tt** *tt-number* **gti** *gti-number*] [**np** *np-number*] [**nai** *nai-number*]

### Syntax Description

|                   |                                                  |
|-------------------|--------------------------------------------------|
| <i>point-code</i> | Point code of table entry                        |
| <i>ssn-number</i> | Sub-System Number (0-255)                        |
| <i>gta-number</i> | Global Title Address number (1 to 15 hex digits) |
| <i>tt-number</i>  | Translation Type number (0-255)                  |
| <i>gti-number</i> | Global Title Indicator number (2 or 4)           |
| <i>np-number</i>  | National Plan number (0-15)                      |
| <i>nai-number</i> | Nature of Address Indicator number (0-127)       |

### Defaults

None.

### Command Modes

billing pc-table submenu

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW4 | This command was introduced. |
| 12.2(33)IRD |                              |

### Usage Guidelines

This command configures the point code and service indicator to meet the accounting criteria.

### Examples

The following example shows how to configure a point code of 1.1.1 and a service indicator of 11:

```
cs7 instance 0 billing pc-table PCTBL_02 sccp
point-code 2.2.2 ssn 8 gta 67890 tt 0 gti 4 np 4 nai 2
```

# post-gtt-address-conversion

After you have defined a GTT address conversion table, you can apply the table on a GTT selector basis. To specify the global title address conversion table to apply after performing local global title translation, use the **post-gtt-address-conversion** *cs7 gtt selector submode* command. To remove the statement, use the **no** form of this command.

**post-gtt-address-conversion** *table-name*

**no post-gtt-address-conversion** *table-name*

| Syntax Description                         | <div><div><i>table-name</i></div><div>Name of an already-defined address conversion table.</div></div>                                                                                                                                                                                                                                                          |  |         |              |                                  |                              |                                            |                                                                                                                |

# power enable unsequence

By default, all SAMIs download the image at the same time, as configured by the **power enable unsequence** command in global configuration mode. To configure ITP so that both SAMIs download the image one at a time, use the **no** form of this command.

**power enable unsequence**

**no power enable unsequence**

## Defaults

All SAMIs download the image at the same time.

## Command Modes

Global configuration mode (config)

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(33)IRG | This command was introduced. |

## Examples

The following example shows how to configure the SAMIs to download the image at the same time:

```
power enable unsequence
```

The following example shows how to configure the SAMIs to download the image one at a time:

```
no power enable unsequence
```

## Related Commands

# pre-gtt-address-conversion

To specify the global title address conversion table to apply before performing local global title translation, use the **pre-gtt-address-conversion** *cs7 gtt selector* submode command. To remove the statement, use the **no** form of this command.

**pre-gtt-address-conversion** *table-name*

**no pre-gtt-address-conversion** *table-name*

|                    | post-gtt-address-conversion                                                                                                                             | Specifies the global title address conversion table to apply after performing local global title translation. |

## preserve-opc (cs7 mlr ruleset)

To preserve the original originating point code (OPC) when an MLR is selected in this instance, use the **preserve-opc** command in cs7 mlr ruleset configuration mode. To remove the specification, use the **no** form of this command.

**preserve-opc**

**no preserve-opc**

### Syntax Description

This command has no arguments or keywords.

### Defaults

The command is disabled. The OPC is modified by the MLR to the ITP local PC.

### Command Modes

cs7 mlr ruleset configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The default mode of MLR operation is for the ITP to place its local PC into the OPC field and insert the original OPC into the SCCP calling party address PC field, if possible. This behavior is consistent with an SCCP relay function, which MLR most closely resembles.

When the **preserve-opc** command is specified, the ITP routes the packet without modifying the original OPC in any way. The SCCP calling party address is also not modified.

### Examples

The following example shows how to specify that, when a rule is matched, the ITP routes the packet without modifying the original OPC:

```
cs7 mlr ruleset ruleset1
 preserve-opc
```

|------------------------------------------------|----------------------------------------------------------------------------------------|
| <a href="#">cs7 mlr ruleset</a>                | Specifies an MLR ruleset and application layer protocol filter for the ruleset.        |
| <a href="#">preserve-opc (cs7 mlr options)</a> | Specifies an MLR result option command and enables cs7 mlr options configuration mode. |

## preserve-opc (cs7 mlr options)

To preserve the original originating point code (OPC) when an MLR is selected in this instance, use the **preserve-opc** command in cs7 mlr options configuration mode. To remove the specification, use the **no** form of this command.

**preserve-opc**

**no preserve-opc**

### Syntax Description

This command has no keywords or arguments.

### Defaults

The command is disabled. The OPC is modified by the MLR to the ITP local PC.

### Command Modes

cs7 mlr options configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXC | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The default mode of MLR operation is for the ITP to place its local PC into the OPC field and insert the original OPC into the SCCP calling party address PC field, if possible. This behavior is consistent with an SCCP relay function, which MLR most closely resembles.

When the **preserve-opc** command is specified, the ITP routes the packet without modifying the original OPC in any way. The SCCP calling party address is also not modified. This **preserve-opc** command applies to all messages that are routed using MLR.

# preventive-txp

To enable preventive transfer prohibited route management messages, use the **preventive-txp** cs7 linkset submode command. To disable preventive transfer prohibited messages, use the **no** form of this command.

**preventive-txp**

**no preventive-txp**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** cs7 linkset submode

| Command History | Release       | Modification                 |
|-----------------|---------------|------------------------------|
|                 | 12.2(18)IXA   | This command was introduced. |
|                 | 12.4(11)SW    |                              |
|                 | 12.2(33)IRA12 |                              |
|                 |               |                              |

**Usage Guidelines**

A preventive transfer prohibited message is normally sent to an adjacent node to indicate that the adjacent node will be used for signaling traffic to a concerned destination. The purpose of the message is to avoid a routing loop by preventing the adjacent node from sending signaling traffic to a node that will route the signaling traffic back to the adjacent node.

This command should only be used to disable preventive transfer prohibited messages to adjacent nodes when the possibility for a routing loop does not exist. Extreme care should be taken when this command is used to disable preventive transfer prohibited messages.

**Examples**

The following example shows how to disable the broadcast of route management messages on linkset1:

```
cs7 linkset linkset1
no preventive-txp
```

## qos-class (cs7 as)

To configure a QoS class for the packets sent to the ASPs in this AS, use the **qos-class** cs7 as submode command. To remove the configuration, use the **no** form of this command.

**qos-class** *class*

**no qos-class** *class*

|                           |              |                                      |
|---------------------------|--------------|--------------------------------------|
| <b>Syntax Description</b> | <i>class</i> | QoS class ID. Valid range is 1 to 7. |
|---------------------------|--------------|--------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                |
|----------------------|----------------|
| <b>Command Modes</b> | cs7 as submode |
|----------------------|----------------|

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

|                         |                                                                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The QoS class must be defined before the class is assigned.                                                                                                 |
|                         | After being configured, this QoS class is applied to all ASPs listed under this AS. The QoS class goes into effect for only the subsequent ASP connections. |
|                         | The QoS class defined under the ASP overrides the QoS class defined under the AS.                                                                           |

|                 |                                                                   |
|-----------------|-------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to configure QoS class 4 for AS1: |
|-----------------|-------------------------------------------------------------------|

```
cs7 as as1 m3ua
  qos-class 4
```

|                         |                        |                                     |
|-------------------------|------------------------|-------------------------------------|
| <b>Related Commands</b> | <b>Command</b>         | <b>Description</b>                  |
|                         | <a href="#">cs7 as</a> | Defines an application server (AS). |

## qos-class (cs7 asp)

To configure a QoS class for the packets sent to this ASP, use the **qos-class** cs7 asp submode command. To remove the configuration, use the **no** form of this command.

**qos-class** *class* [*instance-number*]

**no qos-class** *class* [*instance-number*]

|                           |                        |                                                                                                      |
|---------------------------|------------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>class</i>           | QoS class ID in the range 0 to 7.                                                                    |
|                           | <i>instance-number</i> | Required if multiple instances are configured. The valid range is 0 to 7. The default instance is 0. |

|                 |                            |
|-----------------|----------------------------|
| <b>Defaults</b> | The default instance is 0. |
|-----------------|----------------------------|

|                      |                 |
|----------------------|-----------------|
| <b>Command Modes</b> | cs7 asp submode |
|----------------------|-----------------|

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

|                         |                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The QoS class must be defined before the class is assigned.                       |
|                         | The QoS class goes into effect for only the subsequent ASP connections.           |
|                         | The QoS class defined under the ASP overrides the QoS class defined under the AS. |

|                 |                                                                    |
|-----------------|--------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to configure QoS class 4 for ASP1: |
|-----------------|--------------------------------------------------------------------|

```
cs7 asp ASP1 2904 2905 m3ua
  remote-ip 1.1.1.1
  qos-class 4
```

|-------------------------|-------------------------------|----------------------------------------------------------------------------|
|                         | <a href="#">cs7 asp</a>       | Specifies an application server process (ASP) and enables cs7 asp submode. |
|                         | <a href="#">cs7 qos class</a> | Defines a QoS class.                                                       |
|                         | <a href="#">show cs7 qos</a>  | Displays QoS class information.                                            |

## qos-class (cs7 gtt selector)

To configure a QoS class for a selector, use the **qos-class** cs7 gtt selector submode command. To remove the configuration, use the **no** form of this command.

**qos-class** *class*

**no qos-class** *class*

### Syntax Description

|              |                                      |
|--------------|--------------------------------------|
| <i>class</i> | QoS class ID. Valid range is 0 to 7. |
|--------------|--------------------------------------|

### Defaults

None.

### Command Modes

cs7 gtt selector submode

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

If the QoS class entered for a selector is not defined, SCCP packets for the selector are routed using the default class peer link members.

### Examples

The following example shows how to configure QoS class 4 for the GTT selector named c7gsp:

```
cs7 gtt selector c7gsp 3 2
qos-class 4
```

# qos-class (cs7 mated-sg)

To configure a QoS class for the packets sent to the SG mate, use the **qos-class** cs7 mated-sg submode command. To remove the configuration, use the **no** form of this command.

**qos-class** *class* [*instance-number*]

**no qos-class** *class* [*instance-number*]

|                           |                        |                                                                                                      |
|---------------------------|------------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>class</i>           | QoS class ID. Valid range is 1 to 7.                                                                 |
|                           | <i>instance-number</i> | Required if multiple instances are configured. The valid range is 0 to 7. The default instance is 0. |

**Defaults** The default instance is 0.

**Command Modes** cs7 mated-sg submode

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Usage Guidelines** The QoS class must be defined before the class is assigned to a peer link.  
The QoS class goes into effect for only the subsequent mated-SG connection.

**Examples** The following example shows how to configure QoS class 4 for the mated SG named BLUE:

```
cs7 mated-sg BLUE 2905
remote-ip 5.5.5.5
qos-class 4
```

|                         |                               |                                 |

|                         | <a href="#">show cs7 qos</a>  | Displays QoS class information. |

# qos-ip-dscp

To define the differentiated services code point (DSCP) setting for a QoS class, use the **qos-ip-dscp** **cs7** qos submode command. To set the DSCP setting to the default, use the **no** form of this command.

**qos-ip-dscp** *ip-tos*

**no qos-ip-dscp** *ip-tos*

|                    |                                                                                                                                                                                                                                                              |                                         |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| Syntax Description | <i>ip-tos</i> DSCP setting for the IP TOS byte, in decimal notation. Valid range is 0 to 63. The default is 0.                                                                                                                                               |                                         |
| Defaults           | The IP TOS default is 0.                                                                                                                                                                                                                                     |                                         |
| Command Modes      | cs7 qos submode                                                                                                                                                                                                                                              |                                         |
| Command History    | Release                                                                                                                                                                                                                                                      | Modification                            |
|                    | 12.2(18)IXA                                                                                                                                                                                                                                                  | This command was introduced.            |
|                    | 12.4(11)SW                                                                                                                                                                                                                                                   |                                         |
|                    | 12.2(33)IRA                                                                                                                                                                                                                                                  |                                         |
| Usage Guidelines   | The TOS byte in the IP header is set with the value of <b>qos-ip-dscp</b> on peer links that are members of the specified QoS class. The <b>ip-dscp</b> cs7 link submode command overrides the <b>qos-ip-dscp</b> TOS settings assigned through a QoS class. |                                         |
| Examples           | The following example shows how to set the IP type of service to DSCP 56 for QoS class 2:<br><br>cs7 qos class 2<br>qos-ip-dscp 56                                                                                                                           |                                         |
| Related Commands   | Command                                                                                                                                                                                                                                                      | Description                             |
|                    | <a href="#">cs7 linkset</a>                                                                                                                                                                                                                                  | Specifies a linkset.                    |

## rate-limit rate (cs7 gws as rate-limit-timer)

To enable the rate limit traffic rate on specified GWS AS for a message type, use the **rate-limit rate** command in the cs7 gws as rate-limit-timer configuration mode. To disable the configuration, use the **no** form of this command.

**rate-limit rate** *rate* [**onset-threshold** *othresh* [**abate-threshold** *athresh*]][**sccp-error** *sccp-error*]

**no rate-limit**

|                        |                                                                                                                                              |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rate-limit rate</b> | Enables the rate limit traffic rate feature.                                                                                                 |
| <i>rate</i>            | Specified traffic rate. The range is from 1 to 2147483648 MSUs.                                                                              |
| <b>onset-threshold</b> | (Optional) Sets a configured rate limit to raise an alarm.                                                                                   |
| <i>othresh</i>         | (Optional) Specifies the percentage of the configured rate limit that will raise the alarm. The range is from 11 to 100 percent.             |
| <b>abate-threshold</b> | (Optional) Sets a configured rate limit to clear the alarm.                                                                                  |
| <i>athresh</i>         | (Optional) Specifies the percentage of the configured rate limit that will clear the alarm. The range is from 1 to 99 percent.               |
| <b>sccp-error</b>      | (Optional) Sends a UDTS to the originator with the configured SCCP error code. This requires that the UDTS has a return-on-error configured. |
| <i>sccp-error</i>      | The specified SCCP UDTS return cause value. (The usage guidelines section lists the error definitions.)                                      |

### Defaults

The rate limit traffic rate feature is disabled by default.

If the onset threshold is not set, the default onset threshold is 90%. If the abate threshold is not set, the default abate threshold is 10% lesser than the onset value.

### Command Modes

cs7 gws as rate-limit timer configuration submode

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW6 | This command was introduced. |
| 12.2(33)IRF |                              |

### Usage Guidelines

The rate limit traffic rate feature is not related to the maximum number of MSUs supported on the physical interface. There is no check based on the number of Max MSU supported on the physical interface.

MSUs are silently discarded when the rate limit is reached. The traffic flow resumes at the beginning of the next time window. Message counting also resumes at the beginning of the next time window.

You can specify the sending of a return on error, when SCCP MSUs are discarded. The following table lists the SCCP UDTS return cause values:

| Value | Description                                  |
|-------|----------------------------------------------|
| 0     | No translation for an address of such nature |
| 1     | No translation for this specific address     |
| 2     | Subsystem congestion                         |
| 3     | Subsystem failure                            |
| 4     | Unequipped User                              |
| 5     | MTP failure                                  |
| 6     | Network Congestion                           |
| 7     | Unqualified                                  |
| 8     | XUDTS Error in message transport             |
| 9     | XUDTS Error in local processing              |
| A     | XUDTS Cannot perform reassembly              |
| B     | SCCP failure                                 |
| C     | SCCP Hop counter violation                   |
| D     | Segmentation not supported                   |
| E     | Segmentation failure                         |
| WORD  | ITU SCCP Spare Error Codes in Hex {F..FF}    |

### Examples

In this example, the Cisco ITP counts the ingress messages on GWS AS alpha during a five second period. When the number of packets crosses the configured 2000 message maximum, messages are discarded silently.

For discarded SCCP messages, a UDTs with the configured error-code 3 is sent to the originator.

An alarm is raised when the ingress traffic rate on the GWS alpha reaches 80% of the configured 2000 maximum. The alarm clears if during the next time period the traffic rate drops to 60% or less of the configured 2000 maximum:

```
cs7 instance 0 gws as name alpha
  rate-limit-timer 5
  rate-limit rate 2000 onset-threshold 80 abate-threshold 60 sccp-error 3
  inbound result action-set as1
```

## rate-limit rate (gws as egress-rate-lmt-timer)

To enable the rate limit traffic rate on specified action sets for a message type, use the **rate-limit rate** command in the gws as egress-rate-lmt-timer configuration mode. This feature limits the total outbound traffic rate on the given AS. To disable the configuration, use the **no** form of this command.

**rate-limit rate** *rate* [**onset-threshold** *othresh* [**abate-threshold** *athresh*]]

**no rate-limit**

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <b>rate-limit rate</b> | Enables the rate limit traffic rate feature.                                                               |
| <i>rate</i>            | Specified traffic rate. The range is from 1 to 2147483648 MSUs.                                            |
| <b>onset-threshold</b> | (Optional) Sets a configured rate limit to raise an alarm.                                                 |
| <i>othresh</i>         | (Optional) Percentage of the configured rate limit that will raise the alarm. The range is from 11 to 100. |
| <b>abate-threshold</b> | (Optional) Sets a configured rate limit to clear the alarm.                                                |
| <i>athresh</i>         | (Optional) Percentage of the configured rate limit that will clear the alarm. The range is from 1 to 99.   |

### Defaults

Disabled.

If the onset threshold is not set, the default onset threshold is 90 percent. If the abate threshold is not set, the default abate threshold is 10 percent less than the onset value.

### Command Modes

gws as egress-rate-lmt-timer configuration submode

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW7 | This command was introduced. |
| 12.2(33)IRG |                              |

### Usage Guidelines

The rate limit traffic rate feature is not related to the maximum number of MSUs supported on the physical interface. There is no check based on the number of Max MSUs supported on the physical interface.

MSUs are discarded when the egress rate limit is reached, and an alarm is raised indicating that the threshold has been hit. Both traffic flow and message counting resume at the start of the next time window.

**Examples**

In the following example, the Cisco ITP counts the egress messages on an AS named “as-1” during a five-second period:

```
cs7 instance 0 gws as name as-1
  outbound result action-set as1
  egress-rate-lmt-timer 5
  rate-limit rate 2000 onset-threshold 80 abate-threshold 60
```

An alarm is raised when the egress traffic rate reaches 80 percent of the configured 2000 maximum. This alarm clears if, during the next time period, the traffic rate drops to 60 percent or less of the configured 2000 maximum.

Another alarm is raised when the egress traffic rate exceeds the configured 2000 maximum. Additional MSUs are discarded, and this alarm clears after expiration of the time period.

## rate-limit rate (gws linkset egress-rate-lmt-timer)

To enable the rate limit traffic rate on specified linksets for a message type, use the **rate-limit rate** command in the gws linkset egress-rate-lmt-timer configuration mode. This feature limits the total outbound traffic rate on the given linkset. To disable the configuration, use the **no** form of this command.

**rate-limit rate** *rate* [**onset-threshold** *othresh* [**abate-threshold** *athresh*]]

**no rate-limit**

|                        |                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------|
| <b>rate-limit rate</b> | Enables the rate limit traffic rate feature.                                                               |
| <i>rate</i>            | Specified traffic rate. The range is from 1 to 2147483648 MSUs.                                            |
| <b>onset-threshold</b> | (Optional) Sets a configured rate limit to raise an alarm.                                                 |
| <i>othresh</i>         | (Optional) Percentage of the configured rate limit that will raise the alarm. The range is from 11 to 100. |
| <b>abate-threshold</b> | (Optional) Sets a configured rate limit to clear the alarm.                                                |
| <i>athresh</i>         | (Optional) Percentage of the configured rate limit that will clear the alarm. The range is from 1 to 99.   |

### Defaults

Disabled.

If the onset threshold is not set, the default onset threshold is 90 percent. If the abate threshold is not set, the default abate threshold is 10 percent less than the onset value.

### Command Modes

gws linkset egress-rate-lmt-timer configuration submenu

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW7 | This command was introduced. |
| 12.2(33)IRG |                              |

### Usage Guidelines

The rate limit traffic rate feature is not related to the maximum number of MSUs supported on the physical interface. There is no check based on the number of Max MSU supported on the physical interface.

MSUs are discarded when the egress rate limit is reached, and an alarm is raised indicating that the threshold has been hit. Both traffic flow and message counting resume at the start of the next time window.

**Examples**

In the following example, the Cisco ITP counts the egress messages on a linkset named “ls-1” during a five-second period:

```
cs7 instance 0 gws linkset name ls-1
  outbound result action-set as1
  egress-rate-lmt-timer 5
  rate-limit rate 2000 onset-threshold 80 abate-threshold 60
```

An alarm is raised when the egress traffic rate reaches 80 percent of the configured 2000 maximum. This alarm clears if, during the next time period, the traffic rate drops to 60 percent or less of the configured 2000 maximum.

Another alarm is raised when the egress traffic rate exceeds the configured 2000 maximum. Additional MSUs are discarded, and this alarm clears after expiration of the time period.

## rate-limit rate (gws linkset rate-limit-timer)

To enable the rate limit traffic rate on specified linksets for a message type, use the **rate-limit rate** command in the cs7 gws linkset rate-limit-timer configuration mode. To disable the configuration, use the **no** form of this command.

**rate-limit rate** *rate* [**onset-threshold** *othresh* [**abate-threshold** *athresh*]][**sccp-error** *sccp-error*]

**no rate-limit**

|                        |                                                                                                                                              |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>rate-limit rate</b> | Enables the rate limit traffic rate feature.                                                                                                 |
| <i>rate</i>            | Specified traffic rate. The range is from 1 to 2147483648 MSUs.                                                                              |
| <b>onset-threshold</b> | (Optional) Sets a configured rate limit to raise an alarm.                                                                                   |
| <i>othresh</i>         | (Optional) Specifies the percentage of the configured rate limit that will raise the alarm. The range is from 11 to 100 percent.             |
| <b>abate-threshold</b> | (Optional) Sets a configured rate limit to clear the alarm.                                                                                  |
| <i>athresh</i>         | (Optional) Specifies the percentage of the configured rate limit that will clear the alarm. The range is from 1 to 99 percent.               |
| <b>sccp-error</b>      | (Optional) Sends a UDTs to the originator with the configured SCCP error code. This requires that the UDTs has a return-on-error configured. |
| <i>sccp-error</i>      | The specified SCCP UDTs return cause value. (The usage guidelines section lists the error definitions.)                                      |

### Defaults

The rate limit traffic rate feature is disabled by default.

If the onset threshold is not set, the default onset threshold is 90%. If the abate threshold is not set, the default abate threshold is 10% lesser than the onset value.

### Command Modes

cs7 gws linkset rate-limit timer configuration submode

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW6 | This command was introduced. |
| 12.2(33)IRF |                              |

### Usage Guidelines

The rate limit traffic rate feature is not related to the maximum number of MSUs supported on the physical interface. There is no check based on the number of Max MSU supported on the physical interface.

MSUs are silently discarded when the rate limit is reached. The traffic flow resumes at the beginning of the next time window. Message counting also resumes at the beginning of the next time window.

You can specify the sending of a return on error, when SCCP MSUs are discarded. The following table lists the SCCP UDTs return cause values:

| Value | Description                                  |
|-------|----------------------------------------------|
| 0     | No translation for an address of such nature |
| 1     | No translation for this specific address     |
| 2     | Subsystem congestion                         |
| 3     | Subsystem failure                            |
| 4     | Unequipped User                              |
| 5     | MTP failure                                  |
| 6     | Network Congestion                           |
| 7     | Unqualified                                  |
| 8     | XUDTS Error in message transport             |
| 9     | XUDTS Error in local processing              |
| A     | XUDTS Cannot perform reassembly              |
| B     | SCCP failure                                 |
| C     | SCCP Hop counter violation                   |
| D     | Segmentation not supported                   |
| E     | Segmentation failure                         |
| WORD  | ITU SCCP Spare Error Codes in Hex {F..FF}    |

### Examples

In this example, the Cisco ITP counts the ingress messages on linkset alpha during a five second period. When the number of packets crosses the configured 2000 message maximum, messages are discarded silently.

For discarded SCCP messages, a UDTs with the configured error-code 3 is sent to the originator.

An alarm is raised when the ingress traffic rate on the linkset alpha reaches 80% of the configured 2000 maximum. The alarm clears if during the next time period the traffic rate drops to 60% or less of the configured 2000 maximum:

```
cs7 in 0 gws linkset name alpha
  rate-limit-timer 5
  rate-limit rate 2000 onset-threshold 80 abate-threshold 60 sccp-error 3
  inbound result action-set as1
```

| <a href="#">rate-limit-timer (cs7 gws linkset)</a> | Enables rate limiting for GWS linksets.                                                     |
| <a href="#">show cs7 gws linkset</a>               | Shows the number of MSUs discarded silently or with an error due to the rate limit feature. |

## rate-limit-timer (cs7 gws as)

To enable rate limiting for GWS AS and to configure the rate limit timer, use the **rate-limit-timer** command in the cs7 gws as configuration mode. To disable the configuration, use the **no** form of this command.

**rate-limit-timer** *timer*

**no rate-limit-timer** *timer*

### Syntax Description

|                         |                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>rate-limit-timer</b> | Enables the rate-limit on a given AS and configures the rate limit timer.                                                         |
| <i>timer</i>            | The length of the time period set for the Cisco ITP to count the received MSUs. The range is an integer value of 1 to 60 seconds. |

### Defaults

Rate limiting is disabled.

### Command Modes

cs7 gws as configuration submode

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW6 | This command was introduced. |
| 12.2(33)IRF |                              |

### Usage Guidelines

The rate limit timer screens the MSUs for the configured time and resets on expiration.

The rate-limit-timer is only valid for inbound traffic. The timer resets after each time period expires. The rate-limit-timer parameter is only valid for inbound traffic. This rate-limit option is not available in default or global mode. This feature can only be disabled when its sub mode options are deleted. Also to delete the inbound setting, the rate-limit option needs to be disabled.

### Examples

The following example configures the Cisco ITP to count the ingress messages on the AS named alpha for periods of five seconds:

```
cs7 instance 0 gws as name alpha
  rate-limit-timer 5
```

|                           | 12.2(33)IRA                  |                                                                                                                    |

**Usage Guidelines**

The size of the receive window can affect performance. SCTP adapts its transmission rate to suit the available network capacity by using a congestion-sensitive, sliding-window flow control mechanism described in RFC 2581. At any time, only a certain number of bytes can be outstanding through the network. Keeping the path full of packets requires that both the congestion window (cwnd) and receive window (rwnd) reach the effective size of the “pipe” represented by the bandwidth delay. You can calculate the capacity of the pipe using the following equation:

$$\text{capacity (bits)} = \text{bandwidth (bits/sec)} \times \text{round-trip-time(sec)}$$

The bandwidth delay can vary widely depending on the network speed and round-trip-time (rtt) between the two endpoints. Using the capacity equation, you can estimate the minimum buffer size given the bandwidth of the communication media and the round-trip time between the nodes. For example, if the nodes are connected by a 1,544,000-bits/sec T1 link with a round-trip time of 60 ms, the estimated minimum buffer size is 11,580 bytes. The **receive-window** command defaults to 64,000 bytes. The congestion control and windowing algorithms adjust to network conditions by controlling the number of bytes that can be outstanding through the network.

**Examples**

The following example shows how to set the receive-window size to 6000 bytes:

```
cs7 local-peer 7000
  receive-window 6000
```

# recovery-timeout

The AS recovery timeout is the amount of time after an AS becomes inactive that it will queue traffic waiting for an ASP to become active. If no ASP becomes active within this time, queued messages are lost.

To specify the recovery timeout value, use the **recovery-timeout** *cs7* as submode command. To disable the configuration, use the **no** form of this command.

**recovery-timeout** *msec*

**no recovery-timeout** *msec*

| Syntax Description | <i>msec</i> | Recovery timeout value in milliseconds. The valid range is 0 to 2000 ms. The default is 2000 ms. |
|--------------------|-------------|--------------------------------------------------------------------------------------------------|
|--------------------|-------------|--------------------------------------------------------------------------------------------------|

| Defaults | 2000 ms |

## remote-ip (cs7 asp)

To configure a remote IP address to associate incoming packets from an ASP to a configured ASP, use the **remote-ip** *cs7 asp* submode command. To remove the configuration, use the **no** form of this command.

**remote-ip** *remote-ip*

**no remote-ip** *remote-ip*

| Syntax Description      | <i>remote-ip</i> The remote IP address of the ASP.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |  |         |              |                         |                                                                            |            |             |

| 12.2(33)IRA             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |  |         |              |                         |                                                                            |            |             |
| Usage Guidelines        | <p>With the <b>remote-ip</b> command, you can configure a remote IP address to associate incoming packets from an ASP to a configured ASP. The remote IP address configuration does not require you to configure all the possible IP addresses for multihoming, but the remote IP should be in the list of allowed IP addresses that is learned from the INIT and/or COOKIE SCTP control messages. You can configure up to four remote IP addresses by specifying additional <b>remote-ip</b> commands.</p> |  |         |              |                         |                                                                            |            |             |
| Examples                | <p>The following example shows how to configure remote IP address 2.2.2.2 for M3UA ASP1:</p> <pre>cs7 asp ASP1 5000 5000 m3ua   remote-ip 2.2.2.2</pre>                                                                                                                                                                                                                                                                                                                                                     |  |         |              |                         |                                                                            |            |             |

## remote-ip (cs7 dcs)

To configure an IP address and port for a DCS node, use the **To** to disable the command, use the **no** form of this command.

**remote-ip** *ip\_addr1* [*ip\_addr2*] *port*

**no remote-ip**

|                           |                 |                                                                                                                              |
|---------------------------|-----------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>ip_addr1</i> | An IPv4 address in the form xxx.xxx.xxx.xxx. It is the primary IP address used when sending PMP traffic.                     |
|                           | <i>ip_addr2</i> | (Optional) An IPv4 address in the form xxx.xxx.xxx.xxx. It is a redundant IP address used when the primary IP address fails. |
|                           | <i>port</i>     | IP address port with an integer range of 1024 to 49151.                                                                      |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | <p>You must shut down the DCS node before deleting a remote IP address on that node. You can only modify the remote IP address if the DCS node is not part of any DCS group.</p> <p>We recommend using 33500 for the port number. This port number is recognized by the @WIRESHARK dissector for PMP.</p> <p>The <b>no remote-ip</b> command does not have any keywords or arguments; it deletes all ports and IP addresses.</p> |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | <p>The following example shows how to configure a DCS node with 209.165.201.31 as the primary address, 209.165.201.28 as the secondary address, and 33500 as the port on the CS7 DCS node named dcs1:</p> |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
cs7 dcs dcs1
remote-ip 209.165.201.31 209.165.201.28 33500
local-ip 209.165.201.30 33500
ping-interval 5
timeout-count 3
udp-checksum
```

## remote-ip (cs7 mated-sg)

To configure a remote IP address to associate incoming packets from the mate, use the **remote-ip** cs7 mated-sg submode command. To remove the configuration, use the **no** form of this command.

**remote-ip** *remote-ip*

**no remote-ip** *remote-ip*

|                           |                  |                                    |
|---------------------------|------------------|------------------------------------|
| <b>Syntax Description</b> | <i>remote-ip</i> | The remote IP address of the mate. |
|---------------------------|------------------|------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                      |
|----------------------|----------------------|
| <b>Command Modes</b> | cs7 mated-sg submode |
|----------------------|----------------------|

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | With the <b>remote-ip</b> command, you can configure a remote IP address to associate incoming packets from the mate. The remote IP address configuration does not require you to configure all the possible IP addresses for multihoming, but the remote IP should be in the list of allowed IP addresses that is learned from the INIT and/or COOKIE SCTP control messages. You can configure up to four remote IP addresses by specifying additional <b>remote-ip</b> commands. |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                                                                                                                                                  |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to configure a remote IP address for the mated SG named BLUE:<br><br>cs7 mated-sg BLUE 5000<br>remote-ip 5.5.5.5 |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------|

|                         |                              |                                        |
|-------------------------|------------------------------|----------------------------------------|

|                         | <a href="#">cs7 mated-sg</a> | Configures a connection to a mated SG. |

# remove route (route table)

To remove the active MTP3 route table on the ITP, use the **remove route** route table submode configuration command.

**remove route** *point-code* [*mask* | */length*]

|                           |                   |                                                                                                                                                                |
|---------------------------|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>point-code</i> | Signaling point code of the destination.                                                                                                                       |
|                           | <i>mask</i>       | Specifies the significant bits of the point code.                                                                                                              |
|                           | <i>/length</i>    | Alternate way of specifying the mask. For ANSI, the alternate specification of the default is /24. For ITU, the alternate specification of the default is /14. |

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                                   |
|----------------------|-----------------------------------|
| <b>Command Modes</b> | route table submode configuration |
|----------------------|-----------------------------------|

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

|                         |                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The <b>remove route</b> command is the functional equivalent of “no update.” The specified route is deleted from the active routing table.                               |
|                         | If the configuration contained an <b>update route</b> command for the specified point code, the <b>update route</b> command line is removed from the configuration.      |
|                         | The <b>remove route</b> configuration appears in the ITP configuration until a new route-table is created using the <b>cs7 save route-table</b> privileged EXEC command. |

|                 |                                                                  |
|-----------------|------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to remove an active route table: |
|-----------------|------------------------------------------------------------------|

```
remove route 1.50.2 255.255.255 linkset nyc
```

|                         |                                            |                    |
|-------------------------|--------------------------------------------|--------------------|
| <b>Related Commands</b> | <b>Command</b>                             | <b>Description</b> |
|                         | <a href="#">update route (route-table)</a> | Updates a route.   |

## response-timer (cs7 sms profile parms)

To specify the time lapse allowed between a UCP request and the corresponding UCP response, use the **response-timer** command in cs7 sms profile parameters configuration mode. To remove the specification, use the **no** form of this command.

**response-timer** *msec*

**no response-timer** *msec*

|                           |             |                                                                                                                                           |
|---------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>msec</i> | Time lapse allowed between an UCP request and the corresponding UCP response. Valid range is 1000 ms to 10000 ms. The default is 5000 ms. |
|---------------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------|

|                 |         |
|-----------------|---------|
| <b>Defaults</b> | 5000 ms |
|-----------------|---------|

|                      |                                          |
|----------------------|------------------------------------------|
| <b>Command Modes</b> | cs7 sms profile parameters configuration |
|----------------------|------------------------------------------|

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

**Examples** The following example shows how to configure an SMPP profile named mmprofile and set several parameters:

```
cs7 sms smpp profile mmprofile
bind-type any
inactivity-timer 5000
keepalive-timer 1000
response-timer 2000
send-window 50
session-init-timer 5000
```

| <b>Related Commands</b> | Command                                                       | Description                             |

## result (cs7 mlr ruleset rule)

To specify the processing that will be performed on a packet matching the specified trigger and rule, use the **result** command in cs7 mlr ruleset rule configuration mode. To cancel the processing, use the **no** form of this command.

```
result {gt addr-string [gt-addr-type] | [instance instance-number] pc dest_pc [ssn ssn] | asname
as-name | group result-group | block [sccp-error error | map-error {[default ecdef[subdef]] [v1
ec1 [sub1]] [v2 ec2 [sub2]] [v3 ec3 [sub3]] } | continue | route}
```

**no result**

| Syntax Description | gt              | Routes the message using SCCP global title. The specified address is placed in the SCCP Called Party Address, the routing indicator is changed to RI=GT, and the message is routed based on the locally provisioned global title translation table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                    | addr-string     | Address string of 1 to 15 hexadecimal characters. The string is not input in BCD-String format, but in normal form.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                    | gt-addr-type    | (Optional) Parameters that identify attributes of the global title address being used as a result. The parameters are variant-specific, and are identical to those parameters specified on a <b>cs7 gtt selector</b> command. If not specified, the default is the standard E.164 address type for the network variant being used.<br><br><b>tt tt [gti gti] [np np nai nai]</b><br><b>tt</b> Identifies the translation type specified within the address.<br><b>tt</b> An integer value from 0 to 255.<br><b>gti</b> Identifies the global title indicator value for the specified address. Used only when the <b>cs7 variant</b> command specifies ITU or China.<br><b>gti</b> An integer value of 2 or 4.<br><b>np</b> Identifies the numbering plan of the specified address. Used only when the <b>gti</b> value is 4.<br><b>np</b> An integer value from 0 to 15.<br><b>nai</b> Identifies the nature of address indicator. Used only when the <b>gti</b> value is 4.<br><b>nai</b> Integer value from 0 to 127. |
|                    | instance        | (Optional) Indicates the PC/PCSSN result in a local or other instance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                    | instance-number | (Optional) Instance number. Valid range is 0 to 7. The default instance is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|                    | pc              | Routes the message using the specified destination point code (DPC). The packet is routed in MTP3 with the specified DPC.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|                    | ssn             | Subsystem number in decimal. Valid range is 2 to 255.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                    | asname          | Routes the message to a particular destination M3UA or SUA application server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|                               |                                                                                                                                                                                                                                                              |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>as-name</i>                | Identifies an M3UA or SUA application server name. The name can be 1 to 12 characters in length.                                                                                                                                                             |
| <b>group</b>                  | Routes the message using a result group. A group is used to specify multiple destinations for a given rule match. The MLR result group must be defined before configuring the <b>result</b> command.                                                         |
| <i>result-group</i>           | Identifies the name of the MLR result group containing the desired result possibilities. The name is specified as a character string with a maximum of 12 characters.                                                                                        |
| <b>block sccp-error error</b> | Drops messages matching this rule. Sends a UDTS for dropped packets to the originator with the configured sccp error code if return-on-error was set in the UDT.                                                                                             |
| <b>block map-error</b>        | Performs MAP error handling.<br><br>Defines the MAP error code for MLR/SMS-blocked MSUs based on operation type and version. If an MLR or SMS module matches the rule and the MSU is blocked, an error message is sent instead of dropping the MSU silently. |
| <b>default</b>                | Returns a default MAP error code.                                                                                                                                                                                                                            |
| <i>ecdef</i>                  | The default return MAP error code.                                                                                                                                                                                                                           |
| <i>subdef</i>                 | Specifies a secondary default MAP error code.                                                                                                                                                                                                                |
| <b>v1</b>                     | MAP version 1                                                                                                                                                                                                                                                |
| <b>v2</b>                     | MAP version 2                                                                                                                                                                                                                                                |
| <b>v3</b>                     | MAP version 3                                                                                                                                                                                                                                                |
| <i>ec1</i>                    | Specifies the MAP error code for ec1.                                                                                                                                                                                                                        |
| <i>ec2</i>                    | Specifies the MAP error code for ec2.                                                                                                                                                                                                                        |
| <i>ec3</i>                    | Specifies the MAP error code for ec3.                                                                                                                                                                                                                        |
| <i>sub1</i>                   | Specifies a secondary MAP error code for sub1.                                                                                                                                                                                                               |
| <i>sub2</i>                   | Specifies a secondary MAP error code for sub2.                                                                                                                                                                                                               |
| <i>sub3</i>                   | Specifies a secondary MAP error code for sub3.                                                                                                                                                                                                               |
| <b>continue</b>               | Routes the original message as received.                                                                                                                                                                                                                     |
| <b>route</b>                  | Resumes original routing for the packet with the MLR-modified message.                                                                                                                                                                                       |

### Defaults

If not specified, the default global title address is the standard E.164 address type for the network variant being used.

### Command Modes

cs7 mlr ruleset rule configuration

| Command History | Release                                   | Modification                            |
|-----------------|-------------------------------------------|-----------------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.            |
|                 | 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | The <b>map-error</b> keyword was added. |
|                 | 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | The <b>instance</b> keyword was added.  |

### Usage Guidelines

The MLR result group must be defined before configuring the **result** command.

One result must be specified.

If **sccp-error** *error* is configured and return-on-error is set in the UDT, a UDTS is sent back for dropped SCCP packets to the originating user with the configured error as the return cause. Currently, you can configure block results in MLR rules, triggers, and address table entries.

The **block map-error** MAP error code for a version takes precedence over a default MAP error code. If no MAP error is configured for the special version, the configured default error code is used. If no MAP error is configured, the MSU is blocked and dropped silently.

### Examples

The following example shows how to route a packet that matches the configured trigger and rule routed for processing to the result group SMS-WEIGHTED:

```
cs7 mlr ruleset ruleset1
  rule 10 gsm-map sms-mo
    dest-sme 1234
    orig sme 60920025
    result group SMS-WEIGHTED
```

The following example shows how to configure MLR block map error handling for version 1 and the error code systemFailure:

```
cs7 mlr ruleset mapecset protocol gsm-map
  rule 10 sms-mo default
  result block map-error v1 systemFailure
```

The following example shows how to configure 1 as the instance in the **result** command:

```
cs7 instance 0 mlr ruleset tttt protocol gsm-map
  rule 1 sms-mo default
  result instance 1 pc 3.3.3 ssn 7
```

The following example shows how to route mobile initiated GSM-MAP messages containing USSD string \*123\*/## to DPC 1234:

```
cs7 ins 0 mlr options
  enable ussd-tree-type 2 ussd-timer 180

cs7 ins 0 mlr ruleset abc
  rule 1 gsm-map mobileUSSD
  ussd-string 123
  result pc 1234
```

## ■ result (cs7 mlr ruleset rule)

```
cs7 instance 0 gws action-set ussd_action mlr ruleset abc
cs7 instance 0 gws linkset name from_msc
    inbound result action ussd_action
cs7 instance 0 gws linkset name from_ussd
    inbound result action ussd_action
```

The following example shows how to filter mobile initiated GSM-MAP messages containing USSD string \*123\*/#:

```
cs7 ins 0 mlr options
    enable ussd-tree-type 2 ussd-timer 180

cs7 ins 0 mlr ruleset abc
    rule 1 gsm-map mobileUSSD
        ussd-string 123
        result block
```

### Related Commands

| Command                                 | Description                                                                                                                         |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 mlr result</a>          | Specifies destination resources that process traffic to be routed based on multilayer information.                                  |
| <a href="#">rule (cs7 mlr ruleset)</a>  | Specifies the rules for a routing trigger within a multilayer ruleset table and enables cs7 mlr ruleset rule configuration submode. |
| <a href="#">show cs7 mlr statistics</a> | Displays global MLR statistics.                                                                                                     |

## result (cs7 sms set rule)

To specify the result of a rule, use the **result** command in cs7 sms set rule configuration mode. To delete the result, use the **no** form of this command.

```
result {block | next-rule | group result-group | gt addr [tt tt] | pc dest-pc [ssn ssn] | rule index |
        deliver-mt | obtain-orig-imsi [validate] [next-rule] | validate-orig-msc [exit | gt-mismatch
        next-rule | negative-reply next-rule | no | pc-mismatch next-rule | timeout next-rule] }
```

**no result**

| Syntax Description                        |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>block</b>                              |  | Drops the message.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>next-rule</b>                          |  | Continues message processing with the next rule.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>group</b>                              |  | Routes the message using a result group and specifies the result group name.                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>result-group</i>                       |  | Result group name.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>gt</b>                                 |  | Routes the message using GT.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <i>addr</i>                               |  | Specifies the SCCP address, a string of 1 to 15 hexadecimal digits.                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>tt</b>                                 |  | (Optional) Specifies the translation type.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>tt</i>                                 |  | Translation type, in the range 0 to 255.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>pc</b>                                 |  | Routes the message using a point code and specifies the destination point code.                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>dest-pc</i>                            |  | Destination point code.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ssn</b>                                |  | (Optional) Specifies a subsystem number.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>ssn</i>                                |  | Subsystem number, in the range 2 to 255.                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>rule</b>                               |  | Continues message processing at a specified rule.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>index</i>                              |  | Rule index, in the range 1 to 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>deliver-mt</b>                         |  | Attempts a delivery to the destination SME as a mobile device. (Only valid for SMS-MO rule operations.)                                                                                                                                                                                                                                                                                                                                                                     |
| <b>obtain-origin-imsi</b>                 |  | If the originator's IMSI was not provided on the SMS-MO request, then SMR attempts to obtain its IMSI.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>validate</b>                           |  | Specifies the SMR will obtain the originator's IMSI from the HLR and verify that the returned IMSI matches the origin IMSI received in the SMS-MO request or in a previous rule that obtained the origin IMSI. If the IMSI validation fails, an error is returned unless <b>next-rule</b> has been specified. If the origin IMSI was not previously received or obtained, then validation is successful if the originator's IMSI can be successfully obtained from the HLR. |
| <b>next-rule</b>                          |  | Executes the next rule in the ruleset sequence regardless of whether the origin IMSI was successfully retrieved.                                                                                                                                                                                                                                                                                                                                                            |
| <b>result</b><br><b>validate-orig-msc</b> |  | Validates MO-SMS messages sent from MSC to SMSC or from SGSN to SMSC.                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>exit</b>                               |  | Exits from cs7 sms result original msc/sgsn validation configuration submode.                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>gt-mismatch</b>                        |  | GTA of GT-based CgPA does not match the MSC/SGSN number in the SRI-SM response.                                                                                                                                                                                                                                                                                                                                                                                             |

■ **result (cs7 sms set rule)**

|                       |                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>instance</b>       | Indicates the PC/PCSSN result in a local or other instance.                                                          |
| <b>negative-reply</b> | HLR returns a negative response (reject, abort, cancel, error) for an SRI-SM request.                                |
| <b>no</b>             | Negates a command or sets its defaults.                                                                              |
| <b>pc-mismatch</b>    | GTA generated by applying msc-proxy-addr on PC-based CgPA does not match the MSC/SGSN number in the SRI-SM response. |
| <b>timeout</b>        | Timeout for HLR SRI-SM response.                                                                                     |

cs7 sms set rule configuration

**Command History**

| <b>Release</b>                            | <b>Modification</b>                                    |
|-------------------------------------------|--------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.                           |
| 12.2(18)IXH<br>12.4(15)SW3<br>12.2(33)IRC | The <b>result validate-orig-msc</b> keyword was added. |

**Usage Guidelines**

If a valid result was returned from a rule parameter address table, then the table result overrules the rule result. Otherwise, the rule result is used.

This command with **result validate-orig-msc** keyword prevents a fraudulent party from submitting mobile originated short messages on behalf of an existing mobile subscriber. Its validation checks the originating MSC/SGSN address of an MO-SMS message to verify the true location of the mobile subscriber and prevent SMS MO spoofing.

**Examples**

The following example shows how to specify a ruleset named MO-RULES that includes rules and their results:

```
cs7 sms ruleset MO-RULES
rule 10 sms-mo
result obtain-orig-imsi

rule 20 sms-mo
orig-imsi-table IMSI-BLK
result block

rule 30 sms-mo
orig-imsi-table IMSI-OK
result group POSTPAY
```

## retransmit-cwnd-rate (cs7 asp)

To configure the rate at which the SCTP congestion window size is reduced due to retransmission timer expiration, use the **retransmit-cwnd-rate** *cs7 asp* submode command. To disable the configuration, use the **no** form of this command.

**retransmit-cwnd-rate** *percent* [**sctp-fast-retransmit**]

**no retransmit-cwnd-rate** *percent* [**sctp-fast-retransmit**]

|                           |                             |                                                                                                                                                                 |
|---------------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>percent</i>              | Rate at which the size of the SCTP congestion window is decreased due to retransmission timer expiration. Range is 0 to 100 percent. The default is 50 percent. |
|                           | <b>sctp-fast-retransmit</b> | (Optional) Indicates that the setting of the SCTP congestion window should follow the rules as defined for an SCTP fast retransmission.                         |

**Defaults** The default rate is 50 percent.

**Command Modes** *cs7 asp* submode

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

**Usage Guidelines** The **retransmit-cwnd-rate** command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to retransmission timer expiration. The administrator can select one of two methods for setting the congestion window as a result of the retransmission timer expiration: Either set the congestion window to the defaults as defined in RFC 2960 or RFC 4960 or set the congestion window in the same way as for a fast retransmission.

**Caution**

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command uses values other than the default rate. The rate should not be changed without a thorough understanding of SCTP congestion control algorithms.

**Examples** The following example shows how to set the rate for reducing the congestion window to 70 percent due to a retransmission timer expiration:

```
cs7 asp ASP1 2905 2905 m3ua
  remote-ip 1.1.1
  retransmit-cwnd-rate 70
```

## retransmit-cwnd-rate (cs7 m2pa profile)

To configure the rate at which the SCTP congestion window size is reduced due to retransmission timer expiration, use the **retransmit-cwnd-rate** command in cs7 m2pa profile configuration mode. To disable the configuration, use the **no** form of this command.

**retransmit-cwnd-rate** *percent* [**sctp-fast-retransmit**]

**no retransmit-cwnd-rate** *percent* [**sctp-fast-retransmit**]

|                           |                             |                                                                                                                                                                 |
|---------------------------|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>percent</i>              | Rate at which the size of the SCTP congestion window is decreased due to retransmission timer expiration. Range is 0 to 100 percent. The default is 50 percent. |
|                           | <b>sctp-fast-retransmit</b> | (Optional) Indicates that the setting of the SCTP congestion window should follow the rules as defined for an SCTP fast retransmission.                         |

**Defaults** The default rate is 50 percent.

**Command Modes** cs7 m2pa profile configuration

| <b>Command History</b> | <b>Release</b>                           | <b>Modification</b>          |
|------------------------|------------------------------------------|------------------------------|
|                        | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

**Usage Guidelines** The **retransmit-cwnd-rate** command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to retransmission timer expiration. The administrator can select one of two methods for setting the congestion window as a result of the retransmission timer expiration: Either set the congestion window to the defaults as defined in RFC 2960 or RFC 4960 or set the congestion window in the same way as for a fast retransmission.

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

**Examples** The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the **retransmit-cwnd-rate** command, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
 m2pa
  retransmit-cwnd-rate 70
.
.
.
cs7 linkset to_nyc
```

```
profile m2parfc
```

## retransmit-cwnd-rate (cs7 m3ua)

To configure the rate at which the SCTP congestion window size is reduced due to retransmission timer expiration, use the **retransmit-cwnd-rate** *cs7 m3ua* submode command. To disable the configuration, use the **no** form of this command.

**retransmit-cwnd-rate** *percent* [**sctp-fast-retransmit**]

**no retransmit-cwnd-rate** *percent* [**sctp-fast-retransmit**]

### Syntax Description

|                             |                                                                                                                                                                 |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>percent</i>              | Rate at which the size of the SCTP congestion window is decreased due to retransmission timer expiration. Range is 0 to 100 percent. The default is 50 percent. |
| <b>sctp-fast-retransmit</b> | (Optional) Indicates that the setting of the SCTP congestion window should follow the rules as defined for an SCTP fast retransmission.                         |

### Defaults

The default rate is 50 percent.

### Command Modes

cs7 m3ua submode

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **retransmit-cwnd-rate** command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to retransmission timer expiration. The administrator can select one of two methods for setting the congestion window as a result of the retransmission timer expiration: Either set the congestion window to the defaults as defined in RFC 2960 or RFC 4960 or set the congestion window in the same way as for a fast retransmission.

#### Caution

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

### Examples

The following example shows how to set the rate for reducing the congestion window to 70 percent due to a retransmission timer expiration:

```
cs7 m3ua 2905
  local-ip 4.4.4.4

    retransmit-cwnd-rate 70
```

|                        | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced. |

**Usage Guidelines** The **retransmit-cwnd-rate** command allows the administrator to configure a rate at which the SCTP congestion window is decreased due to retransmission timer expiration. The administrator can select one of two methods for setting the congestion window as a result of the retransmission timer expiration: Either set the congestion window to the defaults as defined in RFC 2960 or RFC 4960 or set the congestion window in the same way as for a fast retransmission.

The behavior of the SCTP congestion control algorithms is not compliant with RFC 2960 or RFC 4960 when this command is changed to values other than the default. This command should not be changed without a thorough understanding of SCTP congestion control algorithms.

**Examples** The following example shows how to set the rate for reducing the congestion window to 70 percent due to a retransmission timer expiration:

```
cs7 mated-sg BLUE 5000
remote-ip 5.5.5.5

retransmit-cwnd-rate 70
```

|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | <p>The retransmission timeout (RTO) should be adjusted for round-trip delay between nodes. Preferably, the retransmission timeout should be greater than the round-trip delay between nodes. You will have to compromise between allowing a long delay and having responsive discovery of lost frames. You can calculate a general estimate of round-trip times (rtt) for various packet sizes (ignoring propagation delay and latencies in transmission equipment) using the following equation:</p> |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

$$\text{estimated rtt} = ( (\text{packet size} * \text{bits per byte}) / \text{link speed} ) * 2$$

For example, if a packet has a 20-byte IP header, a 32-byte SCTP header, 100 bytes of user data, and a 1,544,000-bits/sec link between two nodes, the estimated rtt is 1.5 ms.

SCTP computes RTO values based on rtt measurements. When packet retransmission occurs, the timeout value is doubled for each retransmission, with an upper limit of *rto-max*. Multihomed nodes have to compromise between allowing a long delay and having responsive switching to an alternate IP address, which is important for multihomed nodes. The maximum RTO value for multihomed nodes should be set equal to or just slightly higher than the minimum RTO value. The number of outstanding bytes allowed decreases with each retransmission timeout. The trade-off of bounding the maximum RTO close to the minimum RTO is the frequency of retransmissions versus increasing transmit delays for packets on the transmit queue. During periods of retransmissions multihomed nodes send duplicate packets until

the alternate address becomes the primary path. The alternate address becomes the primary path when the number of retries exceeds the path-retransmit parameter. The default value for minimum and maximum RTO is 1 second. Propagation delays and latencies vary in networks, so select an RTO value carefully.

---

**Examples**

The following example shows how to set the minimum value of the retransmit timeout to 300 milliseconds and the maximum value to 3000 milliseconds:

```
cs7 asp ASP1 2904 2905 m3ua
remote-ip 1.1.1.1
retransmit-timeout 300 3000
```

---

### Usage Guidelines

The retransmission timeout (RTO) should be adjusted for round-trip delay between nodes. Preferably, the retransmission timeout should be greater than the round-trip delay between nodes. You will have to compromise between allowing a long delay and having responsive discovery of lost frames. You can calculate a general estimate of round-trip times (rtt) for various packet sizes (ignoring propagation delay and latencies in transmission equipment) using the following equation:

$$\text{estimated rtt} = ( (\text{packet size} * \text{bits per byte}) / \text{link speed} ) * 2$$

For example, if a packet has a 20-byte IP header, a 32-byte SCTP header, 100 bytes of user data, and a 1,544,000-bits/sec link between two nodes, the estimated rtt is 1.5 ms.

SCTP computes RTO values based on rtt measurements. When packet retransmission occurs, the timeout value is doubled for each retransmission, with an upper limit of *rto-max*. Multihomed nodes have to compromise between allowing a long delay and having responsive switching to an alternate IP address, which is important for multihomed nodes. The maximum RTO value for multihomed nodes should be set equal to or just slightly higher than the minimum RTO value. The number of outstanding bytes allowed decreases with each retransmission timeout. The trade-off of bounding the maximum RTO close to the minimum RTO is the frequency of retransmissions versus increasing transmit delays for packets on the transmit queue. During periods of retransmissions multihomed nodes send duplicate packets until the alternate address becomes the primary path. The alternate address becomes the primary path when

the number of retries exceeds the path-retransmit parameter. The default value for minimum and maximum RTO is 1 second. Propagation delays and latencies vary in networks, so select an RTO value carefully.

---

**Examples**

The following example shows how to set the value of the minimum retransmit timeout to 300 milliseconds and the maximum value to 30000 milliseconds:

```
cs7 linkset michael 10.1.1
link 0 sctp 172.18.44.147 7000 7000
    retransmit-timeout 300 30000
```

---

the number of retries exceeds the path-retransmit parameter. The default value for minimum and maximum RTO is 1 second. Propagation delays and latencies vary in networks, so select an RTO value carefully.

### Examples

The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the **retransmit-timeout** command, and applies to all the links in the linkset named to\_nyc.

```
cs7 profile m2parfc
  m2pa
    retransmit-timeout 300 30000
  .
  .
  .
cs7 linkset to_nyc
  profile m2parfc
```

## retransmit-timeout (cs7 m3ua)

To configure the minimum retransmission timeout value used when a new SCTP association is started, use the **retransmit-timeout** cs7 m3ua submode command. To disable the timeout value, use the **no** form of this command.

**retransmit-timeout** *rto-min rto-max*

**no retransmit-timeout**

### Syntax Description

|                |                                                                                                                            |
|----------------|----------------------------------------------------------------------------------------------------------------------------|
| <i>rto-min</i> | Retransmission timeout minimum value in milliseconds. Range is 40 to 60000 milliseconds. The default is 1000 milliseconds. |
| <i>rto-max</i> | Retransmission timeout maximum value in milliseconds. Range is 40 to 60000 milliseconds. The default is 1000 milliseconds  |

### Defaults

The default *rto-min* value is 1000 milliseconds.

The default *rto-max* value is 1000 milliseconds.

### Command Modes

cs7 m3ua submode

### Command History

| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The retransmission timeout (RTO) should be adjusted for round-trip delay between nodes. Preferably, the retransmission timeout should be greater than the round-trip delay between nodes. You will have to compromise between allowing a long delay and having responsive discovery of lost frames. You can calculate a general estimate of round-trip times (rtt) for various packet sizes (ignoring propagation delay and latencies in transmission equipment) using the following equation:

$$\text{estimated rtt} = ( (\text{packet size} * \text{bits per byte}) / \text{link speed} ) * 2$$

For example, if a packet has a 20-byte IP header, a 32-byte SCTP header, 100 bytes of user data, and a 1,544,000-bits/sec link between two nodes, the estimated rtt is 1.5 ms.

SCTP computes RTO values based on rtt measurements. When packet retransmission occurs, the timeout value is doubled for each retransmission, with an upper limit of *rto-max*. Multihomed nodes have to compromise between allowing a long delay and having responsive switching to an alternate IP address, which is important for multihomed nodes. The maximum RTO value for multihomed nodes should be set equal to or just slightly higher than the minimum RTO value. The number of outstanding bytes allowed decreases with each retransmission timeout. The trade-off of bounding the maximum RTO close to the minimum RTO is the frequency of retransmissions versus increasing transmit delays for packets on the transmit queue. During periods of retransmissions multihomed nodes send duplicate packets until

the alternate address becomes the primary path. The alternate address becomes the primary path when the number of retries exceeds the path-retransmit parameter. The default value for minimum and maximum RTO is 1 second. Propagation delays and latencies vary in networks, so select an RTO value carefully.

---

**Examples**

The following example shows how to set the minimum value of the retransmit timeout to 300 milliseconds and the maximum value to 3000 milliseconds:

```
cs7 m3ua 2905
local-ip 4.4.4.4
retransmit-timeout 300 3000
```

---

|                 |  <b>Note</b> | This modification applies only to the 12.4(15)SW release train. It does not currently apply to any ITP software release for the Cisco 7600 router. |

|                         |                                                                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | In ANSI networks, before transmitting an MSU over an MTP3 link, a node performs SLS rotation—changing the SLS field in the MSU by shifting the lower five bits to the right and moving the first bit to the fifth bit. This feature is described in <i>GR-246, Section T1.115.1 Chapter 7</i> . |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

An SLS value of X7 X6 X5 X4 X3 X2 X1 X0 changes to X7 X6 X5 X0 X4 X3 X2 X1. Because M3UA and SUA nodes might not perform SLS rotation, or might use different schemes for load sharing between multiple ITPs, this enhancement adds a configurable option for an AS to perform ANSI rotation on incoming MSUs before link and linkset selection.

SLS rotation also includes the option to shift these bits by more than one place. For example, if **rotate-sls 4** is configured, then instead of doing the normal ANSI rotation, the ITP shifts the SLS link this way:

X7 X6 X5 X4 X3 X2 X1 X0 changes to X7 X6 X5 X3 X3 X1 X0 X4

Note that unlike the **shift-sls** option in the ITU variant, this option changes the field in the MSU being transmitted later.

---

**Examples**

The following example shows how to disable SLS rotation:

```
no rotate-sls
```

The following example shows how to enable an SLS rotation of 2:

```
rotate-sls 2
```

routing-key rcontext {gtt | dpc [opc pc pc-mask] [si sccp] [[cic cic-min [cic-max]] | [ssn ssn]]}]
```

**no routing-key**

### Syntax Description

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>rcontext</i> | The routing context parameter is an unsigned decimal number that uniquely identifies a routing key. An ASP may include the routing context in the ASP Active Request to register receiving traffic for a specific AS.                                                                                                                                                                                                        |
| <b>gtt</b>      | Global title translation. (Configuring GTT implies a sccp service indicator.)                                                                                                                                                                                                                                                                                                                                                |
| <i>dpc</i>      | Destination point code indicating the point code associated with this AS and routing key. This destination point code may be unique or share the SG's local point code, secondary point code, or capability point code. An M3UA AS or an SUA AS can share only one of the router's local point codes. For more information, refer to <a href="#">“Point Code Assignment and Management”</a> in the Usage Guidelines section. |
| <b>opc</b>      | Originating point code, which further limits traffic directed to an AS to traffic from a specific point code.                                                                                                                                                                                                                                                                                                                |
| <i>pc</i>       | Originating point code.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>pc-mask</i>  | Point code mask, which allows you to specify a range of originating point codes by indicating the number of significant bits.                                                                                                                                                                                                                                                                                                |
| <b>si</b>       | Service indicator. You can specify a service indicator of either isup or sccp. (This parameter applies to M3UA ASes only. SUA ASes imply an sccp service indicator.)                                                                                                                                                                                                                                                         |
| <b>aal2</b>     | AAL2 service indicator (M3UA only).                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>bicc</b>     | BICC service indicator (M3UA only).                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>b-isup</b>   | B ISUP service indicator (M3UA only).                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>h248</b>     | GCP service indicator (M3UA only).                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>isup</b>     | ISUP service indicator (M3UA only).                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>sat-isup</b> | Satellite ISUP service indicator (M3UA only).                                                                                                                                                                                                                                                                                                                                                                                |
| <b>sccp</b>     | SCCP service indicator.                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>tup</b>      | TUP service indicator (M3UA only).                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>cic-min</i>  | CIC number or minimum value in a CIC range.                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>cic-max</i>  | Maximum value in a CIC range.                                                                                                                                                                                                                                                                                                                                                                                                |

|            |                                                                                                                 |
|------------|-----------------------------------------------------------------------------------------------------------------|
| <b>ssn</b> | Subsystem number. (This parameter applies to SUA ASes only. Configuring SSN implies an sccp service indicator.) |
| <i>ssn</i> | Subsystem number value.                                                                                         |

**Defaults**

None.

**Command Modes**

cs7 as submode

**Command History**

|-------------------------------------------|-------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.              |
| 12.2(18)IXH<br>12.4(15)SW3<br>12.2(33)IRC | Additional service indicators were added. |

**Usage Guidelines**

The routing key describes a set of SS7 parameters and parameter values that uniquely define the range of signaling traffic to be handled by a particular AS. Routing key provisioning ensures that traffic is routed correctly. Routing key combinations vary for M3UA and SUA.

If CS7 multiple instance is configured, duplicate routing keys are allowed for ASes or AS routes in different instances.

The ITP SG uses the routing key table to map incoming SS7 messages to the appropriate AS or AS route table. Relevant fields of the incoming SS7 messages are compared to the existing routing keys. An AS is selected based on the best matching routing key. The routing keys are prioritized by selecting the best matching gtt keys first, followed by the longest matching routing key at the highest layer in the protocol stack.

The following list shows the routing key combinations in order of priority. The dpc must match for a non-GTT AS to be selected.

- gtt
- dpc + sccp + ssn + opc      or      dpc + isup + cic + opc
- dpc + sccp + ssn              or      dpc + isup + cic
- dpc + sccp + opc              or      dpc + isup + opc
- dpc + sccp                      or      dpc + isup
- dpc + opc
- dpc

Valid routing key combinations vary for M3UA and SUA.

**Routing Key Definitions for M3UA**

For M3UA ASes, the routing key has the following parameters:

```
routing-key rcontext {gtt [gtt-selector-name [gtt-gta]] | dpc [opc pc pc-mask] [si {aal2 | bicc |
b-isup | h248 | isup| sat-isup | sccp | tup}] cic-min [cic-max]}
```

Specify the following parameters to configure a routing key for M3UA GTT traffic. SI SCCP is enabled by default.

```
routing-key rcontext {gtt [gtt-selector-name [gtt-gta]]
```

Specify the following parameters to configure a routing key for M3UA ISUP traffic. If **cic** is selected, then **si isup** is enabled by default.

```
routing-key rcontext dpc [opc pc pc-mask] si isup [cic cic-min [cic-max]]
```

Use the following parameters to configure a routing key for M3UA SSN traffic. **si sccp** is enabled by default.

```
routing-key rcontext dpc [opc pc pc-mask] si sccp ssn ssn
```

### Routing Key Definitions for SUA

For SUA ASes, the routing key has the following parameters. SUA supports **si sccp** only.

```
routing-key rcontext {gtt [gtt-selector-name [gtt-gta]] | dpc [opc pc pc-mask] si sccp [ssn ssn]}
```

To configure a routing key for SUA TCAP traffic:

```
routing-key rcontext dpc [opc pc pc-mask] si sccp ssn ssn
```

To configure a routing key for SUA GTT traffic:

```
routing-key rcontext {gtt [gtt-selector-name [gtt-gta]]
```

### Point Code Assignment and Management

Take special care when planning the assignment of point codes to ASes. The ITP SG feature allows point code assignment to ASes and ASPs as follows:

- An AS may be assigned the primary local point code or secondary local point code owned by the SG. The AS is sharing the point code with the SG.
- An AS may be assigned a capability code or alias point code of the SG. The AS is sharing the point code with the SG's mated pair.
- An AS may be assigned a unique point code not previously assigned to any of the SGs in the mated-pair.
- An ASP can be assigned a unique point code by being the only ASP in an AS that has been assigned a unique point code.
- All ASes or groups of ASes serviced by the SG may share a given point code. Any group of ASes that shares the same point code is referred to as a Signaling Point Management Cluster (SPMC). Note that an M3UA AS and an SUA AS may share only one of the router's point codes (primary local, secondary local, or capability).

Assigning more than one AS the same point code can have significant effect on the ability of the SG to report ASP, AS, user part, or subsystem outages or unavailability to the SS7 network. Consider the following case:

AS1 and AS2 are sharing point code 2.2.2 in the same network appearance. AS1 handles ISUP traffic for CIC 1 to 500. AS2 handles ISUP traffic for CIC 501 to 1000 from the same OPC. AS1 and AS2 have no ASPs in common. If all of the ASPs in AS1 become unavailable, the SG cannot send a TFP to the SS7 network. Sending a TFP would inaccurately indicate that point code 2.2.2 is totally unreachable through the SG when only a subset of the ASPs in point code 2.2.2 are unreachable. If AS1 and AS2 each had its own point code, then the SG would be able send a TFP to the SS7 network.

### Unallocated MSU processing

When an MSU is received and does not match any of the configured routing keys, that MSU is referred to as an unallocated MSU. The default treatment for unallocated messages varies. If a trap has been enabled for unallocated messages, the DPC, OPC, and SIO of an unallocated MSU are reported to the designated management entity. If the unallocated MSU trap has not been enabled, the MSU is counted and dropped.

To prevent the MSU from being dropped, you can configure routing keys with minimal parameters to catch traffic that does not match more specific routing keys. For example, in the case of ISUP traffic, the following configuration catches errant ISUP traffic for tracking purposes:

```
cs7 as defaultisup m3ua
  routingkey 222 dpc 2.3.3 si isup
  asp isupbucket
```

All ISUP traffic for DPC 2.3.3 that does not match the CIC range of one of the more specific routing keys is sent to the isupbucket ASP. Note that, if the isupbucket ASP is not active, the MSU is dropped with the appropriate warning.

### Examples

The following examples show how to configure routing key provisioning:

```
cs7 as as1 m3ua
  routing-key 01010101 gtt

cs7 as as2 m3ua
  routing-key 02020202 2.2.2

cs7 as as3 m3ua

|---------|---------------------------------------------------------------|
| cs7 as  | Defines an application server (AS) and enters cs7 as submode. |

## rule (cs7 mlr ruleset)

To specify the rules for a routing trigger within a multilayer ruleset table, use the **rule** command in cs7 mlr ruleset configuration mode. To disable the specific rule, use the **no** form of this command.

```
rule order {{ gsm-map | ansi-41 } operation-name [default] | all-operations | default-rule}
```

```
no rule order {{ gsm-map | ansi-41 } operation-name [default] | all-operations | default-rule}
```

| Syntax Description              |  |                                                                                                                                                                                                                                      |
|---------------------------------|--|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>order</i>                    |  | Specifies the order in which rules are searched. The order must be unique among all rules. The routing table is sequentially searched for a match, with the rules being tested in the order specified. Valid numbers are 1 to 1000.  |
| <b>gsm-map</b>   <b>ansi-41</b> |  | Valid application layer protocols are <b>gsm-map</b> or <b>ansi-41</b> . If you specify a protocol in the MLR ruleset, you cannot specify the protocol for a rule.                                                                   |
| <i>operation-name</i>           |  | Specifies the operation of the message that must be matched. Valid operation names are listed in the tables in the Usage Guidelines section.                                                                                         |
| <b>default</b>                  |  | Specifies the processing of messages that match the specified operation name only. Optional for all the operations supported but will be NVGENed for new operations, because only one rule can be configured for each new operation. |
| <b>all-operations</b>           |  | Identifies a match of any valid operation code. If you specify a protocol at the MLR ruleset level, specifying <b>all-operations</b> in a rule applies only for that protocol.                                                       |
| <b>default-rule</b>             |  | Matches default rule when no rule matches.                                                                                                                                                                                           |

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                               |
|----------------------|-------------------------------|

|-----------------|------------------------------------------|--------------------------------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                           |
|                 | 12.2(33)IRG<br>12.4(15)SW7               | The <b>mobileUSSD</b> operation name was introduced.   |
|                 | 12.2(33)IRI<br>12.4(15)SW9               | The <b>default-rule</b> operation name was introduced. |

**Usage Guidelines**

The **rule** command specifies the attributes of an application-layer message to be matched, and the resulting behavior for handling the message. At least one rule must be specified for the ruleset to be valid. Enables mlr ruleset rule configuration mode.

The following command enters into the cs7 mlr set rule configuration submode:

```

ITP(cfg-cs7-mlr-set)# rule 1 default-rule ?
<cr>
ITP(cfg-cs7-mlr-set-rule)# ?
  allow-multi-message-dialogue  Allow multi-message-dialogues to match a default rule
  exit                          Exit from CS7 MLR rule configuration submode
  no                             Negate a command or set its defaults
  pam                           Apply a PAM during result processing
  result                         Configure result

```

Table 34 and Table 35 list GSM-MAP and GSM-MAP Version 1 operation names mapped to ITP operations names. Table 36 lists GSM operations that allow you to route and screen based on MAP parameters and MAP-User parameters.

Valid operation names are presented in the CLI depending on the specified protocol.

**Table 34** GSM-MAP Operation Name Mapping to ITP CLI Operation Name

| Operation Name in GSM-MAP Specification | ITP CLI Operation Name | Opcode Value |

## Examples

In the following example, any MSU that does not match the two defined DPC triggers will match the default trigger. Ruleset GEN\_OPC\_GSM is used in the default cases and the MAP operation is matched with the rules in ascending order. If a rule matches, the result of the rule is applied.

```
cs7 instance 0 mlr ruleset MLR_RULES
rule 5 gsm-map sms-mo
  dest-sme 12345678901234567890 min-digits 20 max-digits 20 np 4

# sack-frequency (cs7 asp)

To configure the selective acknowledgment (SACK) for SCTP associations, use the **sack-frequency** command in cs7 asp configuration mode. To disable the configuration, use the **no** form of this command.

**sack-frequency** *consecutive-packets*

**no sack-frequency** *consecutive-packets*

## Syntax Description

|                            |                                                   |
|----------------------------|---------------------------------------------------|
| <i>consecutive-packets</i> | The number of consecutive packets to send a sack. |
|----------------------------|---------------------------------------------------|

## Defaults

The default value is two consecutive packets.

## Command Modes

cs7 asp configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW5 | This command was introduced. |
| 12.2(33)IRE |                              |

## Usage Guidelines

SCTP is a reliable protocol. When SCTP does not get a acknowledgment for a sent packet, it triggers a retransmission of the same packet. SCTP can use the SACK mechanism to selectively acknowledge packets. This decreases the retransmission burden relative to an open acknowledgement of packets.

The frequency of SACKs can affect the SCTP overhead. The **sack-frequency** command allows you to tune the frequency of SACKs for your network.

## Examples

The following example shows a SACK frequency of three set for the ASP alpha:

```
cs7 multi-instance
cs7 instance 0 variant ANSI
cs7 instance 0 network-name ANSI
cs7 instance 0 point-code 6.0.1
cs7 instance 0 secondary-pc 6.0.2
cs7 instance 0 capability-pc 6.0.3
cs7 instance 0 description ANSI:6.0.1

cs7 instance 2 variant ITU
cs7 instance 2 network-name ITU
cs7 instance 2 point-code 6.2.1
cs7 instance 2 secondary-pc 6.2.2
cs7 instance 2 capability-pc 6.2.3
cs7 instance 2 description ITU:6.2.1
!
cs7 instance 0 linkset to72_rsp 15256
link 0 sctp 192.168.127.102 1377 1377
  sack-frequency 3
!
cs7 asp alpha 7779 7779 sua
```

**sack-frequency (cs7 asp)**

```
remote-ip 10.74.50.146
sack frequency 3
```

**Related Commands!**

| Command                                    | Description                                                        |

| <a href="#">cs7 asp</a>                    | Defines an application server process and enables cs7 asp submode. |
| <a href="#">show cs7 asp</a>               | Displays ASP information.                                          |

# sack-frequency (cs7 link)

To configure the selective acknowledgment (SACK) frequency for SCTP associations, use the **sack-frequency** command in link configuration mode. To disable the configuration, use the **no** form of this command.

**sack-frequency** *consecutive-packets*

**no sack-frequency** *consecutive-packets*

## Syntax Description

|                            |                                                   |
|----------------------------|---------------------------------------------------|
| <i>consecutive-packets</i> | The number of consecutive packets to send a sack. |
|----------------------------|---------------------------------------------------|

## Defaults

The default value is two consecutive packets.

## Command Modes

cs7 link configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW5 | This command was introduced. |
| 12.2(33)IRE |                              |

## Usage Guidelines

SCTP is a reliable protocol. When SCTP does not get a acknowledgment for a sent packet, it triggers a retransmission of the same packet. SCTP can use the SACK mechanism to selectively acknowledge packets. This decreases the retransmission burden relative to an open acknowledgement of packets.

The frequency of SACKs can affect the SCTP overhead. The **sack-frequency** command allows you to tune the frequency of SACKs for your network.

## Examples

The following example shows a sack frequency of three set for the linkset to72\_rsp 15256:

```
cs7 multi-instance
cs7 instance 0 variant ANSI
cs7 instance 0 network-name ANSI
cs7 instance 0 point-code 6.0.1
cs7 instance 0 secondary-pc 6.0.2
cs7 instance 0 capability-pc 6.0.3
cs7 instance 0 description ANSI:6.0.1

cs7 instance 2 variant ITU
cs7 instance 2 network-name ITU
cs7 instance 2 point-code 6.2.1
cs7 instance 2 secondary-pc 6.2.2
cs7 instance 2 capability-pc 6.2.3
cs7 instance 2 description ITU:6.2.1
!
cs7 instance 0 linkset to72_rsp 15256
link 0 sctp 192.168.127.102 1377 1377
sack-frequency 3
```

**sack-frequency (cs7 link)**

```
!  
cs7 asp alph 7779 7779 sua  
  remote-ip 10.74.50.146  
  sack frequency 3  
!
```

# sccp-msg

To specify a SCCP message header table entry, use the **sccp-msg** command in `cs7 gws sccp` header configuration mode. To remove the specification, use the **no** form of this command.

**sccp-msg** *sccp-msg-type* **result** {**action** *action-set-name* | **table** *table-name*}

**no sccp-msg** *sccp-msg-type*

## Syntax Description

|                        |                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------|
| <i>sccp-msg-type</i>   | SCCP message types that are valid in this configuration are listed in <a href="#">Table 37</a> . |
| <b>result</b>          | Specifies the next step.                                                                         |
| <b>action</b>          | Screens the result by action set.                                                                |
| <i>action-set-name</i> | Action set name. Valid names may not exceed 12 alphanumeric characters.                          |
| <b>table</b>           | Screens the result by table.                                                                     |
| <i>table-name</i>      | Table name. Valid names may not exceed 12 alphanumeric characters.                               |

## Command Default

None.

## Command Modes

`cs7 gws sccp` header configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

[Table 37](#) lists valid SCCP message types.

**Table 37**      **SCCP Message Types**

|      |       |      |       |      |
|------|-------|------|-------|------|
| CR   | CC    | CREF | RLSD  | RLC  |
| DT1  | DT2   | AK   | UDT   | XUDT |
| UDTS | XUDTS | LUDT | LUDTS | ED   |
| EA   | RSR   | RSC  | ERR   | IT   |

## Examples

The following example shows how to specify SCCP message type entries:

```
cs7 instance 0 gws table SCCP0 type sccp-msg-hdr
  default result action ALLOW
  sccp-msg udta result action ALLOW
  sccp-msg xudta result action ALLOW
```

**Related Commands**

| Command                       | Description                           |
|-------------------------------|---------------------------------------|
| <a href="#">cs7 gws table</a> | Configures a gateway screening table. |

## sctp-rfc-version (cs7 local peer)

To set the RFC compliance to either SCTP RFC 2960 or SCTP RFC 4960, use the **sctp-rfc-version** command in cs7 local-peer configuration submode.

**sctp-rfc-version {2960 | 4960}**

### Syntax Description

|             |                                                                                 |
|-------------|---------------------------------------------------------------------------------|
| <b>2960</b> | SCTP RFC 2960 is the earlier version of the standard.                           |
| <b>4960</b> | SCTP RFC 4960 is the later version of the standard. It obsoletes SCTP RFC 2960. |

### Defaults

The default is SCTP RFC 2960.

### Command Modes

cs7 local-peer submode configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(33)IRD | This command was introduced. |

### Usage Guidelines

Prior to the ITP releases 12.2(33)IRD and 12.4(15)SW4, ITP was compliant with SCTP RFC 2960 but not compliant with SCTP RFC 4960. Releases 12.2(33)IRD, 12.4(15)SW4 and later bring ITP into compliance with SCTP RFC 4960.

### Examples

The following example shows how to set the compliance to SCTP RFC 4960:

```
sctp-rfc-version 4960
```

### Related Commands

| Command                        | Description               |
|--------------------------------|---------------------------|
| <a href="#">cs7 local-peer</a> | Specifies the local peer. |

## sctp-rfc-version (cs7 m3ua)

To set the RFC compliance to either SCTP RFC 2960 or SCTP RFC 4960, use the **sctp-rfc-version** command in cs7 m3ua configuration submode.

**sctp-rfc-version {2960 | 4960}**

|                           |                                                                                                                                                                                                                             |                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <b>2960</b>                                                                                                                                                                                                                 | SCTP RFC 2960 is the earlier version of the standard.                                             |
|                           | <b>4960</b>                                                                                                                                                                                                                 | SCTP RFC 4960 is the later version of the standard. It replaces and makes obsolete SCTP RFC 2960. |
| <b>Defaults</b>           | The default is SCTP RFC 2960.                                                                                                                                                                                               |                                                                                                   |
| <b>Command Modes</b>      | cs7 m3ua submode configuration                                                                                                                                                                                              |                                                                                                   |

## sctp-rfc-version (cs7 sua)

To set the RFC compliance to either SCTP RFC 2960 or SCTP RFC 4960, use the **sctp-rfc-version** command in cs7 sua configuration submode.

**sctp-rfc-version {2960 | 4960}**

### Syntax Description

|             |                                                                                                   |
|-------------|---------------------------------------------------------------------------------------------------|
| <b>2960</b> | SCTP RFC 2960 is the earlier version of the standard.                                             |
| <b>4960</b> | SCTP RFC 4960 is the later version of the standard. It replaces and makes obsolete SCTP RFC 2960. |

### Defaults

The default is SCTP RFC 2960.

### Command Modes

cs7 sua submode configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(33)IRD | This command was introduced. |

### Usage Guidelines

Prior to the ITP releases 12.2(33)IRD and 12.4(15)SW4, ITP was compliant with SCTP RFC 2960 but not compliant with SCTP RFC 4960. Releases 12.2(33)IRD, 12.4(15)SW4 and later bring ITP into compliance with SCTP RFC 4960.

### Examples

The following example shows how to set the compliance to SCTP RFC 4960:

```
sctp-rfc-version 4960
```

| <a href="#">cs7 sua</a> | Specifies the local port number for SUA and enters sua submode. |

## send-window (cs7 sms profile parms)

To specify the number of outstanding UCP operations between an SMSC and a SMS application, use the **send-window** command in cs7 sms profile parameters configuration mode. To remove the specification, use the **no** form of this command.

**send-window** *operations*

**no send-window** *operations*

| Syntax Description                                            | <i>operations</i> Number of outstanding UCP operations between an SMSC and a SMS application. Valid range is 1 to 100. The default is 10.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |  |         |              |                                                        |                              |                                                               |                                     |                                                              |                                    |                                                        |                                   |                                                            |                                    |

## send-window (cs7 sms session parms)

To specify the number of outstanding UCP operations between an SMSC and an SMS application, use the **send-window** command in cs7 sms session parameters configuration mode. To remove the specification, use the **no** form of this command.

**send-window** *operations*

**no send-window** *operations*

### Syntax Description

|                   |                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>operations</i> | Number of outstanding UCP operations between an SMSC and an SMS application. Valid range is 1 to 100. The default is 10. |
|-------------------|--------------------------------------------------------------------------------------------------------------------------|

### Defaults

10 outstanding UCP operations

### Command Modes

cs7 sms session parameters configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Examples

The following example shows how to create an SMPP connection and configure a destination and several parameters:

```
cs7 sms smpp 5000 local-ip 10.10.10.200 dynamic
destination offisland 10.10.20.2 6000
bind-type any
inactivity-timer 5000
keepalive-timer 1000
response-timer 2000
send-window 50
session-init-timer 5000
```

|---------------------------------------------------------------|-------------------------------------|
| <a href="#">inactivity-timer (cs7 sms session parameters)</a> | Specifies session inactivity timer. |
| <a href="#">keepalive-timer (cs7 sms session parameters)</a>  | Specifies session keepalive timer.  |
| <a href="#">response-timer (cs7 sms session parms)</a>        | Specifies session response timer.   |
| <a href="#">session-init-timer (cs7 sms session parms)</a>    | Specifies session initiation timer. |

## session-init-timer (cs7 sms profile parms)

To specify the time lapse allowed between a network connection being established and the establishment of the UCP connection, use the **sessions-init** command in cs7 sms profile parameters configuration mode. To remove the specification, use the **no** form of this command.

**session-init-timer** *msec*

**no session-init-timer** *msec*

|                           |             |                                                                                                                                                                       |
|---------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>msec</i> | Time lapse allowed between a network connection being established and the establishment of the UCP connection. Range is 500 ms to 120000 ms. The default is 10000 ms. |
|---------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |          |
|-----------------|----------|
| <b>Defaults</b> | 10000 ms |
|-----------------|----------|

|                      |                                          |

|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

|                 |                                                                                                             |
|-----------------|-------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to create an SMPP profile named mmprofile and configure several parameters: |
|-----------------|-------------------------------------------------------------------------------------------------------------|

```
cs7 sms smpp profile mmprofile
bind-type any
inactivity-timer 5000
keepalive-timer 1000
response-timer 2000
send-window 50
session-init-timer 5000
```

## session-init-timer (cs7 sms session parms)

To specify the time lapse allowed between a network connection being established and the establishment of the UCP connection, use the **sessions-init** command in cs7 sms session parameters configuration mode. To remove the specification, use the **no** form of this command.

**session-init-timer** *msec*

**no session-init-timer** *msec*

|                           |             |                                                                                                                                                                       |
|---------------------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>msec</i> | Time lapse allowed between a network connection being established and the establishment of the UCP connection. Range is 500 ms to 120000 ms. The default is 10000 ms. |

# set

To specify GTI conversion, subsystem mapping, and address-conversion tables to be assigned from one instance to another, use the **set** command in **cs7 sccp** instance conversion configuration mode. To remove the configuration, use the **no** form of this command.

**set** { **address-conversion** *table-name* | **gti-conversion** *table-name* | **message-handling** *option* | **national-indicator** *natl-ind* | **ssn-conversion** *table-name* }

**no set** { **address-conversion** *table-name* | **gti-conversion** *table-name* | **message-handling** *option* | **national-indicator** *natl-ind* | **ssn-conversion** *table-name* }

## Syntax Description

|                                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                               |   |                    |     |                                        |           |                                                   |           |                       |                 |                         |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---|--------------------|-----|----------------------------------------|-----------|---------------------------------------------------|-----------|-----------------------|-----------------|-------------------------|
| <b>address-conversion</b> <i>table-name</i> | Specifies an address-conversion table.                                                                                                                                                                                                                                                                                                                                                                                                                        |   |                    |     |                                        |           |                                                   |           |                       |                 |                         |
| <b>gti-conversion</b> <i>table-name</i>     | Specifies a GTI conversion table.                                                                                                                                                                                                                                                                                                                                                                                                                             |   |                    |     |                                        |           |                                                   |           |                       |                 |                         |
| <b>message-handling</b> <i>option</i>       | Specifies the SCCP message handling option.<br>The following values determine message handling:<br><br><table> <tr> <td>0</td><td>no special options</td></tr> <tr> <td>1-7</td><td>spare values (for example, unassigned)</td></tr> <tr> <td>9-15</td><td>additional spare values (for example, unassigned)</td></tr> <tr> <td>no change</td><td>leave field unchanged</td></tr> <tr> <td>return-on-error</td><td>return [x]udts on error</td></tr> </table> | 0 | no special options | 1-7 | spare values (for example, unassigned) | 9-15      | additional spare values (for example, unassigned) | no change | leave field unchanged | return-on-error | return [x]udts on error |
| 0                                           | no special options                                                                                                                                                                                                                                                                                                                                                                                                                                            |   |                    |     |                                        |           |                                                   |           |                       |                 |                         |
| 1-7                                         | spare values (for example, unassigned)                                                                                                                                                                                                                                                                                                                                                                                                                        |   |                    |     |                                        |           |                                                   |           |                       |                 |                         |

| <b>ssn-conversion</b> <i>table-name</i>     | Specifies an SSN conversion table.                                                                                                                                                                                                                                                                                                                                                                                                                            |   |                    |     |                                        |           |                                                   |           |                       |                 |                         |

## Defaults

None.

## Command Modes

cs7 sccp instance conversion configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

All three conversion methods can be used, or just one or two. This command is optional, so if no conversion methods are assigned, the GTT in the MSUs do not change.

---

**Examples**

The following examples show how to use the **set** command with its various keywords:

```
cs7 sccp instance-conversion in-instance 1 out-instance 0
set gti-conversion gti-conv0
```

```
cs7 sccp instance-conversion in-instance 1 out-instance 0
set ssn-conversion ssntable
```

```
cs7 sccp instance-conversion in-instance 1 out-instance 0
set address-conversion addr-conv
```

```
cs7 sccp instance-conversion in-instance 1 out-instance 0
set message-handling 0
```

```
cs7 sccp instance-conversion in-instance 1 out-instance 0
set national-indicator 1
```

|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

|                 |                                                                                  |
|-----------------|----------------------------------------------------------------------------------|
| <b>Examples</b> | The following example includes output from the <b>show access-lists</b> command: |
|-----------------|----------------------------------------------------------------------------------|

```
ITP# show cs7 access-lists
Cisco SS7 access list 2700
  permit dpc 4.100.0 0.0.255
```

[Table 39](#) describes the fields in the display.

**Table 39** *show cs7 access-lists* Field Descriptions

| Field                      | Description                                                                            |
|----------------------------|----------------------------------------------------------------------------------------|
| Cisco SS7 access list 2700 | Information about Cisco access list number 2700.                                       |
| permit                     | Permits access if the conditions match.                                                |
| dpc                        | Applies destination point code 4.100.0 with wildcard mask 0.0.255 to this access list. |

| <b>Related Commands</b> | Command                      | Description                                                                                                        |
|-------------------------|------------------------------|--------------------------------------------------------------------------------------------------------------------|
|                         | <a href="#">access-list</a>  | Defines a Cisco SS7 access list.                                                                                   |
|                         | <a href="#">access-group</a> | Issued from cs7 linkset submode, assigns an access list to a linkset to screen either inbound or outbound packets. |
|                         | <a href="#">cs7 linkset</a>  | Specifies a linkset and enters cs7 linkset submode.                                                                |

# show cs7 accounting

To display ITP accounting details, use the **show cs7 accounting** EXEC command.

```
show cs7 [instance-number] accounting [point-code] [linkset] [[as [as-name]] | [gtt [checkpoint]]
| [checkpoint] | [unrouteable [checkpoint]] | [access-violations [checkpoint]]
```

## Syntax Description

|                          |                                                                                                                                  |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <i>instance-number</i>   | Specifies the instance. The valid range is 0 to 7. The default instance is 0.                                                    |
| <i>point-code</i>        | Point code filter.                                                                                                               |
| <i>linkset</i>           | Linkset name.                                                                                                                    |
| <i>as-name</i>           | Specifies which AS is displayed. If this value is not provided, the accounting information for all ASes is displayed by default. |
| <b>as</b>                | Displays xUA accounting information for all ASes or for a dedicated AS.                                                          |
| <b>gtt</b>               | Displays the CS7 GTT accounting database(s).                                                                                     |
| <b>checkpoint</b>        | Displays the CS7 checkpointed data.                                                                                              |
| <b>unrouteable</b>       | Displays the CS7 unroutable MSU database.                                                                                        |
| <b>access-violations</b> | Displays the CS7 access-violations database.                                                                                     |

## Defaults

The default instance is 0.

If a value for *as-name* is not specified, ITP displays accounting information for all ASes.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example includes output from the **show cs7 accounting** command:

```
ITP# show cs7 accounting
```

```
Checkpoint Interval = 5 min
```

```
Linkset = 'linkset1'
```

| DPC   | OPC   | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |
|-------|-------|----|---------|----------|----------|-----------|
| 3-4-2 | 3-4-4 | 0  | 0       | 0        | 10       | 120       |
| 3-4-4 | 3-4-2 | 2  | 29      | 348      | 0        | 0         |
| 3-4-2 | 3-4-4 | 2  | 0       | 0        | 29       | 348       |

The following example includes output for an accounting report for instance 0:

```
ITP# show cs7 0 accounting
```

Instance Number:0 Checkpoint Interval = 5 min

Linkset = 'linkset1'

| DPC      | OPC      | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |
|----------|----------|----|---------|----------|----------|-----------|
| 1.15.1:0 | 1.11.1:0 | 1  | 1       | 9        | 0        | 0         |
| 1.11.1:0 | 1.15.1:0 | 1  | 0       | 0        | 1        | 9         |

The following example includes output from the **show cs7 accounting** command with the **access-violations** keyword. The sample output shows that access violations occurred for packets destined for 3.3.3 from origin point code 4.4.4. Packets are received on the input, but no packets are being routed to the destination point code.

ITP# **show cs7 accounting access-violations**

Checkpoint Interval = 5 min

Linkset = 'linkset1'

| DPC   | OPC   | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |
|-------|-------|----|---------|----------|----------|-----------|
| 3-7-2 | 3-4-6 | 3  | 84      | 11088    | 0        | 0         |

This data is stored in a two-stage database. The first database is a quick-access table that shows the data accumulated since the last checkpoint event. Checkpointing is the process of moving data records from the quick-access table to the large backend database that stores long-term accounting records. The checkpointed database contains accumulated accounting data since the last clearing or from the time accounting was originally enabled.

The following example includes output from the **show cs7 accounting** command with the **access-violations** and **checkpoint** keywords:

ITP# **show cs7 accounting access-violations checkpoint**

Checkpoint Interval = 5 min

Linkset = 'linkset1'

| DPC   | OPC   | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |
|-------|-------|----|---------|----------|----------|-----------|
| 3-7-2 | 3-4-6 | 3  | 2       | 264      | 0        | 0         |

The following example includes output from the **show cs7 accounting** command with the **checkpoint** keyword, displaying the accumulated checkpointed data:

ITP# **show cs7 accounting checkpoint**

Checkpoint Interval = 5 min

Linkset = 'linkset1'

| DPC   | OPC   | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |
|-------|-------|----|---------|----------|----------|-----------|
| 3-4-4 | 3-4-6 | 0  | 8       | 84       | 0        | 0         |
| 3-4-4 | 3-4-6 | 2  | 7893    | 94716    | 0        | 0         |
| 3-4-6 | 3-4-4 | 0  | 0       | 0        | 6        | 57        |
| 3-4-6 | 3-4-4 | 2  | 0       | 0        | 7893     | 94716     |

GTT accounting is a flow-based accounting method that is performed on a per-linkset basis. This accounting generates records based on traffic entering a given linkset that is processed by the GTT function of the ITP's SCCP layer. Individual records containing output packet and byte counts are kept for traffic that matches a given GTA entry and is translated to a specific point code.

The following example includes output from the **show cs7 accounting** command with the **gtt** keyword:

ITP# **show cs7 accounting gtt**

## show cs7 accounting

Checkpoint Interval = 5 min

Inbound Linkset = 'linkset1'

| Matched<br>Selector | Matched<br>Global Title | Translated<br>Point Code | Input<br>Packets | Bytes |
|---------------------|-------------------------|--------------------------|------------------|-------|
| my_sel              | 919341                  | 3-7-1                    | 38               | 5016  |
| my_sel              | 919341                  | 3-7-2                    | 688              | 90816 |

In the following example the Instance Translation feature has been configured, so the SCCP Accounting tables show an instance number with the translated point code:

ITP# **show cs7 account gtt**

Instance Number:4 Checkpoint Interval = 5 min

Inbound Linkset = 'scp-4'

| Matched<br>Selector | Matched<br>Global Title | Translated<br>Point Code | Input<br>Packets | Bytes |
|---------------------|-------------------------|--------------------------|------------------|-------|
| sel-4               | 919                     | 5.1.1:3                  | 2                | 86    |

The following example includes output from the **show cs7 accounting** command with MTP3 accounting configured:

Router# **show cs7 0 accounting VirtualLS0\_1**

Instance Number:0 Checkpoint Interval = 5 min Count:2

Linkset = 'VirtualLS0\_1'

| DPC      | OPC      | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |
|----------|----------|----|---------|----------|----------|-----------|
| 1.26.1:0 | 1.1.1:0  | 0  | 0       | 0        | 1        | 8         |
| 1.1.1:0  | 1.26.1:0 | 1  | 906     | 8154     | 0        | 0         |

The following example includes output from the **show cs7 accounting** command with virtual linkset GTT accounting configured:

Router# **show cs7 0 accounting VirtualLS0\_1 gtt**

Checkpoint Interval = 5 min

Inbound Linkset = 'VirtualLS0\_1'

| Matched<br>Selector | Matched<br>Global Title | Translated<br>Point Code | Input<br>Packets | Bytes |
|---------------------|-------------------------|--------------------------|------------------|-------|
| test 123            |                         | 6.0.3                    | 1741             | 23418 |

The following example includes output from the **show cs7 accounting as** command for an M3UA AS and no optional keywords:

Router# **show cs7 0 accounting as m3ua\_as\_1**

Instance Number:0 Checkpoint Interval = 5 min Count:2

M3UA AS Name = 'm3ua\_as\_1'

| DPC     | OPC   | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |
|---------|-------|----|---------|----------|----------|-----------|
| 2.8.1:0 | 6.0.3 | 1  | 10      | 90       | 0        | 0         |
| 2.8.1:0 | 6.0.3 | 3  | 146574  | 3810924  | 0        | 0         |

The following example includes output from the **show cs7 accounting as** command for an M3UA AS and the **unrouteable** keyword:

```
Router# show cs7 0 accounting as m3ua_as_1 unroutable
```

```
Instance Number:0 Checkpoint Interval = 5 min Count:2
```

```
M3UA AS Name = 'm3ua_as_1'
```

| DPC     | OPC   | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |
|---------|-------|----|---------|----------|----------|-----------|
| 2.8.1:0 | 6.0.3 | 1  | 10      | 90       | 0        | 0         |
| 2.8.1:0 | 6.0.3 | 3  | 146574  | 3810924  | 0        | 0         |

The following example includes output from the **show cs7 accounting as** command for an M3UA AS and the **gtt** keyword:

```
Router# show cs7 0 accounting as m3ua_as_1 gtt
```

```
Checkpoint Interval = 5 min
```

```
Inbound M3UA AS = 'm3ua_as_1'
```

| Matched Selector | Matched Global Title | Translated Point Code | Input Packets | Input Bytes |
|------------------|----------------------|-----------------------|---------------|-------------|
| test             | 123456               | 6.0.3                 | 1741          | 234183      |

The following example includes output from the **show cs7 accounting as** command for an SUA AS and no optional keywords:

```
Router# show cs7 accounting as sua_as_1
```

```
Checkpoint Interval = 5 min
```

```
SUA AS = 'sua_as_1'
```

| DPC     | OPC   | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |
|---------|-------|----|---------|----------|----------|-----------|
| 2.8.1:0 | 6.0.3 | 3  | 146574  | 3810924  | 0        | 0         |

The following example includes output from the **show cs7 accounting as** command for an SUA AS and the optional keyword **unrouteable**:

```
Router# show cs7 accounting as sua_as_1 unroutable
```

```
Checkpoint Interval = 5 min
```

```
SUA AS = 'sua_as_1'
```

| DPC     | OPC   | SI | In Pkts | In Bytes | Out Pkts | Out Bytes |

# show cs7 as

To display AS and routing key information, use the **show cs7 as** privileged EXEC command.

```
show cs7 [instance-number] as [binding-table | [m3ua [include-gtt | exclude-gtt | only-gtt]] | [sua
[include-gtt | exclude-gtt | only-gtt]] | [all [include-gtt | exclude-gtt | only-gtt]] | [name
as-name]] [operational | active | all] [statistics | detail | brief | event-history]
```

| Syntax Description     |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>binding-table</b>   | Displays binding table.                                                       |
| <b>m3ua</b>            | Filters on M3UA.                                                              |
| <b>include-gtt</b>     | Includes ASes with GTT routing keys (the default).                            |
| <b>exclude-gtt</b>     | Excludes ASes with GTT routing keys.                                          |
| <b>only-gtt</b>        | Displays only those ASes with GTT routing keys.                               |
| <b>sua</b>             | Filters on SUA.                                                               |
| <b>all</b>             | Displays all ASes (the default).                                              |
| <b>name</b>            | Filters on AS name.                                                           |
| <i>as-name</i>         | AS name.                                                                      |
| <b>operational</b>     | Displays operational ASes (non-shut state).                                   |
| <b>active</b>          | Displays active ASes.                                                         |
| <b>statistics</b>      | Displays AS statistics                                                        |
| <b>detail</b>          | Displays information in detailed format.                                      |
| <b>brief</b>           | Displays information in brief format (the default).                           |
| <b>event-history</b>   | Displays AS history.                                                          |

**Defaults** The default display includes ASes with GTT routing keys.

**Command Modes** Privileged EXEC

|                 | 12.2(18)IXH<br>12.4(15)SW3<br>12.2(33)IRC | Enhanced the command output to display the binding table for an AS.                                                                |
|                 | 12.4(15)SW9<br>12.2(33)IRI                | Enhanced the command output to display SCCP class 2 binding feature.                                                               |

**Usage Guidelines**

The ASes and routing keys are displayed in order of priority (with the first entry having the highest priority).

ASes with GTT routing keys are displayed first.

The GTT ASes are ordered alphabetically based on the AS name.

ASes with non-GTT routing keys are grouped by DPC (highest to lowest).

ASes with the same DPC display the AS with the longest matching routing key at the highest layer in the protocol stack first.

**Examples****Syntax examples**

The following command shows how to display all M3UA ASes in detailed format:

```
show cs7 as m3ua detail
```

The following command shows how to display the AS named BLUE:

```
show cs7 as name blue
```

The following command shows how to display all non-GTT ASes (the default):

```
show cs7 as
```

The following command shows how to display the binding table for the AS:

```
show cs7 as binding-table
```

**Output examples**

If multi-instances have been enabled, the instance number is displayed after the colon in the displayed point code.

The following example includes output from the **show cs7 as** command with the **all** keyword. The display is in the default brief format.

```
ITP# show cs7 as all
```

| AS Name      | State | Context | Routing<br>Selector | GTT Routing Key<br>GTT Address |
|--------------|-------|---------|---------------------|--------------------------------|
| asname000012 | down  | 44      |                     |                                |
| green        | down  | 101     | 800TABLE            | 1123456789001                  |

# show cs7 asp

To display ASP information, use the **show cs7 asp** privileged EXEC command.

**show cs7** [*instance-number*] **asp** [**m3ua** | **sua** | **all** | **name** *asp-name* | **asname** *as-name*] [**statistics** | **detail**] | **bindings** | **detail** | **event-history**]

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>all</b>             | Displays all ASPs (the default).                                              |
| <b>asname</b>          | Filters on AS name.                                                           |
| <i>as-name</i>         | AS name.                                                                      |
| <b>bindings</b>        | Displays ASP bindings.                                                        |
| <b>detail</b>          | Displays detail format including the ASP.                                     |
| <b>event-history</b>   | Displays ASP history.                                                         |
| <b>m3ua</b>            | Filters on M3UA.                                                              |
| <b>name</b>            | Filters on ASP name.                                                          |
| <i>asp-name</i>        | ASP name.                                                                     |
| <b>statistics</b>      | Displays ASP statistics.                                                      |
| <b>sua</b>             | Filters on SUA.                                                               |

## Defaults

If no keyword is included, the **all** keyword takes effect.

Unless the **detail** keyword is included, the output defaults to brief format.

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release                                   | Modification                                            |
|-------------------------------------------|---------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.                            |
| 12.2(18)IXH<br>12.4(15)SW3<br>12.2(33)IRC | Output was enhanced with the remote ASP state field.    |
| 12.4(15)SW4<br>12.2(33)IRD                | Output was enhanced with the mate state field.          |
| 12.4(15)SW8<br>12.2(33)IRH                | Output was enhanced with the XUA error messages fields. |

## Usage Guidelines

In the brief format, an entry is displayed for each ASP/AS pair. The ASP name might appear multiple times if the ASP is in multiple ASes.

The AS name filter checks all ASes (regardless of GTT). You can check the remote ASP state by using the **detail** keyword.

## Examples

### Output of the detail format

The following example includes output from the **show cs7 asp** command in the **detail** format and filtering on the ASP name **asp1**. This ASP (type SUA) is down and the association state is closed. It is offloaded to the line card in slot 6.

AspVipId is an internal number used to identify the ASP.

Options for ASP state include: down/inactive/active/standby

The Mate state is the status of the remote ASP. Options include: inactive/active

If the ASP is down or shut down, the remote port and remote IP address display the configured values instead of the actual values.

**Note** Local receive window configured at SCTP or Port number level will take precedence and is effective for the system. All other levels have lower precedence.

```
ITP# show cs7 asp name asp1 detail
ASP name: asp1                               Type: SUA
Availability: enabled                         ASP id: n/a
SCTP association state: closed                Association id: n/a
AS name: asl                                ASP state: down    Mate state: inactive

SCTP congestion level: 0                   SCON congestion level: 0
Transmit queue depth: 1000
Thresholds for congestion on transmit queue
  Level 1 onset: 500                        Level 1 abate: 300
  Level 2 onset: 700                        Level 2 abate: 500
  Level 3 onset: 900                        Level 3 abate: 700
  Level 4 onset: 1000                       Level 4 abate: 900
QOS Class: 4 (instance:4) IP TOS: 0x60
Match Type: Any                            Class:4 (instance:4)
```

The following example shows ASP22, type M3UA, as active for 4 days and 20 hours. The association ID is 0x0301000B. This hexadecimal value can be used in the **show ip sctp association** command. ASP22 is not offloaded to a line card. ASP22 serves the AS as2 with traffic mode **loadshare roundrobin**.

```
ITP# show cs7 asp name asp22 detail
ASP name: asp22                               Type: M3UA

### Output of the event-history format

The **event-history** keyword displays events related to an XUA ASP. The following example includes output from the **show cs7 asp** command with the **event-history** keyword. The output details failed association attempts.

ITP# **show cs7 asp event-history**

Log of failed association attempts:

| AssocID  | RemotePort | LocalPort | RemoteIpAddr | TimeStamp         | ErrorReason   |
|----------|------------|-----------|--------------|-------------------|---------------|
| 15010016 | 1028       | 1024      | 10.2.2.155   | 07/05/06 16:15:54 | ASP not in AS |
| 15010017 | 1028       | 1024      | 10.2.2.155   | 07/05/06 16:15:54 | ASP not in AS |
| 15010018 | 1028       | 1024      | 10.2.2.155   | 07/05/06 16:15:54 | ASP not in AS |

The log size is capped at 5000 in a circular list formation. When 5000 is reached, the earliest entry is deleted and the new entry is added.

If XUA offload is running only on a Cisco 7600 router, the log is sent from the FlexWAN to the line card at a maximum of 100 every 10 seconds.

To clear the log, use the **clear cs7 asp event-history all** or **clear cs7 all** command.

If XUA offload is running only on a Cisco 7600 router, the timestamp refers to the time the log is received on the SUP, not to the time it occurs on the FlexWAN. The log is sorted by the most recent time on the SUP.

The ErrorReason field may list any of the following messages:

|                          |                                 |
|--------------------------|---------------------------------|
| "invalid association id" | /* 05 ASPM_INVALID_ASSOCID */   |
| "AVL insert failed"      | /* 14 ASPM_AVLINSERT_FAILED */  |
| "ASP not found"          | /* 16 ASPM_ASP_NOT_FOUND */     |
| "ASP not in AS"          | /* 25 ASPM_ASP_NOT_IN_AS */     |
| "invalid ASP state"      | /* 29 ASPM_INVALID_ASP_STATE */ |
| "ASP is shutdown"        | /* 32 ASPM_ASP_IS_SHUT */       |
| "protocol is shutdown"   | /* 33 ASPM_PROTOCOL_IS_SHUT */  |

### Related Commands

| Command                           | Description                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 asp</a>           | Specifies an application server process (ASP) and enables cs7 asp submode.                                  |
| <a href="#">cs7 sua</a>           | Specifies the local port number for SUA and enters cs7 sua submode                                          |
| <a href="#">cs7 m3ua</a>          | Specifies the local port number for M3UA and enters m3ua submode.                                           |
| <a href="#">show tech-support</a> | Collects and displays a large amount of ITP configuration information that can be used for troubleshooting. |

# show cs7 audit status

To display the latest audit begin time, end time, and audit status, use the **show cs7 audit status** command in Privileged EXEC mode. The display provides a sampling of information based on the current period.

**show cs7 audit status**

|                           |                                            |
|---------------------------|--------------------------------------------|
| <b>Syntax Description</b> | This command has no arguments or keywords. |
|---------------------------|--------------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                 |
|----------------------|-----------------|
| <b>Command Modes</b> | Privileged EXEC |
|----------------------|-----------------|

|                        |
|------------------------|
| <b>Command History</b> |
|------------------------|

|                 |                                                                                      |
|-----------------|--------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example includes output from the <b>show cs7 audit status</b> command: |
|-----------------|--------------------------------------------------------------------------------------|

```
ITP# show cs7 audit status
Component slot/cpu Status Begin-time End-time Success Fail Abort
GWS 1/0 SUCCESS 15:45:44 15:45:46 10 0 0
GWS 1/1 SUCCESS 15:45:44 15:45:45 10 0 0
MLR 1/0 ABORT 15:45:44 15:45:46 9 1 0
MLR 1/1 ABORT 15:45:45 15:45:45 9 0 1
```

ABORT means configuration changes occurred during the audit. SUCCESS means the configuration is consistent between the LC and RP. FAIL means the configuration is not consistent between the LC and RP.

|------------------|---------------------------|------------------------------------------------------------------------------|
|                  | <a href="#">cs7 audit</a> | Validates and audits the consistency of the content of the LC and SUP files. |

# show cs7 billing configuration

To display the cs7 billing configuration, use the **show cs7 billing configuration** command in Privileged EXEC mode.

**show cs7 billing configuration** [**account** *account-name* | **pc-table** | **options** | **load**]

## Syntax Description

|                     |                                                              |
|---------------------|--------------------------------------------------------------|
| <i>account-name</i> | Displays a configuration for a specific cs7 billing account. |
| <b>pc-table</b>     | Displays billing pc-table configuration.                     |
| <b>options</b>      | Displays billing options configuration.                      |
| <b>load</b>         | Displays billing configuration loading information.          |

## Defaults

The default **show cs7 billing config** with no optional keywords shows the entire billing configuration.

## Command Modes

Privileged EXEC

## Command History

## Examples

The following command displays the cs7 billing configuration loading information:

```
ITP# show cs billing config
cs7 instance 0 billing pc-table mymtp3table mtp3
  point-code 1.1.1 si 2
  point-code 1.1.1 si 4

cs7 instance 1 billing pc-table mysccp sccp
  point-code 1.1.1 gta 222 tt 2 gti 2
cs7 billing options
  backstore 0 ftp://10.74.57.210
```

## Related Commands

|--------------------------------------|---------------------------------------------------|
| <a href="#">cs7 billing pc-table</a> | Configures a pc-table for the billing account.    |
| <a href="#">cs7 billing options</a>  | Configures options for billing.                   |
| <a href="#">cs7 billing load</a>     | Specifies the billing configuration file to load. |

# show cs7 billing statistics

To display the latest collected billing statistics , use the **show cs7 billing statistics** command in Privileged EXEC mode.

**show cs7 billing statistics** [ **account** *acctnt-name* ] [ **type** { **mtp3** | **sccp** | **sms\_sccp** } ]

## Syntax Description

|                    |                                          |
|--------------------|------------------------------------------|
| <i>acctnt-name</i> | Displays a specific cs7 billing account. |
| <b>mtp3</b>        | Specifies the PC table type as MTP3.     |
| <b>sccp</b>        | Specifies the PC table type as SCCP.     |
| <b>sms_sccp</b>    | Specifies the PC table type as SMS.      |

## Defaults

None.

## Command Modes

Privileged EXEC

## Command History

| Release                    | Modification                           |
|----------------------------|----------------------------------------|
| 12.4(15)SW4<br>12.2(33)IRD | This command was introduced.           |
| 12.4(15)SW6<br>12.2(33)IRF | The keyword <b>sms_sccp</b> was added. |

## Examples

The following examples displays cs7 billing statistics information:

```
#show cs7 billing statistics

| show cs7 dcs-group | Displays information about the DCS group.                                                        |

# show cs7 dcs-group

To display information about the DCS group, use the **show cs7 dcs-group** privileged EXEC command.

**show cs7 dcs-group** *name*

| Syntax Description | <i>name</i> DCS group name. |
|--------------------|-----------------------------|
|--------------------|-----------------------------|

| Command Modes | Privileged EXEC |
|---------------|-----------------|
|---------------|-----------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.4(15)SW3 | This command was introduced. |
|                 | 12.2(33)IRC |                              |

**Examples** The following example includes output from the **show cs7 dcs-group** command:

ITP# **show cs7 dcs-group**

| DCS Group   | DCS Name    | State  | Cost |
|-------------|-------------|--------|------|
| -----       | -----       | -----  | ---- |
| polystar    | polystar    | active | 0    |
| to_itp_test | to_itp_test | down   | 0    |

| Related Commands | Command            | Description                                              |
|------------------|--------------------|----------------------------------------------------------|
|                  | cs7 pmp            | Turns probeless monitoring on for all linksets and ASes. |
|                  | cs7 pmp hold-queue | Sets the integer range of PMP hold queue thresholds.     |
|                  | cs7 dcs-group      | Identifies a name to be associated with a DCS group.     |
|                  | cs 7 dcs           | Identifies a name to be associated with a DCS node.      |
|                  | show cs7 pmp       | Displays errors and information about the PMP.           |
|                  | show cs7 dcs       | Displays information about the DCS node.                 |

# show cs7 group

To display ITP group operational information, use the **show cs7 group** privileged EXEC command.

**show cs7 group { counters [detailed] | state | transport }**

|                           |                  |                                           |
|---------------------------|------------------|-------------------------------------------|
| <b>Syntax Description</b> | <b>counters</b>  | Displays ITP group counters.              |
|                           | <b>detailed</b>  | Displays detailed counter information.    |
|                           | <b>state</b>     | Displays ITP group state information.     |
|                           | <b>transport</b> | Displays ITP group transport information. |

**Defaults** None.

**Command Modes** Privileged EXEC

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Examples** The following example shows how to display ITP group state information:

```
ITP# show cs7 group state
ITP Group state information:
  Redundancy Facility state:
    RF State           = 13 (ACTIVE)
    RF Peer State      = 8 (STANDBY HOT)
  Group role information:
    Current State:     Manager
    Previous State:    Negotiating
    Latest event:      NEGO_MANAGER
    Peer name:         group_member2
    Active timer:      none
  Checkpointing state:
    Last seq  sent:      549
    Last seq  rcvd:      0
    Congested:          FALSE
    Current send queue depth: 0
```

[Table 41](#) describes the significant fields shown in the display.

**Table 41** *show cs7 group state Field Descriptions*

| Field                    | Description                                                                  |
|--------------------------|------------------------------------------------------------------------------|
| RF State                 | Current Redundancy Facility state of this device                             |
| RF Peer State            | Current Redundancy Facility state of the group peer                          |
| Current State            | Current Group Finite State Machine (FSM) state                               |
| Previous State           | Group FSM state before latest FSM event                                      |
| Latest event             | Last FSM event processed                                                     |
| Peer name                | Name of group peer                                                           |
| Active timer             | Name of FSM timer running, or <b>none</b>                                    |
| Last seq # sent          | Sequence number of last Group Checkpointing message sent to group peer       |
| Last seq # rcvd          | Sequence number of last Group Checkpointing message received from group peer |
| Congested                | TRUE if congestion is present on communication transport to group peer       |
| Current send queue depth | Number of messages waiting to be sent to group peer                          |

The following example shows how to display ITP group counters information:

```
ITP# show cs7 group counters detail
Checkpointing counters:
  Messages sent:                10
  Messages received:            0
  Max depth reached by send queue: 5
  Requeues to send queue:      0
  Flow control ON indications:  0
  Flow control OFF indications: 0
  Message buffer alloc failures: 0
  Message transmission failures: 0
  Message acknowledgement failures: 0
  Send element alloc failures:  0
  Receive element alloc failures: 0
  Unrecognized messages received: 0
Messages counters:
  Bulk_Sync_Complete   : sent=2
  TPRC_Sync            : sent=2
  Linkset_Sync         : sent=2
  SCCP_Global_Meas     : sent=2
  MIB_seq              : sent=2

Group association drops : 0
RF association drops   : 0
CF association drops    : 0
```

**Related Commands**

| <a href="#">cs7 group</a>         | Configures the ITP group feature.                                                                           |
| <a href="#">show tech-support</a> | Collects and displays a large amount of ITP configuration information that can be used for troubleshooting. |

# show cs7 gtt address-conversion

To display CS7 GTT address-conversion entries, use the **show cs7 gtt address-conversion** privileged EXEC command.

**show** [*instance-number*] **cs7 gtt address-conversion** [*name*]

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <i>name</i>            | Displays output for a specified address-conversion table.                     |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example includes output from the **show cs7 gtt address-conversion** command:

ITP# **show cs7 gtt address-conversion**

Conversion Table Name: e212e214

New NP:

New NAI:

Ref Count: 1

|            |             |     |     |    |
|------------|-------------|-----|-----|----|
| in-address | out-address | np  | nai | es |
| -----      | -----       | --- | --- | 1  |
| 65507 1456 |             |     |     |    |

## Related Commands

|--------------------------------------------|--------------------------------------------|
| <a href="#">cs7 gtt address-conversion</a> | Configures a GTT address-conversion table. |

# show cs7 gtt application-group

To display CS7 GTT application group entries, use the **show cs7 gtt application-group** privileged EXEC command.

**show cs7** [*instance-number*] **gtt application-group** [**brief**] [**name** *app-grp-name*] [**rate-limit**]

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>brief</b>           | Displays a brief form of the output.                                          |
| <b>name</b>            | Displays a specific application group by name.                                |
| <i>app-grp-name</i>    | Application group name.                                                       |
| <b>rate-limit</b>      | Displays the rate-limit of DPC/AS in GTT application group wide.              |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release                                  | Modification                                                       |
|------------------------------------------|--------------------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                                       |
| 12.4(15)SW4<br>12.2(33)IRD               | The <b>rate-limit</b> keyword was introduced.                      |
| 12.4(15)SW8<br>12.2(33)IRH               | Output enhanced with the SCCP Class 1 load balance field.          |
| 12.4(15)SW9<br>12.2(33)IRI               | Output enhanced with <b>sccp-allow-pak-conv</b> conversion option. |

## Examples

The following example includes output from the **show cs7 gtt application-group** command:

```
ITP# show cs7 gtt application-group name abc
Application Group Name      : abc
Distribute-sccp-sequenced: Instance-level
sccp-class1-loadbalance   : Disabled
Multiplicity               : share
Ref Count                 : 0
Instance                  : 0
Application Identifier      RI    Cost  PCST  SST    CONGESTED  AS ST  SCCP-PAK-CONV-OPT
-----
PC=2222:1      SSN=2      pcssn  1    UNAVL  UNAVL  -----      1
PC=6880:0      SSN=2      gt      2    avail  -----
PC=3333:2      SSN=2      pcssn  2    UNAVL  UNAVL  -----      3
PC=6076:0      SSN=2      pcssn  3    avail  avail  -----
```

The following example includes output from the **show cs7 gtt application-group** command with the keyword **name**, the namen argument bbb and the keyword **rate-limit**:

```
ITP# show cs7 7 gtt application-group name bbb rate-limit
# of limited point: 2
      node id: 1504
      rate limit: 1000
configuration type: SCCP App Group Wide
      instance: 7
      xUA AS: ENUM-TITAN
Application Group: bbb

SLOT    QUOTA    IN_PKTS
1/0      1000      500
1/1       66       0
2/0       66       0
2/1       66       0
```

## Usage Guidelines

GTA-MATCH counters apply only for LC. Hence, the counters do not increment on SUP. If the command is executed on SUP, the output is zero for GTA\_MATCH counters.

## Examples

The following example includes output from the **show cs7 gtt gta** command for all GTAs on the selector named sell:

```
ITP# show cs7 gtt gta sell
Selector Name  TT   GTI  NP   NAI   QOS   PreGttConv   PostGttConv   #GTAs   Next-Table Name  NTT
-----
sell          0    2                -----
GTA           PC                RI      SSN   TT   App-Grp      QOS  ASname      PAM   GTA_MATCH
11100         1234:0            gt
SCCP-PAK-CONV-OPT PakConvCounter   PakDropCounter
```

# show cs7 gtt map

To display CS7 GTT MAP entries, use the **show cs7 gtt map** privileged EXEC command.

**show cs7** [*instance-number*] **gtt map** [**pc** *ppc* [**SSN** *ssn*]] [**status**]

| Syntax Description     |  |                                                                               |
|------------------------|--|-------------------------------------------------------------------------------|
| <i>instance-number</i> |  | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>pc</b>              |  | Specifies a primary point code.                                               |
| <i>ppc</i>             |  | Primary SS7 point code, in the form zone.region.sp.                           |
| <b>SSN</b>             |  | Specifies a subsystem number.                                                 |
| <i>ssn</i>             |  | Subsystem number ranging from 2 to 255.                                       |
| <b>status</b>          |  | Displays the status of the subsystems.                                        |

**Defaults** The default instance is 0.

**Command Modes** Privileged EXEC

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Examples** The following example includes output from the **show cs7 gtt map** command with no keywords:

```
ITP# show cs7 gtt map
  PPC      PSSN  MULT  BPC      BSSN  ConPCLst      RRC ADJ  Ref
2.2.2      10    sol   -----   ---              off no   1
2.2.3      10    sol   -----   ---              off no   1
2.2.4      10    sol   -----   ---              off no   1
```

The following example includes output from the **show cs7 gtt map** command with the **statistics** keyword. The output displays the real-time status of each entry in the GTT MAP table.

```
ITP# show cs7 gtt map statistics
 PC      SSN  PCST  SST  CONGESTED
 668      250  UNAVL  avail -----
1003      250  avail  avail -----
1008      250  avail  UNAVL -----
2020      250  avail  avail  level 2
```

[Table 43](#) describes the fields in the display.

**Table 43**      *show cs7 gtt map Field Descriptions*

| Field     | Description                              |
|-----------|------------------------------------------|
| PCST      | Point code status                        |
| SST       | Subsystem status                         |
| CONGESTED | MTP3 congestion level for the point code |

**Related Commands**

| Command                                  | Description                                                            |
|------------------------------------------|------------------------------------------------------------------------|
| <a href="#">cs7 gtt map</a>              | Creates a GTT mated-application entry.                                 |
| <a href="#">show cs7 gtt consistency</a> | Displays GTT point codes that do not have routes provisioned for them. |

# show cs7 gtt measurements

To display a summary of CS7 GTT/SCCP measurements, use the **show cs7 gtt measurements** privileged EXEC command.

```
show cs7 [instance-number] gtt measurements [[app-grp app-grp-name] | [counters] | [map] |
[selector [selector]] | [systot] | [line-card [line-card-num]]]
```

| Syntax Description     |  |                                                                                                                |
|------------------------|--|----------------------------------------------------------------------------------------------------------------|
| <b>app-group</b>       |  | Displays measurements kept on a GTT application group basis.                                                   |
| <i>app-grp-name</i>    |  | GTT application group name.                                                                                    |
| <b>counters</b>        |  | Displays Q.752 counters for GTT.                                                                               |
| <i>instance-number</i> |  | Specifies the instance. The valid range is 0 to 7. The default instance is 0.                                  |
| <b>line-card</b>       |  | Displays measurements kept on a line card basis.                                                               |
| <i>line-card-num</i>   |  | Line card number. If <i>line-card-num</i> is not specified, all measurements for all line cards are displayed. |
| <b>map</b>             |  | Displays measurements kept on a GTT MAP basis.                                                                 |
| <b>selector</b>        |  | Displays statistics kept on a GTT selector basis.                                                              |
| <i>selector</i>        |  | Displays statistics for a specified selector.                                                                  |
| <b>systot</b>          |  | Displays measurements kept on a system-wide basis.                                                             |

**Defaults**

If no keyword is specified, the system totals (systot) are displayed.

The default instance is 0.

**Command Modes**

Privileged EXEC

| Command History | Release                                  | Modification                                                       |
|-----------------|------------------------------------------|--------------------------------------------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                                       |

**Examples**

The following example shows output from the **show cs7 gtt measurements map** command:

```
ITP# show cs7 gtt measurements map
GTT/SCCP Mated Application Measurements Report

Point Code  SSN  USED      CONG_RR  PC_UNAV  SS_UNAV  PC_CONG  SS_CONG  MTP3_FAIL
2.2.2       10   0         0        0        0        0        0        0
2.2.3       10   0         0        0        0        0        0        0
2.2.4       10   0         0        0        0        0        0        0
```

## ■ show cs7 gtt measurements

The following example shows output from the **show cs7 gtt measurements selector** command with no selector specified:

```
ITP# sh cs7 gtt measurements selector
GTT/SCCP Selector Measurements Report

Selector Name  GTT_PERF      GTA_NF      sccpPakConvCounter  sccpPakDropCounter
si_ch          0              0              0                    0
sell           0              0              0                    0
selsample      0              0              0                    0
```

The following example shows output from the **show cs7 gtt measurements selector** command for the selector named sell:

```
ITP# sh cs7 gtt measurements selector sell
GTT/SCCP Selector Measurements Report

Selector Name  GTT_PERF      GTA_NF      sccpPakConvCounter  sccpPakDropCounter
sell           0              0              0                    0
```

The following example shows output from the **show cs7 gtt measurements systot** command:

```
ITP# show cs7 gtt measurements systot
GTT/SCCP System Wide Measurements Report

GTT_PERF      GTTSEL_NF      BAD_GT_FMT      GTA_NF      CONGEST_RR
0              0              0              0              0

GTT_HOP_ERR   GTT_MAP_NF      UNEQUIP_SS      SCCP_UNAV      DPC_UNAV
0              0              0              0              0

SS_UNAV       DPC_CONG      SS_CONG      MTP3_FAIL
0              0              0              0
```

The following example shows output from the **show cs7 gtt measurements app-grp app1** command which includes the total number of packets converted and packets dropped at the app-grp level:

```
ITP# show cs7 gtt measurements app-grp app1
Application Group Name: app1
Multiplicity          : share
Ref Count              : 0
Instance              : 0

Application Identifier RI    Cost  Used Class0    Class1    PakConvCounter  PakDropCounter
-----
PC=6871:0    SSN=2    pcssn 1    0    0              0              410              0
```

The following example shows output from the **show cs7 gtt measurements counters** command:

```
ITP_254# sh cs7 gtt measurements counters

Table 44 describes the fields in the display.

**Table 44** *show cs7 gtt measurements Field Descriptions*

| Field       | Description                                                                                                                                           |
|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| GTT_PERF    | Total number of successful translations performed                                                                                                     |
| GTTSEL_NF   | Total number of times a message requiring GTT was received with a TT, GTI, [NP, NAI] that did not exist in the GTT selector table                     |
| BAD_GT_FMT  | Total number of times a message requiring GTT was received with an invalid or unsupported format                                                      |
| GTA_NF      | Total number of times a message requiring GTT was received with a global title address that did not exist in the GTT table for the matching selector  |
| CONGEST_RR  | Total number of times a message requiring GTT was routed to an alternate backup route because of congestion                                           |
| GTT_HOP_ERR | Total number of times a message requiring GTT was received with a hop count that violated the rules concerning XUDT messages                          |
| GTT_MAP_NF  | Total number of times a message requiring GTT was received and final GTT was performed to a PC and SSN that were not provisioned in the GTT MAP table |
| UNEQUIP_SS  | Total number of times SCCP failed to route due to a subsystem being unequipped in the MAP table                                                       |
| SCCP_UNQUAL | The total number of times SCCP failed due to an error that is unqualified by any of the other errors listed.                                          |
| SCCP_UNAV   | Total number of times SCCP failed to route due to the SCCP subsystem being unavailable on a remote node                                               |
| DPC_UNAV    | Total number of times SCCP failed to route due to the destination point code being unavailable                                                        |
| SS_UNAV     | Total number of times SCCP failed to route due to the subsystem on a remote node being unavailable                                                    |

**Table 44**      *show cs7 gtt measurements Field Descriptions (continued)*

|           |                                                                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| DPC_CONG  | Total number of times SCCP failed to route due to the destination point code being congested                                                              |
| SS_CONG   | Total number of times SCCP failed to route due to the subsystem on a remote node being congested                                                          |
| MTP3_FAIL | Total number of times SCCP failed to route due to an MTP3 failure (a point code used in the GTT table has no configured route in the MTP3 routing tables) |

**Related Commands**

| Command                               | Description                                                                                                 |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">show cs7 gtt map</a>      | Displays a GTT mated-application entry.                                                                     |
| <a href="#">show cs7 gtt selector</a> | Displays GTT selectors.                                                                                     |
| <a href="#">show tech-support</a>     | Collects and displays a large amount of ITP configuration information that can be used for troubleshooting. |

# show cs7 gtt selector

To display CS7 GTT selectors, use the **show cs7 gtt selector** privileged EXEC command.

**show cs7** [*instance-number*] **gtt selector** [**gti** *gti*] [**nai** *nai*] [**name** *selector-name*] [**np** *np*] [**tt** *tt*]

| Syntax Description     |  |                                                                               |
|------------------------|--|-------------------------------------------------------------------------------|
| <i>instance-number</i> |  | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>gti</b>             |  | Specifies a global title indicator.                                           |
| <i>gti</i>             |  | Global title indicator. Valid range is 0 to 4.                                |
| <b>nai</b>             |  | Specifies a nature of address indicator.                                      |
| <i>nai</i>             |  | Nature of address indicator.                                                  |
| <b>name</b>            |  | CS7 GTT selector name.                                                        |
| <i>selector-name</i>   |  | Selector name.                                                                |
| <b>np</b>              |  | Specifies a numbering plan.                                                   |
| <i>np</i>              |  | Numbering plan.                                                               |
| <b>tt</b>              |  | Specifies a translation type.                                                 |
| <i>tt</i>              |  | Translation type.                                                             |

**Defaults** The default instance is 0.

**Command Modes** Privileged EXEC

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |

**Examples** The following example includes output from the **show cs7 gtt selector** command with no keywords:

```
ITP# show cs7 gtt selector
  Selector Name   TT   GTI   NP   NAI   DFLTQOS   #GTAs
  -----
c7gsp             0     4     1     3             3
itp_gtt           0     4     0     4             1
```

| Related Commands | Command                          | Description                            |
|------------------|----------------------------------|----------------------------------------|
|                  | <a href="#">cs7 gtt selector</a> | Creates and configures a GTT selector. |

# show cs7 gws action-set

To display ITP gateway screening action-set information, use the **show cs7 gws action-set EXEC** command.

**show cs7 gws action-set** [*name action-set-name*]

## Syntax Description

|                        |                                                                                   |
|------------------------|-----------------------------------------------------------------------------------|
| <b>name</b>            | Specifies the action set.                                                         |
| <i>action-set-name</i> | Name of the action set. Valid names can contain up to 12 alphanumeric characters. |

## Defaults

None.

## Command Modes

EXEC

## Command History

### Examples

The following example includes output from the **show cs7 gws action-set** command with no keywords:

```
ITP# show cs7 gws action-set
Action-set Name: ALLOW Action: allow Logging:
  Refcount:          42  NumUsed:          0

Action-set Name: BLOCK Action: block Logging:
  RefCount:           4  NumUsed:          0

Action-set Name: DONTALLOW Action: block Logging:
  RefCount:           0  NumUsed:          0

Action-set Name: ALWAYSALLOW Action: allow Logging:
  RefCount:           0  NumUsed:          0

Action-set Name: allowed-ver Action: allow Logging:
  RefCount:           0  NumUsed:          0

Action-set Name: blocked-ver Action: block Logging:
  RefCount:           1  NumUsed:          0
```

[Table 45](#) describes the fields in the display.

**Table 45** *show cs7 gws action-set Field Descriptions*

| Field            | Description                                                                            |
|------------------|----------------------------------------------------------------------------------------|
| Action-set Name: | Action set name                                                                        |
| Action:          | Action either to allow or to block                                                     |
| RefCount:        | Number of times the action set was used by entries in other tables                     |
| NumUsed:         | Number of times the action set was used in screening activity to allow or block an MSU |

**Related Commands**

| Command                            | Description                              |

**Examples** The following example includes output from the **show cs7 gws as** command with no keywords:

```
ITP# show cs7 gws as
AS name: 'default' Instance: 0 Screening: Enabled
  Inbound screening - not defined
  Outbound screening - not defined
AS name: dallas-as Instance: 0 Screening: Enabled
  Inbound Screening ---- Result: Table OPCALLOW
    Inbound Logging : type both file verbose
      MSUs Screened:      0, Allowed:      0, Blocked:      0
      MSUs Suspended:    0, Resumed:      0
  Outbound Screening ---- Result: Action-set ALLOW
    Outbound Logging : type both file verbose
      MSUs Screened:      0, Allowed:      0, Blocked:      0

AS name: dallas-sua Instance: 0 Screening: Enabled
  Inbound Screening ---- Result: Table OPCALLOW
    Inbound Logging : type both file verbose
      MSUs Screened:      0, Allowed:      0, Blocked:      0
      MSUs Suspended:    0, Resumed:      0
  Outbound Screening ---- Result: Action-set ALLOW
    Outbound Logging : type both file verbose
      MSUs Screened:      0, Allowed:      0, Blocked:      0
```

[Table 46](#) describes the fields in the display.

**Table 46** *show cs7 gws as Field Descriptions*

| Field                     | Description                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| AS name                   | AS name                                                                                                                                       |
| Instance                  | Instance number                                                                                                                               |
| Screening                 | Indicates whether screening is enabled or disabled (if corresponding CS7 AS is defined, field indicates <b>enabled</b> )                      |
| Inbound Screening         | Indicates whether inbound screening is defined and, if defined, indicates the result                                                          |
| Result                    | Result action set or table name                                                                                                               |
| Inbound Logging           | Logging parameters that have been configured                                                                                                  |
| MSUs Screened             | Number of MSUs screened                                                                                                                       |
| Allowed:                  | Number of MSUs allowed                                                                                                                        |
| Blocked:                  | Number of MSUs blocked                                                                                                                        |
| MSUs Suspended            | Indicates that, for CDPA screening, MSU screening is suspended for GTT                                                                        |
| Resumed:                  | Indicates that, after GTT, screening is resumed                                                                                               |
| Outbound Screening        | Indicates whether outbound screening is defined and, if defined, indicates the result                                                         |
| Outbound Logging          | Logging parameters that have been configured                                                                                                  |
| MSUs Screened             | Number of MSUs screened                                                                                                                       |
| Allowed:                  | Number of MSUs allowed                                                                                                                        |
| Blocked:                  | Number of MSUs blocked                                                                                                                        |
| Rate Limit                | The GWS rate limit traffic rate feature.                                                                                                      |
| MSUs Discarded silently   | Number of MSUs silently discarded when the rate limit of the GWS rate limit feature is exceeded.                                              |
| MSUs Discarded with error | Number of MSUs discarded with an error message sent when the sending of a return on error option is configured on the GWS rate limit feature. |

**Related Commands**

| Command                    | Description                                  |
|----------------------------|----------------------------------------------|
| <a href="#">cs7 gws as</a> | Specifies an AS table for gateway screening. |

# show cs7 gws config

To display the whole configuration of GWS, including global action sets, linksets, global table entries, tables, and table entries, use the **show cs7 gws config** command in EXEC mode.

**show cs7** [*instance-number*] **gws config**

| <b>Syntax Description</b>             | <i>instance-number</i> Specifies the instance. The valid range is 0 to 7. The default instance is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |         |             |                                    |                                                  |                                       |                                                                                     |                              |                                                                                                                            |                                 |                                                                                                           |

## Examples

The following example includes output from the **show cs7 gws counters** command:

```
Router# show cs7 gws counters
ITP-251#sh cs7 gws counters
GWS Counters instance:
SCCP unable to parse the packet:
Number of UDTs missed:
PC entry not found:
No valid entry for pcssn in table with scmg=0:
SI entry not found in table:
Entry corresponding to MTP3 message not found:
Entry corresponding to ISUP message not found:
Entry for message type is not found:
GTT selector not found in the table:
GTA entry not found in the table:
Invalid routing indicator:
Invalid number of concerned pc's:
Unsupported SCCP message type:
Screening count exceeds the maximum limit:
Action-set or table is not available in the result:
MLR routing info in gws action set is NULL:
Invalid global entry or inbound Screening not defined:
Outbound Screening not defined:
Entry for GWS Ls is invalid:
Default Entry for GWS Ls is invalid:
Ingress rate limit is crossed for LS:
Egress rate limit is crossed for LS:
Entry for GWS as is invalid:
Ingress rate limit is crossed for AS:
Egress rate limit is crossed for AS:
```

# show cs7 gws linkset

To display ITP gateway screening information for a linkset, use the **show cs7 gws linkset EXEC** command.

**show cs7** [*instance-number*] **gws linkset** [**name** *ls-name* | **default**]

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>name</b>            | Specifies the linkset.                                                        |
| <i>ls-name</i>         | Name of the linkset.                                                          |
| <b>default</b>         | Shows the default linkset information.                                        |

## Defaults

The default instance is 0.

## Command Modes

EXEC

## Command History

| Release                    | Modification                                                                                                                                  |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 12.4(15)SW1                | This command was introduced.                                                                                                                  |
| 12.2(18)IXE                | This command was introduced.                                                                                                                  |
| 12.4(15)SW6<br>12.2(33)IRF | This command was modified to show the number of MSUs discarded silently or with an error due to the rate limit feature on inbound screening.  |
| 12.4(15)SW7<br>12.2(33)IRG | This command was modified to show the number of MSUs discarded silently or with an error due to the rate limit feature on outbound screening. |

## Examples

The following example includes output from the **show cs7 gws linkset** command with no keywords:

```
ITP# show cs7 gws linkset name hsl_tg3_0
Linkset name: hsl_tg3_0 Instance: 0 Screening: Enabled
  Inbound Screening ---- Result: Action-set ac1
    Rate Limit timer : 60 Rate Limit Threshold---onset: 90 abate: 80 MSUs Screened :
1200, Allowed: 1200, Blocked: 0
    MSUs MLR routed : 0
    MSUs Suspended: 0, Resumed: 0
  Rate Limit
    MSUs Discarded silently: 20
  Outbound Screening ---- Result: Action-set ac1
    Egress Rate Limit timer : 5 Egress Rate Limit Threshold---onset: 80 abate: 60 MSUs
Screened : 2000, Allowed: 2000, Blocked: 0
    MSUs MLR routed : 0
    MSUs Suspended: 0, Resumed: 0
  Egress Rate Limit
    MSUs Discarded silently: 150
    MSUs Discarded with error: 0
```

[Table 47](#) describes the fields in the display.

**Table 47**      *show cs7 gws linkset Field Descriptions*

| Field                   | Description                                                                                                             |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Linkset name            | Linkset name.                                                                                                           |
| Instance                | Instance number.                                                                                                        |
| Screening               | Indicates whether screening is enabled or disabled (if corresponding CS7 linkset is defined, indicates <b>enabled</b> ) |
| Inbound Screening       | Indicates whether inbound screening is defined and, if defined, indicates the result                                    |
| Result                  | Result action set or table name                                                                                         |
| Inbound Logging         | Logging parameters that have been configured                                                                            |
| MSUs Screened           | Number of MSUs screened                                                                                                 |
| Allowed:                | Number of MSUs allowed                                                                                                  |
| Blocked:                | Number of MSUs blocked                                                                                                  |
| MSUs Suspended          | Indicates that, for CDPA screening, MSU screening is suspended for GTT                                                  |
| Resumed:                | Indicates that, after GTT, screening is resumed                                                                         |
| Outbound Screening      | Indicates whether outbound screening is defined and, if defined, indicates the result                                   |
| Outbound Logging        | Outbound logging parameters that have been configured                                                                   |
| MSUs Screened           | Number of MSUs screened                                                                                                 |
| MSUs Suspended          | Indicates that, for CDPA screening, MSU screening is suspended for GTT                                                  |
| Rate Limit              | The GWS rate limit traffic rate feature.                                                                                |
| MSUs Discarded silently | Number of MSUs silently discarded when the rate limit of the GWS rate limit feature is exceeded.                        |

**Examples**

The following example includes output from the **show cs7 gws table** command:

```
ITP# show cs7 gws table name OPCALLOW
```

```
Table Name:OPCALLOW Type:opc Action Type:allowed Instance:0
```

```

Start-PC      End-PC      Result
-----
default
3.3.3         3.3.4         Table al-cg-pcssn
3.3.5         Table al-cg-pcssn

```

The following example includes output from the **show cs7 gws table** command specified with the **detail** keyword:

```
ITP# show cs7 gws table name OPCALLOW detail
```

```
Table Name:OPCALLOW Type:opc Action Type:allowed Instance:0
```

```
Table Statistics:
```

```

-----
MSUs Screened :      0
MSUs Allowed  :      0
MSUs Blocked  :      0
Num Entries   :      2
Ref Count     :      2

```

```
Parameters:
```

```

-----
Default Result: Action-set ALLOW
Start PC: 3.3.3 End PC: 3.3.4
Result: Table al-cg-pcssn
MSUs Screened:  80
MSUs Allowed   :  60
MSUs Blocked   :  20
Start PC: 3.3.5
Result: Table al-cg-pcssn
MSUs Screened:  70
MSUs Allowed   :  30
MSUs Blocked   :  40

```

[Table 48](#) describes the fields in the display.

**Table 48** *show cs7 gws table Field Descriptions*

| Field             | Description                                             |
|-------------------|---------------------------------------------------------|
| Table Name        | Table name                                              |
| Type              | Table type                                              |
| Action Type       | Type of screening action performed (allowed or blocked) |
| Start-PC          | Starting pc in the range                                |
| End-PC            | Ending pc in the range                                  |
| Result            | Action set or table                                     |
| Table Statistics: |                                                         |
| MSUs Screened     | Number of MSUs screened                                 |
| MSUs Allowed      | Number of MSUs allowed                                  |

**Table 48**      *show cs7 gws table Field Descriptions (continued)*

| Field           | Description                                        |
|-----------------|----------------------------------------------------|
| MSUs Blocked    | Number of MSUs blocked                             |
| Num Entries     | Number of entries defined in this table            |
| Ref Count       | Number of times this table is referenced by others |
| Parameters:     |                                                    |
| Default Result  | Default result action set or table                 |
| Start PC End PC | Start and End point codes                          |
| Result          | Result action set or table                         |
| MSUs Screened   | Number of MSUs screened                            |
| MSUs Allowed    | Number of MSUs allowed                             |
| MSUs Blocked    | Number of MSUs blocked                             |

# show cs7 linkset

To display ITP linkset information, use the **show cs7 linkset** EXEC command.

**show cs7** [*instance-number*] **linkset** [*ls-name* | **cell** | **combined** | **routes** | **sls** | **state** | **statistics** | **timers** | **tmap** | **utilization**] [**brief** | **detailed**]

| Syntax Description     |  |                                                                               |
|------------------------|--|-------------------------------------------------------------------------------|
| <i>instance-number</i> |  | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>brief</b>           |  | Does not display individual links.                                            |
| <b>combined</b>        |  | Displays all combined linksets.                                               |
| <b>cell</b>            |  | Displays HSL cell counts for the linkset.                                     |
| <b>detailed</b>        |  | Displays detailed linkset information.                                        |
| <i>ls-name</i>         |  | Displays information for the specified linkset.                               |
| <b>routes</b>          |  | Displays all routes using a linkset.                                          |
| <b>sls</b>             |  | Displays SLC to SLS relationship.                                             |
| <b>state</b>           |  | Displays MTP3 states for link.                                                |
| <b>statistics</b>      |  | Displays link usage statistics.                                               |
| <b>timers</b>          |  | Displays timer values.                                                        |
| <b>tmap</b>            |  | Displays TT mappings for linkset.                                             |
| <b>utilization</b>     |  | Displays link utilization statistics.                                         |

**Defaults** The default instance is 0.

**Command Modes** EXEC

|                 | 12.4(15)SW3<br>12.2(33)IRC               | PMP status and assigned inbound and/or outbound DCS groups were added to the information displayed with the <b>detailed</b> keyword. |

**Usage Guidelines** The **cs7 util-plan-capacity** command must be configured globally or the **plan-capacity-rcvd** and **plan-capacity-send** commands must be configured in the cs7 link submode for a complete output of the **show cs7 linkset ls-name utilization** command.

## Examples

### Linkset States

- **UNAVAIL** Indicates the linkset does not have any “available” links and cannot transport traffic.
- **shutdown** Indicates the linkset has been shut down in the configuration.

- **avail** Indicates the linkset has at least one available link and can carry traffic.

#### Link States

- **UNAVAIL**

Indicates the link is not available to carry traffic. This unavailability can occur if the link is remotely or locally inhibited by a user. It can also be unavailable if MTP2 or M2PA has not been able to successfully activate the link connection, or the link test messages sent by MTP3 are not being acknowledged.

- **shutdown**

Indicates the link has been shut down in the configuration. A link is in this state when it is shut down at the MTP3 layer.

- **avail**

Indicates the link is active and able to transport traffic.

- **FAILED**

Indicates the link is not shut down but is unavailable at Layer 2 for some reason, or it is unavailable because it has been inhibited or blocked.

- **sys-shutdown**

Indicates the link has been shut down by the system. A link may be in this state when:

- MTP3 offload is configured and the system is performing error recovery on the line card.
- MTP3 offload has been permanently disabled on a line card by the system due to excessive errors. When MTP3 offload has been permanently disabled on a line card (by the system), all links on that line card are in the sys-shutdown state.

The following example includes output from the **show cs7 linkset** command with no keyword options:

```
ITP# show cs7 linkset
lsn=to_sandy      apc=1.4.2      state=avail      available/links=1/1
  SLC  Interface          Service  PeerState      Inhib

|                  | <a href="#">cs7 log</a>            | Enables the ITP to log events, errors, and traces.                                                                          |
|                  | <a href="#">cs7 log checkpoint</a> | Enables automatic archiving of a log to a remote or local destination at a specified interval of every <i>secs</i> seconds. |
|                  | <a href="#">cs7 save log</a>       | Saves a log to a file.                                                                                                      |

# show cs7 m2pa

To display ITP M2PA statistics, use the **show cs7 m2pa** EXEC command.

**show cs7 m2pa** [**congestion** *ls-name* | **local-peer** *port-num* | **peer** *ls-name* [*slc*] | **sctp** {**parameters** | **statistics**} *ls-name* [*slc*] | **state** *ls-name* [*slc*] | **statistics** *ls-name* [*slc*] | **timers** *ls-name* [*slc*]]

| Syntax Description     |  |                                                              |
|------------------------|--|--------------------------------------------------------------|
| <b>congestion</b>      |  | Displays M2PA congestion status.                             |
| <b>local-peer</b>      |  | Displays information about an M2PA local peer.               |
| <i>port-num</i>        |  | Port number of the local peer. Valid range is 4096 to 32767. |
| <b>peer</b>            |  | Displays information about an M2PA remote peer.              |
| <b>sctp parameters</b> |  | Displays SCTP peer parameters.                               |
| <b>sctp statistics</b> |  | Displays SCTP peer statistics.                               |
| <b>state</b>           |  | Displays the M2PA state machine status.                      |
| <b>statistics</b>      |  | Displays the M2PA peer statistics.                           |
| <b>timers</b>          |  | Displays M2PA timers for RFC.                                |
| <i>ls-name</i>         |  | Linkset name.                                                |
| <i>slc</i>             |  | Signaling link code. Valid range is 0 to 15.                 |

**Defaults** None.

**Command Modes** EXEC

| Command History | Release                                   | Modification                                                                                              |
|-----------------|-------------------------------------------|-----------------------------------------------------------------------------------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.                                                                              |
|                 | 12.2(18)IXH<br>12.4(15)SW3<br>12.2(33)IRC | The <b>show cs7 m2pa peer</b> command was added to verify that the large MSU feature is turned on or off. |

## Examples

The following example includes output from the **show cs7 m2pa** command using the **congestion** keyword with the linkset name (*ls-name* argument) **to\_nagshead**:

```
ITP#show cs7 m2pa congestion to_nagshead
```

```
CS7 M2PA Congestion Status for (50.0.0.5 : 4000)
```

```
RxCongestion status      : Abated          RxCongestionCount drops: 0
RxCongestionCount onset: 0          RxCongestionCount abate: 0
```

```
TxCongestion status      : Abated (Level0)
TxCongestionCount Level 1: 0          TxCongestionCount Level 2: 0
TxCongestionCount Level 3: 0          TxCongestionCount Level 4: 0
```

```

Tx Queue (max)      : 1000
Tx Queue (size)     : 0

Tx Level 1 onset    : 500 ( 50% of Tx Queue Depth)
Tx Level 2 onset    : 700 ( 70% of Tx Queue Depth)
Tx Level 3 onset    : 900 ( 90% of Tx Queue Depth)
Tx Level 4 onset    : 1000 (100% of Tx Queue Depth)

```

The following example includes output from the **show cs7 m2pa** command using the **local-peer** keyword with the port number (*port-num* argument) **9000**:

```

ITP#show cs7 m2pa local-peer 9000
CS7 M2PA Local Peer Info for local port = 9000

Local Port          = 9000
Local IP            = 172.18.44.163
SCTP Instance Handle: 8           Offload: No
Instance Local Recv Window: 64000 Instance maxInitRetrans: 8
Instance maxInitTimeout: 1000 ms  Instance Unordered Priority: EQUAL
Instance IP Precedence: 0

```

The following example includes output from the **show cs7 m2pa** command using the **peer** keyword with the linkset name (*ls-name* argument) **alpha**. The **show cs7 m2pa** command with the **peer** keyword displays the status of the large MSU feature with the field *Large MSU Supported*.

```

ITP#show cs7 m2pa peer alpha
CS7 M2PA internal Peer Control Block Info for (172.18.40.46 : 10001)

| Field                   | Description                                                       |
|-------------------------|-------------------------------------------------------------------|
| Peer Protocol           | Transport protocol used by M2PA                                   |
| Peer Port               | Remote peer port number                                           |
| Peer Address            | IP address of remote peer                                         |
| RTO                     | Retransmission timeout value for this remote IP address           |
| SRTT                    | Smoothed Round-Trip-Time for this remote IP address               |
| Primary Peer Address    | Primary remote IP address                                         |
| Effective Peer Address  | Effective remote IP address=50.50.50.2                            |
| Transport Handle        | Identifier assigned by transport layer to identify this peer link |
| Passive Peer            | Indicates whether the remote peer should initiate the connection  |
| M2PA Peer State         | State of the M2PA peer link                                       |
| SCTP Peer State         | State of the SCTP peer link                                       |
| Local Processor Outage  | Indicates whether local processor outage condition is present     |
| Remote Processor Outage | Indicates whether remote processor outage condition is present    |
| T1 aligned/ready        | T1 link alignment timer timeout                                   |
| T6 remote cong          | T6 remote congestion timer timeout                                |

**Table 51**      **show cs7 m2pa peer Field Descriptions (continued)**

| Field                    | Description                                                                                               |
|--------------------------|-----------------------------------------------------------------------------------------------------------|
| Local Recv Window        | Local receive window size                                                                                 |
| Remote Recv Window       | Remote receive window size                                                                                |
| InService LSSU Recv'd    | Indicates whether a Link Status In Service Signal Unit has been received                                  |
| Assoc Retransmission     | Maximum number of retransmissions allowed for the association                                             |
| Peer Init Retransmission | Maximum number of retries allowed for peer initialization packets                                         |
| Peer Init RTO Max        | Maximum retransmission timeout for peer initialization packets                                            |
| Peer Path Retransmission | Maximum number of retries before the corresponding address is marked inactive                             |
| Cumulative Sack Timeout  | Cumulative Acknowledgement timer                                                                          |
| Bundle Status            | Indicates whether bundling is enabled                                                                     |
| Bundle Timeout           | Maximum amount of time SCTP waits for messages from M2PA for bundling                                     |
| Minimum RTO              | Minimum retransmission timeout                                                                            |
| Maximum RTO              | Maximum retransmission timeout                                                                            |
| IP Precedence            | IP precedence bits setting in IP header for this peer                                                     |
| QoS                      | QoS class                                                                                                 |
| Keep Alive               | Indicates whether keepalives are enabled                                                                  |
| Keep Alive Timeout       | Keepalive timeout value                                                                                   |
| Initial cwnd             | Size in bytes of the SCTP initial congestion <i>window-size</i>                                           |
| Idle cwnd rate           | Rate at which the size of the SCTP congestion window is decreased due to the association being idle       |
| Retrans cwnd rate        | Rate at which the size of the SCTP congestion window is decreased due to retransmission timer expiration  |
| Retrans cwnd mode        | Congestion window is set for a fast retransmission                                                        |
| FastRetransmit cwnd rate | Rate at which the size of the SCTP congestion window is decreased due to a fast retransmission            |
| Tx Queue Depth           | Maximum allowed depth of transmitQ: (used by M2PA to determine txCongestion thresholds)                   |
| TxCongestionOnset Level1 | M2PA transmit congestion level threshold (value results from configuration of the tx-queue-depth command) |
| TxCongestionOnset Level2 | M2PA transmit congestion level threshold (value results from configuration of the tx-queue-depth command) |
| TxCongestionOnset Level3 | M2PA transmit congestion level threshold (value results from configuration of the tx-queue-depth command) |
| TxCongestionOnset Level4 | M2PA transmit congestion level threshold (value results from configuration of the tx-queue-depth command) |

**Table 51** *show cs7 m2pa peer Field Descriptions (continued)*

| Field               | Description                                           |
|---------------------|-------------------------------------------------------|
| Debug Mask          | Mask indicating which levels of M2PA debug are active |
| Large MSU Supported | Status of large MSU support                           |

[Table 52](#) describes the fields in the **show cs7 m2pa local-peer** display.

**Table 52** *show cs7 m2pa local peer Field Descriptions*

| Field                       | Description                                                                                                |
|-----------------------------|------------------------------------------------------------------------------------------------------------|
| Local Port                  | Value of local port number                                                                                 |
| Local IP                    | IP addresses assigned to this local peer                                                                   |
| SCTP Instance Handle        | Identifier assigned by transport to identify this local peer                                               |
| Instance Local Recv Window  | Current value of local receive window                                                                      |
| Instance maxInitRetrans     | Default number of retries of initialization packets for peers assigned to this local peer                  |
| Instance maxInitTimeout     | Default maximum transmission timeout for peer initialization packets for peers assigned to this local peer |
| Instance Unordered Priority | Indicates the priority by which unordered packets are delivered to MTP3                                    |
| Instance IP Precedence      | IP ToS setting used for peer link initialization packets                                                   |

# show cs7 m3ua

To display M3UA node information, use the **show cs7 m3ua** privileged EXEC command.

**show cs7** [*instance-number*] **m3ua** [*local-port* | **bundling-stats** | **queues** | **statistics**]

|                           |                        |                                                                               |
|---------------------------|------------------------|-------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
|                           | <i>local-port</i>      | M3UA local port number. Range is 1024 to 65535.                               |
|                           | <b>bundling-stats</b>  | CS7 M3UA bundling statistics.                                                 |
|                           | <b>queues</b>          | CS7 M3UA queues.                                                              |
|                           | <b>statistics</b>      | CS7 M3UA global statistics.                                                   |

**Defaults** The default instance is 0.

**Command Modes** Privileged EXEC

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|------------------------|----------------|------------------------------|
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Examples** The following example includes output from the **show cs7 m3ua** command.

This M3UA version uses SIGTRAN RFC 3332.

This M3UA instance (local port 7100) is **shutdown**. The instance handle is **inactive**.

This M3UA instance is *not* offloaded to any line card.

```
ITP# show cs7 m3ua 7100
```

```
Sigtran M3UA RFC number: 3332
```

```

M3UA Local port: 7100      State: shutdown      SCTP instance handle: inactive
Local ip address:                172.18.48.123
Number of active M3UA peers:      0
Max number of inbound streams allowed: 17
Local receive window:            64000
Max init retransmissions:        8
Max init timeout:                1000 ms
Unordered priority:              equal
Extended UPU support:            disabled
Offload to FlexWAN:              No      Slot: -1
SCTP defaults for new associations
Transmit queue depth: 1000      Cumulative sack timeout: 200 ms

**Related Commands**

| Command                           | Description                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 m3ua</a>          | Specifies the local port number for M3UA and enters cs7 m3ua submode.                                       |
| <a href="#">show tech-support</a> | Collects and displays a large amount of ITP configuration information that can be used for troubleshooting. |

New counters added to the command output include:

Current transaction error code counter increments with map error codes that correspond to the current transaction with CAR. For example, the error can be due to incorrect MAPUA configuration or inactive linkset/AS.

Unsuccessful decode of access request counter increments when the incoming packet cannot be decoded by ITP. This can happen due to the following reasons:

- Failed sanity check.
- Failed decryption of vendor attributes.
- Mismatch of secret configured at ITP.
- MAPUA Vendor Specific Attribute not present.
- MAPUA message authenticator attribute not present.

Invalid radius packet length counter increments when a RADIUS packet is dropped due to invalid length.

Jaguar# **show cs7 mapua statistics**

```

mapua EAP-SIM-Auth ip 10.78.170.198 port 1645 inQ 0 maxQ 0 rtt 0/0/0 ms
  Client      Port  Request In  Duplicate In  Accept Out  Reject Out
  10.78.164.40 00000      0           0           0           0

```

```

Current transaction error code      :          0

```

```

Input requests dropped

```

```

-----
Unsuccessful decode of access request:          0

```

```

Invalid length of radius packet      :          0

```

# show cs7 mated-sg

To display mated-sg information, use the **show cs7 mated-sg** privileged EXEC command.

**show cs7** [*instance-number*] **mated-sg** [**all** | **name** *name*] [**detail** | **event-history** | **fsm-history** | **statistics**]

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>detail</b>          | Displays the information in detailed format.                                  |
| <b>statistics</b>      | Displays mated-sg statistics.                                                 |
| <b>all</b>             | Displays all mated-sgs (the default).                                         |
| <b>detail</b>          | Displays detailed information on mated-sgs.                                   |
| <b>event-history</b>   | Displays mated-sg history.                                                    |
| <b>fsm-history</b>     | (Optional) Displays mated-sgs fsm history.                                    |
| <b>statistics</b>      | Displays mated-sgs statistics.                                                |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release                                   | Modification                                                                                    |
|-------------------------------------------|-------------------------------------------------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.                                                                    |
| 12.2(18)IXH<br>12.4(15)SW3<br>12.2(33)IRC | Enhanced the command output to include the running SGMP version with the <b>detail</b> keyword. |
| 12.2(33)IRD                               | Added the <b>fsm-history</b> keyword.                                                           |

## Examples

The following example includes output from the **show cs7 mated-sg** command in the default **brief** format:

Options for the SG Mate state include: Inactive/Active/Shutdown

If the Mate is shut down, then the remote port and remote IP address display the configured values instead of the actual values.

ITP# **show cs7 mated-sg**

| MATED-SG Name | AS Name  | State  | Type | Effect | Primary      | Rmt Port   | Remote IP Addr | SCTP |
|---------------|----------|--------|------|--------|--------------|------------|----------------|------|
| provencl1     | provence | active | SGMP | 9000   | 10.74.57.218 | 0xA0010028 |                |      |

The following example includes output from the **show cs7 mated-sg** command with the **fsm-history** keyword. The **fsm-history** keyword can display the status change of the status machine:

ITP# **show cs7 mated-sg fsm-history**

```
2008/12/25/10:14:12.239 Mated-sg: matedsg Event: SGMP_as_cfg_done
    FSM STATE: SGMP_idle -> SGMP_ready_to_go
2008/12/25/10:14:22.203 Mated-sg: matedsg Event: SGMP_T1_timer
    FSM STATE: SGMP_ready_to_go -> SGMP_sctp_connecting
```

The following example includes output from the **show cs7 mated-sg** command in **detail** format:

Options for SG Mate state include: Inactive/Active/Shutdown

ITP# **show cs7 mated-sg name provence11 detail**

```
Mated-sg name: provence11                                Type: SGMP

**Related Commands**

| Command                       | Description                            |
|-------------------------------|----------------------------------------|
| <a href="#">cs7 mated-sg</a>  | Configures a connection to a mated SG. |
| <a href="#">show cs7 sgmp</a> | Displays SGMP information.             |

# show cs7 mlr address-table

To display the addresses matched within the MLR address table, use the **show cs7 mlr address-table** privileged EXEC command.

**show cs7** [*instance-number*] **mlr address-table** [*name table-name*] | [**prefix** *digits*] | [**addr** *address*]

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>name</b>            | Filters on address table name.                                                |
| <i>table-name</i>      | The name associated with the multilayer result table.                         |
| <b>prefix</b>          | Filters on addresses prefixed with a specified digit string.                  |
| <i>digits</i>          | Digit string.                                                                 |
| <b>addr</b>            | Filters on matching addresses.                                                |
| <i>address</i>         | Digit string.                                                                 |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example includes output from the **show cs7 mlr address-table** command:

```
ITP# show cs7 1 mlr address-table B-ADDRS
```

```
-----
Name: B-ADDRS      Instance: 1
Table Lookups: 0
Address            Result Type-Address      Match
-----
09200800           PC   1-1-3                   0
09200800*          AS   smsc1                   0

|                        |                                                                                           |
|------------------------|-------------------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0.             |
| <b>name</b>            | Specifies a ruleset.                                                                      |
| <i>ruleset-name</i>    | Ruleset name. A valid ruleset name is a character string with a maximum of 12 characters. |
| <b>detail</b>          | Displays details about the MLR ruleset.                                                   |
| <b>result-summary</b>  | Displays a summary of results within an MLR table.                                        |
| <b>rule-summary</b>    | Displays a summary of all rules and operations.                                           |
| <b>sms-summary</b>     | Displays a summary of SMS rules within an MLR table.                                      |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example includes output from the **show cs7 mlr ruleset** command with no keywords. Output for all rulesets is displayed.

```
ITP# show cs7 mlr ruleset
Name: MLR1          Instance:0  Protocol: n/a
Rule Oper  dest-sme      orig-sme      dest-smsc      Matches
---- ----  -
10  sms-mo -          -              -              0
100 sms-mo Tbl:MLR1    -              -              0
201 sms-mo -          -              -              0
1000 all   n/a         n/a            n/a            0

Name: MLR2          Instance:0  Protocol: n/a      Event-trace:disabled
Rule Oper  dest-sme      orig-sme      dest-smsc      Matches
---- ----  -
2   smdpp -          -              n/a            0
4   sms-mo Tbl:MLR1    -              -              0
7   sms-mo 2323*      -              -              0
9   sms-mo -          -              -              0
10  sms-mo -          -              -              0
```

```

Name: MLR3          Instance:0  Protocol: n/a      Event-trace:disabled
Rule Oper   dest-sme          orig-sme          dest-smsc          Matches
----
10  sms-mo -                  -                  -                  0

```

The following example includes output from the **show cs7 mlr ruleset** command for a specified ruleset:

```

ITP# show cs7 mlr ruleset MLR1
Name: MLR1          Instance:0  Protocol: n/a
Rule Oper   dest-sme          orig-sme          dest-smsc          Matches
----
10  sms-mo -                  -                  -                  0
100 sms-mo Tbl:MLR1          -                  -                  0
201 sms-mo -                  -                  -                  0
1000 all    n/a              n/a              n/a              0
1100 default-rule

```

The following example includes output from the **show cs7 mlr ruleset** with the **rule-summary** keyword:

```

router# show cs7 mlr ruleset rule-summary

Shared opcodes with UNKNOWN MAP version : 0

```

Shared opcodes with UNKNOWN MAP version show the number of times a CONTINUE is received with no dialog and, therefore, no MAP version. The CONTINUE includes a component portion with the opcode value that is shared between different MAP versions.

If a CONTINUE is received with no dialog portion, no MAP version, and the component portion has a shared opcode value, the rule match algorithm looks for matching both operations in v1 and v1+. In the case where two rules are defined for these operations and both match, then the rule with the lesser order is considered the best match.

Table 53 describes the significant fields shown in the display.

**Table 53** *show cs7 mlr statistics Field Descriptions*

| Field                           | Description                                                                                                              |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| Instance                        | ITP instance for these MLR statistics                                                                                    |
| Total packets processed by MLR: | Total number of packets processed by MLR                                                                                 |
| Packets routed by MLR:          | Number of packets routed by MLR                                                                                          |
| Packets returned to SCCP:       | Number of packets returned to the SCCP layer for normal processing                                                       |
| Packets MLR failed or aborted:  | Number of packets dropped by MLR                                                                                         |
| <b>Trigger Matches</b>          |                                                                                                                          |
| Successful trigger matches:     | Number of packets that matched one or more MLR triggers                                                                  |
| Successful rule matches:        | Number of packets that matched a rule                                                                                    |
| Blocking rule matches:          | Number of packets that matched a rule that specifies the result <b>block</b> (drop the packet)                           |
| Continue rule matches:          | Number of packets that matched a rule that specifies the result <b>continue</b> (route the message as received)          |
| Blocking trigger matches:       | Number of packets that match a trigger that specifies the trigger action <b>block</b> (drop the packet)                  |
| Continue trigger matches:       | Number of packets that match a trigger that specifies the trigger action <b>continue</b> (route the message as received) |
| Result trigger matches          | Total number of trigger matches with a result trigger action                                                             |

**Table 53**      *show cs7 mlr statistics Field Descriptions (continued)*

| Field                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| ANSI-41 SMSNotification operations:                           | Number of SMSNotification operations                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>MLR multi-message-dialogue packets successfully parsed</b> | Multi-message-dialogue packets are segmented TCAP messages and concatenated SMS messages that span more than 1 packet. MLR processes multi-message-dialogues for sms-mo and sms-mt operations. Multi-message-dialogues include TCAP BEGIN messages that have no component, TCAP CONTINUE messages, TCAP BEGIN or CONTINUE messages containing an INVOKE component with the More-Messages-to-Send indicator (sms-mt only), and messages that are concatenated at the SMS layer. |
| Segmented Begin without component:                            | Number of packets processed with a TCAP BEGIN message containing no components                                                                                                                                                                                                                                                                                                                                                                                                 |
| Begin with MMS:                                               | Number of packets processed with a TCAP BEGIN message containing an INVOKE component with the More-Messages-To-Send indicator (sms-mt only)                                                                                                                                                                                                                                                                                                                                    |
| Segmented Continue:                                           | Number of packets processed with a TCAP CONTINUE message (including sms-mt messages with MMS)                                                                                                                                                                                                                                                                                                                                                                                  |
| Concatenated messages:                                        | Number of packets processed that are concatenated at the SMS layer. (This count is not mutually exclusive with the counts described above. A packet may be a segmented TCAP CONTINUE message and concatenated at the SMS layer.)                                                                                                                                                                                                                                               |
| <b>MLR Packets routed by MLR</b>                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Result action AS:                                             | Number of packets that matched a trigger and were processed by a rule that specified a result to route the message to a particular destination M3UA or SUA application server                                                                                                                                                                                                                                                                                                  |

| <b>MLR Packets returned to SCCP</b>  |                                                                                                                                                                                                                                                                                                                                                             |
| Unsupported SCCP message type:       | Number of packets of unsupported SCCP message type (not UDT or XUDT)                                                                                                                                                                                                                                                                                        |
| Unsupported segmented SCCP message:  | Number of unsupported segmented SCCP messages (XUDT with segmentation)                                                                                                                                                                                                                                                                                      |
| Trigger action continue:             | Number of packets that matched a trigger that specifies the trigger action <b>continue</b> (route the message as received)                                                                                                                                                                                                                                  |
| Unsupported messages:                | Number of packets that MLR was unable to parse due to unsupported TCAP message type, unsupported MAP operation, and so on                                                                                                                                                                                                                                   |
| Parsing error:                       | Number of packets that MLR was unable to parse due to malformed packet                                                                                                                                                                                                                                                                                      |
| Failed to match rule:                | Number of packets that failed to match any rule                                                                                                                                                                                                                                                                                                             |
| Result action continue:              | Number of packets that match a rule that specifies the rule action <b>continue</b> (route the message as received)                                                                                                                                                                                                                                          |
| Result action route:                 | Indicates the total number of MLR packets that select a result route specified on a <b>rule result</b> . These modified packets continue with their original routing.                                                                                                                                                                                       |
| No available result group member:    | Number of packets returned to SCCP due to no available result group members. Packets are returned to SCCP for routing when no member of a result group is available to route the packet and the unavailable-routing result option is enabled in the <b>cs7 mlr result</b> configuration command.                                                            |
| Failed to modify MSU:                | Indicates the total number of MSUs that failed MLR modification while <b>modify-failure</b> is configured as <b>resume</b> or <b>sccp-error</b> . MLR modification failures include exceeding the maximum MSU or address size when inserting new data, failures when attempting to modify the destination GT, and failures when executing a modify-profile. |
| Failed to match trigger:             | Number of packets that did not match a trigger                                                                                                                                                                                                                                                                                                              |
| <b>MLR Packets failed or aborted</b> |                                                                                                                                                                                                                                                                                                                                                             |
| Unparsed SCCP message:               | Number of unparsed SCCP messages that MLR received and dropped                                                                                                                                                                                                                                                                                              |
| Result block:                        | Number of packets that match a trigger or a rule that specifies the action <b>block</b> (drop the packet)                                                                                                                                                                                                                                                   |
| Destination unavailable              | Number of packets that MLR failed to route to an SCCP destination due to an unavailable destination                                                                                                                                                                                                                                                         |
| No available result group member:    | Number of packets failed or aborted due to no available result group members. Packets are discarded when no member of a result group is available to route the packet and the unavailable-routing discard option (default) is enabled in the <b>cs7 mlr result</b> configuration command.                                                                   |
| Failed to modify MSU:                | Indicates the total number of MSUs that failed MLR modification while <b>modify-failure</b> is configured as <b>discard</b> (default). MLR modification failures include exceeding the maximum MSU or address size when inserting new data, failures when attempting to modify the destination GT, and failures when executing a modify-profile.            |

**Table 53**      *show cs7 mlr statistics Field Descriptions (continued)*

| Field                                                          | Description                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MLR Packets that failed modifications</b>                   |                                                                                                                                                                                                                                                                                  |
| Unable to modify MAP address:                                  | Indicates the total number of MSUs that failed to modify a MAP address                                                                                                                                                                                                           |
| Unable to modify SCCP address:                                 | Indicates the total number of MSUs that failed to modify SCCP addresses (CgPA or CdPA):                                                                                                                                                                                          |
| Unable to rewrite packet with ri=gt for<br>result GT:        0 | <ul style="list-style-type: none"> <li>This existing statistic was moved to this new category. It indicates the total number of MSUs that failed to modify the CdPA with a GT result. In these cases, the packets were being modified from CdPA ri=ssn to CdPA ri=gt.</li> </ul> |
| Unable to convert GTA address:    0                            | <ul style="list-style-type: none"> <li>This existing statistic was moved to this new category. It indicates the total number of MSUs that failed to modify the CdPA GTA.</li> </ul>                                                                                              |

| Related Commands | Command                                | Description                                                                  |
|------------------|----------------------------------------|------------------------------------------------------------------------------|
|                  | <a href="#">rule (cs7 mlr ruleset)</a> | Specifies the rules for a routing trigger within a multilayer ruleset table. |

# show cs7 mlr table

To display multilayer SMS routing information, use the **show cs7 mlr table** privileged EXEC command. The default display is rule-summary.

**show cs7** [*instance-number*] **mlr table** *name* [**detail** | **result-summary** | **rule-summary** | **sms-summary**]

| Syntax Description     |                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance-number</i> | Displays output for a specified instance. Valid range is 0 to 7.                                                                                 |
| <i>name</i>            | The name of the CS7 MLR table.                                                                                                                   |
| <b>detail</b>          | Displays the parameters and results associated with each routing trigger.                                                                        |
| <b>result-summary</b>  | Displays the result parameters associated with a particular rule along with the number of times the rule has been matched for the given trigger. |
| <b>rule-summary</b>    | Displays the rule parameters associated with a particular rule along with the number of times the rule has been matched for the given trigger.   |
| <b>sms-summary</b>     | Displays a summary of SMS rules within an MLR table.                                                                                             |

**Defaults** The default display is rule-summary.

**Command Modes** Privileged EXEC

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Examples** The following example includes output from the **show cs7 mlr table** command:

```
ITP# show cs7 mlr table MLR

ITP# **show cs7 mlr table SMS-WEIGHTED detail**

Name: SMS-WEIGHTED

Trigger: MTP3 DPC: 1-1-1 OPC: N/A SI: 3

Rule: 1 Matches: 5

Operation: smdpp

Protocol: IS-41

Parameters:

Dest-SME: Address-Table SME-ADDRS Orig-SME: 60920025

Dest-SMSC: \* PID: \*

Result:

GT Selector: E.164 (default) Digits: 9991117777

```

-----
Rule: 2      Matches: 2
Operation: sms-mo
Protocol: GSM MAP
Parameters:
  Dest-SME: 60920080  Orig-SME: *
  Dest-SMSC: *        PID: *
Result:
  GT Selector: e164    Digits: 9991117778

```

```

-----
Rule: 3      Matches: 10
Operation: sms-mo
Protocol: IS-41

```

```

Parameters:
  Dest-SME:  6092*      Orig-SME:  *
  Dest-SMSC:  *         PID:      *
Result:
  Dest PC:   3.3.3
-----
Routing Trigger: 4      Matches:  0
Operation:  sms-mo
Protocol:   IS-41
Parameters:
  Dest-SME:  *         Orig-SME:  *
  Dest-SMSC:  *         PID       *
Result:
  GT Selector: E.164 (default) Digits: 9991117779

| Name            | Name of the CS7 MLR table.                                                                                                                                                                                                                                                                                                                                                                                              |
| Protocol        | Name of the protocol.                                                                                                                                                                                                                                                                                                                                                                                                   |
| Primary Trigger | SS7 network layer routing parameters that constitute the routing key, or trigger, used to identify traffic requiring parsing into the application layers.                                                                                                                                                                                                                                                               |
| Ruleset         | Name of the ruleset used to process matching triggers.                                                                                                                                                                                                                                                                                                                                                                  |
| Matches         | Total number of matches.                                                                                                                                                                                                                                                                                                                                                                                                |
| Rule            | The order in which the rules in the ruleset are searched.                                                                                                                                                                                                                                                                                                                                                               |
| Operation       | GSM MAP operation code. The operation name represents a multilayer routing feature that may comprise one or more actual MAP operations. In the current release, sms-mo is the only valid choice for this parameter.<br><br>sms-mo identifies SMS MO request messages for the table-appropriate protocol. This operation is valid for the GSM MAP, and matches all BEGIN requests containing an SMS-MO INVOKE component. |
| Dest-SME        | Address of the destination short message entity (SME) within an SMS operation.                                                                                                                                                                                                                                                                                                                                          |
| Orig-SME        | Address of the origin SME within an SMS operation.                                                                                                                                                                                                                                                                                                                                                                      |
| Dest SMSC       | Address of the destination service center address within an SMS operation.                                                                                                                                                                                                                                                                                                                                              |
| PID             | Protocol identifier value for an SMS-MO rule.                                                                                                                                                                                                                                                                                                                                                                           |
| Result          | Specifies the processing performed on a matching packet.                                                                                                                                                                                                                                                                                                                                                                |

|-------------------------------|---------------------------------------------------------|
| <a href="#">cs7 mlr table</a> | Specifies the name of the multilayer SMS routing table. |

# show cs7 msu-rates

To display information about SS7 MSU rates on a Cisco ITP platform, use the **show cs7 msu-rates** privileged EXEC command.

```
show cs7 msu-rates { configuration [slot] | current [slot] | distribution { msu [slot] | percentage [slot] | history [slot] }
```

## Syntax Description

|                      |                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------|
| <b>configuration</b> | Displays parameter information for the MSU rates.                                             |
| <b>current</b>       | Displays the current MSU rates.                                                               |
| <b>distribution</b>  | Displays the numbers of seconds within a certain percentage range or MSU range configuration. |
| <i>slot</i>          | (Optional) Specifies the slot that contains the processor (0 to 19).                          |
| <b>msu</b>           | Number of seconds with a certain MSU range.                                                   |
| <b>percentage</b>    | Number of seconds with certain percentage.                                                    |
| <b>history</b>       | Shows MSU rates history in graph format.                                                      |

## Defaults

None.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

Each ITP platform is rated to process a certain number of message signal units (MSUs) per second for each processor. Many high-level protocols require several MSUs per transaction. Traffic capacity planning is based on MSU rates, not on transactions. Consequently, when high CPU usage problems occur, it can be difficult to determine if the cause is directly related to high MSU rates.

The **cs7 msu-rates** commands enable the configuration, collection, and analysis of MSU rates per processor for all of the ITP platforms.

The **show cs7 msu-rates** commands display information about the configured MSU rate parameters.

## Examples

The examples in this section are intended only to describe the command parameters and the fields in the output display. They do not represent recommended configurations.

The following example includes output from the **show cs7 msu-rates** command with the **configuration** keyword. Notice that the Slot and Bay field values in the output are 0, indicating a single-processor platform.

```
ITP# show cs7 msu-rates configuration
```

```

Sample Interval:                3
Notification Interval:          60
Notification Enabled:           TRUE
Global Acceptable Threshold:    100
Global Warning Threshold:       200
Global Overloaded Threshold:    300

```

```

          Acceptable Warning  Overloaded
Slot Bay Threshold Threshold Threshold
-----
    0   0         100         150         200

```

Table 55 describes the fields displayed in the **show cs7 msu-rates configuration** output.

**Table 55** *show cs7 msu-rates configuration Field Descriptions*

| Field                 | Description                                                                                                                                                                     |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Slot                  | Specifies the slot that contains the processor. Applies only to those ITP platforms that support multiple processors.                                                           |
| Bay                   | Specifies the bay that contains the processor. Applies only to those ITP platforms that support multiple processors.                                                            |
| Sample Interval       | Configured interval, in seconds, over which MSU rates were calculated.                                                                                                          |
| Notification Interval | Configured interval, in seconds, used to prevent excessive generation of notifications.                                                                                         |
| Notification Enabled  | TRUE if enabled, FALSE if not enabled.                                                                                                                                          |
| Acceptable Threshold  | Configured rate of traffic, in MSUs per second. Traffic <i>at or below</i> this rate is acceptable.                                                                             |
| Warning Threshold     | Configured rate of traffic, in MSUs per second. Traffic <i>at or above</i> this rate and <i>below</i> the overload rate indicates a rate of traffic that may impact the device. |
| Overloaded Threshold  | Configured rate of traffic, in MSUs per second. Traffic <i>at or above</i> this rate indicates a rate of traffic that impacts operation of the device.                          |

The following example includes output from the **show cs7 msu-rates** command with the **current** keyword:

```

ITP# show cs7 msu-rates current
Slot Bay rx/tx  Rate  Size Max  Timestamp
-----
    1   0 receive    0   12   116 2006/06/01/14:05:15.878
    1   0  sent     0   12   116 2006/06/01/14:05:15.878

Table 56 describes the fields displayed in the **show cs7 msu-rates current** output.

**Table 56** *show cs7 msu-rates current Field Descriptions*

| Field     | Description                                                                                                           |
|-----------|-----------------------------------------------------------------------------------------------------------------------|
| Slot      | Specifies the slot that contains the processor. Applies only to those ITP platforms that support multiple processors. |
| Bay       | Specifies the bay that contains the processor. Applies only to those ITP platforms that support multiple processors.  |
| rx/tx     | Transmitted/Received MSUs.                                                                                            |
| Rate      | Current rate of MSUs per second.                                                                                      |
| Size      | Average size of MSU over last interval.                                                                               |
| Max       | Maximum rate of MSUs per second since last <b>clear</b> command.                                                      |
| Timestamp | Time and date when maximum rate of MSUs per second occurred.                                                          |

The following example includes output from the **show cs7 msu-rates** command with the **distribution** keyword:

```
ITP# show cs7 msu-rates distribution 6
Slot Bay Percent RX-Seconds TX-Seconds
-----
  6  0  >=090           0           0
  6  0  080-089           0           0
  6  0  070-079           0           0
  6  0  060-069          114          114
  6  0  050-059           0           0
  6  0  040-049           6           6
  6  0  030-039           0           0
  6  0  020-029           3           3
  6  0  010-019           3           3
  6  0  000-009        320631        320631
```

[Table 57](#) describes the fields displayed in the **show cs7 msu-rates distribution** output.

**Table 57** *cs7 msu-rates distribution Field Descriptions*

| Field      | Description                                                                                                                                                       |
|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Slot       | Slot that contains the processor on this ITP platform.                                                                                                            |
| Bay        | Bay that contains the processor (applies only to a FlexWAN device in the Cisco 7600 series platform; 0 indicates this field is not applicable for this platform). |
| RX-Seconds | Number of seconds that the <b>receive</b> MSU rate for this processor was within the specified range.                                                             |
| TX-Seconds | Number of seconds that the <b>transmit</b> MSU rate for this processor was within the specified range.                                                            |

## Related Commands

| Command                                             | Description                                                                                              |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 msu-rates notification-interval</a> | Configures the notification interval, in seconds, used to prevent excessive generation of notifications. |
| <a href="#">cs7 msu-rates sample-interval</a>       | Configures the sample interval, in seconds, over which MSU rates are calculated.                         |
| <a href="#">cs7 msu-rates threshold-default</a>     | Configures the global MSU rate threshold ranges and defaults for all processors in the ITP platform.     |
| <a href="#">cs7 msu-rates threshold-proc</a>        | Configures MSU rate threshold ranges for a specific processor, overriding the global thresholds.         |

# show cs7 mtp2

To display current modify-profiles and their statistics, use the **show cs7 mtp2** privileged EXEC command.

**show cs7 mtp2** [**congestion** | **state** | **statistics** | **timers** | **variant**] *serial interface*

## Syntax Description

|                         |                            |
|-------------------------|----------------------------|
| <b>congestion</b>       | MTP2 congestion status.    |
| <b>state</b>            | MTP2 state machine status. |
| <b>statistics</b>       | MTP2 link statistics.      |
| <b>timers</b>           | MTP2 timer values.         |
| <b>variant</b>          | MTP2 protocol variant.     |
| <b>serial interface</b> | Serial interface number.   |

## Defaults

None.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

This section includes samples of output from the **show cs7 mtp2** command using the keywords **congestion**, **state**, **statistics**, **timers**, and **variant**.

The following example includes output from the **show cs7 mtp2** command using the **congestion** keyword:

```
ITP# show cs7 mtp2 congestion serial0/1/0:0
CS7 MTP2 congestion status for interface Serial0/1/0:0
Protocol version for interface Serial0/1/0:0 is ITU-T Q.703 (1996) (White Book)
```

```
Layer3 congestion status      = Abate

CongestionRxInd               = Abate
CongestionTxInd               = Abate (Level0)

CongestionTxOnset Level1      = 250 ( 50% of xmitQ maxDepth)
CongestionTxOnset Level2      = 350 ( 70% of xmitQ maxDepth)
CongestionTxOnset Level3      = 450 ( 90% of xmitQ maxDepth)
CongestionTxOnset Level4      = 500 (100% of xmitQ maxDepth)

XmitQ depth (max-used)        = 1
XmitQ depth (max-allowed)     = 500
```

[Table 58](#) describes the fields in the display.

**Table 58**      **show cs7 mtp2 congestion Field Descriptions**

| Field                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Layer3 congestion status | <p>Receive congestion status at Layer 3 (that is, MTP3).</p> <p>Possible values are:</p> <ul style="list-style-type: none"> <li>• Abate =. MTP3 not congested. MTP2 may forward packets to MTP3.</li> <li>• Onset = MTP3 congested. MTP2 may <i>not</i> forward packets to MTP3.</li> </ul> <p>During Layer 3 congestion onset, MTP2 sends SIBs to the remote to indicate the route is “Busy” and cannot accept input packets.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CongestionRxInd          | <p>Receive congestion status at Layer 2 (that is, MTP2).</p> <p>Possible values are:</p> <ul style="list-style-type: none"> <li>• Abate = MTP2 not congested. Remote may send packets to MTP2.</li> <li>• Onset = MTP2 congested. Remote may <i>not</i> send packets to MTP2.</li> </ul> <p>During MTP2 congestion onset, MTP2 sends SIBs to the remote to indicate the route is “Busy” and cannot accept input packets.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| CongestionTxInd          | <p>Transmit congestion status at Layer 2 (that is, MTP2).</p> <p>Possible values are:</p> <ul style="list-style-type: none"> <li>• Abate (Level0) = MTP2 not congested. MTP3 may send packets to MTP2.</li> <li>• Onset (Level1) = MTP2 congested. MTP3 may send priority 1+ packets.</li> <li>• Onset (Level2) = MTP2 congested. MTP3 may send priority 2+ packets.</li> <li>• Onset (Level3) = MTP2 congested. MTP3 may send priority 3+ packets.</li> <li>• Onset (Level4) = MTP2 congested. MTP3 may <i>not</i> send packets to MTP2.</li> </ul> <p>The levels correspond to ANSI congestion levels. (ITU has a similar option.)</p> <p>MTP3 packets have an associated priority (0 to 3).</p> <p>For example, if CongestionTxInd is Onset (Level2), MTP3 may continue sending packets with a priority of 2 or higher, but must drop any packets with a priority of 1 or lower.</p> |

**Table 58** *show cs7 mtp2 congestion Field Descriptions (continued)*

| Field                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CongestionTxOnset Level1        | MTP2 transmit congestion level thresholds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| CongestionTxOnset Level2        | MTP2 determines its txCongestion level as a percentage of packets waiting on its transmitQ (that is, XmitQ depth (max-allowed)).                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CongestionTxOnset Level3        | <p>The thresholds are documented in this output (and may <i>not</i> be configured or changed by the user).</p> <p>The XmitQ depth (max-allowed) value is configurable by the user and the new threshold values are reflected in the output.</p> <p>For example, if you configure a new xmitQ maxDepth via cs7 mtp2 transmitQ 256:</p> <p>CongestionTxOnset Level1 = 128 ( 50% of xmitQ maxDepth)</p> <p>CongestionTxOnset Level2 = 179 ( 70% of xmitQ maxDepth)</p> <p>CongestionTxOnset Level3 = 230 ( 90% of xmitQ maxDepth)</p> <p>CongestionTxOnset Level4 = 256 (100% of xmitQ maxDepth)</p> |
| CongestionTxOnset Level4        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| OMtimeNotINSV (secs)    | Length of time link has been out of service                |
| OMIACAlignAttemptCount  | Number of times IAC has attempted link alignment           |
| OMIACAlignFailCount     | Number of times alignment attempt has failed               |
| OMIACAlignCompleteCount | Number of times alignment attempt has succeeded            |
| OMMSU_L3_XMIT_Count     | Number of MSUs queued from Layer 3 for transmit            |
| OMMSU_XMIT_Count        | Number of MSUs actually transmitted (includes retransmits) |
| OMMSUBytesTransmitted   | Number of MSU bytes transmitted (includes retransmits)     |

**Table 60** *show cs7 mtp2 statistics Field Descriptions (continued)*

| Field                   | Description                                                  |
|-------------------------|--------------------------------------------------------------|
| OMMSU_RE_XMIT_Count     | Number of MSU retransmitted                                  |
| OMMSUBytesRetransmitted | Number of MSU bytes retransmitted                            |
| OMMSU_RCV_Count         | Number of MSUs received                                      |
| OMBytesReceived         | Number of MSU bytes received                                 |
| OMFISU_XMIT_Count       | Number of FISUs transmitted (not counting autoTx-FISU)       |
| OMFISU_RCV_Count        | Number of FISUs received (not counting filtered-FISU)        |
| OMLSSU_XMIT_Count       | Number of LSSUs transmitted (not counting autoTx-LSSU)       |
| OMLSSU_XMIT_SINCount    | Number of SINS transmitted (not counting autoTx-LSSU)        |
| OMLSSU_XMIT_SIECount    | Number of SIEs transmitted (not counting autoTx-LSSU)        |
| OMLSSU_XMIT_SIOCount    | Number of SIOs transmitted (not counting autoTx-LSSU)        |
| OMLSSU_XMIT_SIOSCount   | Number of SIOSs transmitted (not counting autoTx-LSSU)       |
| OMLSSU_XMIT_SIPOCount   | Number of SIPOs transmitted (not counting autoTx-LSSU)       |
| OMLSSU_XMIT_SIBCount    | Number of SIBs transmitted (not counting autoTx-LSSU)        |
| OMLSSU_RCV_Count        | Number of LSSUs received (not counting filtered-LSSU)        |
| OMLSSU_RCV_SINCount     | Number of SINS received (not counting filtered-LSSU)         |
| OMLSSU_RCV_SIECount     | Number of SIEs received (not counting filtered-LSSU)         |
| OMLSSU_RCV_SIOCount     | Number of SIOs received (not counting filtered-LSSU)         |
| OMLSSU_RCV_SIOSCount    | Number of SIOSs received (not counting filtered-LSSU)        |
| OMLSSU_RCV_SIPOCount    | Number of SIPOs received (not counting filtered-LSSU)        |
| OMLSSU_RCV_SIBCount     | Number of SIBs received (not counting filtered-LSSU)         |
| OMT1_TMO_Count          | Number of times T1 timer has expired                         |
| OMT2_TMO_Count          | Number of times T2 timer has expired                         |
| OMT3_TMO_Count          | Number of times T3 timer has expired                         |
| OMT4_TMO_Count          | Number of times T4 timer has expired                         |
| OMT5_TMO_Count          | Number of times T5 timer has expired                         |
| OMT6_TMO_Count          | Number of times T6 timer has expired                         |
| OMT7_TMO_Count          | Number of times T7 timer has expired                         |
| OMAERMCCount            | Number of times AERM has been activated                      |
| OMAERMFaileCount        | Number of times AERM has failed                              |
| OMSUERMCount            | Number of times SUERM has been activated                     |
| OMSUERMFaileCount       | Number of times SUERM has failed                             |
| OMCongestionRxCount     | Number of times link has entered RxCongestionOnset           |
| OMCongestionTxCount     | Number of times link has entered TxCongestionOnset           |
| OMRemote_Congestion_Cnt | Number of times remote has gone into RxCongestion            |
| OMxmitQ_maxcount        | Maximum number of packets that were allowed to wait on xmitQ |
| OMNACK_XMIT_Count       | Number of negative acknowledgements transmitted on link      |

**Table 60** *show cs7 mtp2 statistics Field Descriptions (continued)*

| Field                   | Description                                                            |
|-------------------------|------------------------------------------------------------------------|
| OMNACK_RCV_Count        | Number of negative acknowledgements received on link                   |
| OMunreasonableFSN_rcvdv | Number of invalid FSNs received from remote                            |
| OMunreasonableBSN_rcvd  | Number of invalid BSNs received from remote                            |
| OMabnormalBSN_rcvd      | Number of abnormal BSNs received from remote (2 invalid BSNs in a row) |
| OMabnormalFIB_rcvd      | Number of abnormal FIBs received from remote (2 invalid FIBs in a row) |
| OMFISU_notAccepted      | Number of FISUs dropped due to MTP2 NoAccept state                     |
| OMMSU_notAccepted       | Number of FISUs dropped due to MTP2 NoAccept state                     |
| OMFISU_congestionDrops  | Number of FISU packets dropped due to rxCongestion                     |
| OMMSU_congestionDrops   | Number of MSU packets dropped due to rxCongestion                      |
| OMMSU_too_long          | Number of MSUs dropped due to exceed max pakSize                       |
| OMMSU_unexpectedFSN     | Number of MSU packets dropped due to unexpected FSN received           |
| OMMSU_discarded         | Number of MSUs dropped (total)                                         |

The following example includes output from the **show cs7 mtp2** command using the **timers** keyword. The variant is TTC.

```
ITP# show cs7 mtp2 timers serial0/1/0:0
CS7 MTP2 Timers for interface Serial0/1/0:0 (in milliseconds)
Protocol version for interface Serial0/1/0:0 is ITU-T Q.703 (1996) (White Book)
```

```
t1 (aligned/ready)      = 15000
t2 (not aligned)        = 5000
t3 (aligned)            = 3000
t4 (emergency proving)   = 3000
t4 (normal proving)      = 200
t5 (sending SIB)        = 100
t6 (remote congestion)  = 3000
t7 (excess ack delay)   = 3000
tx (TTC timers)         = 24
```

Table 61 describes the fields in the display.

**Table 61** *show cs7 mtp2 timers Field Descriptions*

| Field                        | Description                                                                                        |
|------------------------------|----------------------------------------------------------------------------------------------------|
| T1 (aligned/ready) = 40000   | Alignment ready timer. ANSI default is 13000 milliseconds. ITU default is 40000 milliseconds.      |
| T2 (not aligned) = 5000      | Not aligned timer. ANSI default is 11500 milliseconds. ITU default is 5000 milliseconds.           |
| T3 (aligned) = 1500          | Aligned timer. ANSI default is 11500 milliseconds. ITU default is 1500 milliseconds.               |
| T4 (emergency proving) = 500 | Emergency proving period timer. ANSI default is 600 milliseconds. ITU default is 500 milliseconds. |

**Table 61** *show cs7 mtp2 timers Field Descriptions (continued)*

| Field                         | Description                                                                                                   |
|-------------------------------|---------------------------------------------------------------------------------------------------------------|
| t4 (normal proving) = 8200    | Normal proving period timer. ANSI default is 2300 milliseconds. ITU default is 8200 milliseconds.             |
| t5 (sending SIB) = 100        | Sending SIB timer. ANSI default is 80 milliseconds. ITU default is 100 milliseconds.                          |
| t6 (remote congestion) = 3000 | Remote congestion timer. ANSI default is 1000 milliseconds. ITU default is 3000 milliseconds.                 |
| t7 (excess ack delay) = 1000  | Excessive delay of acknowledgment timer. ANSI default is 1000 milliseconds. ITU default is 1000 milliseconds. |
| tx (TTC timers) = 24          | TTC timers (TA, TF, TO, TS). Default is 20 milliseconds.                                                      |

**Note**

Ranges are defined by ANSI or ITU.

The following example includes output from the **show cs7 mtp2** command using the **variant** keyword:

```
ITP# show cs7 mtp2 variant serial0/1/0:0
Protocol version for interface Serial0/1/0:0 is ITU-T Q.703 (1996) (White Book)
```

[Table 62](#) describes the fields in the display.

**Table 62** *show cs7 mtp2 variant Field Descriptions*

| Field                                                                           | Description                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol version for interface Serial0/1/0:0 is ITU-T Q.703 (1996) (White Book) | Identifies the variant supported on the interface. Possible values are: <ul style="list-style-type: none"> <li>ansi ANSI SS7 protocol variant</li> <li>china CHINA SS7 protocol variant</li> <li>itu ITU SS7 protocol variant</li> <li>ttc Japan TTC SS7 protocol variant</li> </ul> |

**Related Commands**

| Command                    | Description                                                                         |
|----------------------------|-------------------------------------------------------------------------------------|
| <a href="#">mtp2-timer</a> | Tunes MTP2 encapsulation timers or specifies the threshold for transmit congestion. |

# show cs7 mtp3 counters

To display the MTP3 counter for MSUs dropped due to failed OPC verification, use the **show cs7 mtp3 counters** EXEC command.

**show cs7** [*instance-number*] **mtp3 counters**

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
|------------------------|-------------------------------------------------------------------------------|

## Defaults

The default instance is 0.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXG | This command was introduced. |
| 12.4(15)SW2 |                              |
| 12.2(33)IRB |                              |

## Examples

The following example includes output from the **show cs7 mtp3 counters** command:

```
ITP# show cs7 mtp3 counters
Instance: 0
Counter Value
-----
OPC Verif Fail 99999
```

## Related Commands

| Command                                     | Description                  |
|---------------------------------------------|------------------------------|
| <a href="#">show cs7 mtp3 event-history</a> | Displays MTP3 logged events. |

# show cs7 mtp3 errors

To display a list of MTP errors, use the **show cs7 mtp3 errors** EXEC command.

## show cs7 mtp3 errors

**Syntax Description** This command has no arguments or keywords

**Defaults** None.

**Command Modes** EXEC

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |
|                 |             |                              |

**Examples** The following example includes output from the **show cs7 mtp3 errors** command. The error type is preceded by the number of occurrences of the error.

```
ITP# show cs7 mtp3 errors
32      - Undefined Error Type
19      - SLT undefined OPC
4       - MTP3 Management process not started
```

[Table 63](#) provides descriptions of the various types of MTP errors encountered on the devices supporting the IP Transfer Point product. The errors are listed in alphabetical order.

**Table 63** *show cs7 mtp3 errors*

| Error                           | Description                                                                                                                                                                     |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ACL received linkset match      | Access list applied to all MSUs arriving on a linkset matched and the result was to drop MSUs.                                                                                  |
| ACL send linkset match          | Access list applied to all MSUs to be transmitted on a linkset matched and the result was to drop MSUs.                                                                         |
| AS not found for routingContext | Unable to locate routing context for application service. No error message is issued and packet is dropped.                                                                     |
| Denied                          | Packet was received and an output linkset was selected. The destination point code was denied (TFP) or an access list outbound linkset indicated that packet should be dropped. |
| Detected looping packet         | A packet was received that specified OPC that matches the signaling points primary or secondary point codes. The packet is dropped and no messages are issued.                  |

**Table 63**      *show cs7 mtp3 errors (continued)*

| Error                                          | Description                                                                                                                                                                                                                                                                        |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Failure inserting M3UA headers in message      | Unable to insert necessary information into header of M3UA message. No error message is issued and packet is dropped.                                                                                                                                                              |
| Failure to locate active ASP                   | Unable to locate active application server process. No error message is issued and packet is dropped.                                                                                                                                                                              |
| HMRT event overflow                            | The signaling message handling - message routing queue has reached limit and MSU is discarded without error message being issued.                                                                                                                                                  |
| Incorrect HO value in SLTC message             | A packet was received that contained an incorrect value for H0 field. An error message is logged to console indicating source of packet and packet is dropped.                                                                                                                     |
| Incorrect H1 value in SLTC message             | A packet was received that contained an incorrect value for H1 field. An error message is logged to console indicating source of packet and packet is dropped.                                                                                                                     |
| Incorrect link type                            | A packet was received that contained an undefined link type in "lp->type" field, probably because of a software error. Packet is dropped without issuing error message.                                                                                                            |
| Incorrect Network Indicator received in packet | A packet was received with a different network indicator. The packet is dropped.                                                                                                                                                                                                   |
| Incorrect peer protocol                        | Error type not currently used.                                                                                                                                                                                                                                                     |
| Incorrect SCTP link status                     | Error type not currently used.                                                                                                                                                                                                                                                     |
| Incorrect SCTP stream number                   | Error type not currently used.                                                                                                                                                                                                                                                     |
| Invalid packet size (MSU size exceeded)        | An MSU was received that exceeded specified limit. No error message is issued and packet is dropped.                                                                                                                                                                               |
| Link event discarded (verification failed)     | An MTP3 event was queued for processing. However, event cannot be processed because the target resource does not exist. This situation can occur when links or linkset are not configured. MTP3 event is discarded without issuing error message.                                  |
| Local Point Code not defined                   | A packet was received before local point code was defined. The packet is dropped.                                                                                                                                                                                                  |
| MTP3 Management process not started            | A packet was received and did not contain a valid link pointer in packet.                                                                                                                                                                                                          |
| Multi-layer Routing abort                      | An MSU processed by multilayer routing has matched rule indicating it should be aborted. No error message is issued and packet is dropped.                                                                                                                                         |
| No instance                                    | An MSU was received on a link and the instance information is inconsistent. This situation can occur when instances are removed or linksets are moved between instances. It may also occur as a byproduct of some software error. MSU is discarded without issuing message to log. |
| No link                                        | An MSU was received that specified a destination point code. The output linkset did not have any operational links. MSU is dropped and no error messages are displayed.                                                                                                            |

**Table 63**      *show cs7 mtp3 errors (continued)*

| Error                           | Description                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| No link pointer in packet       | A packet was received and did not contain a valid link pointer in packet.                                                                                                                                                                                                                                                                                                            |
| No linkset                      | An MSU was received that specified a destination point code. The destination was either unavailable from the reception of TFP or no route had been configured to destination. MSU is dropped and no error messages are displayed.                                                                                                                                                    |
| No memory for cs7_info chunk    | An MSU was received but could not be processed because necessary additional storage was unavailable. No error message is issued. Packet is dropped.                                                                                                                                                                                                                                  |
| No memory for SCTP buffer       | A packet was received but could not be processed because the SCTP layer was unable to obtain packet buffer. No error message is issued. Packet is dropped.                                                                                                                                                                                                                           |
| Received partial SCTP buffer    | A partial packet was received and could not be processed by SCTP layer. No error message is issued. Packet is dropped.                                                                                                                                                                                                                                                               |
| Remote congestion               | A link used to transport MSU to next Signaling point is congested. MSUs are discarded as required by congestion control. Messages are logged to console when link enters and exits congestions.                                                                                                                                                                                      |
| Send failure                    | An error occurred when attempting to send packet on link. Packet is dropped without issuing error message.                                                                                                                                                                                                                                                                           |
| SLT failed                      | <p>A Signaling Link Test Message failed. This error occurs when the sender of the SLT messages did not receive a response in the required time frame.</p> <ul style="list-style-type: none"> <li>• The variant is misconfigured.</li> <li>• The link has some type of mismatch on configuration.</li> <li>• Link has some type of hardware problem.</li> </ul>                       |
| SLT incorrect network indicator | A Signaling Link Test Message was received with a different network indicator. An error message is logged to console indicating link receiving SLTM.                                                                                                                                                                                                                                 |
| SLT incorrect OPC               | A Signaling Link Test Message was received from a different Origination Point-Code than was expected for the linkset containing link. For example, a linkset is configured to connect to point code 1.1.1 and received a response from 1.2.1. Error messages are logged to console indicating the linkset on which link was received and the linkset that should have received SLTM. |
| SLT incorrect SLC               | A Signaling Link Test Message was received from a different Signaling Link Code than was expected for the link. For example, a link is configured with SLC of 5 and is incorrectly connected to link with SLC of 15.2.1. Error messages are logged to console indicating the link that was misconfigured.                                                                            |
| SLT invalid                     | A Signaling Link Test Message that contained incorrectly formatted data and could not be processed.                                                                                                                                                                                                                                                                                  |

**Table 63**      *show cs7 mtp3 errors (continued)*

| Error                                      | Description                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SLT received bad pattern                   | A Signaling Link Test Message received with an incorrectly formatted pattern. This situation can occur in the following situations: <ul style="list-style-type: none"> <li>• The variant is incorrectly configured.</li> <li>• The link has some type of mismatch on configuration.</li> <li>• Link has some type of hardware problem.</li> </ul> |
| SLT received from non-adjacent OPC         | A Signaling Link Test Message was received from an Origination Point-Code that could not be accessed by directly attached linkset and the OPC is specified in the routing table indicating the OPC is not directly attached to device. Error messages are logged to console indicating the linkset on which this SLTM was received.               |
| SLT undefined OPC                          | A Signaling Link Test Message was received from an Origination Point-Code that is not defined to any linkset.                                                                                                                                                                                                                                     |
| SLT undefined SLC                          | A Signaling Link Test Message was received from a Signaling Link Code not in use for linkset. An error message is logged indicating which link received SLTM messages and the incorrect SLC.                                                                                                                                                      |
| Undefined Error Type                       | An error unknown error type was encountered that probably indicates some type of software problem has occurred.                                                                                                                                                                                                                                   |
| Unlock requested lock count!=0<br>cs7_info | An internal software error has occurred during the processing of an MSU. No error message is issued. Packet is dropped.                                                                                                                                                                                                                           |
| Unsupported management messages            | Error type not currently used.                                                                                                                                                                                                                                                                                                                    |
| Variant not defined                        | A packet was received before all variant information has been defined. The packet is dropped.                                                                                                                                                                                                                                                     |

| Command                                     | Description                                                                                                 |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">show cs7 mtp3 event-history</a> | Displays MTP3 logged events.                                                                                |
| <a href="#">show tech-support</a>           | Collects and displays a large amount of ITP configuration information that can be used for troubleshooting. |

## show cs7 mtp3 event-history

The events exchanged among the three MTP components—traffic, link, and route management—are logged in memory by default. To display logged events, use the **show cs7 mtp3 event-history** EXEC command.

**show cs7** [*instance-number*] **mtp3 event-history** *number*

|                           |                        |                                                                               |
|---------------------------|------------------------|-------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
|                           | <i>number</i>          | Number of events to display. Valid numbers range from 0 to 5000.              |

**Defaults** The default instance is 0.

**Command Modes** EXEC

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

**Usage Guidelines** To capture all events in one display, configure the **terminal length** EXEC command to 0.

**Examples** The following example includes output from the **show cs7 mtp3 event-history** command with the number of events to display (*number* argument) being **10**:

```
ITP# show cs7 mtp3 event-history 10
22:26:01 CS7 MTP3 MGMT event history. Max configured to be saved: 1024
Num of events currently saved: 16. Num to be displayed: 10
NOTE: Event history logging will be suspended while events are being displayed

00:00:13 LOG MTP3 Event: To: TPRC Fm: MGMT Ev: SP_restart_indication
00:00:13 LOG MTP3 Event: To: LLSC Fm: TPRC Ev: restart_begins tony
00:00:13 LOG MTP3 Event: To: LLSC Fm: TPRC Ev: restart_begins michael
00:00:13 LOG MTP3 Event: To: TSRC Fm: TPRC Ev: restart_begins
00:00:13 LOG MTP3 Event: To: TSFC Fm: TPRC Ev: restart_begins
00:00:13 LOG MTP3 Event: To: TLAC Fm: TPRC Ev: restart_begins tony 0
00:00:13 LOG MTP3 Event: To: TLAC Fm: TPRC Ev: restart_begins michael 0
00:00:13 LOG MTP3 Event: To: RSRT Fm: TPRC Ev: restart_begins
00:00:13 LOG MTP3 Event: To: LSAC Fm: LLSC Ev: activate_link tony 0
00:00:13 LOG MTP3 Event: To: LSAC Fm: LLSC Ev: activate_link michael 0
```

|-------------------------|---------------------------------------------|------------------------------|
|                         | <a href="#">show cs7 mtp3 event-history</a> | Displays MTP3 logged events. |

# show cs7 nso

To display NSO (Nonstop Operation) information, use the **show cs7 nso** privileged EXEC command.

**show cs7 nso {counters [detailed] | state}**

|                           |                 |                                      |
|---------------------------|-----------------|--------------------------------------|
| <b>Syntax Description</b> | <b>counters</b> | Displays counters maintained by NSO. |
|                           | <b>detailed</b> | Displays detailed output.            |
|                           | <b>state</b>    | Displays NSO state information.      |

**Defaults** None.

**Command Modes** Privileged EXEC

|                        |                |                              |
|------------------------|----------------|------------------------------|
| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Examples** The following example shows how to display NSO state information:

```
ITP# show cs7 nso state
ITP NSO state information:
  Current State:                operative
  Operating Redundancy Mode:    sso
  Configured Redundancy Mode:  sso
  Redundancy State:            ACTIVE
  Peer Redundancy State:       STANDBY HOT
  Checkpointing state:
    Last seq # sent:            143657
    Last seq # rcvd:            0
    Congested:                  FALSE
    Current send queue depth: 0
```

[Table 64](#) describes the significant fields shown in the display.

**Table 64** *show cs7 nso Field Descriptions*

| Field                      | Description                                       |
|----------------------------|---------------------------------------------------|
| Current State              | Fields describe the current state                 |
| Operating Redundancy Mode  | Current operational redundancy mode               |
| Configured Redundancy Mode | Current setting of redundancy mode command        |
| Redundancy State           | Current redundancy state                          |
| Peer Redundancy State      | Current redundancy state of other Route Processor |

**Table 64**      *show cs7 nso Field Descriptions (continued)*

| Field                    | Description                                                                           |
|--------------------------|---------------------------------------------------------------------------------------|
| Checkpointing state      | Fields describe current state of checkpointing                                        |
| Last seq # sent          | Sequence number of last NSO Checkpointing message sent to other Route Processor       |
| Last seq # rcvd:         | Sequence number of last NSO Checkpointing message received from other Route Processor |
| Congested                | TRUE if congestion is present on communication to other Route Processor               |
| Current send queue depth | Number of messages waiting to be sent to other Route Processor                        |

**Related Commands**

|-----------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">cs7 nso</a>           | Enables ITP Nonstop Operation (NSO).                                                                        |
| <a href="#">show tech-support</a> | Collects and displays a large amount of ITP configuration information that can be used for troubleshooting. |

# show cs7 offload

To display the current status, counters, and events maintained by the cs7 offload feature, use the **show cs7 offload instance** EXEC command.

## show cs7 offload instance

| Syntax Description | offload | The transfer of data operations. |
|--------------------|---------|----------------------------------|
|--------------------|---------|----------------------------------|

| Defaults | None. |
|----------|-------|
|----------|-------|

| Command Modes | EXEC |
|---------------|------|
|---------------|------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Usage Guidelines | The <b>show cs7 offload instance</b> command is used for a Cisco ITP FlexWan. For use on the Cisco ITP Supervisor Module the user enters the command <b>execute-on {flex-wan-number   all-flex} all show cs7 offload instance</b> . |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Examples | The following output excerpt includes some of the most significant output fields for the <b>show cs7 offload instance</b> command. <a href="#">Table 65</a> defines these output fields. |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
ITP# show cs7 offload instance

Instance 1
Point Code          235-33-0:1
SS7 Variant         ANSI

Dropped MSUs:

    tfc_attempt_count 0
loop_detected_drops 0
in_acl_drop         0
dcs7_route_pak_fail 125
no_route_link       124
out_acl_drop        0
alias_route_pak_fail 0
no_olink_err        0
invalid_pak_size_drops 0
circ rt detection drops 0
```

```

opc verification drops 0
no_rt_handle
current interval      0      total 6

```

**Table 65**Significant Output Fields for the **show cs7 offload** command

| Field                    | Description                                                                                                                                                                                                                 |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| bufferedPak_drops        | Cisco ITP has capability to buffer packets at link level equal to bufferPak_threshold per instance. If the packets to be buffered exceed this threshold for an instance, ITP drops these packets and increase this counter. |
| bufferedPak_flushes      | When the link or route is removed, then Cisco ITP flushes the packets if any are already buffered for that link/route. This counter is increased for every packet flushed.                                                  |
| tfc_attempt_drops        | Increases to count number of times TFC was dropped.                                                                                                                                                                         |
| tfc_attempt_count        | Increases to count number of times TFC was send.                                                                                                                                                                            |
| loop_detected_drops      | Increases for packets drop due to loop detection by ITP.                                                                                                                                                                    |
| in_acl_drop              | Increases for the packet dropped due to inbound ACL/GWS.                                                                                                                                                                    |
| dcs7_route_pak_fail      | Increases when the routing of the packet is unsuccessful because no link is available in a linkset.                                                                                                                         |
| no_route_link            | Increases when current route is not available due to the non-availability of the links in a linkset.                                                                                                                        |
| out_acl_drop             | Increases for the outbound packet dropped due to ACL/GWS.                                                                                                                                                                   |
| alias_route_pak_fail     | Increases when the routing to the alias pc failed.                                                                                                                                                                          |
| no_olink_err             | Increases when the outgoing link is not                                                                                                                                                                                     |
| invalid_pak_size_drops   | Increases when the sizeof mtp3 packet received at ITP is invalid.                                                                                                                                                           |
| circ rt detection drops  | Increases when MSUs dropped due to CRD                                                                                                                                                                                      |
| mgmt_pak_drops           | Increases when MGMT paks drop                                                                                                                                                                                               |
| opc verification drops   | Increase for packet drop due to opc verification failed when CRD is enabled.                                                                                                                                                |
| no_rt_handle/Count/total | Increases when there is no route info for the destination.                                                                                                                                                                  |

The following output is from the **execute-on {flex-wan-number | all-flex} all show cs7 offload instance** command. The **execute-on {flex-wan-number | all-flex} all show cs7 offload instance** command is the version of the **show cs7 offload instance** command used on the supervisor module.

# show cs7 offload mtp3

To display the current status, counters, and events maintained by the MTP3 offload feature, use the **show cs7 offload mtp3** EXEC command.

**show cs7 offload mtp3** [*slot*] [**detailed**] [**events** [**combined**] [**detailed**] ]

## Syntax Description

|                 |                                                                                                                                                                                                                                       |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>slot</i>     | Line card slot number. Valid numbers range from 0 to 12.                                                                                                                                                                              |
| <b>events</b>   | Displays all the events logged in the maintenance of the configuration and status on the line card. If the slot number and <b>combined</b> keyword are not specified, then the events are displayed independently for each line card. |
| <b>detailed</b> | Displays the counters maintained for the configuration download to the line card. When the <b>detailed</b> keyword is specified with the <b>events</b> keyword, additional information related to the event is also displayed.        |
| <b>combined</b> | When specified without a slot number, displays the events for all line cards in the timestamp order in which they occurred.                                                                                                           |

## Defaults

None.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example includes output from the **show cs7 offload mtp3** command. The output indicates that MTP3 offload is enabled on line cards 2 and 4, and is functioning normally.

```
ITP# show cs7 offload mtp3
```

```
MTP3 offload enabled.
```

```
Slot  Status    Offload
2      Normal     Enabled
4      Normal     Enabled
```

Table 67 describes the fields in the display, including the possible values that can be displayed in the Status and Offload columns.

**Table 66** *show cs7 offload mtp3 Field Descriptions*

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Slot         | Line card slot.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Status       | Indicates which phase is currently applicable for the MTP3 offload on each line card. The possible values that can be displayed in the Status column are <b>Disabled</b> , <b>Init</b> , <b>Normal</b> , and <b>PermDisabled</b> .                                                                                                                                                                                                                                                                      |
| Disabled     | MTP3 offload is temporarily disabled on the line card. This status is indicated when error recovery is in progress.                                                                                                                                                                                                                                                                                                                                                                                     |
| Init         | MTP3 offload is being initialized on the line card.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Normal       | MTP3 offload is enabled and operating normally.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| PermDisabled | <p>MTP3 offload has been permanently disabled on the line card. This status is indicated when excessive errors have been encountered on the line card and repeated error recovery attempts have failed.</p> <p>When a line card enters this state, the status of all links on the line card is displayed as “sys-shutdown” when the <b>show cs7 linkset</b> command is executed.</p> <p>A line card in this state can be restarted manually by issuing the <b>cs7 offload mtp3 restart</b> command.</p> |
| Offload      | The Offload column indicates whether or not MTP3 is operational on the line card. The possible values that can be displayed in the Offload column are <b>DisabledSys</b> and <b>Enabled</b> .                                                                                                                                                                                                                                                                                                           |
| DisabledSys  | MTP3 offload has been disabled by the system. This status is displayed whenever the ITP is performing error recovery or when MTP3 offload has been permanently disabled on the line card.                                                                                                                                                                                                                                                                                                               |
| Enabled      | MTP3 offload has been enabled on the line card.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <a href="#">cs7 offload mtp3</a> | Enables MTP3 offload on all line cards. |

# show cs7 pc-conversion

To display mapping of real point codes to alias point codes, use the **show cs7 pc-conversion** EXEC command.

**show cs7** [*instance-number*] **pc-conversion** [*point-code*]

## Syntax Description

|                        |                  |
|------------------------|------------------|
| <i>instance-number</i> | Instance number. |
| <i>point-code</i>      | Point code.      |

## Defaults

None.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

This command can be issued either globally or on an instance.

## Examples

The following example includes output from the **show cs7 pc-conversion** command:

```
ITP# show cs7 0 pc-conversion
PC                ALIAS PC
-----
1.84.1:1          0.85.7:4
1.84.4:4          1.85.7:1
```

|                  | <a href="#">ping cs7</a> | Starts a ping to a point code. |

# show cs7 pmp

To display PMP-related errors, use the **show cs7 pmp** privileged EXEC command.

**show cs7 pmp** [**errors** | **context** {**as** *as-name* | **linkset** *ls-name*}]

| Syntax Description |  |                                                                                |
|--------------------|--|--------------------------------------------------------------------------------|
| <b>errors</b>      |  | Displays link and/or ASP context ID, and inbound/outbound/dropped PMP packets. |
| <b>as</b>          |  | Specifies an AS.                                                               |
| <i>as-name</i>     |  | Name of the AS.                                                                |
| <b>linkset</b>     |  | Specifies a linkset.                                                           |
| <i>ls-name</i>     |  | Name of the linkset.                                                           |

|                 | 12.4(15)SW3 | This command was introduced. |
|                 | 12.2(33)IRC |                              |

**Examples** The following example includes output from the **show cs7 pmp error** command:

```
ITP#sh cs7 pmp errors
12          - No active DCS
```

The following example includes output from the **show cs7 pmp context** command used on a specific linkset:

```
ITP#sh cs7 pmp context linkset to_halley_6
SLC  Context  PMP In      PMP Out      PMP Drops
---  -
0    66        26355       26355        0
1    67        26338       26339        0
2    68        26336       26336        0
3    69        26335       26335        0
```

The following example includes output from the **show cs7 pmp context** command used on a specific AS:

```
ITP#sh cs7 pmp context as as_to_bal_1
ASP Name      Context  PMP In      PMP Out      PMP Drops
-----
asp_to_bal12  57       2           4            0
asp_to_bal_1  55       64          5            7
```

**Related Commands**

| show cs7 dcs       | Displays information about the DCS node.                 |

# show cs7 point-codes

To display the point codes that this router is responding to, use the **show cs7 point-codes** privileged EXEC command.

**show cs7** [*instance-number*] **point-codes** [**event-history** | **ssn** | **statistics**]

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>event-history</b>   | Displays point code history.                                                  |
| <b>ssn</b>             | Displays SUA point code/SSN status.                                           |
| <b>statistics</b>      | Displays XUA point code statistics.                                           |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The **show cs7 point-codes** command displays the point codes that this router is responding to. These point codes include the local point code, secondary point code, capability point code, AS point codes (DPC in the routing key), and AS Route point codes.

## Examples

The following example includes output from the **show cs7 point-codes** command:

ITP# **show cs7 point-codes**

| CS7 Point Code | Type      | Status          |
|----------------|-----------|-----------------|
| -----          | -----     | -----           |
| 0.0.4          | local     | active          |
| 0.0.4          | AS        | M3UA inactive   |
| 0.0.3          | secondary | active          |
| 0.0.3          | AS        | M3UA inactive   |
| 0.0.6          | AS        | M3UA inactive   |
| 1.2.3          | AS        | M3UA active     |
| 7.8.9          | AS        | M3UA inactive   |
| 8.7.5          | AS Route  | M3UA inactive   |
| 8.8.8          | AS Route  | M3UA restricted |
| 9.9.9          | AS        | M3UA active     |

**Related Commands**

|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| <a href="#">clear cs7 pointcode event-history</a> | Clears the CS7 M3UA or SUA point code measurements.                                                         |
| <a href="#">show tech-support</a>                 | Collects and displays a large amount of ITP configuration information that can be used for troubleshooting. |

# show cs7 qos

To display the QoS class information, use the **show cs7 qos** privileged EXEC command.

**show cs7** [*instance-number*] **qos** {**class** *class* | **statistics** *ls-name*}

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>class</b>           | Specifies a QoS class.                                                        |
| <i>class</i>           | QoS class identifier. Valid range is 0 to 7.                                  |
| <b>statistics</b>      | Displays QoS link usage statistics.                                           |
| <i>ls-name</i>         | Linkset name.                                                                 |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example includes output from the **show cs7 qos** command with the **class** keyword:

```

ITP# show cs7 qos class
  QoS  Prec  DSCP  Acc-Grp  MatchType      Input Linkset
  ---  ----  ----  -
  0      1      14      none
  1      3      2701  any      to_nyc
  2      4      none   access-group to_la
  3      4      none

```

[Table 67](#) describes the fields in the display.

**Table 67** *show cs7 qos class* Field Descriptions

| Field         | Description                                              |
|---------------|----------------------------------------------------------|
| QoS           | QoS class                                                |
| Prec          | IP precedence value assigned to QoS class                |
| DSCP          | Differential services code point assigned to QoS class   |
| Acc-Grp       | Access group assigned to QoS class                       |
| Match Type    | Packet matching criteria assigned to QoS class           |
| Input Linkset | Input linkset where packet matching criteria are defined |

The following example includes output from the **show cs7 qos** command with the **statistics** keyword:

```
ITP# show cs7 qos statistics michael
lsn=michael      apc=3.3.3      state=avail      available/links=2/3
  SLC  QoS      MSU In    MSU Out  Drops ByteCnt In ByteCnt Out
  00   0         520      488      0    10320      8784
  01   1         488      520      0     8784    10320
  02   2          0        0      0         0         0
```

Table 68 describes the fields in the display.

**Table 68** *show cs7 qos statistics Field Descriptions*

| Field       | Description                     |
|-------------|---------------------------------|
| SLC         | Signal Link Code                |
| QoS         | QoS class assigned to this link |
| MSU In      | MSUs received on this link      |
| MSU Out     | MSUs sent on this link          |
| Drops       | MSUs dropped                    |
| ByteCnt In  | Byte count of MSUs received     |
| ByteCnt Out | Byte count of MSUs sent         |

|                         | <a href="#">cs7 rate-limit</a>            | Limits traffic rate to a specified DPC/AS in an MTP over-flow load-share that uses a GTT application group. Adds or changes a point code and optional subsystem number in the application group |

| Command                                            | Description                                                                          |
|----------------------------------------------------|--------------------------------------------------------------------------------------|
| <a href="#">pc (cs7 gtt application group)</a>     | Adds or changes a point code and optional subsystem number in the application group. |
| <a href="#">asname (cs7 gtt application group)</a> | Assigns an M3UA or SUA AS directly to a global title.                                |

# show cs7 route

To display the ITP routing table, use the **show cs7 route** EXEC command.

**show cs7** [*instance-number*] **route** [*pc* [**summary-routes**]] [**circular**] [**brief** | **detailed**]

## Syntax Description

|                        |                                                                                                                                                  |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>instance-number</i> | Required only if the <b>cs7 multi-instance</b> feature is enabled. Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <i>pc</i>              | Point code.                                                                                                                                      |
| <b>summary-routes</b>  | Displays summary routes information for the specified pc.                                                                                        |
| <b>circular</b>        | Displays only those routes that are flagged as prohibited due to circular route detection.                                                       |
| <b>brief</b>           | Displays a brief form of the output.                                                                                                             |
| <b>detailed</b>        | Displays a detailed form of the output including marking any route prohibited due to CRD procedures with CIRC for route status.                  |

| 12.2(18)IXC<br>12.4(11)SW<br>12.2(33)IRA  | The displayed XUA point code status added the MTP destination status of that point code.                                                                                                   |
| 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | The <b>detailed</b> keyword was modified so that any route prohibited due to CRD procedures is marked with CIRC for route status.                                                          |
| 12.2(18)IXG<br>12.4(15)SW2<br>12.2(33)IRB | The <b>show cs7 route</b> command was enhanced with a new optional keyword, <b>circular</b> , to display only those routes that are flagged as prohibited due to circular route detection. |
| 12.4(15)SW6<br>12.2(33)IRF                | The <b>show cs7 route</b> command output was enhanced with a new <i>Load Share</i> column that indicates whether the linkset load sharing feature is enabled.                              |

## Usage Guidelines

The output of the **show cs7 route** command varies based on the options specified, the variant, the masks used to configure routes, and the configuration options.

Routes are two basic types. The first type of route is fully qualified. A fully qualified route has a mask specifying all of the allowed bits of the destination point code. For example, a fully qualified route for the ANSI variant has a mask of 255.255.255 or a mask length of 24 bits. When the variant is ITU, the fully qualified route has a mask of 7.255.7 or a mask length of 14 bits. The second type of route is a

summary route that represents a group of destination point codes. For example, with a variant of ITU, a point code of 5.11.0, and a mask of 7.255.0, the route represents all points in the range of 5.11.0 to 5.11.7. A special type of summary route is a cluster route. Cluster routes are only defined for the ANSI variant and mask; the mask must be 255.255.0.

In ITP release 12.2(18)IXC, the displayed XUA point code status includes the MTP destination status of that point code.

The following configuration options affect the route and destination status information:

#### summary-routing-exception

This option indicates whether to use the summary routes when the fully qualified route is not available. By default, this option is off and summary route can be used to route MTP3 messages. In this case, when a summary route is available and a fully qualified route is unavailable, the destination status for the fully qualified route is restricted rather than unavailable. When this option is enabled, the destination status for the fully qualified route is unavailable.

#### max-dynamic-routes

This option defines the maximum number of dynamic routes allowed for the signaling point. If the limit is reached, the status of some routes does not reflect the information reflected in the MTP3 management packets.

#### national-options TFR

This option applies only to ITU and China variants and indicates whether transfer-restricted MTP3 management messages will be exchanged between signaling points. When this option is enabled, route and destination statuses can display the restricted state.

#### national-options multiple-congestion

#### Note

Changing any of the global configuration options on an operational box does not update all route and destination statuses. Routing behavior changes correctly, although it might not match what is indicated by some destination statuses. These options are intended to be a one-time configuration before the box is put in service.

## Examples

The **show cs7 route** command without options produces a list of destinations and the associated routes used to access each destination. The following examples include output from the **show cs7 route** command executed with no modifying keywords. The Load Share column was introduced in 12.2(33)IRF and 12.4(15)SW6 and indicates that the linkset load sharing feature is enabled.

```
ITP# show cs7 route
Destination          Prio Linkset Name      Route Load Share
-----
1.1.1/14             acces  1 m2pa_194_00         avail  T
                   1 m2pa_194_01         avail  T
1.1.0/12             acces  2 m2pa_194_00         avail  F
1.1.5/14             acces  1 VirtualLS0-4        avail  F
```

The **show cs7 route** command with the **brief** keyword produces only a list of destinations. The following example includes output from the **show cs7 route** command executed with the **brief** keyword.

```
ITP# show cs7 route brief
Routing table = system

Destination          Cong
```

```

-----
1.1.0/11      acces
1.1.1/14      acces
3.1.1/14      acces

Routing table = XUA

Destination      Type
-----
2.1.1/14      INACC  AS
2.2.2/14      RESTR  AS Route
4.1.1/14      INACC  AS
4.4.4/14      RESTR  AS Route

```

The **show cs7 route** command with the **detailed** option produces a list of destinations and associated routes with the available management information. Any route that is prohibited due to CRD procedures is marked with CIRC to make it distinct from ordinary prohibited status. The following example includes output from the **show cs7 route** command with the **detailed** keyword.

```

ITP# show cs7 route detailed
Dynamic Routes 0 of 1000
Routing table = system Destinations = 3 Routes = 4
C=Cong Q=QoS P=Prio
Destination C Q P Linkset Name Linkset Non-adj Route
-----
1.10.1/14 INACC 1 sunset avail PROHIB CIRC

```

The **show cs7 route** command with the optional **circular** keyword displays only those routes that are flagged as prohibited due to circular route detection. The following example includes output from the **show cs7 route** command with the **circular** keyword.

```

Router#show cs7 route circular
Dynamic Routes 0 of 1000
Routing table = system Destinations = 3 Routes = 4
Destination Prio Linkset Name Route
-----
1.10.1/14 INACC 1 sunset CIRC

```

The following example includes output from the **show cs7 route** command executed with a destination point code (*pc* argument) of 4.1.1:

```

ITP# show cs7 route 4.1.1
Routing table = XUA

```

```

Destination      Type
-----
4.1.1/14      INACC  AS

```

The **show cs7 route** command with a point-code destination argument (*pc*) and **summary-routes** keyword produces a list of routes matching the specified destination. The following example includes output from the **show cs7 route** command executed with the *pc* argument and **summary-routes** keyword.

```

ITP# show cs7 route 1.1.1 summary-routes detail
Routing table = system
C=Cong Q=QoS P=Prio
Destination      C Q P Linkset Name Linkset Non-adj Route
-----
1.1.0/11      acces      1 barbados      avail      allowed avail
1.1.1/14      acces      1 bermuda       avail      allowed avail
5 bimini avail allowed avail

```

Table 69 describes the fields in the display.

**Table 69**      **show cs7 route Field Descriptions**

| Field        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |       |            |         |              |       |            |

# show cs7 sample sls

To display the results from the latest SLS sample, use the **show cs7 sample sls** privileged EXEC command.

**show cs7 sample sls**

| Syntax Description | sls | Field in MSUs used for load sharing. |
|--------------------|-----|--------------------------------------|
|--------------------|-----|--------------------------------------|

| Defaults | None. |
|----------|-------|
|----------|-------|

| Command Modes | Privileged EXEC |
|---------------|-----------------|
|---------------|-----------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXF | This command was introduced. |
|                 | 12.4(15)SW1 |                              |
|                 | 12.2(33)IRA |                              |

| Usage Guidelines | <p>This command fails if:</p> <ul style="list-style-type: none"> <li>• No sample has been performed.</li> <li>• A sample is currently in progress.</li> <li>• The link or linkset that was last sampled has been deleted.</li> </ul> |

|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Examples | The following example includes output from the <b>show cs7 sample sls</b> command: |
|----------|------------------------------------------------------------------------------------|
|----------|------------------------------------------------------------------------------------|

```
router# show cs7 sample sls
SLS Received Report for linkset LS-A from Nov 27 2007 13:44:32
  SLS number      SLS number      SLS number      SLS number
    rcvd          rcvd          rcvd          rcvd
 000 0002        004 0002        008 0000        012 0000
 001 0002        005 0002        009 0000        013 0000
 002 0002        006 0002        010 0000        014 0000
 003 0002        007 0002        011 0000        015 0000
```

The next example shows ANSI output. ANSI uses 8-bit SLS, so it has 256 SLS values. This amount differs from ITU, China, and Japan's TTC Variants, which use 4-bit SLS and have 16 SLS values.

The following example includes output from the **show cs7 sample sls** command:

```
router# show cs7 sample sls
SLS Received Report for linkset LS-B from Nov 27 2007 13:44:32
SLS number      SLS number      SLS number      SLS number
  rcvd          rcvd          rcvd          rcvd
 000 0037        064 0004        128 0005        192 0005
 001 0005        065 0004        129 0005        193 0005
```

 show cs7 sample sls

# show cs7 sccp gti-conversion

To display the CS7 GTI conversion table, use the **show cs7 sccp gti-conversion** privileged EXEC command.

**show cs7 sccp gti-conversion [measurements]**

| Syntax Description | measurements | Displays a count of how many MSUs matched each rule in the GTI table. |
|--------------------|--------------|-----------------------------------------------------------------------|
|--------------------|--------------|-----------------------------------------------------------------------|

| Defaults | None. |
|----------|-------|
|----------|-------|

| Command Modes | Privileged EXEC |
|---------------|-----------------|
|---------------|-----------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Usage Guidelines | If the <b>measurements</b> keyword is specified, a count of how many MSUs matched each rule in the GTI table is displayed. This count is cleared by the <b>clear cs7 all</b> command |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Examples | The following example includes output from the <b>show cs7 sccp gti-conversion</b> command: |
|----------|---------------------------------------------------------------------------------------------|
|----------|---------------------------------------------------------------------------------------------|

```
ITP# show cs7 sccp gti-conversion
SCCP GTI Conversion Table: gti4
```

| GTI | TT  | SSN | NP | NAI | ES | --> | OUT-GTI | OUT-TT | OUT-SSN | OUT-NP | OUT-NAI | OUT-ES |
|-----|-----|-----|----|-----|----|-----|---------|--------|---------|--------|---------|--------|
| 2   | 10  | *   | -  | -   | -  |     | 4       | 11     | *       | 1      | 1       | 2      |
| 2   | 250 | *   | -  | -   | -  |     | 4       | 34     | *       | 1      | 3       | 2      |

```
SCCP GTI Conversion Table: gti2
```

```
-OUT
```

| GTI | TT  | SSN | NP | NAI | ES | --> | OUT-GTI | OUT-TT | OUT-SSN | OUT-NP | OUT-NAI | OUT-ES |

# show cs7 sccp instance-conversion

To display the CS7 SCCP instance conversion table, use the **show cs7 sccp instance-conversion** privileged EXEC command.

**show cs7 sccp instance-conversion [measurements]**

## Syntax Description

|                     |                                                                                     |
|---------------------|-------------------------------------------------------------------------------------|
| <b>measurements</b> | Displays a count of how many SCCP MSUs were converted from one instance to another. |
|---------------------|-------------------------------------------------------------------------------------|

## Defaults

None.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

If the **measurements** keyword is specified, a count of how many SCCP MSUs were converted from one instance to another is displayed. This count is cleared by the **clear cs7 all** command.

## Examples

The following examples include output from the **show cs7 sccp instance-conversion** command:

ITP# **show cs7 sccp instance-conversion**

| InInst->OutInst | GTI-CONV | SSN-CONV | ADDR-CONV | MsgHandling | NatInd |
|-----------------|----------|----------|-----------|-------------|--------|
| 0 -> 6          | test     | none     | none      | return-on-e | 0      |
| 0 -> 1          | none     | ssn1     | none      | no-chg      | 1      |
| 1 -> 0          | none     | ssn0     | none      | no-chg      | no-chg |
| 3 -> 4          | gti4     | none     | addr4     | no-chg      | no-chg |
| 4 -> 3          | gti2     | none     | addr3     | no-chg      | no-chg |

ITP# **show cs7 sccp instance-conversion measurements**

| InInst->OutInst | PKTS    |
|-----------------|---------|
| 0 -> 6          | 0       |
| 0 -> 1          | 133393  |
| 1 -> 0          | 0       |
| 3 -> 4          | 0       |
| 4 -> 3          | 3934984 |

# show cs7 sgmp

To display Signaling Gateway Mate Protocol (SGMP) information, use the **show cs7 sgmp** privileged EXEC command.

**show cs7** [*instance-number*] **sgmp** *local-port*

|                           |                        |                                                                               |
|---------------------------|------------------------|-------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
|                           | <i>local-port</i>      | Local port number for SGMP link offloaded to line card.                       |

**Defaults** The default instance is 0.

**Command Modes** Privileged EXEC

|                        |                                           |                                                                  |
|------------------------|-------------------------------------------|------------------------------------------------------------------|
| <b>Command History</b> | <b>Release</b>                            | <b>Modification</b>                                              |
|                        | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.                                     |
|                        | 12.2(18)IXH<br>12.4(15)SW3<br>12.2(33)IRC | Enhanced the command output to include the running SGMP version. |

**Examples** The following example includes output from the **show cs7 sgmp** command:

```
ITP# show cs7 sgmp
SGMP Local port: 14002      State: active      SCTP instance handle: 5
Local ip address:          172.18.48.39
Number of active SGMP peers: 0
Max number of inbound streams allowed: 17
Local receive window:      5555
Max init retransmissions:   8
Max init timeout:           1000 ms
Unordered priority:         equal
Offload to FlexWAN: No      Slot: -1
SCTP defaults for new associations
  Transmit queue depth:    1000      Cumulative sack timeout: 200 ms
  Assoc retransmissions:   17        Path retransmissions:    4
  Minimum RTO:             1000 ms   Maximum RTO:             1000 ms
  Bundle status:           on        Bundle timeout:          5 ms
  Keep alive status:       true      Keep alive timeout:      500 ms
  Initial cwnd:            3000      Idle cwnd rate:          50
  Retrans cwnd rate:       50        Retrans cwnd mode:       RFC
  FastRetrans rate:        50
SGMP Offload Version: 1
```

|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Examples** The following example includes output from the **show cs7 sms address-table** command:

```
ITP#show cs7 sms address-table
```

```
Name: shortcodes      Instance: 0    Address Count: 4
```

| Address | Matches | Result   |
|---------|---------|----------|
| 11112*  | 0       | GRP grp2 |
| 1111*   | 4000    | GRP grp1 |
| 2222*   | 1000    | GRP grp1 |
| 5551212 | 0       | GRP grp3 |

[Table 71](#) describes the significant fields shown in the display.

**Table 71** *show cs7 sms address-table Field Descriptions*

| Field    | Description         |
|----------|---------------------|
| Name     | Address table name. |
| Instance | Instance number.    |

**Table 71**      *show cs7 sms address-table Field Descriptions (continued)*

| Field   | Description                                                                                                                                |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------|
| Address | Address as specified in the address table. The asterisk (*) indicates that longer addresses that match this prefix are considered a match. |
| Matches | Indicates the number of times this address has been invoked where this address matched the value in the request.                           |
| Result  | Indicates the result, if specified, that will be executed when a match occurs.                                                             |

**Related Commands**

| Command                               | Description                     |
|---------------------------------------|---------------------------------|
| <a href="#">cs7 sms address-table</a> | Specifies an SMS address table. |

# show cs7 sms dest-sme-binding

To display SMS information about the specified dest-sme address, use the **show cs7 sms dest-sme-binding** privileged EXEC command.

**show cs7 sms dest-sme-binding** *dest-sme* [*result-group-name*]

|                    |                          |                                                                                                                                                                                                                                   |
|--------------------|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Syntax Description | <i>dest-sme</i>          | Specifies the dest-sme address whose result you want to display. Valid addresses are from 1 to 20 hexadecimal characters in length. Only the last four digits of the address are needed to determine the dest-sme-binding result. |
|                    | <i>result-group-name</i> | Specifies which result group to use. If <i>result-group-name</i> is not specified, then this display outputs the dest-sme-binding result for the input dest-sme for each result group in dest-sme-binding mode.                   |

|          |       |

## Examples

The following example includes output from the **show cs7 sms gsm-map** command with the **ssn** keyword:

```
ITP#show cs7 sms gsm ssn 8
SMS GSM MAP Transport
SSN: 8
map-source-addr: use national digits 9193922900 tt 10 gti 2
Invoke Timer:    10 SMSC MAP Version:    3
```

The following example includes output from the **show cs7 sms gsm-map** command with the **statistics** and **detail** keywords:

```
ITP#show cs7 sms gsm statistics detail
GSM MAP Statistics:

Total outstanding SMS dialogues:                                0

Total SMS-MO ForwardSM indications:                            1510
  Outstanding / Max:                                           0 /      10

# show cs7 sms route-table

To display attributes of the SMS route table, use the **show cs7 sms route-table** privileged EXEC command.

**show cs7** [*instance-number*] **sms route-table** [**gsm-map** [*sms-mo*]]

## Syntax Description

|                        |                                                                               |
|------------------------|-------------------------------------------------------------------------------|
| <i>instance-number</i> | Specifies the instance. The valid range is 0 to 7. The default instance is 0. |
| <b>gsm-map</b>         | Displays information regarding handling of inbound GSM MAP messages.          |
| <b>sms-mo</b>          | Displays information regarding handling of inbound SMS MO operations.         |

## Defaults

The default instance is 0.

## Command Modes

Privileged EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

The only currently supported protocol-operation-correlation filter is gsm-map/sms-mo.

## Examples

The following examples include output from the **show cs7 sms route-table** command with no keywords:

ITP# **show cs7 sms route-table**

SMS Route-table

Transaction-timer: 60

Traffic-rate-timer: 60 CDR-Service: pds

Protocol: ansi41 Operation: smsNot

Ruleset: proxy Status: Enabled

ITP# **show cs7 sms route-table**

SMS Route-table

Transaction-timer: 0

Traffic-rate-timer: 60 CDR-Service: pds

Protocol: gsm-map Operation: sms-mo

Ruleset: smsc-rules Status: Enabled

Proxy-error-use: True Max-messages: 2500

Modify Prefix: Dest-sme \* Ton:0 Np:1

Result ton 1

Result np 3

Protocol: ucp Operation: submit-sm

Ruleset: ao-rules Status: Enabled

The following example includes output from the **show cs7 sms route-table** command with the **gsm-map** and **sms-mo** keywords:

```
ITP# show cs7 sms route-table gsm-map sms-mo
SMS Route-table
Transaction-timer: 300          CDR-Service: pds

Protocol:          gsm-map Operation:  sms-mo Correlator: SSN 8
Ruleset:           smsc-rules Status: Enabled
map-source-addr:   use national digits 9193923943 tt 10 gti 2
Invoke Timer:      30 Max-messages:    0
SMSC MAP Version:  3 Proxy-error-use: True
MNP Primary TT:    11 Secondary TT:    10
GPRS Delivery:     Prefer MSC
```

Table 73 describes the significant fields shown in the display.

**Table 73** *show cs7 sms route-table Field Descriptions*

| Field                  | Description                                                                                                                                                         |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transaction-timer: 300 | Displays the configured maximum lifetime of a message transaction in seconds.                                                                                       |
| CDR-Service: pds       | Displays the name of the CDR service used by the SMS routing subsystem.                                                                                             |
| Protocol: gsm-map      | Identifies the protocol routing instance. Currently, only gsm-map is supported.                                                                                     |
| Operation: sms-mo      | Identifies the SMS MO operation.                                                                                                                                    |
| Correlator: SSN 8      | Identifies the subsystem number.                                                                                                                                    |
| Ruleset: smsc-rules    | Identifies the configured SMS ruleset name.                                                                                                                         |
| Status: enabled        | Indicates that the protocol is enabled.                                                                                                                             |
| map-source-addr        | Identifies the address used as the calling party address for all MAP-generated messages.                                                                            |
| Invoke Timer           | Indicates the timer value, in seconds, configured to supervise initiated dialogs.                                                                                   |
| Max-messages           | Indicates the maximum number of open SMS MO messages allowed before a congestion response is generated.                                                             |
| SMSC MAP Version       | Indicates the SMSC MAP version.                                                                                                                                     |
| Proxy-error-use: True  | Specifies to return the error received from the last MO Proxy procedure.                                                                                            |
| MNP Primary TT         | Identifies the primary tt in the SCCP called party address used to send all SRI-SM messages to the HLR.                                                             |
| Secondary TT           | Identifies the secondary tt, to be used to send a second request if the response to a message sent with the MNP primary tt contains the error "Unknown Subscriber." |
| GPRS Delivery          | Indicates that DSMR will attempt SMS MT delivery to the SGSN address when the HLR provides both MSC and SGSN addresses in an SRI confirmation.                      |

**Examples** The following example includes output from the **show cs7 tcap** command with the no keywords:

```
ITP# show cs7 tcap
TCAP protocol layer is up
TCAP variant is ANSI
  554600 bytes input, 1969300 bytes output
  0 active transactions/dialogues
  42300 transaction/dialogue requests
  23500 transaction/dialogue indications
  0 total error conditions detected
New transaction work queue is not congested: depth 0
  0 P-ABORTs sent due to queue backlog
  0 BEGINS dropped due to queue backlog
```

# show cs7 virtual-linkset

To display information about virtual linksets, including link utilization and associated measurements, use the **show cs7 virtual-linkset** privileged EXEC command.

**show cs7 virtual-linkset** [*linkset-name*] [**brief**] [**routes**] [**statistics**] | [**utilization**]

|                           |                     |                                                                     |
|---------------------------|---------------------|---------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>linkset-name</i> | Displays information about a specific linkset.                      |
|                           | <b>brief</b>        | Displays output in brief format. Does not display individual links. |
|                           | <b>routes</b>       | Displays all routes using the linkset.                              |
|                           | <b>statistics</b>   | Displays link usage statistics.                                     |
|                           | <b>utilization</b>  | Displays link utilization for the linkset.                          |

**Defaults** None.

**Command Modes** Privileged EXEC

| <b>Command History</b> | <b>Release</b> | <b>Modification</b>          |
|------------------------|----------------|------------------------------|
|                        | 12.2(18)IXA    | This command was introduced. |
|                        | 12.4(11)SW     |                              |
|                        | 12.2(33)IRA    |                              |

**Usage Guidelines** A virtual linkset is a connection from one instance to another. In ITP, any two instances have two virtual linksets between them. For example, between instanceX and instanceY are virtual linksets VirtualLSx-y and VirtualLSy-x. VirtualLSx-y appears to be a linkset in Instance x, and it will appear in Instance x's route table for alias destinations whose true point code exists in Instance y. VirtualLSy-x appears to be a linkset in Instance y, and it will appear in Instance y's route table for alias destinations whose true point code exists in Instance x.

Virtual linksets are not the same as real linksets. Virtual linksets do not have queues, and are not limited by bandwidth.

Virtual linksets are created automatically when a new instance is created. When an alias point code is defined, the alias point code is automatically entered in the alias instance's routing table using the virtual linkset.

**Examples** The following example includes partial output from the **show cs7 virtual-linkset** command with no keywords:

```
ITP# show cs7 virtual-linkset
lsn=VirtualLS1-0      apc=0.30.1:0      state=avail      avail/links=1/1
  SLC  Interface      Service  PeerState      Inhib
   00   Virtual      avail    -----      ----

lsn=VirtualLS0-1      apc=1.30.1:1      state=avail      avail/links=1/1
```

## show cs7 virtual-linkset

|     |           |         |           |       |
|-----|-----------|---------|-----------|-------|
| SLC | Interface | Service | PeerState | Inhib |
| 00  | Virtual   | avail   | -----     | ----  |

The following example includes output from the **show cs7 virtual-linkset** command with the **brief** keyword:

```
ITP# show cs7 virtual-linkset brief
lsn=VirtualLS1-0      apc=0.30.1:0      state=avail      avail/links=1/1
lsn=VirtualLS3-0      apc=0.30.1:0      state=avail      avail/links=1/1
lsn=VirtualLS0-1      apc=1.30.1:1      state=avail      avail/links=1/1
lsn=VirtualLS3-1      apc=1.30.1:1      state=avail      avail/links=1/1
lsn=VirtualLS0-3      apc=3.30.1:3      state=avail      avail/links=1/1
lsn=VirtualLS1-3      apc=3.30.1:3      state=avail      avail/links=1/1
```

The following example includes output from the **show cs7 virtual-linkset** command with the **routes** keyword:

```
ITP# show cs7 virtual-linkset routes
lsn=VirtualLS1-0      apc=0.30.1:0      state=avail      avail/links=1/1
Destination           Cong Prio QoS Route  Route Table
-----
0.1.1/24              acces          1      avail  system1

lsn=VirtualLS3-0      apc=0.30.1:0      state=avail      avail/links=1/1
Destination           Cong Prio QoS Route  Route Table
-----
0.1.2/14              acces          1      avail  system3

lsn=VirtualLS0-1      apc=1.30.1:1      state=avail      avail/links=1/1
Destination           Cong Prio QoS Route  Route Table
-----
1.2.1/24              acces          1      avail  system

lsn=VirtualLS3-1      apc=1.30.1:1      state=avail      avail/links=1/1
Destination           Cong Prio QoS Route  Route Table
-----

lsn=VirtualLS0-3      apc=3.30.1:3      state=avail      avail/links=1/1
Destination           Cong Prio QoS Route  Route Table
-----
3.2.1/24              acces          1      avail  system

lsn=VirtualLS1-3      apc=3.30.1:3      state=avail      avail/links=1/1
Destination           Cong Prio QoS Route  Route Table
-----
```

The following example includes output from the **show cs7 virtual-linkset** command with the **statistics** keyword:

```
ITP# show cs7 virtual-linkset VirtualLS0-1 statistics
lsn=VirtualLS0-1      apc=1.30.1:1      state=avail      avail/links=1/1
  SLC    MSU In    MSU Out Drops  LSSU In  LSSU Out  ByteCnt In  ByteCnt Out

# show ip sctp

To display ITP SCTP statistics, use the **show ip sctp** EXEC command.

**show ip sctp** { **association** [**list** | **parameters** *assoc-id* | **statistics** *assoc-id*] | **errors** | **instances** *local-port* | **statistics** }

## Syntax Description

|                    |                                                  |
|--------------------|--------------------------------------------------|
| <b>association</b> | Specifies an SCTP connection.                    |
| <b>list</b>        | Current SCTP association.                        |
| <b>parameters</b>  | SCTP association parameters.                     |
| <i>assoc-id</i>    | Association ID number. Valid range is 0 to 1024. |
| <b>statistics</b>  | SCTP association statistics.                     |
| <b>errors</b>      | SCTP error statistics.                           |
| <b>instances</b>   | SCTP local peer instances.                       |
| <b>statistics</b>  | SCTP internal statistics.                        |

## Defaults

None.

## Examples

This section shows sample output from various forms of the **show ip sctp** command. Each example is followed by a table describing the fields in the output display.

The following example includes output from the **show ip sctp** command using the **association** and **list** keywords:

```
ITP# show ip sctp association list
** SCTP Association List **

AssocID:0, Instance ID:0x30010043
Current state:ESTABLISHED, uptime:00:21:24
Local port:9000, Addrs:172.18.44.162
Remote port:9000, Addrs:172.18.44.170
```

[Table 77](#) describes the fields in the **show ip sctp association list** display.

**Table 77** *show ip sctp association list Field Descriptions*

| Field         | Description                                   |
|---------------|-----------------------------------------------|
| AssocID       | SCTP association identifier.                  |
| Current state | State of SCTP association.                    |
| uptime        | Duration of time association has been active. |
| Local Port    | Local port number                             |
| Addrs         | Local or remote peer addresses                |
| Remote Port   | Remote port number                            |

The following example includes output from the **show ip sctp** command using the **association** and **parameters** keywords with *assoc-id* 0:

```
ITP# show ip sctp association parameters 0

```

Table 80 describes all possible fields of the **show ip sctp errors** output. In actual output, each field includes a value that represents the number of times the error has occurred since errors were last cleared.

**Table 80** *show ip sctp errors Field Descriptions*

| Field                          | Description                                                        |
|--------------------------------|--------------------------------------------------------------------|
| Not Ready                      | SCTP is not initialized.                                           |
| Memory Unavail                 | No memory available.                                               |
| Attempt to Free Null Ptr       | Attempt to free a null pointer.                                    |
| Attempt to Free Not In Use     | Attempt to free memory that is not in use.                         |
| Rcvd Dgram too small           | Received datagram length is invalid; too small.                    |
| Partial chunk rcvd             | Received datagram contains a partial chunk.                        |
| Dgram with no chunks           | Received datagram does not contain any chunks.                     |
| Invalid Adler checksum         | Adler checksum of received datagram is invalid.                    |
| Invalid Crc32 checksum         | CRC32 checksum of received datagram is invalid.                    |
| Invalid bundled chunks         | Received datagram contains chunks that cannot be bundled together. |
| Invalid verification tag       | Received datagram contains invalid verification tag.               |
| Rcvd dgram unconfig local addr | Received a datagram with an unconfigured local address.            |
| Out-of-the-blue dgrams         | Received an unexpected datagram based on state of the association. |
| Invalid stream rcvd            | Received chunk has invalid stream number.                          |
| Unknown Appl Req type          | Unknown internal application request.                              |
| Communication Lost             | Association failed because communication was lost to peer.         |
| Destination Address Failed     | Destination address marked unreachable due to max number retries.  |
| Unknown INIT params rcvd       | Unknown parameter field found in Init or Init-Ack chunk            |
| Null Timer Id specified        | Invalid timer ID. Internal error                                   |
| Unknown Timer type expired     | Unknown timer expiration. Internal error.                          |
| Chunk ordering errors          | Chunks received in datagram are out of order as specified in RFC.  |
| ECNE chunk type rcvd           | Explicit congestion notification echo chunk received.              |
| CWR chunk type rcvd            | Congestion window reduced chunk received.                          |
| Unknown chunk type rcvd        | Unknown chunk type detected in received datagram.                  |
| Unknown Init params rcvd       | Unknown parameter field found in Init or Init-Ack chunk.           |
| Invalid cookie signature       | Invalid cookie signature computed.                                 |
| Expired cookie                 | Cookie lifetime expired. Cookie is invalid.                        |
| Peer restarted                 | Received cookie chunk while association was already established.   |
| Incoming assoc disallowed      | Association denied because port instance is being deleted.         |
| No Listening Instance          | No port instance found for incoming datagram.                      |
| Invalid linktype rcvd          | Received datagram link type is not IP.                             |
| IPv6 addr params rcvd          | IPv6 parameters received in Init or Init-Ack chunks.               |
| Invalid stream error rcvd      | Invalid stream error cause received in error chunk.                |

**Table 80** *show ip sctp errors Field Descriptions*

| Field                       | Description                                                              |
|-----------------------------|--------------------------------------------------------------------------|
| Missing param error rcvd    | Missing parameter error cause received in error chunk.                   |
| Stale cookie error rcvd     | Stale cookie error cause received in error chunk.                        |
| Out of resource error rcvd  | Out of resource error cause received in error chunk.                     |
| Unresolvable addr err rcvd  | Unresolved address error cause received in error chunk.                  |
| Unrecognized chunk err rcvd | Unrecognized error type received in error chunk.                         |
| Invalid param err rcvd      | Invalid mandatory parameter error cause received in error chunk.         |
| Unrecognized param err rcvd | Unrecognized parameter error cause received in error chunk.              |
| No user data error rcvd     | No user data error cause received in error chunk.                        |
| Cookie in shutdown err rcvd | Cookie received while shutting down error cause received in error chunk. |
| Chunk too small             | Received chunk is too small.                                             |
| Chunk too large             | Received chunk is too large.                                             |
| Missing parameters          | Parameter missing from received chunk.                                   |
| No room for incoming data   | Local receive window is full.                                            |
| Low IO memory               | I/O memory is low. Packets are dropped.                                  |

The following example includes output from the **show ip sctp** command using the **instances** keyword:

```
ITP# show ip sctp instances

** SCTP Instances **

Instance ID:9000 Local port:9000
Instance state:available
Local addrs:172.18.44.162
Default streams inbound:2 outbound:2
Current associations: (max allowed:100)
  AssocID:0 State:ESTABLISHED Remote port:9000
  Dest addrs:172.18.44.170
```

[Table 81](#) describes the fields in the **show ip sctp instances** display.

**Table 81** *show ip sctp instances Field Descriptions*

| Field                | Description                                              |
|----------------------|----------------------------------------------------------|
| Instance ID          | CTP instance ID, which is equal to the local port number |
| Local Port           | Local port number                                        |
| Instance state       | SCTP instance state                                      |
| Local Addrs          | Local IP address                                         |
| Default streams      | Default inbound and outbound streams                     |
| Current Associations | Current SCTP associations                                |

The following example includes output from the **show ip sctp** command using the **statistics** keyword:

```
ITP# show ip sctp statistics
```

# show ip sctp

```

** Sctp Overall Statistics **

|                         | clear ip sctp statistics  | Resets all SCTP global counters and clears counters for all SCTP associations.        |
|                         | clear ip sctp association | Clears the errors, statistics, and monitor values for the specified SCTP association. |

# show ip sctp association monitor

To display the SCTP association history monitor data graph, use the **show ip sctp association monitor EXEC** command.

```
show ip sctp association monitor [ assoc-id ] [ all | application | cwnd-hw | cwnd-lw | dup-chunks
| fast-retrans | octets-rx | octets-tx | oor-chunks | packets-rx | packets-tx | rto | rtt-avg |
rtt-max | rwnd-local-hw | rwnd-local-lw | rwnd-remote-hw | rwnd-remote-lw | ulpd-hw |
ulpd-lw ]
```

## Syntax Description

|                       |                                                   |
|-----------------------|---------------------------------------------------|
| <i>assoc-id</i>       | Association ID number. Valid range is 0 to 1024.  |
| <b>all</b>            | Displays all measurement history.                 |
| <b>application</b>    | Displays application-processing history.          |
| <b>cwnd-hw</b>        | Displays congestion window high-mark history.     |
| <b>cwnd-lw</b>        | Displays congestion window low-mark history.      |
| <b>dup-chunks</b>     | Displays duplicate-chunks history.                |
| <b>fast-retrans</b>   | Displays fast-retransmission history.             |
| <b>octets-rx</b>      | Displays octet received history.                  |
| <b>octets-tx</b>      | Displays octet sent history.                      |
| <b>oor-chunks</b>     | Displays out-of-order chunks history.             |
| <b>packets-rx</b>     | Displays packet received history.                 |
| <b>packets-tx</b>     | Displays packet sent history.                     |
| <b>rto</b>            | Displays retransmission timeout history.          |
| <b>rtt-avg</b>        | Displays round-trip-time average history.         |
| <b>rtt-max</b>        | Displays round-trip-time maximum history.         |
| <b>rwnd-local-hw</b>  | Displays local receive window high-mark history.  |
| <b>rwnd-local-lw</b>  | Displays local receive window low-mark history.   |
| <b>rwnd-remote-hw</b> | Displays remote receive window high-mark history. |
| <b>rwnd-remote-lw</b> | Displays remote receive window low-mark history.  |
| <b>ulpd-hw</b>        | Displays upper level datagram high-mark history.  |
| <b>ulpd-lw</b>        | Displays upper level datagram low-mark history.   |

## Defaults

None.

## Command Modes

EXEC

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXH | This command was introduced. |
| 12.4(15)SW3 |                              |
| 12.2(33)IRC |                              |

**Usage Guidelines**

The output from the **show ip sctp association monitor** command is displayed in the form of a graph. The Y-axis of the graph is the round trip time (RTT) value. The X-axis of the graph is the increment within the period displayed in the graph; for example, the individual minutes during the previous hour.

**Examples**

This example includes output from the **show ip sctp association monitor** command detailing a 1-hour RTT measurement. The most recent measurement is on the left end of the X-axis. The top three rows, read vertically, displays the highest value as it exceeds the maximum of the Y-axis value.

```

2          2
          2      1
          0      4

## show monitor event-trace

To display event trace messages for Cisco IOS software subsystem components, use the **show monitor event-trace** privileged EXEC command.

```
show monitor event-trace [all-traces] [component {all | back time | clock time | from-boot
[seconds | detail] | latest | parameters}]
```

| Syntax Description |  |                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <i>component</i>   |  | Name of the Cisco IOS software subsystem component that is the object of the event trace.<br><br>To display event trace messages for the ITP Group feature, enter <b>itp-group</b> as the component.<br><br>To display event trace messages for the ITP MLR Call Trace feature, enter <b>cs7 mlr</b> as the component.<br><br>To get a list of components that support event tracing in this release, use the <b>monitor event-trace ?</b> command. |
| <b>all</b>         |  | Displays all event trace messages currently in memory for the specified component.                                                                                                                                                                                                                                                                                                                                                                  |
| <b>back</b>        |  | Specifies how far back from the current time you want to view messages. For example, you can gather messages from the last 30 minutes.                                                                                                                                                                                                                                                                                                              |
| <i>time</i>        |  | Length of time in hours and minutes (hh:mm).                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>clock</b>       |  | Displays event trace messages starting from a specific clock time.                                                                                                                                                                                                                                                                                                                                                                                  |
| <i>time</i>        |  | Time from which to display messages in hours and minutes (hh:mm).                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>from-boot</b>   |  | Displays event trace messages starting from a specified number of seconds after booting.                                                                                                                                                                                                                                                                                                                                                            |
| <i>seconds</i>     |  | Number of seconds since the networking device was last booted (uptime). To view the uptime, enter the <b>show monitor event-trace component from-boot ?</b> command.                                                                                                                                                                                                                                                                                |
| <b>detail</b>      |  | Displays information in detailed format.                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>latest</b>      |  | Displays only the event trace messages since the last <b>show monitor event-trace</b> command was entered.                                                                                                                                                                                                                                                                                                                                          |
| <b>parameters</b>  |  | Displays the trace parameters. Currently, the only parameter displayed is the size (number of trace messages) of the trace file.                                                                                                                                                                                                                                                                                                                    |

| 12.2(8)T    | This feature was integrated into Cisco IOS Release 12.2(8)T. |
| 12.2(25)SW3 | The <b>itp-group</b> component was added.                    |
| 12.2(25)SW5 | The <b>cs7 mlr</b> component was added.                      |

**Usage Guidelines**

Use the **show monitor event-trace** command to display trace message information.

The trace function is not locked while information is being displayed to the console, which means that new trace messages can accumulate in memory. If entries accumulate faster than they can be displayed, some messages can be lost. If this situation occurs, the **show monitor event-trace** command generates a message indicating that some messages might be lost; however, messages will continue to display on the console. If the number of lost messages is excessive, the **show monitor event-trace** command stops displaying messages.

**Examples**

The following example includes output from the **show monitor event-trace** command with **itp-group** as the *component* argument and the **all** keyword:

```
ITP# show monitor event-trace itp-group all
00:00:15.581: ITP Group: starting 60 sec peer timer

The following example includes output from the **show monitor event-trace** command with **cs7 mlr** as the *component* argument and the **all** keyword. Notice the “one or more entries lost” message. The trace function is not locked while information is being displayed to the console, which means that new trace messages can accumulate in memory. If entries accumulate faster than they can be displayed, some messages can be lost. If this situation occurs, the “one or more entries lost” message is displayed in the output.

```

ITP# show monitor event-trace cs7 mlr all

```

The following example includes output from the **show monitor event-trace** command with **cs7 mlr** as the *component* argument and the **parameters** keyword. The example shows that the trace is enabled and the size of the trace memory.

```

ITP# show monitor event-trace cs7 mlr parameters
Trace has 10000 entries
Stacktrace is disabled by default
Trace is enabled in instance 0 with ruleset MLR2

```

## Syntax of MLR Call Trace Records

The **show monitor event-trace cs7 mlr** command displays three types of MLR call trace records: MLRI (inbound message record), MLRO (outbound message record), and MLRE (error record). The syntax of the information contained in call records is provided in the following list:

- Syntax for information common to all MLR trace records. The fields are described in [Table 83](#).

```
{MLRI | MLRO | MLRE}:instance-number rule:order ils-name dpc:dpc opc:opc cdPa:cdPa
cgPa:cgPa tcapMsg otid:otid [dtid:dtid]
```

- Syntax for MLRI sms-mo operation-specific information. The fields are described in [Table 84](#).

```
SMS-MO [pduType] dstSme:dest-sme orgSme:orig-sme dstSmsc:dest-smsc imsi:imsi
smRpUiLen:len
```

- Syntax for MLRI smdpp operation-specific information. The fields are described in [Table 85](#).

```
SMDPP dstSme:dest-sme orgSme:orig-sme [min min] [imsi:imsi] smsDataLen:len
```

- Syntax for MLRO result-specific information. The fields are described in [Table 86](#).

```
Result {Resume SCCP routing | Resume SCCP GTT modified | Route to MLR destination}
[Group:result-group-name] Type:result-type Matched:ruleset-name rule number
```

- Syntax for MLRE result-specific information. The fields are described in [Table 87](#).

```
Result {Resume SCCP routing | Routing failure} [Group:result-group-name]
Type:result-type Error:error-description [Matched:ruleset-name rule number]
```

[Table 83](#) describes the syntax of fields common to all MLR trace records.

**Table 83** *show monitor event-trace Fields Common to all MLR Trace Records*

| Field                                                                | Description                                                                                                                                                                                                                                                                                                         |

[Table 85](#) describes the fields for MLRI SMDPP operation-specific information.

For SMDPP messages:

- The **dstSme** keyword is used to indicate which parameter was used for dest-sme rule matching. Even if multiple parameters are present in the message, only the parameter used for dest-sme rule matching is displayed.

- The **orgSme** keyword also indicates which parameter was used for dest-sme rule matching. Even if multiple parameters are present in the message, only the parameter used for orig-sme rule matching is displayed.

**Table 85** *show monitor event-trace Fields in SMDPP Operation MLRI Trace Records*

# show redundancy states

To display information about the redundancy state of the Cisco 7600 ITP platform during the Non-Disruptive Upgrade process, use the **show redundancy states** privileged EXEC command.

## show redundancy states

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** Privileged EXEC

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Examples** The following output shows the redundancy state on the active supervisor before the switchover:

```
ITP#show redundancy states
    my state = 13 -ACTIVE
    peer state = 8  -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 5
Redundancy Mode (Operational) = sso
Redundancy Mode (Configured)  = sso
Redundancy State               = sso

    Split Mode = Disabled
    Manual Swact = Enabled
    Communications = Up

    client count = 62
    client_notification_TMR = 30000 milliseconds
        keep_alive TMR = 9000 milliseconds
        keep_alive count = 1
        keep_alive threshold = 18
        RF debug mask = 0x0
```

The following output shows the redundancy state on the active supervisor after the switchover:

```
itp#sh red states
    my state = 13 -ACTIVE
    peer state = 8  -STANDBY HOT

# show redundancy inter-device

To display redundancy information, use the **show redundancy inter-device** privileged EXEC command.

## show redundancy inter-device

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** Privileged EXEC

| Command History | Release     | Modification                         |
|-----------------|-------------|--------------------------------------|
|                 | 12.2(18)IXA | This command was introduced for ITP. |
|                 | 12.4(11)SW  |                                      |
|                 | 12.2(33)IRA |                                      |

**Examples** The following example shows how to display interdevice redundancy information:

```
ITP# show redundancy inter-device
Redundancy inter-device state: RF_INTERDEV_STATE_ACT
      Scheme: Platform
      Peer present: RF_INTERDEV_PEER_COMM
```

[Table 88](#) describes the significant fields shown in the display.

**Table 88** *show redundancy inter-device Field Descriptions*

| Field                         | Description                                                                              |
|-------------------------------|------------------------------------------------------------------------------------------|
| Redundancy inter-device state | Displays internal state of interdevice redundancy finite state machine.                  |
| RF_INTERDEV_STATE_INIT        | Initial state.                                                                           |
| RF_INTERDEV_STATE_PC_NO_PLAT  | Peer communication established but redundancy role has not been determined.              |
| RF_INTERDEV_STATE_PNC_NO_PLAT | Peer communication has not been established and redundancy role has not been determined. |
| RF_INTERDEV_STATE_ACT         | This device is the Active device.                                                        |
| RF_INTERDEV_STATE_STDBY       | This device is the Standby device.                                                       |
| Scheme                        | Entity that determines redundancy role.                                                  |
| Platform                      | Redundancy role is determined based on platform state.                                   |
| Standby                       | Redundancy role is determined by HSRP.                                                   |
| Peer Present                  | Fields describe communication with peer device.                                          |

**Table 88** *show redundancy inter-device Field Descriptions (continued)*

| Field                    | Description                                     |
|--------------------------|-------------------------------------------------|
| RF_INTERDEV_PEER_COMM    | Communication established with peer device.     |
| RF_INTERDEV_PEER_NO_COMM | Communication not established with peer device. |

**Related Commands**

# show sscf-nni

To display SSCF information, use the **show sscf-nni** EXEC command.

**show sscf-nni** [*interface*]

|                           |                  |                                                                                        |
|---------------------------|------------------|----------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>interface</i> | If no interface number is specified, all interfaces supporting SSCF-NNI are displayed. |
|---------------------------|------------------|----------------------------------------------------------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |      |
|----------------------|------|
| <b>Command Modes</b> | EXEC |
|----------------------|------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Examples** The following example includes output from the **show sscf-nni** command for the ATM interface:

```
ITP# show sscf-nni atm
SSCF-NNI details for interface ATM5/0/0
SSCF-NNI Current State = In Service
ULP Current State = In Service
SSCF-NNI Configured Parameters:
N1 = 90000 T1 = 5 T2 = 120
T3 = 1 SSCOP Rec = 60 Force Proving = 10
No Credit = 2 NRP = 0
SSCF-NNI Dynamic Parameters:
C1 = 0 MaxNRP = 1
MPS = 11 UPS = 4 Congestion Level = 0
SSCF-NNI Most Recent SSCOP-UU values:
Local Proving Status= 4 Local Release Status= 1
Remote Proving Status= 4 Remote Release Status= 0
SSCF-NNI Statistics:
MSU's Sent = 3334178, MSU's Received = 3346602, MSU's Ignored = 0
LSSU's Sent = 1010831, LSSU's Received = 796648, LSSU's Ignored = 0
Byte's Sent = 119636773, Byte's Received = 120107750
```

[Table 89](#) describes the fields in the **show sscf** display.

**Table 89** *show sscf Field Descriptions*

| Field                  | Description                                                                       |
|------------------------|-----------------------------------------------------------------------------------|
| SSCF-NNI Current State | Current state as defined in Q.2140.                                               |
| ULP Current State -    | Current state of Upper Layer Protocol as viewed by SSCF and as defined in Q.2140. |

**Table 89**      *show sscf Field Descriptions*

| Field                 | Description                                               |
|-----------------------|-----------------------------------------------------------|
| Configured parameters | The configured parameters.                                |
| Dynamic parameters    | Variables used by SSCF as defined in Q.2140.              |
| SSCOP-UU values       | Most recent values sent or received as defined in Q.2140. |
| Stats                 | Statistics.                                               |

# show sscop

To display Service-Specific Connection-Oriented Protocol (SSCOP) details for all ATM interfaces, use the **show sscop** EXEC command.

**show sscop** [*interface*]

|                           |                  |                                                                              |
|---------------------------|------------------|------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>interface</i> | If no interface is specified, all interfaces supporting SSCOP are displayed. |
| <b>Defaults</b>           | None.            |                                                                              |
| <b>Command Modes</b>      | EXEC             |                                                                              |
| <b>Command History</b>    | <b>Release</b>   | <b>Modification</b>                                                          |
|                           | 10.0             | This command was introduced.                                                 |

## Examples

The following example includes output from the **show sscop** command:

```
ITP# show sscop
SSCOP details for interface ATM4/0/0
  Current State = Active,   Uni version = NNI
  Send Sequence Number: Current = 1118,   Maximum = 2142
  Send Sequence Number Acked = 1118
  Rcv Sequence Number: Lower Edge = 1137, Upper Edge = 1137, Max = 2161
  Poll Sequence Number = 35181, Poll Ack Sequence Number = 35181
  Vt(Pd) = 0   Vt(Sq) = 1   MaxPd = 500
  Timer_IDLE = 100 - Inactive
  Timer_CC = 200 - Inactive
  Timer_POLL = 100 - Inactive
  Timer_KEEPLIVE = 100 - Inactive
  Timer_NO-RESPONSE = 1500 - Inactive
  Current Retry Count = 0, Maximum Retry Count = 10
  AckQ count = 0, RcvQ count = 0, TxQ count = 0
  AckQ HWM = 279, RcvQ HWM = 0, TxQ HWM = 42
  Local connections currently pending = 0
  Max local connections allowed pending = 0
  Statistics -
    Pdu's Sent = 61744, Pdu's Received = 61903, Pdu's Ignored = 0
    Begin = 0/2, Begin Ack = 2/0, Begin Reject = 0/0
    End = 0/6, End Ack = 0/0
    Resync = 0/0, Resync Ack = 0/0
    Sequenced Data = 49840/49660, Sequenced Poll Data = 0/0
    Poll = 6099/5997, Stat = 5982/6099, Unsolicited Stat = 0/0
    Unassured Data = 0/0, Mgmt Data = 0/0, Unknown Pdu's = 0
    Error Recovery/Ack = 0/0, lack of credit 0
```

Table 90 describes the fields in the **show sscop** display.

**Note**

“Inactive” status (in the Timer fields) does not mean that the timer is disabled. It means that the timer is currently not running.

**Table 90** *show sscop Field Descriptions*

| Field                       | Description                                                                                   |
|-----------------------------|-----------------------------------------------------------------------------------------------|
| SSCOP details for interface | Interface slot and port.                                                                      |
| Current State               | SSCOP state for the interface.                                                                |
| Uni Version                 | The version of the SSCF layer. For ITP, the Uni Version is NNI.                               |
| Send Sequence Number        | Current and maximum send sequence number.                                                     |
| Send Sequence Number Acked  | Sequence number of packets already acknowledged.                                              |
| Rcv Sequence Number         | Sequence number of packets received.                                                          |
| Poll Sequence Number        | Current poll sequence number.                                                                 |
| Poll Ack Sequence Number    | Poll sequence number already acknowledged.                                                    |
| Vt(Pd)                      | Number of sequenced data (SD) frames sent, which triggers a sending of a poll frame.          |
| Vt(Sq)                      | Transmitter connection sequence number that helps peer detect connection message retransmits. |
| MaxPd                       | Maximum number of packets sent before a poll packet is sent.                                  |
| Timer_IDLE                  | Configured sscop idle-timer in milliseconds and the Active/Inactive status.                   |
| Timer_CC                    | Configured sscop cc-timer in milliseconds.                                                    |
| Timer_POLL                  | Configured sscop poll-timer in milliseconds.                                                  |
| Timer_KEEPAKALIVE           | Configured sscop keepalive-timer in milliseconds.                                             |
| Timer_NO-RESPONSE           | Configured sscop noResponse-timer in milliseconds.                                            |
| Connection Control          | Timer used for establishing and terminating SSCOP.                                            |
| Keep Alive Timer            | Timer used to send keepalives on an idle link.                                                |
| Current Retry Count         | Current count of the retry counter.                                                           |
| Maximum Retry Count         | Maximum value the retry counter can take.                                                     |
| AckQ HWM                    | Current number of packets waiting for acknowledgement and the high-water mark.                |
| RcvQ HWM                    | Current number of packets in receive queue yet to be processed and high-water mark.           |
| TxQ HWM                     | Current number of packets in transmit queue waiting to be sent.                               |
| Pdu's Sent                  | Total number of SSCOP frames sent.                                                            |
| Pdu's Received              | Total number of SSCOP frames received.                                                        |
| Pdu's Ignored               | Number of invalid SSCOP frames ignored.                                                       |
| Begin                       | Number of Begin frames sent/received.                                                         |
| Begin Ack                   | Number of Begin Ack frames sent/received.                                                     |

**Table 90**      *show sscop Field Descriptions (continued)*

| <b>Field</b>        | <b>Description</b>                                                                                 |
|---------------------|----------------------------------------------------------------------------------------------------|
| Begin Reject        | Number of Begin Reject frames sent/received.                                                       |
| End                 | Number of End frames sent/received.                                                                |
| End Ack             | Number of End Ack frames sent/received.                                                            |
| Resync              | Number of Resync frames sent/received.                                                             |
| Resync Ack          | Number of Resync Ack frames sent/received.                                                         |
| Sequenced Data      | Number of Sequenced Data frames sent/received.                                                     |
| Sequenced Poll Data | Number of Sequenced Poll Data frames sent/received.                                                |
| Poll                | Number of Poll frames received/sent.                                                               |
| Stat                | Number of Stat frames received/sent.                                                               |
| Unsolicited Stat    | Number of Unsolicited Stat frames received/sent.                                                   |
| Unassured Data      | Number of Unassured Data frames received/sent.                                                     |
| Mgmt Data           | Number of Mgmt Data frames received/sent.                                                          |
| Unknown Pdu's       | Number of Unknown PDU frames sent/received.                                                        |
| Error Recovery/Ack  | Number of error recovery PDUs sent/number of error recovery ACK PDUs sent.                         |
| Lack of credit      | Number of times an attempt to transmit data failed because the send window was closed by the peer. |

# show tech-support

To collect and display information for troubleshooting your system, use the **show tech-support** privileged EXEC command.

|                           |                                            |
|---------------------------|--------------------------------------------|
| <b>Syntax Description</b> | This command has no arguments or keywords. |
|---------------------------|--------------------------------------------|

|                 |       |
|-----------------|-------|
| <b>Defaults</b> | None. |
|-----------------|-------|

|                      |                 |

| <b>Command Modes</b> | Privileged EXEC |
|----------------------|-----------------|

| Command History | Release                                  | Modification                                                |
|-----------------|------------------------------------------|-------------------------------------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was enhanced to display information about ITP. |

**Usage Guidelines**

The **show tech-support** command is useful for collecting a large amount of information about your ITP configuration for troubleshooting purposes. The output of this command can be provided to technical support representatives when reporting a problem.

The **show tech-support** command displays the output of a number of show commands at once. The output from this command will vary depending on your platform and configuration.

For information about general output, refer to the **show tech-support** entry in the “Troubleshooting and Fault Management Commands” section of the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.2*.

Specific ITP information collected by the following commands is displayed as output from the **show tech-support** command:

- show cs7
- show cs7 mtp3 errors
- show cs7 route
- show cs7 linkset
- show cs7 linkset statistics
- show cs7 accounting
- show cs7 gtt measurements

When M3UA or SUA is configured, output from the following commands is displayed:

- show cs7 m3ua
- show cs7 sua
- show cs7 asp
- show cs7 as

- show cs7 point-codes

When ITP Nonstop Operation (NSO) is configured, output from the following commands is displayed:

- show cs7 nso state
- show cs7 nso counters detailed

When an ITP group is configured, output from the following commands is displayed:

- show cs7 group state
- show cs7 group counters detailed
- show cs7 group transport

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Examples

The following example shows how to disable M3UA on port 2905:

```
cs7 m3ua 2905
shutdown
```

|                         | <a href="#">cs7 asp</a> | Specifies an application server process (ASP) and enables cs7 asp submode. |

# shutdown (cs7 dcs)

To stop sending PMP packets and pings to a DCS node, use the **shutdown** command in cs7 dcs submode. To reenale sending packets and pings, use the **no** form of this command.

**shutdown**

**no shutdown**

## Syntax Description

This command has no arguments or keywords.

## Defaults

The DCS node is shut down by default.

## Command Modes

cs7 dcs submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Examples

The following example shows how to disable the DCS node named alpha:

```
cs7 dcs alpha
shutdown
```

## Related Commands

| Command            | Description                                              |
|--------------------|----------------------------------------------------------|
| cs7 pmp            | Turns probeless monitoring on for all linksets and ASes. |
| cs7 pmp hold-queue | Sets the integer range of PMP hold queue thresholds.     |
| cs7 dcs-group      | Identifies a name to be associated with a DCS group.     |
| cs 7 dcs           | Identifies a name to be associated with a DCS node.      |
| show cs7 pmp       | Displays errors and information about the PMP.           |
| show cs7 dcs-group | Displays information about the DCS group.                |
| show cs7 dcs       | Displays information about the DCS node.                 |

# shutdown (cs7 link)

To disable a link, use the **shutdown** cs7 link submode command. To bring a link into the active state (under the condition that its parent linkset is already in the active state), use the **no** form of this command.

**shutdown**

**no shutdown**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** cs7 link submode

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |
|                 |             |                              |

**Usage Guidelines** A link can be brought back into the active state with the **no shutdown** command only if its parent link is in the active state.

**Note**

The **cs7 prompt enhanced** command is an optional global configuration command that changes the prompt in linkset configuration mode to display the linkset (and, where applicable, the link) that is currently being configured. This command is intended to help avoid the possibility of inadvertently shutting down the wrong linkset or link.

**Examples** The following example shows how to disable the link:

```
cs7 linkset michael 10.1.1
link 0 sctp 172.18.44.147 7000 7000
shutdown
```

| Related Commands | Command                                | Description                                                                                                                                   |
|------------------|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
|                  | <a href="#">cs7 ignore-sccp-pcconv</a> | Inhibits a link.                                                                                                                              |
|                  | <a href="#">cs7 prompt enhanced</a>    | Changes the prompt in linkset configuration mode to display the linkset (and, where applicable, the link) that is currently being configured. |

# shutdown (cs7 linkset)

To disable a linkset, use the **shutdown** cs7 linkset submode command. To reactivate a disabled linkset, use the **no** form of this command.

**shutdown**

**no shutdown**

**Syntax Description** This command has no arguments or keywords.

**Defaults** None.

**Command Modes** cs7 linkset submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

A linkset can be activated or deactivated with the (no) **shutdown** command.

When you deactivate a linkset with the **shutdown** command, all links in that linkset are deactivated. The linkset is shown as “SHUTDOWN” in the output of the **show term** command.

However, the links in the linkset do not appear as “SHUTDOWN” because they were not administratively shut down.

When a link is administratively shut down, it remains in the shutdown state (and is not activated, even when its linkset is activated) until a **no shutdown** command is specified for the link. The reason for requiring an explicit reactivation (no shutdown) of a link is to allow users to maintain the state of the link when linksets are activated, in case they do not want a link to be activated.

### Note

The **cs7 prompt enhanced** command is an optional global configuration command that changes the prompt in linkset configuration mode to display the linkset (and, where applicable, the link) that is currently being configured. This command is intended to help avoid the possibility of inadvertently shutting down the wrong linkset or link.

## Examples

The following example shows how to shut down the linkset, and all links in the linkset:

```
cs7 linkset rosebud
shutdown
```

The following example shows how to reactivate the linkset named rosebud, but all links belonging to the linkset remain deactivated until explicitly activated with the link subcommand **no shut**:

```
cs7 linkset rosebud
no shutdown
```

# si

To specify a service indicator in an MTP message type table, use the **si** command in cs7 gws mtp message table configuration mode. To remove the specification, use the **no** form of this command.

```
si si mtp-msg-h0 mtp-msg-h0 mtp-msg-h1-range mtp-msg-h1-start [mtp-msg-h1-end] result
    {action action-set-name | table table-name}
```

```
no si si mtp-msg-h0 mtp-msg-h0 mtp-msg-h1-range mtp-msg-h1-start [mtp-msg-h1-end] result
    {action action-set-name | table table-name}
```

or

```
si si mtp-msg-type mtp-msg-type result {action action-set-name | table table-name}
```

```
no si si mtp-msg-type mtp-msg-type result {action action-set-name | table table-name}
```

To specify a service indicator in an SIO type table, use the **si** command in cs7 gws sio table configuration mode. To remove the specification, use the **no** form of this command.

```
si si [priority-range pri-start [pri-end]] result {action action-set-name | table table-name}
```

```
no si si [priority-range pri-start [pri-end]] result {action action-set-name | table table-name}
```

## Syntax Description

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>table</b>           | Screens by table by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <i>table-name</i>      | Table name. Valid names may not exceed 12 alphanumeric characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Defaults** None.

**Command Modes** cs7 gws mtp message table configuration

| Command History | Release                                   | Modification                              |
|-----------------|-------------------------------------------|-------------------------------------------|
|                 | 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA  | This command was introduced.              |
|                 | 12.2(18)IXH<br>12.4(15)SW3<br>12.2(33)IRC | Additional service indicators were added. |
|                 |                                           |                                           |

**Usage Guidelines** The **si** command is valid in the following table types: mtp-msg-type, sio.

**Examples** The following example shows how to specify a management service indicator (mgmt) entry in table MTP0:

```
cs7 instance 0 gws table MTP0 type mtp-msg-type action allowed
default result action ALLOW
si mgmt mtp-msg-type CBD result table PCSSN1
si mgmt mtp-msg-type CBA result action ALLOW
```

The following example shows how to specify SCCP and ISUP service indicator (sccp and isup) entries in table SIO0:

```
cs7 instance 0 gws table SIO0 type sio action allowed
si sccp result table PCSSN1
si isup result action ALLOW
```

| Related Commands | Command                       | Description                           |
|------------------|-------------------------------|---------------------------------------|
|                  | <a href="#">cs7 gws table</a> | Configures a gateway screening table. |

# sls-shift

When the variant is ITU, to shift which signaling link selection (SLS) bits are used for link and linkset selection, use the **sls-shift** command in cs7 linkset configuration mode. To disable the specification, use the **no** form of this command.

**sls-shift [0-3]**

**no sls-shift**

## Syntax Description

|            |                                                                                                                                                                     |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>0-3</b> | This argument indicates a range, from least significant bit (0) to most significant bit (3) of the SLS, to be used for linkset selection within a combined linkset. |
|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Defaults

The default is bit 0, the equivalent of the **no sls-shift** command.

## Command Modes

cs7 linkset configuration

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

This command is valid only when the variant is ITU. It affects MSUs received on the linkset, and changes which bit in the SLS is used for linkset selection.

ITP provides the ability to change which bit to use for linkset selection because ITU, unlike ANSI, does not perform SLS rotation. If all nodes in the network use the same bit for linkset selection, traffic will not balance evenly.

## Examples

The following example shows how to specify that the most significant bit (3) of the SLS is to be used for linkset selection within a combined linkset:

```
cs7 linkset linkset1
sls-shift 3
```

# snmp-server enable traps bits-clock

To enable Simple Network Management Protocol (SNMP) to generate notifications about the building integrated timing supply (BITS) clocking sources and modes of operations, use the **snmp-server enable traps bits-clock** global configuration command. To disable the sending of traps, use the **no** form of this command.

**snmp-server enable traps bits-clock**

**no snmp-server enable traps bits-clock**

## snmp-server enable traps cs7

To enable ITP Simple Network Management Protocol (SNMP) traps to be sent, use the **snmp-server enable traps cs7** global configuration command. To disable the sending of ITP SNMP traps, use the **no** form of this command.

```
snmp-server enable traps cs7 [crd-state][dsmr-smpp-dest] [dsmr-table-load] [dsmr-ucp-dest]
[gtt-map-state] [gw-dest-r1-state] [gw-dest-state] [gw-gtt-errors] [gw-gtt-load]
[gw-isolation] [gw-link-congestion] [gw-link-state] [gw-link-utilization] [gw-linkset-state]
[gw-map-state] [gw-route-load] [gw-route-mgmt-state] [gw-route-r1-mgmt-state]
[link-congestion] [link-state] [link-utilization] [linkset-state] [mlr-table-load]
[monitor-congestion] [monitor-state] [route-state] [msu-rate] [xua-state]
```

```
no snmp-server enable traps cs7 [crd-state][dsmr-smpp-dest] [dsmr-table-load]
[dsmr-ucp-dest] [gtt-map-state] [gw-dest-r1-state] [gw-dest-state] [gw-gtt-errors]
[gw-gtt-load] [gw-isolation] [gw-link-congestion] [gw-link-state] [gw-link-utilization]
[gw-linkset-state] [gw-map-state] [gw-route-load] [gw-route-mgmt-state]
[gw-route-r1-mgmt-state] [link-congestion] [link-state] [link-utilization] [linkset-state]
[mlr-table-load] [monitor-congestion] [monitor-state] [route-state] [msu-rate] [xua-state]
```

| <b>gw-link-state</b>      | Enables the gateway link-state trap (ciscoGspLinkStateChange) in CISCO-ITP-GSP-MIB.my.                                                                                                                                                                |

|                               |                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>gw-link-utilization</b>    | Enables gateway link-utilization traps (ciscoGspLinkRcvdUtilChange, ciscoGspLinkSentUtilChange) in CISCO-ITP-GSP-MIB.my.                                                                                                                                                                                                                        |
| <b>gw-linkset-state</b>       | Enables the gateway linkset-state trap (ciscoGspLinksetStateChange) in CISCO-ITP-GSP-MIB.my.                                                                                                                                                                                                                                                    |
| <b>gw-map-state</b>           | Enables the gateway Mated Appl (MAP) state trap.                                                                                                                                                                                                                                                                                                |
| <b>gw-route-load</b>          | Enables the gateway route table load trap (ciscoGrtRouteTableLoad) in CISCO-ITP-GRT-MIB.my.                                                                                                                                                                                                                                                     |
| <b>gw-route-mgmt-state</b>    | Enables the gateway route management state change trap (ciscoGrtMgmtStateChange) in CISCO-ITP-GRT-MIB.my.                                                                                                                                                                                                                                       |
| <b>gw-route-r1-mgmt-state</b> | Enables the gateway route management state change rev1 trap (ciscoGrtMgmtStateChange) in CISCO-ITP-GRT-MIB.my.                                                                                                                                                                                                                                  |
| <b>link-congestion</b>        | Enables the link-congestion trap (cItpSpCongestionChange) in CISCO-ITP-SP-MIB.my.<br><i>Deprecated and replaced by <b>gw-link-congestion</b>.</i>                                                                                                                                                                                               |
| <b>link-state</b>             | Enables the link-state trap (cItpSpLinkStateChange) in CISCO-ITP-SP-MIB.my.<br><i>Deprecated and replaced by <b>gw-link-state</b>.</i>                                                                                                                                                                                                          |
| <b>link-utilization</b>       | Enables the link-utilization trap.<br><i>Deprecated and replaced by <b>gw-link-utilization</b>.</i>                                                                                                                                                                                                                                             |
| <b>linkset-state</b>          | Enables the linkset-state trap (cItpSpLinksetStateChange) in CISCO-ITP-SP-MIB.my.<br><i>Deprecated and replaced by <b>gw-linkset-state</b>.</i>                                                                                                                                                                                                 |
| <b>mlr-table-load</b>         | Enables the MLR table load trap in CISCO-ITP-MLR-MIB.my. This notification is generated whenever a load operation is started or completed. Route table configurations can be loaded by CLI requests. In addition, route tables can be loaded using configuration statements, which allows MLR tables to be reloaded whenever a device restarts. |
| <b>monitor-congestion</b>     | Enables the ciscoItpMonitorCongestion notification in CISCO-ITP-MONITOR-MIB.my.                                                                                                                                                                                                                                                                 |
| <b>monitor-state</b>          | Enables the monitor-state trap in CISCO-ITP-MONITOR-MIB.my. Notification is generated when a connection changes states. The value of cItpmConnMonitorState indicates the new state.                                                                                                                                                             |
| <b>route-state</b>            | Enables the route-state trap (cItpRouteStateChange) in CISCO-ITP-RT-MIB.my.<br><i>Deprecated and replaced by <b>gw-route-mgmt-state</b>.</i>                                                                                                                                                                                                    |
| <b>msu-rate</b>               | Enables the msu-rate trap.                                                                                                                                                                                                                                                                                                                      |
| <b>xua-state</b>              | Enables the following traps in CISCO-ITP-XUA-MIB.my:<br>ciscoItpXuaAspStateChange - ASP state change<br>ciscoItpXuaSgmStateChange - Mated-SG state change<br>ciscoItpXuaAsStateChange - AS state change<br>ciscoItpXuaAspCongChange - ASP congestion state change<br>ciscoItpXuaSgmCongChange - Mated-SG congestion state change                |

**Defaults**

This command is disabled.

**Command Modes** Global configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** When you enable CS7 traps, the default value for trap queue length (10 events) might cause traps to be lost. To avoid this situation, set the trap queue length to 100 using the **snmp-server queue-length** global configuration command.

For more information about SNMP, refer to “Configuring SNMP Support” in the Cisco IOS Release 12.1 *Configuration Fundamentals Configuration Guide*, Part 3, Cisco IOS System Management, at the following URL:

[http://www.cisco.com/univercd/cc/td/doc/product/software/ios121/121cgcr/fun\\_c/fcprt3/fcd301.htm](http://www.cisco.com/univercd/cc/td/doc/product/software/ios121/121cgcr/fun_c/fcprt3/fcd301.htm)

**Examples** The following example shows how to enable SNMP network management traps to be sent to the specified host for the Cisco ITP. The example also increases the trap queue length (from the default of 10 events) to 100 events to reduce the possibility of dropping traps.

```
snmp-server enable traps cs7
snmp community public R0
snmp host 64.102.86.159 version 2c public
snmp-server queue-length 100
```

## snmp-server enable traps sctp

To enable Simple Network Management Protocol (SNMP) SCTP traps to be sent, use the **snmp-server enable traps sctp** global configuration command. To disable the sending of traps, use the **no** form of this command.

**snmp-server enable traps sctp** [**dest-address-state**]

**no snmp-server enable traps sctp** [**dest-address-state**]

|                    |                                                                                                                                              |                                                                                                                                     |

To specify SSCF NNI parameters for the CS7 HSL profile, use the **sscf-nni** *cs7 hsl* profile command. To remove the configuration, use the **no** form of this command.

**sscf-nni** {**force-proving** *minutes* | **n1** *number* | **no-credit** *seconds* | **nrp** *number* | **sscop-recovery** *minutes* | **t1** *seconds* | **t2** *seconds* | **t3** *milliseconds*}

**no sscf-nni** {**force-proving** *minutes* | **n1** *number* | **no-credit** *seconds* | **nrp** *number* | **sscop-recovery** *minutes* | **t1** *seconds* | **t2** *seconds* | **t3** *milliseconds*}

## Syntax Description

|                                      |                                                                                                                                                                    |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>force-proving</b> <i>minutes</i>  | Specifies the time (in minutes) to monitor the link after proving. The range is 0 to 20 minutes. The default is 10 minutes.                                        |
| <b>n1</b> <i>number</i>              | Specifies the number of PDUs sent during proving. The range is 5 to 180000 PDUs. The default for ITU is 1000 PDUs. The default for ANSI is 60000 PDUs.             |
| <b>no-credit</b> <i>seconds</i>      | Specifies the time (in seconds) allowed with no credit. The range is 1 to 6 seconds. The default is 2 seconds.                                                     |
| <b>nrp</b> <i>number</i>             | Specifies the maximum number of retransmissions allowed during proving. The range is 1 to 10 retransmissions. The default is 1 retransmission.                     |
| <b>sscop-recovery</b> <i>minutes</i> | Specifies the time (in minutes) for SSCOP recovery. The range is 30 to 1440 minutes. The default is 60 minutes.                                                    |
| <b>t1</b> <i>seconds</i>             | Specifies the time (in seconds) to reestablish connection. The range is 1 to 15 seconds. The default is 5 seconds.                                                 |
| <b>t2</b> <i>seconds</i>             | Specifies the time (in seconds) for alignment to complete. The range is 15 to 180 seconds. The default for ITU is 30 seconds. The default for ANSI is 120 seconds. |
| <b>t3</b> <i>milliseconds</i>        | Specifies the time (in milliseconds) to send proving packets. The range is 1 to 5000 milliseconds. The default is 1 millisecond.                                   |

## Defaults

The default for **force-proving** *minutes* is 10 minutes.

The default for **n1** *number* is 1000 (ITU) or 60000 (ANSI).

The default for **no-credit** *seconds* is 2 seconds.

The default for **nrp** *number* is 1 retransmission.

The default for **sscop-recovery** *minutes* is 60 minutes.

The default for **t1** *seconds* is 5 seconds.

The default for **t2** *seconds* is 30 milliseconds (ITU) or 120 seconds (ANSI).

The default for **t3** *milliseconds* is 1 millisecond.

## Command Modes

cs7 hsl profile, cs7 linkset

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Usage Guidelines

SSCF NNI parameters can be configured in either a CS7 HSL profile or individually under a link.

| Related Commands | Command                       | Description                |
|------------------|-------------------------------|----------------------------|

# sscop

To specify SSCOP parameters for the CS7 HSL profile, use the **sscop cs7 hsl** profile command.  
To remove the configuration, use the **no** form of this command.

**sscop** {**cc-timer** *msecs* | **idle-timer** *msecs* | **keepalive-timer** *msecs* | **max-cc** *number* | **max-pd** *number* | **noResponse-timer** *msecs* | **poll-timer** *msecs* | **receive-window** *number* | **send-window** *number*}

**no sscop** {**cc-timer** *msecs* | **idle-timer** *msecs* | **keepalive-timer** *msecs* | **max-cc** *number* | **max-pd** *number* | **noResponse-timer** *msecs* | **poll-timer** *msecs* | **receive-window** *number* | **send-window** *number*}

| Syntax Description                   |  |                                                                                                                                                                         |
|--------------------------------------|--|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cc-timer</b> <i>msecs</i>         |  | Specifies the time (in milliseconds) to send BGN/END/RS/ER PDU at the connection control phase. The range is 100 to 2000 milliseconds. The default is 200 milliseconds. |
| <b>idle-timer</b> <i>msecs</i>       |  | Specifies the time (in milliseconds) to send poll PDU at the idle phase. The range is 25 to 1000 milliseconds. The default is 100 milliseconds.                         |
| <b>keepalive-timer</b> <i>msecs</i>  |  | Specifies the time (in milliseconds) to send poll PDU at the transient phase. The range is 25 to 500 milliseconds. The default is 100 milliseconds.                     |
| <b>max-cc</b> <i>number</i>          |  | Specifies the maximum number of retries for connection control operations. The range is 1 to 127 retries. The default is 4 retries.                                     |
| <b>max-pd</b> <i>number</i>          |  | Specifies the maximum number of Sd frames to send before sending a Poll. The range is 1 to 500 Sd frames. The default is 500 Sd frames.                                 |
| <b>noResponse-timer</b> <i>msecs</i> |  | Specifies the time (in milliseconds) in which at least one STAT PDU must be received. The range is 200 to 2000 milliseconds. The default is 1500 milliseconds.          |
| <b>poll-timer</b> <i>msecs</i>       |  | Specifies the times (in milliseconds) to send poll PDU at the active phase. The range is 25 to 500 milliseconds. The default is 100 milliseconds.                       |
| <b>receive-window</b> <i>number</i>  |  | Specifies the maximum number of Sd(p) frames a partner can send. The range is 1 to 1024 Sd(p) frames. The default is 1024 Sd(p) frames.                                 |
| <b>send-window</b> <i>number</i>     |  | Specifies the maximum number of Sd frames to send before waiting for acknowledgement. The range is 1 to 1024 Sd frames. The default is 1024 Sd frames.                  |

## Defaults

The default for **cc-timer** is 200 milliseconds.

The default for **idle-timer** is 100 milliseconds.

The default for **keepalive-timer** is 100 milliseconds.

The default for **max-cc** is 4 retries.

The default for **max-pd** is 500 Sd frames.

The default for **noResponse-timer** is 1500 milliseconds.

The default for **poll-timer** is 100 milliseconds.

The default for **receive-window** is 1024 SD(p) frames.

The default for **send-window** is 1024 frames.

# timeout-count

To set the number of times the ITP retries the ping before marking the DCS node as unavailable, use the **timeout-count** cs7 dcs configuration submode command. To stop the action, use the **no** form of this command.

**timeout-count** *count*

**no timeout-count**

## Syntax Description

|              |                                                                                      |
|--------------|--------------------------------------------------------------------------------------|
| <i>count</i> | Number of times the ITP retries the ping before marking the DCS node as unavailable. |
|--------------|--------------------------------------------------------------------------------------|

## Defaults

The default rate is 3 retries.

## Command Modes

cs7 dcs configuration submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Examples

The following example shows how to configure two ping retries between the remote IP address and the local IP address:

```
cs7 dcs dcs5
 remote-ip 209.165.201.29 209.165.201.28 3033
 local-ip 1209.165.20127 3033
 ping-interval 5
 timeout-count 2
 udp-checksum
```

| Command            | Description                                              |
|--------------------|----------------------------------------------------------|
| cs7 pmp            | Turns probeless monitoring on for all linksets and ASes. |
| cs7 pmp hold-queue | Sets the integer range of PMP hold queue thresholds.     |
| cs7 dcs-group      | Identifies a name to be associated with a DCS group.     |
| cs 7 dcs           | Identifies a name to be associated with a DCS node.      |
| show cs7 pmp       | Displays errors and information about the PMP.           |
| show cs7 dcs-group | Displays information about the DCS group.                |
| show cs7 dcs       | Displays information about the DCS node.                 |

## timer (cs7 hs-mtp2 profile)

You can define high-speed MTP2 timers in a CS7 profile and apply the profile to a linkset. To configure high-speed MTP2 encapsulation timers in a CS7 profile, use the **timer** command in cs7 hs-mtp2 profile configuration mode. To reset the timers, use the **no** form of this command.

**timer** {**t1** msec | **t2** msec | **t3** msec | **t4e** msec | **t4n** msec | **t5** msec | **t6** msec | **t7** msec | **t8** msec}

**no timer** {**t1** msec | **t2** msec | **t3** msec | **t4e** msec | **t4n** msec | **t5** msec | **t6** msec | **t7** msec | **t8** msec}

| Syntax Description |                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>t1</b>          | Alignment ready timer.<br>ANSI range: 165 to 200 seconds. Default is 170 seconds.<br>ITU range: 25 to 350 seconds. Default is 300 seconds.                                              |
| <b>t2</b>          | Not aligned timer.<br>ANSI range: 5 to 14 seconds. Default is 11.5 seconds.<br>ITU range: 5 to 150 seconds. Default is 5 seconds.                                                       |
| <b>t3</b>          | Aligned timer.<br>ANSI range: 5 to 14 seconds. Default is 11.5 seconds.<br>ITU range: 1 to 2 seconds. Default is 1.5 seconds.                                                           |
| <b>t4e</b>         | Emergency proving period timer.<br>ANSI range: 4.5 to 5.5 seconds. Default is 5 seconds.<br>ITU range: 400 to 600 milliseconds. Default is 500 milliseconds.                            |
| <b>t4n</b>         | Normal proving period timer.<br>ANSI range: 27 to 33 seconds. Default is 30 seconds.<br>ITU range: 3 to 70 seconds. Default is 30 seconds.                                              |
| <b>t5</b>          | Sending SIB timer.<br>ANSI range: 80 to 120 milliseconds. Default is 100 milliseconds.<br>ITU range: 80 to 120 milliseconds. Default is 100 milliseconds.                               |
| <b>t6</b>          | Remote congestion timer.<br>ANSI range: 1 to 6 seconds. Default is 1 second.<br>ITU range: 3 to 6 seconds. Default is 3 seconds.                                                        |
| <b>t7</b>          | Excessive delay of acknowledgment timer.<br>ANSI range: 500 to 2000 milliseconds. Default is 1000 milliseconds.<br>ITU range: 500 to 2000 milliseconds. Default is 1000 milliseconds.   |
| <b>t8</b>          | Interval timer for errored interval monitor.<br>ANSI range: 80 to 12000 milliseconds. Default is 100 milliseconds.<br>ITU range: 80 to 12000 milliseconds. Default is 100 milliseconds. |

### Defaults

T1: ANSI = 170 seconds; ITU = 300 seconds

T2: ANSI = 11.5 seconds; ITU = 5 seconds

T3: ANSI = 11.5 seconds; ITU = 1.5 seconds

T4E: ANSI = 5 seconds; ITU = 500 milliseconds

T4N: ANSI = 30 seconds; ITU = 30 seconds

T5: ANSI = 100 milliseconds; ITU = 100 milliseconds

T6: ANSI = 1 second; ITU = 3 seconds

## ■ timer (cs7 hs-mtp2 profile)

T7: ANSI = 1000 milliseconds; ITU = 1000 seconds

T8: ANSI = 100 milliseconds; ITU = 100 milliseconds

**Command Modes** cs7 hs-mtp2 profile configuration

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

High-speed MTP2 parameters can also be specified in cs7 linkset configuration mode.

**Examples**

The following example shows how to define a profile named **TIMER**. The profile supports high-speed MTP2, configures the t1 and t2 settings, and applies to all the links in the linkset named **ITP\_A**.

```
cs7 profile TIMERS
  hs-mtp2
    timer t1 100
    timer t2 10
.
.
.
cs7 linkset ITP_A
  profile TIMERS
```

**Related Commands**

| Command                                              | Description                                                                            |
|------------------------------------------------------|----------------------------------------------------------------------------------------|
| <a href="#">cs7 profile</a>                          | Defines a profile of MTP2 parameters that you can apply to all the links in a linkset. |
| <a href="#">tx-queue-depth (cs7 hs-mtp2 profile)</a> | Configures the high-speed MTP2 transmit queue depth.                                   |

## timer (cs7 linkset)

To configure the ITP MTP3 management timers that control the linkset (and, optionally, a link on the linkset), use the **timer** cs7 linkset submode command. To reset a timer to its default value, use the **no** form of this command.

```
timer { retry msec | slt-t01 msec | slt-t02 msec | t01 msec | t02 msec | t03 msec | t04 msec | t05 msec  
| t12 msec | t13 msec | t14 msec | t17 msec | t19 msec | t20 msec | t21 msec | t22 msec | t23 msec  
| t24 msec | t25 msec | t28 msec | t29 msec | t30 msec | t32 msec }
```

```
no timer { retry | slt-t1 | slt-t2 | t01 | t02 | t03 | t04 | t05 | t12 | t13 | t14 | t17 | t19 | t20 | t21 | t22 |  
t23 | t24 | t25 | t28 | t29 | t30 | t32 }
```

### Note

Ranges are defined by ANSI or ITU.

### Syntax Description

| <b>t20</b> <i>msec</i> | (ANSI) Waiting to repeat local inhibit test.<br>(ANSI) Range of <i>msec</i> is 90000 to 120000 milliseconds.<br>(ANSI) Default is 105000 milliseconds.                                                                                                                                                                                              |
| <b>t21</b> <i>msec</i> | (ANSI) Waiting to repeat remote inhibit test.<br>(ANSI) Range of <i>msec</i> is 90000 to 120000 milliseconds.<br>(ANSI) Default is 105000 milliseconds.<br><br>(ITU) MTP restart timer at signaling point adjacent to one whose MTP restarts.<br>(ITU) Range of <i>msec</i> is 63000 to 65000 milliseconds.<br>(ITU) Default is 64000 milliseconds. |
| <b>t22</b> <i>msec</i> | (ITU) Local inhibit test timer.<br>(ITU) Range of <i>msec</i> is 180000 to 360000 milliseconds.<br>(ITU) Default is 300000 milliseconds.                                                                                                                                                                                                            |
| <b>t23</b> <i>msec</i> | (ITU) Remote inhibit test timer.<br>(ITU) Range of <i>msec</i> is 180000 to 360000 milliseconds.<br>(ITU) Default is 300000 milliseconds.                                                                                                                                                                                                           |
| <b>t24</b> <i>msec</i> | (ITU) Stabilizing timer after removal of local processor outage; used in LPO latching to RPO.<br>(ITU) Range of <i>msec</i> is 400 to 600 milliseconds.<br>(ITU) Default is 500 milliseconds.                                                                                                                                                       |
| <b>t25</b> <i>msec</i> | (ANSI) Timer at SP adjacent to restarting SP, waiting for traffic restart allowed message.<br>(ANSI) Range of <i>msec</i> is 30000 to 35000 milliseconds.<br>(ANSI) Default is 30000 milliseconds.                                                                                                                                                  |
| <b>t28</b> <i>msec</i> | (ANSI) Timer at SP adjacent to restarting SP, waiting for traffic restart waiting message.<br>(ANSI) Range of <i>msec</i> is 3000 to 35000 milliseconds.<br>(ANSI) Default is 30000 milliseconds.                                                                                                                                                   |
| <b>t29</b> <i>msec</i> | (ANSI) Timer started when TRA sent in response to unexpected TRA or TRW.<br>(ANSI) Range of <i>msec</i> is 60000 to 65000 milliseconds.<br>(ANSI) Default is 63000 milliseconds.                                                                                                                                                                    |

|                 |                                                                                                                                                                                            |
|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>t30 msec</b> | (ANSI) Timer to limit sending TFPs and TFRs in response to unexpected TRA and TRW.<br>(ANSI) Range of <i>msec</i> is 30000 to 35000 milliseconds.<br>(ANSI) Default is 33000 milliseconds. |
| <b>t32 msec</b> | (ANSI) Link oscillation timer - Procedure A.<br>Range of <i>msec</i> is 60000 to 120000 milliseconds.<br>Default is 60000 milliseconds.                                                    |

**Defaults**

See the defaults listed in Syntax Description.

**Command Modes**

cs7 linkset submode

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

MTP3 timers can be defined at three levels: global, linkset, and link.

All global, linkset, and link specific timers can be defined at the global level. These values serve as defaults and are propagated down to the lower levels.

All linkset and link specific timers can be defined at the linkset level. These values serve as defaults for the linkset and all links defined within that linkset. Any values defined here override any global values.

All timers defined at the link level apply to the link and override any values for that timer defined at either the linkset or global level.

**Examples**

The following example shows how to set the ITP MTP3 T1 timer to 1000 milliseconds:

```
timer t01 1000
```

**Related Commands**

| Command                          | Description                          |
|----------------------------------|--------------------------------------|
| <a href="#">cs7 mtp3 timer</a>   | Globally configures all MTP3 timers. |
| <a href="#">show cs7 linkset</a> | Displays ITP linkset information.    |
| <a href="#">link-timer</a>       | Configures timers for a link.        |

## timer (cs7 profile)

Traditional SS7 links use serial interfaces. ITP interfaces can be configured to use encapsulation MTP2. You can define several MTP2 timers in a CS7 profile and apply the profile to a linkset.

To configure MTP2 encapsulation timers in a CS7 profile, use the **timer** command in cs7 profile configuration mode. To reset the timers, use the **no** form of this command.

**timer** {**t1** msec | **t2** msec | **t3** msec | **t4e** msec | **t4n** msec | **t5** msec | **t6** msec | **t7** msec | **ttc** timer msec }

**no timer** {**t1** msec | **t2** msec | **t3** msec | **t4e** msec | **t4n** msec | **t5** msec | **t6** msec | **t7** msec | **ttc** timer msec }

### Note

Ranges are defined by ANSI or ITU.

### Syntax Description

**Command Modes** cs7 profile configuration

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** MTP2 parameters can also be specified in cs7 linkset configuration mode.

**Examples** The following example shows how to define a profile named timers. The profile supports MTP2, configures the t1 and t2 settings, and applies to all the links in the linkset named itpa.

```
cs7 profile timers
 mtp2
  timer t1 15000
  timer t2 9000
.
.
.
cs7 linkset itpa
 profile timers
```

|                  | <a href="#">cs7 profile</a>               | Defines a profile of MTP2 parameters that you can apply to all the links in a linkset. |
|                  | <a href="#">show cs7 mtp2</a>             | Displays ITP MTP2 status.                                                              |
|                  | <a href="#">tx-queue-depth (cs7 link)</a> | Configures the MTP2 transmit queue depth.                                              |

## traffic-mode (cs7 as)

To identify the traffic mode of operation of the ASP within an AS, use the **traffic-mode** cs7 as submode command. To remove the configuration, use the **no** form of this command.

```
traffic-mode {broadcast | loadshare [bindings [sls [opc-sls [opc-shift {opc-shift-number}]] |
cgpa-sls | bind-sccp-class2] [redistribute-active] | cic [redistribute-active] ] | roundrobin] |
override}
```

```
[no] traffic-mode {broadcast | loadshare [bindings [sls [opc-sls [opc-shift {opc-shift-number}]] |
cgpa-sls | bind-sccp-class2] [redistribute-active] | cic [redistribute-active] ] | roundrobin] |
override}
```

| Syntax Description         |  |                                                                                                                                                                                               |
|----------------------------|--|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>broadcast</b>           |  | Broadcast mode. In broadcast mode, the ASP receives the same messages as any other currently active ASP.                                                                                      |
| <b>loadshare</b>           |  | Loadshare mode. In loadshare mode, an ASP shares in the traffic distribution with any other currently active ASPs. You can load share based on ASP bindings or using a round-robin algorithm. |
| <b>bindings</b>            |  | Loadshare based on ASP bindings. Default setting. Bindings are established for CIC and SLS values and bindings are not redistributed when they are active on the SGMP mate.                   |
| <b>sls</b>                 |  | Establishes SLS bindings only.                                                                                                                                                                |
| <b>opc-sls</b>             |  | Extends SLS-based ASP binding to OPC-SLS combination-based binding.                                                                                                                           |
| <b>opc-shift</b>           |  | Shifts the OPC bits that are used.                                                                                                                                                            |
| <i>opc-shift-number</i>    |  | Number of OPC bits that are shifted. The range is 0 to 2 for ITU variants. The range is 0 to 8 for ANSI variants. The default number is 0.                                                    |
| <b>cgpa-sls</b>            |  | Extends SLS-based ASP binding to CGPA-SLS combination-based binding.                                                                                                                          |
| <b>bind-sccp-class2</b>    |  | Bind SCCP class 2 packets.                                                                                                                                                                    |
| <b>cic</b>                 |  | Establishes CIC bindings only.                                                                                                                                                                |
| <b>redistribute-active</b> |  | Redistributes bindings to a newly active ASP even when the bindings are active on the SGMP mate.                                                                                              |
| <b>roundrobin</b>          |  | Loadshare based on round-robin algorithm.                                                                                                                                                     |
| <b>override</b>            |  | Override mode. In override mode, one ASP takes over all traffic for an AS (primary/backup operation), possibly overriding any currently active ASP in the AS.                                 |

**Defaults** Load sharing is based on ASP bindings.

**Usage Guidelines** None.

### Syntax Description

Usage guidelines for this command fall into two categories, general and loadshare binding.

- **General usage**

Generally, this command is used to validate the traffic mode specified on ASP Active messages. ASPs fail if they connect with a different traffic mode.

The traffic mode type supported by an AS is determined dynamically. For example, if the first valid ASP Active message received from an ASP in the AS has the traffic mode type set to loadshare, the traffic mode of the AS is set to loadshare.

If no traffic mode is specified, bindings are established for CIC and SLS values and are not redistributed when they are active on the mate ITP.

- **Loadshare binding usage**

In loadshare binding mode, you can configure the **sls** and/or **cic** keyword so that traffic binds to an ASP according to those keywords. The **sls** keyword includes the following options:

- The **opc-sls** keyword extracts more bits from the OPC.
- The **opc-shift** keyword specifies where the OPC bits are extracted. For variants with a 14-bit pc format (ITU), the shift range is 0 to 2, which ensures that 12 significant bits are extracted. For variants with a 24-bit pc format (ANSI), the shift range is 0 to 8, which ensures 16 significant bits.

If the **cgpa-sls** keyword is specified, more bits are calculated from CgPA digits and combined with the SLS to generate a new hash value. The **bind-sccp-class2** keyword enables loadshare binding for SCCP class 2 packets.

If **sls** or **cic** is not specified, traffic binds according to the SLS and CIC based on the traffic type. You can specify **opc-sls** and **cgpa-sls** to indicate that SLS-based binding extends.

For traffic types such as BISUP, Satellite ISUP, AAL type 2 signaling, or GCP, only OPC-SLS options apply.

When you configure the traffic mode for an AS, if the AS's routing key is specified and the SI indicates the above SLS-based traffic type, the **cgpa-sls** keyword is not displayed. You can configure the traffic mode and specify the **cgpa-sls** keyword before the routing key configuration. Now, when

## Examples

The following example shows how to set the traffic mode to loadshare mode:

```
cs7 as BLUE m3ua
  routing-key 100 10.3.8
  asp ASP1
  asp ASP2
  traffic-mode loadshare
```

The following example shows how to set the traffic mode to loadshare mode and the ASP bindings to use opc-sls with opc-shift or CIC:

```
cs7 instance 1 as AS1 m3ua
  routing-key 200 2.0.0
  asp asp1 weight 10
  asp asp2
  traffic-mode loadshare bindings opc-sls opc-shift 1
!
```

The following example shows how to set the traffic mode to loadshare mode and the ASP bindings to use cgpa-sls or CIC.

```
cs7 instance 1 as AS2 m3ua
  routing-key 201 2.0.1
  asp asp1 weight 10
  asp asp2
  traffic-mode loadshare bindings cgpa-sls
!
```

The following example shows how to set the traffic mode to loadshare mode and the ASP bindings to only use opc-sls with opc-shift:

```
cs7 instance 1 as AS3 m3ua
  routing-key 202 2.0.2
  asp asp1 weight 10
  asp asp2
  traffic-mode loadshare bindings sls opc-sls opc-shift 1
!
```

The following example shows how to set the traffic mode to loadshare mode and the ASP bindings to only use cgpa-sls:

```
cs7 instance 1 as AS4 m3ua
  routing-key 203 2.0.3
  asp asp1 weight 10
  asp asp2
  traffic-mode loadshare bindings sls cgpa-sls
!
```

# traffic-rate-timer

To configure the data collection interval that is used to calculate traffic rate information, use the **traffic-rate-timer** command in cs7 sms route table configuration mode. To remove the configuration, use the **no** form of this command.

**traffic-rate-timer** *timer*

**no traffic-rate-timer** *timer*

| Syntax Description | <i>timer</i> | Data collection interval, in seconds. Valid range is 60 to 3600 seconds. The default is 600 seconds. |
|--------------------|--------------|------------------------------------------------------------------------------------------------------|
|--------------------|--------------|------------------------------------------------------------------------------------------------------|

| Defaults | 600 seconds |
|----------|-------------|

## transaction-timer (cs7 sms route table)

To specify the amount of time in seconds that DSMR allows any message transaction to remain open, use the **transaction-timer** command in cs7 sms route table configuration mode. To remove the configuration, use the **no** form of this command.

**transaction-timer** *seconds*

**no transaction-timer**

|                    |                                                                                                                                                                                                                                              |                               |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------|
| Syntax Description | <i>seconds</i> Maximum lifetime of a message transaction. Valid range is 5 to 3600 seconds. The default is no limit.                                                                                                                         |                               |
| Defaults           | The transaction timer is disabled and there is no limit to the maximum lifetime of a message transaction.                                                                                                                                    |                               |

## trigger cdpa (cs7 mlr table)

To specify the routing key, or trigger, for a multilayer SMS routing table and indicate that the routing trigger is located in the SCCP called party address (CdPA) field of the incoming MSU, use the **trigger cdpa** command in cs7 mlr table mode. To delete a specific routing trigger, use the **no** form of this command.

```
trigger cdpa {gt addr-string [gt-addr-type] | pc point-code ssn ssn} [block | continue | ruleset
ruleset-name | result {pc pc [ssn ssn] | asname as-name | gt gt [gt-addr-type] | group
group-name}]
```

```
no trigger cdpa
```

| Syntax Description  |                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>gt</b>           | Indicates that the CdPA trigger being defined is received with RI=GT.                                                                                                                                                                                                                                                      |
| <i>addr-string</i>  | Address string of 1 to 15 hexadecimal characters. The string is input in normal form instead of BCD-String format.                                                                                                                                                                                                         |
| <i>gt-addr-type</i> | Parameters that identify attributes of the global title address being used as a trigger. The parameters are variant-specific, and are identical to those parameters specified on the <b>cs7 gtt selector</b> command. If not specified, the default is the standard E.164 address type for the network variant being used. |
|                     | <b>tt</b> <i>tt</i> [ <b>gti</b> <i>gti</i> ] [ <b>np</b> <i>np</i> <b>nai</b> <i>nai</i> ]                                                                                                                                                                                                                                |
|                     | <b>tt</b> Identifies the translation type specified within the address.                                                                                                                                                                                                                                                    |
|                     | <i>tt</i> An integer value from 0 to 255.                                                                                                                                                                                                                                                                                  |
|                     | <b>gti</b> Identifies the global title indicator value for the specified address. This value is specified only when the <b>cs7 variant</b> command specifies ITU or China.                                                                                                                                                 |
|                     | <i>gti</i> Integer value of 2 or 4.                                                                                                                                                                                                                                                                                        |
|                     | <b>np</b> Identifies the numbering plan of the specified address. Used only when the <i>gti</i> value is 4.                                                                                                                                                                                                                |
|                     | <i>np</i> Integer value from 0 to 15.                                                                                                                                                                                                                                                                                      |
|                     | <b>nai</b> Identifies the nature of address indicator. Used only when the <i>gti</i> value is 4.                                                                                                                                                                                                                           |
|                     | <i>nai</i> Integer value from 0 to 127.                                                                                                                                                                                                                                                                                    |
| <b>pc</b>           | Matches the trigger if it contains the specified point code. The PC within the SCCP CdPA is inspected first. If the PC is not present, then the DPC in the routing label is used.                                                                                                                                          |
| <i>point-code</i>   | Point code in variant-specific point code format.                                                                                                                                                                                                                                                                          |
| <b>ssn</b>          | Matches the trigger if it contains the specified subsystem.                                                                                                                                                                                                                                                                |
| <i>ssn</i>          | Subsystem number in decimal. Valid range is 2 to 255.                                                                                                                                                                                                                                                                      |
| <b>block</b>        | Drops messages matching this trigger. This keyword is ignored if combination triggers are defined within cs7 mlr trigger configuration submode.                                                                                                                                                                            |

## ■ trigger cdpa (cs7 mlr table)

|                     |                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>continue</b>     | Routes messages matching this trigger as received. This behavior is the same as if no primary trigger had been matched. This keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                                      |
| <b>ruleset</b>      | Specifies the MLR ruleset table that should be used if this trigger is matched and not overruled by a secondary trigger ruleset. This keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                             |
| <i>ruleset-name</i> | Name of a defined CS7 MLR ruleset table. The name is specified as a character string with a maximum of 12 characters.                                                                                                                                                                                                                                 |
| <b>result</b>       | Routes messages based on the trigger alone. If a trigger result is configured, the TCAP/MAP/SMS layers are not parsed. If a message matches a trigger with a <b>result</b> trigger action, then the message is redirected as indicated in the trigger result.<br><b>Note:</b> Result groups with dest-sme-binding mode are not valid trigger results. |
| <b>pc</b>           | Routes based on point code.                                                                                                                                                                                                                                                                                                                           |
| <i>pc</i>           | Point code.                                                                                                                                                                                                                                                                                                                                           |
| <b>ssn</b>          | Routes based on PC and subsystem number.                                                                                                                                                                                                                                                                                                              |
| <i>ssn</i>          | Subsystem number.                                                                                                                                                                                                                                                                                                                                     |
| <b>asname</b>       | Routes based on AS name.                                                                                                                                                                                                                                                                                                                              |
| <i>as-name</i>      | AS name.                                                                                                                                                                                                                                                                                                                                              |
| <b>gt</b>           | Routes based on global title.                                                                                                                                                                                                                                                                                                                         |
| <i>gt</i>           | Global title address.                                                                                                                                                                                                                                                                                                                                 |
| <b>group</b>        | Routes based on result group.                                                                                                                                                                                                                                                                                                                         |
| <i>group-name</i>   | Result group name.                                                                                                                                                                                                                                                                                                                                    |

**Defaults**

If you configure a default trigger with the **trigger default** command, it is defined as the last trigger in the MLR table. The default trigger is used only if all other triggers are unmatched. If a default trigger is not configured, then packets not matching a trigger are routed according to standard SCCP or MTP3 procedures.

**Command Modes**

cs7 mlr table

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

The **trigger cdpa** command configures a primary routing key to route or block messages based on the CdPA. (If no primary triggers are specified, the MLR table will not be created.)

**Trigger Rules**

- Trigger values must be unique.

- **cdpa gt** triggers must specify a defined GTT GTA or GTT selector entry.

### Trigger Match Hierarchy

If primary CdPA and CgPA triggers are configured, the triggers are not searched sequentially. The first trigger match is used based on the following hierarchy:

1. The defined default trigger (the only trigger configured)
2. SCCP CdPA GT address
3. SCCP CdPA GT selector
4. SCCP CdPA PC/SSN
5. SCCP CgPA GT address
6. SCCP CgPA GT selector
7. SCCP CgPA PC/SSN

### Trigger Terminology

[Table 91](#) describes the types of triggers and the commands you use to specify triggers at various configuration levels.

**Table 91**      **Trigger Terminology**

| Term            | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>trigger</b>  | A trigger represents the SS7 network-layer routing parameters that are used to efficiently identify traffic requiring parsing into the application layers.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| primary trigger | <p>The primary trigger represents the network-layer information that is first compared to an incoming packet for possible MLR routing.</p> <p>A primary trigger is specified in cs7 mlr table mode (after the <b>cs7 mlr table</b> command has been specified).</p> <p>The following example shows how to specify a primary trigger. (Note that the CLI prompt changes to indicate that cs7 mlr trigger mode has been enabled.)</p> <pre>Router(config-cs7 mlr)# <b>trigger mtp3 dpc 1-1-1</b> Router(cfg-cs7-mlr-trigger)#</pre> <p>Primary trigger values must be unique.</p> <p>Possible primary trigger commands are <b>trigger cdpa</b>, <b>trigger cgpa</b>, <b>trigger default</b>, and <b>trigger mtp3</b>.</p> <p>MTP3 may be specified as a primary trigger only.</p> |

**Table 91**      **Trigger Terminology (continued)**

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| secondary trigger   | <p>A secondary trigger is specified in cs7 mlr trigger mode (after the primary trigger has been specified). If one or more secondary triggers are specified, then the primary <i>and</i> one of the secondary trigger values must match for MLR to further process the message. If no secondary triggers are specified, then the primary trigger alone is used for MLR processing. Secondary triggers are matched sequentially in the order in which they are defined.</p> <p>The following example shows how to specify a secondary trigger. Note that configuring a secondary trigger does not enable a new mode. The prompt does not change.</p> <pre>Router(cfg-cs7-mlr-trigger)# <b>cgpa pc 1-1-1 ssn 11</b> Router(cfg-cs7-mlr-trigger)#</pre> <p>Secondary triggers do not have to be unique.</p> <p>Possible secondary trigger commands are <b>cdpa</b>, <b>cgpa</b>, and <b>default</b>.</p> <p>The primary trigger must be for a called party for the <b>cgpa</b> submode command to be valid.</p> <p>The primary trigger must be for a calling party for the <b>cdpa</b> submode command to be valid.</p> |
| tertiary trigger    | <p>A tertiary trigger is specified in cs7 mlr trigger mode (after the secondary trigger has been specified). If a tertiary trigger is specified, then one of the primary, secondary, <i>and</i> tertiary trigger values must match for MLR to further process the message. If no tertiary triggers are specified, then the primary and secondary triggers are only used for MLR processing. Tertiary triggers are matched sequentially in the order in which they are defined.</p> <p>The following example shows how to specify a tertiary trigger. Note that configuring a tertiary trigger does not enable a new mode. The prompt does not change.</p> <pre>Router(cfg-cs7-mlr-trigger)#<b>cgpa pc 2-2-2 ssn 8</b></pre> <p>Tertiary triggers need not be unique.</p> <p>Possible tertiary trigger commands are <b>cdpa</b>, <b>cgpa</b>, and <b>default</b>.</p>                                                                                                                                                                                                                                                 |
| subtrigger          | <p>A subtrigger is a generic term used to describe a trigger defined within another trigger's submode. A default trigger cannot have subtriggers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| combination trigger | <p>A combination trigger is a composite MLR trigger comprised of more than one trigger. The two possible combination triggers are primary+secondary or primary+secondary+tertiary. When a combination trigger is matched, the trigger action defined on the lowest trigger in the hierarchy is used for MLR processing.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Examples**

The following example shows how to specify a trigger to route messages based on the CdPA field of the incoming MSU. The trigger is specified for the table named SMS-TABLE.

```
cs7 mlr table SMS-TABLE
trigger cdpa gt 9991117770 ruleset ruleset1
```

The following example shows how to configure triggers to block messages based on a specified CdPA. The trigger is specified for the table named SMS-BLOCKING.

```
cs7 mlr table SMS-BLOCKING
trigger cdpa gt 9991117770 tt 10 block
```

**Related Commands**

| Command                                      | Description                                                                                                      |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| cgpa                                         | Creates a secondary trigger based on the CgPA, to be used with a primary trigger based on the CdPA.              |
| <a href="#">cs7 mlr table</a>                | Specifies the name of the multilayer SMS routing table and enables cs7 mlr table mode.                           |
| <a href="#">trigger cgpa (cs7 mlr table)</a> | Specifies a primary routing trigger that is located in the SCCP calling party address field of the incoming MSU. |

## trigger cgpa (cs7 mlr table)

To specify the routing key, or trigger, for a multilayer SMS routing table and indicate that the routing trigger is located in the SCCP calling party address (CgPA) field of the incoming MSU, use the **trigger cgpa** command in cs7 mlr table mode. To delete the trigger command and disable the specific routing trigger, use the **no** form of this command.

```
trigger cgpa {gt addr-string [gt-addr-type] | pc point-code ssn ssn} [block | continue | ruleset
ruleset-name | result {pc pc [ssn ssn] | asname as-name | gt gta [gt-addr-type] | group
group-name}]
```

```
no trigger cgpa
```

| Syntax Description  |                                                                                                                                                                                                                                                                                                                            |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>gt</b>           | Indicates that the CgPA trigger being defined is received with RI=GT.                                                                                                                                                                                                                                                      |
| <i>addr-string</i>  | Address string of 1 to 15 hexadecimal characters. The string is input in normal form instead of BCD-String format.                                                                                                                                                                                                         |
| <i>gt-addr-type</i> | Parameters that identify attributes of the global title address being used as a trigger. The parameters are variant-specific, and are identical to those parameters specified on the <b>cs7 gtt selector</b> command. If not specified, the default is the standard E.164 address type for the network variant being used. |
|                     | <b>tt</b> <i>tt</i> [ <b>gti</b> <i>gti</i> ] [ <b>np</b> <i>np</i> <b>nai</b> <i>nai</i> ]                                                                                                                                                                                                                                |
|                     | <b>tt</b> Identifies the translation type specified within the address.                                                                                                                                                                                                                                                    |
|                     | <i>tt</i> An integer value from 0 to 255.                                                                                                                                                                                                                                                                                  |
|                     | <b>gti</b> Identifies the global title indicator value for the specified address. This value is specified only when the <b>cs7 variant</b> command specifies ITU or China.                                                                                                                                                 |
|                     | <i>gti</i> Integer value of 2 or 4.                                                                                                                                                                                                                                                                                        |
|                     | <b>np</b> Identifies the numbering plan of the specified address. Used only when the <i>gti</i> value is 4.                                                                                                                                                                                                                |
|                     | <i>np</i> Integer value from 0 to 15.                                                                                                                                                                                                                                                                                      |
|                     | <b>nai</b> Identifies the nature of address indicator. Used only when the <i>gti</i> value is 4.                                                                                                                                                                                                                           |
|                     | <i>nai</i> Integer value from 0 to 127.                                                                                                                                                                                                                                                                                    |
| <b>pc</b>           | Matches the trigger if it contains the specified point code. The PC within the SCCP CgPA is inspected first. If the PC is not present, then the OPC is used.                                                                                                                                                               |
| <i>point-code</i>   | Point code in variant-specific point code format.                                                                                                                                                                                                                                                                          |
| <b>ssn</b>          | Matches the trigger if it contains the specified subsystem.                                                                                                                                                                                                                                                                |
| <i>ssn</i>          | Subsystem number in decimal. Valid range is 2 to 255.                                                                                                                                                                                                                                                                      |
| <b>block</b>        | Drops messages matching this trigger. This keyword is ignored if combination triggers are defined within cs7 mlr trigger configuration submode.                                                                                                                                                                            |

|                     |                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>continue</b>     | Routes messages matching this trigger as received. This behavior is the same as if no primary trigger had been matched. The <b>continue</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                       |
| <b>ruleset</b>      | Uses the specified MLR ruleset table if this trigger is matched and not overruled by a secondary trigger ruleset. The <b>ruleset</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                              |
| <i>ruleset-name</i> | Name of a defined CS7 MLR ruleset table. The name is specified as a character string with a maximum of 12 characters.                                                                                                                                                                                                                                 |
| <b>result</b>       | Routes messages based on the trigger alone. If a trigger result is configured, the TCAP/MAP/SMS layers are not parsed. If a message matches a trigger with a <b>result</b> trigger action, then the message is redirected as indicated in the trigger result.<br><b>Note:</b> Result groups with dest-sme-binding mode are not valid trigger results. |
| <b>pc</b>           | Routes based on point code.                                                                                                                                                                                                                                                                                                                           |
| <i>pc</i>           | Point code.                                                                                                                                                                                                                                                                                                                                           |
| <b>ssn</b>          | Routes based on PC and subsystem number.                                                                                                                                                                                                                                                                                                              |
| <i>ssn</i>          | Subsystem number.                                                                                                                                                                                                                                                                                                                                     |
| <b>asname</b>       | Routes based on AS name.                                                                                                                                                                                                                                                                                                                              |
| <i>as-name</i>      | AS name.                                                                                                                                                                                                                                                                                                                                              |
| <b>gt</b>           | Routes based on global title.                                                                                                                                                                                                                                                                                                                         |
| <i>gta</i>          | Global title address.                                                                                                                                                                                                                                                                                                                                 |
| <b>group</b>        | Routes based on result group.                                                                                                                                                                                                                                                                                                                         |
| <i>group-name</i>   | Result group name.                                                                                                                                                                                                                                                                                                                                    |

### Defaults

If you configure a default trigger with the **trigger default** command, it is defined as the last trigger in the MLR table. The default trigger is used only if all other triggers are unmatched. If a default trigger is not configured, then packets not matching a trigger are routed according to standard SCCP or MTP3 procedures.

### Command Modes

cs7 mlr table

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Usage Guidelines

The **trigger cgpa** command configures a primary routing key to route or block messages based on the CgPA. (If no primary triggers are specified, the MLR table will not be created.)

If primary CdPA and CgPA triggers are configured, the triggers are not searched sequentially. The first trigger match is used based on the following hierarchy:

1. The defined default trigger (the only trigger configured)

2. SCCP CdPA GT address
3. SCCP CdPA GT selector
4. SCCP CdPA PC/SSN
5. SCCP CgPA GT address
6. SCCP CgPA GT selector
7. SCCP CgPA PC/SSN

#### Trigger Rules

- Primary trigger values must be unique.
- **cdpa gt** triggers must have a matching GTT GTA or GTT selector entry.

#### Examples

The following example shows how to specify a trigger to route messages based on the CgPA field of the incoming MSU. The trigger is specified for the table named SMS-TABLE.

```
cs7 mlr table SMS-TABLE
trigger cgpa gt 9991117770 ruleset ruleset1
```

The following example shows how to configure triggers to block messages based on a specified CgPA. The trigger is specified for the table named SMS-BLOCKING.

```
cs7 mlr table SMS-BLOCKING
trigger cgpa gt 9991117770 tt 10 block
```

#### Related Commands

| Command                                      | Description                                                                                                        |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| cgpa                                         | Creates a secondary trigger based on the CgPA, to be used in conjunction with a primary trigger based on the CdPA. |
| <a href="#">cs7 mlr table</a>                | Specifies the name of the multilayer SMS routing table and enables cs7 mlr table mode.                             |
| <a href="#">trigger cdpa (cs7 mlr table)</a> | Specifies a primary routing trigger that is located in the SCCP CdPA field of the incoming MSU.                    |

# trigger default

To specify a trigger to match all packets received, use the **trigger default** command in cs7 mlr table mode. To delete a specific routing trigger, use the **no** form of this command.

```
trigger default [block | continue | ruleset ruleset-name] result { pc pc [ssn ssn] | asname as-name
| gt gt [gt-addr-type] | group group-name }
```

```
no trigger default
```

| Syntax              | Description                                                                                                                                                                                                                                                                                                                                           |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>block</b>        | Drops messages matching this trigger. The <b>block</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                                                                                                            |
| <b>continue</b>     | Routes messages matching this trigger as received. This behavior is the same as if no primary trigger had been matched. The <b>continue</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                       |
| <b>ruleset</b>      | Uses the specified MLR ruleset table if this trigger is matched and not overruled by a secondary trigger ruleset. The <b>ruleset</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                                              |
| <i>ruleset-name</i> | Name of a defined CS7 MLR ruleset table. The name is specified as a character string with a maximum of 12 characters.                                                                                                                                                                                                                                 |
| <b>result</b>       | Routes messages based on the trigger alone. If a trigger result is configured, the TCAP/MAP/SMS layers are not parsed. If a message matches a trigger with a <b>result</b> trigger action, then the message is redirected as indicated in the trigger result.<br><b>Note:</b> Result groups with dest-sme-binding mode are not valid trigger results. |
| <b>pc</b>           | Routes based on point code.                                                                                                                                                                                                                                                                                                                           |
| <i>pc</i>           | Point code.                                                                                                                                                                                                                                                                                                                                           |
| <b>ssn</b>          | Routes based on PC and subsystem number.                                                                                                                                                                                                                                                                                                              |
| <i>ssn</i>          | Subsystem number.                                                                                                                                                                                                                                                                                                                                     |
| <b>asname</b>       | Routes based on AS name.                                                                                                                                                                                                                                                                                                                              |
| <i>as-name</i>      | AS name.                                                                                                                                                                                                                                                                                                                                              |
| <b>gt</b>           | Routes based on global title.                                                                                                                                                                                                                                                                                                                         |

| <b>group</b>        | Routes based on result group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>group-name</i>   | Result group name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Defaults**

None.

**Command Modes**

cs7 mlr table

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**The **trigger default** command enables cs7 mlr trigger mode.**Examples**

The following example shows how to match the trigger to all packets received. The trigger is specified for the table named SMS-TABLE.

```
cs7 mlr table SMS-TABLE
  trigger default ruleset ruleset1
```

| <a href="#">cs7 mlr table</a> | Specifies the name of the multilayer SMS routing table and enables cs7 mlr table mode. |

## trigger mtp3

To specify the routing key, or trigger, for a multilayer SMS routing table and indicate that the trigger is based on an MTP3 routing label field, use the **trigger mtp3** cs7 mlr table mode command. To delete the trigger command and disable the specific routing trigger, use the **no** form of this command.

```
trigger mtp3 {[dpc point-code] [opc point-code] [si indicator]} [block | continue | ruleset
ruleset-name | result {pc pc [ssn ssn] | as-name | gt gta [gt-addr-type] | group group-name}]
```

```
no trigger mtp3
```

| Syntax Description  |  |                                                                                                                                                                                                                                                                                                                                                       |
|---------------------|--|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dpc</b>          |  | Locates the trigger within the MTP3 destination point code field of the routing label.                                                                                                                                                                                                                                                                |
| <i>point-code</i>   |  | The point code in instance-specific point code format.                                                                                                                                                                                                                                                                                                |
| <b>opc</b>          |  | Locates the trigger within the MTP3 origination point code field of the routing label.                                                                                                                                                                                                                                                                |
| <i>point-code</i>   |  | The point code in instance-specific point code format.                                                                                                                                                                                                                                                                                                |
| <b>si</b>           |  | Specifies that the trigger will be matched only if the specified service indicator is received in the packet.                                                                                                                                                                                                                                         |
| <i>indicator</i>    |  | Service indicator. An integer ranging from 3 to 15.                                                                                                                                                                                                                                                                                                   |
| <b>block</b>        |  | Specifies that messages matching this trigger should be dropped. The <b>block</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger configuration submenu.                                                                                                                                                                |
| <b>continue</b>     |  | Specifies that messages matching this trigger should be routed as received. This behavior is the same as if no primary trigger had been matched. The <b>continue</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                              |
| <b>ruleset</b>      |  | Specifies the MLR ruleset table that should be used if this trigger is matched and not overruled by a secondary trigger ruleset. The <b>ruleset</b> keyword is ignored if combination triggers are defined within cs7 mlr trigger mode.                                                                                                               |
| <i>ruleset-name</i> |  | Name of a defined cs7 mlr ruleset table. The name is specified as a character string with a maximum of 12 characters.                                                                                                                                                                                                                                 |
| <b>result</b>       |  | Routes messages based on the trigger alone. If a trigger result is configured, the TCAP/MAP/SMS layers are not parsed. If a message matches a trigger with a <b>result</b> trigger action, then the message is redirected as indicated in the trigger result.<br><b>Note:</b> Result groups with dest-sme-binding mode are not valid trigger results. |
| <b>pc</b>           |  | Routes based on point code.                                                                                                                                                                                                                                                                                                                           |
| <i>pc</i>           |  | Point code.                                                                                                                                                                                                                                                                                                                                           |
| <b>ssn</b>          |  | Routes based on PC and subsystem number.                                                                                                                                                                                                                                                                                                              |
| <i>ssn</i>          |  | Subsystem number.                                                                                                                                                                                                                                                                                                                                     |
| <b>asname</b>       |  | Routes based on AS name.                                                                                                                                                                                                                                                                                                                              |
| <i>as-name</i>      |  | AS name.                                                                                                                                                                                                                                                                                                                                              |
| <b>gt</b>           |  | Routes based on global title.                                                                                                                                                                                                                                                                                                                         |

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <i>gt-addr-type</i> | <p>Parameters that identify attributes of the global title address being used as a trigger. The parameters are variant-specific, and are identical to those parameters specified on the <b>cs7 gtt selector</b> command. If not specified, the default is the standard E.164 address type for the network variant being used.</p> <p><b>tt tt [gti gti] [np np nai nai]</b></p> <p><b>tt</b> Identifies the translation type specified within the address.</p> <p><i>tt</i> An integer value from 0 to 255.</p> <p><b>gti</b> Identifies the global title indicator value for the specified address. This value is specified only when the CS7 variant is ITU or China.</p> <p><i>gti</i> Integer value of 2 or 4.</p> <p><b>np</b> Identifies the numbering plan of the specified address. Specified only when the <i>gti</i> value is 4.</p> <p><i>np</i> Integer value from 0 to 15.</p> <p><b>nai</b> Identifies the nature of address indicator. Specified only when the <i>gti</i> value is 4.</p> <p><i>nai</i> Integer value from 0 to 127.</p> |
| <i>gta</i>          | Global title address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>group</b>        | Routes based on result group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <i>group-name</i>   | Result group name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Defaults**

None.

**Command Modes**

cs7 mlr table

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**The **trigger mtp3** command enables cs7 mlr trigger mode.**Examples**

The following example shows how to specify a trigger to route messages based on the CdPA field of the incoming MSU. The trigger is specified for the table named SMS-TABLE.

```
cs7 mlr table SMS-TABLE
trigger cdpa gt 9991117770 ruleset ruleset1
```

The following example shows how to configure triggers to block messages based on a specified CdPA. The trigger is specified for the table named SMS-BLOCKING.

```
cs7 mlr table SMS-BLOCKING
```

```
trigger cdpa gt 9991117770 tt 10 block
```

|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| cgpa                                         | Creates a secondary trigger based on the CgPA, to be used in conjunction with a primary trigger based on the CdPA. |
| <a href="#">cs7 mlr table</a>                | Specifies the name of the multilayer SMS routing table and enables cs7 mlr table mode.                             |
| <a href="#">trigger cgpa (cs7 mlr table)</a> | Specifies a primary routing trigger that is located in the SCCP calling party address field of the incoming MSU.   |

# ttl

To specify the amount of elapsed time in seconds that a cached authentication triplet is stored, use the **ttl** cs7 authent-vlr submode command. To return to the default value of 604800 seconds (7 days), use the **no** form of this command.

**ttl** *time-to-live*

**no ttl** *time-to-live*

|                           |                     |                                                                                                                                                     |
|---------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>time-to-live</i> | Amount of elapsed time in seconds that a cached authentication triplet is stored. Valid values are decimal numbers in the range of 0 to 2147483647. |
|---------------------------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|

|                 |                         |
|-----------------|-------------------------|
| <b>Defaults</b> | 604800 seconds (7 days) |
|-----------------|-------------------------|

|                      |                         |
|----------------------|-------------------------|
| <b>Command Modes</b> | cs7 authent-vlr submode |
|----------------------|-------------------------|

| <b>Command History</b> | Release     | Modification                 |
|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |

**Examples** The following example shows how to specify 300000 seconds as the elapsed time that a cached authentication triplet is stored:

```
gsm-authent-vlr
 cache-size 100
 max-return 2
 ttl 300000
```

| <b>Related Commands</b> | Command                         | Description                                                                                                                                |
|-------------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------|
|                         | <a href="#">cache-size</a>      | Specifies the total number of IMSIs for which authentication triplets are cached.                                                          |
|                         | <a href="#">gsm-authent-vlr</a> | Enables authent-vlr submode, in which you can provision parameters specific to the GSM MAP Process_Obtain_Authentication_Sets_VLR service. |
|                         | <a href="#">max-return</a>      | Specifies the maximum number of authentication triplets that may be returned to a MAPUA client for a single request.                       |

# ttmap

TT mapping rules can be added to existing linksets. To add a rule, use the **ttmap** cs7 linkset submode command. To remove a TT map rule, use the **no** form of this command.

**ttmap** *existing-tt mapped-tt* [**in** | **out**]

**no ttmap** *existing-tt mapped-tt* [**in** | **out**]

## Syntax Description

|                    |                                                     |
|--------------------|-----------------------------------------------------|
| <i>existing-tt</i> | Existing translation type. Valid range is 0 to 255. |
| <i>mapped-tt</i>   | Mapped translation type. Valid range is 0 to 255.   |
| <b>in</b>          | Performs TT mapping on inbound messages only.       |
| <b>out</b>         | Performs TT mapping on outbound messages only.      |

## Defaults

None.

## Command Modes

cs7 linkset submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXE | This command was introduced. |

## Usage Guidelines

This command is available for all variants. The TT map feature is supported for UDT and XUDT only, not for UDTS or any other message.

## Examples

The following example shows how to add a rule that maps all incoming messages that have a TT of 6 to now have a TT of 254:

```
cs7 linkset to_doc
  ttmap 6 254 in
```

## Related Commands

| Command                | Description                                |
|------------------------|--------------------------------------------|
| show cs7 linkset ttmap | Displays TT mapping rules for the linkset. |

## ttnmap (cs7 as)

Global title translation type (TT) mapping rules can be added to application servers. To add a rule, use the **ttnmap** cs7 as submode command. To remove a TT mapping rule, use the **no** form of this command.

**ttnmap** *existing-tt mapped-tt* [**in** | **out**]

**no ttnmap** *existing-tt mapped-tt* [**in** | **out**]

### Syntax Description

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <i>existing-tt</i> | Received existing translation type. Valid range is 0 to 255. |
| <i>mapped-tt</i>   | New mapped translation type. Valid range is 0 to 255.        |
| <b>in</b>          | Performs TT mapping on inbound messages only.                |
| <b>out</b>         | Performs TT mapping on outbound messages only.               |

### Defaults

If neither **in** nor **out** is specified, then TT mapping is performed for both inbound and outbound messages. If the inbound AS cannot be determined from the received message, then TT mapping is not applied.

### Command Modes

cs7 as submode

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXE | This command was introduced. |

### Usage Guidelines

Up to 256 input TT mappings may be specified per AS, and up to 256 output TT mappings may be specified per AS.

Inbound TT mapping is applied after ACL and gateway screening, but before MLR and GTT processing. Outbound TT mapping is applied after MLR, GTT, ACL, and gateway screening.

The TT map feature is supported for UDT and XUDT only, not for UDTS or any other message.

|-------------------------|--------------------------------------------|
| show cs7 linkset ttnmap | Displays TT mapping rules for the linkset. |

# tt-range

To specify a translation type range entry in a CdPA SCCP selector table or CgPA SCCP selector table, use the **tt-range** command in gateway screening table configuration mode.

**tt-range** *tt-start* [*tt-end*] [**gti** *gti* [**np** *np* **nai** *nai*]] **result** {**action** *action-set-name* | **table** *table-name*}

**no tt-range** *tt-start* [*tt-end*] [**gti** *gti* [**np** *np* **nai** *nai*]]

| Syntax Description     |  |                                                                                                                                 |
|------------------------|--|---------------------------------------------------------------------------------------------------------------------------------|
| <i>tt-start</i>        |  | Starting pc in the range.                                                                                                       |
| <i>tt-end</i>          |  | Ending pc in the range.                                                                                                         |
| <b>gti</b>             |  | Identifies the global title indicator for the specified address. This value is specified only when the variant is ITU or China. |
| <i>gti</i>             |  | Integer value of 2 or 4.                                                                                                        |
| <b>np</b>              |  | Identifies the numbering plan of the specified address. Configured only when <i>gti</i> is 4.                                   |
| <i>np</i>              |  | Integer in the range 0 to 15.                                                                                                   |
| <b>nai</b>             |  | Identifies the nature of the specified address. Configured only when <i>gti</i> is 4.                                           |
| <i>nai</i>             |  | Integer in the range 0 to 127.                                                                                                  |
| <b>result</b>          |  | Specifies the next step.                                                                                                        |
| <b>action</b>          |  | Screens by action set by default.                                                                                               |
| <i>action-set-name</i> |  | Action set name. Valid names may not exceed 12 alphanumeric characters.                                                         |
| <b>table</b>           |  | Screens by table by default.                                                                                                    |
| <i>table-name</i>      |  | Table name. Valid names may not exceed 12 alphanumeric characters.                                                              |

**Defaults** None.

|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

**Usage Guidelines** The **tt-range** command is valid for the following table types: CgPA SCCP selector, CdPA SCCP selector. Wildcards (\*) are allowed.

The following example shows how to specify a tt-range entry for table SEL1:

```
cs7 instance 0 gws table SEL1 type cgpa-selector action allowed
  tt-range 5 10 gti 2 result table PGTA1
  default result table PGTA1
```

| Command                       | Description                           |
|-------------------------------|---------------------------------------|
| <a href="#">cs7 gws table</a> | Configures a gateway screening table. |

## tx-queue-depth (cs7 asp)

To configure the maximum transmit queue depth for the association, use the **tx-queue-depth** cs7 asp submode command. To remove the configuration, use the **no** form of this command.

**tx-queue-depth** *depth*

**no tx-queue-depth** *depth*

| Syntax Description | <i>depth</i> | Number of packets to be queued. The range is 100 to 20000 packets. |
|--------------------|--------------|--------------------------------------------------------------------|
|--------------------|--------------|--------------------------------------------------------------------|

| Defaults | The default transmit queue depth is the value specified under the local port instance. |
|----------|----------------------------------------------------------------------------------------|
|----------|----------------------------------------------------------------------------------------|

| Command Modes | cs7 asp submode |

## tx-queue-depth (cs7 hs-mtp2 profile)

You can adjust the number of packets that can be queued for transmission. To configure the transmit queue depth, use the **tx-queue-depth** command in cs7 hs-mtp2 profile configuration mode. To return to the default queue depth, use the **no** form of this command.

**tx-queue-depth** *depth*

**no tx-queue-depth** *depth*

|                           |              |                                                                                                 |
|---------------------------|--------------|-------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | <i>depth</i> | Number of packets to be queued. The range is 250 to 50000 packets. The default is 5000 packets. |
|---------------------------|--------------|-------------------------------------------------------------------------------------------------|

|                 |              |
|-----------------|--------------|
| <b>Defaults</b> | 5000 packets |
|-----------------|--------------|

|------------------------|-------------|------------------------------|
|                        | 12.2(18)IXA | This command was introduced. |
|                        | 12.4(11)SW  |                              |
|                        | 12.2(33)IRA |                              |

|                         |                                                                                                                                                                                                                                                                                                                         |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | The <b>tx-queue-depth</b> command controls the number of packets allowed on the transmit queue. The queue's function is to absorb traffic bursts. When you select the queue depth, you will have to compromise between transmit congestion thresholds, which can drop packets, or transmit delays due to queuing times. |
|                         | Applications that are sensitive to small delays should account for transmit delays due to queuing times. When links are congested, the queue depth controls the number of packets that can be queued before they are discarded. Discarding packets causes application retransmissions.                                  |

|                 |                                                                                                                                                                                                                |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to define a profile named HSMTP2. The profile supports high-speed MTP2, specifies the <b>tx-queue-depth</b> command, and applies to all the links in the linkset named TO_NYC. |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
cs7 profile HSMTP2
  hs-mtp2
    tx-queue-depth 2000
  .
  .
  .
cs7 linkset TO_NYC
  profile HSMTP2
```

|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Examples</b> | The following example shows how to define a profile named m2parfc. The profile supports M2PA RFC, specifies the <b>tx-queue-depth</b> command, and applies to all the links in the linkset named to_nyc. |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

```
cs7 profile m2parfc
 m2pa
  tx-queue-depth 2000
.
.
.
cs7 linkset to_nyc
 profile m2parfc
```

 tx-queue-depth (cs7 m2pa profile)**Related Commands**

| Command              | Description                                 |
|----------------------|---------------------------------------------|
| <a href="#">m2pa</a> | Specifies M2PA parameters in a CS7 profile. |

## tx-queue-depth (cs7 m3ua)

To configure the maximum transmit queue depth for new SCTP associations established with this local port, use the **tx-queue-depth** cs7 m3ua submode command. To return to the default queue depth, use the **no** form of this command.

**tx-queue-depth** *queue-depth*

**no tx-queue-depth** *queue-depth*

## tx-queue-depth (cs7 sua)

To configure the maximum transmit queue depth for new SCTP associations established with this local port, use the **tx-queue-depth** cs7 sua submode command. To return to the default queue depth, use the **no** form of this command.

**tx-queue-depth** *queue-depth*

**no tx-queue-depth** *queue-depth*

|                    |                                                                                                                              |                                                                     |

## tx-queue-depth (group peer)

You can adjust the number of packets that can be queued for transmission. To configure the transmit queue depth, use the **tx-queue-depth** group peer submode command. To return to the default queue depth, use the **no** form of this command.

**tx-queue-depth** *queue-depth*

**no tx-queue-depth** *queue-depth*

| Syntax Description | <i>queue-depth</i> | Number of packets to be queued. The values for this argument vary depending on the type of link. For an SCTP link, the range is 100 to 20000 packets with a default of 1000 packets. For an MTP2 link, the range is 25 to 5000 packets with a default of 500 packets. |
|--------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|--------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Defaults | 1000 packets (SCTP link)<br>500 packets (MTP2 link) |
|----------|-----------------------------------------------------|
|----------|-----------------------------------------------------|

| Command Modes | Group peer submode |
|---------------|--------------------|
|---------------|--------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |
|                 | 12.4(11)SW  |                              |
|                 | 12.2(33)IRA |                              |

| Usage Guidelines | The <b>tx-queue-depth</b> command controls the number of packets allowed on the transmit queue. The queue's function is to absorb traffic bursts. When you select the queue depth, you will have to compromise between transmit congestion thresholds, which can drop packets, or transmit delays due to queuing times. |
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Applications that are sensitive to small delays should account for transmit delays due to queuing times. When links are congested, the queue depth controls the number of packets that can be queued before they are discarded. Discarding packets causes application retransmissions.

| Examples | The following example shows how to set the transmit queue depth to 2000 packets: |
|----------|----------------------------------------------------------------------------------|
|----------|----------------------------------------------------------------------------------|

```
cs7 group ITP1 3333
 local-ip 1.1.1.1
 peer 4444
 remote-ip 1.1.1.2
 tx-queue-depth 2000
```

**Related Commands**

|------------------------------|---------------------------------------------------------------------------------------------|
| <a href="#">peer (group)</a> | Enables ITP to initiate the SCTP association with its peers and enables group peer submode. |

## ucp (cs7 sms group)

To specify that messages will be routed on a UCP session, use the **ucp** command in cs7 sms group configuration mode. To remove the configuration, use the **no** form of this command.

**ucp** *session-name* [**weight** *weight*]

**no ucp** *session-name* [**weight** *weight*]

### Syntax Description

|                     |                                                                           |
|---------------------|---------------------------------------------------------------------------|
| <i>session-name</i> | UCP session name.                                                         |
| <b>weight</b>       | Specifies the weight applied to the weighted round robin (WRR) algorithm. |
| <i>weight</i>       | Weight value, in the range 0 to 10.                                       |

### Defaults

None.

### Command Modes

cs7 sms group configuration

### Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

### Examples

The following example shows how to configure a result group named OFFISLAND and specify that messages will be routed in SMPP sessions:

```
CS7 sms group OFFISLAND smsc protocol ucp
 ucp OFFISLAND1 weight 3
 ucp OFFISLAND2 weight 4
```

### Related Commands

| Command       | Description                     |
|---------------|---------------------------------|
| cs7 sms group | Configures an SMS result group. |

# udp-checksum

To turn on the optional calculation of a UDP checksum sent in the PMP stream, use the **udp-checksum** *cs7* *dc*s configuration submode command. To stop the action, use the **no** form of this command.

**udp-checksum** *udp-checksum*

**no udp-checksum** *udp-checksum*

## Syntax Description

|                     |                                                                                                    |
|---------------------|----------------------------------------------------------------------------------------------------|
| <i>udp-checksum</i> | A 16-bit field used for error checking of the header and data of the UDP transport layer protocol. |
|---------------------|----------------------------------------------------------------------------------------------------|

## Defaults

This command is disabled.

## Command Modes

cs7 dcs configuration submode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.4(15)SW3 | This command was introduced. |
| 12.2(33)IRC |                              |

## Examples

The following example shows how to turn on the UDP checksum for the DCS node named alpha:

```
cs7 dcs alpha
  remote-ip 209.165.201.29 209.165.201.28 3033
  local-ip 1209.165.20127 3033
  ping-interval 5
  timeout-count 3
  udp-checksum
```

|                    | cs7 sgmp                                                                                                                                                | Establishes an association to the mated-signaling gateway and enters cs7 sgmp submode. |

# unordered-priority (cs7 sua)

To configure the priority of unordered packets, use the **unordered-priority** cs7 sua command. To remove the configuration, use the **no** form of this command.

**unordered-priority {equal | high}**

**no unordered-priority**

## Syntax Description

|              |                                                        |
|--------------|--------------------------------------------------------|
| <b>equal</b> | Unordered packets delivered in the order received.     |
| <b>high</b>  | Unordered packets delivered before any sequenced data. |

## Defaults

Unordered packets are delivered in the order received.

## Command Modes

cs7 sua

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

## Examples

The following example shows how to specify that unordered packets are delivered before any sequenced data:

```
cs7 sua 15000
 unordered-priority high
```

## Related Commands

|                         |                                                                                                                                                                                                                                                 |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Usage Guidelines</b> | If the command is issued for an M3UA AS, unroutable accounting counts the payload data messages received from M3UA AS. These payload data messages need routing to an inaccessible destination and are classified by an OPC+DPC+SI combination. |
|-------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

If the command is issued for an SUA AS, unroutable accounting counts the CLDT messages received from the SUA AS. These CDLT messages need routing to an inaccessible destination, or the GTT is translated to an inaccessible point code.

## update (cs7 gtt address conversion)

To add, remove, or change a GTT address-conversion entry, use the **update** cs7 gtt address conversion submode command. To delete the entry, use the **no** form of this command.

**update** [**in-address** *in-address*] [**nai** *nai*] [**np** *np*] [**out-address** *out-address*] [**es** *es-val*] [**remove** *ndigits*]

**no update** [**in-address** *in-address*] [**nai** *nai*] [**np** *np*] [**out-address** *out-address*] [**es** *es-val*] [**remove** *ndigits*]

| Syntax Description |  |                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>remove</b>      |  | Specifies the number of digits to remove from the input address before inserting the output address prefix. If not specified, then only the digits specified with the <b>in-address</b> keyword are removed.                                                                                                                                                       |
| <i>ndigits</i>     |  | The number of digits to remove, specified as an integer in the range 0 to 15.                                                                                                                                                                                                                                                                                      |
| <b>in-address</b>  |  | Specifies the input address prefix that must match for the following modifications to be made. A new default input address may be specified. The default input address is used if no other input addresses within the address conversion table match the input packet. Only one <b>update</b> command within an address table may specify a default input address. |
| <i>in-address</i>  |  | SCCP address. Valid numbers are 1 to 15 hexadecimal digits in length, or a default address configured as an asterisk (*).                                                                                                                                                                                                                                          |
| <b>nai</b>         |  | Specifies a new nature of address indicator.                                                                                                                                                                                                                                                                                                                       |
| <i>nai</i>         |  | NAI value. Range is 0 to 127.                                                                                                                                                                                                                                                                                                                                      |
| <b>np</b>          |  | Specifies a new numbering plan.                                                                                                                                                                                                                                                                                                                                    |
| <i>np</i>          |  | NP value. Range is 0 to 15.                                                                                                                                                                                                                                                                                                                                        |
| <b>out-address</b> |  | Specifies the output address.                                                                                                                                                                                                                                                                                                                                      |
| <i>out-address</i> |  | SCCP address. Valid numbers are 1 to 15 hexadecimal digits in length.                                                                                                                                                                                                                                                                                              |
| <b>es</b>          |  | Specifies a specific encoding scheme for the address conversion result.                                                                                                                                                                                                                                                                                            |
| <i>es-val</i>      |  | Encoding scheme value. Valid range is 0 to 2:<br>0 = unknown encoding scheme<br>1 = bcd odd encoding scheme<br>2 = bcd even encoding scheme                                                                                                                                                                                                                        |

**Defaults** None.

**Command Modes** cs7 gtt address conversion submode

**Usage Guidelines** If the specified number of digits to remove is greater than the number of digits in the input address, then all digits are removed before the new prefix specified by the output address is inserted. If no output address is specified, then the address conversion fails and the MSU is not routed.

**Command History**

| Release                                  | Modification                                                      |
|------------------------------------------|-------------------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                                      |
| 12.2(18)IXE                              | The <b>remove</b> keyword and <i>ndigits</i> argument were added. |

**Examples**

```
cs7 gtt address-conversion CONVERT
```

```
update in-address 23480500 out-address 919821900201 remove 12
```

In this example, an input address of 234805001234567 is first converted

- by removing 12 digits from the address prefix: 234805001234567 -> 567
- then prepending the out-address string: 567 -> 919821900201567

An input address of 2348050034 is converted by

- removing 12 digits from the address prefix: 2348050034 -> NULL
- then prepending the out-address string: NULL -> 919821900201

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |
| 12.4(11)SW  |                              |
| 12.2(33)IRA |                              |

**Usage Guidelines**

GTI conversion can be used to update the GTI, TT, SSN, encoding scheme, numbering plan, and nature of address indicator in an SCCP address. You specify sets of input parameters and output parameters. For ANSI, GTI 2 is supported. For ITU, GTI 2 and 4 are supported.

**Examples**

The following example shows how to convert all MSUs with GTI 2 to GTI 4 and set the encoding scheme to 2, the numbering plan to 1, and the nature of address indicator to 3, but not change the TT and SSN:

```
cs7 sccp gti-conversion gti-conv1
update gti-in 2 gti-out 4 es-out 2 np-out 1 nai-out 3
```

# update route (route-table)

To update a route, use the **update route** route-table submode command.

**update route** *point-code* [*mask* | *length*] **linkset** *ls-name* [**priority** *priority-value*] [**qos-class** { *class* | **default** }] [**load\_share**]

## Syntax Description

|                       |                                                                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>point-code</i>     | Signaling point code of the destination.                                                                                                                                                                                                         |
| <i>mask</i>           | Specifies the significant bits of the point code.                                                                                                                                                                                                |
| <i>length</i>         | Alternate way of specifying the mask. For ANSI, this alternate specification of the default is /24. For ITU, the alternate specification of the default is /14.                                                                                  |
| <b>linkset</b>        | Specifies the linkset.                                                                                                                                                                                                                           |
| <i>ls-name</i>        | Name of the previously created linkset.                                                                                                                                                                                                          |
| <b>priority</b>       | Configures route priority.                                                                                                                                                                                                                       |
| <i>priority-value</i> | Priority of the route to the destination. Valid range is 1 to 9 (the smaller the number, the higher the priority). The default is 5. Two routes to the same destination using two different linksets but equal priority form a combined linkset. |
| <b>qos-class</b>      | Specifies the QoS class assigned to the destination.                                                                                                                                                                                             |
| <i>class</i>          | QoS class. Valid range is 1 to 7.                                                                                                                                                                                                                |
| <b>load_share</b>     | Enables loadsharing among linksets in combined linkset as per Q.704.                                                                                                                                                                             |

## Defaults

The default priority value is 5.

## Command Modes

Route-table submode

## Command History

| Release                                  | Modification                                                               |
|------------------------------------------|----------------------------------------------------------------------------|
| 12.2(18)IXA<br>12.4(11)SW<br>12.2(33)IRA | This command was introduced.                                               |
| 12.4(15)SW6<br>12.2(33)IRF               | The <b>load_share</b> keyword was introduced.                              |
| 12.4(15)SW7<br>12.2(33)IRG               | The number of maximum routes with the same priority increased from 2 to 4. |

## Usage Guidelines

For ITU networks, the mask must be 7.255.7 if the default 3-8-3 bit point code format is used.

For ANSI networks, the mask must be 255.255.255 if the default 8-8-8 bit point code format is used.

You must specify either *mask* or *length*.

A lower number for *priority-value* gives the route a higher priority.

Setting a priority value of 9 is not recommended. This value should be reserved for dynamic routes created when summary routing is enabled. See the “[Summary Routing and ANSI Cluster Routing](#)” chapter for an explanation of summary routing.

A QoS class assignment is based on a destination point code. All routes to a specific DPC will have the same QoS class. When creating multiple routes to the same destination point code, the same QoS class must be specified for the DPC on each **update route** command. If the QoS class value is changed on a route for a DPC, the QoS class for all the routes to that DPC is changed. Omitting a QoS class value for a route to a DPC removes the QoS class from all existing routes to that DPC.

To preserve the priority of an existing route when adding or modifying the QoS class, the priority specified on the existing route must be specified on the modified route. If the priority is omitted, the priority of the modified route changes to the default priority of 5.

The **load\_share** keyword enables Q.704 linkset load sharing. The scheme equally divides traffic between the linksets. It then divides the allocated linkset traffic among the links that comprise the linkset.

For example, traffic is first equally distributed over the linkset A and linkset B (50 percent each). It is then divided among the links that make up linkset A or the links that make up linkset B.

ITP performs verification of route availability when a new route for a DPC is added. In the case of a link restart, the status of the route will go to accessible by default in case no TFP is received from any of the adjacent nodes.

## Examples

The following two examples show acceptable ways to create a route to destination 1.50.2 using linkset nyc and the default priority:

```
update route 1.50.2 255.255.255 linkset nyc
```

```
update route 1.50.2/24 linkset nyc
```

The following example shows how to create a route to destination 1.50.3 using linkset washington with priority 3:

```
update route 1.50.3 255.255.255 linkset washington priority 3
```

The following example shows how to create a combined linkset:

```
update route 1.50.3 255.255.255 linkset philly priority 3
```

The following two examples show that the lower priority value sets a higher priority for the route. In the examples, LSA is the primary route to 1.1.1 and LSC is the alternate route to 1.1.1.

```
update-route 1.1.1/14 linkset LSA priority 1
```

```
update route 1.1.1/14 linkset LSC priority 9
```

The following example shows how to create a route to destination 1.50.3 using linkset washington with QoS class 2:

```
update-route 1.50.3 255.255.255 linkset washington priority 3 qos-class 2
```

The following examples show how to create routes to destination 1.50.3 with QoS class 3. LSA is the primary route and LSC is the alternate route to 1.50.3.

```
update route 1.50.3 255.255.255 linkset LSA priority 1 qos-class 3
```

```
update route 1.50.3 255.255.255 linkset LSC priority 9 qos-class 3
```

### Note

In this example, note that if the **qos-class** keyword is omitted from alternate route LSC, QoS functionality is disabled for destination 1.50.3. If another QoS class is specified on alternate route LSC instead of QoS class 3, that class is assigned to both primary route LSA and alternate route LSC.

In the following example, the second statement modifies an existing route to destination 1.50.3 using linkset washington and priority 3 with QoS class 2:

```
update-route 1.50.3 255.255.255 linkset washington priority 3
update route 1.50.3 255.255.255 linkset washington priority 3 qos-class 2
```

**Note**

In this example, note that if the **priority** keyword is omitted when adding the **qos-class** keyword, the priority of the route changes to the default priority of 5.

In the following example, under the destination 1.1.1, the linksets m2pa\_194\_00 and m2pa\_194\_01 have the load share feature enabled:

```
update route 1.1.1/14 linkset m2pa_194_00 priority 1 qos-class 2 load_share
update route 1.1.1/14 linkset m2pa_194_01 priority 1 qos-class 2 load_share
```

## ussd-string (cs7 mlr ruleset rule)

To specify the USSD string used in filtering and routing mobile initiated GSM-MAP messages, use the **ussd-string** command in the cs7 mlr ruleset rule submode. To remove the string, use the **no** form of this command.

**ussd-string** *string*

**no ussd-string**

| Syntax Description | <i>string</i> | Character string with a maximum length of 20 and not containing * or #. |
|--------------------|---------------|-------------------------------------------------------------------------|
|--------------------|---------------|-------------------------------------------------------------------------|

| Defaults | There is no default string. |
|----------|-----------------------------|
|----------|-----------------------------|

| Command Modes | cs7 mlr ruleset rule submode |
|---------------|------------------------------|
|---------------|------------------------------|

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.4(15)SW7 | This command was introduced. |
|                 | 12.2(33)IRG |                              |

| Usage Guidelines | Configure the USSD string to be used in filtering and routing mobile-initiated GSM-MAP messages. |
|------------------|--------------------------------------------------------------------------------------------------|
|------------------|--------------------------------------------------------------------------------------------------|

| Examples | The following example shows how to filter mobile-initiated GSM-MAP messages containing USSD string 123 and route them to DPC 1234: |
|----------|------------------------------------------------------------------------------------------------------------------------------------|
|----------|------------------------------------------------------------------------------------------------------------------------------------|

```
cs7 instance 0 mlr ruleset abc
rule 1 gsm-map mobileUSSD
  ussd-string 123
  result pc 1234
```

| Command    | Description                                                        |
|------------|--------------------------------------------------------------------|
| controller | Specifies the controller and enters controller configuration mode. |

# wait-timeout

To configure the amount of time an ITP group member waits after bootup to establish communication with its peer, before it assumes it is operating independently, use the **wait-timeout** command in group configuration mode. To reset the peer wait timeout period to its default setting, use the **no** form of this command.

**wait-timeout** *seconds*

**no wait-timeout**

| Syntax Description        | <i>seconds</i><br>The number of seconds an ITP group member waits to establish communication with a peer. Valid values range from 45 to 300 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                        |  |         |              |                           |                              |            |             |

| 12.2(33)IRA               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |  |         |              |                           |                              |            |             |
| Usage Guidelines          | <p>For most situations the default value of 60 seconds is an adequate amount of time for an ITP group member to establish communication with its peer, assuming the peer is present and initialized, and an operational communication link exists between ITPs.</p> <p>This command only affects the amount of time an ITP group member waits to establish communication with its peer after bootup, before it assumes it is operating independently. The ITP always attempts to establish communication with its peer on a periodic basis when communication has not been established.</p> |  |         |              |                           |                              |            |             |
| Examples                  | <p>The following example shows how to set the wait-timeout period to 120 seconds:</p> <pre>cs7 group ITP1 3333  wait-timeout 120</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |  |         |              |                           |                              |            |             |

- `debug cs7 sua`
- `debug cs7 tcap`

---

**Note**

Enabling debugging during periods of heavy traffic can cause link failure.

---

Short Message Peer-to-Peer (SMPP) protocol is not supported. Some DSMR functionality is also not supported. It is recommended that commands pertaining to these features are not configured.

# debug cs7 gws

To display debug information for the gateway screening feature, use the **debug cs7 gws** command in privileged EXEC mode. To disable the display, use the **no** form of this command.

**debug cs7 gws** {all | api | error | info | packet} [verbose]

**no debug cs7 gws** {all | api | error | info | packet}

## Syntax Description

|                |                                               |
|----------------|-----------------------------------------------|
| <b>all</b>     | Enable all Enhanced Gateway Screening debugs. |
| <b>api</b>     | GWS API tracing.                              |
| <b>error</b>   | GWS error events.                             |
| <b>info</b>    | GWS informational events.                     |
| <b>packet</b>  | GWS packet tracing.                           |
| <b>verbose</b> | Display detailed packet tracing.              |

## Command Default

No default behavior or values.

## Command Modes

Privileged EXEC mode

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(25)SW4 | This command was introduced. |

## Usage Guidelines

We recommend that use of this and all debug commands be performed with the advice of the Cisco Technical Assistance Center (TAC).

# debug cs7 gws rate-limit

To display debug information for the API call and some internal events when processing MSUs at GWS level, use the **debug cs7 gws rate-limit** command in privileged EXEC mode. To disable the display, use the **no** form of this command.

```
debug cs7 gws rate-limit {ingress | egress | both}
```

```
no debug cs7 gws rate-limit
```

## Syntax Description

|                |                                              |
|----------------|----------------------------------------------|
| <b>ingress</b> | Specifies inbound traffic.                   |
| <b>egress</b>  | Specifies outbound traffic.                  |
| <b>both</b>    | Specifies both inbound and outbound traffic. |

## Command Default

None.

## Command Modes

Privileged EXEC (#)

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(33)IRG | This command was introduced. |
| 12.4(15)SW7 |                              |

## Usage Guidelines

We recommend that use of this and all debug commands be performed with the advice of the Cisco Technical Assistance Center (TAC).

# debug cs7 gws rmt-packet-drop

To display the number of MSUs dropped in a timer window, use the **debug cs7 gws rmt-packet-drop** command in privileged EXEC mode. To disable the display, use the **no** form of this command.

**debug cs7 gws rmt-packet-drop {ingress | egress | both}**

**no debug cs7 gws rmt-packet-drop**

## Syntax Description

|                |                                              |
|----------------|----------------------------------------------|
| <b>ingress</b> | Specifies inbound traffic.                   |
| <b>egress</b>  | Specifies outbound traffic.                  |
| <b>both</b>    | Specifies both inbound and outbound traffic. |

## Command Default

None.

## Command Modes

Privileged EXEC (#)

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(33)IRG | This command was introduced. |
| 12.4(15)SW7 |                              |

## Usage Guidelines

We recommend that use of this and all debug commands be performed with the advice of the Cisco Technical Assistance Center (TAC).

# debug cs7 m2pa

To display debug messages for M2PA, use the **debug cs7 m2pa** EXEC command.

```
debug cs7 m2pa { cong | error | iac | l3api | lsc | packet | poc | retrieval | rxc | peer | sctp | timers
               | txc } linkset slc
```

## Note

Enabling debug during high traffic can cause the link to fail.

## Syntax Description

|                  |                                         |
|------------------|-----------------------------------------|
| <b>cong</b>      | Debugs Congestion Control events.       |
| <b>error</b>     | Debugs Error events.                    |
| <b>iac</b>       | Debug Initial Alignment Control events. |
| <b>l3api</b>     | Debugs M2PA Layer 3 API events.         |
| <b>lsc</b>       | Debug Link State Control events.        |
| <b>packet</b>    | Debugs M2PA Packet tracing.             |
| <b>poc</b>       | Debug Processor Outage Control events.  |
| <b>retrieval</b> | Debug Retrieval events.                 |
| <b>rxc</b>       | Debug Reception Control events.         |
| <b>peer</b>      | Debugs M2PA Peer events.                |
| <b>sctp</b>      | Debugs M2PA SCTP events.                |
| <b>timers</b>    | Debug Timer events.                     |
| <b>txc</b>       | Debug Transmission Control events.      |
| <i>linkset</i>   | Linkset                                 |
| <i>slc</i>       | Signalling link selector value          |

## Defaults

No default behavior or values.

## Command History

| Release     | Modification                                                                                                                 |
|-------------|------------------------------------------------------------------------------------------------------------------------------|
| 12.2(18)IXA | This command was introduced.                                                                                                 |
| 12.2(25)SW3 | The <b>iac</b> , <b>lsc</b> , <b>poc</b> , <b>retrieval</b> , <b>rxc</b> , <b>timers</b> and <b>txc</b> keywords were added. |

# debug cs7 m3ua

To display debug messages for M3UA, use the **debug cs7 m3ua** EXEC command.

```
debug cs7 m3ua [all | congestion | error | l3api | mgmt {api | state {as-name ASname | asp-name ASPname} | pointcode {dpc pointcode}} | packet {short} {asp-name ASPname} | sctp {asp-name ASPname} | timer {as-name ASname}]
```

## Note

Enabling debug during high traffic can cause the link to fail.

## Syntax Description

|                   |                                         |
|-------------------|-----------------------------------------|
| <b>all</b>        | Enables all debugs.                     |
| <b>api</b>        | Debugs API events.                      |
| <b>as-name</b>    | Specify an AS.                          |
| <i>ASname</i>     | AS name.                                |
| <b>asp-name</b>   | Specify an ASP                          |
| <i>ASPname</i>    | AS P name.                              |
| <b>congestion</b> | Debugs Congestion Control events        |
| <b>dpc</b>        | Specify a point code.                   |
| <b>error</b>      | Debugs Error events.                    |
| <b>l3api</b>      | Debugs M3UA Layer 3 API events.         |
| <b>mgmt</b>       | Debugs Management events.               |
| <b>packet</b>     | Packet tracing                          |
| <b>point-code</b> | Point code                              |
| <i>point-code</i> | Point code                              |
| <b>sctp</b>       | SCTP API events.                        |
| <b>state</b>      | State machine events.                   |
| <b>timer</b>      | AS timer events.                        |
| <b>short</b>      | Truncate displayed payload at 32 bytes. |

## Defaults

No default behavior or values.

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |

# debug cs7 mlr

To display debug messages for Multi-layer routing, use the **debug cs7 mlr** command in privileged EXEC mode.

**debug cs7 mlr table** [**all** | **error** | **info** | **packet**] [**verbose** [*paklen*]]

| Syntax Description |  |                                                               |
|--------------------|--|---------------------------------------------------------------|
| <b>all</b>         |  | Enables all debugs.                                           |
| <b>error</b>       |  | Debugs error events.                                          |
| <b>info</b>        |  | Display informational events.                                 |
| <b>packet</b>      |  | Displays packet events.                                       |
| <b>verbose</b>     |  | Display detailed information.                                 |
| <i>paklen</i>      |  | Number of bytes of TCAP message to display. The default is 0. |

**Defaults** No default behavior or values.

**Command Modes** Privileged EXEC

| Command History | Release     | Modification                 |
|-----------------|-------------|------------------------------|
|                 | 12.2(18)IXA | This command was introduced. |

**Examples** The following is sample output from the **debug cs7 mlr** command:

```
Router# debug cs7 mlr
*Mar 1 02:08:11.600: CS7 MLR PACKET: Packet 815448A8 received for SCCP MLR processing
*Mar 1 02:08:11.600: CS7 MLR INFO: Primary CdPA GT trigger match on 9991117770
*Mar 1 02:08:11.600: CS7 MLR INFO: mlr_parse_itu_tcap_msg: TC_DLG_BEGIN Tag Decoded
*Mar 1 02:08:11.600: CS7 MLR INFO: mlr_get_tcap_invoke_opCode: Operation Code Decoded

|-------------------------------|-----------------------------------------------------------------------------------------|
| <a href="#">cs7 mlr table</a> | Specifies the name of the multi-layer SMS routing table and enables CS7 MLR table mode. |

# debug cs7 mtp2

To display debug messages for MTP2, use the **debug cs7 mtp2 EXEC** command. The **debug cs7 mtp2** command is not available on the Cisco 7507 or Cisco 7513 platforms.

```
debug cs7 mtp2 {aerm | all | cong | error | iac | l3api | lsc | msu | rcv | suerm | timers | txc} serial
interface
```

## Note

Enabling debug during high traffic can cause the link to fail.

## Syntax Description

|                  |                                                   |
|------------------|---------------------------------------------------|
| <b>aerm</b>      | Debugs Alignment Error Rate Monitor events.       |

| <b>txc</b>       | Debugs Transmission Control events.               |
| <b>serial</b>    | Serial interface.                                 |
| <i>interface</i> | Interface number.                                 |

## Defaults

No default behavior or values.

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |

## Usage Guidelines

The **debug cs7 mtp2** command is not available on the Cisco 7507 or Cisco 7513 platforms.

## debug cs7 mtp3

To display debug messages for ITP MTP3, use the **debug cs7 mtp3** EXEC command. To disable debug, use the **no** form of this command.

```
debug cs7 mtp3 [destination ss7-access-list-num] [error linkset] [l2api linkset]  
[mgmt {error error} | {event event} | {packet point-code [in | out]}]
```

```
no debug cs7 mtp3 [destination ss7-access-list-num] [error linkset] [l2api linkset]  
[mgmt {error error} | {event event} | {packet point-code [in | out]}]
```

**Note**

Enabling debug during high traffic can cause the link to fail.

**Syntax Description**

|                            |                                                     |
|----------------------------|-----------------------------------------------------|
| <b>destination</b>         | DPC status changes.                                 |
| <i>ss7-access-list-num</i> | SS7 Access list number. Range is 2700 through 2999. |
| <b>error</b>               | Error events.                                       |
| <i>linkset</i>             | Linkset name.                                       |
| <b>l2api</b>               | MTP3-Layer2 API events.                             |
| <i>linkset</i>             | Linkset name.                                       |
| <b>mgmt</b>                | MTP3 MGMT Debug options.                            |
| <b>error</b>               | MTP3 MGMT errors                                    |

| <b>packet</b>     | MTP3 MGMT MSUs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <i>point-code</i> | Point Code.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>in</b>         | ITP MTP3 MGMT packet level debugging incoming.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>out</b>        | ITP MTP3 MGMT packet level debugging outgoing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Defaults**

No default behavior or values.

**Command History**

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |

# debug cs7 mtp3 paklog

To send selected message signaling units (MSU) to an appropriate monitoring tool (chosen by user), use the **debug cs7 mtp3 paklog EXEC** command.

```
debug cs7 mtp3 paklog access-list-number [linkset-name] [incoming] [outgoing]
                        [number-of-packets] [verbose]
```

```
no debug cs7 mtp3 paklog access-list-number [linkset-name] [incoming] [outgoing]
                        [number-of-packets] [verbose]
```

## Note

Enabling debug during high traffic can cause the link to fail.

## Syntax Description

|                           |                                                                                                                                                                                               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>access-list-number</i> | Integer in the range 2700 to 2999, corresponding to an existing CS7 access list number, used to select packets for logging.                                                                   |
| <i>linkset-name</i>       | An existing CS7 linkset for which packet debugging is intended. If no linkset is specified packet debugging is implemented on all linksets.                                                   |
| <b>incoming</b>           | Perform debugging on incoming MSUs. If neither <b>incoming</b> nor <b>outgoing</b> is specified, debugging is performed on both incoming and outgoing MSUs.                                   |
| <b>outgoing</b>           | Perform debugging on outgoing MSUs. If neither incoming nor outgoing is specified, debugging is performed on both incoming and outgoing MSUs.                                                 |
| <i>number-of-packets</i>  | Maximum number of MSUs to copy out via UDP. Valid range is 1 to 1000000 packets. If no number is specified, all MSUs matching the access list will be sent out until the debug is turned off. |
| <b>verbose</b>            | Display information to the console concerning the message being logged. It is recommended that the verbose display be used with low traffic rates only.                                       |

## Defaults

If no linkset is specified packet debugging is implemented on all linksets.

If neither **incoming** nor **outgoing** is specified, debugging is performed on both incoming and outgoing MSUs.

If no *number-of-packets* is specified, all MSUs matching the access list will be sent out until the debug is turned off.

Verbose display is disabled.

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |

## Usage Guidelines

You must configure the **cs7 paklog** command before enabling the **debug cs7 mtp3 paklog** command. If you do not, the following error message will be displayed:

```
%Error: paklog debug will not work without configuring 'cs7 paklog'.
```

## Examples

In the following example, debugging is turned on for the linkset named `to_chicago` for all MSUs matching access list 2700:

```
debug cs7 mtp3 paklog 2700 to_chicago
```

The following is sample output from the **debug cs7 mtp3 paklog** command with the verbose display:

```
router# debug cs7 mtp3 paklog 2700 to_chicago verbose
```

```
16:10:44: CS7 PAKLOG Data:<135> April 23 14:33
MainITP:00003852,msu=B2001AEE00C0EE0011201112
16:10:44: CS7 PAKLOG DEBUG: sent 110 bytes to 10.4.0.90 on port 5514
16:10:44: CS7 PAKLOG Data:<135> April 23 14:33
MainITP:00003853,msu=B200C0EE001AEE0021201112
16:10:44: CS7 PAKLOG DEBUG: sent 110 bytes to 10.4.0.90 on port 5514
```

The following is sample output from the **show debug** command after the ITP packet logging facility has been configured and **debug cs7 mtp3 paklog** enabled for access list 2700.

Examples for linksets named `to_hurricane` and `to_fastnet`:

```
CS7 MTP3 (to_hurricane):
  MTP3 incoming paklog debugging is on, acl=2700, MSUs=infinite
  MTP3 outgoing paklog debugging is on, acl=2700, MSUs=infinite

CS7 MTP3 (to_fastnet):
  MTP3 incoming paklog debugging is on, acl=2700, MSUs=infinite
  MTP3 outgoing paklog debugging is on, acl=27
```

Verbose examples for linksets named `to_okracoke` and `to_okracoke2`:

```
CS7 MTP3 (to_okracoke):
  MTP3 verbose incoming paklog debugging is on, acl=2700, MSUs=infinite
  MTP3 verbose outgoing paklog debugging is on, acl=2700, MSUs=infinite

CS7 MTP3 (to_okracoke2):
  MTP3 verbose incoming paklog debugging is on, acl=2700, MSUs=infinite
  MTP3 verbose outgoing paklog debugging is on, acl=2700, MSUs=infinite
```

Examples with a specific number of MSU:

```
CS7 MTP3 (to_okracoke2):
  MTP3 incoming paklog debugging is on, acl=2701, MSUs=100
  MTP3 outgoing paklog debugging is on, acl=2700, MSUs=100
```

# debug cs7 nso

To display all the ITP Non-Stop Operation (NSO) events or errors, use the **debug cs7 nso** command in privileged EXEC mode.

**debug cs7 nso** {**all** | **client** | **error** | **event** | | **packet** | **state**} [**verbose**]

## Syntax Description

|                |                                 |
|----------------|---------------------------------|
| <b>all</b>     | Display all NSO activity.       |
| <b>client</b>  | Display NSO RF client activity. |
| <b>error</b>   | Display NSO errors.             |
| <b>event</b>   | Display NSO events.             |
| <b>packet</b>  | Display NSO control messages.   |
| <b>state</b>   | Display NSO state transitions.  |
| <b>verbose</b> | Generate detailed debug output. |

## Defaults

No default behavior or values.

## Command Modes

Privileged EXEC

## Command History

| Release    | Modification                 |
|------------|------------------------------|
| 12.2(23)SW | This command was introduced. |

## Examples

The following example displays all NSO activity in the verbose format:

```
Router# debug cs7 nso error verbose
```

## Related Commands

| Command                 | Description                          |
|-------------------------|--------------------------------------|
| <a href="#">cs7 nso</a> | Enable ITP Non-Stop Operation (NSO). |

# debug cs7 nso chkpt

To display all the ITP Non-Stop Operation (NSO) checkpointing activity, use the **debug cs7 nso chkpt** command in privileged EXEC mode.

**debug cs7 nso chkpt** [*instance-number*] {**all** | **client** | **error** | **event** | **packet**} [**verbose**]

## Syntax Description

|                        |                                                     |
|------------------------|-----------------------------------------------------|
| <i>instance-number</i> | Limit debug output to a particular ITP instance.    |
| <b>all</b>             | Display all activity related to NSO checkpointing.  |
| <b>client</b>          | Display NSO checkpointing facility client activity. |
| <b>error</b>           | Display NSO checkpointing errors.                   |
| <b>event</b>           | Display NSO checkpointing events.                   |
| <b>packet</b>          | Display NSO checkpointing messages.                 |
| <b>verbose</b>         | Generate detailed debug output.                     |

## Defaults

No default behavior or values.

## Command Modes

Privileged EXEC

## Command History

| Release    | Modification                 |
|------------|------------------------------|
| 12.2(23)SW | This command was introduced. |

## Examples

The following example displays all NSO checkpointing activity for instance 2 in the verbose format:

```
Router# debug cs7 nso chkpt 2 error verbose
```

## Related Commands

| Command                 | Description                          |
|-------------------------|--------------------------------------|
| <a href="#">cs7 nso</a> | Enable ITP Non-Stop Operation (NSO). |

# debug cs7 offload mtp3

To display debug messages for the ITP MTP3 Offload feature, use the **debug cs7 offload mtp3 EXEC** command. To disable debug, use the **no** form of this command.

```
debug cs7 offload mtp3 {error error} | {event event}
```

```
nodebug cs7 offload mtp3
```

## Warning

Enabling debug during high traffic can cause the link to fail.

## Syntax Description

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <i>error/event</i> | Event or Error can be monitored for the following functions: <ul style="list-style-type: none"> <li>• <b>ALL</b> All RP errors.</li> <li>• <b>DWNLD</b> Configuration and status messages from RP to LC.</li> <li>• <b>GNRL</b> RP general</li> <li>• <b>IPC</b> IPC</li> <li>• <b>LCMSG</b> Control messages from RP to LC</li> <li>• <b>MTP3_MGMT</b> MTP3 MGMT event messages from RP to LC.</li> <li>• <b>RPMSG</b> Control messages from RP to LC.</li> <li>• <b>UPLD</b> Statistics and accounting messages from LC to RP.</li> </ul> |

## Defaults

No default behavior or values.

## debug cs7 sccp

To display debug messages for ITP SCCP, use the **debug cs7 sccp** EXEC command. To disable debug, use the **no** form of this command.

```
debug cs7 sccp [{error error} | {event event} | gtt-accounting | map-table | {packet [verbose]
[bytes] [packets]}]
```

```
no debug cs7 sccp
```

### Warning

Enabling debug during high traffic can cause the link to fail.

### Syntax Description

|              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Defaults**

No default behavior or values.

# debug cs7

To display debug messages for , use the **debug cs7 EXEC** command.

**debug cs7 {all | congestion | error | event | mgmt {api | state} | packet [short] | sctp | timer}**

## Note

Enabling debug during high traffic can cause the link to fail.

## Syntax Description

|                   |                                   |
|-------------------|-----------------------------------|
| <b>all</b>        | Enable all debugs.                |
| <b>api</b>        | Management API events.            |
| <b>congestion</b> | Congestion Control events         |
| <b>error</b>      | Error events.                     |
| <b>event</b>      | Events                            |
| <b>mgmt</b>       | Management events.                |
| <b>packet</b>     | packet tracing to the mated SG.   |
| <b>sctp</b>       | SCTP API events for the mated SG. |
| <b>state</b>      | management state machine events.  |
| <b>timers</b>     | timer events.                     |

## Defaults

No default behavior or values.

## Command History

| Release     | Modification                 |
|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |

# debug cs7 snmp

To display debug messages for SNMP, use the **debug cs7 snmp** privileged EXEC command.

```
debug cs7 snmp {itp-acl | itp-act itp-gact | itp-grt | itp-gsccp | itp-gsp | itp-gsp2 | itp-rt | itp-sccp  
| itp-sp | itp-sp2 | itp-traps | itp-xua}
```

| Syntax Description |  |                                                                                               |
|--------------------|--|-----------------------------------------------------------------------------------------------|
| <b>itp-acl</b>     |  | Display debugging information about CISCO-ITP-ACL-MIB: Access Lists for ITP.                  |
| <b>itp-act</b>     |  | Display debugging information about CISCO-ITP-ACT-MIB: Accounting for ITP.                    |
| <b>itp-gact</b>    |  | Display debugging information about CISCO-ITP-GACT-MIB                                        |
| <b>itp-grt</b>     |  | Display debugging information about CISCO-ITP-GRT-MIB                                         |
| <b>itp-gsccp</b>   |  | Display debugging information about CISCO-ITP-GSCCP-MIB                                       |
| <b>itp-gsp</b>     |  | Display debugging information about CISCO-ITP-GSP-MIB                                         |
| <b>itp-gsp2</b>    |  | Display debugging information about CISCO-ITP-GSP2-MIB                                        |
| <b>itp-rt</b>      |  | Display debugging information about CISCO-ITP-RT-MIB: Route Table for ITP.                    |
| <b>itp-sccp</b>    |  | Display debugging information about CISCO-ITP-SCCP-MIB: Signaling Connection Control for ITP. |
| <b>itp-sp</b>      |  | Display debugging information about CISCO-ITP-SP-MIB: Signaling Point for ITP.                |
| <b>itp-sp2</b>     |  | Display debugging information about CISCO-ITP-SP2-MIB.                                        |
| <b>itp-traps</b>   |  | Display debugging information about ITP traps.                                                |
| <b>itp-xua</b>     |  | Display debugging information about CISCO-ITP-XUA-MIB                                         |

## Defaults

No default behavior or values.

# debug cs7 sua

To display debug messages for SUA, use the **debug cs7 sua** EXEC command.

**debug cs7 sua** [**all** | **congestion** | **error** | **mgmt** {**api** | **state** {**as-name** *ASname* | **asp-name** *ASPname*} | **pointcode** {**dpc** *pointcode*}} | **packet** {**short**} {**asp-name** *ASPname*} | **sccp** | **sctp** {**asp-name** *ASPname*} | **timer** {**as-name** *ASname*}

## Note

Enabling debug during high traffic can cause the link to fail.

|-------------|------------------------------|
| 12.2(18)IXA | This command was introduced. |

# debug cs7 tcap

To display debug messages for Cisco TCAP, use the **debug cs7 tcap** command in privileged EXEC mode.

**debug cs7 tcap** [**all** | **api** | **error** | **info** | **packet** [**verbose**] | **state**]

## Syntax Description

|                |                                  |
|----------------|----------------------------------|
| <b>all</b>     | Display all debugs.              |
| <b>api</b>     | Display API events.              |
| <b>error</b>   | Display error events.            |
| <b>info</b>    | Display informational events.    |
| <b>packet</b>  | Display packet tracing.          |
| <b>verbose</b> | Display detailed packet tracing. |
| <b>state</b>   | Display state machine tracing.   |

## Defaults

No default behavior or values.

## Command Modes

Privileged EXEC

## Command History

| Release      | Modification                 |
|--------------|------------------------------|
| 12.2(18)IXA7 | This command was introduced. |

## Examples

The following is sample output from the **debug cs7 tcap** command:

```
*Mar 11 18:58:27.177: CS7 TCAP State: New Dialogue state -> IDLE, tid[10]
*Mar 11 18:58:27.177: CS7 TCAP State: New Transaction state -> IDLE, tid[10]
*Mar 11 18:58:27.177: CS7 TCAP State: New operation Invoke state -> IDLE, iid[1] tid[10]
*Mar 11 18:58:27.181: CS7 TCAP State: Invoke state -> OP_SENT,class[1],iid[1],tid[10]
*Mar 11 18:58:27.181: CS7 TCAP State: Dialogue state -> IS, tid[10]
*Mar 11 18:58:27.181: CS7 TCAP State: Transaction state -> IS, tid[10]
*Mar 11 18:58:27.181: CS7 TCAP Pkt: SCCP SEND_DATA called (by MAP user layer)
*Mar 11 18:58:27.181: CS7 TCAP Pkt: data address [0x814BE510],data size [0x3C]
*Mar 11 18:58:27.185: CS7 TCAP Pkt: Calling address:
    ai [92] np [01] es [02] ssn [07] tt [00] noa [04] pc [0.0.0]
    gtd [0x814BE4B9], gt [1939294477|000A92]
    Called address:
    ai [92] np [06] es [01] ssn [06] tt [00] noa [04] pc [0.0.0]
    gtd [0x814BE48D], gt [01020304050607F8]
*Mar 11 18:58:27.185: CS7 TCAP Pkt: SCCP SEND_DATA returned without error
*Mar 11 18:58:27.189: %CS7SCCP-5-SCCPCUNAV: SCCP failed to translate: DPC=1.1.1 is not
available.
LS=NONE OPC=1.6.6 GTI=4 TT=0 NP= 6 NAI= 4 GTA=102030405060708
*Mar 11 18:58:27.189: CS7 TCAP Info: SCCP freeing TCAP data buffer routine called with
data ptr = 814BE510
```

■ `debug cs7 tcap`

## ITP System Messages

---

This document lists and describes Cisco ITP system messages. The system software sends these messages to the console (and, optionally, to a logging server on another system) during operation. Not all system messages indicate problems with your system. Some are purely informational, and others may help diagnose problems with communications lines, internal hardware, or the system software.

Short Message Peer-to-Peer (SMPP) protocol is not supported. Some DSMR functionality is also not supported. It is recommended that commands pertaining to these features are not configured.

This document includes ITP system messages only. For a complete list of all IOS system messages, please refer to the Cisco IOS Software System Messages document at <http://www.cisco.com/univercd/cc/td/doc/product/software/ios123/123sup/123sems/index.htm>

### How This Manual Is Organized

The messages are organized according to the particular system facility that produces the messages. The facility sections appear in alphabetical order, and within each facility section, messages are listed alphabetically by mnemonic. The messages are described in the following sections:

- [How to Read System Messages](#)
- [CS7ADDRTBL Messages](#)
- [CS7CDR Messages](#)
- [CS7CHKPT Messages](#)
- [CS7GROUP Messages](#)
- [CS7HSL Messages](#)
- [CS7M2PA Messages](#)
- [CS7MLR Messages](#)
- [CS7MTP2 Messages](#)
- [CS7MTP3 Messages](#)
- [CS7NSO Messages](#)
- [CS7PING Messages](#)
- [CS7RF Messages](#)
- [CS7ROUTE Messages](#)
- [CS7SCCP Messages](#)
- [CS7SMS Messages](#)

- [CS7TCAP Messages](#)
- [CS7XUA Messages](#)
- [DCS7 Messages](#)

## How to Read System Messages

System messages begin with a percent sign (%) and are structured as follows:

%FACILITY-SUBFACILITY-SEVERITY-MNEMONIC: Message-text

FACILITY is a code consisting of two or more uppercase letters that indicate the facility to which the message refers. A facility can be a hardware device, a protocol, or a module of the system software.

SEVERITY is a single-digit code from 0 to 7 that reflects the severity of the condition. The lower the number, the more serious the situation.

MNEMONIC is a code that uniquely identifies the error message.

Message-text is a text string describing the condition. This portion of the message sometimes contains detailed information about the event, including terminal port numbers, network addresses, or addresses that correspond to locations in the system memory address space. Because the information in these variable fields changes from message to message, it is represented here by short strings enclosed in square brackets ([ ]). A decimal number, for example, is represented as [dec].

## CS7ADDRTBL Messages

### Explanation

#### Error Message

%CS7ADDRTBL-5-DBCHANGED: Notice: The Address Table may have changed while reading. Operation aborted.

**Explanation** While attempting to read, copy, or save an address table, another process modified the table.

**Recommended Action** Repeat the last operation and avoid making configuration changes until complete.

#### Error Message

%CS7ADDRTBL-3-IFSERR: Internal File System Error:

**Explanation** An error occurred while trying to load/parse a CS7 Address Table.

**Recommended Action** This problem is probably due to a corrupt or invalid file format.

#### Error Message

%CS7ADDRTBL-5-LOADCOMPLETE: NOTICE: Address-Table [chars] loaded from [chars].

**Explanation** An address-table has finished loading.

**Recommended Action** No action is required.

**Error Message**

%CS7ADDRDTBL-5-SLAVETIMEOUT: NOTICE: Address-Table loader timeout waiting on config sync to slave.

**Explanation** The IOS High Availability sync to the slave did not complete in an expected window

**Recommended Action** Reboot slave and if problem persists contact Cisco TAC.

**Error Message**

%CS7ADDRDTBL-5-SYNCCOMPLETE: NOTICE: Address-Table [chars] loaded on slave.

**Explanation** An address-table has been synchronized on the slave processor.

**Recommended Action** No action is required.

**Error Message**

%CS7ADDRDTBL-5-SYNCFAIL: NOTICE: Address-Table [chars] failed on slave.

**Explanation** An address-table has failed to be synchronized on the slave processor.

**Recommended Action** See the slave log for failure reason and contact TAC for assistance.

## CS7CDR Messages

**Error Message**

%CS7CDR-5-CDRHASRSRC: Notice: CDR Destination [chars] has changed from no resources available to resources available.

**Explanation** The CDR destination may have had a disk that is full, but that condition has cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7CDR-5-CDRNORSRC: Notice: CDR Destination [chars] has reported no resources available to store records.

**Explanation** The CDR destination may have a disk that is full.

**Recommended Action** No action is required.

**Error Message**

%CS7CDR-5-CDRSERCONGEST: Notice: CDR Service [chars] has reached its congestion threshold.

**Explanation** The CDR destinations within the service are not processing records fast enough

**Recommended Action** No action is required.

**Error Message**

%CS7CDR-5-CDRSEQFULL: Notice: CDR Service [chars] has reached its max queue size.

**Explanation** The CDR destinations within the service are not processing the records fast enough

**Recommended Action** No action is required.

**Error Message**

%CS7CDR-5-CDRSTATCHG: [chars] changed state from [chars] to [chars]

**Explanation** A CDR Destination changed state

**Recommended Action** No action is required.

## CS7CHKPT Messages

**Error Message**

%CS7CHKPT-3-INTERR: [chars]

**Explanation** An internal software error has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7CHKPT-3-INVALIDINSTANCE: Invalid instance ([int])

**Explanation** A reference to an undefined variant instance was detected.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7CHKPT-3-MSGERR: [chars]

**Explanation** A Checkpointing message error has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7CHKPT-3-NOMEMORY: Insufficient memory for [chars]

**Explanation** The requested memory allocation failed because of a low memory condition

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce other system activity. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7CHKPT-5-NORCVBUF: No buffer for received checkpointing message

**Explanation** A buffer to hold a received Checkpointing message was not available.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7CHKPT-3-SYNCERR: [chars]

**Explanation** A Checkpointing synchronization error has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7CHKPT-5-SYNCFAILURE: ITP sync failure, peer reset

**Explanation** A failure occurred while synchronizing information to the High Availability peer.

**Recommended Action** No action required.

## CS7GROUP Messages

**Error Message**

%CS7GROUP-3-DLINKMSG: NULL

**Explanation** An internal software error in ITP Group message handling has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7GROUP-3-FSMERR: [chars] event in [chars] state

**Explanation** An unexpected condition was encountered in the Group finite state machine.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7GROUP-3-INITERR: NULL

**Explanation** An internal software error in ITP Group initialization has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7GROUP-3-INTERR: NULL

**Explanation** An internal software error has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7GROUP-3-INVALIDINSTANCE: Invalid instance ([int])

**Explanation** A reference to an undefined variant instance was detected.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7GROUP-3-NEGOERR: Unexpected negotiation condition - state: [chars], peer state: [chars]

**Explanation** An unexpected condition was encountered in Group role negotiation.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7GROUP-3-NOMEMORY: Insufficient memory for [chars]

**Explanation** The requested memory allocation failed because of a low memory condition

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce other system activity. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7GROUP-5-NOTICE: NULL

**Explanation** Communicating Group information to the user.

**Recommended Action** No action is required.

## CS7HSL Messages

**Error Message**

%CS7HSL-4-BADSTATE\_ERROR: ([chars]): State = [chars], size = [dec]

**Explanation** This message indicates a SSCF-NNI is in not in a state for receiving packets. The message will display more specific information about the problem location.

**Recommended Action** Check the endpoint that the router is communicating with for proper configuration and operation.

**Error Message**

%CS7HSL-3-NOINIT: Could not initialize HSL on the [chars] interface ([chars])

**Explanation** Software could not initialize the interface for HSL.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7HSL-3-NOSSCFDB: No interface information provided for processing

**Explanation** Software requires the interface information for continued processing.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7HSL-3-NOSWIDB: No interface information provided for processing

**Explanation** Software requires the interface information for continued processing.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7HSL-3-NOVARIANT: Must configure CS7 variant before NNI on the interface

**Explanation** User may not configure NNI on the interface before CS7 variant.

**Recommended Action** Configure CS7 variant first, then add NNI on the interface.

**Error Message**

%CS7HSL-4-PKTSIZE\_ERROR: ([chars]):State = [chars] size = [dec]

**Explanation** This message indicates a SSCF-NNI is receiving invalid sized packets. The message will display more specific information about the problem location.

**Recommended Action** Check the endpoint that the router is communicating with for proper configuration and operation.

**Error Message**

%CS7HSL-4-PROTOCOL\_ERROR: ([chars]): State = [chars], status = [dec]

**Explanation** This message indicates a SSCF-NNI is receiving malformed packets. The message will display more specific information about the problem location.

**Recommended Action** Check the endpoint that the router is communicating with for proper configuration and operation.

## CS7M2PA Messages

**Error Message**

%CS7M2PA-3-DESTADDRACT: Destination IP Address [IP\_address] active for linkset:slc [chars]:[dec]

**Explanation** The specified destination IP address can be used by Stream Control transmission Protocol associations.

**Recommended Action** No action is required.

**Error Message**

%CS7M2PA-3-DESTADDRINA: Destination IP Address [IP\_address] inactive for linkset:slc [chars]:[dec]

**Explanation** The specified destination IP address cannot be used by Stream Control transmission Protocol associations.

**Recommended Action** An destination IP address used to support a Stream Control Transmission Protocol association has failed. The association will remain active if other destination IP addresses are available. Determine the reason why this destination address failed and take appropriate action to rectify the failure.

**Error Message**

%CS7M2PA-5-LISTENFAILURE: Could not post listen for local peer port [int]

**Explanation** Software failed to post listen for the specified local peer

**Recommended Action** This can occur due to several reasons. Possibilities are: maximum number of local peers already created, invalid local peer parameters, local peer port is already in use, resources unavailable, etc. Peer links using this local peer will be unavailable. Problem determination should be performed for the above possibilities.

**Error Message**

%CS7M2PA-3-NEWIPADDR: New IP address ([IP\_address]) on [chars] conflicts with cs7 local-peer [dec] local-ip [IP\_address] definition.

**Explanation** The new IP address on the interface conflicts with the local peer configuration and may cause link failure.

**Recommended Action** Local and remote peer parameters must be re-configured to use the new IP address.

**Error Message**

%CS7M2PA-3-NOENQUEUE: Could not enqueue event to [chars] event queue.

**Explanation** An internal software error occurred.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7M2PA-3-NOMEMORY: Insufficient memory for [chars]

**Explanation** The requested memory allocation failed because of a low memory condition

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce other system activity. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7M2PA-3-NOPAKBUFFER: Could not get a [chars] packet buffer

**Explanation** Software failed to obtain a packet buffer from the global buffer pool

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce the number of CS7 interfaces. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7M2PA-3-NOPROC: Could not create [chars] process

**Explanation** Insufficient internal resources available to create process.

**Recommended Action** This problem is due to an internal software error. Check available memory capacity on router. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7M2PA-3-NOPTR2PEER: No CS7 M2PA Peer Link information

**Explanation** Software requires the M2PA link information for continued processing.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

## CS7MLR Messages

**Error Message**

%CS7MLR-3-GTTTRIGGERDISABLED: MLR [chars] GT trigger disabled: GTI=[dec] TT=[dec]  
NP=[dec] NAI=[dec] GTA=[chars]

**Explanation** A primary multi-layer routing global title trigger has been disabled.

**Recommended Action** This message informs the operator that the specified multi-layer routing trigger is no longer operational. If this was not the expected result of an issued command, contact a technical support representative for assistance.

**Error Message**

%CS7MLR-3-GTTTRIGGERENABLED: MLR [chars] GT trigger enabled: GTI=[dec] TT=[dec]  
NP=[dec] NAI=[dec] GTA=[chars]

**Explanation** A primary multi-layer routing global title trigger has been enabled.

**Recommended Action** This message informs the operator that the specified multi-layer routing trigger is operational. If this was not the expected result of an issued command, contact a technical support representative for assistance.

**Error Message**

%CS7MLR-7-INTERR: Internal Software Error Detected: [chars]

**Explanation** An internal software error has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7MLR-3-SSNTRIGGERDISABLED: MLR [chars] PC/SSN trigger disabled: PC=[chars]  
SSN=[dec]

**Explanation** A primary multi-layer routing PC-SSN trigger has been disabled.

**Recommended Action** This message informs the operator that the specified multi-layer routing trigger is no longer operational. If this was not the expected result of an issued command, contact a technical support representative for assistance.

**Error Message**

%CS7MLR-3-SSNTRIGGERENABLED: MLR [chars] PC/SSN trigger enabled: PC=[chars]  
SSN=[dec]

**Explanation** A primary multi-layer routing PC-SSN trigger has been enabled.

**Recommended Action** This message informs the operator that the specified multi-layer routing trigger is operational. If this was not the expected result of an issued command, contact a technical support representative for assistance.

## CS7MTP2 Messages

**Error Message**

%CS7MTP2-3-ENCAPSFAILURE: Interface [chars] could not be configured for MTP2.

**Explanation** The interface encapsulation command for MTP2 failed.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP2-3-INVALIDPORT: Could not initialize MTP2 ([chars] cannot support SS7)

**Explanation** Software could not initialize the interface for MTP2 because of hardware limitations for SS7 support.

**Recommended Action** This problem is due to a hardware limitation for SS7 support.

**Error Message**

%CS7MTP2-3-MAXSS7: Maximum SS7 interfaces ([dec]) already configured on the port adapter.

**Explanation** Each port adapter supports a limited number of SS7 interfaces. Configuring this interface for MTP2 will exceed the maximum allowed number for the port adapter.

**Recommended Action** Configure MTP2 on a different port adapter.

**Error Message**

%CS7MTP2-3-MULTITIMESLOT: [chars] uses [dec] timeslots (multiple timeslots not supported)

**Explanation** User may not configure MTP2 encap on channelized interfaces that are using multiple timeslots.

**Recommended Action** Configure channelized interface to use one timeslot only.

**Error Message**

%CS7MTP2-3-NOINIT: Could not initialize MTP2 on the [chars] interface ([chars])

**Explanation** Software could not initialize the interface for MTP2.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP2-3-NOMTP2SB: No CS7 MTP2 interface information

**Explanation** Software requires the MTP2 interface information for continued processing.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP2-3-NOPAKBUFFER: Could not get a [chars] packet buffer for [chars]

**Explanation** Software failed to obtain a packet buffer from the interface buffer pool.

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce the number of CS7 interfaces. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7MTP2-3-NOPAKIFINPUT: Packet does not contain input interface information

**Explanation** Software requires the input interface information for continued processing.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP2-3-NOPOWERON: PowerOn failed for the [chars] interface

**Explanation** Software failed to powerOn the MTP2 interface

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP2-3-NOPTR2CCB: No CS7 MTP2 link information

**Explanation** Software requires the MTP2 link information for continued processing.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP2-3-NOSS7: SS7 is not supported on the [chars] interface.

**Explanation** SS7 is not supported on the interface.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP2-3-NOSWIDB: No interface information provided for processing

**Explanation** Software requires the interface information for continued processing.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP2-3-NOVARIANT: Must configure CS7 variant before MTP2 encap on the interface

**Explanation** User may not configure MTP2 encap on the interface before CS7 variant.

**Recommended Action** Configure CS7 variant first, then add MTP2 encap on the interface.

**Error Message**

%CS7MTP2-3-NOXMITQ: Failed to create transmitQ elements for [chars]

**Explanation** Software failed to create a pool of transmitQ elements for the interface.

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce the number of CS7 interfaces. If this message persists, call your technical support representative for assistance.

## CS7MTP3 Messages

**Error Message**

%CS7MTP3-5-ACTDEACTLINK: Link [dec] linkset [chars] [chars] is in progress

**Explanation** The link activation or deactivation procedure has started.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-ACTDEACTLINKSET: Linkset [chars] [chars] is in progress

**Explanation** Activation or deactivation of links in the linkset has started.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-ADJRBEGN: Adjacent SP restart beginning for linkset [chars]

**Explanation** Adjacent SP restart processing has been initiated on behalf of the node adjacent to the specified linkset.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-ADJRCANC: Adjacent SP restart cancelled for linkset [chars]

**Explanation** Adjacent SP restart was cancelled because there are no active links to the adjacent linkset.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-ADJRDSBL: Adjacent SP restart disabled for linkset [chars]

**Explanation** Adjacent SP restart processing has been disabled for the node adjacent to the specified linkset.

**Recommended Action** Adjacent SP restart processing has been disabled by the configuration. If the adjacent node is restart capable, reconfigure the router to enable restart processing for the adjacent node.

**Error Message**

%CS7MTP3-5-ADJRENDS: Adjacent SP restart ending for linkset [chars]

**Explanation** Adjacent SP restart processing has completed on behalf of the node adjacent to the specified linkset.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-BADCLUSTERMSG: [chars] received from [chars] with non-zero member part in destination [chars]

**Explanation** The received cluster management message is badly formatted. It has a non-zero member part.

**Recommended Action** Verify adherence to ANSI standard on adjacent point.

**Error Message**

%CS7MTP3-5-BADMSG: [chars] received for route ([chars] [chars]) but cluster route is [chars]

**Explanation** The received message would cause the cluster route to become more restrictive than the member route.

**Recommended Action** Verify cluster and member route status on adjacent point are consistent

**Error Message**

%CS7MTP3-5-BUFPAKDROP: Buffered packets for transmit exceeds maximum ([dec])

**Explanation** When one MTP3 link goes down, MTP3 buffers the transmit packets for that link to another link; however, MTP3 must limit the total number of buffered packets to prevent using up all of the packet buffer resources. When the number of buffered packets exceeds the maximum limit, MTP3 will drop the packets rather than buffer.

**Recommended Action** The user may increase the buffered packet threshold using the buffered-packet-threshold config command. However, increasing this threshold may allow MTP3 to use up all packet buffer resources and cause buffer failures for other processes in the router.

**Error Message**

%CS7MTP3-3-CBDROP: Packets dropped during changeback to [chars] [dec] dropped = [dec] congestion = [dec]

**Explanation** The software attempted a changeback procedure to the indicated link. Some packets were dropped during the changeback due to congestion.

**Recommended Action** Increase the congestion threshold for the specified link.

**Error Message**

%CS7MTP3-3-CBLINKS: Exceeded number of alternate links ([dec]) for changeback to [chars]

**Explanation** The software attempted a changeback procedure to the indicated linkset. The maximum number of alternate links from which messages will be diverted has been exceeded.

**Recommended Action** Reduce the number of alternate links defined for the linkset.

**Error Message**

%CS7MTP3-3-CBLINKSETS: Exceeded number of alternate linksets ([dec]) for changeback to [chars]

**Explanation** The software attempted a changeback procedure to the indicated linkset. The maximum number of alternate linksets from which messages will be diverted has been exceeded.

**Recommended Action** Reduce the number of alternate linksets defined for the linkset.

**Error Message**

%CS7MTP3-5-CLRACCESSVIO: Access-violations accounting database cleared by [chars]

**Explanation** Access-violations accounting database database has been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CLRACCT: MTP3 real-time accounting database cleared by [chars]

**Explanation** The MTP3 real-time accounting database has been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CLRACCTCHKPT: MTP3 checkpointed accounting database cleared by [chars]

**Explanation** The MTP3 checkpointed accounting database has been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CLRALL: All real-time accounting and statistics cleared by [chars]

**Explanation** All real-time accounting and statistics have been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CLRALLCHKPT: All accounting and statistics cleared including all checkpoint databases by [chars]

**Explanation** All accounting and statistics cleared including all checkpoint databases have been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CLRDYNRT: Dynamic routes for [chars] cleared by [chars]

**Explanation** MTP3 dynamic route entries have been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CLREVENTHIS: MTP3 event-history cleared by [chars]. Event history max = [dec]

**Explanation** MTP3 event-history have been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CLRGTT: SCCP GTT real-time accounting database cleared by [chars]

**Explanation** SCCP GTT real-time accounting database database has been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CLRGTTCHKPT: SCCP GTT checkpointed accounting database cleared by [chars]

**Explanation** SCCP GTT checkpointed accounting database has been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CLRSTAT: Link statistics for [chars] [chars] cleared by [chars]

**Explanation** Link statistics have been cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-CNVTONOALIAS: Unable to convert PC [chars], no alias defined for instance [dec]

**Explanation** MTP3 is attempting to convert a packet from one instance to another but is unable to convert a point code in the message using the point code conversion table. Since MTP3 cannot convert the point code it will drop the packet.

**Recommended Action** The user can configure an alias point code for the PC in the specified instance using the **cs7 pc-conversion** command

**Error Message**

%CS7MTP3-5-DESTSTATUS: Destination [chars] is [chars]

**Explanation** There was a change in the accessibility status of the destination due to a change in the status of a route to that destination.

**Recommended Action** The **show cs7 route** command should be used to determine the reason why a destination became inaccessible.

**Error Message**

%CS7MTP3-6-GROUPROLE: MTP3 Mgmt state is '[chars]'

**Explanation** The ITP belongs to an ITP Group and has changed MTP3 management state within the group.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-HA\_QUIECE: Quiece [chars] links for switchover type [dec]

**Explanation** MTP3 links are being quieced due to an Route Processor switchover

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-HA\_UNQUIECE: Unquiece [chars] links for switchover type [dec]

**Explanation** MTP3 links are being unquieced due to an Route Processor switchover

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-3-IFSERR: Cannot load route table - ifs\_copy\_file failed to load '[chars]'

**Explanation** IOS failed to access the specified url for the route table.

**Recommended Action** Verify the url is correct and accessible

**Error Message**

%CS7MTP3-3-INHIB: Link [dec] in linkset [chars] [chars] inhibited

**Explanation** The specified link was either locally or remotely inhibited. Only signalling traffic between the two adjacent nodes will be transported on this link.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-3-INHIBDENY: Inhibit denied on link [dec] in linkset [chars]

**Explanation** Either a local or remote inhibit requested was denied. Inhibit requests are denied when there are no alternative links that can carry the traffic.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-3-INHIBTIMEO: [chars] request timeout on link [dec] in linkset [chars]

**Explanation** The inhibit or uninhibit request timed out while waiting for an acknowledgement from the remote end.

**Recommended Action** For inhibit request, increase the T14 timer value and re-issue the **cs7 inhibit** command. For uninhibit request, increase the T12 timer value and re-issue the **cs7 uninhibit** command.

**Error Message**

%CS7MTP3-5-INNI: Received [chars] message with incorrect NI - OPC = [chars] NI = [dec] on link [chars] [dec]

**Explanation** Received a message with incorrect network indicator.

**Recommended Action** This can occur due to several reasons. Possibilities are: the linkset has become congested and a changeover has occurred, causing buffered messages to be transmitted on another link, or the link is not configured correctly. If a changeover has occurred, then no action is required. For all other possibilities, the configuration should be verified and problem determination should take place.

**Error Message**

%CS7MTP3-5-INOPC: Received [chars] message from incorrect - OPC = [chars] SLC = [dec] message received on ls = [chars] slc = [dec] expected on ls = [chars]

**Explanation** Received either a MTP3 management message or a signalling link test message with an incorrect OPC. For example, a message was received from OPC 1.1.1. However, the link that received the message was configured in a linkset expecting traffic from OPC 2.2.2. The received OPC was configured as the adjacent point-code for a different linkset in the signalling point

**Recommended Action** Verify the configuration of the linksets at this node and the originating node.

**Error Message**

%CS7MTP3-5-INSLC: Received [chars] message with an incorrect SLC value - OPC = [chars] SLC = [dec] message received on ls = [chars] slc = [dec]

**Explanation** Received either a MTP3 management message or a signalling link test message with an incorrect SLC value. For example, a message was received from SLC value of 5. However, the link that received the message was configured with SLC value 1.

**Error Message**

%CS7MTP3-7-INTERR: Internal Software Error Detected: [chars]

**Explanation** An internal software error has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7MTP3-5-INVH0H1: Received MTP3 message with invalid H0H1: SI: [dec] H0: [dec] H1: [dec] from [chars]

**Explanation** The ITP received an MTP3 message that is not supported.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-ISOLATED: MTP3 node has been isolated for instance [dec]

**Explanation** The MTP3 node has been isolated. If the node remains isolated after an automatic attempt to uninhibit inhibited links, a full restart procedure will be performed.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-3-LINKCONG: Link [dec] in linkset [chars] is in congestion level [dec]

**Explanation** A link has become congested

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-3-LINKINTERR: Link Internal error - [chars] [chars] [dec] [hex]

**Explanation** An internal software error occurred.

**Recommended Action** Copy the message exactly as it appears, and report it your technical support representative.

**Error Message**

%CS7MTP3-5-LINKNOCONG: Link [dec] in linkset [chars] has cleared congestion

**Explanation** A link has abated congested

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-3-LINKNOTUP: Link [dec] in linkset [chars] failed. Reason=[chars]

**Explanation** A link in a linkset is no longer active. Link restoration/activation procedures will be initiated.

**Recommended Action** No action is required. Link should return to active state once changeover is complete. If the serial interface does not automatically recover, issue the **clear interface** command for the serial link. If that does not help, perform physical line diagnostics.

**Error Message**

%CS7MTP3-3-LINKSETREMOTE: Linkset [chars] received remote processor [chars] indication

**Explanation** A remote processor outage or remote processor recovered indication was received on one of the links in the linkset.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-3-LINKSETSTATE: Linkset [chars] is [chars]

**Explanation** If the linkset is unavailable, it indicates that there are no active links in the linkset. This may be a transient condition if the links are attempting recovery. If the linkset is available, it indicates that there is at least one link in the active state.

**Recommended Action** If the linkset is unavailable, check the status of the links in the linkset. Also look up the reason code provided in the link inactive message and take appropriate action to rectify the deactivation.

**Error Message**

%CS7MTP3-6-LINKSUPDOWN: [chars]

**Explanation** All links on the specified FlexWAN have been activated or deactivated. This event can be triggered by two means. Either the user issued a test CLI, or the CS7 software automatically shut/started the links. To determine if this event was invoked by the CS7 software, look for a CS7 messages preceding this one, which will provide the reason for the action. If no message is found, it implies that a user issued the test cs7 CLI command to shut/start the links. If the links were shut, the state of the affected links will be displayed as sys-shut when the **show cs7 linkset** command is issued.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-3-LINKTESTFAIL: Link test failed on link [dec] linkset [chars]  
Reason=[chars]

**Explanation** Signaling link test has failed on the specified link. Link restoration/activation procedures will be initiated.

**Recommended Action** This can occur due to several reasons. Possibilities are: mismatch in point code definitions on either STP, quality of transmission line, memory corruption in either STP (local or remote), etc. Problem determination should be performed for the above possibilities. Link testing can be disabled in the link configuration sub-mode.

**Error Message**

%CS7MTP3-5-LINKUPDOWN: Link [dec] in linkset [chars] is [chars]

**Explanation** The link is either available, unavailable or down.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-7-LSACINTERR: Internal Software Error Detected: [chars] LS [chars] [dec]  
[chars] [dec] [chars] [chars] [dec]

**Explanation** An internal software error has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTs. If you find none, write a DDTs for this problem.

**Error Message**

%CS7MTP3-5-MAXDYN: Maximum ([dec]) dynamic route table entries exceeded

**Explanation** The system could not create a dynamic route table entry, or x-list member for ANSI, because the total number is at the maximum allowed.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-4-NOBSNT: Timeout waiting for BSNT on link [dec] in linkset [chars]

**Explanation** A response to the BSNT request was not received from MTP2 during changeover.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP3-3-NOBUF: No event buffers ([chars])

**Explanation** The software did not have enough available memory to perform a required action.

**Recommended Action** If condition persists, it may be necessary to increase memory configuration.

**Error Message**

%CS7MTP3-2-NOCLS: An internal software error occurred.

**Explanation** An internal software error occurred.

**Recommended Action** Copy the error message exactly as it appears on the console or in the system log. Research and attempt to resolve the error using the Output Interpreter <https://www.cisco.com/cgi-bin/Support/OutputInterpreter/home.pl>. Also perform a search of the Bug Toolkit <http://www.cisco.com/cgi-bin/Support/Bugtool/home.pl>. If you still require assistance, open a case with the Technical Assistance Center via the Internet [http://www.cisco.com/cgi-bin/front.x/case\\_tools/caseOpen.pl](http://www.cisco.com/cgi-bin/front.x/case_tools/caseOpen.pl), or contact your Cisco technical support representative and provide the representative with the gathered information.

**Error Message**

%CS7MTP3-3-NOINSTANCE: No CS7 MTP3 instance information

**Explanation** Software requires the MTP3 instance information to perform this operation.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP3-3-NOLINK: No CS7 MTP3 link information

**Explanation** Software requires the MTP3 link information to perform this operation.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP3-3-NOLINKSET: An internal software error occurred.

**Explanation** An internal software error occurred.

**Recommended Action** Copy the error message exactly as it appears on the console or in the system log. Research and attempt to resolve the error using the Output Interpreter <https://www.cisco.com/cgi-bin/Support/OutputInterpreter/home.pl>. Also perform a search of the Bug Toolkit <http://www.cisco.com/cgi-bin/Support/Bugtool/home.pl>. If you still require assistance, open a case with the Technical Assistance Center via the Internet [http://www.cisco.com/cgi-bin/front.x/case\\_tools/caseOpen.pl](http://www.cisco.com/cgi-bin/front.x/case_tools/caseOpen.pl), or contact your Cisco technical support representative and provide the representative with the gathered information.

**Error Message**

%CS7MTP3-3-NOMEM: No memory is available

**Explanation** The software did not have enough available memory to perform a required action.

**Recommended Action** Reduce other system activity to ease memory demands. If condition persists, it may be necessary to increase memory configuration.

**Error Message**

%CS7MTP3-5-NONADJSIG: Received [chars] message from non adjacent node OPC = [chars]

**Explanation** Received either a MTP3 management message or a signalling link test message from a non adjacent node.

**Recommended Action** This can occur due to several reasons. Possibilities are : the linkset has become congested and a changeover has occurred, causing buffered messages to be transmitted on another link, or the link is not configured correctly. If a changeover has occurred, then no action is required. For all other possibilities, the configuration should be verified and problem determination should take place.

**Error Message**

%CS7MTP3-3-NOPAK: No packet parameter provided

**Explanation** Software requires a packet parameter to perform this operation.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP3-4-NORETRIEVE: Timeout waiting for message to be retrieved on link [dec] in linkset [chars]

**Explanation** A response to the retrieve request was not received from MTP2 during changeover.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP3-3-NOROUTETABLE: No route table

**Explanation** No mtp3 route table could be loaded due to an internal error.

**Recommended Action** Verify provisioning of the route table. A load command with a valid url must be present

**Error Message**

%CS7MTP3-7-NOTFR: Restricted destination [chars] changed to available

**Explanation** The system is not configured to allow restricted destinations. The specified restricted destination is being changed to available.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7MTP3-6-NSOINPROG: CS7 NSO in progress for instance [dec]

**Explanation** Non Stop Operation has performed a failover to the Standby Route Processor. Link recovery is in progress for this instance.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-6-NSOLINK: CS7 NSO Recived link status from slot [dec] for instance [dec]  
[chars] [dec]

**Explanation** The link status for the indicated link required to perform Non Stop Operation has been received. When the link status is receive for all links in the instance, Non stop operation will proceed.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-6-NSOPROCEED: CS7 NSO Proceeding for instance [dec]

**Explanation** Non Stop Operation has performed a failover to the Standby Route Processor. The Standby Route Processor is now ready to proceed with normal link management operations for links within this instance.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-6-NSORESsync: CS7 NSO Resync request received from FlexWAN in slot [dec]

**Explanation** Non Stop operation is in process. The FlexWAN in slot [dec] is ready to be resynchronized with the Route Processor.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-6-NSOSTANDBY: CS7 NSO is in STANDBY for instance [dec]

**Explanation** Non Stop Operation will be attempted for this instance in the event of a Primary Route Processor failure

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-6-NSOTIMEOUT: CS7 NSO Timeout for instance [dec]

**Explanation** Non Stop Operation has performed a failover to the Standby Route Processor. The Standby Route Processor has timed out while attempting to perform non-stop operation on one or more links in the instance. The affected links will be restarted. The Standby Route Processor is ready to begin normal link management operations for links within this instance.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-PAKLOGCOMP: CS7 Paklog facility for linkset [chars] has completed.

**Explanation** The maximum amount of paklog messages for the linkset has been reached.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-QOSPAKDROP: Packets dropped due to QoS class [dec] link unavailable

**Explanation** MTP3 is attempting to forward packets that have been marked for a specific QoS class. When the outbound linkset does not have any links available that support the marked QoS class, MTP3 tries to forward the packets over the default class (class 0) links. If QoS class 0 links are not available, MTP3 will drop the packets.

**Recommended Action** The **show cs7 accounting access-violations** command can be used to determine the origin and destination point codes of the dropped packets. A link can be unavailable for a QoS class for several reasons. Possibilities are: link or linkset is shut down, link failure, QoS class not assign to link. For all other possibilities, the configuration should be verified and problem determination should take place.

**Error Message**

%CS7MTP3-5-REMCONG: Destination [chars] is in congestion status [dec]

**Explanation** Remote congestion status for this destination changed due to received TFC or due to routeset congestion test procedure.

**Recommended Action** Investigate destination network element for cause of local link congestion.

**Error Message**

%CS7MTP3-4-RETRIEVE: Message retrieved after timeout on link [dec] in linkset [chars]

**Explanation** A retrieved message was received from MTP2 after the timer expired.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7MTP3-5-ROUTETABLELOADED: Route table '[chars]' has been loaded from '[chars]'

**Explanation** Route table has been successful loaded

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-RSRTBEGN: MTP3 full restart beginning for instance [dec]

**Explanation** MTP3 full restart processing has been initiated.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-RSRTCONT: MTP3 restart continuing for Instance [dec]

**Explanation** MTP3 restart has detected a sufficient number of available links to continue with the restart.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-RSRTENDS: MTP3 full restart completed for instance [dec]

**Explanation** MTP3 full restart processing has completed.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-RSRTFRST: MTP3 full restart is disabled for instance [dec]

**Explanation** The MTP3 fast restart option has been configured. This option bypasses the normal MTP3 full restart processing.

**Recommended Action** Reconfigure the router to disable the fast restart option and restart the router.

**Error Message**

%CS7MTP3-5-RSRTNOACT: Expected links in linkset [chars] are not active instance [dec]

**Explanation** The expected number of links in the linkset did not become available during the link activation phase of the MTP3 restart procedure.

**Recommended Action** Check that the links that are expected to become available during MTP3 restart are able to become available at layer 2. Links that are not expected to become available should be administratively shutdown.

**Error Message**

%CS7MTP3-5-RSRTNOTRA: No TRA received from the adjacent node on linkset [chars]  
instance [dec]

**Explanation** The ITP expected to receive a TRA message from the adjacent node.

**Recommended Action** Check that the adjacent node is restart capable. If the adjacent node is not restart capable, reconfigure the ITP to disable adjacent restart for the concerned linkset.

**Error Message**

%CS7MTP3-5-RSRTSEND: MTP3 restart has entered the send status phase for instance  
[dec]

**Explanation** MTP3 restart has entered the send status phase. TFP and TFR signals are sent to adjacent nodes during the send status phase.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-RSRTT18: MTP3 restart T18 Expired instance [dec]

**Explanation** A sufficient number of TRAs were not available to proceed with a normal MTP3 restart.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-RSRTT22: MTP3 restart T22 Expired instance [dec]

**Explanation** A sufficient number of links were not available to proceed with a normal MTP3 restart.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-RSRTT23: MTP3 restart T23 Expired instance [dec]

**Explanation** MTP3 restart did not receive an expected TRA from every adjacent node

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-RSRTTIMO: MTP3 restart terminating before send status completed for  
instance [dec]

**Explanation** MTP3 restart timeout out while in the send status phase.

**Recommended Action** Verify that the MTP3 timers T22, T23, and T24 have been configured to appropriate values. Increase the timer values as required.

**Error Message**

%CS7MTP3-5-RSRTXTRA: MTP3 restart expected TRAs have been received for instance [dec]

**Explanation** MTP3 restart has received a TRA for every active linkset and is continuing with the restart.

**Recommended Action** No action is required.

**Recommended Action**

**Error Message**

%CS7MTP3-6-SRTFAILTMR: CS7 Signaling Route Test (SRT) FAILED (timer expiration) to: [chars] from: [chars] sls: [dec]

**Explanation** TTC Signaling Route Test was performed and failed

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-6-SRTPASS: CS7 Signaling Route Test (SRT) PASSED to: [chars] from: [chars] sls: [dec]

**Explanation** TTC Signaling Route Test was performed and succeeded

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-6-SRTRESP: CS7 Signaling Route Test (SRT) request received, response sent to: [chars] from: [chars] sls: [dec]

**Explanation** TTC Signaling Route Test request was received and an SRTA acknowledgement was sent in response

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-TFRINVALID: Received TFR from [chars], TFR option is off

**Explanation** The use of TFR messages is a National Option and this node is configured to not use TFRs.

**Recommended Action** If TFRs should be used in this network, the option can be turned on with the command **cs7 national-options TFR**. If TFRs should not be used, the adjacent node may be misconfigured.

**Error Message**

%CS7MTP3-5-UNEXPECTRA: An unexpected TRA was received on linkset [chars]

**Explanation** A TRA message was received on the linkset but the linkset is not configured to perform an adjacent SP restart.

**Recommended Action** Verify that the adjacent node is restart capable. If the adjacent node is restart capable, reconfigure the router to enable restart processing for the adjacent node. If the adjacent node is not restart capable, then investigate why it is sending a TRA message on the linkset.

**Error Message**

%CS7MTP3-5-UNEXPECTRW: An unexpected TRW was received on linkset [chars]

**Explanation** A TRW message was received on the linkset but the linkset is not configured to perform an adjacent SP restart.

**Recommended Action** Verify that the adjacent node is restart capable. If the adjacent node is restart capable, reconfigure the router to enable restart processing for the adjacent node. If the adjacent node is not restart capable, then investigate why it is sending a TRWE message on the linkset.

**Error Message**

%CS7MTP3-3-UNINHBNOTP: Uninhibit is not possible on link [dec] in linkset [chars]

**Explanation** Uninhibit is not possible on the link since the remote SP is not accessible. This could be due the fact that the link has failed.

**Recommended Action** Restart the failed link.

**Error Message**

%CS7MTP3-5-UNINHIB: Link [dec] in linkset [chars] [chars] uninhibited

**Explanation** The specified link was either locally or remotely uninhibited. Normal traffic will now be transported on this link.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-UNOPC: Received [chars] message from undefined - OPC = [chars] SLC = [dec] message received on ls = [chars] slc = [dec]

**Explanation** Received either a MTP3 management message or a signalling link test message with an undefined OPC. For example, a message was received from OPC 1.1.1. However, the link that received the message was configured in a linkset expecting traffic from OPC 2.2.2. The received OPC has not been defined as the adjacent point-code for any other linkset configured for this signalling point.

**Recommended Action** Verify the configuration of the linksets at this node and the originating node.

**Error Message**

%CS7MTP3-5-UNSLIO: Received [chars] message with unsupported SIO: [dec] on link [chars] [dec]

**Explanation** Received a message with unsupported service indicator octet.

**Recommended Action** No action is required.

**Error Message**

%CS7MTP3-5-UNSLC: Received [chars] message with an undefined SLC value - OPC = [chars] SLC = [dec] message received on ls = [chars] slc = [dec]

**Explanation** Received either a MTP3 management message or a signalling link test message with an unknown SLC value. For example, a message was received from SLC value of 5. However, the link that received the message was configured with SLC value 1. The linkset on which the packet was received does not have a link configured with the received SLC value.

**Recommended Action**

## CS7NSO Messages

**Error Message**

%CS7NSO-5-CONFIGINOPER: ITP NSO is going inoperative due to a configuration change. Reset of standby is required.

**Explanation** ITP NSO is now inoperative because it has been disabled in the configuration. This causes a reset of the Standby unit.

**Recommended Action** No action is required.

**Error Message**

%CS7NSO-5-CONFIGOPER: ITP NSO is going operative due to a configuration change

**Explanation** ITP NSO is now operative because it has been enabled in the configuration.

**Recommended Action** No action is required.

**Error Message**

%CS7NSO-3-INITERR: [chars]

**Explanation** An internal software error in ITP NSO initialization has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTs. If you find none, write a DDTs for this problem.

**Error Message**

%CS7NSO-3-INTERR: [chars]

**Explanation** An internal software error in ITP NSO has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7NSO-3-IPCERROR: [chars] [chars]

**Explanation** An error has occurred establishing an interprocess communication channel between the active system and the standby system.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7NSO-3-MSGERR: [chars]

**Explanation** An internal software error in ITP NSO message handling has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7NSO-3-NOEVENTQLEM: No NSO event queue elements

**Explanation** An element for queueing an internal NSO event was not available.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7NSO-3-NOMEMORY: Insufficient memory for [chars]

**Explanation** The requested memory allocation failed because of a low memory condition

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce other system activity. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7NSO-3-NOMSGQLEM: No NSO message queue elements for received message

**Explanation** An element for queueing a received NSO message was not available.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTs. If you find none, write a DDTs for this problem.

## CS7PING Messages

**Error Message**

%CS7PING-3-CONTEXT: Q.755 Test: [chars] context

**Explanation** Internal software error

**Recommended Action** If problem persists call your Cisco technical support representative and provide the representative with the gathered information.

**Error Message**

%CS7PING-6-DUP: Test Q.755 [chars]: duplicate test request ignored

**Explanation** An attempt was made to start a second traffic test between signalling points. Only a single MTP traffic way be started between a pair of signalling points.

**Recommended Action** Wait till existing test has completed or issue command to cancel current test prior to stating new test

**Error Message**

%CS7PING-3-FAIL: Q.755 Test [chars]: cannot create [chars]

**Explanation** Software could not allocate resources required to run requested traffic test.

**Recommended Action** Retry request.

**Error Message**

%CS7PING-3-FSM: Test Q.755 [chars]: fsm error ([chars]/[chars]/[dec])

**Explanation** An internal software error occurred.

**Recommended Action** Stop the running traffic test with 'ping cs7 stop x.x.x'

**Error Message**

%CS7PING-3-INTERN: Test Q.755 [chars]: internal error ([chars]/[chars])

**Explanation** An internal software error occurred.

**Recommended Action** Stop the running traffic test with 'ping cs7 stop x.x.x' command

**Error Message**

%CS7PING-3-NOPAK: Test Q.755 [chars]: no packet buffer ([chars]/[chars])

**Explanation** Software could not find a packet buffer to send a message.

**Recommended Action** Stop the running traffic test with 'ping cs7 stop x.x.x'.

**Error Message**

%CS7PING-6-NORoute Processor: [chars]: No response from target node.

**Explanation** The node timed out while waiting for a response from the target node.

**Recommended Action** Ensure that the target node is reachable.

**Error Message**

%CS7PING-6-RTT: Test Q.755 [chars]: MTP Traffic test rtt [dec]/[dec]/[dec]

**Explanation** The MTP Traffic test to the specified point code has completed.

**Recommended Action** No action is required.

**Error Message**

%CS7PING-3-SEND: Test Q.755 [chars]: failed to send [chars] message

**Explanation** Software could not allocate resources required to run requested traffic test.

**Recommended Action** Retry request.

**Error Message**

%CS7PING-4-SEQ: Test Q.755 [chars]: received sequence [dec], expected [dec]

**Explanation** Traffic test verification received an out of sequence packet.

**Recommended Action** Verify network topology and configuration.

**Error Message**

%CS7PING-6-STAT: Test Q.755 [chars]: MTP Traffic test [dec]% successful  
([dec]/[dec])

**Explanation** The MTP Traffic test to the specified signalling point has completed.

**Recommended Action** No action is required.

**Error Message**

%CS7PING-6-TERM: Test Q.755 [chars]: MTP Traffic test terminated.

**Explanation** Q.755 traffic test terminated.

**Recommended Action** No action is required.

**Error Message**

%CS7PING-6-TURN: Q.755 Test [chars]: MTP Traffic test requested

**Explanation** A remote signalling point requested a MTP traffic test

**Recommended Action** No action is required.

## CS7RF Messages

**Recommended Action****Error Message**

%CS7RF-3-BADCLIENT: Unknown RF client [int]

**Explanation** An RF message was received from an unknown RF client.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7RF-3-INTERR: NULL

**Explanation** An internal software error in ITP NSO has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7RF-3-MSGERR: NULL

**Explanation** An internal software error in ITP RF message handling has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7RF-3-NOMEMORY: Insufficient memory for [chars]

**Explanation** The requested memory allocation failed because of a low memory condition

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce other system activity. If this message persists, call your technical support representative for assistance.

## CS7ROUTE Messages

**Error Message**

%CS7ROUTE-3-BADLS: Error in route table file, line [dec], byte [dec]: no linkset with index [dec]

**Explanation** Error in route table

**Recommended Action** Correct the error in the route table file

**Error Message**

%CS7ROUTE-3-DUPLS: Error in route table file, line [dec], byte [dec]: linkset number defined twice

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-INFO: Error in route table file, line [dec], byte [dec]: expected info element

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-INFOLS: Error in route table file, line [dec], byte [dec]: expected linkset index

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-INSERT: Error loading route table file, line [dec]: cannot insert route [chars]/[dec]

**Explanation** Internal error inserting node into rtree

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7ROUTE-3-INSINFO: Error loading route table file, line [dec]: cannot activate route [chars]/[dec] linkset [chars] priority [dec]

**Explanation** Error in route table

**Recommended Action** Correct the error in the route table file

**Error Message**

%CS7ROUTE-3-LSIND: Error in route table file, line [dec], byte [dec]: linkset index too high

**Explanation** Attempt to load more than 1024 linkset definitions

**Recommended Action** ITP configuration is too big

**Error Message**

%CS7ROUTE-3-LSNUM: Error in route table file, line [dec], byte [dec]: expected linkset number

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-MASK: Error in route table file, line [dec], byte [dec]: invalid mask length [dec]

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-NOLS: Error in route table file, line [dec], byte [dec]: linkset [chars] does not exist

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-NOMASK: Error in route table file, line [dec], byte [dec]: expected mask

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-NOPRIO: Error in route table file, line [dec], byte [dec]: expected priority

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-NOQOS: Error in route table file, line [dec], byte [dec]: expected QoS value

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-PC: Error in route table file, line [dec], byte [dec]: linkset [chars] does not exist

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-PRIO: Error in route table file, line [dec], byte [dec]: invalid priority [dec]

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-QOS: Error in route table file, line [dec], byte [dec]: invalid QoS value [hex]

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file

**Error Message**

%CS7ROUTE-3-RECORD: Error in route table file, line [dec]: expected L/R record

**Explanation** Syntax error in route table

**Recommended Action** Correct the syntax error in the route table file.

## CS7SCCP Messages

**Error Message**

%CS7SCCP-5-BADGT: SCCP MGMT received message with invalid routing indicator.  
LS=[chars] DPC=[chars] OPC=[chars] GTI=[dec] RI=[dec]

**Explanation** SCCP MGMT received a message that was not supported.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-CLRGTTMEAS: Global GTT measurements were cleared by [chars]

**Explanation** The SCCP global GTT measurements were cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-GTTIFSPARSE: GTT file parse error: [chars]

**Explanation** A syntax or semantic error occurred while trying to read in the GTT config

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-GTTIFPARSEWARN: NOTICE: GTT file parse warning: [chars]

**Explanation** A syntax or semantic error occurred while trying to read in the GTT config

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-GTTREPFALL: GTT Replace of file:[chars] failed. Previous database retained.

**Explanation** The file specified in the error failed to be bulk loaded to the ITP. Probably the result of a bad or corrupt file.

**Recommended Action** Re-issue the **cs7 gtt replace-db** command with a valid file free of errors.

**Error Message**

%CS7SCCP-5-GTTTBL\_LOAD\_BEGIN: GTT load of [chars] begins.

**Explanation** The load process of reading a GTT table into main memory has begun.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-GTTTBL\_LOAD\_END: GTT load of [chars] has completed

**Explanation** The load process of reading a GTT table into main memory has finished.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-GTTTBL\_SAVE\_BEGIN: GTT save to [chars] has begun

**Explanation** The save process of a GTT table has begun.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-GTTTBL\_SAVE\_END: GTT save to [chars] has completed

**Explanation** The save process of a GTT table has completed.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-HOPCNT: SCCP received message with hop counter expired.  
LS=[chars] MSG\_TYPE=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars]  
GTA=[chars]

**Explanation** SCCP received a message with an expired hop counter.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-3-IFSEERR: Cannot load gtt configuration - ifs\_copy\_file failed to load  
'[chars]'

**Explanation** IOS failed to access the specified url for the gtt configuration.

**Recommended Action** Verify the URL is correct and accessible.

**Error Message**

%CS7SCCP-7-INTERR: Internal Software Error Detected: [chars]

**Explanation** An internal software error has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7SCCP-5-INV\_GTI: SCCP received message with invalid Global Title Indicator.  
LS=[chars] DPC=[chars] OPC=[chars] GTI=[dec] RI=[dec]

**Explanation** SCCP received message with an invalid or not supported Global Title Indicator.

**Recommended Action** Notify originator of message to correct the invalid or unsupported message.

**Error Message**

%CS7SCCP-5-INVMSGTYPE: SCCP received message for GTT of an invalid type.  
LS=[chars] DPC=[chars] OPC=[chars] Type=[dec] Class=[chars]

**Explanation** SCCP received a message for GTT that was not supported.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-MTP3FAIL: MTP3 was unable to route the message, PC=[chars] SSN=[dec].  
LS=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars] GTA=[chars]

**Explanation** MTP3 failed to route the message due to user misconfiguration or software error

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-NIMISMATCH: SCCP received msu with wrong network ind. in Called Party.  
LS=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars] GTA=[chars]  
NI=[dec]

**Explanation** SCCP received a message which contain a unsupported network indicator.

**Recommended Action** Notify originator of message to send supported network indicator in SCCP Called Party.

**Error Message**

%CS7SCCP-5-NOAPPGRPMEM: SCCP translated message to app-group with no available members.

LS=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars] GTA=[chars]  
SSN=[chars] AppGrp=[chars]

**Explanation** SCCP received a message that translated to a application group with no available members.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-NOCLDSSN: SCCP received message with no called party SSN present.

LS=[chars] MSG\_TYPE=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars]  
GTA=[chars]

**Explanation** SCCP received a message that did not contain a SSN where it was required.

**Recommended Action** Verify that the source of the MSU is sending properly formatted messages.

**Error Message**

%CS7SCCP-5-NOSELECT: SCCP received message for which no selector is defined.

LS=[chars] MSG\_TYPE=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars]  
GTA=[chars]

**Explanation** No matching selector entry was found in the CS7 GTT Selector table for the given translation.

**Recommended Action** Use the **cs7 gtt selector** command to add the referenced selector to the database.

**Error Message**

%CS7SCCP-5-NOTRANS: SCCP received message with no translation for GTA.

LS=[chars] MSG\_TYPE=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars]  
GTA=[chars]

**Explanation** No matching GTA entry was found in the CS7 GTT GTA table for the given translation.

**Recommended Action** Use the **cs7 gtt gta** command to add the referenced GTA into to the table under the appropriate selector.

**Error Message**

%CS7SCCP-5-REASSUNSUPP: SCCP received message requiring reassembly.

LS=[chars] OPC=[chars] DPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars]  
GTA=[chars] RI=[dec] SSN=[chars]

**Explanation** SCCP received a message that requires reassembly, which is not supported.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-SCCCPRPTTERM: NOTICE: report terminated due to DB change

**Explanation** The last show command for SCCP/GTT related data was prematurely terminated because a config change occurred during the reports execution

**Recommended Action** Re-issue the SCCP/GTT show command that was terminated.

**Error Message**

%CS7SCCP-5-SCCPAVL: SCCP at [chars] is available.

**Explanation** A SSA (subsystem available) message was received for SCCP. GTT translations destined for the SP will be processed

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-SCCPCONVFAIL: SCCP failed conversion to alternate instance.  
LS=[chars] MSG\_TYPE=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars]  
GTA=[chars]

**Explanation** SCCP received a message which was GT translated to an alternate instance. During the instance conversion a failure occurred.

**Recommended Action** Check the configuration of alias point-codes for the desired conversion.

**Error Message**

%CS7SCCP-5-SCCPGNRL: Translated DPC unavailable LS=[chars] MSG\_TYPE=[chars]  
OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars] GTA=[chars] SSN=[chars]

**Explanation** An error has occurred at the SCCP layer.

**Recommended Action** Refer to the message details for more information about the error.

**Error Message**

%CS7SCCP-5-SCCPGTTDBCHANGED: SCCP GTT database changed during read

**Explanation** A read of cs7:gtt-tables/gtt\_default was aborted because the GTT database changed during the read.

**Recommended Action** Retry the read or save that was aborted. Do not make make GTT changes while the read or save is in progress.

**Error Message**

%CS7SCCP-5-SCCPGTTREPSYNCFAIL: GTT config sync to slave failed

**Explanation** A failure has occurred while trying to copy the GTT running config to the slave processor.

**Recommended Action** Reset the slave processor and verify the GTT config is copied over after reset.

**Error Message**

%CS7SCCP-5-SCCPGTTSYNC\_BEGIN: GTT config sync to slave has begun. GTT config commands are currently disabled.

**Explanation** An information message indicating that the GTT tables have begun the sync process to the slave RP. During this process no GTT config commands can be executed.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-SCCPGTTSYNC\_END: GTT config sync to slave has completed. GTT config commands are enabled.

**Explanation** An information message indicating that the GTT tables have been copied to the slave RP successfully.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-SCCPNOMAP: SSCP failed to translate, no MAP entry.  
CDPA PC=[chars] SSN=[dec] LS=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars]  
NAI=[chars] GTA=[chars]

**Explanation** No matching GTT MAP entry was found for the CdPA PC/SSN.

**Recommended Action** Configure the PC/SSN in the GTT MAP table.

**Error Message**

%CS7SCCP-5-SCCPPCCONG: SSCP failed to translate: DPC=[chars] is congested.  
LS=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars] GTA=[chars]

**Explanation** Translation resulted in new PC, but the PC is congested.

**Recommended Action** Check traffic load and distribution to given MAP.

**Error Message**

%CS7SCCP-5-SCCPUNAV: SSCP failed to translate: DPC=[chars] is not available.  
LS=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars] GTA=[chars]

**Explanation** Translation resulted in new PC, but the PC is not available.

**Recommended Action** Ensure MTP3 has available route to the PC.

**Error Message**

%CS7SCCP-5-SCCPSSCONG: SSN is congested for the translated node, CDPA PC=[chars]  
SSN=[dec].  
LS=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars] GTA=[chars]

**Explanation** Translation resulted in new PC/SSN, but the SSN is congested.

**Recommended Action** Check traffic load and distribution to given MAP.

**Error Message**

%CS7SCCP-5-SCCPSSUNAV: SSN is not available for the translated node, CDPA  
PC=[chars] SSN=[dec].  
LS=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars] GTA=[chars]

**Explanation** Translation resulted in new PC/SSN, but the SSN is unavailable.

**Recommended Action** Check the MAP's subsystem status.

**Error Message**

%CS7SCCP-5-SCCPUNAV: SSCP is not available on CDPA PC=[chars] SSN=[dec].  
LS=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars] GTA=[chars]

**Explanation** Translation resulted in new PC/SSN, but a UPU has been received for the MAP.

**Recommended Action** Check the MAP's subsystem status.

**Error Message**

%CS7SCCP-5-SSA: Subsystem [dec] at [chars] is available.

**Explanation** A subsystem available message was received for the specified SS.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-SSP: Subsystem [dec] at [chars] is not available.

**Explanation** A subsystem prohibited message was received for the specified SS.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-UNEQUIPSS: SCCP received message for invalid or unequipped SSN.  
 LS=[chars] OPC=[chars] DPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars]  
 GTA=[chars] RI=[dec] SSN=[chars]

**Explanation** SCCP received a message that was not supported.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-UNQUALIFIED: SCCP received message which caused an unqualified error.  
 LS=[chars] MSG\_TYPE=[chars] OPC=[chars] GTI=[dec] TT=[dec] NP=[chars] NAI=[chars]  
 GTA=[chars]

**Explanation** SCCP received a message which produced an unqualified internal software error.

**Recommended Action** Contact Cisco Technical Assistance Center.

**Error Message**

%CS7SCCP-5-UPU: SCCP at [chars] is unavailable.

**Explanation** An UPU (user part unavailable) message was received for the specified SP. GTT translations destined for the SP will fail.

**Recommended Action** No action is required.

**Error Message**

%CS7SCCP-5-UPU\_NOT\_EQP: No SCCP at [chars].

**Explanation** An UPU (user part unavailable) message with cause code of <<missing text>>

**Recommended Action** No action is required.

**Error Message**

%Error: command is not applied to xUA DPC

**Explanation** The command is not applicable to xUA DPC.

**Recommended Action** Apply the command to SS7/M2PA DPC.

**Error Message**

%Error: BPC and BSSN must both be specified for dominant or shared multiplicity

**Explanation** A backup point code and subsystem is not specified when mode is set as dominant or shared.

**Recommended Action** A backup point code and subsystem must be specified if mode (multiplicity) is dominant or shared.

**Error Message**

%Error: PC/SSN is being used as a backup.

**Explanation** Cannot delete an entry for which a backup entry already exists.

**Recommended Action** A PC/SSN entry cannot be deleted if it is referenced by an entry in the GTA table.

**Error Message**

%Error: SSN specified is referenced by gta, sua, mapua, pc-conversion or mlr

**Explanation** Cannot delete a referenced entry.

**Recommended Action** A PC/SSN entry cannot be deleted if it is referenced by an entry in the GTA table.

**Error Message**

%Error: Primary and backup point codes cannot be equal.

**Explanation** The primary and backup point codes are set to be identical.

**Recommended Action** Set the primary and backup point codes to not be identical.

## CS7SMS Messages

**Error Message**

%CS7SMS-7-INTERR: Internal Software Error Detected: [chars]

**Explanation** An internal software error has occurred.

**Recommended Action** Report this occurrence to Engineering. Use Topic to search for a similar DDTS. If you find none, write a DDTS for this problem.

**Error Message**

%CS7SMS-3-MSCPROXYADDRFAIL: SMS GSM MAP msc-proxy-addr lookup failed. MSC PC [chars] is not defined in msc-proxy-addr table.

**Explanation** A SMS GSM MAP MSC proxy address lookup has failed.

**Recommended Action** This message informs the operator that the specified calling address MSC PC was not found in the SMS GSM MAP msc-proxy-addr table. Therefore, the MO-ForwardSM could not be built. Define this MSC PC in the msc-proxy-addr table to resolve this issue.

**Error Message**

%CS7SMS-3-SESSACTIVE: SMS [chars] session active, [chars] [IP\_address]:[dec]

**Explanation** An SMS SMPP or UCP session has become active.

**Recommended Action** This message informs the operator that the specified SMPP or UCP session is now operational. No operator action is required.

**Error Message**

%CS7SMS-3-SESSBINDFAIL: SMS [chars] session failed, [chars] [IP\_address]:[dec], reason:[chars]

**Explanation** An SMS SMPP or UCP session activation attempt has failed.

**Recommended Action** This message informs the operator that the specified SMPP or UCP session could not be activated. Modify the local or remote configuration to resolve the connectivity issue.

**Error Message**

%CS7SMS-3-SESSCONNECTFAIL: SMS connection attempt failed, ip=[IP\_address] port=[dec], reason:[chars]

**Explanation** An SMS SMPP or UCP session connection attempt has failed.

**Recommended Action** This message informs the operator that the specified SMPP or UCP session could not be activated. Modify the local or remote configuration to resolve the connectivity issue.

**Error Message**

%CS7SMS-3-SESSINACTIVE: SMS [chars] session inactive, [chars] [IP\_address]:[dec]

**Explanation** An SMS SMPP or UCP session has become inactive.

**Recommended Action** This message informs the operator that the specified SMPP or UCP session is no longer operational. If this event was not expected, check the remote application and network for connectivity issues.

## CS7TCAP Messages

**Error Message**

%CS7TCAP-5-CLRTCAP: TCAP stats cleared by [chars]

**Explanation** TCAP stats cleared.

**Recommended Action** No action is required.

## CS7XUA Messages

### Error Message

CS7XUA-3- IPADDRFAIL: IP Address Failed: IP Address [chars] Association [hex]  
[chars] [chars]

**Explanation** : IP Address has failed.

**Recommended Action** No action is required.

### Error Message

CS7XUA-3-ASSOCFAIL: Association [hex] for [chars] [chars] has failed, reason:  
[chars]

**Explanation** Association has failed for given reason.

**Recommended Action** No action is required.

### Error Message

CS7XUA-3-ASSOCTERMINATE: Association [hex] for [chars][chars] has terminated

**Explanation** Association has been terminated by the remote end.

**Recommended Action** No action is required.

### Error Message

%CS7XUA-5-ASPSTATE: ASP [chars] is [chars] in AS [chars]

**Explanation** An ASP entered or exited active state in an AS.

**Recommended Action** No action is required.

### Error Message

%CS7XUA-5-ASROUTESTATUS: Route [chars] in AS route [chars] is [chars]

**Explanation** An AS Route changed status.

**Recommended Action** No action is required.

### Error Message

%CS7XUA-5-ASSTATE: AS [chars] is [chars]

**Explanation** An AS entered or exited active state.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-CLRASEVENT: AS event tables for [chars] cleared by [chars]

**Explanation** AS event tables cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-CLRASPEVENT: ASP event tables for [chars] cleared by [chars]

**Explanation** ASP event tables cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-CLRASPCSTAT: ASP statistic tables for [chars] cleared by [chars]

**Explanation** ASP statistic tables cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-CLRASRTEVENT: AS route events for [chars] cleared by [chars]

**Explanation** AS route events cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-CLRASRTSTAT: AS route statistic tables for [chars] cleared by [chars]

**Explanation** AS route statistic tables cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-CLRASSTAT: AS statistic tables for [chars] cleared by [chars]

**Explanation** AS statistic tables cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-CLRPCEVENTS: Point code events cleared by [chars]

**Explanation** Point code events cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-CLRPCSTATS: Point code statistics cleared by [chars]

**Explanation** Point code statistics cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-CLRSGMATESTAT: SG mate statistics cleared by [chars]

**Explanation** SG mate statistics cleared.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-3-ENQUEUEFAIL: Could not enqueue event to [chars] event queue.

**Explanation** An internal software error occurred.

**Recommended Action** This problem is due to an internal software error. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7XUA-3-LISTFAIL: List [chars] operation failed for [chars]

**Explanation** A list operation failed, probably due to memory corruption

**Recommended Action** This problem is due to an internal software error. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7XUA-3-NOMEMORY: Insufficient memory for [chars]

**Explanation** The requested memory allocation failed because of a low memory condition

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce other system activity. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7XUA-3-NOPAKBUFFER: Could not get a [chars] packet buffer

**Explanation** Software failed to obtain a packet buffer from the global buffer pool

**Recommended Action** This problem is probably due to a lack of memory in the router. Either add more memory or reduce the number of CS7 interfaces. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7XUA-3-NOPROC: Could not create [chars] process

**Explanation** Insufficient internal resources available to create process.

**Recommended Action** This problem is due to an internal software error. Check available memory capacity on router. If any of these messages recur, call your technical support representative for assistance.

**Error Message**

%CS7XUA-3-NOTIMPLEMENTED: [chars] not implemented

**Explanation** The requested function is not implemented

**Recommended Action** This function is intended for a future release. Call your technical support representative for assistance.

**Error Message**

%CS7XUA-3-PROTOCOLERROR: [chars] error message with error code [chars] for ASP [chars]

**Explanation** A protocol error message was sent or received

**Recommended Action** This problem is due to an internal software error or an incompatibility with an M3UA or SUA peer. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7XUA-3-RTREEFAIL: Radix tree [chars] operation failed for [chars]

**Explanation** A radix tree operation failed, probably due to memory corruption

**Recommended Action** This problem is due to an internal software error. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7XUA-5-SCTPCONGESTABATE: [chars]([chars]) Level [dec] -> Level [dec]

**Explanation** An ASP or SG Mate has transitioned to a lower level of congestion.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-SCTPCONGESTONSET: [chars]([chars]) Level [dec] -> Level [dec]

**Explanation** An ASP or SG Mate has transitioned to a higher level of congestion.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-3-VARIABLEWRAP: [chars] wrapped

**Explanation** The value of a variable exceeded its maximum size

**Recommended Action** This problem is due to an internal software error. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7XUA-3-WAVLFAIL: AVL [chars] operation failed for [chars] [chars]

**Explanation** An AVL tree operation failed, probably due to memory corruption

**Recommended Action** This problem is due to an internal software error. If this message persists, call your technical support representative for assistance.

**Error Message**

%CS7XUA-5-XUAPCSSNSTATUS: XUA PC [chars] SSN [dec] is [chars]

**Explanation** An XUA PC/SSN combination changed status.

**Recommended Action** No action is required.

**Error Message**

%CS7XUA-5-XUAPCSTATUS: XUA PC [chars] is [chars]

**Explanation** An XUA PC or changed status.

**Recommended Action** No action is required.

## DCS7 Messages

### Error Message

%DCS7-3-DATAINCON: [chars] RC=[dec]. Configuration information is inconsistent with Route Processor on FlexWAN slot [dec]

**Explanation** Route Processor was unable to send configuration or status information update to the specified FlexWAN, due to an internal software error.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status.

Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

### Error Message

%DCS7-3-DCS7BADXDRIPC: Invalid IPC/XDR. IPC len/XDRs len [dec]/[dec]. IPC at [hex]

**Explanation** An internal software error occurred.

**Recommended Action** Copy the message exactly as it appears, and report it your technical support representative.

### Error Message

%DCS7-3-DCS7BADXDRTYPE: Invalid XDR type. Type [dec]. XDR at [hex]

**Explanation** An internal software error occurred.

**Recommended Action** Copy the message exactly as it appears, and report it your technical support representative.

### Error Message

%DCS7-3-DCS7DISABLE: Fatal error, slot [dec]: [chars] RC=[dec]

**Explanation** An internal software error has occurred because of an IPC problem between the LC and the RP.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status.

Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-3-DCS7IPCERR: IPC error: [chars] [dec] [hex]

**Explanation** CS7 encountered an error with the IPC component for the specified slot. This may cause the configuration and status on the FlexWAN to be inconsistent with the Route Processor. This is an internal software error.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status.

Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-4-DCS7MSG: Invalid message received. Type [dec], field [chars], value [hex], length [dec]

**Explanation** An internal software error occurred.

**Recommended Action** Copy the message exactly as it appears, and report it to your technical support representative.

**Error Message**

%DCS7-2-DCS7\_OVERLENGTH\_XDR: Overlength DCS7 XDR message - len [dec] > [dec] from [chars]

**Explanation** An internal software error occurred preventing the sending of an DCS7 XDR message.

**Recommended Action** Copy the message exactly as it appears, and report it to your technical support representative.

**Error Message**

%DCS7-1-DCS7PERMMDIS: MTP3 offload has been permanently disabled on FlexWAN [dec]

**Explanation** CS7 has exhausted all error recovery procedures on the specified FlexWAN. All MTP3 links on the FlexWAN have been shut down.

**Recommended Action** Investigate the cause of errors and correct them if possible. To re-enable the links and MTP3 offload on the FlexWAN, issue the **cs7 offload mtp3 slot restart** command. Inform your support representative of this occurrence.

**Error Message**

%DCS7-4-DCS7RATE: [chars] rate limit status [dec]

**Explanation** An internal software error occurred.

**Recommended Action** Copy the message exactly as it appears, and report it to your technical support representative.

**Error Message**

%DCS7-1-DCS7RELDFlexWAN: CS7 is reloading microcode on FlexWAN in slot [dec].  
Reason: [chars]

**Explanation** If the reason is fatal errors, it means CS7 has exhausted all error recovery procedures on the specified FlexWAN. The IOS image will be reloaded on the FlexWAN by simulating an OIR remove and insert.

**Recommended Action** Copy the error message exactly as it appears on the console or in the system log. Research and attempt to resolve the error using the Output Interpreter <https://www.cisco.com/cgi-bin/Support/OutputInterpreter/home.pl>. Also perform a search of the Bug Toolkit <http://www.cisco.com/cgi-bin/Support/Bugtool/home.pl>. If you still require assistance, open a case with the Technical Assistance Center via the Internet [http://www.cisco.com/cgi-bin/front.x/case\\_tools/caseOpen.pl](http://www.cisco.com/cgi-bin/front.x/case_tools/caseOpen.pl), or contact your Cisco technical support representative and provide the representative with the gathered information.

**Error Message**

%DCS7-4-DCS7RESTART: Restarting MTP3 offload on FlexWAN [dec] due to fatal error

**Explanation** MTP3 offload has been restarted on the FlexWAN due to a fatal error reported in an earlier error message. All links on the FlexWAN will be shut and re-started after the CS7 configuration has been downloaded to the FlexWAN.

**Recommended Action** Issue CS7 show commands on the Route Processor to determine the current status. Inform your support representative of this occurrence.

**Error Message**

%DCS7-3-DCS7SEQ: Out of sequence. State [dec] Rcvd [dec]

**Explanation** The line card has received an out-of-sequence IPC from the RP.

**Recommended Action** Copy the message exactly as it appears, and report it to your technical support representative.

**Error Message**

%DCS7-1-DCS7SYNC: MTP3 offload configuration is incorrect on FlexWAN in slot [dec]

**Explanation** CS7 has detected a loss of MTP3 configuration or status update message on the specified FlexWAN. This indicates that the MTP3 data on the FlexWAN (for example, route, link, linkset) is inconsistent with the master copy on the Route Processor.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status.

Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-3-DCS7XDRLEN: Invalid XDR length. Type [dec][chars]. XDR/buffer len [dec]/[dec]

**Explanation** An internal software error occurred.

**Recommended Action** Copy the message exactly as it appears, and report it your technical support representative.

**Error Message**

%DCS7-5-INFO: [chars] [dec] [hex] [hex]

**Explanation** This is an informational message. If it occurs frequently, it can indicate a problem.

**Recommended Action** Monitor the system resources and status. If the message appears frequently, copy the message exactly as it appears, and report it your technical support representative.

**Error Message**

%DCS7-5-INFOG: [chars] [dec] [hex] [hex]

**Explanation** This is an informational message. If it occurs frequently, it can indicate a problem.

**Recommended Action** Monitor the system resources and status. If the message appears frequently, copy the message exactly as it appears, and report it your technical support representative.

**Error Message**

%DCS7-3-INTERR: Internal error - [chars] [dec] [hex]

**Explanation** An internal software error occurred.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status.

Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-3-INTERRF: Internal error - [chars] [dec] [hex]

**Explanation** An internal software error occurred.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status. Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-3-INTERRG: Internal error - [chars] [dec] [hex]

**Explanation** An internal software error occurred.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status. Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-3-INTERRM: Internal error - [chars] [dec] [hex]

**Explanation** An internal software error occurred.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status. Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-3-INVALIDSTATE: Internal state error [chars] Slot [dec] Flags [hex]

**Explanation** An internal software error occurred. Linecard is in incorrect state

**Recommended Action** Copy the message exactly as it appears, and report it to your technical support representative.

**Error Message**

%DCS7-2-LCINITFAIL: Linecard could not initialize DCS7 forwarding

**Explanation** Initialization of the line card for distributed CS7 failed. This is most likely due to insufficient memory on the line card.

**Recommended Action** Reduce other system activity to ease memory demands. If conditions warrant, upgrade to a larger memory configuration.

**Error Message**

%DCS7-5-MTP3OFFLDBEG: MTP3 offload activation on FlexWAN slot [dec] is in progress

**Explanation** MTP3 offload has been enabled on the FlexWAN.

**Recommended Action** No action is required.

**Error Message**

%DCS7-6-MTP3OFFLDRESP: MTP3 offload has been [chars] on FlexWAN slot [dec].  
[chars]

**Explanation** MTP3 offload has been enabled on the FlexWAN.

**Recommended Action** No action is required.

**Error Message**

%DCS7-2-NODEST: An internal software error occurred.

**Explanation** An internal software error occurred.

**Recommended Action** Copy the error message exactly as it appears on the console or in the system log. Research and attempt to resolve the error using the Output Interpreter <https://www.cisco.com/cgi-bin/Support/OutputInterpreter/home.pl>. Also perform a search of the Bug Toolkit <http://www.cisco.com/cgi-bin/Support/Bugtool/home.pl>. If you still require assistance, open a case with the Technical Assistance Center via the Internet [http://www.cisco.com/cgi-bin/front.x/case\\_tools/caseOpen.pl](http://www.cisco.com/cgi-bin/front.x/case_tools/caseOpen.pl), or contact your Cisco technical support representative and provide the representative with the gathered information.

**Error Message**

%DCS7-2-NOHWIDB: An internal software error occurred.

**Explanation** An internal software error occurred.

**Recommended Action** Copy the error message exactly as it appears on the console or in the system log. Research and attempt to resolve the error using the Output Interpreter <https://www.cisco.com/cgi-bin/Support/OutputInterpreter/home.pl>. Also perform a search of the Bug Toolkit <http://www.cisco.com/cgi-bin/Support/Bugtool/home.pl>. If you still require assistance, open a case with the Technical Assistance Center via the Internet [http://www.cisco.com/cgi-bin/front.x/case\\_tools/caseOpen.pl](http://www.cisco.com/cgi-bin/front.x/case_tools/caseOpen.pl), or contact your Cisco technical support representative and provide the representative with the gathered information.

**Error Message**

%DCS7-3-NOMEM: Malloc Failure. [chars]

**Explanation** A memory shortage has caused an internal software error.

**Recommended Action** Copy the message exactly as it appears, and report it to your technical support representative.

**Error Message**

%DCS7-2-NOROUTE: An internal software error occurred.

**Explanation** An internal software error occurred.

**Recommended Action** Copy the error message exactly as it appears on the console or in the system log. Research and attempt to resolve the error using the Output Interpreter <https://www.cisco.com/cgi-bin/Support/OutputInterpreter/home.pl>. Also perform a search of the Bug Toolkit <http://www.cisco.com/cgi-bin/Support/Bugtool/home.pl>. If you still require assistance, open a case with the Technical Assistance Center via the Internet [http://www.cisco.com/cgi-bin/front.x/case\\_tools/caseOpen.pl](http://www.cisco.com/cgi-bin/front.x/case_tools/caseOpen.pl), or contact your Cisco technical support representative and provide the representative with the gathered information.

**Error Message**

%DCS7-2-NOROUTETABLE: An internal software error occurred.

**Explanation** An internal software error occurred.

**Recommended Action** Copy the error message exactly as it appears on the console or in the system log. Research and attempt to resolve the error using the Output Interpreter <https://www.cisco.com/cgi-bin/Support/OutputInterpreter/home.pl>. Also perform a search of the Bug Toolkit <http://www.cisco.com/cgi-bin/Support/Bugtool/home.pl>. If you still require assistance, open a case with the Technical Assistance Center via the Internet [http://www.cisco.com/cgi-bin/front.x/case\\_tools/caseOpen.pl](http://www.cisco.com/cgi-bin/front.x/case_tools/caseOpen.pl), or contact your Cisco technical support representative and provide the representative with the gathered information.

**Error Message**

%DCS7-3-OFFLDNOACK: [chars] MTP3 offload command acknowledgement not received from FlexWAN [dec]

**Explanation** An enable/disable MTP3 offload command was not acknowledged by the specified FlexWAN. The system will resend the command. The FlexWAN offload operation may not be operating as expected.

**Recommended Action** Issue CS7 show commands to determine the status. If condition is unacceptable, issue the **cs7 offload mtp3 slot restart** command. Inform your support representative of this occurrence

**Error Message**

%DCS7-3-OOSEQ: Sequence error encountered on Slot [dec] - FlexWAN Expected [dec], received [dec]

**Explanation** The CS7 software on the FlexWAN encountered loss of message(s) from the Route Processor. This indicates the configuration and status on the FlexWAN may be out of sync with that on the Route Processor. The configuration will be reloaded on the FlexWAN.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status. Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-3-Route ProcessorIPCERR: IPC error. [chars] RC = [hex]

**Explanation** CS7 encountered an error with the IPC component on the Route Processor. This will prevent exchange of configuration and status information between the Route Processor and the FlexWAN. This is an internal software error.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status. Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-5-SLMOFFLDALL: SLM offload [chars] on all FlexWAN's is in progress

**Explanation** SLM offload has been enabled or disabled on all the FlexWAN's.

**Recommended Action** No action is required.

**Error Message**

%DCS7-1-SLMOFFLDFlexWAN: SLM offload has been [chars] on FlexWAN slot [dec]. [chars]

**Explanation** SLM offload has been enabled or disabled on the FlexWAN.

**Recommended Action** No action is required.

**Error Message**

%DCS7-3-FlexWANERR: [chars]. FlexWAN in slot [dec]

**Explanation** CS7 encountered an abnormal error related to the specified FlexWAN. This will prevent exchange of configuration and status information between the Route Processor and the FlexWAN. This is an internal software error.

**Recommended Action** No action is required. The ITP will automatically perform error recovery and re-start the links on the FlexWAN. Issue CS7 show commands on the Route Processor to determine the current status. Copy the error message exactly as it appears on the console or in the system log, contact your Cisco technical support representative, and provide the representative with the gathered information.

**Error Message**

%DCS7-2-XDRINIT: Error initializing DCS7 xdr chunks

**Explanation** Initialization of the DCS7 xdr chunks could not be accomplished because of a low memory condition.

**Recommended Action** Reduce other system activity to ease memory demands. If conditions warrant, upgrade to a larger memory configuration.
