About Cisco IOS and Cisco IOS XE Software Documentation

Last updated: August 6, 2008

This document describes the objectives, audience, conventions, and organization used in Cisco IOS and Cisco IOS XE software documentation, collectively referred to in this document as Cisco IOS documentation. Also included are resources for obtaining technical assistance, additional documentation, and other information from Cisco. This document is organized into the following sections:

- [Documentation Objectives, page i](#)
- [Audience, page i](#)
- [Documentation Conventions, page ii](#)
- [Documentation Organization, page iii](#)
- [Additional Resources and Documentation Feedback, page xi](#)

Documentation Objectives

Cisco IOS documentation describes the tasks and commands available to configure and maintain Cisco networking devices.

Audience

The Cisco IOS documentation set is intended for users who configure and maintain Cisco networking devices (such as routers and switches) but who may not be familiar with the configuration and maintenance tasks, the relationship among tasks, or the Cisco IOS commands necessary to perform particular tasks. The Cisco IOS documentation set is also intended for those users experienced with Cisco IOS who need to know about new features, new configuration options, and new software characteristics in the current Cisco IOS release.

Documentation Conventions

In Cisco IOS documentation, the term *router* may be used to refer to various Cisco products; for example, routers, access servers, and switches. These and other networking devices that support Cisco IOS software are shown interchangeably in examples and are used only for illustrative purposes. An example that shows one product does not necessarily mean that other products are not supported.

This section includes the following topics:

- [Typographic Conventions, page ii](#)
- [Command Syntax Conventions, page ii](#)
- [Software Conventions, page iii](#)
- [Reader Alert Conventions, page iii](#)

Typographic Conventions

Cisco IOS documentation uses the following typographic conventions:

Convention	Description
^ or Ctrl	Both the ^ symbol and Ctrl represent the Control (Ctrl) key on a keyboard. For example, the key combination ^D or Ctrl-D means that you hold down the Control key while you press the D key. (Keys are indicated in capital letters but are not case sensitive.)
<i>string</i>	A string is a nonquoted set of characters shown in italics. For example, when setting a Simple Network Management Protocol (SNMP) community string to <i>public</i> , do not use quotation marks around the string; otherwise, the string will include the quotation marks.

Command Syntax Conventions

Cisco IOS documentation uses the following command syntax conventions:

Convention	Description
bold	Bold text indicates commands and keywords that you enter as shown.
<i>italic</i>	Italic text indicates arguments for which you supply values.
[x]	Square brackets enclose an optional keyword or argument.
	A vertical line, called a pipe, indicates a choice within a set of keywords or arguments.
[x y]	Square brackets enclosing keywords or arguments separated by a pipe indicate an optional choice.
{x y}	Braces enclosing keywords or arguments separated by a pipe indicate a required choice.
[x {y z}]	Braces and a pipe within square brackets indicate a required choice within an optional element.

Software Conventions

Cisco IOS uses the following program code conventions:

Convention	Description
Courier font	Courier font is used for information that is displayed on a PC or terminal screen.
Bold Courier font	Bold Courier font indicates text that the user must enter.
< >	Angle brackets enclose text that is not displayed, such as a password. Angle brackets also are used in contexts in which the italic font style is not supported; for example, ASCII text.
!	An exclamation point at the beginning of a line indicates that the text that follows is a comment, not a line of code. An exclamation point is also displayed by Cisco IOS software for certain processes.
[]	Square brackets enclose default responses to system prompts.

Reader Alert Conventions

The Cisco IOS documentation set uses the following conventions for reader alerts:

Caution

Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

Note

Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the manual.

Timesaver

Means *the described action saves time*. You can save time by performing the action described in the paragraph.

Documentation Organization

This section describes the Cisco IOS documentation set, how it is organized, and how to access it on Cisco.com. Included are lists of configuration guides, command references, and supplementary references and resources that make up the documentation set. The following topics are included:

- [Cisco IOS Documentation Set, page iv](#)
- [Cisco IOS Documentation on Cisco.com, page iv](#)
- [Configuration Guides, Command References, and Supplementary Resources, page v](#)

Cisco IOS Documentation Set

Cisco IOS documentation consists of the following:

- Release notes and caveats provide information about platform, technology, and feature support for a release and describe severity 1 (catastrophic), severity 2 (severe), and severity 3 (moderate) defects in released Cisco IOS code. Review release notes before other documents to learn whether or not updates have been made to a feature.
- Sets of configuration guides and command references organized by technology and published for each standard Cisco IOS release.
 - Configuration guides—Compilations of documents that provide informational and task-oriented descriptions of Cisco IOS features.
 - Command references—Compilations of command pages that provide detailed information about the commands used in the Cisco IOS features and processes that make up the related configuration guides. For each technology, there is a single command reference that covers all Cisco IOS releases and that is updated at each standard release.
- Lists of all the commands in a specific release and all commands that are new, modified, removed, or replaced in the release.
- Command reference book for **debug** commands. Command pages are listed in alphabetical order.
- Reference book for system messages for all Cisco IOS releases.

Cisco IOS Documentation on Cisco.com

The following sections describe the documentation organization and how to access various document types.

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

New Features List

The New Features List for each release provides a list of all features in the release with hyperlinks to the feature guides in which they are documented.

Feature Guides

Cisco IOS features are documented in feature guides. Feature guides describe one feature or a group of related features that are supported on many different software releases and platforms. Your Cisco IOS software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release.

Configuration Guides

Configuration guides are provided by technology and release and comprise a set of individual feature guides relevant to the release and technology.

Command References

Command reference books describe Cisco IOS commands that are supported in many different software releases and on many different platforms. The books are provided by technology. For information about all Cisco IOS commands, use the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or the *Cisco IOS Master Command List, All Releases*, at http://www.cisco.com/en/US/docs/ios/mcl/all_release/all_mcl.html.

Cisco IOS Supplementary Documents and Resources

Supplementary documents and resources are listed in [Table 2 on page xi](#).

Configuration Guides, Command References, and Supplementary Resources

[Table 1](#) lists, in alphabetical order, Cisco IOS and Cisco IOS XE software configuration guides and command references, including brief descriptions of the contents of the documents. The Cisco IOS command references are comprehensive, meaning that they include commands for both Cisco IOS software and Cisco IOS XE software, for all releases. The configuration guides and command references support many different software releases and platforms. Your Cisco IOS software release or platform may not support all these technologies.

For additional information about configuring and operating specific networking devices, go to the Product Support area of Cisco.com at <http://www.cisco.com/web/psa/products/index.html>.

[Table 2](#) lists documents and resources that supplement the Cisco IOS software configuration guides and command references. These supplementary resources include release notes and caveats; master command lists; new, modified, removed, and replaced command lists; system messages; and the debug command reference.

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS AppleTalk Configuration Guide</i>	AppleTalk protocol.
<i>Cisco IOS XE AppleTalk Configuration Guide</i>	
<i>Cisco IOS AppleTalk Command Reference</i>	
<i>Cisco IOS Asynchronous Transfer Mode Configuration Guide</i>	LAN ATM, multiprotocol over ATM (MPoA), and WAN ATM.
<i>Cisco IOS Asynchronous Transfer Mode Command Reference</i>	

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS Bridging and IBM Networking Configuration Guide</i> <i>Cisco IOS Bridging Command Reference</i> <i>Cisco IOS IBM Networking Command Reference</i>	<ul style="list-style-type: none"> Transparent and source-route transparent (SRT) bridging, source-route bridging (SRB), Token Ring Inter-Switch Link (TRISL), and token ring route switch module (TRRSM). Data-link switching plus (DLSw+), serial tunnel (STUN), block serial tunnel (BSTUN); logical link control, type 2 (LLC2), synchronous data link control (SDLC); IBM Network Media Translation, including Synchronous Data Logical Link Control (SDLLC) and qualified LLC (QLLC); downstream physical unit (DSPU), Systems Network Architecture (SNA) service point, SNA frame relay access, advanced peer-to-peer networking (APPN), native client interface architecture (NCIA) client/server topologies, and IBM Channel Attach.
<i>Cisco IOS Broadband and DSL Configuration Guide</i> <i>Cisco IOS XE Broadband and DSL Configuration Guide</i> <i>Cisco IOS Broadband and DSL Command Reference</i>	Point-to-Point Protocol (PPP) over ATM (PPPoA) and PPP over Ethernet (PPPoE).
<i>Cisco IOS Carrier Ethernet Configuration Guide</i> <i>Cisco IOS Carrier Ethernet Command Reference</i>	Connectivity fault management (CFM), Ethernet Local Management Interface (ELMI), IEEE 802.3ad link bundling, Link Layer Discovery Protocol (LLDP), media endpoint discovery (MED), and operations, administration, and maintenance (OAM).
<i>Cisco IOS Configuration Fundamentals Configuration Guide</i> <i>Cisco IOS XE Configuration Fundamentals Configuration Guide</i> <i>Cisco IOS Configuration Fundamentals Command Reference</i>	Autoinstall, Setup, Cisco IOS command-line interface (CLI), Cisco IOS file system (IFS), Cisco IOS web browser user interface (UI), basic file transfer services, and file management.
<i>Cisco IOS DECnet Configuration Guide</i> <i>Cisco IOS XE DECnet Configuration Guide</i> <i>Cisco IOS DECnet Command Reference</i>	DECnet protocol.
<i>Cisco IOS Dial Technologies Configuration Guide</i> <i>Cisco IOS XE Dial Technologies Configuration Guide</i> <i>Cisco IOS Dial Technologies Command Reference</i>	Asynchronous communications, dial backup, dialer technology, dial-in terminal services and AppleTalk remote access (ARA), large scale dialout, dial-on-demand routing, dialout, modem and resource pooling, ISDN, multilink PPP (MLP), PPP, virtual private dialup network (VPDN).
<i>Cisco IOS Flexible NetFlow Configuration Guide</i> <i>Cisco IOS Flexible NetFlow Command Reference</i>	Flexible NetFlow.

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS H.323 Configuration Guide</i>	Gatekeeper enhancements for managed voice services, Gatekeeper Transaction Message Protocol, gateway codec order preservation and shutdown control, H.323 dual tone multifrequency relay, H.323 version 2 enhancements, Network Address Translation (NAT) support of H.323 v2 Registration, Admission, and Status (RAS) protocol, tokenless call authorization, and VoIP gateway trunk and carrier-based routing.
<i>Cisco IOS High Availability Configuration Guide</i> <i>Cisco IOS XE High Availability Configuration Guide</i> <i>Cisco IOS High Availability Command Reference</i>	A variety of High Availability (HA) features and technologies that are available for different network segments (from enterprise access to service provider core) to facilitate creation of end-to-end highly available networks. Cisco IOS HA features and technologies can be categorized in three key areas: system-level resiliency, network-level resiliency, and embedded management for resiliency.
<i>Cisco IOS Integrated Session Border Controller Command Reference</i>	A VoIP-enabled device that is deployed at the edge of networks. An SBC is a toolkit of functions, such as signaling interworking, network hiding, security, and quality of service (QoS).
<i>Cisco IOS Intelligent Service Gateway Configuration Guide</i> <i>Cisco IOS Intelligent Service Gateway Command Reference</i>	Subscriber identification, service and policy determination, session creation, session policy enforcement, session life-cycle management, accounting for access and service usage, session state monitoring.
<i>Cisco IOS Interface and Hardware Component Configuration Guide</i> <i>Cisco IOS XE Interface and Hardware Component Configuration Guide</i> <i>Cisco IOS Interface and Hardware Component Command Reference</i>	LAN interfaces, logical interfaces, serial interfaces, virtual interfaces, and interface configuration.
<i>Cisco IOS IP Addressing Services Configuration Guide</i> <i>Cisco IOS XE Addressing Services Configuration Guide</i> <i>Cisco IOS IP Addressing Services Command Reference</i>	Address Resolution Protocol (ARP), Network Address Translation (NAT), Domain Name System (DNS), Dynamic Host Configuration Protocol (DHCP), and Next Hop Address Resolution Protocol (NHRP).
<i>Cisco IOS IP Application Services Configuration Guide</i> <i>Cisco IOS XE IP Application Services Configuration Guide</i> <i>Cisco IOS IP Application Services Command Reference</i>	Enhanced Object Tracking (EOT), Gateway Load Balancing Protocol (GLBP), Hot Standby Router Protocol (HSRP), IP Services, Server Load Balancing (SLB), Stream Control Transmission Protocol (SCTP), TCP, Web Cache Communication Protocol (WCCP), User Datagram Protocol (UDP), and Virtual Router Redundancy Protocol (VRRP).
<i>Cisco IOS IP Mobility Configuration Guide</i> <i>Cisco IOS IP Mobility Command Reference</i>	Mobile ad hoc networks (MANet) and Cisco mobile networks.
<i>Cisco IOS IP Multicast Configuration Guide</i> <i>Cisco IOS XE IP Multicast Configuration Guide</i> <i>Cisco IOS IP Multicast Command Reference</i>	Protocol Independent Multicast (PIM) sparse mode (PIM-SM), bidirectional PIM (bidir-PIM), Source Specific Multicast (SSM), Multicast Source Discovery Protocol (MSDP), Internet Group Management Protocol (IGMP), and Multicast VPN (MVPN).

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS IP Routing Protocols Configuration Guide</i> <i>Cisco IOS XE IP Routing Protocols Configuration Guide</i> <i>Cisco IOS IP Routing Protocols Command Reference</i>	Border Gateway Protocol (BGP), multiprotocol BGP, multiprotocol BGP extensions for IP multicast, bidirectional forwarding detection (BFD), Enhanced Interior Gateway Routing Protocol (EIGRP), Interior Gateway Routing Protocol (IGRP), Intermediate System-to-Intermediate System (IS-IS), on-demand routing (ODR), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP).
<i>Cisco IOS IP SLAs Configuration Guide</i> <i>Cisco IOS XE IP SLAs Configuration Guide</i> <i>Cisco IOS IP SLAs Command Reference</i>	Cisco IOS IP Service Level Agreements (IP SLAs).
<i>Cisco IOS IP Switching Configuration Guide</i> <i>Cisco IOS XE IP Switching Configuration Guide</i> <i>Cisco IOS IP Switching Command Reference</i>	Cisco Express Forwarding, fast switching, and Multicast Distributed Switching (MDS).
<i>Cisco IOS IPv6 Configuration Guide</i> <i>Cisco IOS XE IPv6 Configuration Guide</i> <i>Cisco IOS IPv6 Command Reference</i>	For IPv6 features, protocols, and technologies, go to the IPv6 “Start Here” document at the following URL: http://www.cisco.com/en/US/docs/ios/ipv6/configuration/guide/ip6-roadmap.html
<i>Cisco IOS ISO CLNS Configuration Guide</i> <i>Cisco IOS XE ISO CLNS Configuration Guide</i> <i>Cisco IOS ISO CLNS Command Reference</i>	ISO connectionless network service (CLNS).
<i>Cisco IOS LAN Switching Configuration Guide</i> <i>Cisco IOS XE LAN Switching Configuration Guide</i> <i>Cisco IOS LAN Switching Command Reference</i>	VLANs, Inter-Switch Link (ISL) encapsulation, IEEE 802.10 encapsulation, IEEE 802.1Q encapsulation, and multilayer switching (MLS).
<i>Cisco IOS Mobile Wireless Gateway GPRS Support Node Configuration Guide</i> <i>Cisco IOS Mobile Wireless Gateway GPRS Support Node Command Reference</i>	Cisco IOS Gateway GPRS Support Node (GGSN) in a 2.5-generation general packet radio service (GPRS) and 3-generation universal mobile telecommunication system (UMTS) network.
<i>Cisco IOS Mobile Wireless Home Agent Configuration Guide</i> <i>Cisco IOS Mobile Wireless Home Agent Command Reference</i>	Cisco Mobile Wireless Home Agent, an anchor point for mobile terminals for which mobile IP or proxy mobile IP services are provided.
<i>Cisco IOS Mobile Wireless Packet Data Serving Node Configuration Guide</i> <i>Cisco IOS Mobile Wireless Packet Data Serving Node Command Reference</i>	Cisco Packet Data Serving Node (PDSN), a wireless gateway that is between the mobile infrastructure and standard IP networks and that enables packet data services in a code division multiple access (CDMA) environment.
<i>Cisco IOS Mobile Wireless Radio Access Networking Configuration Guide</i> <i>Cisco IOS Mobile Wireless Radio Access Networking Command Reference</i>	Cisco IOS radio access network products.

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS Multiprotocol Label Switching Configuration Guide</i> <i>Cisco IOS XE Multiprotocol Label Switching Configuration Guide</i> <i>Cisco IOS Multiprotocol Label Switching Command Reference</i>	MPLS Label Distribution Protocol (LDP), MPLS Layer 2 VPNs, MPLS Layer 3 VPNs, MPLS Traffic Engineering (TE), and MPLS Embedded Management (EM) and MIBs.
<i>Cisco IOS Multi-Topology Routing Configuration Guide</i> <i>Cisco IOS Multi-Topology Routing Command Reference</i>	Unicast and multicast topology configurations, traffic classification, routing protocol support, and network management support.
<i>Cisco IOS NetFlow Configuration Guide</i> <i>Cisco IOS XE NetFlow Configuration Guide</i> <i>Cisco IOS NetFlow Command Reference</i>	Network traffic data analysis, aggregation caches, export features.
<i>Cisco IOS Network Management Configuration Guide</i> <i>Cisco IOS XE Network Management Configuration Guide</i> <i>Cisco IOS Network Management Command Reference</i>	Basic system management; system monitoring and logging; troubleshooting, logging, and fault management; Cisco Discovery Protocol; Cisco IOS Scripting with Tool Control Language (Tcl); Cisco networking services (CNS); DistributedDirector; Embedded Event Manager (EEM); Embedded Resource Manager (ERM); Embedded Syslog Manager (ESM); HTTP; Remote Monitoring (RMON); SNMP; and VPN Device Manager Client for Cisco IOS Software (XSM Configuration).
<i>Cisco IOS Novell IPX Configuration Guide</i> <i>Cisco IOS XE Novell IPX Configuration Guide</i> <i>Cisco IOS Novell IPX Command Reference</i>	Novell Internetwork Packet Exchange (IPX) protocol.
<i>Cisco IOS Optimized Edge Routing Configuration Guide</i> <i>Cisco IOS Optimized Edge Routing Command Reference</i>	Optimized edge routing (OER) monitoring, policy configuration, routing control, logging and reporting, and VPN IPsec/generic routing encapsulation (GRE) tunnel interface optimization.
<i>Cisco IOS Quality of Service Solutions Configuration Guide</i> <i>Cisco IOS XE Quality of Service Solutions Configuration Guide</i> <i>Cisco IOS Quality of Service Solutions Command Reference</i>	Class-based weighted fair queuing (CBWFQ), custom queuing, distributed traffic shaping (DTS), generic traffic shaping (GTS), IP- to-ATM class of service (CoS), low latency queuing (LLQ), modular QoS CLI (MQC), Network-Based Application Recognition (NBAR), priority queuing, Security Device Manager (SDM), Multilink PPP (MLPPP) for QoS, header compression, AutoQoS, QoS features for voice, Resource Reservation Protocol (RSVP), weighted fair queuing (WFQ), and weighted random early detection (WRED).
<i>Cisco IOS Security Configuration Guide</i> <i>Cisco IOS XE Security Configuration Guide</i> <i>Cisco IOS Security Command Reference</i>	Access control lists (ACLs), authentication, authorization, and accounting (AAA), firewalls, IP security and encryption, neighbor router authentication, network access security, network data encryption with router authentication, public key infrastructure (PKI), RADIUS, TACACS+, terminal access security, and traffic filters.

Table 1 Cisco IOS and Cisco IOS XE Configuration Guides and Command References (continued)

Configuration Guide and Command Reference Titles	Features/Protocols/Technologies
<i>Cisco IOS Service Selection Gateway Configuration Guide</i> <i>Cisco IOS Service Selection Gateway Command Reference</i>	Subscriber authentication, service access, and accounting.
<i>Cisco IOS Software Activation Configuration Guide</i> <i>Cisco IOS Software Activation Command Reference</i>	An orchestrated collection of processes and components to activate Cisco IOS software feature sets by obtaining and validating Cisco software licenses.
<i>Cisco IOS Software Modularity Installation and Configuration Guide</i> <i>Cisco IOS Software Modularity Command Reference</i>	Installation and basic configuration of software modularity images, including installations on single and dual route processors, installation rollbacks, software modularity binding, software modularity processes and patches.
<i>Cisco IOS Terminal Services Configuration Guide</i> <i>Cisco IOS Terminal Services Command Reference</i> <i>Cisco IOS XE Terminal Services Command Reference</i>	DEC, local-area transport (LAT), and X.25 packet assembler/disassembler (PAD).
<i>Cisco IOS Virtual Switch Command Reference</i>	<p>Virtual switch redundancy, high availability, and packet handling; converting between standalone and virtual switch modes; virtual switch link (VSL); Virtual Switch Link Protocol (VSLP).</p> <p>Note For information about virtual switch configuration, refer to the product-specific software configuration information for the Cisco Catalyst 6500 series switch or for the Metro Ethernet 6500 series switch.</p>
<i>Cisco IOS Voice Configuration Library</i> <i>Cisco IOS Voice Command Reference</i>	Cisco IOS support for voice call control protocols, interoperability, physical and virtual interface management, and troubleshooting. The library includes documentation for IP telephony applications.
<i>Cisco IOS VPDN Configuration Guide</i> <i>Cisco IOS XE VPDN Configuration Guide</i> <i>Cisco IOS VPDN Command Reference</i>	Layer 2 Tunneling Protocol (L2TP) dial-out load balancing and redundancy, L2TP extended failover, L2TP security VPDN, multihop by Dialed Number Identification Service (DNIS), timer and retry enhancements for L2TP and Layer 2 Forwarding (L2F), RADIUS Attribute 82: tunnel assignment ID, shell-based authentication of VPDN users, tunnel authentication via RADIUS on tunnel terminator.
<i>Cisco IOS Wide-Area Networking Configuration Guide</i> <i>Cisco IOS XE Wide-Area Networking Configuration Guide</i> <i>Cisco IOS Wide-Area Networking Command Reference</i>	Frame Relay, Layer 2 Tunneling Protocol Version 3 (L2TPv3), Link Access Procedure, Balanced (LAPB), Switched Multimegabit Data Service (SMDS), and X.25.
<i>Cisco IOS Wireless LAN Configuration Guide</i> <i>Cisco IOS Wireless LAN Command Reference</i>	Broadcast key rotation, IEEE 802.11x support, IEEE 802.1x authenticator, IEEE 802.1x local authentication service for Extensible Authentication Protocol-Flexible Authentication via Secure Tunneling (EAP-FAST), Multiple Basic Service Set ID (BSSID), Wi-Fi Multimedia (WMM) required elements, and Wi-Fi Protected Access (WPA).

Table 2 Cisco IOS Supplementary Documents and Resources

Document Title	Description
<i>Cisco IOS Master Command List, All Releases</i>	Alphabetical list of all the commands documented in all Cisco IOS releases.
<i>Cisco IOS New, Modified, Removed, and Replaced Commands</i>	List of all the new, modified, removed, and replaced commands for a Cisco IOS release.
<i>Cisco IOS Software System Messages</i>	List of Cisco IOS system messages and descriptions. System messages may indicate problems with your system; be informational only; or may help diagnose problems with communications lines, internal hardware, or the system software.
<i>Cisco IOS Debug Command Reference</i>	Alphabetical list of debug commands including brief descriptions of use, command syntax, and usage guidelines.
Release Notes and Caveats	Information about new and changed features, system requirements, and other useful information about specific software releases; information about defects in specific Cisco IOS software releases.
MIBs	Files used for network monitoring. To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator at the following URL: http://www.cisco.com/go/mibs
RFCs	Standards documents maintained by the Internet Engineering Task Force (IETF) that Cisco IOS documentation references where applicable. The full text of referenced RFCs may be obtained at the following URL: http://www.rfc-editor.org/

Additional Resources and Documentation Feedback

What's New in Cisco Product Documentation is published monthly and describes all new and revised Cisco technical documentation. The *What's New in Cisco Product Documentation* publication also provides information about obtaining the following resources:

- Technical documentation
- Cisco product security overview
- Product alerts and field notices
- Technical assistance

Cisco IOS technical documentation includes embedded feedback forms where you can rate documents and provide suggestions for improvement. Your feedback helps us improve our documentation.

Using the Command-Line Interface in Cisco IOS and Cisco IOS XE Software

Last updated: August 6, 2008

This document provides basic information about the command-line interface (CLI) in Cisco IOS and Cisco IOS XE software and how you can use some of the CLI features. This document contains the following sections:

- [Initially Configuring a Device, page i](#)
- [Using the CLI, page ii](#)
- [Saving Changes to a Configuration, page xii](#)
- [Additional Information, page xii](#)

For more information about using the CLI, see the “[Using the Cisco IOS Command-Line Interface](#)” section of the *Cisco IOS Configuration Fundamentals Configuration Guide*.

For information about the software documentation set, see the “[About Cisco IOS and Cisco IOS XE Software Documentation](#)” document.

Initially Configuring a Device

Initially configuring a device varies by platform. For information about performing an initial configuration, see the hardware installation documentation that is provided with the original packaging of the product or go to the Product Support area of Cisco.com at <http://www.cisco.com/web/psa/products/index.html>.

After you have performed the initial configuration and connected the device to your network, you can configure the device by using the console port or a remote access method, such as Telnet or Secure Shell (SSH), to access the CLI or by using the configuration method provided on the device, such as Security Device Manager.

Changing the Default Settings for a Console or AUX Port

There are only two changes that you can make to a console port and an AUX port:

- Change the port speed with the **config-register 0x** command. Changing the port speed is not recommended. The well-known default speed is 9600.
- Change the behavior of the port; for example, by adding a password or changing the timeout value.

**Note**

The AUX port on the Route Processor (RP) installed in a Cisco ASR1000 series router does not serve any useful customer purpose and should be accessed only under the advisement of a customer support representative.

Using the CLI

This section describes the following topics:

- [Understanding Command Modes, page ii](#)
- [Using the Interactive Help Feature, page v](#)
- [Understanding Command Syntax, page vi](#)
- [Understanding Enable and Enable Secret Passwords, page viii](#)
- [Using the Command History Feature, page viii](#)
- [Abbreviating Commands, page ix](#)
- [Using Aliases for CLI Commands, page ix](#)
- [Using the no and default Forms of Commands, page x](#)
- [Using the debug Command, page x](#)
- [Filtering Output Using Output Modifiers, page x](#)
- [Understanding CLI Error Messages, page xi](#)

Understanding Command Modes

The CLI command mode structure is hierarchical, and each mode supports a set of specific commands. This section describes the most common of the many modes that exist.

[Table 1](#) lists common command modes with associated CLI prompts, access and exit methods, and a brief description of how each mode is used.

Table 1 *CLI Command Modes*

Command Mode	Access Method	Prompt	Exit Method	Mode Usage
User EXEC	Log in.	Router>	Issue the logout or exit command.	<ul style="list-style-type: none"> • Change terminal settings. • Perform basic tests. • Display device status.
Privileged EXEC	From user EXEC mode, issue the enable command.	Router#	Issue the disable command or the exit command to return to user EXEC mode.	<ul style="list-style-type: none"> • Issue show and debug commands. • Copy images to the device. • Reload the device. • Manage device configuration files. • Manage device file systems.
Global configuration	From privileged EXEC mode, issue the configure terminal command.	Router(config)#	Issue the exit command or the end command to return to privileged EXEC mode.	Configure the device.
Interface configuration	From global configuration mode, issue the interface command.	Router(config-if)#	Issue the exit command to return to global configuration mode or the end command to return to privileged EXEC mode.	Configure individual interfaces.
Line configuration	From global configuration mode, issue the line vty or line console command.	Router(config-line)#	Issue the exit command to return to global configuration mode or the end command to return to privileged EXEC mode.	Configure individual terminal lines.

Table 1 CLI Command Modes (continued)

Command Mode	Access Method	Prompt	Exit Method	Mode Usage
ROM monitor	From privileged EXEC mode, issue the reload command. Press the Break key during the first 60 seconds while the system is booting.	rommon # > The # symbol represents the line number and increments at each prompt.	Issue the continue command.	<ul style="list-style-type: none"> Run as the default operating mode when a valid image cannot be loaded. Access the fall-back procedure for loading an image when the device lacks a valid image and cannot be booted. Perform password recovery when a CTRL-Break sequence is issued within 60 seconds of a power-on or reload event.
Diagnostic (available only on the Cisco ASR1000 series router)	<p>The router boots or enters diagnostic mode in the following scenarios. When a Cisco IOS process or processes fail, in most scenarios the router will reload.</p> <ul style="list-style-type: none"> A user-configured access policy was configured using the transport-map command, which directed the user into diagnostic mode. The router was accessed using an RP auxiliary port. A break signal (Ctrl-C, Ctrl-Shift-6, or the send break command) was entered, and the router was configured to enter diagnostic mode when the break signal was received. 	Router(diag)#	<p>If a Cisco IOS process failure is the reason for entering diagnostic mode, the failure must be resolved and the router must be rebooted to exit diagnostic mode.</p> <p>If the router is in diagnostic mode because of a transport-map configuration, access the router through another port or using a method that is configured to connect to the Cisco IOS CLI.</p> <p>If the RP auxiliary port was used to access the router, use another port for access. Accessing the router through the auxiliary port is not useful for customer purposes.</p>	<ul style="list-style-type: none"> Inspect various states on the router, including the Cisco IOS state. Replace or roll back the configuration. Provide methods of restarting the Cisco IOS software or other processes. Reboot hardware, such as the entire router, an RP, an ESP, a SIP, a SPA, or possibly other hardware components. Transfer files into or off of the router using remote access methods such as FTP, TFTP, and SCP.

EXEC commands are not saved when the software reboots. Commands that you issue in a configuration mode can be saved to the startup configuration. If you save the running configuration to the startup configuration, these commands will execute when the software is rebooted. Global configuration mode is the highest level of configuration mode. From global configuration mode, you can enter a variety of other configuration modes, including protocol-specific modes.

ROM monitor mode is a separate mode that is used when the software cannot load properly. If a valid software image is not found when the software boots or if the configuration file is corrupted at startup, the software might enter ROM monitor mode. Use the question symbol (?) to view the commands that you can use while the device is in ROM monitor mode.

```
rommon 1 > ?
alias                set and display aliases command
boot                 boot up an external process
confreg              configuration register utility
cont                 continue executing a downloaded image
context              display the context of a loaded image
cookie               display contents of cookie PROM in hex
.
.
.
rommon 2 >
```

The following example shows how the command prompt changes to indicate a different command mode:

```
Router> enable
Router# configure terminal
Router(config)# interface ethernet 1/1
Router(config-if)# ethernet
Router(config-line)# exit
Router(config)# end
Router#
```

Note

A keyboard alternative to the **end** command is Ctrl-Z.

Using the Interactive Help Feature

The CLI includes an interactive Help feature. [Table 2](#) describes how to use the Help feature.

Table 2 CLI Interactive Help Commands

Command	Purpose
help	Provides a brief description of the help feature in any command mode.
?	Lists all commands available for a particular command mode.
<i>partial command?</i>	Provides a list of commands that begin with the character string (no space between the command and the question mark).
<i>partial command</i> <Tab>	Completes a partial command name (no space between the command and <Tab>).
<i>command ?</i>	Lists the keywords, arguments, or both associated with the command (space between the command and the question mark).
<i>command keyword ?</i>	Lists the arguments that are associated with the keyword (space between the keyword and the question mark).

The following examples show how to use the help commands:

help

```
Router> help
```

Help may be requested at any point in a command by entering a question mark '?'. If nothing matches, the help list will be empty and you must backup until entering a '?' shows the available options.

Two styles of help are provided:

1. Full help is available when you are ready to enter a command argument (e.g. 'show ?') and describes each possible argument.
2. Partial help is provided when an abbreviated argument is entered and you want to know what arguments match the input (e.g. 'show pr?'.)

?

```
Router# ?
```

Exec commands:

access-enable	Create a temporary access-List entry
access-profile	Apply user-profile to interface
access-template	Create a temporary access-List entry
alps	ALPS exec commands
archive	manage archive files

```
<snip>
```

partial command?

```
Router(config)# zo?
```

```
zone zone-pair
```

partial command<Tab>

```
Router(config)# we<Tab> webvpn
```

command ?

```
Router(config-if)# pppoe ?
```

enable	Enable pppoe
max-sessions	Maximum PPPOE sessions

command keyword ?

```
Router(config-if)# pppoe enable ?
```

group	attach a BBA group
-------	--------------------

```
<cr>
```

Understanding Command Syntax

Command syntax is the format in which a command should be entered in the CLI. Commands include the name of the command, keywords, and arguments. Keywords are alphanumeric strings that are used literally. Arguments are placeholders for values that a user must supply. Keywords and arguments may be required or optional.

Specific conventions convey information about syntax and command elements. [Table 3](#) describes these conventions.

Table 3 *CLI Syntax Conventions*

Symbol/Text	Function	Notes
< > (angle brackets)	Indicate that the option is an argument.	Sometimes arguments are displayed without angle brackets.
A.B.C.D.	Indicates that you must enter a dotted decimal IP address.	Angle brackets (< >) are not always used to indicate that an IP address is an argument.
WORD (all capital letters)	Indicates that you must enter one word.	Angle brackets (< >) are not always used to indicate that a WORD is an argument.
LINE (all capital letters)	Indicates that you must enter more than one word.	Angle brackets (< >) are not always used to indicate that a LINE is an argument.
<cr> (carriage return)	Indicates the end of the list of available keywords and arguments, and also indicates when keywords and arguments are optional. When <cr> is the only option, you have reached the end of the branch or the end of the command if the command has only one branch.	—

The following examples show syntax conventions:

```

Router(config)# ethernet cfm domain ?
WORD    domain name
Router(config)# ethernet cfm domain dname ?
level
Router(config)# ethernet cfm domain dname level ?
<0-7>  maintenance level number
Router(config)# ethernet cfm domain dname level 7 ?
<cr>
Router(config)# snmp-server file-transfer access-group 10 ?
protocol protocol options
<cr>
Router(config)# logging host ?
Hostname or A.B.C.D  IP address of the syslog server
ipv6                  Configure IPv6 syslog server
Router(config)# snmp-server file-transfer access-group 10 ?
protocol protocol options
<cr>

```

Understanding Enable and Enable Secret Passwords

Some privileged EXEC commands are used for actions that impact the system, and it is recommended that you set a password for these commands to prevent unauthorized use. Two types of passwords, enable (not encrypted) and enable secret (encrypted), can be set. The following commands set these passwords and are issued in global configuration mode:

- **enable** *password*
- **enable secret** *password*

Using an enable secret password is recommended because it is encrypted and more secure than the enable password. When you use an enable secret password, text is encrypted (unreadable) before it is written to the config.text file. When you use an enable password, the text is written as entered (readable) to the config.text file.

Each type of password is case sensitive, can contain from 1 to 25 uppercase and lowercase alphanumeric characters, and can start with a number. Spaces are also valid password characters; for example, “two words” is a valid password. Leading spaces are ignored, but trailing spaces are recognized.

**Note**

Both password commands have numeric keywords that are single integer values. If you choose a number for the first character of your password followed by a space, the system will read the number as if it were the numeric keyword and not as part of your password.

When both passwords are set, the enable secret password takes precedence over the enable password.

To remove a password, use the **no** form of the commands: **no enable** *password* or **no enable secret** *password*.

For more information about password recovery procedures for Cisco products, see http://www.cisco.com/en/US/products/sw/iosswrel/ps1831/products_tech_note09186a00801746e6.shtml.

Using the Command History Feature

The CLI command history feature saves the commands you enter during a session in a command history buffer. The default number of commands saved is 10, but the number is configurable within the range of 0 to 256. This command history feature is particularly useful for recalling long or complex commands.

To change the number of commands saved in the history buffer for a terminal session, issue the **terminal history size** command:

```
Router# terminal history size num
```

A command history buffer is also available in line configuration mode with the same default and configuration options. To set the command history buffer size for a terminal session in line configuration mode, issue the **history** command:

```
Router(config-line)# history [size num]
```

To recall commands from the history buffer, use the following methods:

- Press Ctrl-P or the up arrow key—Recalls commands beginning with the most recent command. Repeat the key sequence to recall successively older commands.

- Press Ctrl-N or the down arrow key—Recalls the most recent commands in the history buffer after they have been recalled using Ctrl-P or the up arrow key. Repeat the key sequence to recall successively more recent commands.

Note The arrow keys function only on ANSI-compatible terminals such as the VT100.

- Issue the **show history** command in user EXEC or privileged EXEC mode—Lists the most recent commands that you entered. The number of commands that are displayed is determined by the setting of the **terminal history size** and **history** commands.

The CLI command history feature is enabled by default. To disable this feature for a terminal session, issue the **terminal no history** command in user EXEC or privileged EXEC mode or the **no history** command in line configuration mode.

Abbreviating Commands

Typing a complete command name is not always required for the command to execute. The CLI recognizes an abbreviated command when the abbreviation contains enough characters to uniquely identify the command. For example, the **show version** command can be abbreviated as **sh ver**. It cannot be abbreviated as **s ver** because **s** could mean **show**, **set**, or **systat**. The **sh v** abbreviation also is not valid because the **show** command has **vrp** as a keyword in addition to **version**. (Command and keyword examples from Cisco IOS Release 12.4(13)T.)

Using Aliases for CLI Commands

To save time and the repetition of entering the same command multiple times, you can use a command alias. An alias can be configured to do anything that can be done at the command line, but an alias cannot move between modes, type in passwords, or perform any interactive functions.

Table 4 shows the default command aliases.

Table 4 Default Command Aliases

Command Alias	Original Command
h	help
lo	logout
p	ping
s	show
u or un	undebug
w	where

To create a command alias, issue the **alias** command in global configuration mode. The syntax of the command is **alias mode command-alias original-command**. Following are some examples:

- Router(config)# **alias exec prt partition**—privileged EXEC mode
- Router(config)# **alias configure sb source-bridge**—global configuration mode
- Router(config)# **alias interface rl rate-limit**—interface configuration mode

To view both default and user-created aliases, issue the **show alias** command.

For more information about the **alias** command, see

http://www.cisco.com/en/US/docs/ios/fundamentals/command/reference/cf_book.html.

Using the no and default Forms of Commands

Most configuration commands have a **no** form that is used to reset a command to its default value or disable a feature or function. For example, the **ip routing** command is enabled by default. To disable this command, you would issue the **no ip routing** command. To re-enable IP routing, you would issue the **ip routing** command.

Configuration commands may also have a **default** form, which returns the command settings to their default values. For commands that are disabled by default, using the **default** form has the same effect as using the **no** form of the command. For commands that are enabled by default and have default settings, the **default** form enables the command and returns the settings to their default values.

The **no** and **default** forms of commands are described in the command pages of command references.

Using the debug Command

A **debug** command produces extensive output that helps you troubleshoot problems in your network. These commands are available for many features and functions within Cisco IOS and Cisco IOS XE software. Some **debug** commands are **debug all**, **debug aaa accounting**, and **debug mpls packets**. To use **debug** commands during a Telnet session with a device, you must first enter the **terminal monitor** command. To turn off debugging completely, you must enter the **undebug all** command.

For more information about **debug** commands, see the *Cisco IOS Debug Command Reference* at

http://www.cisco.com/en/US/docs/ios/debug/command/reference/db_book.html.

Caution

Debugging is a high priority and high CPU utilization process that can render your device unusable. Use **debug** commands only to troubleshoot specific problems. The best times to run debugging are during periods of low network traffic and when few users are interacting with the network. Debugging during these periods decreases the likelihood that the **debug** command processing overhead will affect network performance or user access or response times.

Filtering Output Using Output Modifiers

Many commands produce lengthy output that may use several screens to display. Using output modifiers, you can filter this output to show only the information that you want to see.

Three output modifiers are available and are described as follows:

- **begin** *regular expression*—Displays the first line in which a match of the regular expression is found and all lines that follow.
- **include** *regular expression*—Displays all lines in which a match of the regular expression is found.
- **exclude** *regular expression*—Displays all lines except those in which a match of the regular expression is found.

To use one of these output modifiers, type the command followed by the pipe symbol (|), the modifier, and the regular expression that you want to search for or filter. A regular expression is a case-sensitive alphanumeric pattern. It can be a single character or number, a phrase, or a more complex string.

The following example illustrates how to filter output of the **show interface** command to display only lines that include the expression “protocol.”

```
Router# show interface | include protocol

FastEthernet0/0 is up, line protocol is up
Serial4/0 is up, line protocol is up
Serial4/1 is up, line protocol is up
Serial4/2 is administratively down, line protocol is down
Serial4/3 is administratively down, line protocol is down
```

Understanding CLI Error Messages

You may encounter some error messages while using the CLI. [Table 5](#) shows the common CLI error messages.

Table 5 Common CLI Error Messages

Error Message	Meaning	How to Get Help
% Ambiguous command: “show con”	You did not enter enough characters for the command to be recognized.	Reenter the command followed by a space and a question mark (?). The keywords that you are allowed to enter for the command appear.
% Incomplete command.	You did not enter all the keywords or values required by the command.	Reenter the command followed by a space and a question mark (?). The keywords that you are allowed to enter for the command appear.
% Invalid input detected at “^” marker.	You entered the command incorrectly. The caret (^) marks the point of the error.	Enter a question mark (?) to display all the commands that are available in this command mode. The keywords that you are allowed to enter for the command appear.

For more system error messages, see the following documents:

- [Cisco IOS Release 12.2SR System Message Guide](#)
- [Cisco IOS System Messages, Volume 1 of 2](#) (Cisco IOS Release 12.4)
- [Cisco IOS System Messages, Volume 2 of 2](#) (Cisco IOS Release 12.4)

Saving Changes to a Configuration

To save changes that you made to the configuration of a device, you must issue the **copy running-config startup-config** command or the **copy system:running-config nvram:startup-config** command. When you issue these commands, the configuration changes that you made are saved to the startup configuration and saved when the software reloads or power to the device is turned off or interrupted. The following example shows the syntax of the **copy running-config startup-config** command:

```
Router# copy running-config startup-config
Destination filename [startup-config]?
```

You press Enter to accept the startup-config filename (the default), or type a new filename and then press Enter to accept that name. The following output is displayed indicating that the configuration was saved:

```
Building configuration...
[OK]
Router#
```

On most platforms, the configuration is saved to NVRAM. On platforms with a Class A flash file system, the configuration is saved to the location specified by the CONFIG_FILE environment variable. The CONFIG_FILE variable defaults to NVRAM.

Security Overview

This chapter contains the following sections:

- [About This Guide](#)

Preview the topics in this guide.

- [Creating Effective Security Policies](#)

Learn tips and hints for creating a security policy for your organization. A security policy should be finalized and up to date *before* you configure any security features.

- [Identifying Security Risks and Cisco IOS Solutions](#)

Identify common security risks that might be present in your network, and find the right Cisco IOS security feature to prevent security break-ins.

About This Guide

The *Cisco IOS Security Configuration Guide* describes how to configure Cisco IOS security features for your Cisco networking devices. These security features can protect your network against degradation or failure and also against data loss or compromise resulting from intentional attacks and from unintended but damaging mistakes by well-meaning network users.

This guide is divided into seven parts:

- [Authentication, Authorization, and Accounting \(AAA\)](#)
- [Security Server Protocols](#)
- [Traffic Filtering, Firewalls, and Virus Detection](#)
- [IP Security \(IPSec\) and Internet Key Exchange \(IKE\)](#)
- [Public Key Infrastructure \(PKI\)](#)
- [Other Security Features](#)
- [Cisco IOS Secure Infrastructure](#)

[Appendixes](#) follow the seven main divisions.

The following sections briefly describe each of these sections and the appendixes.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Authentication, Authorization, and Accounting (AAA)

This part describes how to configure Cisco's authentication, authorization, and accounting (AAA) paradigm. AAA is an architectural framework for configuring a set of three independent security functions in a consistent, modular manner.

- **Authentication**—Provides the method of identifying users, including login and password dialog, challenge and response, messaging support, and, depending on the security protocol you select, encryption. Authentication is the way a user is identified prior to being allowed access to the network and network services. You configure AAA authentication by defining a named list of authentication methods and then applying that list to various interfaces.
- **Authorization**—Provides the method for remote access control, including one-time authorization or authorization for each service, per-user account list and profile, user group support, and support of IP, IPX, ARA, and Telnet.

Remote security servers, such as RADIUS and TACACS+, authorize users for specific rights by associating attribute-value (AV) pairs, which define those rights, with the appropriate user. AAA authorization works by assembling a set of attributes that describe what the user is authorized to perform. These attributes are compared with the information contained in a database for a given user, and the result is returned to AAA to determine the user's actual capabilities and restrictions.

- **Accounting**—Provides the method for collecting and sending security server information used for billing, auditing, and reporting, such as user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes. Accounting enables you to track the services users are accessing, as well as the amount of network resources they are consuming.

**Note**

You can configure authentication outside of AAA. However, you must configure AAA if you want to use RADIUS, TACACS+, or Kerberos or if you want to configure a backup authentication method.

Security Server Protocols

In many circumstances, AAA uses security protocols to administer its security functions. If your router or access server is acting as a network access server, AAA is the means through which you establish communication between your network access server and your RADIUS, TACACS+, or Kerberos security server.

The chapters in this part describe how to configure the following security server protocols:

- **RADIUS**—A distributed client/server system implemented through AAA that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.
- **TACACS+**—A security application implemented through AAA that provides centralized validation of users attempting to gain access to a router or network access server. TACACS+ services are maintained in a database on a TACACS+ daemon running, typically, on a UNIX or Windows NT workstation. TACACS+ provides for separate and modular authentication, authorization, and accounting facilities.
- **Kerberos**—A secret-key network authentication protocol implemented through AAA that uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication. Kerberos was designed to authenticate requests for network resources. Kerberos is based on the concept of a trusted third party that performs secure verification of users and services. The primary use of Kerberos is to verify that users and the network services they use are really who and what

they claim to be. To accomplish this, a trusted Kerberos server issues tickets to users. These tickets, which have a limited lifespan, are stored in a user's credential cache and can be used in place of the standard username-and-password authentication mechanism.

Traffic Filtering, Firewalls, and Virus Detection

This part describes how to configure your networking devices to filter traffic, function as a firewall, or detect potential viruses.

- Cisco implements traffic filters with access control lists (also called access lists). Access lists determine what traffic is blocked and what traffic is forwarded at router interfaces. Cisco provides both basic and advanced access list capabilities.
 - Basic access lists

An overview of basic access lists is in the chapter “Access Control Lists: Overview and Guidelines.” This chapter describes tips, cautions, considerations, recommendations, and general guidelines for configuring access lists for the various network protocols. You should configure basic access lists for all network protocols that will be routed through your networking device, such as IP, IPX, AppleTalk, and so forth.
 - Advanced access lists

The advanced access list capabilities and configuration are described in the remaining chapters in the “Traffic Filtering, Firewalls, and Virus Detection” part of this document. The advanced access lists provide sophisticated and dynamic traffic filtering capabilities for stronger, more flexible network security.
- Cisco IOS Firewall provides an extensive set of security features, allowing you to configure a simple or elaborate firewall, according to your particular requirements. The following features are key components of Cisco IOS Firewall:
 - Context-based Access Control (CBAC)

CBAC intelligently filters TCP and UDP packets based on application-layer protocol session information. You can configure CBAC to permit specified TCP and UDP traffic through a firewall only when the connection is initiated from within the network you want to protect. CBAC can inspect traffic for sessions that originate from either side of the firewall, and CBAC can be used for intranet, extranet, and Internet perimeters of your network.
 - Cisco IOS Intrusion Prevention System (IPS)

Cisco IOS IPS acts as an in-line intrusion detection sensor, “watching” packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When Cisco IOS IPS detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE).

Customers can download the Cisco IOS IPS (via a signature detection file [SDF]) to their router from Cisco.com via the VPN and Security Management Solution (VMS) IDS Management Console (MC) 2.3 network management device or via the Cisco Router and Security Device Manager (SDM). Thus VMS IDS MC or SDM can immediately begin scanning for new signatures.
 - Authentication Proxy

The Cisco IOS Firewall authentication proxy feature allows network administrators to apply specific security policies on a per-user basis. Previously, user identity and related authorized access were associated with a user's IP address, or a single security policy had to be applied to

an entire user group or sub network. Now, users can be identified and authorized on the basis of their per-user policy, and access privileges tailored on an individual basis are possible, as opposed to general policy applied across multiple users.

- Port to Application Mapping (PAM)

Port to Application Mapping (PAM) is a feature of Cisco Secure Integrated Software. PAM allows you to customize TCP or UDP port numbers for network services or applications. PAM uses this information to support network environments that run services using ports that are different from the registered or well-known ports associated with an application. For example, the information in the PAM table enables Context-based Access Control (CBAC) supported services to run on non-standard ports.

Firewalls are discussed in the chapters “Cisco IOS Firewall Overview” and “Configuring Context-Based Access Control.”

- Cisco addresses the increased threat and impact of worms and viruses to networked businesses with Cisco Network Admission Control (NAC). NAC enables Cisco routers to enforce access privileges when an endpoint attempts to connect to a network. This access decision is made on the basis of information about the endpoint device, such as its current antivirus state. The antivirus state includes information such as the version of antivirus software, virus definitions, and version of the scan engine.

NAC systems allow noncompliant devices to be denied access, placed in a quarantined area, or given restricted access to computing resources, thus keeping insecure nodes from infecting the network.

IP Security (IPSec) and Internet Key Exchange (IKE)

This section describes how to configure security for VPNs via IPSec and IKE:

- Configuring Security for VPNs with IPSec

This module describes how to configure IPSec. IPSec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPSec provides data authentication and anti-replay services in addition to data confidentiality services.

- Configuring Internet Key Exchange for IPSec VPNs

This module describes how to configure IKE for use with IPSec VPNs. IKE is a key management protocol standard that is used in conjunction with the IPSec standard. IPSec can be configured without IKE, but IKE enhances IPSec by providing additional features, flexibility, and ease of configuration for the IPSec standard.

Public Key Infrastructure (PKI)

This section describes how to implement and manage a Cisco IOS PKI, which provides certificate management to support security protocols such as IPSec, secure shell (SSH), and secure socket layer (SSL). This section is divided into the following modules:

- Cisco IOS PKI Overview: Understanding and Planning a PKI

This module identifies general concepts necessary to understand how a PKI functions.

- Deploying RSA Keys Within a PKI

This module explains how to set up and deploy Rivest, Shamir, and Adelman (RSA) keys within a PKI. An RSA key pair is required before you can obtain a certificate for your router; that is, the end host must generate a pair of RSA keys and exchange the public key with the certification authority (CA) to obtain a certificate and enroll in a PKI.

- **Configuring Revocation and Authorization of Certificates in a PKI**

This module describes how to configure revocation and authorization of certificates in a PKI. After a certificate is validated as a properly signed certificate, it is authorized (via methods such as, certificate maps, PKI-AAA, or a certificate-based ACL) and the revocation status is checked by the issuing CA to ensure that the certificate has not been revoked.

- **Configuring Certificate Enrollment for a PKI**

Certificate enrollment, which is the process of obtaining a certificate from a CA, occurs between the end host requesting the certificate and the CA. Each peer that participates in the PKI must enroll with a CA. This module describes the different methods available for certificate enrollment and describes how to set up each method for a participating PKI peer.

- **Setting Up Secure Device Provisioning (SDP) for Enrollment in a PKI**

This module describes how to use SDP in a PKI. SDP is a web-based certificate enrollment interface that can be used to easily deploy PKI between two end devices, such as a Cisco IOS client and a Cisco IOS certificate server. SDP provides a solution for users deploying a large number of peer devices, including certificates and configurations.

- **Configuring and Managing a Cisco IOS Certificate Server for PKI Deployment**

This module describes how to set up and manage a Cisco IOS Certificate Server (CS) for PKI deployment. A CS embeds a simple certificate server, with limited CA functionality, into the Cisco IOS software.

- **Storing PKI Credentials External to the Router**

This module explains how to store RSA keys on device external to the router via a USB eToken. eTokens provide secure configuration distribution and allow users to store PKI credentials, such as RSA keys, for deployment.

Other Security Features

This section describes six security features in the following chapters:

- **Neighbor Router Authentication: Overview and Guidelines**

This chapter briefly describes the security benefits and operation of neighbor router authentication.

When neighbor authentication is configured on a router, the router authenticates its neighbor router before accepting any route updates from that neighbor. This ensures that a router always receives reliable routing update information from a trusted source.

- **Configuring IP Security Options**

This chapter describes how to configure IP Security Options (IPSO) as described in RFC 1108. IPSO is generally used to comply with the security policy of the U.S. government's Department of Defense.

- **Configuring Unicast Reverse Path Forwarding**

This chapter describes the Unicast Reverse Path Forwarding (Unicast RPF) feature, which helps mitigate problems caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribe Flood

Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers (ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

- **Configuring Secure Shell**

This chapter describes the Secure Shell (SSH) feature. SSH is an application and a protocol that provides a secure replacement to a suite of Unix r-commands such as rsh, rlogin and rcp. (Cisco IOS supports rlogin.) The protocol secures the sessions using standard cryptographic mechanisms, and the application can be used similarly to the Berkeley rexec and rsh tools. There are currently two versions of SSH available: SSH Version 1 and SSH Version 2.

- **Configuring 802.1x Authentication Services**

This section describes how to configure local authentication and VPN access via the Institute of Electrical and Electronics Engineers (IEEE) 802.1X protocol framework.

- **WebVPN**

WebVPN provides end users with unrestricted, secure remote access to enterprise sites without having VPN installed on their end devices. Users can access the enterprise sites from anywhere on the Internet and can access enterprise applications such as e-mail and web browsing.

Cisco IOS Secure Infrastructure

- This section contains features that help users secure their network infrastructure. Some of the available features are as follows: Autosecure (which simplifies the security configuration of a router and hardens the router configuration); Image Verification (which enables routers to automatically detect when the integrity of an image is accidentally corrupted as a result of transmission errors or disk corruption); Role-Based CLI Access (which allows network administrators to exercise better control over access to Cisco networking devices), and “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices” (which is a guide to implementing a baseline level of security for your networking devices).

Appendixes

The appendixes describe the supported RADIUS attributes and TACACS+ attribute-value pairs as follows:

- **RADIUS Attributes**

RADIUS attributes are used to define specific AAA elements in a user profile, which is stored on the RADIUS daemon. This appendix lists the RADIUS attributes currently supported.

- **TACACS+ Attribute-Value Pairs**

TACACS+ attribute-value pairs are used to define specific AAA elements in a user profile, which is stored on the TACACS+ daemon. This appendix lists the TACACS+ attribute-value pairs currently supported.

Creating Effective Security Policies

An effective security policy works to ensure that your organization's network assets are protected from sabotage and from inappropriate access—both intentional and accidental.

All network security features should be configured in compliance with your organization's security policy. If you do not have a security policy, or if your policy is out of date, you should ensure that the policy is created or updated before you decide how to configure security on your Cisco device.

The following sections provide guidelines to help you create an effective security policy:

- [The Nature of Security Policies](#)
- [Two Levels of Security Policies](#)
- [Tips for Developing an Effective Security Policy](#)

The Nature of Security Policies

You should recognize these aspects of security policies:

- Security policies represent trade-offs.

With all security policies, there is some trade-off between user productivity and security measures that can be restrictive and time consuming. The goal of any security design is to provide maximum security with minimum impact on user access and productivity. Some security measures, such as network data encryption, do not restrict access and productivity. On the other hand, cumbersome or unnecessarily redundant verification and authorization systems can frustrate users and even prevent access to critical network resources.

- Security policies should be determined by business needs.

Business needs should dictate the security policy; a security policy should not determine how a business operates.

- Security policies are living documents.

Because organizations are constantly subject to change, security policies must be systematically updated to reflect new business directions, technological changes, and resource allocations.

Two Levels of Security Policies

You can think of a security policy as having two levels: a requirements level and an implementation level.

- At the requirements level, a policy defines the degree to which your network assets must be protected against intrusion or destruction and also estimates the cost (consequences) of a security breach. For example, the policy could state that only human resources personnel should be able to access personnel records, or that only IS personnel should be able to configure the backbone routers. The policy could also address the consequences of a network outage (due to sabotage), and the consequences of inadvertently making sensitive information public.
- At the implementation level, a policy defines guidelines to implement the requirements-level policy, using specific technology in a predefined way. For example, the implementation-level policy could require access lists to be configured so that only traffic from human resources host computers can access the server containing personnel records.

When creating a policy, define security requirements before defining security implementations so that you do not end up merely justifying particular technical solutions that might not actually be required.

Tips for Developing an Effective Security Policy

To develop an effective security policy, consider the recommendations in the following sections:

- [Identifying Your Network Assets to Protect](#)
- [Determining Points of Risk](#)
- [Limiting the Scope of Access](#)
- [Identifying Assumptions](#)
- [Determining the Cost of Security Measures](#)
- [Considering Human Factors](#)
- [Keeping a Limited Number of Secrets](#)
- [Implementing Pervasive and Scalable Security](#)
- [Understanding Typical Network Functions](#)
- [Remembering Physical Security](#)

Identifying Your Network Assets to Protect

The first step to developing a security policy is to understand and identify your organization's network assets. Network assets include the following:

- Networked hosts (such as PCs; includes the hosts' operating systems, applications, and data)
- Networking devices (such as routers)
- Network data (data that travels across the network)

You must both identify your network's assets and determine the degree to which each of these assets must be protected. For example, one subnetwork of hosts might contain extremely sensitive data that should be protected at all costs, while a different subnetwork of hosts might require only modest protection against security risks because there is less cost involved if the subnetwork is compromised.

Determining Points of Risk

You must understand how potential intruders can enter your organization's network or sabotage network operation. Special areas of consideration are network connections, dial-up access points, and misconfigured hosts. Misconfigured hosts, frequently overlooked as points of network entry, can be systems with unprotected login accounts (guest accounts), employ extensive trust in remote commands (such as rlogin and rsh), have illegal modems attached to them, and use easy-to-break passwords.

Limiting the Scope of Access

Organizations can create multiple barriers within networks, so that unlawful entry to one part of the system does not automatically grant entry to the entire infrastructure. Although maintaining a high level of security for the entire network can be prohibitively expensive (in terms of systems and equipment as well as productivity), you can often provide higher levels of security to the more sensitive areas of your network.

Identifying Assumptions

Every security system has underlying assumptions. For example, an organization might assume that its network is not tapped, that intruders are not very knowledgeable, that intruders are using standard software, or that a locked room is safe. It is important to identify, examine, and justify your assumptions: one hidden assumption is a potential security hole.

Determining the Cost of Security Measures

In general, providing security comes at a cost. This cost can be measured in terms of increased connection times or inconveniences to legitimate users accessing the assets, or in terms of increased network management requirements, and sometimes in terms of actual dollars spent on equipment or software upgrades.

Some security measures inevitably inconvenience some sophisticated users. Security can delay work, create expensive administrative and educational overhead, use significant computing resources, and require dedicated hardware.

When you decide which security measures to implement, you must understand their costs and weigh these against potential benefits. If the security costs are out of proportion to the actual dangers, it is a disservice to the organization to implement them.

Considering Human Factors

If security measures interfere with essential uses of the system, users resist these measures and sometimes even circumvent them. Many security procedures fail because their designers do not take this fact into account. For example, because automatically generated “nonsense” passwords can be difficult to remember, users often write them on the undersides of keyboards. A “secure” door that leads to a system’s only tape drive is sometimes propped open. For convenience, unauthorized modems are often connected to a network to avoid cumbersome dial-in security procedures. To ensure compliance with your security measures, users must be able to get their work done as well as understand and accept the need for security.

Any user can compromise system security to some degree. For example, an intruder might learn passwords by simply calling legitimate users on the telephone claiming to be a system administrator and asking for them. If users understand security issues and understand the reasons for them, they are far less likely to compromise security in this way.

Defining such human factors and any corresponding policies needs to be included as a formal part of your complete security policy.

At a minimum, users must be taught never to release passwords or other secrets over unsecured telephone lines (especially through cordless or cellular telephones) or electronic mail. They should be wary of questions asked by people who call them on the telephone. Some companies have implemented formalized network security training for their employees in which employees are not allowed access to the network until they have completed a formal training program.

Keeping a Limited Number of Secrets

Most security is based on secrets; for example, passwords and encryption keys are secrets. But the more secrets there are, the harder it is to keep all of them. It is prudent, therefore, to design a security policy that relies on a limited number of secrets. Ultimately, the most important secret an organization has is the information that can help someone circumvent its security.

Implementing Pervasive and Scalable Security

Use a systematic approach to security that includes multiple, overlapping security methods.

Almost any change that is made to a system can affect security. This is especially true when new services are created. System administrators, programmers, and users need to consider the security implications of every change they make. Understanding the security implications of a change takes practice; it requires lateral thinking and a willingness to explore every way that a service could potentially be manipulated. The goal of any security policy is to create an environment that is not susceptible to every minor change.

Understanding Typical Network Functions

Understand how your network system normally functions, know what is expected and unexpected behavior, and be familiar with how devices are usually used. This kind of awareness helps the organization detect security problems. Noticing unusual events can help catch intruders before they can damage the system. Software auditing tools can help detect, log, and track unusual events. In addition, an organization should know exactly what software it relies on to provide auditing trails, and a security system should not operate on the assumption that all software is bug free.

Remembering Physical Security

The physical security of your network devices and hosts cannot be neglected. For example, many facilities implement physical security by using security guards, closed circuit television, card-key entry systems, or other means to control physical access to network devices and hosts. Physical access to a computer or router usually gives a sophisticated user complete control over that device. Physical access to a network link usually allows a person to tap into that link, jam it, or inject traffic into it. Software security measures can often be circumvented when access to the hardware is not controlled.

Identifying Security Risks and Cisco IOS Solutions

Cisco IOS software provides a comprehensive set of security features to guard against specific security risks. This section describes a few common security risks that might be present in your network, and describes how to use Cisco IOS software to protect against each of these risks:

- [Preventing Unauthorized Access into Networking Devices](#)
- [Preventing Unauthorized Access into Networks](#)
- [Preventing Network Data Interception](#)
- [Preventing Fraudulent Route Updates](#)

Preventing Unauthorized Access into Networking Devices

If someone were to gain console or terminal access into a networking device, such as a router, switch, or network access server, that person could do significant damage to your network—perhaps by reconfiguring the device, or even by simply viewing the device's configuration information.

Typically, you want administrators to have access to your networking device; you do not want other users on your local-area network or those dialing in to the network to have access to the router.

Users can access Cisco networking devices by dialing in from outside the network through an asynchronous port, connecting from outside the network through a serial port, or connecting via a terminal or workstation from within the local network.

To prevent unauthorized access into a networking device, you should configure one or more of the following security features:

- At a minimum, you should configure passwords and privileges at each networking device for all device lines and ports, as described in the module “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices.” These passwords are stored on the networking device. When users attempt to access the device through a particular line or port, they must enter the password applied to the line or port before they can access the device.
- For an additional layer of security, you can also configure username/password pairs, stored in a database on the networking device, as described in the module “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices.” These pairs are assigned to lines or interfaces and authenticate each user before that user can access the device. If you have defined privilege levels, you can also assign a specific privilege level (with associated rights and privileges) to each username/password pair.
- If you want to use username/password pairs, but you want to store them centrally instead of locally on each individual networking device, you can store them in a database on a security server. Multiple networking devices can then use the same database to obtain user authentication (and, if necessary, authorization) information. Cisco supports a variety of security server protocols, such as RADIUS, TACACS+, and Kerberos. If you decide to use the database on a security server to store login username/password pairs, you must configure your router or access server to support the applicable protocol; in addition, because most supported security protocols must be administered through the AAA security services, you will probably need to enable AAA. For more information about security protocols and AAA, refer to the chapters in the “Authentication, Authorization, and Accounting (AAA)” part of this document.

Note Cisco recommends that, whenever possible, AAA be used to implement authentication.

- If you want to authorize individual users for specific rights and privileges, you can implement AAA’s authorization feature, using a security protocol such as TACACS+ or RADIUS. For more information about security protocol features and AAA, refer to the chapters in the “Authentication, Authorization, and Accounting (AAA)” part of this document.
- If you want to have a backup authentication method, you must configure AAA. AAA allows you to specify the primary method for authenticating users (for example, a username/password database stored on a TACACS+ server) and then specify backup methods (for example, a locally stored username/password database.) The backup method is used if the primary method’s database cannot be accessed by the networking device. To configure AAA, refer to the chapters in the “Authentication, Authorization, and Accounting (AAA)” part of this document. You can configure up to four sequential backup methods.

Note If you do not have backup methods configured, you will be denied access to the device if the username/password database cannot be accessed for any reason.

- If you want to keep an audit trail of user access, configure AAA accounting as described in the chapter “Configuring Accounting.”

Preventing Unauthorized Access into Networks

If someone were to gain unauthorized access to your organization's internal network, that person could cause damage in many ways, perhaps by accessing sensitive files from a host, by planting a virus, or by hindering network performance by flooding your network with illegitimate packets.

This risk can also apply to a person within your network attempting to access another internal network such as a Research and Development subnetwork with sensitive and critical data. That person could intentionally or inadvertently cause damage; for example, that person might access confidential files or tie up a time-critical printer.

To prevent unauthorized access through a networking device into a network, you should configure one or more of these security features:

- **Traffic Filtering**

Cisco uses access lists to filter traffic at networking devices. Basic access lists allow only specified traffic through the device; other traffic is simply dropped. You can specify individual hosts or subnets that should be allowed into the network, and you can specify what type of traffic should be allowed into the network. Basic access lists generally filter traffic based on source and destination addresses, and protocol type of each packet.

Advanced traffic filtering is also available, providing additional filtering capabilities; for example, the Lock-and-Key Security feature requires each user to be authenticated via a username/password before that user's traffic is allowed onto the network.

All the Cisco IOS traffic filtering capabilities are described in the chapters in the "Traffic Filtering, Firewalls, and Virus Detection" part of this document.

- **Authentication**

You can require users to be authenticated before they gain access into a network. When users attempt to access a service or host (such as a web site or file server) within the protected network, they must first enter certain data such as a username and password, and possibly additional information such as their date of birth or mother's maiden name. After successful authentication (depending on the method of authentication), users will be assigned specific privileges, allowing them to access specific network assets. In most cases, this type of authentication would be facilitated by using CHAP or PAP over a serial PPP connection in conjunction with a specific security protocol, such as TACACS+ or RADIUS.

Just as in preventing unauthorized access to specific network devices, you need to decide whether or not you want the authentication database to reside locally or on a separate security server. In this case, a local security database is useful if you have very few routers providing network access. A local security database does not require a separate (and costly) security server. A remote, centralized security database is convenient when you have a large number of routers providing network access because it prevents you from having to update each router with new or changed username authentication and authorization information for potentially hundreds of thousands of dial-in users. A centralized security database also helps establish consistent remote access policies throughout a corporation.

Cisco IOS software supports a variety of authentication methods. Although AAA is the primary (and recommended) method for access control, Cisco IOS software provides additional features for simple access control that are outside the scope of AAA. For more information, refer to the chapter "Configuring Authentication."

Preventing Network Data Interception

When packets travel across a network, they are susceptible to being read, altered, or “hijacked.” (Hijacking occurs when a hostile party intercepts a network traffic session and poses as one of the session endpoints.)

If the data is traveling across an unsecured network such as the Internet, the data is exposed to a fairly significant risk. Sensitive or confidential data could be exposed, critical data could be modified, and communications could be interrupted if data is altered.

To protect data as it travels across a network, configure network data encryption, as described in the chapter “Configuring IPSec Network Security.”

IPSec provides the following network security services. These services are optional. In general, local security policy will dictate the use of one or more of the following services:

- **Data Confidentiality**—The IPSec sender can encrypt packets before transmitting them across a network.
- **Data Integrity**—The IPSec receiver can authenticate packets sent by the IPSec sender to ensure that the data has not been altered during transmission.
- **Data Origin Authentication**—The IPSec receiver can authenticate the source of the IPSec packets sent. This service is dependent upon the data integrity service.
- **Anti-Replay**—The IPSec receiver can detect and reject replayed packets.

Cisco IPSec prevents routed traffic from being examined or tampered with while it travels across a network. This feature causes IP packets to be encrypted at a Cisco router, routed across a network as encrypted information, and decrypted at the destination Cisco router. In between the two routers, the packets are in encrypted form and therefore the packets’ contents cannot be read or altered. You define what traffic should be encrypted between the two routers, according to what data is more sensitive or critical.

If you want to protect traffic for protocols other than IP, you can encapsulate those other protocols into IP packets using GRE encapsulation, and then encrypt the IP packets.

Typically, you do not use IPSec for traffic that is routed through networks that you consider secure. Consider using IPSec for traffic that is routed across unsecured networks, such as the Internet, if your organization could be damaged if the traffic is examined or tampered with by unauthorized individuals.

Preventing Fraudulent Route Updates

All routing devices determine where to route individual packets by using information stored in route tables. This route table information is created using route updates obtained from neighboring routers.

If a router receives a fraudulent update, the router could be tricked into forwarding traffic to the wrong destination. This could cause sensitive data to be exposed, or could cause network communications to be interrupted.

To ensure that route updates are received only from known, trusted neighbor routers, configure neighbor router authentication as described in the chapter “Neighbor Router Authentication: Overview and Guidelines.”

Authentication, Authorization, and Accounting (AAA)

AAA Overview

Access control is the way you control who is allowed access to the network server and what services they are allowed to use once they have access. Authentication, authorization, and accounting (AAA) network security services provide the primary framework through which you set up access control on your router or access server.

In This Chapter

This chapter includes the following sections:

- [About AAA Security Services](#)
- [Where to Begin](#)
- [What to Do Next](#)

About AAA Security Services

AAA is an architectural framework for configuring a set of three independent security functions in a consistent manner. AAA provides a modular way of performing the following services:

- **Authentication**—Provides the method of identifying users, including login and password dialog, challenge and response, messaging support, and, depending on the security protocol you select, encryption.

Authentication is the way a user is identified prior to being allowed access to the network and network services. You configure AAA authentication by defining a named list of authentication methods, and then applying that list to various interfaces. The method list defines the types of authentication to be performed and the sequence in which they will be performed; it must be applied to a specific interface before any of the defined authentication methods will be performed. The only exception is the default method list (which is named “default”). The default method list is automatically applied to all interfaces if no other method list is defined. A defined method list overrides the default method list.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

All authentication methods, except for local, line password, and enable authentication, must be defined through AAA. For information about configuring all authentication methods, including those implemented outside of the AAA security services, refer to the chapter “Configuring Authentication.”

- **Authorization**—Provides the method for remote access control, including one-time authorization or authorization for each service, per-user account list and profile, user group support, and support of IP, IPX, ARA, and Telnet.

AAA authorization works by assembling a set of attributes that describe what the user is authorized to perform. These attributes are compared to the information contained in a database for a given user and the result is returned to AAA to determine the user’s actual capabilities and restrictions. The database can be located locally on the access server or router or it can be hosted remotely on a RADIUS or TACACS+ security server. Remote security servers, such as RADIUS and TACACS+, authorize users for specific rights by associating attribute-value (AV) pairs, which define those rights with the appropriate user. All authorization methods must be defined through AAA.

As with authentication, you configure AAA authorization by defining a named list of authorization methods, and then applying that list to various interfaces. For information about configuring authorization using AAA, refer to the chapter “Configuring Authorization.”

- **Accounting**—Provides the method for collecting and sending security server information used for billing, auditing, and reporting, such as user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

Accounting enables you to track the services users are accessing as well as the amount of network resources they are consuming. When AAA accounting is activated, the network access server reports user activity to the RADIUS or TACACS+ security server (depending on which security method you have implemented) in the form of accounting records. Each accounting record is comprised of accounting AV pairs and is stored on the access control server. This data can then be analyzed for network management, client billing, and/or auditing. All accounting methods must be defined through AAA. As with authentication and authorization, you configure AAA accounting by defining a named list of accounting methods, and then applying that list to various interfaces. For information about configuring accounting using AAA, refer to the chapter “Configuring Accounting.”

In many circumstances, AAA uses protocols such as RADIUS, TACACS+, or Kerberos to administer its security functions. If your router or access server is acting as a network access server, AAA is the means through which you establish communication between your network access server and your RADIUS, TACACS+, or Kerberos security server.

Although AAA is the primary (and recommended) method for access control, Cisco IOS software provides additional features for simple access control that are outside the scope of AAA, such as local username authentication, line password authentication, and enable password authentication. However, these features do not provide the same degree of access control that is possible by using AAA.

This section includes the following sections:

- [Benefits of Using AAA](#)
- [AAA Philosophy](#)
- [Method Lists](#)

Benefits of Using AAA

AAA provides the following benefits:

- Increased flexibility and control of access configuration

- Scalability
- Standardized authentication methods, such as RADIUS, TACACS+, and Kerberos
- Multiple backup systems

**Note**

The deprecated protocols, TACACS and extended TACACS, are not compatible with AAA; if you select these security protocols, you will not be able to take advantage of the AAA security services.

AAA Philosophy

AAA is designed to enable you to dynamically configure the type of authentication and authorization you want on a per-line (per-user) or per-service (for example, IP, IPX, or VPDN) basis. You define the type of authentication and authorization you want by creating method lists, then applying those method lists to specific services or interfaces.

For information about applications that use AAA, such as per-user configuration and virtual profiles, refer to the chapters “Configuring Per-User Configuration” and “Configuring Virtual Profiles” in the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.2.

Method Lists

A method list is a sequential list that defines the authentication methods used to authenticate a user. Method lists enable you to designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. Cisco IOS software uses the first method listed to authenticate users; if that method does not respond, Cisco IOS software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or the authentication method list is exhausted, in which case authentication fails.

**Note**

Cisco IOS software attempts authentication with the next listed authentication method only when there is no response from the previous method. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops and no other authentication methods are attempted.

[Figure 1](#) shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers.

Figure 1 Typical AAA Network Configuration

Suppose the system administrator has defined a method list where R1 will be contacted first for authentication information, then R2, T1, T2, and finally the local username database on the access server itself. When a remote user attempts to dial in to the network, the network access server first queries R1 for authentication information. If R1 authenticates the user, it issues a PASS response to the network access server and the user is allowed to access the network. If R1 returns a FAIL response, the user is denied access and the session is terminated. If R1 does not respond, then the network access server processes that as an ERROR and queries R2 for authentication information. This pattern continues through the remaining designated methods until the user is either authenticated or rejected, or until the session is terminated. If all of the authentication methods return errors, the network access server will process the session as a failure, and the session will be terminated.

**Note**

A FAIL response is significantly different from an ERROR. A FAIL means that the user has not met the criteria contained in the applicable authentication database to be successfully authenticated. Authentication ends with a FAIL response. An ERROR means that the security server has not responded to an authentication query. Because of this, no authentication has been attempted. Only when an ERROR is detected will AAA select the next authentication method defined in the authentication method list.

Where to Begin

You must first decide what kind of security solution you want to implement. You need to assess the security risks in your particular network and decide on the appropriate means to prevent unauthorized entry and attack. For more information about assessing your security risks and possible security solutions, refer to the chapter “Security Overview.” Cisco recommends that you use AAA, no matter how minor your security needs might be.

This section includes the following subsections:

- [Overview of the AAA Configuration Process](#)
- [Enabling AAA](#)
- [Disabling AAA](#)

Overview of the AAA Configuration Process

Configuring AAA is relatively simple after you understand the basic process involved. To configure security on a Cisco router or access server using AAA, follow this process:

1. Enable AAA by using the **aaa new-model** global configuration command.
2. If you decide to use a separate security server, configure security protocol parameters, such as RADIUS, TACACS+, or Kerberos.
3. Define the method lists for authentication by using an AAA authentication command.
4. Apply the method lists to a particular interface or line, if required.
5. (Optional) Configure authorization using the **aaa authorization** command.
6. (Optional) Configure accounting using the **aaa accounting** command.

For a complete description of the commands used in this chapter, refer to the chapter “Authentication Commands” of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

Enabling AAA

Note

Before you can use any of the services AAA network security services provide, you must enable AAA.

When you enable AAA, you can no longer access the commands to configure the older protocols, TACACS or extended TACACS. If you decided to use TACACS or extended TACACS in your security solution, do not enable AAA.

To enable AAA, use the following command in global configuration mode:

Command	Purpose
Router (config)# aaa new-model	Enables AAA.

Disabling AAA

You can disable AAA functionality with a single command if you decide that your security needs cannot be met by AAA but can be met by using TACACS, extended TACACS, or a line security method that can be implemented without AAA. To disable AAA, use the following command in global configuration mode:

Command	Purpose
Router(config)# no aaa new-model	Disables AAA.

What to Do Next

Once you have enabled AAA, you are ready to configure the other elements relating to your selected security solution. [Table 3](#) describes AAA configuration tasks and where to find more information.

Table 3 **AAA Access Control Security Solutions Methods**

Task	Chapter in the <i>Cisco IOS Security Configuration Guide</i>
Configuring local login authentication	“Configuring Authentication”
Controlling login using security server authentication	“Configuring Authentication”
Defining method lists for authentication	“Configuring Authentication”
Applying method lists to a particular interface or line	“Configuring Authentication”
Configuring RADIUS security protocol parameters	“Configuring RADIUS”
Configuring TACACS+ security protocol parameters	“Configuring TACACS+”
Configuring Kerberos security protocol parameters	“Configuring Kerberos”
Enabling TACACS+ authorization	“Configuring Authorization”
Enabling RADIUS authorization	“Configuring Authorization”
Viewing supported IETF RADIUS attributes	“RADIUS Attributes” (Appendix)
Viewing supported vendor-specific RADIUS attributes	“RADIUS Attributes” (Appendix)
Viewing supported TACACS+ AV pairs	“TACACS+ AV Pairs” (Appendix)
Enabling accounting	“Configuring Accounting”

If you have elected not to use the AAA security services, see the “Configuring Authentication” chapter for the non-AAA configuration task “Configuring Login Authentication.”

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Authentication

Configuring Authentication

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Authentication verifies users before they are allowed access to the network and network services. The Cisco IOS software implementation of authentication is divided into two main categories:

- [AAA Authentication Methods Configuration Task List](#)
- [Non-AAA Authentication Methods](#)

Authentication, for the most part, is implemented through the AAA security services. Cisco recommends that, whenever possible, AAA be used to implement authentication.

This chapter describes both AAA and non-AAA authentication methods. For authentication configuration examples, refer to the “[Authentication Examples](#)” section at the end of this chapter. For a complete description of the AAA commands used in this chapter, refer to the “Authentication, Authorization, and Accounting (AAA)” part of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature, or refer to the software release notes for a specific release. For more information, see the section “Identifying Supported Platforms” in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter contains the following sections:

- [Named Method Lists for Authentication](#)
- [AAA Authentication Methods Configuration Task List](#)

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

- [Non-AAA Authentication Methods](#)
- [Authentication Examples](#)

Named Method Lists for Authentication

To configure AAA authentication, you must first define a named list of authentication methods, and then apply that list to various interfaces. The method list defines the types of authentication to be performed and the sequence in which they will be performed; it must be applied to a specific interface before any of the defined authentication methods will be performed. The only exception is the default method list (which is named “default”). The default method list is automatically applied to all interfaces except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list is a sequential list describing the authentication methods to be queried in order to authenticate a user. Method lists enable you to designate one or more security protocols to be used for authentication, thus ensuring a backup system for authentication in case the initial method fails. Cisco IOS software uses the first listed method to authenticate users. If that method fails to respond, the Cisco IOS software selects the next authentication method listed in the method list. This process continues until there is successful communication with a listed authentication method, or all methods defined in the method list are exhausted.

It is important to note that the Cisco IOS software attempts authentication with the next listed authentication method only when there is no response from the previous method. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops and no other authentication methods are attempted.

**Note**

Effective with Cisco IOS Release 12.3, the number of AAA method lists that can be configured is 250.

This section contains the following subsections:

- [Method Lists and Server Groups](#)
- [Method List Examples](#)
- [AAA Authentication General Configuration Procedure](#)

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. [Figure 2](#) shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers and T1 and T2 are TACACS+ servers. R1 and R2 make up the group of RADIUS servers. T1 and T2 make up the group of TACACS+ servers.

Figure 2 **Typical AAA Network Configuration**

Using server groups, you can specify a subset of the configured server hosts and use them for a particular service. For example, server groups allow you to define R1 and R2 as a server group, and define T1 and T2 as a separate server group. For example, you can specify R1 and T1 in the method list for authentication login, while specifying R2 and T2 in the method list for PPP authentication.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, authentication—the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order in which they are configured.)

For more information about configuring server groups and about configuring server groups based on Dialed Number Identification Service (DNIS) numbers, refer to the “Configuring RADIUS” or “Configuring TACACS+” chapter.

Method List Examples

Suppose the system administrator has decided on a security solution where all interfaces will use the same authentication methods to authenticate PPP connections. In the RADIUS group, R1 is contacted first for authentication information, then if there is no response, R2 is contacted. If R2 does not respond, T1 in the TACACS+ group is contacted; if T1 does not respond, T2 is contacted. If all designated servers fail to respond, authentication falls to the local username database on the access server itself. To implement this solution, the system administrator would create a default method list by entering the following command:

```
aaa authentication ppp default group radius group tacacs+ local
```

In this example, “default” is the name of the method list. The protocols included in this method list are listed after the name, in the order they are to be queried. The default list is automatically applied to all interfaces.

When a remote user attempts to dial in to the network, the network access server first queries R1 for authentication information. If R1 authenticates the user, it issues a PASS response to the network access server and the user is allowed to access the network. If R1 returns a FAIL response, the user is denied access and the session is terminated. If R1 does not respond, then the network access server processes that as an ERROR and queries R2 for authentication information. This pattern would continue through the remaining designated methods until the user is either authenticated or rejected, or until the session is terminated.

It is important to remember that a FAIL response is significantly different from an ERROR. A FAIL means that the user has not met the criteria contained in the applicable authentication database to be successfully authenticated. Authentication ends with a FAIL response. An ERROR means that the security server has not responded to an authentication query. Because of this, no authentication has been attempted. Only when an ERROR is detected will AAA select the next authentication method defined in the authentication method list.

Suppose the system administrator wants to apply a method list only to a particular interface or set of interfaces. In this case, the system administrator creates a named method list and then applies this named list to the applicable interfaces. The following example shows how the system administrator can implement an authentication method that will be applied only to interface 3:

```
aaa authentication ppp default group radius group tacacs+ local
aaa authentication ppp apple group radius group tacacs+ local none
interface async 3
 ppp authentication chap apple
```

In this example, “apple” is the name of the method list, and the protocols included in this method list are listed after the name in the order in which they are to be performed. After the method list has been created, it is applied to the appropriate interface. Note that the method list name (apple) in both the AAA and PPP authentication commands must match.

In the following example, the system administrator uses server groups to specify that only R2 and T2 are valid servers for PPP authentication. To do this, the administrator must define specific server groups whose members are R2 (172.16.2.7) and T2 (172.16.2.77), respectively. In this example, the RADIUS server group “rad2only” is defined as follows using the **aaa group server** command:

```
aaa group server radius rad2only
 server 172.16.2.7
```

The TACACS+ server group “tac2only” is defined as follows using the **aaa group server** command:

```
aaa group server tacacs+ tac2only
 server 172.16.2.77
```

The administrator then applies PPP authentication using the server groups. In this example, the default methods list for PPP authentication follows this order: **group rad2only**, **group tac2only**, and **local**:

```
aaa authentication ppp default group rad2only group tac2only local
```

AAA Authentication General Configuration Procedure

To configure AAA authentication, perform the following tasks:

1. Enable AAA by using the **aaa new-model** global configuration command. For more information about configuring AAA, refer to the chapter “AAA Overview”.
2. Configure security protocol parameters, such as RADIUS, TACACS+, or Kerberos if you are using a security server. For more information about RADIUS, refer to the chapter “Configuring RADIUS”. For more information about TACACS+, refer to the chapter “Configuring TACACS+”. For more information about Kerberos, refer to the chapter “Configuring Kerberos”.

3. Define the method lists for authentication by using an AAA authentication command.
4. Apply the method lists to a particular interface or line, if required.

AAA Authentication Methods Configuration Task List

This section discusses the following AAA authentication methods:

- [Configuring Login Authentication Using AAA](#)
- [Configuring PPP Authentication Using AAA](#)
- [Configuring AAA Scalability for PPP Requests](#)
- [Configuring ARAP Authentication Using AAA](#)
- [Configuring NASI Authentication Using AAA](#)
- [Specifying the Amount of Time for Login Input](#)
- [Enabling Password Protection at the Privileged Level](#)
- [Changing the Text Displayed at the Password Prompt](#)
- [Configuring Message Banners for AAA Authentication](#)
- [Configuring AAA Packet of Disconnect](#)
- [Enabling Double Authentication](#)
- [Enabling Automated Double Authentication](#)

Note

AAA features are not available for use until you enable AAA globally by issuing the **aaa new-model** command. For more information about enabling AAA, refer to the “AAA Overview” chapter.

For authentication configuration examples using the commands in this chapter, refer to the section “[Authentication Examples](#)” at the end of the this chapter.

Configuring Login Authentication Using AAA

The AAA security services facilitate a variety of login authentication methods. Use the **aaa authentication login** command to enable AAA authentication no matter which of the supported login authentication methods you decide to use. With the **aaa authentication login** command, you create one or more lists of authentication methods that are tried at login. These lists are applied using the **login authentication** line configuration command.

To configure login authentication by using AAA, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA globally.
Step 2	Router(config)# aaa authentication login {default list-name} method1 [method2...]	Creates a local authentication list.

	Command	Purpose
Step 3	Router(config)# line [aux console tty vty] line-number [ending-line-number]	Enters line configuration mode for the lines to which you want to apply the authentication list.
Step 4	Router(config-line)# login authentication { default <i>list-name</i> }	Applies the authentication list to a line or set of lines.

The *list-name* is a character string used to name the list you are creating. The method argument refers to the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

For example, to specify that authentication should succeed even if (in this example) the TACACS+ server returns an error, enter the following command:

```
aaa authentication login default group tacacs+ none
```

Note

Because the **none** keyword enables *any* user logging in to successfully authenticate, it should be used only as a backup method of authentication.

To create a default list that is used when a named list is *not* specified in the **login authentication** command, use the **default** keyword followed by the methods that are to be used in default situations. The default method list is automatically applied to all interfaces.

For example, to specify RADIUS as the default method for user authentication during login, enter the following command:

```
aaa authentication login default group radius
```

Table 4 lists the supported login authentication methods.

Table 4 AAA Authentication Login Methods

Keyword	Description
enable	Uses the enable password for authentication.
krb5	Uses Kerberos 5 for authentication.
krb5-telnet	Uses Kerberos 5 Telnet authentication protocol when using Telnet to connect to the router. If selected, this keyword must be listed as the first method in the method list.
line	Uses the line password for authentication.
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group <i>group-name</i>	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

**Note**

The **login** command only changes username and privilege level but does not execute a shell; therefore autocommands will not be executed. To execute autocommands under this circumstance, you need to establish a Telnet session back into the router (loop-back). Make sure that the router has been configured for secure Telnet sessions if you choose to implement autocommands this way.

This section includes the following sections:

- [Login Authentication Using Enable Password](#)
- [Login Authentication Using Kerberos](#)
- [Login Authentication Using Line Password](#)
- [Login Authentication Using Local Password](#)
- [Login Authentication Using Group RADIUS](#)
- [Login Authentication Using Group TACACS+](#)
- [Login Authentication Using group group-name](#)

Login Authentication Using Enable Password

Use the **aaa authentication login** command with the **enable method** keyword to specify the enable password as the login authentication method. For example, to specify the enable password as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default enable
```

Before you can use the enable password as the login authentication method, you need to define the enable password. For more information about defining enable passwords, refer to the chapter “Configuring Passwords and Privileges.”

Login Authentication Using Kerberos

Authentication via Kerberos is different from most other authentication methods: the user’s password is never sent to the remote access server. Remote users logging in to the network are prompted for a username. If the key distribution center (KDC) has an entry for that user, it creates an encrypted ticket granting ticket (TGT) with the password for that user and sends it back to the router. The user is then prompted for a password, and the router attempts to decrypt the TGT with that password. If it succeeds, the user is authenticated and the TGT is stored in the user’s credential cache on the router.

While **krb5** does use the KINIT program, a user does not need to run the KINIT program to get a TGT to authenticate to the router. This is because KINIT has been integrated into the login procedure in the Cisco IOS implementation of Kerberos.

Use the **aaa authentication login** command with the **krb5 method** keyword to specify Kerberos as the login authentication method. For example, to specify Kerberos as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default krb5
```

Before you can use Kerberos as the login authentication method, you need to enable communication with the Kerberos security server. For more information about establishing communication with a Kerberos server, refer to the chapter “Configuring Kerberos.”

Login Authentication Using Line Password

Use the **aaa authentication login** command with the **line method** keyword to specify the line password as the login authentication method. For example, to specify the line password as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default line
```

Before you can use a line password as the login authentication method, you need to define a line password. For more information about defining line passwords, refer to the section [“Configuring Line Password Protection”](#) in this chapter.

Login Authentication Using Local Password

Use the **aaa authentication login** command with the **local method** keyword to specify that the Cisco router or access server will use the local username database for authentication. For example, to specify the local username database as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default local
```

For information about adding users into the local username database, refer to the section [“Establishing Username Authentication”](#) in this chapter.

Login Authentication Using Group RADIUS

Use the **aaa authentication login** command with the **group radius method** to specify RADIUS as the login authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default group radius
```

Before you can use RADIUS as the login authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

Configuring RADIUS Attribute 8 in Access Requests

Once you have used the **aaa authentication login** command to specify RADIUS and your login host has been configured to request its IP address from the NAS, you can send attribute 8 (Framed-IP-Address) in access-request packets by using the **radius-server attribute 8 include-in-access-req** command in global configuration mode. This command makes it possible for a NAS to provide the RADIUS server with a hint of the user IP address in advance of user authentication. For more information about attribute 8, refer to the appendix “RADIUS Attributes” at the end of the book.

Login Authentication Using Group TACACS+

Use the **aaa authentication login** command with the **group tacacs+ method** to specify TACACS+ as the login authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default group tacacs+
```

Before you can use TACACS+ as the login authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Login Authentication Using group group-name

Use the **aaa authentication login** command with the **group group-name** method to specify a subset of RADIUS or TACACS+ servers to use as the login authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group loginrad**:

```
aaa group server radius loginrad
  server 172.16.2.3
  server 172.16.2.17
  server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *loginrad*.

To specify **group loginrad** as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication login default group loginrad
```

Before you can use a group name as the login authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.” For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Configuring PPP Authentication Using AAA

Many users access network access servers through dialup via async or ISDN. Dialup via async or ISDN bypasses the CLI completely; instead, a network protocol (such as PPP or ARA) starts as soon as the connection is established.

The AAA security services facilitate a variety of authentication methods for use on serial interfaces running PPP. Use the **aaa authentication ppp** command to enable AAA authentication no matter which of the supported PPP authentication methods you decide to use.

To configure AAA authentication methods for serial lines using PPP, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA globally.
Step 2	Router(config)# aaa authentication ppp {default list-name} method1 [method2...]	Creates a local authentication list.

	Command	Purpose
Step 3	Router(config)# interface <i>interface-type</i> <i>interface-number</i>	Enters interface configuration mode for the interface to which you want to apply the authentication list.
Step 4	Router(config-if)# ppp authentication { <i>protocol1</i> [<i>protocol2</i> ...]} [if-needed] [default <i>list-name</i>] [callin] [one-time] [optional]	Applies the authentication list to a line or set of lines. In this command, <i>protocol1</i> and <i>protocol2</i> represent the following protocols: CHAP, MS-CHAP, and PAP. PPP authentication is attempted first using the first authentication method, specified by <i>protocol1</i> . If <i>protocol1</i> is unable to establish authentication, the next configured protocol is used to negotiate authentication.

With the **aaa authentication ppp** command, you create one or more lists of authentication methods that are tried when a user tries to authenticate via PPP. These lists are applied using the **ppp authentication** line configuration command.

To create a default list that is used when a named list is *not* specified in the **ppp authentication** command, use the **default** keyword followed by the methods you want used in default situations.

For example, to specify the local username database as the default method for user authentication, enter the following command:

```
aaa authentication ppp default local
```

The *list-name* is any character string used to name the list you are creating. The method argument refers to the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

For example, to specify that authentication should succeed even if (in this example) the TACACS+ server returns an error, enter the following command:

```
aaa authentication ppp default group tacacs+ none
```

Note

Because **none** allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

Table 5 lists the supported login authentication methods.

Table 5 AAA Authentication PPP Methods

Keyword	Description
if-needed	Does not authenticate if user has already been authenticated on a TTY line.
krb5	Uses Kerberos 5 for authentication (can only be used for PAP authentication).
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS servers for authentication.

Table 5 **AAA Authentication PPP Methods (continued)**

Keyword	Description
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group <i>group-name</i>	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

This section includes the following sections:

- [PPP Authentication Using Kerberos](#)
- [PPP Authentication Using Local Password](#)
- [PPP Authentication Using Group RADIUS](#)
- [PPP Authentication Using Group TACACS+](#)
- [PPP Authentication Using group group-name](#)

PPP Authentication Using Kerberos

Use the **aaa authentication ppp** command with the **krb5 method** keyword to specify Kerberos as the authentication method for use on interfaces running PPP. For example, to specify Kerberos as the method of user authentication when no other method list has been defined, enter the following command:

```
aaa authentication ppp default krb5
```

Before you can use Kerberos as the PPP authentication method, you need to enable communication with the Kerberos security server. For more information about establishing communication with a Kerberos server, refer to the chapter “Configuring Kerberos”.

**Note**

Kerberos login authentication works only with PPP PAP authentication.

PPP Authentication Using Local Password

Use the **aaa authentication ppp** command with the *method* keyword **local** to specify that the Cisco router or access server will use the local username database for authentication. For example, to specify the local username database as the method of authentication for use on lines running PPP when no other method list has been defined, enter the following command:

```
aaa authentication ppp default local
```

For information about adding users into the local username database, refer to the section “[Establishing Username Authentication](#)” in this chapter.

PPP Authentication Using Group RADIUS

Use the **aaa authentication ppp** command with the **group radius method** to specify RADIUS as the login authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication ppp default group radius
```

Before you can use RADIUS as the PPP authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

Configuring RADIUS Attribute 44 in Access Requests

Once you have used the **aaa authentication ppp** command with the **group radius method** to specify RADIUS as the login authentication method, you can configure your router to send attribute 44 (Acct-Section-ID) in access-request packets by using the **radius-server attribute 44 include-in-access-req** command in global configuration mode. This command allows the RADIUS daemon to track a call from the beginning of the call to the end of the call. For more information on attribute 44, refer to the appendix “RADIUS Attributes” at the end of the book.

PPP Authentication Using Group TACACS+

Use the **aaa authentication ppp** command with the **group tacacs+ method** to specify TACACS+ as the login authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication ppp default group tacacs+
```

Before you can use TACACS+ as the PPP authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

PPP Authentication Using group group-name

Use the **aaa authentication ppp** command with the **group group-name method** to specify a subset of RADIUS or TACACS+ servers to use as the login authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group ppprad**:

```
aaa group server radius ppprad
server 172.16.2.3
server 172.16.2.17
server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *ppprad*.

To specify **group ppprad** as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication ppp default group ppprad
```

Before you can use a group name as the PPP authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS”. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Configuring AAA Scalability for PPP Requests

You can configure and monitor the number of background processes allocated by the PPP manager in the network access server (NAS) to deal with AAA authentication and authorization requests. In previous Cisco IOS releases, only one background process was allocated to handle all AAA requests for PPP. This meant that parallelism in AAA servers could not be fully exploited. The AAA Scalability feature enables you to configure the number of processes used to handle AAA requests for PPP, thus increasing the number of users that can be simultaneously authenticated or authorized.

To allocate a specific number of background processes to handle AAA requests for PPP, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa processes <i>number</i>	Allocates a specific number of background processes to handle AAA authentication and authorization requests for PPP.

The argument *number* defines the number of background processes earmarked to process AAA authentication and authorization requests for PPP and can be configured for any value from 1 to 2147483647. Because of the way the PPP manager handles requests for PPP, this argument also defines the number of new users that can be simultaneously authenticated. This argument can be increased or decreased at any time.

Note

Allocating additional background processes can be expensive. You should configure the minimum number of background processes capable of handling the AAA requests for PPP.

Configuring ARAP Authentication Using AAA

With the **aaa authentication arap** command, you create one or more lists of authentication methods that are tried when AppleTalk Remote Access Protocol (ARAP) users attempt to log in to the router. These lists are used with the **arap authentication** line configuration command.

Use the following commands starting in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA globally.
Step 2	Router(config)# aaa authentication arap { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]	Enables authentication for ARAP users.
Step 3	Router(config)# line <i>number</i>	(Optional) Changes to line configuration mode.
Step 4	Router(config-line)# autoselect arap	(Optional) Enables autoselection of ARAP.
Step 5	Router(config-line)# autoselect during-login	(Optional) Starts the ARAP session automatically at user login.
Step 6	Router(config-line)# arap authentication <i>list-name</i>	(Optional—not needed if default is used in the aaa authentication arap command) Enables TACACS+ authentication for ARAP on a line.

The *list-name* is any character string used to name the list you are creating. The method argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered.

To create a default list that is used when a named list is *not* specified in the **arap authentication** command, use the **default** keyword followed by the methods you want to be used in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

**Note**

Because **none** allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

Table 6 lists the supported login authentication methods.

Table 6 **AAA Authentication ARAP Methods**

Keyword	Description
auth-guest	Allows guest logins only if the user has already logged in to EXEC.
guest	Allows guest logins.
line	Uses the line password for authentication.
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group <i>group-name</i>	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

For example, to create a default AAA authentication method list used with ARAP, enter the following command:

```
aaa authentication arap default if-needed none
```

To create the same authentication method list for ARAP but name the list *MIS-access*, enter the following command:

```
aaa authentication arap MIS-access if-needed none
```

This section includes the following sections:

- [ARAP Authentication Allowing Authorized Guest Logins](#)
- [ARAP Authentication Allowing Guest Logins](#)
- [ARAP Authentication Using Line Password](#)
- [ARAP Authentication Using Local Password](#)
- [ARAP Authentication Using Group RADIUS](#)
- [ARAP Authentication Using Group TACACS+](#)
- [ARAP Authentication Using Group group-name](#)

ARAP Authentication Allowing Authorized Guest Logins

Use the **aaa authentication arap** command with the **auth-guest** keyword to allow guest logins only if the user has already successfully logged in to the EXEC. This method must be the first listed in the ARAP authentication method list but it can be followed by other methods if it does not succeed. For example, to allow all authorized guest logins—meaning logins by users who have already successfully logged in to the EXEC—as the default method of authentication, using RADIUS only if that method fails, enter the following command:

```
aaa authentication arap default auth-guest group radius
```

For more information about ARAP authorized guest logins, refer to the chapter “Configuring AppleTalk” in the *Cisco IOS AppleTalk and Novell IPX Configuration Guide*.

Note

By default, guest logins through ARAP are disabled when you initialize AAA. To allow guest logins, you must use the **aaa authentication arap** command with either the **guest** or the **auth-guest** keyword.

ARAP Authentication Allowing Guest Logins

Use the **aaa authentication arap** command with the **guest** keyword to allow guest logins. This method must be the first listed in the ARAP authentication method list but it can be followed by other methods if it does not succeed. For example, to allow all guest logins as the default method of authentication, using RADIUS only if that method fails, enter the following command:

```
aaa authentication arap default guest group radius
```

For more information about ARAP guest logins, refer to the chapter “Configuring AppleTalk” in the *Cisco IOS AppleTalk and Novell IPX Configuration Guide*.

ARAP Authentication Using Line Password

Use the **aaa authentication arap** command with the *method* keyword **line** to specify the line password as the authentication method. For example, to specify the line password as the method of ARAP user authentication when no other method list has been defined, enter the following command:

```
aaa authentication arap default line
```

Before you can use a line password as the ARAP authentication method, you need to define a line password. For more information about defining line passwords, refer to the section “[Configuring Line Password Protection](#)” in this chapter.

ARAP Authentication Using Local Password

Use the **aaa authentication arap** command with the *method* keyword **local** to specify that the Cisco router or access server will use the local username database for authentication. For example, to specify the local username database as the method of ARAP user authentication when no other method list has been defined, enter the following command:

```
aaa authentication arap default local
```

For information about adding users to the local username database, refer to the section “[Establishing Username Authentication](#)” in this chapter.

ARAP Authentication Using Group RADIUS

Use the **aaa authentication arap** command with the **group radius** *method* to specify RADIUS as the ARAP authentication method. For example, to specify RADIUS as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication arap default group radius
```

Before you can use RADIUS as the ARAP authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

ARAP Authentication Using Group TACACS+

Use the **aaa authentication arap** command with the **group tacacs+** *method* to specify TACACS+ as the ARAP authentication method. For example, to specify TACACS+ as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication arap default group tacacs+
```

Before you can use TACACS+ as the ARAP authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

ARAP Authentication Using Group group-name

Use the **aaa authentication arap** command with the **group group-name** *method* to specify a subset of RADIUS or TACACS+ servers to use as the ARAP authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group araprad**:

```
aaa group server radius araprad
server 172.16.2.3
server 172.16.2.17
server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *araprad*.

To specify **group araprad** as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication arap default group araprad
```

Before you can use a group name as the ARAP authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.” For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Configuring NASL Authentication Using AAA

With the **aaa authentication nasi** command, you create one or more lists of authentication methods that are tried when NetWare Asynchronous Services Interface (NASI) users attempt to log in to the router. These lists are used with the **nasi authentication** line configuration command.

To configure NASI authentication using AAA, use the following commands starting in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA globally.
Step 2	Router(config)# aaa authentication nasi { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]	Enables authentication for NASI users.
Step 3	Router(config)# line <i>number</i>	(Optional—not needed if default is used in the aaa authentication nasi command) Enters line configuration mode.
Step 4	Router(config-line)# nasi authentication <i>list-name</i>	(Optional—not needed if default is used in the aaa authentication nasi command) Enables authentication for NASI on a line.

The *list-name* is any character string used to name the list you are creating. The method argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered.

To create a default list that is used when a named list is *not* specified in the **aaa authentication nasi** command, use the **default** keyword followed by the methods you want to be used in default situations.

The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

Note

Because **none** allows all users logging in to authenticate successfully, it should be used as a backup method of authentication.

Table 7 lists the supported NASI authentication methods.

Table 7 AAA Authentication NASI Methods

Keyword	Description
enable	Uses the enable password for authentication.
line	Uses the line password for authentication.
local	Uses the local username database for authentication.
local-case	Uses case-sensitive local username authentication.
none	Uses no authentication.
group radius	Uses the list of all RADIUS servers for authentication.
group tacacs+	Uses the list of all TACACS+ servers for authentication.
group <i>group-name</i>	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

This section includes the following sections:

- [NASI Authentication Using Enable Password](#)
- [NASI Authentication Using Line Password](#)
- [NASI Authentication Using Local Password](#)

- [NASI Authentication Using Group RADIUS](#)
- [NASI Authentication Using Group TACACS+](#)
- [NASI Authentication Using group group-name](#)

NASI Authentication Using Enable Password

Use the **aaa authentication nasi** command with the *method* keyword **enable** to specify the enable password as the authentication method. For example, to specify the enable password as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default enable
```

Before you can use the enable password as the authentication method, you need to define the enable password. For more information about defining enable passwords, refer to the chapter “Configuring Passwords and Privileges.”

NASI Authentication Using Line Password

Use the **aaa authentication nasi** command with the *method* keyword **line** to specify the line password as the authentication method. For example, to specify the line password as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default line
```

Before you can use a line password as the NASI authentication method, you need to define a line password. For more information about defining line passwords, refer to the section “[Configuring Line Password Protection](#)” in this chapter.

NASI Authentication Using Local Password

Use the **aaa authentication nasi** command with the *method* keyword **local** to specify that the Cisco router or access server will use the local username database for authentication information. For example, to specify the local username database as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default local
```

For information about adding users to the local username database, refer to the section “[Establishing Username Authentication](#)” in this chapter.

NASI Authentication Using Group RADIUS

Use the **aaa authentication nasi** command with the **group radius** *method* to specify RADIUS as the NASI authentication method. For example, to specify RADIUS as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default group radius
```

Before you can use RADIUS as the NASI authentication method, you need to enable communication with the RADIUS security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS.”

NASI Authentication Using Group TACACS+

Use the **aaa authentication nasi** command with the **group tacacs+ method** keyword to specify TACACS+ as the NASI authentication method. For example, to specify TACACS+ as the method of NASI user authentication when no other method list has been defined, enter the following command:

```
aaa authentication nasi default group tacacs+
```

Before you can use TACACS+ as the authentication method, you need to enable communication with the TACACS+ security server. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

NASI Authentication Using group group-name

Use the **aaa authentication nasi** command with the **group group-name** method to specify a subset of RADIUS or TACACS+ servers to use as the NASI authentication method. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group nasirad**:

```
aaa group server radius nasirad
server 172.16.2.3
server 172.16.2.17
server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *nasirad*.

To specify **group nasirad** as the method of user authentication at login when no other method list has been defined, enter the following command:

```
aaa authentication nasi default group nasirad
```

Before you can use a group name as the NASI authentication method, you need to enable communication with the RADIUS or TACACS+ security server. For more information about establishing communication with a RADIUS server, refer to the chapter “Configuring RADIUS”. For more information about establishing communication with a TACACS+ server, refer to the chapter “Configuring TACACS+.”

Specifying the Amount of Time for Login Input

The **timeout login response** command allows you to specify how long the system will wait for login input (such as username and password) before timing out. The default login value is 30 seconds; with the **timeout login response** command, you can specify a timeout value from 1 to 300 seconds. To change the login timeout value from the default of 30 seconds, use the following command in line configuration mode:

Command	Purpose
Router(config-line)# timeout login response <i>seconds</i>	Specifies how long the system will wait for login information before timing out.

Enabling Password Protection at the Privileged Level

Use the **aaa authentication enable default** command to create a series of authentication methods that are used to determine whether a user can access the privileged EXEC command level. You can specify up to four authentication methods. The additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all methods return an error, specify **none** as the final method in the command line.

Use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa authentication enable default <i>method1 [method2...]</i>	<p>Enables user ID and password checking for users requesting privileged EXEC level.</p> <p>Note All aaa authentication enable default requests sent by the router to a RADIUS server include the username "\$enab15\$." Requests sent to a TACACS+ server will include the username that is entered for login authentication.</p>

The method argument refers to the actual list of methods the authentication algorithm tries, in the sequence entered. [Table 8](#) lists the supported enable authentication methods.

Table 8 AAA Authentication Enable Default Methods

Keyword	Description
enable	Uses the enable password for authentication.
line	Uses the line password for authentication.
none	Uses no authentication.
group radius	<p>Uses the list of all RADIUS hosts for authentication.</p> <p>Note The RADIUS method does not work on a per-username basis.</p>
group tacacs+	Uses the list of all TACACS+ hosts for authentication.
group <i>group-name</i>	Uses a subset of RADIUS or TACACS+ servers for authentication as defined by the aaa group server radius or aaa group server tacacs+ command.

Changing the Text Displayed at the Password Prompt

Use the **aaa authentication password-prompt** command to change the default text that the Cisco IOS software displays when prompting a user to enter a password. This command changes the password prompt for the enable password as well as for login passwords that are not supplied by remote security servers. The **no** form of this command returns the password prompt to the following default value:

Password:

The **aaa authentication password-prompt** command does not change any dialog that is supplied by a remote TACACS+ or RADIUS server.

The **aaa authentication password-prompt** command works when RADIUS is used as the login method. You will be able to see the password prompt defined in the command shown even when the RADIUS server is unreachable. The **aaa authentication password-prompt** command does not work with

TACACS+. TACACS+ supplies the NAS with the password prompt to display to the users. If the TACACS+ server is reachable, the NAS gets the password prompt from the server and uses that prompt instead of the one defined in the **aaa authentication password-prompt** command. If the TACACS+ server is not reachable, the password prompt defined in the **aaa authentication password-prompt** command may be used.

Use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa authentication password-prompt <i>text-string</i>	Changes the default text displayed when a user is prompted to enter a password.

Configuring Message Banners for AAA Authentication

AAA supports the use of configurable, personalized login and failed-login banners. You can configure message banners that will be displayed when a user logs in to the system to be authenticated using AAA and when, for whatever reason, authentication fails.

This section includes the following sections:

- [Configuring a Login Banner](#)
- [Configuring a Failed-Login Banner](#)

Configuring a Login Banner

To create a login banner, you need to configure a delimiting character, which notifies the system that the following text string is to be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the banner. The delimiting character can be any single character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.

To configure a banner that will be displayed whenever a user logs in (replacing the default message for login), use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables AAA.
Step 2	Router(config)# aaa authentication banner <i>delimiter string delimiter</i>	Creates a personalized login banner.

The maximum number of characters that can be displayed in the login banner is 2996 characters.

Configuring a Failed-Login Banner

To create a failed-login banner, you need to configure a delimiting character, which notifies the system that the following text string is to be displayed as the banner, and then the text string itself. The delimiting character is repeated at the end of the text string to signify the end of the failed-login banner. The delimiting character can be any single character in the extended ASCII character set, but once defined as the delimiter, that character cannot be used in the text string making up the banner.

To configure a message that will be displayed whenever a user fails login (replacing the default message for failed login), use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config) # aaa new-model	Enables AAA.
Step 2	Router(config) # aaa authentication fail-message <i>delimiter string delimiter</i>	Creates a message to be displayed when a user fails login.

The maximum number of characters that can be displayed in the failed-login banner is 2996 characters.

Configuring AAA Packet of Disconnect

Packet of disconnect (POD) terminates connections on the network access server (NAS) when particular session attributes are identified. By using session information obtained from AAA, the POD client residing on a UNIX workstation sends disconnect packets to the POD server running on the network access server. The NAS terminates any inbound user session with one or more matching key attributes. It rejects requests when required fields are missing or when an exact match is not found.

To configure POD, perform the following tasks in global configuration mode:

	Command	Purpose
Step 1	Router(config) # aaa accounting network default <i>start-stop radius</i>	Enables AAA accounting records.
Step 2	Router(config) # aaa accounting delay-start	(Optional) Delays generation of the start accounting record until the Framed-IP-Address is assigned, allowing its use in the POD packet.
Step 3	Router(config) # aaa pod server server-key <i>string</i>	Enables POD reception.
Step 4	Router(config) # radius-server host <i>IP address</i> non-standard	Declares a RADIUS host that uses a vendor-proprietary version of RADIUS.

Enabling Double Authentication

Previously, PPP sessions could only be authenticated by using a single authentication method: either PAP or CHAP. Double authentication requires remote users to pass a second stage of authentication—after CHAP or PAP authentication—before gaining network access.

This second (“double”) authentication requires a password that is known to the user but *not* stored on the user’s remote host. Therefore, the second authentication is specific to a user, not to a host. This provides an additional level of security that will be effective even if information from the remote host is stolen. In addition, this also provides greater flexibility by allowing customized network privileges for each user.

The second stage authentication can use one-time passwords such as token card passwords, which are not supported by CHAP. If one-time passwords are used, a stolen user password is of no use to the perpetrator.

This section includes the following subsections:

- [How Double Authentication Works](#)

- [Configuring Double Authentication](#)
- [Accessing the User Profile After Double Authentication](#)

How Double Authentication Works

With double authentication, there are two authentication/authorization stages. These two stages occur after a remote user dials in and a PPP session is initiated.

In the first stage, the user logs in using the remote host name; CHAP (or PAP) authenticates the remote host, and then PPP negotiates with AAA to authorize the remote host. In this process, the network access privileges associated with the remote host are assigned to the user.

Note

We suggest that the network administrator restrict authorization at this first stage to allow only Telnet connections to the local host.

In the second stage, the remote user must Telnet to the network access server to be authenticated. When the remote user logs in, the user must be authenticated with AAA login authentication. The user then must enter the **access-profile** command to be reauthorized using AAA. When this authorization is complete, the user has been double authenticated, and can access the network according to per-user network privileges.

The system administrator determines what network privileges remote users will have after each stage of authentication by configuring appropriate parameters on a security server. To use double authentication, the user must activate it by issuing the **access-profile** command.

Caution

Double authentication can cause certain undesirable events if multiple hosts share a PPP connection to a network access server, as shown in [Figure 3](#).

First, if a user, Bob, initiates a PPP session and activates double authentication at the network access server (per [Figure 3](#)), any other user will automatically have the same network privileges as Bob until Bob's PPP session expires. This happens because Bob's authorization profile is applied to the network access server's interface during the PPP session and any PPP traffic from other users will use the PPP session Bob established.

Second, if Bob initiates a PPP session and activates double authentication, and then—before Bob's PPP session has expired—another user, Jane, executes the **access-profile** command (or, if Jane Telnets to the network access server and **autocommand access-profile** is executed), a reauthorization will occur and Jane's authorization profile will be applied to the interface—replacing Bob's profile. This can disrupt or halt Bob's PPP traffic, or grant Bob additional authorization privileges Bob should not have.

Figure 3 **Possibly Risky Topology: Multiple Hosts Share a PPP Connection to a Network Access Server**

Configuring Double Authentication

To configure double authentication, you must complete the following steps:

1. Enable AAA by using the **aaa-new model** global configuration command. For more information about enabling AAA, refer to the chapter “AAA Overview.”
2. Use the **aaa authentication** command to configure your network access server to use login and PPP authentication method lists, then apply those method lists to the appropriate lines or interfaces.
3. Use the **aaa authorization** command to configure AAA network authorization at login. For more information about configuring network authorization, refer to the “Configuring Authorization” chapter.
4. Configure security protocol parameters (for example, RADIUS or TACACS+). For more information about RADIUS, refer to the chapter “Configuring RADIUS”. For more information about TACACS+, refer to the chapter “Configuring TACACS+.”
5. Use access control list AV pairs on the security server that the user can connect to the local host only by establishing a Telnet connection.
6. (Optional) Configure the **access-profile** command as an autocommand. If you configure the autocommand, remote users will not have to manually enter the **access-profile** command to access authorized rights associated with their personal user profile. To learn about configuring autocommands, refer to the **autocommand** command in the *Cisco IOS Dial Technologies Command Reference: Network Services*.

Note

If the **access-profile** command is configured as an autocommand, users will still have to Telnet to the local host and log in to complete double authentication.

Follow these rules when creating the user-specific authorization statements (These rules relate to the default behavior of the **access-profile** command):

- Use valid AV pairs when configuring access control list AV pairs on the security server. For a list of valid AV pairs, refer to the chapter “Authentication Commands” in the *Cisco IOS Security Command Reference*.
- If you want remote users to use the interface’s existing authorization (that which existed prior to the second stage authentication/authorization), but you want them to have different access control lists (ACLs), you should specify *only* ACL AV pairs in the user-specific authorization definition. This might be desirable if you set up a default authorization profile to apply to the remote host, but want to apply specific ACLs to specific users.

- When these user-specific authorization statements are later applied to the interface, they can either be *added* to the existing interface configuration or they can *replace* the existing interface configuration—depending on which form of the **access-profile** command is used to authorize the user. You should understand how the **access-profile** command works before configuring the authorization statements.
- If you will be using ISDN or Multilink PPP, you must also configure virtual templates at the local host.

To troubleshoot double authentication, use the **debug aaa per-user** debug command. For more information about this command, refer to the *Cisco IOS Debug Command Reference*.

Accessing the User Profile After Double Authentication

In double authentication, when a remote user establishes a PPP link to the local host using the local host name, the remote host is CHAP (or PAP) authenticated. After CHAP (or PAP) authentication, PPP negotiates with AAA to assign network access privileges associated with the remote host to the user. (We suggest that privileges at this stage be restricted to allow the user to connect to the local host only by establishing a Telnet connection.)

When the user needs to initiate the second phase of double authentication, establishing a Telnet connection to the local host, the user enters a personal username and password (different from the CHAP or PAP username and password). This action causes AAA reauthentication to occur according to the personal username/password. The initial rights associated with the local host, though, are still in place. By using the **access-profile** command, the rights associated with the local host are replaced by or merged with those defined for the user in the user's profile.

To access the user profile after double authentication, use the following command in EXEC configuration mode:

Command	Purpose
Router> access-profile [merge replace] [ignore-sanity-checks]	Accesses the rights associated for the user after double authentication.

If you configured the **access-profile** command to be executed as an autocommand, it will be executed automatically after the remote user logs in.

Enabling Automated Double Authentication

You can make the double authentication process easier for users by implementing automated double authentication. Automated double authentication provides all of the security benefits of double authentication, but offers a simpler, more user-friendly interface for remote users. With double authentication, a second level of user authentication is achieved when the user Telnets to the network access server or router and enters a username and password. With automated double authentication, the user does not have to Telnet to the network access server; instead the user responds to a dialog box that requests a username and password or personal identification number (PIN). To use the automated double authentication feature, the remote user hosts must be running a companion client application. As of Cisco IOS Release 12.0, the only client application software available is the Glacier Bay application server software for PCs.

**Note**

Automated double authentication, like the existing double authentication feature, is for Multilink PPP ISDN connections only. Automated double authentication cannot be used with other protocols such as X.25 or SLIP.

Automated double authentication is an enhancement to the existing double authentication feature. To configure automated double authentication, you must first configure double authentication by completing the following steps:

1. Enable AAA by using the **aaa-new model** global configuration command. For more information about enabling AAA, refer to the chapter “AAA Overview.”
2. Use the **aaa authentication** command to configure your network access server to use login and PPP authentication method lists, then apply those method lists to the appropriate lines or interfaces.
3. Use the **aaa authorization** command to configure AAA network authorization at login. For more information about configuring network authorization, refer to the chapter “Configuring Authorization.”
4. Configure security protocol parameters (for example, RADIUS or TACACS+). For more information about RADIUS, refer to the chapter “Configuring RADIUS”. For more information about TACACS+, refer to the chapter “Configuring TACACS+.”
5. Use access control list AV pairs on the security server that the user can connect to the local host only by establishing a Telnet connection.
6. Configure the **access-profile** command as an autocommand. If you configure the autocommand, remote users will not have to manually enter the **access-profile** command to access authorized rights associated with their personal user profile. To learn about configuring autocommands, refer to the **autocommand** command in the *Cisco IOS Dial Technologies Command Reference*, Release 12.2.

**Note**

If the **access-profile** command is configured as an autocommand, users will still have to Telnet to the local host and log in to complete double authentication.

Follow these rules when creating the user-specific authorization statements (These rules relate to the default behavior of the **access-profile** command):

- Use valid AV pairs when configuring access control list AV pairs on the security server. For a list of valid AV pairs, refer to the chapter “Authentication Commands” in the *Cisco IOS Security Command Reference*.
- If you want remote users to use the interface’s existing authorization (that which existed prior to the second stage authentication/authorization), but you want them to have different access control lists (ACLs), you should specify *only* ACL AV pairs in the user-specific authorization definition. This might be desirable if you set up a default authorization profile to apply to the remote host, but want to apply specific ACLs to specific users.
- When these user-specific authorization statements are later applied to the interface, they can either be *added* to the existing interface configuration, or *replace* the existing interface configuration—depending on which form of the **access-profile** command is used to authorize the user. You should understand how the **access-profile** command works before configuring the authorization statements.
- If you will be using ISDN or Multilink PPP, you must also configure virtual templates at the local host.

To troubleshoot double authentication, use the **debug aaa per-user** debug command. For more information about this command, refer to the *Cisco IOS Debug Command Reference*.

After you have configured double authentication, you are ready to configure the automation enhancement.

To configure automated double authentication, use the following commands, starting in global configuration mode.

:

	Command	Purpose
Step 1	<code>Router(config)# ip trigger-authentication [timeout seconds] [port number]</code>	Enables automation of double authentication.
Step 2	<code>Router(config)# interface bri number</code> or <code>Router(config)# interface serial number:23</code>	Selects an ISDN BRI or ISDN PRI interface and enter the interface configuration mode.
Step 3	<code>Router(config-if)# ip trigger-authentication</code>	Applies automated double authentication to the interface.

To troubleshoot automated double authentication, use the following commands in privileged EXEC mode:

	Command	Purpose
Step 1	<code>Router# show ip trigger-authentication</code>	Displays the list of remote hosts for which automated double authentication has been attempted (successfully or unsuccessfully).
Step 2	<code>Router# clear ip trigger-authentication</code>	Clears the list of remote hosts for which automated double authentication has been attempted. (This clears the table displayed by the show ip trigger-authentication command.)
Step 3	<code>Router# debug ip trigger-authentication</code>	Displays debug output related to automated double authentication.

Non-AAA Authentication Methods

This section discusses the following non-AAA authentication tasks:

- [Configuring Line Password Protection](#)
- [Establishing Username Authentication](#)
- [Enabling CHAP or PAP Authentication](#)
- [Using MS-CHAP](#)

Configuring Line Password Protection

You can provide access control on a terminal line by entering the password and establishing password checking. To do so, use the following commands in line configuration mode:

	Command	Purpose
Step 1	<code>Router(config-line)# password password</code>	Assigns a password to a terminal or other device on a line.
Step 2	<code>Router(config-line)# login</code>	Enables password checking at login.

The password checker is case sensitive and can include spaces; for example, the password “Secret” is different from the password “secret,” and “two words” is an acceptable password.

You can disable line password verification by disabling password checking. To do so, use the following command in line configuration mode:

Command	Purpose
<code>Router(config-line)# no login</code>	Disables password checking or allow access to a line without password verification.

If you configure line password protection and then configure TACACS or extended TACACS, the TACACS username and password take precedence over line passwords. If you have not yet implemented a security policy, we recommend that you use AAA.

**Note**

The **login** command only changes username and privilege level but it does not execute a shell; therefore autocommands will not be executed. To execute autocommands under this circumstance, you need to establish a Telnet session back into the router (loop-back). Make sure that the router has been configured for secure Telnet sessions if you choose to implement autocommands this way.

Establishing Username Authentication

You can create a username-based authentication system, which is useful in the following situations:

- To provide a TACACS-like username and encrypted password-authentication system for networks that cannot support TACACS
- To provide special-case logins: for example, access list verification, no password verification, autocommand execution at login, and “no escape” situations

To establish username authentication, use the following commands in global configuration mode as needed for your system configuration:

	Command	Purpose
Step 1	<code>Router(config)# username name [nopassword password password password encryption-type encrypted password]</code> or <code>Router(config)# username name [access-class number]</code>	Establishes username authentication with encrypted passwords. or (Optional) Establishes username authentication by access list.
Step 2	<code>Router(config)# username name [privilege level]</code>	(Optional) Sets the privilege level for the user.

	Command	Purpose
Step 3	<code>Router(config)# username name [autocommand command]</code>	(Optional) Specifies a command to be executed automatically.
Step 4	<code>Router(config)# username name [noescape] [nohangup]</code>	(Optional) Sets a “no escape” login environment.

The keyword **noescape** prevents users from using escape characters on the hosts to which they are connected. The **nohangup** feature does not disconnect after using the autocommand.

**Caution**

Passwords will be displayed in clear text in your configuration unless you enable the **service password-encryption** command. For more information about the **service password-encryption** command, refer to the chapter “Passwords and Privileges Commands” in the *Cisco IOS Security Command Reference*.

Enabling CHAP or PAP Authentication

One of the most common transport protocols used in Internet service providers’ (ISPs’) dial solutions is the Point-to-Point Protocol (PPP). Traditionally, remote users dial in to an access server to initiate a PPP session. After PPP has been negotiated, remote users are connected to the ISP network and to the Internet.

Because ISPs want only customers to connect to their access servers, remote users are required to authenticate to the access server before they can start up a PPP session. Normally, a remote user authenticates by typing in a username and password when prompted by the access server. Although this is a workable solution, it is difficult to administer and awkward for the remote user.

A better solution is to use the authentication protocols built into PPP. In this case, the remote user dials in to the access server and starts up a minimal subset of PPP with the access server. This does not give the remote user access to the ISP’s network—it merely allows the access server to talk to the remote device.

PPP currently supports two authentication protocols: Password Authentication Protocol (PAP) and Challenge Handshake Authentication Protocol (CHAP). Both are specified in RFC 1334 and are supported on synchronous and asynchronous interfaces. Authentication via PAP or CHAP is equivalent to typing in a username and password when prompted by the server. CHAP is considered to be more secure because the remote user’s password is never sent across the connection.

PPP (with or without PAP or CHAP authentication) is also supported in dialout solutions. An access server utilizes a dialout feature when it initiates a call to a remote device and attempts to start up a transport protocol such as PPP.

See the chapter “Configuring Interfaces” in the *Cisco IOS Configuration Fundamentals Configuration Guide* for more information about CHAP and PAP.

**Note**

To use CHAP or PAP, you must be running PPP encapsulation.

When CHAP is enabled on an interface and a remote device attempts to connect to it, the access server sends a CHAP packet to the remote device. The CHAP packet requests or “challenges” the remote device to respond. The challenge packet consists of an ID, a random number, and the host name of the local router.

When the remote device receives the challenge packet, it concatenates the ID, the remote device's password, and the random number, and then encrypts all of it using the remote device's password. The remote device sends the results back to the access server, along with the name associated with the password used in the encryption process.

When the access server receives the response, it uses the name it received to retrieve a password stored in its user database. The retrieved password should be the same password the remote device used in its encryption process. The access server then encrypts the concatenated information with the newly retrieved password—if the result matches the result sent in the response packet, authentication succeeds.

The benefit of using CHAP authentication is that the remote device's password is never transmitted in clear text. This prevents other devices from stealing it and gaining illegal access to the ISP's network.

CHAP transactions occur only at the time a link is established. The access server does not request a password during the rest of the call. (The local device can, however, respond to such requests from other devices during a call.)

When PAP is enabled, the remote router attempting to connect to the access server is required to send an authentication request. If the username and password specified in the authentication request are accepted, the Cisco IOS software sends an authentication acknowledgment.

After you have enabled CHAP or PAP, the access server will require authentication from remote devices dialing in to the access server. If the remote device does not support the enabled protocol, the call will be dropped.

To use CHAP or PAP, you must perform the following tasks:

1. Enable PPP encapsulation.
2. Enable CHAP or PAP on the interface.
3. For CHAP, configure host name authentication and the secret or password for each remote system with which authentication is required.

This section includes the following sections:

- [Enabling PPP Encapsulation](#)
- [Enabling PAP or CHAP](#)
- [Inbound and Outbound Authentication](#)
- [Enabling Outbound PAP Authentication](#)
- [Refusing PAP Authentication Requests](#)
- [Creating a Common CHAP Password](#)
- [Refusing CHAP Authentication Requests](#)
- [Delaying CHAP Authentication Until Peer Authenticates](#)

Enabling PPP Encapsulation

To enable PPP encapsulation, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# encapsulation ppp</code>	Enables PPP on an interface.

Enabling PAP or CHAP

To enable CHAP or PAP authentication on an interface configured for PPP encapsulation, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# ppp authentication { <i>protocol1</i> [<i>protocol2...</i>] [<i>if-needed</i>] [<i>default</i> <i>list-name</i>] [<i>callin</i>] [<i>one-time</i>]	Defines the authentication protocols supported and the order in which they are used. In this command, <i>protocol1</i> , <i>protocol2</i> represent the following protocols: CHAP, MS-CHAP, and PAP. PPP authentication is attempted first using the first authentication method, which is <i>protocol1</i> . If <i>protocol1</i> is unable to establish authentication, the next configured protocol is used to negotiate authentication.

If you configure **ppp authentication chap** on an interface, all incoming calls on that interface that initiate a PPP connection will have to be authenticated using CHAP; likewise, if you configure **ppp authentication pap**, all incoming calls that start a PPP connection will have to be authenticated via PAP. If you configure **ppp authentication chap pap**, the access server will attempt to authenticate all incoming calls that start a PPP session with CHAP. If the remote device does not support CHAP, the access server will try to authenticate the call using PAP. If the remote device does not support either CHAP or PAP, authentication will fail and the call will be dropped. If you configure **ppp authentication pap chap**, the access server will attempt to authenticate all incoming calls that start a PPP session with PAP. If the remote device does not support PAP, the access server will try to authenticate the call using CHAP. If the remote device does not support either protocol, authentication will fail and the call will be dropped. If you configure the **ppp authentication** command with the **callin** keyword, the access server will only authenticate the remote device if the remote device initiated the call.

Authentication method lists and the **one-time** keyword are only available if you have enabled AAA—they will not be available if you are using TACACS or extended TACACS. If you specify the name of an authentication method list with the **ppp authentication** command, PPP will attempt to authenticate the connection using the methods defined in the specified method list. If AAA is enabled and no method list is defined by name, PPP will attempt to authenticate the connection using the methods defined as the default. The **ppp authentication** command with the **one-time** keyword enables support for one-time passwords during authentication.

The **if-needed** keyword is only available if you are using TACACS or extended TACACS. The **ppp authentication** command with the **if-needed** keyword means that PPP will only authenticate the remote device via PAP or CHAP if they have not yet authenticated during the life of the current call. If the remote device authenticated via a standard login procedure and initiated PPP from the EXEC prompt, PPP will not authenticate via CHAP if **ppp authentication chap if-needed** is configured on the interface.

Caution

If you use a *list-name* that has not been configured with the **aaa authentication ppp** command, you disable PPP on the line.

For information about adding a **username** entry for each remote system from which the local router or access server requires authentication, see the section “[Establishing Username Authentication](#).”

Inbound and Outbound Authentication

PPP supports two-way authentication. Normally, when a remote device dials in to an access server, the access server requests that the remote device prove that it is allowed access. This is known as inbound authentication. At the same time, the remote device can also request that the access server prove that it is who it says it is. This is known as outbound authentication. An access server also does outbound authentication when it initiates a call to a remote device.

Enabling Outbound PAP Authentication

To enable outbound PAP authentication, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp pap sent-username username password password</code>	Enables outbound PAP authentication.

The access server uses the username and password specified by the **ppp pap sent-username** command to authenticate itself whenever it initiates a call to a remote device or when it has to respond to a remote device's request for outbound authentication.

Refusing PAP Authentication Requests

To refuse PAP authentication from peers requesting it, meaning that PAP authentication is disabled for all calls, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp pap refuse</code>	Refuses PAP authentication from peers requesting PAP authentication.

If the **refuse** keyword is not used, the router will not refuse any PAP authentication challenges received from the peer.

Creating a Common CHAP Password

For remote CHAP authentication only, you can configure your router to create a common CHAP secret password to use in response to challenges from an unknown peer; for example, if your router calls a rotary of routers (either from another vendor, or running an older version of the Cisco IOS software) to which a new (that is, unknown) router has been added. The **ppp chap password** command allows you to replace several username and password configuration commands with a single copy of this command on any dialer interface or asynchronous group interface.

To enable a router calling a collection of routers to configure a common CHAP secret password, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp chap password secret</code>	Enables a router calling a collection of routers to configure a common CHAP secret password.

Refusing CHAP Authentication Requests

To refuse CHAP authentication from peers requesting it, meaning that CHAP authentication is disabled for all calls, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp chap refuse [callin]</code>	Refuses CHAP authentication from peers requesting CHAP authentication.

If the **callin** keyword is used, the router will refuse to answer CHAP authentication challenges received from the peer, but will still require the peer to answer any CHAP challenges the router sends.

If outbound PAP has been enabled (using the **ppp pap sent-username** command), PAP will be suggested as the authentication method in the refusal packet.

Delaying CHAP Authentication Until Peer Authenticates

To specify that the router will not authenticate to a peer requesting CHAP authentication until after the peer has authenticated itself to the router, use the following command in interface configuration mode:

Command	Purpose
<code>Router(config-if)# ppp chap wait secret</code>	Configures the router to delay CHAP authentication until after the peer has authenticated itself to the router.

This command (which is the default) specifies that the router will not authenticate to a peer requesting CHAP authentication until the peer has authenticated itself to the router. The **no ppp chap wait** command specifies that the router will respond immediately to an authentication challenge.

Using MS-CHAP

Microsoft Challenge Handshake Authentication Protocol (MS-CHAP) is the Microsoft version of CHAP and is an extension of RFC 1994. Like the standard version of CHAP, MS-CHAP is used for PPP authentication; in this case, authentication occurs between a PC using Microsoft Windows NT or Microsoft Windows 95 and a Cisco router or access server acting as a network access server.

MS-CHAP differs from the standard CHAP as follows:

- MS-CHAP is enabled by negotiating CHAP Algorithm 0x80 in LCP option 3, Authentication Protocol.
- The MS-CHAP Response packet is in a format designed to be compatible with Microsoft Windows NT 3.5 and 3.51, Microsoft Windows 95, and Microsoft LAN Manager 2.x. This format does not require the authenticator to store a clear or reversibly encrypted password.
- MS-CHAP provides an authenticator-controlled authentication retry mechanism.
- MS-CHAP provides an authenticator-controlled change password mechanism.
- MS-CHAP defines a set of “reason-for failure” codes returned in the Failure packet message field.

Depending on the security protocols you have implemented, PPP authentication using MS-CHAP can be used with or without AAA security services. If you have enabled AAA, PPP authentication using MS-CHAP can be used in conjunction with both TACACS+ and RADIUS. Table 9 lists the vendor-specific RADIUS attributes (IETF Attribute 26) that enable RADIUS to support MS-CHAP.

Table 9 Vendor-Specific RADIUS Attributes for MS-CHAP

Vendor-ID Number	Vendor-Type Number	Vendor-Proprietary Attribute	Description
311	11	MSCHAP-Challenge	Contains the challenge sent by a network access server to an MS-CHAP user. It can be used in both Access-Request and Access-Challenge packets.
211	11	MSCHAP-Response	Contains the response value provided by a PPP MS-CHAP user in response to the challenge. It is only used in Access-Request packets. This attribute is identical to the PPP CHAP Identifier.

To define PPP authentication using MS-CHAP, use the following commands in interface configuration mode:

	Command	Purpose
Step 1	Router(config-if)# encapsulation ppp	Enables PPP encapsulation.
Step 2	Router(config-if)# ppp authentication ms-chap [if-needed] [list-name default] [callin] [one-time]	Defines PPP authentication using MS-CHAP.

If you configure **ppp authentication ms-chap** on an interface, all incoming calls on that interface that initiate a PPP connection will have to be authenticated using MS-CHAP. If you configure the **ppp authentication** command with the **callin** keyword, the access server will only authenticate the remote device if the remote device initiated the call.

Authentication method lists and the **one-time** keyword are only available if you have enabled AAA—they will not be available if you are using TACACS or extended TACACS. If you specify the name of an authentication method list with the **ppp authentication** command, PPP will attempt to authenticate the connection using the methods defined in the specified method list. If AAA is enabled and no method list is defined by name, PPP will attempt to authenticate the connection using the methods defined as the default. The **ppp authentication** command with the **one-time** keyword enables support for one-time passwords during authentication.

The **if-needed** keyword is only available if you are using TACACS or extended TACACS. The **ppp authentication** command with the **if-needed** keyword means that PPP will only authenticate the remote device via MS-CHAP if that device has not yet authenticated during the life of the current call. If the remote device authenticated through a standard login procedure and initiated PPP from the EXEC prompt, PPP will not authenticate through MS-CHAP if **ppp authentication chap if-needed** is configured.

**Note**

If PPP authentication using MS-CHAP is used with username authentication, you must include the MS-CHAP secret in the local username/password database. For more information about username authentication, refer to the “Establish Username Authentication” section.

Authentication Examples

The following sections provide authentication configuration examples:

- [RADIUS Authentication Examples](#)
- [TACACS+ Authentication Examples](#)
- [Kerberos Authentication Examples](#)
- [AAA Scalability Example](#)
- [Login and Failed Banner Examples](#)
- [AAA Packet of Disconnect Server Key Example](#)
- [Double Authentication Examples](#)
- [Automated Double Authentication Example](#)
- [MS-CHAP Example](#)

RADIUS Authentication Examples

This section provides two sample configurations using RADIUS.

The following example shows how to configure the router to authenticate and authorize using RADIUS:

```
aaa authentication login radius-login group radius local
aaa authentication ppp radius-ppp if-needed group radius
aaa authorization exec default group radius if-authenticated
aaa authorization network default group radius
line 3
login authentication radius-login
interface serial 0
ppp authentication radius-ppp
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The **aaa authentication login radius-login group radius local** command configures the router to use RADIUS for authentication at the login prompt. If RADIUS returns an error, the user is authenticated using the local database.
- The **aaa authentication ppp radius-ppp if-needed group radius** command configures the Cisco IOS software to use PPP authentication using CHAP or PAP if the user has not already logged in. If the EXEC facility has authenticated the user, PPP authentication is not performed.
- The **aaa authorization exec default group radius if-authenticated** command queries the RADIUS database for information that is used during EXEC authorization, such as autocommands and privilege levels, but only provides authorization if the user has successfully authenticated.
- The **aaa authorization network default group radius** command queries RADIUS for network authorization, address assignment, and other access lists.
- The **login authentication radius-login** command enables the radius-login method list for line 3.

- The **ppp authentication radius-ppp** command enables the radius-ppp method list for serial interface 0.

The following example shows how to configure the router to prompt for and verify a username and password, authorize the user's EXEC level, and specify it as the method of authorization for privilege level 2. In this example, if a local username is entered at the username prompt, that username is used for authentication.

If the user is authenticated using the local database, EXEC authorization using RADIUS will fail because no data is saved from the RADIUS authentication. The method list also uses the local database to find an autocommand. If there is no autocommand, the user becomes the EXEC user. If the user then attempts to issue commands that are set at privilege level 2, TACACS+ is used to attempt to authorize the command.

```
aaa authentication login default group radius local
aaa authorization exec default group radius local
aaa authorization command 2 default group tacacs+ if-authenticated
radius-server host 172.16.71.146 auth-port 1645 acct-port 1646
radius-server attribute 44 include-in-access-req
radius-server attribute 8 include-in-access-req
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The **aaa authentication login default group radius local** command specifies that the username and password are verified by RADIUS or, if RADIUS is not responding, by the router's local user database.
- The **aaa authorization exec default group radius local** command specifies that RADIUS authentication information be used to set the user's EXEC level if the user authenticates with RADIUS. If no RADIUS information is used, this command specifies that the local user database be used for EXEC authorization.
- The **aaa authorization command 2 default group tacacs+ if-authenticated** command specifies TACACS+ authorization for commands set at privilege level 2, if the user has already successfully authenticated.
- The **radius-server host 172.16.71.146 auth-port 1645 acct-port 1646** command specifies the IP address of the RADIUS server host, the UDP destination port for authentication requests, and the UDP destination port for accounting requests.
- The **radius-server attribute 44 include-in-access-req** command sends RADIUS attribute 44 (Acct-Section-ID) in access-request packets.
- The **radius-server attribute 8 include-in-access-req** command sends RADIUS attribute 8 (Framed-IP-Address) in access-request packets.

TACACS+ Authentication Examples

The following example shows how to configure TACACS+ as the security protocol to be used for PPP authentication:

```
aaa new-model
aaa authentication ppp test group tacacs+ local
interface serial 0
ppp authentication chap pap test
tacacs-server host 10.1.2.3
tacacs-server key goaway
```

The lines in this sample TACACS+ authentication configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “test,” to be used on serial interfaces running PPP. The keywords **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **interface** command selects the line.
- The **ppp authentication** command applies the test method list to this line.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3.
- The **tacacs-server key** command defines the shared encryption key to be “goaway.”

The following example shows how to configure AAA authentication for PPP:

```
aaa authentication ppp default if-needed group tacacs+ local
```

In this example, the keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP is not necessary and can be skipped. If authentication is needed, the keywords **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.

The following example shows how to create the same authentication algorithm for PAP, but it calls the method list “MIS-access” instead of “default”:

```
aaa authentication ppp MIS-access if-needed group tacacs+ local
interface serial 0
ppp authentication pap MIS-access
```

In this example, because the list does not apply to any interfaces (unlike the default list, which applies automatically to all interfaces), the administrator must select interfaces to which this authentication scheme should apply by using the **interface** command. The administrator must then apply this method list to those interfaces by using the **ppp authentication** command.

Kerberos Authentication Examples

To specify Kerberos as the login authentication method, use the following command:

```
aaa authentication login default krb5
```

To specify Kerberos authentication for PPP, use the following command:

```
aaa authentication ppp default krb5
```

AAA Scalability Example

The following example shows a general security configuration using AAA with RADIUS as the security protocol. In this example, the network access server is configured to allocate 16 background processes to handle AAA requests for PPP.

```
aaa new-model
radius-server host alcatraz
radius-server key myRaDiUSpassWoRd
radius-server configure-nas
username root password ALongPassword
```

```

aaa authentication ppp dialins group radius local
aaa authentication login admins local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa processes 16
line 1 16
  autoselect ppp
  autoselect during-login
  login authentication admins
  modem dialin
interface group-async 1
  group-range 1 16
  encapsulation ppp
  ppp authentication pap dialins

```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **radius-server configure-nas** command defines that the Cisco router or access server will query the RADIUS server for static routes and IP pool definitions when the device first starts up.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication, then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **aaa authentication login admins local** command defines another method list, “admins,” for login authentication.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.
- The **aaa processes** command allocates 16 background processes to handle AAA requests for PPP.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the “admins” method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.

- The **ppp authentication pap dialins** command applies the “dialins” method list to the specified interfaces.

Login and Failed Banner Examples

The following example shows how to configure a login banner (in this case, the phrase “Unauthorized Access Prohibited”) that will be displayed when a user logs in to the system. The asterisk (*) is used as the delimiting character. (RADIUS is specified as the default login authentication method.)

```
aaa new-model
aaa authentication banner *Unauthorized Access Prohibited*
aaa authentication login default group radius
```

This configuration produces the following login banner:

```
Unauthorized Access Prohibited
Username:
```

The following example shows how to additionally configure a failed login banner (in this case, the phrase “Failed login. Try again.”) that will be displayed when a user tries to log in to the system and fails. The asterisk (*) is used as the delimiting character. (RADIUS is specified as the default login authentication method.)

```
aaa new-model
aaa authentication banner *Unauthorized Access Prohibited*
aaa authentication fail-message *Failed login. Try again.*
aaa authentication login default group radius
```

This configuration produces the following login and failed login banner:

```
Unauthorized Access Prohibited
Username:
Password:
Failed login. Try again.
```

AAA Packet of Disconnect Server Key Example

The following example shows how to configure POD (packet of disconnect), which terminates connections on the network access server (NAS) when particular session attributes are identified.

```
aaa new-model
aaa authentication ppp default radius
aaa accounting network default start-stop radius
aaa accounting delay-start
aaa pod server server-key xyz123
radius-server host 172.16.0.0 non-standard
radius-server key rad123
```

Double Authentication Examples

The examples in this section illustrate possible configurations to be used with double authentication. Your configurations could differ significantly, depending on your network and security requirements.

This section includes the following examples:

- [Configuration of the Local Host for AAA with Double Authentication Examples](#)
- [Configuration of the AAA Server for First-Stage \(PPP\) Authentication and Authorization Example](#)

- [Configuration of the AAA Server for Second-Stage \(Per-User\) Authentication and Authorization Examples](#)
- [Complete Configuration with TACACS+ Example](#)

**Note**

These configuration examples include specific IP addresses and other specific information. This information is for illustration purposes only: your configuration will use different IP addresses, different usernames and passwords, and different authorization statements.

Configuration of the Local Host for AAA with Double Authentication Examples

These two examples show how to configure a local host to use AAA for PPP and login authentication, and for network and EXEC authorization. One example is shown for RADIUS and one example for TACACS+.

In both examples, the first three lines configure AAA, with a specific server as the AAA server. The next two lines configure AAA for PPP and login authentication, and the last two lines configure network and EXEC authorization. The last line is necessary only if the **access-profile** command will be executed as an autocommand.

The following example shows router configuration with a RADIUS AAA server:

```
aaa new-model
radius-server host secureserver
radius-server key myradiuskey
aaa authentication ppp default group radius
aaa authentication login default group radius
aaa authorization network default group radius
aaa authorization exec default group radius
```

The following example shows router configuration with a TACACS+ server:

```
aaa new-model
tacacs-server host security
tacacs-server key mytacacskey
aaa authentication ppp default group tacacs+
aaa authentication login default group tacacs+
aaa authorization network default group tacacs+
aaa authorization exec default group tacacs+
```

Configuration of the AAA Server for First-Stage (PPP) Authentication and Authorization Example

This example shows a configuration on the AAA server. A partial sample AAA configuration is shown for RADIUS.

TACACS+ servers can be configured similarly. (See the section “[Complete Configuration with TACACS+ Example](#)” later in this chapter.)

This example defines authentication/authorization for a remote host named “hostx” that will be authenticated by CHAP in the first stage of double authentication. Note that the ACL AV pair limits the remote host to Telnet connections to the local host. The local host has the IP address 10.0.0.2.

The following example shows a partial AAA server configuration for RADIUS:

```
hostx Password = "welcome"
      User-Service-Type = Framed-User,
      Framed-Protocol = PPP,
      cisco-avpair = "lcp:interface-config=ip unnumbered ethernet 0",
      cisco-avpair = "ip:inacl#3=permit tcp any 172.21.114.0 0.0.0.255 eq telnet",
```

```
cisco-avpair = "ip:inacl#4=deny icmp any any",
cisco-avpair = "ip:route#5=55.0.0.0 255.0.0.0",
cisco-avpair = "ip:route#6=66.0.0.0 255.0.0.0",
cisco-avpair = "ipx:inacl#3=deny any"
```

Configuration of the AAA Server for Second-Stage (Per-User) Authentication and Authorization Examples

This section contains partial sample AAA configurations on a RADIUS server. These configurations define authentication and authorization for a user (Pat) with the username "patuser," who will be user-authenticated in the second stage of double authentication.

TACACS+ servers can be configured similarly. (See the section "[Complete Configuration with TACACS+ Example](#)" later in this chapter.)

Three examples show sample RADIUS AAA configurations that could be used with each of the three forms of the **access-profile** command.

The first example shows a partial sample AAA configuration that works with the default form (no keywords) of the **access-profile** command. Note that only ACL AV pairs are defined. This example also sets up the **access-profile** command as an autocommand.

```
patuser Password = "welcome"
User-Service-Type = Shell-User,
cisco-avpair = "shell:autocmd=access-profile"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "ip:inacl#3=permit tcp any host 10.0.0.2 eq telnet",
cisco-avpair = "ip:inacl#4=deny icmp any any"
```

The second example shows a partial sample AAA configuration that works with the **access-profile merge** form of the **access-profile** command. This example also sets up the **access-profile merge** command as an autocommand.

```
patuser Password = "welcome"
User-Service-Type = Shell-User,
cisco-avpair = "shell:autocmd=access-profile merge"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "ip:inacl#3=permit tcp any any"
cisco-avpair = "ip:route=10.0.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.1.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.2.0.0 255.255.0.0"
```

The third example shows a partial sample AAA configuration that works with the **access-profile replace** form of the **access-profile** command. This example also sets up the **access-profile replace** command as an autocommand.

```
patuser Password = "welcome"
User-Service-Type = Shell-User,
cisco-avpair = "shell:autocmd=access-profile replace"
User-Service-Type = Framed-User,
Framed-Protocol = PPP,
cisco-avpair = "ip:inacl#3=permit tcp any any",
cisco-avpair = "ip:inacl#4=permit icmp any any",
cisco-avpair = "ip:route=10.10.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.11.0.0 255.255.0.0",
cisco-avpair = "ip:route=10.12.0.0 255.255.0.0"
```

Complete Configuration with TACACS+ Example

This example shows TACACS+ authorization profile configurations both for the remote host (used in the first stage of double authentication) and for specific users (used in the second stage of double authentication). This TACACS+ example contains approximately the same configuration information as shown in the previous RADIUS examples.

This sample configuration shows authentication/authorization profiles on the TACACS+ server for the remote host “hostx” and for three users, with the usernames “pat_default,” “pat_merge,” and “pat_replace.” The configurations for these three usernames illustrate different configurations that correspond to the three different forms of the **access-profile** command. The three user configurations also illustrate setting up the autocommand for each form of the **access-profile** command.

Figure 4 shows the topology. The example that follows the figure shows a TACACS+ configuration file.

Figure 4 **Example Topology for Double Authentication**

This sample configuration shows authentication/authorization profiles on the TACACS+ server for the remote host “hostx” and for three users, with the usernames “pat_default,” “pat_merge,” and “pat_replace.”

```
key = "mytacacskey"

default authorization = permit

#-----Remote Host (BRI)-----
#
# This allows the remote host to be authenticated by the local host
# during fist-stage authentication, and provides the remote host
# authorization profile.
#
#-----

user = hostx
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

    service = ppp protocol = lcp {
        interface-config="ip unnumbered ethernet 0"
    }

    service = ppp protocol = ip {
        # It is important to have the hash sign and some string after
        # it. This indicates to the NAS that you have a per-user
        # config.

        inacl#3="permit tcp any 172.21.114.0 0.0.0.255 eq telnet"
        inacl#4="deny icmp any any"
```

```

        route#5="55.0.0.0 255.0.0.0"
        route#6="66.0.0.0 255.0.0.0"
    }

    service = ppp protocol = ipx {
        # see previous comment about the hash sign and string, in protocol = ip
        inacl#3="deny any"
    }

}

#----- "access-profile" default user "only acls" -----
#
# Without arguments, access-profile removes any access-lists it can find
# in the old configuration (both per-user and per-interface), and makes sure
# that the new profile contains ONLY access-list definitions.
#
#-----

user = pat_default
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

    service = exec

    {
        # This is the autocommand that executes when pat_default logs in.
        autocmd = "access-profile"
    }

    service = ppp protocol = ip {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IP
        # access-lists (not even the ones installed prior to
        # this)!

        inacl#3="permit tcp any host 10.0.0.2 eq telnet"
        inacl#4="deny icmp any any"
    }

    service = ppp protocol = ipx {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IPX
        # access-lists (not even the ones installed prior to
        # this)!
    }

}

#----- "access-profile merge" user -----
#
# With the 'merge' option, first all old access-lists are removed (as before),
# but then (almost) all AV pairs are uploaded and installed. This will allow
# for uploading any custom static routes, sap-filters, and so on, that the user
# may need in his or her profile. This needs to be used with care, as it leaves
# open the possibility of conflicting configurations.

```

```

#
#-----

user = pat_merge
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

    service = exec
    {
        # This is the autocommand that executes when pat_merge logs in.
        autocmd = "access-profile merge"
    }

    service = ppp protocol = ip
    {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IP
        # access-lists (not even the ones installed prior to
        # this)!

        inacl#3="permit tcp any any"
        route#2="10.0.0.0 255.255.0.0"
        route#3="10.1.0.0 255.255.0.0"
        route#4="10.2.0.0 255.255.0.0"

    }

    service = ppp protocol = ipx
    {
        # Put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IPX
        # access-lists (not even the ones installed prior to
        # this)!

    }

}

#----- "access-profile replace" user -----
#
# With the 'replace' option, ALL old configuration is removed and ALL new
# configuration is installed.
#
# One caveat: access-profile checks the new configuration for address-pool and
# address AV pairs. As addresses cannot be renegotiated at this point, the
# command will fail (and complain) when it encounters such an AV pair.
# Such AV pairs are considered to be "invalid" for this context.
#-----

user = pat_replace
{
    login = cleartext "welcome"
    chap = cleartext "welcome"

        # access-lists (not even the ones installed prior to
        # this)!

        inacl#3="permit tcp any any"
        inacl#4="permit icmp any any"

        route#2="10.10.0.0 255.255.0.0"
        route#3="10.11.0.0 255.255.0.0"
        route#4="10.12.0.0 255.255.0.0"
    }

    service = ppp protocol = ipx
    {
        # put whatever access-lists, static routes, whatever
        # here.
        # If you leave this blank, the user will have NO IPX
        # access-lists (not even the ones installed prior to
        # this)!
    }
}

```

Automated Double Authentication Example

This example shows a complete configuration file for a Cisco 2509 router with automated double authentication configured. The configuration commands that apply to automated double authentication are preceded by descriptions with a double asterisk (**).

Current configuration:

```

!
version 11.3
no service password-encryption
!
hostname myrouter
!
!
! **The following AAA commands are used to configure double authentication:
!
! **The following command enables AAA:
aaa new-model
! **The following command enables user authentication via the TACACS+ AAA server:
aaa authentication login default group tacacs+
aaa authentication login console none
! **The following command enables device authentication via the TACACS+ AAA server:
aaa authentication ppp default group tacacs+
! **The following command causes the remote user's authorization profile to be
! downloaded from the AAA server to the Cisco 2509 router when required:
aaa authorization exec default group tacacs+
! **The following command causes the remote device's authorization profile to be
! downloaded from the AAA server to the Cisco 2509 router when required:
aaa authorization network default group tacacs+
enable password mypassword

```

```

!
ip host blue 172.21.127.226
ip host green 172.21.127.218
ip host red 172.21.127.114
ip domain-name example.com
ip name-server 171.69.2.75
! **The following command globally enables automated double authentication:
ip trigger-authentication timeout 60 port 7500
isdn switch-type basic-5ess
!
!
interface Ethernet0
 ip address 172.21.127.186 255.255.255.248
 no ip route-cache
 no ip mroute-cache
 no keepalive
 ntp disable
 no cdp enable
!
interface Virtual-Template1
 ip unnumbered Ethernet0
 no ip route-cache
 no ip mroute-cache
!
interface Serial0
 ip address 172.21.127.105 255.255.255.248
 encapsulation ppp
 no ip mroute-cache
 no keepalive
 shutdown
 clockrate 2000000
 no cdp enable
!
interface Serial1
 no ip address
 no ip route-cache
 no ip mroute-cache
 shutdown
 no cdp enable
!
! **Automated double authentication occurs via the ISDN BRI interface BRI0:
interface BRI0
 ip unnumbered Ethernet0
! **The following command turns on automated double authentication at this interface:
 ip trigger-authentication
! **PPP encapsulation is required:
 encapsulation ppp
 no ip route-cache
 no ip mroute-cache
 dialer idle-timeout 500
 dialer map ip 172.21.127.113 name myrouter 60074
 dialer-group 1
 no cdp enable

```

```

! **The following command specifies that device authentication occurs via PPP CHAP:
ppp authentication chap
!
router eigrp 109
 network 172.21.0.0
 no auto-summary
!
ip default-gateway 172.21.127.185
no ip classless
ip route 172.21.127.114 255.255.255.255 172.21.127.113
! **Virtual profiles are required for double authentication to work:
virtual-profile virtual-template 1
dialer-list 1 protocol ip permit
no cdp run
! **The following command defines where the TACACS+ AAA server is:
tacacs-server host 171.69.57.35 port 1049
tacacs-server timeout 90
! **The following command defines the key to use with TACACS+ traffic (required):
tacacs-server key mytacacskey
snmp-server community public RO
!
line con 0
 exec-timeout 0 0
 login authentication console
line aux 0
 transport input all
line vty 0 4
 exec-timeout 0 0
 password lab
!
end

```

MS-CHAP Example

The following example shows how to configure a Cisco AS5200 Universal Access Server (enabled for AAA and communication with a RADIUS security server) for PPP authentication using MS-CHAP:

```

aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius

username root password ALongPassword

radius-server host alcatraz
radius-server key myRaDiUSpassWoRd

interface group-async 1
 group-range 1 16
 encapsulation ppp
 ppp authentication ms-chap dialins

line 1 16
 autoselect ppp
 autoselect during-login
 login authentication admins
 modem dialin

```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **aaa authentication login admins local** command defines another method list, “admins”, for login authentication.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.
- The **ppp authentication ms-chap dialins** command selects MS-CHAP as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the “admins” method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

AAA Double Authentication Secured by Absolute Timeout

First Published: March 1, 2004

Last Updated: January 2, 2008

The AAA Double Authentication Secured by Absolute Timeout feature allows you to secure the double authentication mechanism by protecting it with a per-user session timeout. This feature optimizes the connection to the network by service providers to only connections that are authorized, and it increases the security of the overall access to the network by ensuring that no unwanted sessions are connected.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for AAA Double Authentication Secured by Absolute Timeout](#)” section on page 10.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for AAA Double Authentication Secured by Absolute Timeout

- You need access to a Cisco RADIUS or TACACS+ server and should be familiar with configuring RADIUS or TACACS+.
- You should be familiar with configuring authentication, authorization, and accounting (AAA).
- You should be familiar with enabling AAA automated double authentication.

Restrictions for AAA Double Authentication Secured by Absolute Timeout

- The AAA Double Authentication Secured by Absolute Timeout feature, like the existing double authentication feature, is for PPP connections only. Automated double authentication cannot be used with other protocols, such as X.25 or Serial Line Internet Protocol (SLIP).
- There may be a minimal impact on performance if a TACACS+ server is used. However, there is no performance impact if a RADIUS server is used.

Information About AAA Double Authentication Secured by Absolute Timeout

To configure the AAA Double Authentication Secured by Absolute Timeout feature, you should understand the following concept:

- [AAA Double Authentication, page 2](#)

AAA Double Authentication

With the current AAA double authentication mechanism, a user must pass the first authentication using a host username and password. The second authentication, after Challenge Handshake Authentication Protocol (CHAP) or Password Authentication Protocol (PAP), uses a login username and password. In the first authentication, a PPP session timeout will be applied to the virtual access interface if it is configured locally or remotely. The AAA Double Authentication Secured by Absolute Timeout feature allows you to secure the double authentication mechanism by protecting it with a per-user session timeout. The per-user timeout, which can be customized, supersedes the generic absolute timeout value. This method works on the same principle as per-user access control lists (ACLs) in double authentication.

How to Apply AAA Double Authentication Secured by Absolute Timeout

This section contains the following procedures:

- [Applying AAA Double Authentication Secured by Absolute Timeout, page 3](#)
- [Verifying AAA Double Authentication Secured by Absolute Timeout, page 3](#)

Applying AAA Double Authentication Secured by Absolute Timeout

To apply the absolute timeout, you need to configure “Session-Timeout” in the login user profile as a link control protocol (LCP) per-user attribute. There is no new or modified command-line interface (CLI) for this feature, but before you use the **access-profile** command when enabling AAA double authentication, you must first reauthorize LCP per-user attributes (for example, Session-Timeout) and then reauthorize Network Control Protocols (NCPs) to apply other necessary criteria, such as ACLs and routes. See the “[Examples for AAA Double Authentication Secured by Absolute Timeout](#)” section on [page 5](#).

Note

Timeout configuration in a TACACS+ user profile is a little different from the configuration in a RADIUS user profile. In a RADIUS profile, only one “Session-Timeout” is configured, along with the autocommand “access-profile.” The timeout will be applied to the EXEC session and to the PPP session. In TACACS+, however, the timeout must be configured under the service types “exec” and “ppp” (LCP) to apply a timeout to the EXEC session and to the PPP session. If the timeout is configured only under the service type “ppp,” the timeout value is not available while doing an EXEC authorization—and the timeout will not be applied to the EXEC session.

Verifying AAA Double Authentication Secured by Absolute Timeout

To verify that AAA double authentication has been secured by absolute timeout and to see information about various attributes associated with the authentication, perform the following steps. These **show** and **debug** commands can be used in any order.

SUMMARY STEPS

1. **enable**
 2. **show users**
 3. **show interfaces virtual-access *number* [configuration]**
 4. **debug aaa authentication**
 5. **debug aaa authorization**
 6. **debug aaa per-user**
 7. **debug ppp authentication**
 8. **debug radius**
- or
- debug tacacs**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	show users enable Example: Router# show users	Displays information about the active lines on the router.
Step 3	show interfaces virtual-access <i>number</i> [configuration] Example: Router# show interfaces virtual-access 2 configuration	Displays status, traffic data, and configuration information about a specified virtual access interface.
Step 4	debug aaa authentication Example: Router# debug aaa authentication	Displays information about AAA TACACS+ authentication.
Step 5	debug aaa authorization Example: Router# debug aaa authorization	Displays information about AAA TACACS+ authorization.
Step 6	debug aaa per-user Example: Router# debug aaa per-user	Displays the attributes that are applied to each user as the user authenticates.
Step 7	debug ppp authentication Example: Router# debug ppp authentication	Displays whether a user is passing authentication.
Step 8	debug radius Example: Router# debug radius or debug tacacs Example: Router# debug tacacs	Displays information associated with the RADIUS server. or Displays information associated with the TACACS+ server.

Examples

The following sample output is from the **show users** command:

```
Router# show users
```

Line	User	Host(s)	Idle	Location
* 0 con 0	aaapbx2	idle	00:00:00	aaacon2 10
8 vty 0	broker_def	idle	00:00:08	192.168.1.8

Interface	User	Mode	Idle	Peer Address
Vi2	broker_default	VDP	00:00:01	192.168.1.8 <=====
Se0:22	aaapbx2	Sync PPP	00:00:23	

The following sample output is from the **show interfaces virtual-access** command:

```
Router# show interfaces virtual-access 2 configuration
```

Virtual-Access2 is a Virtual Profile (sub)interface

Derived configuration: 150 bytes

```
!
interface Virtual-Access2
  ip unnumbered Serial0:23
  no ip route-cache
  timeout absolute 3 0
! The above line shows that the per-user session timeout has been applied.
  ppp authentication chap
  ppp timeout idle 180000
! The above line shows that the absolute timeout has been applied.
```

Examples for AAA Double Authentication Secured by Absolute Timeout

This section includes the following examples:

- [RADIUS User Profile: Example, page 5](#)
- [TACACS+ User Profile: Example, page 6](#)

RADIUS User Profile: Example

The following sample output shows that a RADIUS user profile has been applied and that AAA double authentication has been secured by an absolute timeout:

```
aaapbx2 Password = "cisco",
  Service-Type = Framed,
  Framed-Protocol = PPP,
  Session-Timeout = 180,
  Idle-Timeout = 180000,
  cisco-avpair = "ip:inacl#1=permit tcp any any eq telnet"
  cisco-avpair = "ip:inacl#2=permit icmp any any"

broker_default Password = "cisco",
  Service-Type = Administrative,
  cisco-avpair = "shell:autocmd=access-profile",
  Session-Timeout = 360,
```

```
cisco-avpair = "ip:inacl#1=permit tcp any any"
cisco-avpair = "ip:inacl#2=permit icmp any any"
```

```
broker_merge Password = "cisco",
  Service-Type = Administrative,
  cisco-avpair = "shell:autocmd=access-profile merge",
  Session-Timeout = 360,
  cisco-avpair = "ip:inacl#1=permit tcp any any"
  cisco-avpair = "ip:inacl#2=permit icmp any any"
  cisco-avpair = "ip:route#3=10.4.0.0 255.0.0.0"
  cisco-avpair = "ip:route#4=10.5.0.0 255.0.0.0"
  cisco-avpair = "ip:route#5=10.6.0.0 255.0.0.0"

broker_replace Password = "cisco",
  Service-Type = Administrative,
  cisco-avpair = "shell:autocmd=access-profile replace",
  Session-Timeout = 360,
  cisco-avpair = "ip:inacl#1=permit tcp any any"
  cisco-avpair = "ip:inacl#2=permit icmp any any"
  cisco-avpair = "ip:route#3=10.4.0.0 255.0.0.0"
  cisco-avpair = "ip:route#4=10.5.0.0 255.0.0.0"
  cisco-avpair = "ip:route#5=10.6.0.0 255.0.0.0"
```

TACACS+ User Profile: Example

The following sample output shows that a TACACS+ user profile has been applied and that AAA double authentication has been secured by an absolute timeout.

Remote Host

The following allows the remote host to be authenticated by the local host during first-stage authentication and provides the remote host authorization profile.

```
user = aaapbx2
  chap = cleartext Cisco
  pap = cleartext cisco
  login = cleartext cisco

service = ppp protocol = lcp
  idletime = 3000
  timeout = 3

service = ppp protocol = ip
  inacl#1="permit tcp any any eq telnet"

service = ppp protocol = ipx
```

access-profile Command Without Any Arguments

Using the **access-profile** command without any arguments causes the removal of any access lists that are found in the old configuration (both per-user and per-interface) and ensures that the new profile contains only access-list definitions.

```
user = broker_default
  login = cleartext Cisco
  chap = cleartext "cisco"

service = exec

  autocmd = "access-profile"
```

```
! This is the autocommand that executes when broker_default logs in.
timeout = 6

service = ppp protocol = lcp
timeout = 6

service = ppp protocol = ip
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!

inacl#1="permit tcp any any"
inacl#2="permit icmp host 10.0.0.0 any"

service = ppp protocol = ipx
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!
```

access-profile Command with merge Keyword

With the “merge” option, all old access lists are removed (as before), but then almost any AV pair is allowed to be uploaded and installed. This merge will allow for the uploading of any custom static routes, Service Advertisement Protocol (SAP) filters, and other requirements that the user may need in his or her profile. This merge must be used with care because it leaves everything open in terms of conflicting configurations.

```
user = broker_merge
login = cleartext Cisco
chap = cleartext "cisco"

service = exec

autocmd = "access-profile merge"
! This is the autocommand that executes when broker_merge logs in.
timeout = 6

service = ppp protocol = lcp
timeout = 6

service = ppp protocol = ip
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!

route#1="10.4.0.0 255.0.0.0"
route#2="10.5.0.0 255.0.0.0"
route#3="10.6.0.0 255.0.0.0"
inacl#5="permit tcp any any"
inacl#6="permit icmp host 10.60.0.0 any"

service = ppp protocol = ipx
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!
```

access-profile Command with the replace Keyword

If you use the **access-profile** command with the **replace** keyword, the command works as it does currently; that is, any old configuration is removed and any new configuration is installed.

**Note**

When the **access-profile** command is configured, the new configuration is checked for address pools and address attribute-value (AV) pairs. Because addresses cannot be renegotiated at this point, the command will fail to work when it encounters such an address AV pair.

```

user = broker_replace

login = cleartext Cisco
chap = cleartext "cisco"

service = exec

autocmd = "access-profile replace"
! This is the autocommand that executes when broker_replace logs in.
timeout = 6

service = ppp protocol = lcp
timeout = 6

service = ppp protocol = ip
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!

route#1="10.7.0.0 255.0.0.0"
route#2="10.8.0.0 255.0.0.0"
route#3="10.9.0.0 255.0.0.0"
inacl#4="permit tcp any any"

service = ppp protocol = ipx
! Put access lists, static routes, and other requirements that are
! needed here. Read the software specifications for details. If you leave
! this blank, the user will have no access lists (not even the ones that were
! installed prior to the creation of this user profile)!

```

**Note**

Timeout configuration in a TACACS+ user profile is a little different from the configuration in a RADIUS user profile. In a RADIUS profile, only one “Session-Timeout” is configured, along with the autocommand **access-profile**. The timeout will be applied to the EXEC session and to the PPP session. In TACACS+, however, the timeout must be configured under the service types “exec” and “ppp” (LCP) to apply a timeout to the EXEC session and to the PPP session. If the timeout is configured only under the service type “ppp,” the timeout value is not available while doing an EXEC authorization—and the timeout will not be applied to the EXEC session.

Feature Information for AAA Double Authentication Secured by Absolute Timeout

Table 1 lists the release history for this feature. Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for AAA Double Authentication Secured by Absolute Timeout

Feature Name	Releases	Feature Information
AAA Double Authentication Secured by Absolute Timeout	12.3(7)T 12.2(28)SB	The AAA Double Authentication Secured by Absolute Timeout feature allows you to secure the double authentication mechanism by protecting it with a per-user session timeout. This feature optimizes the connection to the network by service providers to only connections that are authorized, and it increases the security of the overall access to the network by ensuring that no unwanted sessions are connected.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Login Password Retry Lockout

The Login Password Retry Lockout feature allows system administrators to lock out a local authentication, authorization, and accounting (AAA) user account after a configured number of unsuccessful attempts by the user to log in.

Feature History for Login Password Retry Lockout

Release	Modification
12.3(14)T	This feature was introduced.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Prerequisites for Login Password Retry Lockout

- You must be running a Cisco IOS image that contains the AAA component.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Restrictions for Login Password Retry Lockout

- Authorized users can lock themselves out because there is no distinction between an attacker who is guessing passwords and an authorized user who is entering the password incorrectly multiple times.
- A denial of service (DoS) attack is possible, that is, an authorized user could be locked out by an attacker if the username of the authorized user is known to the attacker.

Information About Login Password Retry Lockout

To configure the Login Password Retry Lockout feature, you should understand the following concept:

- [Locking Out a Local AAA User Account, page 2](#)

Locking Out a Local AAA User Account

The Login Password Retry Lockout feature allows system administrators to lock out a local AAA user account after a configured number of unsuccessful attempts by the user to log in using the username that corresponds to the AAA user account. A locked-out user cannot successfully log in again until the user account is unlocked by the administrator.

A system message is generated when a user is either locked by the system or unlocked by the system administrator. The following is an example of such a system message:

```
%AAA-5-USER_LOCKED: User user1 locked out on authentication failure.
```

The system administrator cannot be locked out.

Note

The system administrator is a special user who has been configured using the maximum privilege level (root privilege—level 15). A user who has been configured using a lesser privilege level can change the privilege level using the **enable** command. If the user can change to the root privilege (level 15), that user is able to act as a system administrator.

This feature is applicable to any login authentication method, such as ASCII, Challenge Handshake Authentication Protocol (CHAP), and Password Authentication Protocol (PAP).

Note

No messages are displayed to users after authentication failures that are due to the locked status (that is, there is no distinction between a normal authentication failure and an authentication failure due to the locked status of the user).

How to Configure Login Password Retry Lockout

This section contains the following procedures:

- [Configuring Login Password Retry Lockout, page 3](#)
- [Unlocking a Locked-Out User, page 4](#)
- [Clearing the Unsuccessful Attempts of a User, page 5](#)

- [Monitoring and Maintaining Login Password Retry Lockout, page 5](#)

Configuring Login Password Retry Lockout

To configure Login Password Retry Lockout, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **username** *name* [**privilege** *level*] **password** *encryption-type password*
4. **aaa new-model**
5. **aaa local authentication attempts max-fail** *number-of-unsuccessful-attempts*
6. **aaa authentication login default** *method*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	username name [privilege level] password encryption-type password Example: Router (config)# username user1 privilege 15 password 0 cisco	Establishes a username-based authentication system.
Step 4	aaa new-model Example: Router (config)# aaa new-model	Enables the AAA access control model.
Step 5	aaa local authentication attempts max-fail number-of-unsuccessful-attempts Example: Router (config)# aaa local authentication attempts max-fail 3	Specifies the maximum number of unsuccessful attempts before a user is locked out.
Step 6	aaa authentication login default method Example: Router (config)# aaa authentication login default local	Method list for login, specifying to authenticate using the local AAA user database.

Unlocking a Locked-Out User

To unlock the locked-out user, perform the following steps.

**Note**

This task can be performed only by users having root privilege (level 15).

SUMMARY STEPS

1. enable
2. clear aaa local user logout {username username | all}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	clear aaa local user lockout {username username all} Example: Router# clear aaa local user lockout username user1	Unlocks a locked-out user.

Clearing the Unsuccessful Attempts of a User

To clear the unsuccessful attempts of a user that have already been logged, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **clear aaa local user fail-attempts {username username | all}**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	clear aaa local user fail-attempts {username username all} Example: Router# clear aaa local user fail-attempts username user1	Clears the unsuccessful attempts of the user. <ul style="list-style-type: none"> This command is useful for cases in which the user configuration was changed and the unsuccessful attempts that are already logged must be cleared.

Monitoring and Maintaining Login Password Retry Lockout

To monitor and maintain the Login Password Retry Lockout configuration, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **show aaa local user locked**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	show aaa local user locked Example: Router# show aaa local user locked	Displays a list of the locked-out users.

Configuration Examples for Login Password Retry Lockout

This section provides the following configuration examples:

- [Login Password Retry Lockout: Example, page 6](#)
- [show aaa local user lockout Command: Example, page 7](#)

Login Password Retry Lockout: Example

The following **show running-config** command output illustrates that the maximum number of failed user attempts has been set for 2:

```
Router # show running-config

Building configuration...

Current configuration : 1214 bytes
!
version 12.3
no service pad
service timestamps debug uptime
service timestamps log uptime
no service password-encryption
!
hostname LAC-2
!
boot-start-marker
boot-end-marker
!
!
username sysadmin
username sysad privilege 15 password 0 cisco
username user1 password 0 cisco
aaa new-model
aaa local authentication attempts max-fail 2
!
!
aaa authentication login default local
aaa dnis map enable
aaa session-id common
```

show aaa local user lockout Command: Example

The following output shows that user1 is locked out:

```
Router# show aaa local user lockout
```

Local-user	Lock time
user1	04:28:49 UTC Sat Jun 19 2004

MSCHAP Version 2

First Published: January 23, 2003

Last Updated: April 17, 2006

The MSCHAP Version 2 feature (introduced in Cisco IOS Release 12.2(2)XB5) allows Cisco routers to utilize Microsoft Challenge Handshake Authentication Protocol Version 2 (MSCHAP V2) authentication for PPP connections between a computer using a Microsoft Windows operating system and a network access server (NAS).

For Cisco IOS Release 12.4(6)T, MSCHAP V2 now supports a new feature: AAA Support for MSCHAPv2 Password Aging. Prior to Cisco IOS Release 12.4(6)T, when Password Authentication Protocol (PAP)-based clients sent username and password values to the authentication, authorization, and accounting (AAA) subsystem, AAA generated an authentication request to the RADIUS server. If the password expired, the RADIUS server replied with an authentication failure message. The reason for the authentication failure was not passed back to AAA subsystem; thus, users were denied access because of authentication failure but were not informed why they were denied access.

The Password Aging feature, available in Cisco IOS Release 12.4(6)T, notifies crypto-based clients that the password has expired and provides a generic way for the user to change the password. The Password Aging feature supports only crypto-based clients.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for MSCHAP Version 2](#)” section on page 11.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Contents

This document includes the following sections:

- [Prerequisites for MSCHAP Version 2, page 2](#)
- [Restrictions for MSCHAP Version 2, page 2](#)
- [Information About MSCHAP Version 2, page 3](#)
- [How to Configure MSCHAP Version 2, page 3](#)
- [Configuration Examples, page 6](#)
- [Additional References, page 8](#)
- [Command Reference, page 11](#)
- [Feature Information for MSCHAP Version 2, page 11](#)

Prerequisites for MSCHAP Version 2

- Configure an interface type and enter interface configuration mode by using the **interface** command.
- Configure the interface for PPP encapsulation by using the **encapsulation** command.
- Be sure that the client operating system supports all MSCHAP V2 capabilities.
- For Cisco IOS Release 12.4(6)T, the Password Aging feature only supports RADIUS authentication for crypto-based clients.
- To ensure that the MSCHAP Version 2 features correctly interpret the authentication failure attributes sent by the RADIUS server, you must configure the **ppp max-bad-auth** command and set the number of authentication retries at two or more.
- In order for the MSCHAP Version 2 feature to support the ability to change a password, the authentication failure attribute, which is sent by the RADIUS server, must be correctly interpreted as described in “[Configuring MSCHAP V2 Authentication](#)” section on page 3.

In addition, the **radius server vsa send authentication** command must be configured, allowing the RADIUS client to send a vendor-specific attribute to the RADIUS server. The Change Password feature is supported only for RADIUS authentication.

- The Microsoft Windows 2000, Microsoft Windows XP, and Microsoft Windows NT operating systems have a known caveat that prevents the Change Password feature from working. You must download a patch from Microsoft at the following URL:

<http://support.microsoft.com/default.aspx?scid=kb;en-us;Q326770>

For more information on completing these tasks, see the section “PPP Configuration” in the [Cisco IOS Dial Technologies Configuration Guide](#), Release 12.2. The RADIUS server must be configured for authentication. Refer to vendor-specific documentation for information on configuring RADIUS authentication on the RADIUS server.

Restrictions for MSCHAP Version 2

- MSCHAP V2 authentication is not compatible with MSCHAP V1 authentication.
- The change password option is supported only for RADIUS authentication and is not available for local authentication.

Information About MSCHAP Version 2

MSCHAP V2 authentication is the default authentication method used by the Microsoft Windows 2000 operating system. Cisco routers that support this authentication method enable Microsoft Windows 2000 operating system users to establish remote PPP sessions without configuring an authentication method on the client.

MSCHAP V2 authentication introduced an additional feature not available with MSCHAP V1 or standard CHAP authentication: the Change Password feature. This feature allows the client to change the account password if the RADIUS server reports that the password has expired.

**Note**

MSCHAP V2 authentication is an updated version of MSCHAP that is similar to but incompatible with MSCHAP Version 1 (V1). MSCHAP V2 introduces mutual authentication between peers and a Change Password feature.

How to Configure MSCHAP Version 2

See the following sections for configuration tasks for the MSCHAP Version 2 feature.

- [“Configuring MSCHAP V2 Authentication” section on page 3](#) (required)
- [“Verifying MSCHAP V2 Configuration” section on page 5](#) (optional)
- [“Configuring Password Aging for Crypto-Based Clients” section on page 5](#) (optional)

Configuring MSCHAP V2 Authentication

To configure the NAS to accept MSCHAP V2 authentication for local or RADIUS authentication and to allow proper interpretation of authentication failure attributes and vendor-specific RADIUS attributes for RADIUS authentication, use the following commands beginning in global configuration mode.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **radius-server vsa send authentication**
4. **interface** *type number*
5. **ppp max-bad-auth** *number*
6. **ppp authentication ms-chap-v2**
7. **end**

	Command	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	radius-server vsa send authentication Example: Router(config)# radius-server vsa send authentication	Configures the NAS to recognize and use vendor-specific attributes.
Step 4	interface type number Example: Router(config)# interface FastEthernet 0/1	Configures an interface type and enters interface configuration mode.
Step 5	ppp max-bad-auth number Example: Router(config-if)# ppp max-bad-auth 2	Configures a point-to-point interface to reset immediately after an authentication failure or within a specified number of authentication retries. <ul style="list-style-type: none"> The default value for the <i>number</i> argument is 0 seconds (immediately). The range is between 0 and 255. <div>  Note The <i>number</i> argument must be set to a value of at least 2 for authentication failure attributes to be interpreted by the NAS. </div>
Step 6	ppp authentication ms-chap-v2 Example: Router(config-if)# ppp authentication ms-chap-v2	Enables MSCHAP V2 authentication on a NAS.
Step 7	end Example: Router(config-if)# end	Returns to privileged EXEC mode.

Verifying MSCHAP V2 Configuration

To verify that the MSCHAP Version 2 feature is configured properly, perform the following steps.

SUMMARY STEPS

1. **show running-config interface** *type number*
2. **debug ppp negotiation**
3. **debug ppp authentication**

DETAILED STEPS

	Command or Action	Purpose
Step 1	show running-config interface <i>type number</i> Example: Router# show running-config interface Asynch65	Verifies the configuration of MSCHAP V2 as the authentication method for the specified interface.
Step 2	debug ppp negotiation Example: Router# debug ppp negotiation	Verifies successful MSCHAP V2 negotiation.
Step 3	debug ppp authentication Example: Router# debug ppp authentication	Verifies successful MSCHAP V2 authentication.

Configuring Password Aging for Crypto-Based Clients

The AAA security services facilitate a variety of login authentication methods. Use the **aaa authentication login** command to enable AAA authentication no matter which of the supported login authentication methods you decide to use. With the **aaa authentication login** command, you create one or more lists of authentication methods that are tried at login. These lists are applied using the **login authentication** line configuration command.

After the RADIUS server requests a new password, AAA queries the crypto client, which in turn prompts the user to enter a new password.

To configure login authentication and password aging for crypto-based clients, use the following commands beginning in global configuration mode.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa authentication login** {**default** | *list-name*} **passwd-expiry** *method1* [*method2*...]
5. **crypto map** *map-name* **client authentication list** *list-name*

	Command	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Router(config)# aaa new-model	Enables AAA globally.
Step 4	aaa authentication login {default list-name} passwd-expiry method1 [method2...] Example: Router(config)# aaa authentication login userauthen passwd-expiry group radius	Enables password aging for crypto-based clients on a local authentication list.
Step 5	crypto map map-name client authentication list list-name Example: Router(config)# crypto map clientmap client authentication list userauthen	Configures user authentication (a list of authentication methods) on an existing crypto map.

Configuration Examples

This section provides the following configuration examples:

- [“Configuring Local Authentication: Example” section on page 6](#)
- [“Configuring RADIUS Authentication: Example” section on page 7](#)
- [“Configuring Password Aging with Crypto Authentication: Example” section on page 7](#)

Configuring Local Authentication: Example

The following example configures PPP on an asynchronous interface and enables MSCHAP V2 authentication locally:

```
interface Async65
 ip address 10.0.0.2 255.0.0.0
 encapsulation ppp
 async mode dedicated
 no peer default ip address
 ppp max-bad-auth 3
 ppp authentication ms-chap-v2
 username client password secret
```

Configuring RADIUS Authentication: Example

The following example configures PPP on an asynchronous interface and enables MSCHAP V2 authentication via RADIUS:

```
interface Async65
  ip address 10.0.0.2 255.0.0.0
  encapsulation ppp
  async mode dedicated
  no peer default ip address
  ppp max-bad-auth 3
  ppp authentication ms-chap-v2
  exit
aaa authentication ppp default group radius
radius-server host 10.0.0.2 255.0.0.0
radius-server key secret
radius-server vsa send authentication
```

Configuring Password Aging with Crypto Authentication: Example

The following example configures password aging by using AAA with a crypto-based client:

```
aaa authentication login userauthen passwd-expiry group radius
!
aaa session-id common
!
crypto isakmp policy 3
  encr 3des
  authentication pre-share
  group 2
!
crypto isakmp client configuration group 3000client
  key cisco123
  dns 10.1.1.10
  wins 10.1.1.20
  domain cisco.com
  pool ippool
  acl 153
!
crypto ipsec transform-set myset esp-3des esp-sha-hmac
!
crypto dynamic-map dynmap 10
  set transform-set myset
!
crypto map clientmap client authentication list userauthen
!
radius-server host 10.140.15.203 auth-port 1645 acct-port 1646
radius-server domain-stripping prefix-delimiter $
radius-server key cisco123
radius-server vsa send authentication
radius-server vsa send authentication 3gpp2
!
end
```

RADIUS EAP Support

First Published: October 15, 2001

Last Updated: February 28, 2006

The RADIUS EAP Support feature allows users to apply to the client authentication methods that may not be supported by the network access server; this is done via the Extensible Authentication Protocol (EAP). Before this feature was introduced, support for various authentication methods for PPP connections required custom vendor-specific work and changes to the client and NAS.

History for the RADIUS EAP Support Feature

Release	Modification
12.2(2)XB5	This feature was introduced on the Cisco 2650, Cisco 3640, Cisco 3660, Cisco AS5300, and Cisco AS400 platforms.
12.2(13)T	This feature was integrated into Cisco IOS Release 12.2(13)T.
12.2(28)SB	This feature was integrated into Cisco IOS Release 12.2(28)SB.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Feature Overview

EAP is an authentication protocol for PPP that supports multiple authentication mechanisms that are negotiated during the authentication phase (instead of the link control protocol [LCP] phase). EAP allows a third-party authentication server to interact with a PPP implementation through a generic interface.

How EAP Works

By default, EAP runs in proxy mode. This means that EAP allows the entire authentication process to be negotiated by the NAS to a back-end server that may reside on or be accessed via a RADIUS server. After EAP is negotiated between the client and the NAS during LCP exchange, all further authentication messages are transparently transmitted between the client and the back-end server. The NAS is no longer directly involved in the authentication process; that is, the NAS works as a proxy, sending EAP messages between the remote peers.

Note

EAP can also run in a local mode; the session is authenticated using the Message Digest 5 (MD5) algorithm and obeys the same authentication rules as Challenge Handshake Authentication Protocol (CHAP). To disable proxy mode and authenticate locally, you must use the **ppp eap local** command.

Newly Supported Attributes

The RADIUS EAP Support feature introduces support for the following RADIUS attributes:

Number	IETF Attribute	Description
79	EAP-Message	Encapsulates one fragment of an EAP message, which includes the PPP type, request-id, length, and EAP-type fields.
80	Message Authenticator	Ensures source integrity of the message; all messages that are received with invalid checksums are silently discarded by either end. This attribute contains an HMAC-MD5 checksum of the entire RADIUS request or response message and uses the RADIUS server secret as the key.

Benefits

The RADIUS EAP Support feature makes it possible to apply to the client various authentication methods within PPP (including proprietary authentication) that are not supported by the NAS. Thus, customers can use standard support mechanisms for authentication schemes, such as token cards and public key, to strengthen end-user and device authenticated access to their networks.

Restrictions

When EAP is running in proxy mode, there may be a significant increase in the authentication time because every packet from the peer must be sent to the RADIUS server and every EAP packet from the RADIUS server must be sent back to the client. Although this extra processing will cause delays, you can increase the default authentication timeout value by using the **ppp timeout authentication** command.

Prerequisites

Before enabling EAP RADIUS on the client, you must perform the following tasks:

- Configure an interface type and enter interface configuration mode by using the **interface** command.
- Configure the interface for PPP encapsulation by using the **encapsulation** command.

For more information on completing these tasks, refer to the chapter “Configuring Media-Independent PPP and Multilink PPP” in the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.4.

Configuration Tasks

See the following sections for configuration tasks for the RADIUS EAP Support feature. Each task in the list is identified as either required or optional.

- [Configuring EAP, page 3](#) (required)
- [Verifying EAP, page 4](#) (optional)

Configuring EAP

To configure EAP on an interface configured for PPP encapsulation, use the following commands in interface configuration mode:

Command	Purpose
Router(config-if)# ppp authentication eap	Enables EAP as the authentication protocol.
Router(config-if)# ppp eap identity <i>string</i>	(Optional) Specifies the EAP identity when requested by the peer.
Router(config-if)# ppp eap password [<i>number</i>] <i>string</i>	(Optional) Sets the EAP password for peer authentication. Note This command should only be configured on the client.
Router(config-if)# ppp eap local	(Optional) Authenticates locally instead of using a RADIUS back-end server, which is the default. Note This command should only be configured on the NAS.

Command	Purpose
Router(config-if)# ppp eap wait	(Optional) Waits for the caller to authenticate itself first. By default, the client always authenticates itself before the caller does. Note This command should only be configured on the NAS.
Router(config-if)# ppp eap refuse [callin]	(Optional) Refuses to authenticate using EAP. If the callin keyword is enabled, only incoming calls will not be authenticated. Note This command should only be configured on the NAS.

Verifying EAP

To verify EAP configurations on your client or NAS, use at least one of the following commands in privileged EXEC configuration mode:

Command	Purpose
Router# show users	Displays information about the active lines on the router.
Router# show interfaces	Displays statistics for all interfaces configured on the router or access server.
Router# show running-config	Ensures that your configurations appear as part of the running configuration.

Configuration Examples

This section provides the following configuration examples:

- [EAP Local Configuration on Client Example, page 4](#)
- [EAP Proxy Configuration for NAS Example, page 5](#)

EAP Local Configuration on Client Example

The following example is a sample configuration for a client configured for EAP:

```
interface Ethernet0/0
 ip address 10.1.1.202 255.255.255.0
 no ip mroute-cache
 half-duplex
!
interface BRI0/0
 ip address 192.168.101.100 255.255.255.0
 encapsulation ppp
 no ip mroute-cache
 dialer map ip 192.168.101.101 56167
 dialer-group 1
 isdn switch-type basic-5ess
 ppp eap identity user
 ppp eap password 7 141B1309
!
```

```

!
ip default-gateway 10.1.1.1
ip classless
ip route 192.168.101.101 255.255.255.255 BRI0/0
no ip http server
!
dialer-list 1 protocol ip permit

```

EAP Proxy Configuration for NAS Example

The following example is a sample configuration for a NAS configured to use EAP proxy:

```

aaa authentication login default group radius
aaa authentication login NOAUTH none
aaa authentication ppp default if-needed group radius
aaa session-id common
enable secret 5 $1$x5D0$cfTL/D8Be.34PgTbdGdgl/
!
username dtw5 password 0 lab
username user password 0 lab

ip subnet-zero
no ip domain-lookup
ip host lab24-boot 172.19.192.254
ip host lb 172.19.192.254
!
isdn switch-type primary-5ess
!
controller T1 3
    framing esf
    linecode b8zs
    pri-group timeslots 1-24
!
interface Ethernet0
    ip address 10.1.1.108 255.255.255.0
    no ip route-cache
    no ip mroute-cache
!
interface Serial3:23
    ip address 192.168.101.101 255.255.255.0
    encapsulation ppp
    dialer map ip 192.168.101.100 60213
    dialer-group 1
    isdn switch-type primary-5ess
    isdn T321 0
    ppp authentication eap
    ppp eap password 7 011F0706
!
!
ip default-gateway 10.0.190.1
ip classless
ip route 192.168.101.0 255.255.255.0 Serial3:23
no ip http server
!
dialer-list 1 protocol ip permit
!
radius-server host 10.1.1.201 auth-port 1645 acct-port 1646 key lab
radius-server retransmit 3

Glossary

attribute—A RADIUS Internet Engineering Task Force (IETF) attribute is one of the original set of 255 standard attributes that are used to communicate authentication, authorization, and accounting (AAA) information between a client and a server. Because IETF attributes are standard, the attribute data is predefined and well known; thus all clients and servers that exchange AAA information via IETF attributes must agree on attribute data such as the exact meaning of the attributes and the general bounds of the values for each attribute.

CHAP—Challenge Handshake Authentication Protocol. Security feature that is supported on lines using PPP encapsulation and prevents unauthorized access. CHAP does not itself prevent unauthorized access; it merely identifies the remote end. The router or access server then determines whether that user is allowed access.

EAP—Extensible Authentication Protocol. A PPP authentication protocol that supports multiple authentication mechanisms that are negotiated during the authentication phase (instead of the Link Control Protocol [LCP] phase). EAP allows a third-party authentication server to interact with the PPP implementation through a generic interface.

LCP—link control protocol. Protocol that establishes, configures, and tests data-link connections for use by PPP.

MD5 (HMAC variant)—Message Digest 5. A hash algorithm used to authenticate packet data. HMAC is a key hashing for message authentication.

NAS—network access server. A device providing local network access to users across a remote access network such as the public switched telephone network (PSTN).

PAP—Password Authentication Protocol. Authentication protocol that allows PPP peers to authenticate one another. The remote router attempting to connect to the local router is required to send an authentication request. Unlike CHAP, PAP passes the password and host name or username in the clear (unencrypted). PAP does not itself prevent unauthorized access; it merely identifies the remote end. The router or access server then determines if that user is allowed access. PAP is supported only on PPP lines.

PPP—Point-to-Point Protocol. A protocol that encapsulates network layer protocol information over point-to-point links. PPP is defined in RFC 1661.

RADIUS—Remote Authentication Dial-In User Service. Database for authenticating modem and ISDN connections and for tracking connection time.

RADIUS Packet of Disconnect

Feature History

Release	Modification
12.1(2)XH	This command was introduced.
12.1(3)T	This command was integrated into Cisco IOS Release 12.1(3)T.
12.2(2)XB	Support for the voice applications as well as support for the Cisco AS5350, Cisco AS5400, and Cisco 3600 series routers was added.
12.2(2)XB1	Support for the Cisco AS5800 was added.
12.2(11)T	This feature was integrated into Cisco IOS Release 12.2(11)T and support for the Cisco AS5850 was added.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This document describes the RADIUS Packet of Disconnect feature in Cisco IOS Release 12.2(11)T. It includes the following sections.

Feature Overview

This feature consists of a method for terminating a call that has already been connected. This “Packet of Disconnect” (POD) is a RADIUS `access_request` packet and is intended to be used in situations where the authenticating agent server wants to disconnect the user after the session has been accepted by the RADIUS `access_accept` packet. This may be needed in at least two situations:

- Detection of fraudulent use, which cannot be performed before accepting the call. A price structure so complex that the maximum session duration cannot be estimated before accepting the call. This may be the case when certain types of discounts are applied or when multiple users use the same subscription simultaneously.
- To prevent unauthorized servers from disconnecting users, the authorizing agent that issues the POD packet must include three parameters in its packet of disconnect request. For a call to be disconnected, all parameters must match their expected values at the gateway. If the parameters do not match, the gateway discards the packet of disconnect packet and sends a NACK (negative acknowledgement message) to the agent.

The parameters are the following:

- An `h323-conf-id` vendor-specific attribute (VSA) with the same content as received from the gateway for this call.
- An `h323-call-origin` VSA with the same content as received from the gateway for the leg of interest.
- A 16-byte MD5 hash value that is carried in the *authentication* field of the POD request.

Benefits

- Ability to terminate an in-progress voice call

Restrictions

Proper matching identification information must be communicated by the:

- billing server and gateway configuration
- the gateway’s original accounting start request
- the server’s POD request

Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at <http://www.cisco.com/register>.

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

Availability of Cisco IOS Software Images

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

Supported Standards, MIBs, and RFCs

Standards

None

MIBs

None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB web site on Cisco.com at

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

RFCs

- RFC 2865, *Remote Authentication Dial-in User Service*

Prerequisites

- Configure AAA as described in *Cisco IOS Security Configuration Guide*, Cisco IOS Release 12.2.
- Use Cisco IOS Release 12.2(11)T or later.

Configuration Tasks

See the following sections for configuration tasks for this Packet of Disconnect feature. Each task in the list is identified as either required or optional.

- [Configuring AAA POD Server](#) (required)
- [Verifying AAA POD Server](#) (optional)

Configuring AAA POD Server

To configure POD, perform the following tasks in global configuration mode:

	Command	Purpose
Step 1	<pre>Router(config)# aaa pod server [port port-number] [auth-type {any all session-key}] server-key [encryption-type] <i>string</i></pre>	<p>Enables inbound user sessions to be disconnected when specific session attributes are presented.</p> <p>port <i>port-number</i>—(Optional) The network access server User Datagram Protocol (UDP) port to use for POD requests. Default value is 1700.</p> <p>auth-type—(Optional) The type of authorization required for disconnecting sessions.</p> <p>any—Session that matches all of the attributes sent in the POD packet is disconnected. The POD packet may contain one or more of four key attributes (user-name, framed-IP-address, session-ID, and session-key).</p> <p>all—Only a session that matches all four key attributes is disconnected. All is the default.</p> <p>session-key—Session with a matching session-key attribute is disconnected. All other attributes are ignored.</p> <p>server-key—Configures the shared-secret text string.</p> <p>encryption-type—(Optional) Single-digit number that defines whether the text immediately following is encrypted, and, if so, what type of encryption is used. Defined encryption types are 0, which means that the text immediately following is not encrypted, and 7, which means that the text is encrypted using an encryption algorithm defined by Cisco.</p> <p><i>string</i>—The shared-secret text string that is shared between the network access server and the client workstation. This shared-secret string must be the same on both systems.</p>

Verifying AAA POD Server

To verify that the gateway is configured correctly to perform as an AAA POD server, enter the **show running-configuration** command in privileged EXEC mode to display the command settings for the router.

```
Router# show running-configuration
!
aaa authentication login h323 group radius
aaa authorization exec h323 group radius
aaa accounting update newinfo
aaa accounting connection h323 start-stop group radius
aaa pod server server-key cisco
aaa session-id common
!
```

Troubleshooting Tips

- Ensure that the POD port is configured correctly in both the gateway(using **aaa pod server** command) and the radius server. Both should be the same.
- Ensure that the shared-secret key configured in the gateway (using **aaa pod server** command) and in the AAA server are the same.
- Turn on **debug aaa pod** command to see what's going on. This will let you know if the gateway receives the POD packet from the server and if so, it will display any errors encountered.

The following example shows output from a successful POD request, when using the **show debug** command.

```
Router# debug aaa pod
AAA POD packet processing debugging is on
Router# show debug
General OS:
  AAA POD packet processing debugging is on
Router#

Configuration Examples

This section provides a configuration example for a gateway performing as an AAA POD server:

- [AAA POD Server Example](#)

AAA POD Server Example

```
Router(config)# aaa pod server server-key xyz123
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **aaa pod server**
- **debug aaa pod**

Glossary

AAA—authentication, authorization, and accounting.

NACK—negative acknowledgement message.

POD—packet of disconnect. An access_reject packet sent from a RADIUS server to the gateway in order to disconnect a call which has been connected already. After validation of the packet, the gateway disconnects the user. The packet contains the information to disconnect the call.

POD server—a Cisco gateway configured to accept and process POD requests from a RADIUS authentication/authorization agent.

RADIUS—Remote Authentication Dial-In User Service. An authentication and accounting system used by many Internet service providers.

UDP—User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, requiring that error processing and retransmission be handled by other protocols. UDP is defined in RFC 768.

VoIP—voice over IP. The ability to carry normal telephony-style voice over an IP-based Internet with POTS-like functionality, reliability, and voice quality. VoIP is a blanket term that generally refers to the Cisco standards-based (for example, H.323) approach to IP voice traffic.

VSA—vendor-specific attribute.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Configuring Authorization

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

AAA authorization enables you to limit the services available to a user. When AAA authorization is enabled, the network access server uses information retrieved from the user's profile, which is located either in the local user database or on the security server, to configure the user's session. Once this is done, the user will be granted access to a requested service only if the information in the user profile allows it.

For a complete description of the authorization commands used in this chapter, refer to the chapter "Authorization Commands" in the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter "Identifying Supported Platforms" section in the "Using Cisco IOS Software."

In This Chapter

This chapter contains the following sections:

- [Named Method Lists for Authorization](#)
- [AAA Authorization Methods](#)
- [Method Lists and Server Groups](#)

- [Authorization Attribute-Value Pairs](#)
- [Authorization Configuration Examples](#)

Named Method Lists for Authorization

Method lists for authorization define the ways that authorization will be performed and the sequence in which these methods will be performed. A method list is simply a named list describing the authorization methods to be queried (such as RADIUS or TACACS+), in sequence. Method lists enable you to designate one or more security protocols to be used for authorization, thus ensuring a backup system in case the initial method fails. Cisco IOS software uses the first method listed to authorize users for specific network services; if that method fails to respond, the Cisco IOS software selects the next method listed in the method list. This process continues until there is successful communication with a listed authorization method, or all methods defined are exhausted.

Note

The Cisco IOS software attempts authorization with the next listed method only when there is no response from the previous method. If authorization fails at any point in this cycle—meaning that the security server or local username database responds by denying the user services—the authorization process stops and no other authorization methods are attempted.

Method lists are specific to the authorization type requested:

- **Auth-proxy**—Applies specific security policies on a per-user basis. For detailed information on the authentication proxy feature, refer to the chapter “Configuring Authentication Proxy” in the “Traffic Filtering and Firewalls” part of this book.
- **Commands**—Applies to the EXEC mode commands a user issues. Command authorization attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **EXEC**—Applies to the attributes associated with a user EXEC terminal session.
- **Network**—Applies to network connections. This can include a PPP, SLIP, or ARAP connection.
- **Reverse Access**—Applies to reverse Telnet sessions.

When you create a named method list, you are defining a particular list of authorization methods for the indicated authorization type.

Once defined, method lists must be applied to specific lines or interfaces before any of the defined methods will be performed. The only exception is the default method list (which is named “default”). If the **aaa authorization** command for a particular authorization type is issued without a named method list specified, the default method list is automatically applied to all interfaces or lines except those that have a named method list explicitly defined. (A defined method list overrides the default method list.) If no default method list is defined, local authorization takes place by default.

AAA Authorization Methods

AAA supports five different methods of authorization:

- **TACACS+**—The network access server exchanges authorization information with the TACACS+ security daemon. TACACS+ authorization defines specific rights for users by associating attribute-value pairs, which are stored in a database on the TACACS+ security server, with the appropriate user.

- **If-Authenticated**—The user is allowed to access the requested function provided the user has been authenticated successfully.
- **None**—The network access server does not request authorization information; authorization is not performed over this line/interface.
- **Local**—The router or access server consults its local database, as defined by the **username** command, for example, to authorize specific rights for users. Only a limited set of functions can be controlled via the local database.
- **RADIUS**—The network access server requests authorization information from the RADIUS security server. RADIUS authorization defines specific rights for users by associating attributes, which are stored in a database on the RADIUS server, with the appropriate user.

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. [Figure 5](#) shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers. R1 and R2 make up the group of RADIUS servers. T1 and T2 make up the group of TACACS+ servers.

Figure 5 *Typical AAA Network Configuration*

Using server groups, you can specify a subset of the configured server hosts and use them for a particular service. For example, server groups allow you to define R1 and R2 as separate server groups, and T1 and T2 as separate server groups. This means you can specify either R1 and T1 in the method list or R2 and T2 in the method list, which provides more flexibility in the way that you assign RADIUS and TACACS+ resources.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, authorization—the second host entry configured acts as fail-over

backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order they are configured.)

For more information about configuring server groups and about configuring server groups based on DNIS numbers, refer to the chapter “Configuring RADIUS” or the chapter “Configuring TACACS+”

AAA Authorization Types

Cisco IOS software supports five different types of authorization:

- **Auth-proxy**—Applies specific security policies on a per-user basis. For detailed information on the authentication proxy feature, refer to the “Configuring Authentication Proxy” chapter in the “Traffic Filtering and Firewalls” section of this book.
- **Commands**—Applies to the EXEC mode commands a user issues. Command authorization attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **EXEC**—Applies to the attributes associated with a user EXEC terminal session.
- **Network**—Applies to network connections. This can include a PPP, SLIP, or ARAP connection.
- **Reverse Access**—Applies to reverse Telnet sessions.
- **Configuration**—Applies to downloading configurations from the AAA server.
- **IP Mobile**—Applies to authorization for IP mobile services.

AAA Authorization Prerequisites

Before configuring authorization using named method lists, you must first perform the following tasks:

- Enable AAA on your network access server. For more information about enabling AAA on your Cisco router or access server, refer to the “AAA Overview” chapter.
- Configure AAA authentication. Authorization generally takes place after authentication and relies on authentication to work properly. For more information about AAA authentication, refer to the “Configuring Authentication” chapter.
- Define the characteristics of your RADIUS or TACACS+ security server if you are issuing RADIUS or TACACS+ authorization. For more information about configuring your Cisco network access server to communicate with your RADIUS security server, refer to the chapter “Configuring RADIUS”. For more information about configuring your Cisco network access server to communicate with your TACACS+ security server, refer to the chapter “Configuring TACACS+”.
- Define the rights associated with specific users by using the **username** command if you are issuing local authorization. For more information about the **username** command, refer to the *Cisco IOS Security Command Reference*.

AAA Authorization Configuration Task List

This section describes the following configuration tasks:

- [Configuring AAA Authorization Using Named Method Lists](#)

- [Disabling Authorization for Global Configuration Commands](#)
- [Configuring Authorization for Reverse Telnet](#)

For authorization configuration examples using the commands in this chapter, refer to the section “[Authorization Configuration Examples](#)” at the end of the this chapter.

Configuring AAA Authorization Using Named Method Lists

To configure AAA authorization using named method lists, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa authorization { auth-proxy network exec commands <i>level</i> reverse-access configuration ipmobile } { default <i>list-name</i> } [<i>method1</i> [<i>method2</i> ...]]	Creates an authorization method list for a particular authorization type and enable authorization.
Step 2	Router(config)# line [aux console tty vty] <i>line-number</i> [<i>ending-line-number</i>] or Router(config)# interface <i>interface-type interface-number</i>	Enters the line configuration mode for the lines to which you want to apply the authorization method list. Alternately, enters the interface configuration mode for the interfaces to which you want to apply the authorization method list.
Step 3	Router(config-line)# authorization { arap commands <i>level</i> exec reverse-access } { default <i>list-name</i> } or Router(config-line)# ppp authorization { default <i>list-name</i> }	Applies the authorization list to a line or set of lines. Alternately, applies the authorization list to an interface or set of interfaces.

This section includes the following sections:

- [Authorization Types](#)
- [Authorization Methods](#)

Authorization Types

Named authorization method lists are specific to the indicated type of authorization.

To create a method list to enable authorization that applies specific security policies on a per-user basis, use the **auth-proxy** keyword. For detailed information on the authentication proxy feature, refer to the chapter “Configuring Authentication Proxy” in the “Traffic Filtering and Firewalls” part of this book.

To create a method list to enable authorization for all network-related service requests (including SLIP, PPP, PPP NCPs, and ARAP), use the **network** keyword.

To create a method list to enable authorization to determine if a user is allowed to run an EXEC shell, use the **exec** keyword.

To create a method list to enable authorization for specific, individual EXEC commands associated with a specific privilege level, use the **commands** keyword. (This allows you to authorize all commands associated with a specified command level from 0 to 15.)

To create a method list to enable authorization for reverse Telnet functions, use the **reverse-access** keyword.

For information about the types of authorization supported by the Cisco IOS software, refer to the “[AAA Authorization Types](#)” section of this chapter.

Authorization Methods

To have the network access server request authorization information via a TACACS+ security server, use the **aaa authorization** command with the **group tacacs+ method** keyword. For more specific information about configuring authorization using a TACACS+ security server, refer to the chapter “Configuring TACACS+.” For an example of how to enable a TACACS+ server to authorize the use of network services, including PPP and ARA, see the section “[TACACS+ Authorization Examples](#)” at the end of this chapter.

To allow users to have access to the functions they request as long as they have been authenticated, use the **aaa authorization** command with the **if-authenticated method** keyword. If you select this method, all requested functions are automatically granted to authenticated users.

There may be times when you do not want to run authorization from a particular interface or line. To stop authorization activities on designated lines or interfaces, use the **none method** keyword. If you select this method, authorization is disabled for all actions.

To select local authorization, which means that the router or access server consults its local user database to determine the functions a user is permitted to use, use the **aaa authorization** command with the **local method** keyword. The functions associated with local authorization are defined by using the **username** global configuration command. For a list of permitted functions, refer to the chapter “Configuring Authentication.”

To have the network access server request authorization via a RADIUS security server, use the **radius method** keyword. For more specific information about configuring authorization using a RADIUS security server, refer to the chapter “Configuring RADIUS.”

To have the network access server request authorization via a RADIUS security server, use the **aaa authorization** command with the **group radius method** keyword. For more specific information about configuring authorization using a RADIUS security server, refer to the chapter “Configuring RADIUS”. For an example of how to enable a RADIUS server to authorize services, see the “[RADIUS Authorization Example](#)” section at the end of this chapter.

Note

Authorization method lists for SLIP follow whatever is configured for PPP on the relevant interface. If no lists are defined and applied to a particular interface (or no PPP settings are configured), the default setting for authorization applies.

Disabling Authorization for Global Configuration Commands

The **aaa authorization** command with the keyword **commands** attempts authorization for all EXEC mode commands, including global configuration commands, associated with a specific privilege level. Because there are configuration commands that are identical to some EXEC-level commands, there can be some confusion in the authorization process. Using **no aaa authorization config-commands** stops the network access server from attempting configuration command authorization.

To disable AAA authorization for all global configuration commands, use the following command in global configuration mode:

Command	Purpose
Router(config)# no aaa authorization config-commands	Disables authorization for all global configuration commands.

Configuring Authorization for Reverse Telnet

Telnet is a standard terminal emulation protocol used for remote terminal connection. Normally, you log in to a network access server (typically through a dialup connection) and then use Telnet to access other network devices from that network access server. There are times, however, when it is necessary to establish a reverse Telnet session. In reverse Telnet sessions, the Telnet connection is established in the opposite direction—from inside a network to a network access server on the network periphery to gain access to modems or other devices connected to that network access server. Reverse Telnet is used to provide users with dialout capability by allowing them to Telnet to modem ports attached to a network access server.

It is important to control access to ports accessible through reverse Telnet. Failure to do so could, for example, allow unauthorized users free access to modems where they can trap and divert incoming calls or make outgoing calls to unauthorized destinations.

Authentication during reverse Telnet is performed through the standard AAA login procedure for Telnet. Typically the user has to provide a username and password to establish either a Telnet or reverse Telnet session. Reverse Telnet authorization provides an additional (optional) level of security by requiring authorization in addition to authentication. When enabled, reverse Telnet authorization can use RADIUS or TACACS+ to authorize whether or not this user is allowed reverse Telnet access to specific asynchronous ports, after the user successfully authenticates through the standard Telnet login procedure.

Reverse Telnet authorization offers the following benefits:

- An additional level of protection by ensuring that users engaged in reverse Telnet activities are indeed authorized to access a specific asynchronous port using reverse Telnet.
- An alternative method (other than access lists) to manage reverse Telnet authorization.

To configure a network access server to request authorization information from a TACACS+ or RADIUS server before allowing a user to establish a reverse Telnet session, use the following command in global configuration mode:

Command	Purpose
<code>Router(config)# aaa authorization reverse-access method1 [method2 ...]</code>	Configures the network access server to request authorization information before allowing a user to establish a reverse Telnet session.

This feature enables the network access server to request reverse Telnet authorization information from the security server, whether RADIUS or TACACS+. You must configure the specific reverse Telnet privileges for the user on the security server itself.

Authorization Attribute-Value Pairs

RADIUS and TACACS+ authorization both define specific rights for users by processing attributes, which are stored in a database on the security server. For both RADIUS and TACACS+, attributes are defined on the security server, associated with the user, and sent to the network access server where they are applied to the user's connection.

For a list of supported RADIUS attributes, refer to the appendix "RADIUS Attributes". For a list of supported TACACS+ AV pairs, refer to the appendix "TACACS+ Attribute-Value Pairs."

Authorization Configuration Examples

The following sections provide authorization configuration examples:

- [Named Method List Configuration Example](#)
- [TACACS+ Authorization Examples](#)
- [RADIUS Authorization Example](#)
- [Reverse Telnet Authorization Examples](#)

Named Method List Configuration Example

The following example shows how to configure a Cisco AS5300 (enabled for AAA and communication with a RADIUS security server) for AAA services to be provided by the RADIUS server. If the RADIUS server fails to respond, then the local database will be queried for authentication and authorization information, and accounting services will be handled by a TACACS+ server.

```
aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
aaa authorization network scoobee group radius local
aaa accounting network charley start-stop group radius

username root password ALongPassword

radius-server host alcatraz
radius-server key myRaDiUSpassWoRd

interface group-async 1
 group-range 1 16
 encapsulation ppp
 ppp authentication chap dialins
 ppp authorization scoobee
 ppp accounting charley

line 1 16
 autoselect ppp
 autoselect during-login
 login authentication admins
 modem dialin
```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **aaa authentication login admins local** command defines a method list, admins, for login authentication.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **aaa authorization network scoobee group radius local** command defines the network authorization method list named scoobee, which specifies that RADIUS authorization will be used on serial lines using PPP. If the RADIUS server fails to respond, then local network authorization will be performed.

- The **aaa accounting network charley start-stop group radius** command defines the network accounting method list named charley, which specifies that RADIUS accounting services (in this case, start and stop records for specific events) will be used on serial lines using PPP.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.
- The **ppp authentication chap dialins** command selects Challenge Handshake Authentication Protocol (CHAP) as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.
- The **ppp authorization scoobee** command applies the scoobee network authorization method list to the specified interfaces.
- The **ppp accounting charley** command applies the charley network accounting method list to the specified interfaces.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the admins method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.

TACACS+ Authorization Examples

The following examples show how to use a TACACS+ server to authorize the use of network services, including PPP and ARA. If the TACACS+ server is not available or an error occurs during the authorization process, the fallback method (none) is to grant all authorization requests:

```
aaa authorization network default group tacacs+ none
```

The following example shows how to allow network authorization using TACACS+:

```
aaa authorization network default group tacacs+
```

The following example shows how to provide the same authorization, but it also creates address pools called “mci” and “att”:

```
aaa authorization network default group tacacs+
ip address-pool local
ip local-pool mci 172.16.0.1 172.16.0.255
ip local-pool att 172.17.0.1 172.17.0.255
```

These address pools can then be selected by the TACACS daemon. A sample configuration of the daemon follows:

```
user = mci_customer1 {
    login = cleartext "some password"
    service = ppp protocol = ip {
        addr-pool=mci
    }
}

user = att_customer1 {
    login = cleartext "some other password"
    service = ppp protocol = ip {
        addr-pool=att
    }
}
```

RADIUS Authorization Example

The following example shows how to configure the router to authorize using RADIUS:

```
aaa new-model
aaa authorization exec default group radius if-authenticated
aaa authorization network default group radius
radius-server host ip
radius-server key
```

The lines in this sample RADIUS authorization configuration are defined as follows:

- The **aaa authorization exec default group radius if-authenticated** command configures the network access server to contact the RADIUS server to determine if users are permitted to start an EXEC shell when they log in. If an error occurs when the network access server contacts the RADIUS server, the fallback method is to permit the CLI to start, provided the user has been properly authenticated.

The RADIUS information returned may be used to specify an autocommand or a connection access list be applied to this connection.

- The **aaa authorization network default group radius** command configures network authorization via RADIUS. This can be used to govern address assignment, the application of access lists, and various other per-user quantities.

Note

Because no fallback method is specified in this example, authorization will fail if, for any reason, there is no response from the RADIUS server.

Reverse Telnet Authorization Examples

The following examples show how to cause the network access server to request authorization information from a TACACS+ security server before allowing a user to establish a reverse Telnet session:

```
aaa new-model
aaa authentication login default group tacacs+
aaa authorization reverse-access default group tacacs+
!
tacacs-server host 172.31.255.0
tacacs-server timeout 90
tacacs-server key goaway
```

The lines in this sample TACACS+ reverse Telnet authorization configuration are defined as follows:

- The **aaa new-model** command enables AAA.
- The **aaa authentication login default group tacacs+** command specifies TACACS+ as the default method for user authentication during login.
- The **aaa authorization reverse-access default group tacacs+** command specifies TACACS+ as the method for user authorization when trying to establish a reverse Telnet session.
- The **tacacs-server host** command identifies the TACACS+ server.
- The **tacacs-server timeout** command sets the interval of time that the network access server waits for the TACACS+ server to reply.
- The **tacacs-server key** command defines the encryption key used for all TACACS+ communications between the network access server and the TACACS+ daemon.

The following example shows how to configure a generic TACACS+ server to grant a user, pat, reverse Telnet access to port tty2 on the network access server named “maple” and to port tty5 on the network access server named “oak”:

```
user = pat
  login = cleartext lab
  service = raccess {
    port#1 = maple/tty2
    port#2 = oak/tty5
```

Note

In this example, “maple” and “oak” are the configured host names of network access servers, not DNS names or alias.

The following example shows how to configure the TACACS+ server (CiscoSecure) to grant a user named pat reverse Telnet access:

```
user = pat
profile_id = 90
profile_cycle = 1
member = Tacacs_Users
service=shell {
  default cmd=permit
}
service=raccess {
  allow "c2511e0" "tty1" ".*"
  refuse ".*" ".*" ".*"
  password = clear "goaway"
```

Note

CiscoSecure only supports reverse Telnet using the command line interface in versions 2.1(x) through version 2.2(1).

An empty “service=raccess { }” clause permits a user to have unconditional access to network access server ports for reverse Telnet. If no “service=raccess” clause exists, the user is denied access to any port for reverse Telnet.

For more information about configuring TACACS+, refer to the chapter “Configuring TACACS+.” For more information about configuring CiscoSecure, refer to the *CiscoSecure Access Control Server User Guide*, version 2.1(2) or greater.

The following example shows how to cause the network access server to request authorization from a RADIUS security server before allowing a user to establish a reverse Telnet session:

```
aaa new-model
```

```
aaa authentication login default group radius
aaa authorization reverse-access default group radius
!
radius-server host 172.31.255.0
radius-server key go away
auth-port 1645 acct-port 1646
```

The lines in this sample RADIUS reverse Telnet authorization configuration are defined as follows:

- The **aaa new-model** command enables AAA.
- The **aaa authentication login default group radius** command specifies RADIUS as the default method for user authentication during login.
- The **aaa authorization reverse-access default group radius** command specifies RADIUS as the method for user authorization when trying to establish a reverse Telnet session.
- The **radius-server host** command identifies the RADIUS server.
- The **radius-server key** command defines the encryption key used for all RADIUS communications between the network access server and the RADIUS daemon.

The following example shows how to send a request to the RADIUS server to grant a user named “pat” reverse Telnet access at port tty2 on the network access server named “maple”:

```
Username = "pat"
Password = "goaway"
User-Service-Type = Shell-User
cisco-avpair = "raccess:port#1=maple/tty2"
```

The syntax "raccess:port=any/any" permits a user to have unconditional access to network access server ports for reverse Telnet. If no "raccess:port={nasname}/{tty number}" clause exists in the user profile, the user is denied access to reverse Telnet on all ports.

For more information about configuring RADIUS, refer to the chapter “Configuring RADIUS.”

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Configuring Accounting

The AAA accounting feature allows the services that users are accessing and the amount of network resources that users are consuming to be tracked. When AAA accounting is enabled, the network access server reports user activity to the TACACS+ or RADIUS security server (depending on which security method is implemented) in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, and auditing.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Configuring Accounting” section on page 28](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Configuring Accounting

The following tasks must be performed before configuring accounting using named method lists:

- Enable AAA on the network access server. For more information about enabling AAA on the Cisco router or access server, see “AAA Overview” in the *Cisco IOS Security Configuration Guide*.
- Define the characteristics of the RADIUS or TACACS+ security server if RADIUS or TACACS+ authorization is issued. For more information about configuring the Cisco network access server to communicate with the RADIUS security server, see “Configuring RADIUS” in the *Cisco IOS Security Configuration Guide*. For more information about configuring the Cisco network access server to communicate with the TACACS+ security server, see “Configuring TACACS+” in the *Cisco IOS Security Configuration Guide*.

Restrictions for Configuring Accounting

The AAA Accounting feature has the following restrictions:

- Accounting information can be sent simultaneously to a maximum of four AAA servers.
- SSG Restriction—For SSG systems, the **aaa accounting network broadcast** command broadcasts only **start-stop** accounting records. If interim accounting records are configured using the **ssg accounting interval** command, the interim accounting records are sent only to the configured default RADIUS server.

Information About Configuring Accounting

The following sections discuss how Accounting feature:

- [Named Method Lists for Accounting, page 2](#)
- [AAA Accounting Types, page 5](#)
- [AAA Accounting Enhancements, page 14](#)

Named Method Lists for Accounting

Like authentication and authorization method lists, method lists for accounting define the way accounting is performed and the sequence in which these methods are performed.

Named accounting method lists allow particular security protocol to be designated and used on specific lines or interfaces for accounting services. The only exception is the default method list (which, by coincidence, is named “default”). The default method list is automatically applied to all interfaces except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list is simply a named list describing the accounting methods to be queried (such as RADIUS or TACACS+), in sequence. Method lists allow one or more security protocols to be designated and used for accounting, thus ensuring a backup system for accounting in case the initial method fails. Cisco IOS software uses the first method listed to support accounting; if that method fails to respond, the Cisco IOS software selects the next accounting method listed in the method list. This process continues until there is successful communication with a listed accounting method, or all methods defined are exhausted.

**Note**

The Cisco IOS software attempts accounting with the next listed accounting method only when there is no response from the previous method. If accounting fails at any point in this cycle—meaning that the security server responds by denying the user access—the accounting process stops and no other accounting methods are attempted.

Accounting method lists are specific to the type of accounting being requested. AAA supports six different types of accounting:

- **Network**—Provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.
- **EXEC**—Provides information about user EXEC terminal sessions of the network access server.
- **Commands**—Provides information about the EXEC mode commands that a user issues. Command accounting generates accounting records for all EXEC mode commands, including global configuration commands, associated with a specific privilege level.
- **Connection**—Provides information about all outbound connections made from the network access server, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin.
- **System**—Provides information about system-level events.
- **Resource**—Provides “start” and “stop” records for calls that have passed user authentication, and provides “stop” records for calls that fail to authenticate.

**Note**

System accounting does not use named accounting lists; only the default list for system accounting can be defined.

Once again, when a named method list is created, a particular list of accounting methods for the indicated accounting type are defined.

Accounting method lists must be applied to specific lines or interfaces before any of the defined methods are performed. The only exception is the default method list (which is named “default”). If the **aaa accounting** command for a particular accounting type is issued without a named method list specified, the default method list is automatically applied to all interfaces or lines except those that have a named method list explicitly defined. (A defined method list overrides the default method list.) If no default method list is defined, then no accounting takes place.

This section includes the following subsections:

- [Method Lists and Server Groups, page 4](#)
- [AAA Accounting Methods, page 5](#)

Method Lists and Server Groups

A server group is a way to group existing RADIUS or TACACS+ server hosts for use in method lists. [Figure 1](#) shows a typical AAA network configuration that includes four security servers: R1 and R2 are RADIUS servers, and T1 and T2 are TACACS+ servers. R1 and R2 comprise the group of RADIUS servers. T1 and T2 comprise the group of TACACS+ servers.

Figure 1 *Typical AAA Network Configuration*

In Cisco IOS software, RADIUS and TACACS+ server configurations are global. A subset of the configured server hosts can be specified using server groups. These server groups can be used for a particular service. For example, server groups allow R1 and R2 to be defined as separate server groups (SG1 and SG2), and T1 and T2 as separate server groups (SG3 and SG4). This means either R1 and T1 (SG1 and SG3) can be specified in the method list or R2 and T2 (SG2 and SG4) in the method list, which provides more flexibility in the way that RADIUS and TACACS+ resources are assigned.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server tries the second host entry configured on the same device for accounting services. (The RADIUS host entries are tried in the order in which they are configured.)

For more information about configuring server groups and about configuring server groups based on DNIS numbers, see “Configuring RADIUS” or “Configuring TACACS+” in the *Cisco IOS Security Configuration Guide*.

AAA Accounting Methods

Cisco IOS supports the following two methods for accounting:

- **TACACS+**—The network access server reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server.
- **RADIUS**—The network access server reports user activity to the RADIUS security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server.

AAA Accounting Types

AAA supports six different accounting types:

- [Network Accounting](#)
- [Connection Accounting](#)
- [EXEC Accounting](#)
- [System Accounting](#)
- [Command Accounting](#)
- [Resource Accounting](#)

Network Accounting

Network accounting provides information for all PPP, SLIP, or ARAP sessions, including packet and byte counts.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through an EXEC session:

```
Wed Jun 27 04:44:45 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 5
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "562"
  Acct-Status-Type = Start
  Acct-Authentic = RADIUS
  Service-Type = Exec-User
  Acct-Session-Id = "0000000D"
  Acct-Delay-Time = 0
  User-Id = "username1"
  NAS-Identifier = "172.16.25.15"
```

```
Wed Jun 27 04:45:00 2001
  NAS-IP-Address = "172.16.25.15"
  NAS-Port = 5
  User-Name = "username1"
  Client-Port-DNIS = "4327528"
  Caller-ID = "562"
  Acct-Status-Type = Start
  Acct-Authentic = RADIUS
  Service-Type = Framed
  Acct-Session-Id = "0000000E"
  Framed-IP-Address = "10.1.1.2"
```

```

Framed-Protocol = PPP
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:47:46 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 5
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000E"
Framed-IP-Address = "10.1.1.2"
Framed-Protocol = PPP
Acct-Input-Octets = 3075
Acct-Output-Octets = 167
Acct-Input-Packets = 39
Acct-Output-Packets = 9
Acct-Session-Time = 171
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:48:45 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 5
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "408"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "0000000D"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who first started an EXEC session:

```

Wed Jun 27 04:00:35 2001 172.16.25.15 username1 tty4 562/4327528
starttask_id=28 service=shell
Wed Jun 27 04:00:46 2001 172.16.25.15 username1 tty4 562/4327528 starttask_id=30
addr=10.1.1.1 service=ppp
Wed Jun 27 04:00:49 2001 172.16.25.15 username1 tty4 408/4327528 update
task_id=30 addr=10.1.1.1 service=ppp protocol=ip addr=10.1.1.1
Wed Jun 27 04:01:31 2001 172.16.25.15 username1 tty4 562/4327528
stoptask_id=30 addr=10.1.1.1 service=ppp protocol=ip addr=10.1.1.1
bytes_in=2844 bytes_out=1682 paks_in=36 paks_out=24 elapsed_time=51
Wed Jun 27 04:01:32 2001 172.16.25.15 username1 tty4 562/4327528
stoptask_id=28 service=shell elapsed_time=57

```

**Note**

The precise format of accounting packets records may vary depending on the security server daemon.

The following example shows the information contained in a RADIUS network accounting record for a PPP user who comes in through autoselect:

```

Wed Jun 27 04:30:52 2001

```

```

NAS-IP-Address = "172.16.25.15"
NAS-Port = 3
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000B"
Framed-Protocol = PPP
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:36:49 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 3
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "562"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Framed
Acct-Session-Id = "0000000B"
Framed-Protocol = PPP
Framed-IP-Address = "10.1.1.1"
Acct-Input-Octets = 8630
Acct-Output-Octets = 5722
Acct-Input-Packets = 94
Acct-Output-Packets = 64
Acct-Session-Time = 357
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ network accounting record for a PPP user who comes in through autoselect:

```

Wed Jun 27 04:02:19 2001 172.16.25.15 username1 Async5 562/4327528
starttask_id=35 service=ppp
Wed Jun 27 04:02:25 2001 172.16.25.15 username1 Async5 562/4327528 update
task_id=35 service=ppp protocol=ip addr=10.1.1.2
Wed Jun 27 04:05:03 2001 172.16.25.15 username1 Async5 562/4327528
stoptask_id=35 service=ppp protocol=ip addr=10.1.1.2 bytes_in=3366
bytes_out=2149 paks_in=42 paks_out=28 elapsed_time=164

```

Connection Accounting

Connection accounting provides information about all outbound connections made from the network access server, such as Telnet, local-area transport (LAT), TN3270, packet assembler/disassembler (PAD), and rlogin.

The following example shows the information contained in a RADIUS connection accounting record for an outbound Telnet connection:

```

Wed Jun 27 04:28:00 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Start

```

```

Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "00000008"
Login-Service = Telnet
Login-IP-Host = "10.68.202.158"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

```

Wed Jun 27 04:28:39 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "00000008"
Login-Service = Telnet
Login-IP-Host = "10.68.202.158"
Acct-Input-Octets = 10774
Acct-Output-Octets = 112
Acct-Input-Packets = 91
Acct-Output-Packets = 99
Acct-Session-Time = 39
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ connection accounting record for an outbound Telnet connection:

```

Wed Jun 27 03:47:43 2001      172.16.25.15      username1      tty3      5622329430/4327528
start      task_id=10      service=connection      protocol=telnet      addr=10.68.202.158
cmd=telnet      username1-sun
Wed Jun 27 03:48:38 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=10      service=connection      protocol=telnet      addr=10.68.202.158
cmd=telnet      username1-sun      bytes_in=4467      bytes_out=96      paks_in=61      paks_out=72
elapsed_time=55

```

The following example shows the information contained in a RADIUS connection accounting record for an outbound rlogin connection:

```

Wed Jun 27 04:29:48 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "0000000A"
Login-Service = Rlogin
Login-IP-Host = "10.68.202.158"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:30:09 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 2
User-Name = "username1"

```

```

Client-Port-DNIS = "4327528"
Caller-ID = "5622329477"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Login
Acct-Session-Id = "0000000A"
Login-Service = Rlogin
Login-IP-Host = "10.68.202.158"
Acct-Input-Octets = 18686
Acct-Output-Octets = 86
Acct-Input-Packets = 90
Acct-Output-Packets = 68
Acct-Session-Time = 22
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ connection accounting record for an outbound rlogin connection:

```

Wed Jun 27 03:48:46 2001      172.16.25.15      username1      tty3      5622329430/4327528
start      task_id=12      service=connection      protocol=rlogin      addr=10.68.202.158
cmd=rlogin username1-sun /user username1
Wed Jun 27 03:51:37 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=12      service=connection      protocol=rlogin      addr=10.68.202.158
cmd=rlogin username1-sun /user username1      bytes_in=659926      bytes_out=138      paks_in=2378
paks_
out=1251      elapsed_time=171

```

The following example shows the information contained in a TACACS+ connection accounting record for an outbound LAT connection:

```

Wed Jun 27 03:53:06 2001      172.16.25.15      username1      tty3      5622329430/4327528
start      task_id=18      service=connection      protocol=lat      addr=VAX      cmd=lat
VAX
Wed Jun 27 03:54:15 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=18      service=connection      protocol=lat      addr=VAX      cmd=lat
VAX      bytes_in=0      bytes_out=0      paks_in=0      paks_out=0      elapsed_time=6

```

EXEC Accounting

EXEC accounting provides information about user EXEC terminal sessions (user shells) on the network access server, including username, date, start and stop times, the access server IP address, and (for dial-in users) the telephone number the call originated from.

The following example shows the information contained in a RADIUS EXEC accounting record for a dial-in user:

```

Wed Jun 27 04:26:23 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 1
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329483"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000006"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

```

Wed Jun 27 04:27:25 2001

```

```

NAS-IP-Address = "172.16.25.15"
NAS-Port = 1
User-Name = "username1"
Client-Port-DNIS = "4327528"
Caller-ID = "5622329483"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000006"
Acct-Session-Time = 62
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ EXEC accounting record for a dial-in user:

```

Wed Jun 27 03:46:21 2001      172.16.25.15      username1      tty3      5622329430/4327528
start      task_id=2      service=shell
Wed Jun 27 04:08:55 2001      172.16.25.15      username1      tty3      5622329430/4327528
stop      task_id=2      service=shell      elapsed_time=1354

```

The following example shows the information contained in a RADIUS EXEC accounting record for a Telnet user:

```

Wed Jun 27 04:48:32 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 26
User-Name = "username1"
Caller-ID = "10.68.202.158"
Acct-Status-Type = Start
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000010"
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

Wed Jun 27 04:48:46 2001
NAS-IP-Address = "172.16.25.15"
NAS-Port = 26
User-Name = "username1"
Caller-ID = "10.68.202.158"
Acct-Status-Type = Stop
Acct-Authentic = RADIUS
Service-Type = Exec-User
Acct-Session-Id = "00000010"
Acct-Session-Time = 14
Acct-Delay-Time = 0
User-Id = "username1"
NAS-Identifier = "172.16.25.15"

```

The following example shows the information contained in a TACACS+ EXEC accounting record for a Telnet user:

```

Wed Jun 27 04:06:53 2001      172.16.25.15      username1      tty26      10.68.202.158
starttask_id=41      service=shell
Wed Jun 27 04:07:02 2001      172.16.25.15      username1      tty26      10.68.202.158
stoptask_id=41      service=shell      elapsed_time=9

```

System Accounting

System accounting provides information about all system-level events (for example, when the system reboots or when accounting is turned on or off).

The following accounting record shows a typical TACACS+ system accounting record server indicating that AAA accounting has been turned off:

```
Wed Jun 27 03:55:32 2001      172.16.25.15   unknown unknown unknown start   task_id=25
service=system event=sys_acct reason=reconfigure
```

Note

The precise format of accounting packets records may vary depending on the TACACS+ daemon.

The following accounting record shows a TACACS+ system accounting record indicating that AAA accounting has been turned on:

```
Wed Jun 27 03:55:22 2001      172.16.25.15   unknown unknown unknown stop    task_id=23
service=system event=sys_acct reason=reconfigure
```

Additional tasks for measuring system resources are covered in the Cisco IOS software configuration guides. For example, IP accounting tasks are described in the “Configuring IP Services” feature module in the *Cisco IOS IP Configuration Guide*.

Command Accounting

Command accounting provides information about the EXEC shell commands for a specified privilege level that are being executed on a network access server. Each command accounting record includes a list of the commands executed for that privilege level, as well as the date and time each command was executed, and the user who executed it.

The following example shows the information contained in a TACACS+ command accounting record for privilege level 1:

```
Wed Jun 27 03:46:47 2001      172.16.25.15   username1 tty3   5622329430/4327528
stop task_id=3 service=shell priv-lvl=1 cmd=show version <cr>
Wed Jun 27 03:46:58 2001      172.16.25.15   username1 tty3   5622329430/4327528
stop task_id=4 service=shell priv-lvl=1 cmd=show interfaces Ethernet 0
<cr>
Wed Jun 27 03:47:03 2001      172.16.25.15   username1 tty3   5622329430/4327528
stop task_id=5 service=shell priv-lvl=1 cmd=show ip route <cr>
```

The following example shows the information contained in a TACACS+ command accounting record for privilege level 15:

```
Wed Jun 27 03:47:17 2001      172.16.25.15   username1 tty3   5622329430/4327528
stop task_id=6 service=shell priv-lvl=15 cmd=configure terminal <cr>
Wed Jun 27 03:47:21 2001      172.16.25.15   username1 tty3   5622329430/4327528
stop task_id=7 service=shell priv-lvl=15 cmd=interface Serial 0 <cr>
Wed Jun 27 03:47:29 2001      172.16.25.15   username1 tty3   5622329430/4327528
stop task_id=8 service=shell priv-lvl=15 cmd=ip address 10.1.1.1
255.255.255.0 <cr>
```

Note

The Cisco Systems implementation of RADIUS does not support command accounting.

Resource Accounting

The Cisco implementation of AAA accounting provides “start” and “stop” record support for calls that have passed user authentication. The additional feature of generating “stop” records for calls that fail to authenticate as part of user authentication is also supported. Such records are necessary for users employing accounting records to manage and monitor their networks.

This section includes the following subsections:

- [AAA Resource Failure Stop Accounting, page 12](#)
- [AAA Resource Accounting for Start-Stop Records, page 14](#)

AAA Resource Failure Stop Accounting

Before AAA resource failure stop accounting, there was no method of providing accounting records for calls that failed to reach the user authentication stage of a call setup sequence. Such records are necessary for users employing accounting records to manage and monitor their networks and their wholesale customers.

This functionality generates a “stop” accounting record for any calls that do not reach user authentication; “stop” records are generated from the moment of call setup. All calls that pass user authentication behave as they did before; that is, no additional accounting records are seen.

**Note**

For Cisco IOS Release 12.2, this function is supported only on the Cisco AS5300 and Cisco AS5800.

[Figure 2](#) illustrates a call setup sequence with normal call flow (no disconnect) and without AAA resource failure stop accounting enabled.

Figure 2 Modem Dial-In Call Setup Sequence With Normal Flow and Without Resource Failure Stop Accounting Enabled

[Figure 3](#) illustrates a call setup sequence with normal call flow (no disconnect) and with AAA resource failure stop accounting enabled.

Figure 3 *Modem Dial-In Call Setup Sequence With Normal Flow and With Resource Failure Stop Accounting Enabled*

Figure 4 illustrates a call setup sequence with call disconnect occurring before user authentication and with AAA resource failure stop accounting enabled.

Figure 4 *Modem Dial-In Call Setup Sequence With Call Disconnect Occurring Before User Authentication and With Resource Failure Stop Accounting Enabled*

Figure 11 illustrates a call setup sequence with call disconnect occurring before user authentication and without AAA resource failure stop accounting enabled.

Figure 5 *Modem Dial-In Call Setup Sequence With Call Disconnect Occurring Before User Authentication and Without Resource Failure Stop Accounting Enabled*

AAA Resource Accounting for Start-Stop Records

AAA resource accounting for start-stop records supports the ability to send a “start” record at each call setup, followed by a corresponding “stop” record at the call disconnect. This functionality can be used to manage and monitor wholesale customers from one source of data reporting, such as accounting records.

With this feature, a call setup and call disconnect “start-stop” accounting record tracks the progress of the resource connection to the device. A separate user authentication “start-stop” accounting record tracks the user management progress. These two sets of accounting records are interlinked by using a unique session ID for the call.

**Note**

For Cisco IOS Release 12.2, this function is supported only on the Cisco AS5300 and Cisco AS5800.

Figure 6 illustrates a call setup sequence with AAA resource start-stop accounting enabled.

Figure 6 *Modem Dial-In Call Setup Sequence With Resource Start-Stop Accounting Enabled*

AAA Accounting Enhancements

The section includes the following enhancements:

- [AAA Broadcast Accounting, page 14](#)
- [AAA Session MIB, page 15](#)

AAA Broadcast Accounting

AAA broadcast accounting allows accounting information to be sent to multiple AAA servers at the same time; that is, accounting information can be broadcast to one or more AAA servers simultaneously. This functionality allows service providers to send accounting information to their own private AAA servers and to the AAA servers of their end customers. It also provides redundant billing information for voice applications.

Broadcasting is allowed among groups of RADIUS or TACACS+ servers, and each server group can define its backup servers for failover independently of other groups.

Thus, service providers and their end customers can use different protocols (RADIUS or TACACS+) for the accounting server. Service providers and their end customers can also specify their backup servers independently. As for voice applications, redundant accounting information can be managed independently through a separate group with its own failover sequence.

AAA Session MIB

The AAA session MIB feature allows customers to monitor and terminate their authenticated client connections using Simple Network Management Protocol (SNMP). The data of the client is presented so that it correlates directly to the AAA accounting information reported by either the RADIUS or the TACACS+ server. AAA session MIB provides the following information:

- Statistics for each AAA function (when used in conjunction with the **show radius statistics** command)
- Status of servers providing AAA functions
- Identities of external AAA servers
- Real-time information (such as idle times), providing additional criteria for use by SNMP networks for assessing whether or not to terminate an active call

Note

This command is supported only on Cisco AS5300 and Cisco AS5800 universal access server platforms.

[Table 1](#) shows the SNMP user-end data objects that can be used to monitor and terminate authenticated client connections with the AAA session MIB feature.

Table 1 *SNMP End-User Data Objects*

SessionId	The session identification used by the AAA accounting protocol (same value as reported by RADIUS attribute 44 (Acct-Session-ID)).
UserId	The user login ID or zero-length string if a login is unavailable.
IpAddr	The IP address of the session or 0.0.0.0 if an IP address is not applicable or unavailable.
IdleTime	The elapsed time in seconds that the session has been idle.
Disconnect	The session termination object used to disconnect the given client.
CallId	The entry index corresponding to this accounting session that the Call Tracker record stored.

[Table 2](#) describes the AAA summary information provided by the AAA session MIB feature using SNMP on a per-system basis.

Table 2 *SNMP AAA Session Summary*

ActiveTableEntries	Number of sessions currently active.
ActiveTableHighWaterMark	Maximum number of sessions present at once since last system reinstallation.
TotalSessions	Total number of sessions since last system reinstallation.
DisconnectedSessions	Total number of sessions that have been disconnected using since last system reinstallation.

How to Configure AAA Accounting

This section describes the following configuration tasks involved in configuring AAA Accounting:

- [Configuring AAA Accounting Using Named Method Lists](#)
- [Suppressing Generation of Accounting Records for Null Username Sessions](#)
- [Generating Interim Accounting Records](#)
- [Generating Accounting Records for Failed Login or Session](#)
- [Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records](#)
- [Configuring AAA Resource Failure Stop Accounting](#)
- [Configuring AAA Resource Accounting for Start-Stop Records](#)
- [Configuring AAA Broadcast Accounting](#)
- [Configuring AAA Resource Failure Stop Accounting](#)
- [Configuring AAA Session MIB](#)
- [Establishing a Session with a Router if the AAA Server is Unreachable](#)
- [Monitoring Accounting](#)
- [Troubleshooting Accounting](#)

Configuring AAA Accounting Using Named Method Lists

To configure AAA accounting using named method lists, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa accounting { system network exec connection commands <i>level</i> } { default <i>list-name</i> } { start-stop stop-only none } [<i>method1</i> [<i>method2</i> ...]]	Creates an accounting method list and enables accounting. The argument <i>list-name</i> is a character string used to name the created list.
Step 2	Router(config)# line [aux console tty vty] <i>line-number</i> [<i>ending-line-number</i>] or Router(config)# interface <i>interface-type</i> <i>interface-number</i>	Enters the line configuration mode for the lines to which the accounting method list is applied. or Enters the interface configuration mode for the interfaces to which the accounting method list is applied.
Step 3	Router(config-line)# accounting { arap commands <i>level</i> connection exec } { default <i>list-name</i> } or Router(config-if)# ppp accounting { default <i>list-name</i> }	Applies the accounting method list to a line or set of lines. or Applies the accounting method list to an interface or set of interfaces.

Note

System accounting does not use named method lists. For system accounting, define only the default method list.

This section includes the following sections:

- [Accounting Types, page 17](#)
- [Accounting Record Types, page 17](#)
- [Accounting Methods, page 17](#)

Accounting Types

Named accounting method lists are specific to the indicated type of accounting.

- **network**—To create a method list to enable authorization for all network-related service requests (including SLIP, PPP, PPP NCPs, and ARA protocols), use the **network** keyword. For example, to create a method list that provides accounting information for ARAP (network) sessions, use the **arap** keyword.
- **exec**—To create a method list that provides accounting records about user EXEC terminal sessions on the network access server, including username, date, start and stop times, use the **exec** keyword.
- **commands**—To create a method list that provides accounting information about specific, individual EXEC commands associated with a specific privilege level, use the **commands** keyword.
- **connection**—To create a method list that provides accounting information about all outbound connections made from the network access server, use the **connection** keyword.
- **resource**—Creates a method list to provide accounting records for calls that have passed user authentication or calls that failed to be authenticated.

Note

System accounting does not support named method lists.

Accounting Record Types

For minimal accounting, use the **stop-only** keyword, which instructs the specified method (RADIUS or TACACS+) to send a stop record accounting notice at the end of the requested user process. For more accounting information, use the **start-stop** keyword to send a start accounting notice at the beginning of the requested event and a stop accounting notice at the end of the event. To stop all accounting activities on this line or interface, use the **none** keyword.

Accounting Methods

[Table 3](#) lists the supported accounting methods.

Table 3 *AAA Accounting Methods*

Keyword	Description
group radius	Uses the list of all RADIUS servers for accounting.
group tacacs+	Uses the list of all TACACS+ servers for accounting.
group group-name	Uses a subset of RADIUS or TACACS+ servers for accounting as defined by the server group <i>group-name</i> .

The method argument refers to the actual method the authentication algorithm tries. Additional methods of authentication are used only if the previous method returns an error, not if it fails. To specify that the authentication should succeed even if all other methods return an error, specify additional methods in the command. For example, to create a method list named `acct_tac1` that specifies RADIUS as the backup method of authentication in the event that TACACS+ authentication returns an error, enter the following command:

```
aaa accounting network acct_tac1 stop-only group tacacs+ group radius
```

To create a default list that is used when a named list is *not* specified in the **aaa accounting** command, use the **default** keyword followed by the methods that are wanted to be used in default situations. The default method list is automatically applied to all interfaces.

For example, to specify RADIUS as the default method for user authentication during login, enter the following command:

```
aaa accounting network default stop-only group radius
```

AAA accounting supports the following methods:

- **group tacacs**—To have the network access server send accounting information to a TACACS+ security server, use the **group tacacs+ method** keyword. For more specific information about configuring TACACS+ for accounting services, see “Configuring TACACS+” in the *Cisco IOS Security Configuration Guide*.
- **group radius**—To have the network access server send accounting information to a RADIUS security server, use the **group radius method** keyword. For more specific information about configuring RADIUS for accounting services, see “Configuring RADIUS” in the *Cisco IOS Security Configuration Guide*.

Note

Accounting method lists for SLIP follow whatever is configured for PPP on the relevant interface. If no lists are defined and applied to a particular interface (or no PPP settings are configured), the default setting for accounting applies.

- **group group-name**—To specify a subset of RADIUS or TACACS+ servers to use as the accounting method, use the **aaa accounting** command with the **group group-name method**. To specify and define the group name and the members of the group, use the **aaa group server** command. For example, use the **aaa group server** command to first define the members of **group loginrad**:

```
aaa group server radius loginrad
server 172.16.2.3
server 172.16.2.17
server 172.16.2.32
```

This command specifies RADIUS servers 172.16.2.3, 172.16.2.17, and 172.16.2.32 as members of the group *loginrad*.

To specify **group loginrad** as the method of network accounting when no other method list has been defined, enter the following command:

```
aaa accounting network default start-stop group loginrad
```

Before a group name can be used as the accounting method, communication with the RADIUS or TACACS+ security server must be enabled. For more information about establishing communication with a RADIUS server, see “Configuring RADIUS” in the *Cisco IOS Security Configuration Guide*. For more information about establishing communication with a TACACS+ server, see “Configuring TACACS+” in the *Cisco IOS Security Configuration Guide*.

Suppressing Generation of Accounting Records for Null Username Sessions

When AAA accounting is activated, the Cisco IOS software issues accounting records for all users on the system, including users whose username string, because of protocol translation, is NULL. An example of this is users who come in on lines where the **aaa authentication login method-list none** command is applied. To prevent accounting records from being generated for sessions that do not have usernames associated with them, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting suppress null-username	Prevents accounting records from being generated for users whose username string is NULL.

Generating Interim Accounting Records

To enable periodic interim accounting records to be sent to the accounting server, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting update {[newinfo] [periodic] number}	Enables periodic interim accounting records to be sent to the accounting server.

When the **aaa accounting update** command is activated, the Cisco IOS software issues interim accounting records for all users on the system. If the keyword **newinfo** is used, interim accounting records are sent to the accounting server every time there is new accounting information to report. An example of this would be when IPCP completes IP address negotiation with the remote peer. The interim accounting record includes the negotiated IP address used by the remote peer.

When used with the keyword **periodic**, interim accounting records are sent periodically as defined by the argument number. The interim accounting record contains all of the accounting information recorded for that user up to the time the interim accounting record is sent.

Caution

Using the **aaa accounting update periodic** command can cause heavy congestion when many users are logged in to the network.

Generating Accounting Records for Failed Login or Session

When AAA accounting is activated, the Cisco IOS software does not generate accounting records for system users who fail login authentication, or who succeed in login authentication but fail PPP negotiation for some reason.

To specify that accounting stop records be generated for users who fail to authenticate at login or during session negotiation, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting send stop-record authentication failure	Generates “stop” records for users who fail to authenticate at login or during session negotiation using PPP.

Specifying Accounting NETWORK-Stop Records Before EXEC-Stop Records

For PPP users who start EXEC terminal sessions, it can be specified that NETWORK records be generated before EXEC-stop records. In some cases, such as billing customers for specific services, it can be desirable to keep network start and stop records together, essentially “nesting” them within the framework of the EXEC start and stop messages. For example, a user dialing in using PPP can create the following records: EXEC-start, NETWORK-start, EXEC-stop, NETWORK-stop. By nesting the accounting records, NETWORK-stop records follow NETWORK-start messages: EXEC-start, NETWORK-start, NETWORK-stop, EXEC-stop.

To nest accounting records for user sessions, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting nested	Nests network accounting records.

Configuring AAA Resource Failure Stop Accounting

To enable resource failure stop accounting, use the following command in global configuration:

Command	Purpose
Router(config)# aaa accounting resource <i>method-list stop-failure group server-group</i>	<p>Generates a “stop” record for any calls that do not reach user authentication.</p> <p>Note Before configuring this feature, the tasks described in the section “Prerequisites for Configuring Accounting” section on page 2” must be performed, and SNMP must be enabled on the network access server. For more information about enabling SNMP on a Cisco router or access server, see “Configuring SNMP Support” of the <i>Cisco IOS Configuration Fundamentals Configuration Guide</i>.</p>

Configuring AAA Resource Accounting for Start-Stop Records

To enable full resource accounting for start-stop records, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa accounting resource <i>method-list start-stop group server-group</i>	Supports the ability to send a “start” record at each call setup, followed with a corresponding “stop” record at the call disconnect. Note Before configuring this feature, the tasks described in the section ““ Prerequisites for Configuring Accounting ” section on page 2” must be performed, and SNMP must be enabled on the network access server. For more information about enabling SNMP on a Cisco router or access server, see “Configuring SNMP Support” of the <i>Cisco IOS Configuration Fundamentals Configuration Guide</i> .

Configuring AAA Broadcast Accounting

To configure AAA broadcast accounting, use the **aaa accounting** command in global configuration mode. This command has been modified to allow the **broadcast** keyword.

Command	Purpose
Router(config)# aaa accounting { system network exec connection commands level } { default <i>list-name</i> } { start-stop stop-only none } [broadcast] <i>method1</i> [<i>method2...</i>]	Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.

Configuring Per-DNIS AAA Broadcast Accounting

To configure AAA broadcast accounting per Dialed Number Identification Service (DNIS), use the **aaa dnis map accounting network** command in global configuration mode. This command has been modified to allow the **broadcast** keyword and multiple server groups.

Command	Purpose
Router(config)# aaa dnis map <i>dnis-number</i> accounting network [start-stop stop-only none] [broadcast] <i>method1</i> [<i>method2...</i>]	Allows per-DNIS accounting configuration. This command has precedence over the global aaa accounting command. Enables sending accounting records to multiple AAA servers. Simultaneously sends accounting records to the first server in each group. If the first server is unavailable, failover occurs using the backup servers defined within that group.

Configuring AAA Session MIB

The following tasks must be performed before configuring the AAA session MIB feature:

- Configure SNMP. For information on SNMP, see “Configuring SNMP Support” in the *Cisco IOS Configuration Fundamentals Configuration Guide*.
- Configure AAA.
- Define the RADIUS or TACACS+ server characteristics.

Note

Overusing SNMP can affect the overall system performance; therefore, normal network management performance must be considered when this feature is used.

To configure AAA session MIB, use the following command in global configuration mode

	Command	Purpose
Step 1	Router(config)# aaa session-mib disconnect	Monitors and terminates authenticated client connections using SNMP. To terminate the call, the disconnect keyword must be used.

Establishing a Session with a Router if the AAA Server is Unreachable

To establish a console or telnet session with a router if the AAA server is unreachable, use the following command in Global Configuration mode:

Command	Purpose
Router(config)# no aaa accounting system guarantee-first	The aaa accounting system guarantee-first command guarantees system accounting as the first record, which is the default condition. In some situations, users may be prevented from starting a session on the console or terminal connection until after the system reloads, which can take more than three minutes. To resolve this problem, the no aaa accounting system guarantee-first command can be used.

Note

Entering the **no aaa accounting system guarantee-first** command is not the only condition by which the console or telnet session can be started. For example, if the Privileged EXEC session is being authenticated by TACACS and the TACACS server is not reachable, then the session cannot start.

Monitoring Accounting

No specific **show** command exists for either RADIUS or TACACS+ accounting. To obtain accounting records displaying information about users currently logged in, use the following command in privileged EXEC mode:

Command	Purpose
Router# show accounting	Allows display of the active accountable events on the network and helps collect information in the event of a data loss on the accounting server.

Troubleshooting Accounting

To troubleshoot accounting information, use the following command in privileged EXEC mode:

Command	Purpose
Router# debug aaa accounting	Displays information on accountable events as they occur.

Accounting Attribute-Value Pairs

The network access server monitors the accounting functions defined in either TACACS+ attribute-value (AV) pairs or RADIUS attributes, depending on which security method is implemented. For a list of supported RADIUS accounting attributes, see the appendix “RADIUS Attributes.” For a list of supported TACACS+ accounting AV pairs, see the appendix “TACACS+ Attribute-Value Pairs.”

Configuration Examples for AAA Accounting

This section contains the following examples:

- [Configuring Named Method List: Example](#)
- [Configuring AAA Resource Accounting: Example](#)
- [Configuring AAA Broadcast Accounting: Example](#)
- [Configuring Per-DNIS AAA Broadcast Accounting: Example](#)
- [AAA Session MIB: Example](#)

Configuring Named Method List: Example

The following example shows how to configure a Cisco AS5200 (enabled for AAA and communication with a RADIUS security server) in order for AAA services to be provided by the RADIUS server. If the RADIUS server fails to respond, then the local database is queried for authentication and authorization information, and accounting services are handled by a TACACS+ server.

```
aaa new-model
aaa authentication login admins local
aaa authentication ppp dialins group radius local
aaa authorization network blue1 group radius local
aaa accounting network red1 start-stop group radius group tacacs+

username root password ALongPassword

tacacs-server host 172.31.255.0
tacacs-server key goaway

radius-server host 172.16.2.7
radius-server key myRaDiUSpassWoRd

interface group-async 1
 group-range 1 16
 encapsulation ppp
 ppp authentication chap dialins
 ppp authorization blue1
 ppp accounting red1

line 1 16
 autoselect ppp
 autoselect during-login
 login authentication admins
 modem dialin
```

The lines in this sample RADIUS AAA configuration are defined as follows:

- The **aaa new-model** command enables AAA network security services.
- The **aaa authentication login admins local** command defines a method list, “admins”, for login authentication.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins”, which specifies that first RADIUS authentication and then (if the RADIUS server does not respond) local authentication is used on serial lines using PPP.
- The **aaa authorization network blue1 group radius local** command defines the network authorization method list named “blue1”, which specifies that RADIUS authorization is used on serial lines using PPP. If the RADIUS server fails to respond, then local network authorization is performed.
- The **aaa accounting network red1 start-stop group radius group tacacs+** command defines the network accounting method list named red1, which specifies that RADIUS accounting services (in this case, start and stop records for specific events) are used on serial lines using PPP. If the RADIUS server fails to respond, accounting services are handled by a TACACS+ server.
- The **username** command defines the username and password to be used for the PPP Password Authentication Protocol (PAP) caller identification.
- The **tacacs-server host** command defines the name of the TACACS+ server host.
- The **tacacs-server key** command defines the shared secret text string between the network access server and the TACACS+ server host.

- The **radius-server host** command defines the name of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **interface group-async** command selects and defines an asynchronous interface group.
- The **group-range** command defines the member asynchronous interfaces in the interface group.
- The **encapsulation ppp** command sets PPP as the encapsulation method used on the specified interfaces.
- The **ppp authentication chap dialins** command selects Challenge Handshake Authentication Protocol (CHAP) as the method of PPP authentication and applies the “dialins” method list to the specified interfaces.
- The **ppp authorization blue1** command applies the blue1 network authorization method list to the specified interfaces.
- The **ppp accounting red1** command applies the red1 network accounting method list to the specified interfaces.
- The **line** command switches the configuration mode from global configuration to line configuration and identifies the specific lines being configured.
- The **autoselect ppp** command configures the Cisco IOS software to allow a PPP session to start up automatically on these selected lines.
- The **autoselect during-login** command is used to display the username and password prompt without pressing the Return key. After the user logs in, the autoselect function (in this case, PPP) begins.
- The **login authentication admins** command applies the admins method list for login authentication.
- The **modem dialin** command configures modems attached to the selected lines to only accept incoming calls.

The **show accounting** command yields the following output for the preceding configuration:

```
Active Accounted actions on tty1, User username2 Priv 1
Task ID 5, Network Accounting record, 00:00:52 Elapsed
task_id=5 service=ppp protocol=ip address=10.0.0.98
```

Table 4 describes the fields contained in the preceding output.

Table 4 *show accounting Field Descriptions*

Field	Description
Active Accounted actions on	Terminal line or interface name user with which the user logged in.
User	User's ID.
Priv	User's privilege level.
Task ID	Unique identifier for each accounting session.
Accounting Record	Type of accounting session.
Elapsed	Length of time (hh:mm:ss) for this session type.
attribute=value	AV pairs associated with this accounting session.

Configuring AAA Resource Accounting: Example

The following example shows how to configure the resource failure stop accounting and resource accounting for start-stop records functions:

```
!Enable AAA on your network access server.
aaa new-model
!Enable authentication at login and list the AOL string name to use for login
authentication.
aaa authentication login AOL group radius local
!Enable authentication for ppp and list the default method to use for PPP authentication.
aaa authentication ppp default group radius local
!Enable authorization for all exec sessions and list the AOL string name to use for
authorization.
aaa authorization exec AOL group radius if-authenticated
!Enable authorization for all network-related service requests and list the default method
to use for all network-related authorizations.
aaa authorization network default group radius if-authenticated
!Enable accounting for all exec sessions and list the default method to use for all
start-stop accounting services.
aaa accounting exec default start-stop group radius
!Enable accounting for all network-related service requests and list the default method to
use for all start-stop accounting services.
aaa accounting network default start-stop group radius
!Enable failure stop accounting.
aaa accounting resource default stop-failure group radius
!Enable resource accounting for start-stop records.
aaa accounting resource default start-stop group radius
```

Configuring AAA Broadcast Accounting: Example

The following example shows how to turn on broadcast accounting using the global **aaa accounting** command:

```
aaa group server radius isp
server 10.0.0.1
server 10.0.0.2

aaa group server tacacs+ isp_customer
server 172.0.0.1

aaa accounting network default start-stop broadcast group isp group isp_customer

radius-server host 10.0.0.1
radius-server host 10.0.0.2
radius-server key key1
tacacs-server host 172.0.0.1 key key2
```

The **broadcast** keyword causes “start” and “stop” accounting records for network connections to be sent simultaneously to server 10.0.0.1 in the group isp and to server 172.0.0.1 in the group isp_customer. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group isp_customer.

Configuring Per-DNIS AAA Broadcast Accounting: Example

The following example shows how to turn on per DNIS broadcast accounting using the global **aaa dnis map accounting network** command:

```
aaa group server radius isp
  server 10.0.0.1
  server 10.0.0.2

aaa group server tacacs+ isp_customer
  server 172.0.0.1

aaa dnis map enable
aaa dnis map 7777 accounting network start-stop broadcast group isp group isp_customer

radius-server host 10.0.0.1
radius-server host 10.0.0.2
radius-server key key_1
tacacs-server host 172.0.0.1 key key_2
```

The **broadcast** keyword causes “start” and “stop” accounting records for network connection calls having DNIS number 7777 to be sent simultaneously to server 10.0.0.1 in the group **isp** and to server 172.0.0.1 in the group **isp_customer**. If server 10.0.0.1 is unavailable, failover to server 10.0.0.2 occurs. If server 172.0.0.1 is unavailable, no failover occurs because backup servers are not configured for the group **isp_customer**.

AAA Session MIB: Example

The following example shows how to set up the AAA session MIB feature to disconnect authenticated client connections for PPP users:

```
aaa new-model
aaa authentication ppp default group radius
aaa authorization network default group radius
aaa accounting network default start-stop group radius
aaa session-mib disconnect
```

Feature Information for Configuring Accounting

Table 5 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Releases 12.2(1) or 12.0(3)S or a later release appear in the table.

Not all commands may be available in the Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 5 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 5 Feature Information for Configuring Accounting

Feature Name	Releases	Feature Information
—	Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
AAA Broadcast Accounting	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
AAA Session MIB	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
Connection Accounting	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

About RADIUS

RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

RADIUS is a fully open protocol, distributed in source code format, that can be modified to work with any security system currently available on the market.

Cisco supports RADIUS under its AAA security paradigm. RADIUS can be used with other AAA security protocols, such as TACACS+, Kerberos, and local username lookup. RADIUS is supported on all Cisco platforms, but some RADIUS-supported features run only on specified platforms.

RADIUS has been implemented in a variety of network environments that require high levels of security while maintaining network access for remote users.

Use RADIUS in the following network environments that require access security:

- Networks with multiple-vendor access servers, each supporting RADIUS. For example, access servers from several vendors use a single RADIUS server-based security database. In an IP-based network with multiple vendors' access servers, dial-in users are authenticated through a RADIUS server that has been customized to work with the Kerberos security system.
- Turnkey network security environments in which applications support the RADIUS protocol, such as in an access environment that uses a "smart card" access control system. In one case, RADIUS has been used with Enigma's security cards to validate users and grant access to network resources.
- Networks already using RADIUS. You can add a Cisco router with RADIUS to the network. This might be the first step when you make a transition to a Terminal Access Controller Access Control System Plus (TACACS+) server.
- Networks in which a user must only access a single service. Using RADIUS, you can control user access to a single host, to a single utility such as Telnet, or to a single protocol such as Point-to-Point Protocol (PPP). For example, when a user logs in, RADIUS identifies this user as having authorization to run PPP using IP address 10.2.3.4 and the defined access list is started.
- Networks that require resource accounting. You can use RADIUS accounting independent of RADIUS authentication or authorization. The RADIUS accounting functions allow data to be sent at the start and end of services, indicating the amount of resources (such as time, packets, bytes, and so on) used during the session. An Internet service provider (ISP) might use a freeware-based version of RADIUS access control and accounting software to meet special security and billing needs.
- Networks that wish to support preauthentication. Using the RADIUS server in your network, you can configure AAA preauthentication and set up the preauthentication profiles. Preauthentication enables service providers to better manage ports using their existing RADIUS solutions, and to efficiently manage the use of shared resources to offer differing service-level agreements.

RADIUS is not suitable in the following network security situations:

- Multiprotocol access environments. RADIUS does not support the following protocols:
 - AppleTalk Remote Access (ARA)
 - NetBIOS Frame Control Protocol (NBFCP)
 - NetWare Asynchronous Services Interface (NASI)
 - X.25 PAD connections

- Router-to-router situations. RADIUS does not provide two-way authentication. RADIUS can be used to authenticate from one router to a non-Cisco router if the non-Cisco router requires RADIUS authentication.
- Networks using a variety of services. RADIUS generally binds a user to one service model.

RADIUS Operation

When a user attempts to log in and authenticate to an access server using RADIUS, the following steps occur:

1. The user is prompted for and enters a username and password.
2. The username and encrypted password are sent over the network to the RADIUS server.

3. The user receives one of the following responses from the RADIUS server:
 - a. **ACCEPT**—The user is authenticated.
 - b. **REJECT**—The user is not authenticated and is prompted to reenter the username and password, or access is denied.
 - c. **CHALLENGE**—A challenge is issued by the RADIUS server. The challenge collects additional data from the user.
 - d. **CHANGE PASSWORD**—A request is issued by the RADIUS server, asking the user to select a new password.

The **ACCEPT** or **REJECT** response is bundled with additional data that is used for **EXEC** or network authorization. You must first complete RADIUS authentication before using RADIUS authorization. The additional data included with the **ACCEPT** or **REJECT** packets consists of the following:

- Services that the user can access, including Telnet, rlogin, or local-area transport (LAT) connections, and PPP, Serial Line Internet Protocol (SLIP), or **EXEC** services.
- Connection parameters, including the host or client IP address, access list, and user timeouts.

RADIUS Configuration Task List

To configure RADIUS on your Cisco router or access server, you must perform the following tasks:

- Use the **aaa new-model** global configuration command to enable AAA. AAA must be configured if you plan to use RADIUS. For more information about using the **aaa new-model** command, refer to the “AAA Overview” chapter.
- Use the **aaa authentication** global configuration command to define method lists for RADIUS authentication. For more information about using the **aaa authentication** command, refer to the “Configuring Authentication” chapter.
- Use **line** and **interface** commands to enable the defined method lists to be used. For more information, refer to the “Configuring Authentication” chapter.

The following configuration tasks are optional:

- You may use the **aaa group server** command to group selected RADIUS hosts for specific services. For more information about using the **aaa group server** command, refer to the “[Configuring AAA Server Groups](#)” section in this chapter.
- You may use the **aaa dnis map** command to select RADIUS server groups based on DNIS number. To use this command, you must define RADIUS server groups using the **aaa group server** command. For more information about using the **aaa dnis map** command, refer to the section “[Configuring AAA Server Group Selection Based on DNIS](#)” in this chapter.
- You may use the **aaa authorization** global command to authorize specific user functions. For more information about using the **aaa authorization** command, refer to the chapter “Configuring Authorization.”
- You may use the **aaa accounting** command to enable accounting for RADIUS connections. For more information about using the **aaa accounting** command, refer to the chapter “Configuring Accounting.”
- You may use the **dialer aaa** interface configuration command to create remote site profiles that contain outgoing call attributes on the AAA server. For more information about using the **dialer aaa** command, refer to the section “[Configuring Suffix and Password in RADIUS Access Requests](#)” in this chapter.

This section describes how to set up RADIUS for authentication, authorization, and accounting on your network, and includes the following sections:

- [Configuring Router to RADIUS Server Communication](#) (Required)
- [Configuring Router to Use Vendor-Specific RADIUS Attributes](#) (Optional)
- [Configuring Router for Vendor-Proprietary RADIUS Server Communication](#) (Optional)
- [Configuring Router to Query RADIUS Server for Static Routes and IP Addresses](#) (Optional)
- [Configuring Router to Expand Network Access Server Port Information](#) (Optional)
- [Configuring AAA Server Groups](#) (Optional)
- [Configuring AAA Server Groups with Deadtme](#) (Optional)
- [Configuring AAA DNIS Authentication](#)
- [Configuring AAA Server Group Selection Based on DNIS](#) (Optional)
- [Configuring AAA Preauthentication](#)
- [Configuring a Guard Timer](#)
- [Specifying RADIUS Authentication](#)
- [Specifying RADIUS Authorization](#) (Optional)
- [Specifying RADIUS Accounting](#) (Optional)
- [Configuring RADIUS Login-IP-Host](#) (Optional)
- [Configuring RADIUS Prompt](#) (Optional)
- [Configuring Suffix and Password in RADIUS Access Requests](#) (Optional)

For RADIUS configuration examples using the commands in this chapter, refer to the section “[RADIUS Configuration Examples](#)” at the end of this chapter.

Configuring Router to RADIUS Server Communication

The RADIUS host is normally a multiuser system running RADIUS server software from Cisco (CiscoSecure ACS), Livingston, Merit, Microsoft, or another software provider. Configuring router to RADIUS server communication can have several components:

- Host name or IP address
- Authentication destination port
- Accounting destination port
- Timeout period
- Retransmission value
- Key string

RADIUS security servers are identified on the basis of their host name or IP address, host name and specific UDP port numbers, or IP address and specific UDP port numbers. The combination of the IP address and UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to multiple UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as fail-over backup to the first one. Using this

example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order they are configured.)

A RADIUS server and a Cisco router use a shared secret text string to encrypt passwords and exchange responses. To configure RADIUS to use the AAA security commands, you must specify the host running the RADIUS server daemon and a secret text (key) string that it shares with the router.

The timeout, retransmission, and encryption key values are configurable globally for all RADIUS servers, on a per-server basis, or in some combination of global and per-server settings. To apply these settings globally to all RADIUS servers communicating with the router, use the three unique global commands: **radius-server timeout**, **radius-server retransmit**, and **radius-server key**. To apply these values on a specific RADIUS server, use the **radius-server host** command.

**Note**

You can configure both global and per-server timeout, retransmission, and key value commands simultaneously on the same Cisco network access server. If both global and per-server functions are configured on a router, the per-server timer, retransmission, and key value commands override global timer, retransmission, and key value commands.

To configure per-server RADIUS server communication, use the following command in global configuration mode:

Command	Purpose
<pre>Router(config)# radius-server host {hostname ip-address} [auth-port port-number] [acct-port port-number] [timeout seconds] [retransmit retries] [key string] [alias {hostname ip address}]</pre>	<p>Specifies the IP address or host name of the remote RADIUS server host and assign authentication and accounting destination port numbers. Use the auth-port <i>port-number</i> option to configure a specific UDP port on this RADIUS server to be used solely for authentication. Use the acct-port <i>port-number</i> option to configure a specific UDP port on this RADIUS server to be used solely for accounting. Use the alias keyword to configure up to eight multiple IP addresses for use when referring to RADIUS servers.</p> <p>To configure the network access server to recognize more than one host entry associated with a single IP address, simply repeat this command as many times as necessary, making sure that each UDP port number is different. Set the timeout, retransmit, and encryption key values to use with the specific RADIUS host.</p> <p>If no timeout is set, the global value is used; otherwise, enter a value in the range 1 to 1000. If no retransmit value is set, the global value is used; otherwise enter a value in the range 1 to 1000. If no key string is specified, the global value is used.</p> <p>Note The key is a text string that must match the encryption key used on the RADIUS server. Always configure the key as the last item in the radius-server host command syntax because the leading spaces are ignored, but spaces within and at the end of the key are used. If you use spaces in your key, do not enclose the key in quotation marks unless the quotation marks themselves are part of the key.</p>

To configure global communication settings between the router and a RADIUS server, use the following **radius-server** commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# radius-server key {0 string 7 string string}	Specifies the shared secret text string used between the router and a RADIUS server. Use the 0 line option to configure an unencrypted shared secret. Use the 7 line option to configure an encrypted shared secret.
Step 2	Router(config)# radius-server retransmit retries	Specifies how many times the router transmits each RADIUS request to the server before giving up (the default is 3).
Step 3	Router(config)# radius-server timeout seconds	Specifies for how many seconds a router waits for a reply to a RADIUS request before retransmitting the request.
Step 4	Router(config)# radius-server deadtime minutes	Specifies for how many minutes a RADIUS server that is not responding to authentication requests is passed over by requests for RADIUS authentication.

Configuring Router to Use Vendor-Specific RADIUS Attributes

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the network access server and the RADIUS server by using the vendor-specific attribute (attribute 26). Vendor-specific attributes (VSAs) allow vendors to support their own extended attributes not suitable for general use. The Cisco RADIUS implementation supports one vendor-specific option using the format recommended in the specification. Cisco's vendor-ID is 9, and the supported option has vendor-type 1, which is named "cisco-avpair." The value is a string of the following format:

```
protocol : attribute sep value *
```

"Protocol" is a value of the Cisco "protocol" attribute for a particular type of authorization; protocols that can be used include IP, IPX, VPDN, VOIP, SHELL, RSVP, SIP, AIRNET, OUTBOUND. "Attribute" and "value" are an appropriate attribute-value (AV) pair defined in the Cisco TACACS+ specification, and "sep" is "=" for mandatory attributes and "*" for optional attributes. This allows the full set of features available for TACACS+ authorization to also be used for RADIUS.

For example, the following AV pair causes Cisco's "multiple named ip address pools" feature to be activated during IP authorization (during PPP's IPCP address assignment):

```
cisco-avpair= "ip:addr-pool=first"
```

If you insert an "*", the AV pair "ip:addr-pool=first" becomes optional. Note that any AV pair can be made optional.

```
cisco-avpair= "ip:addr-pool*first"
```

The following example shows how to cause a user logging in from a network access server to have immediate access to EXEC commands:

```
cisco-avpair= "shell:priv-lvl=15"
```

Other vendors have their own unique vendor-IDs, options, and associated VSAs. For more information about vendor-IDs and VSAs, refer to RFC 2138, Remote Authentication Dial-In User Service (RADIUS).

To configure the network access server to recognize and use VSAs, use the following command in global configuration mode:

Command	Purpose
Router(config)# radius-server vsa send [accounting authentication]	Enables the network access server to recognize and use VSAs as defined by RADIUS IETF attribute 26.

For a complete list of RADIUS attributes or more information about vendor-specific attribute 26, refer to the appendix “RADIUS Attributes.”

Configuring Router for Vendor-Proprietary RADIUS Server Communication

Although an Internet Engineering Task Force (IETF) draft standard for RADIUS specifies a method for communicating vendor-specific information between the network access server and the RADIUS server, some vendors have extended the RADIUS attribute set in a unique way. Cisco IOS software supports a subset of vendor-specific RADIUS attributes.

As mentioned earlier, to configure RADIUS (whether vendor-specific or IETF draft-compliant), you must specify the host running the RADIUS server daemon and the secret text string it shares with the Cisco device. You specify the RADIUS host and secret text string by using the **radius-server** commands. To identify that the RADIUS server is using a vendor-specific implementation of RADIUS, use the **radius-server host non-standard** command. Vendor-specific attributes will not be supported unless you use the **radius-server host non-standard** command.

To specify a vendor-specific RADIUS server host and a shared secret text string, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# radius-server host {hostname ip-address} non-standard	Specifies the IP address or host name of the remote RADIUS server host and identifies that it is using a vendor-specific implementation of RADIUS.
Step 2	Router(config)# radius-server key {0 string 7 string string}	Specifies the shared secret text string used between the router and the vendor-specific RADIUS server. The router and the RADIUS server use this text string to encrypt passwords and exchange responses.

Configuring Router to Query RADIUS Server for Static Routes and IP Addresses

Some vendor-specific implementations of RADIUS let the user define static routes and IP pool definitions on the RADIUS server instead of on each individual network access server in the network. Each network access server then queries the RADIUS server for static route and IP pool information.

To have the Cisco router or access server query the RADIUS server for static routes and IP pool definitions when the device first starts up, use the following command in global configuration mode:

Command	Purpose
Router(config)# radius-server configure-nas	Tells the Cisco router or access server to query the RADIUS server for the static routes and IP pool definitions used throughout its domain.

**Note**

Because the **radius-server configure-nas** command is performed when the Cisco router starts up, it will not take effect until you issue a **copy system:running config nvram:startup-config** command.

Configuring Router to Expand Network Access Server Port Information

There are some situations when PPP or login authentication occurs on an interface different from the interface on which the call itself comes in. For example, in a V.120 ISDN call, login or PPP authentication occurs on a virtual asynchronous interface “**ttt**” but the call itself occurs on one of the channels of the ISDN interface.

The **radius-server attribute nas-port extended** command configures RADIUS to expand the size of the NAS-Port attribute (RADIUS IETF attribute 5) field to 32 bits. The upper 16 bits of the NAS-Port attribute display the type and number of the controlling interface; the lower 16 bits indicate the interface undergoing authentication.

To display expanded interface information in the NAS-Port attribute field, use the following command in global configuration mode:

Command	Purpose
Router(config)# radius-server attribute nas-port format	Expands the size of the NAS-Port attribute from 16 to 32 bits to display extended interface information.

**Note**

This command replaces the **radius-server extended-portnames** command and the **radius-server attribute nas-port extended** command.

On platforms with multiple interfaces (ports) per slot, the Cisco RADIUS implementation will not provide a unique NAS-Port attribute that permits distinguishing between the interfaces. For example, if a dual PRI interface is in slot 1, calls on both Serial1/0:1 and Serial1/1:1 will appear as NAS-Port = 20101.

Once again, this is because of the 16-bit field size limitation associated with RADIUS IETF NAS-Port attribute. In this case, the solution is to replace the NAS-Port attribute with a vendor-specific attribute (RADIUS IETF attribute 26). Cisco's vendor-ID is 9, and the Cisco-NAS-Port attribute is subtype 2. Vendor-specific attributes (VSAs) can be turned on by entering the **radius-server vsa send** command. The port information in this attribute is provided and configured using the **aaa nas port extended** command.

To replace the NAS-Port attribute with RADIUS IETF attribute 26 and to display extended field information, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# radius-server vsa send [accounting authentication]	Enables the network access server to recognize and use vendor-specific attributes as defined by RADIUS IETF attribute 26.
Step 2	Router(config)# aaa nas port extended	Expands the size of the VSA NAS-Port field from 16 to 32 bits to display extended interface information.

The standard NAS-Port attribute (RADIUS IETF attribute 5) will continue to be sent. If you do not want this information to be sent, you can suppress it by using the **no radius-server attribute nas-port** command. When this command is configured, the standard NAS-Port attribute will no longer be sent.

For a complete list of RADIUS attributes, refer to the appendix “RADIUS Attributes.”

For information about configuring RADIUS port identification for PPP, see the *Cisco IOS Wide-Area Networking Configuration Guide*.

Configuring AAA Server Groups

Configuring the router to use AAA server groups provides a way to group existing server hosts. This allows you to select a subset of the configured server hosts and use them for a particular service. A server group is used in conjunction with a global server-host list. The server group lists the IP addresses of the selected server hosts.

Server groups also can include multiple host entries for the same server, as long as each entry has a unique identifier. The combination of an IP address and a UDP port number creates a unique identifier, allowing different ports to be individually defined as RADIUS hosts providing a specific AAA service. In other words, this unique identifier enables RADIUS requests to be sent to different UDP ports on a server at the same IP address. If two different host entries on the same RADIUS server are configured for the same service—for example, accounting—the second host entry configured acts as failover backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry configured on the same device for accounting services. (The RADIUS host entries will be tried in the order in which they are configured.)

To define a server host with a server group name, enter the following commands in global configuration mode. The listed server must exist in global configuration mode:

	Command	Purpose
Step 1	Router(config)# radius-server host {hostname ip-address} [auth-port port-number] [acct-port port-number] [timeout seconds] [retransmit retries] [key string] [alias {hostname ip address}]	Specifies and defines the IP address of the server host before configuring the AAA server-group. Refer to the section “ Configuring Router to RADIUS Server Communication ” of this chapter for more information on the radius-server host command.

	Command	Purpose
Step 2	Router(config-if)# aaa group server { radius tacacs+ } <i>group-name</i>	Defines the AAA server group with a group name. All members of a group must be the same type; that is, RADIUS or TACACS+. This command puts the router in server group subconfiguration mode.
Step 3	Router(config-sg)# server <i>ip-address</i> [auth-port <i>port-number</i>] [acct-port <i>port-number</i>]	<p>Associates a particular RADIUS server with the defined server group. Each security server is identified by its IP address and UDP port number.</p> <p>Repeat this step for each RADIUS server in the AAA server group.</p> <p>Note Each server in the group must be defined previously using the radius-server host command.</p>

Configuring AAA Server Groups with Deadtime

After you have configured a server host with a server name, you can use the **deadtime** command to configure each server per server group. Configuring deadtime within a server group allows you to direct AAA traffic to separate groups of servers that have different operational characteristics.

Configuring deadtime is no longer limited to a global configuration. A separate timer has been attached to each server host in every server group. Therefore, when a server is found to be unresponsive after numerous retransmissions and timeouts, the server is assumed to be dead. The timers attached to each server host in all server groups are triggered. In essence, the timers are checked and subsequent requests to a server (once it is assumed to be dead) are directed to alternate timers, if configured. When the network access server receives a reply from the server, it checks and stops all configured timers (if running) for that server in all server groups.

If the timer has expired, only the server to which the timer is attached is assumed to be alive. This becomes the only server that can be tried for later AAA requests using the server groups to which the timer belongs.

Note

Since one server has different timers and may have different deadtime values configured in the server groups, the same server may in the future have different states (dead and alive) at the same time.

Note

To change the state of a server, you must start and stop all configured timers in all server groups.

The size of the server group will be slightly increased because of the addition of new timers and the deadtime attribute. The overall impact of the structure depends on the number and size of the server groups and how the servers are shared among server groups in a specific configuration.

To configure deadtime within a server group, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa group server radius <i>group1</i>	Defines a RADIUS type server group.
Step 2	Router(config-sg)# deadtime <i>1</i>	Configures and defines deadtime value in minutes. Note Local server group deadtime will override the global configuration. If omitted from the local server group configuration, the value will be inherited from the master list.
Step 3	Router(config-sg)# exit	Exits server group configuration mode.

Configuring AAA DNIS Authentication

DNIS preauthentication enables preauthentication at call setup based on the number dialed. The DNIS number is sent directly to the security server when a call is received. If authenticated by AAA, the call is accepted.

To configure DNIS authentication, perform the following tasks in global configuration mode:

	Command	Purpose
Step 1	Router# config term	Enters global configuration mode.
Step 2	Router(config)# aaa preauth	Enters AAA preauthentication mode.
Step 3	Router(config-preauth)# group { radius tacacs+ <i>server-group</i> }	(Optional) Selects the security server to use for AAA preauthentication requests. The default is RADIUS.
Step 4	Router(config-preauth)# dnis [password <i>string</i>]	Enables preauthentication using DNIS and optionally specifies a password to use in Access-Request packets.

Configuring AAA Server Group Selection Based on DNIS

Cisco IOS software allows you to assign a Dialed Number Identification Service (DNIS) number to a particular AAA server group so that the server group can process authentication, authorization, and accounting requests for users dialing in to the network using that particular DNIS. Any phone line (a regular home phone or a commercial T1/PRI line) can be associated with several phone numbers. The DNIS number identifies the number that was called to reach you.

For example, suppose you want to share the same phone number with several customers, but you want to know which customer is calling before you pick up the phone. You can customize how you answer the phone because DNIS allows you to know which customer is calling when you answer.

Cisco routers with either ISDN or internal modems can receive the DNIS number. This functionality allows users to assign different RADIUS server groups for different customers (that is, different RADIUS servers for different DNIS numbers). Additionally, using server groups you can specify the same server group for AAA services or a separate server group for each AAA service.

Cisco IOS software provides the flexibility to implement authentication and accounting services in several ways:

- Globally—AAA services are defined using global configuration access list commands and applied in general to all interfaces on a specific network access server.
- Per Interface—AAA services are defined using interface configuration commands and applied specifically to the interface being configured on a specific network access server.
- DNIS mapping—You can use DNIS to specify an AAA server to supply AAA services.

Because each of these AAA configuration methods can be configured simultaneously, Cisco has established an order of precedence to determine which server or groups of servers provide AAA services. The order of precedence is as follows:

- Per DNIS—If you configure the network access server to use DNIS to identify/determine which server group provides AAA services, then this method takes precedence over any additional AAA selection method.
- Per interface—If you configure the network access server per interface to use access lists to determine how a server provides AAA services, this method takes precedence over any global configuration AAA access lists.
- Globally—If you configure the network access server by using global AAA access lists to determine how the security server provides AAA services, this method has the least precedence.

Note

Prior to configuring AAA Server Group Selection Based on DNIS, you must configure the list of RADIUS server hosts and configure the AAA server groups. See the sections [“Configuring Router to RADIUS Server Communication”](#) and [“Configuring AAA Server Groups”](#) of this chapter.

To configure the router to select a particular AAA server group based on the DNIS of the server group, configure DNIS mapping. To map a server group with a group name with DNIS number, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa dnis map enable	Enables DNIS mapping.
Step 2	Router(config)# aaa dnis map <i>dnis-number</i> authentication ppp group <i>server-group-name</i>	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for authentication.
Step 3	Router(config)# aaa dnis map <i>dnis-number</i> authorization network group <i>server-group-name</i>	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for authorization.
Step 4	Router(config)# aaa dnis map <i>dnis-number</i> accounting network [none start-stop stop-only] group <i>server-group-name</i>	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for accounting.

Configuring AAA Preauthentication

Configuring AAA preauthentication with ISDN PRI or channel-associated signalling (CAS) allows service providers to better manage ports using their existing RADIUS solutions and efficiently manage the use of shared resources to offer differing service-level agreements. With ISDN PRI or CAS, information about an incoming call is available to the network access server (NAS) before the call is connected. The available call information includes the following:

- The Dialed Number Identification Service (DNIS) number, also referred to as the called number
- The Calling Line Identification (CLID) number, also referred to as the calling number
- The call type, also referred to as the bearer capability

This feature allows a Cisco NAS to decide—on the basis of the DNIS number, the CLID number, or the call type—whether to connect an incoming call. (With ISDN PRI, it enables user authentication and authorization before a call is answered. With CAS, the call must be answered; however, the call can be dropped if preauthentication fails.)

When an incoming call arrives from the public network switch, but before it is connected, AAA preauthentication enables the NAS to send the DNIS number, CLID number, and call type to a RADIUS server for authorization. If the server authorizes the call, then the NAS accepts the call. If the server does not authorize the call, then the NAS sends a disconnect message to the public network switch to reject the call.

In the event that the RADIUS server application becomes unavailable or is slow to respond, a guard timer can be set in the NAS. When the timer expires, the NAS uses a configurable parameter to accept or reject the incoming call that has no authorization.

This feature supports the use of attribute 44 by the RADIUS server application and the use of RADIUS attributes that are configured in the RADIUS preauthentication profiles to specify preauthentication behavior. They may also be used, for instance, to specify whether subsequent authentication should occur and, if so, what authentication method should be used.

The following restrictions apply to AAA preauthentication with ISDN PRI and CAS:

- Attribute 44 is available for CAS calls only when preauthentication or resource pooling is enabled.
- MMP is not available with ISDN PRI.
- AAA preauthentication is available only on the Cisco AS5300, Cisco AS5400, and Cisco AS5800 platforms.

Note

Prior to configuring AAA preauthentication, you must enable the **aaa new-model** command and make sure the supporting preauthentication application is running on a RADIUS server in your network.

To configure AAA preauthentication, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa preauth	Enters AAA preauthentication configuration mode.
Step 2	Router(config-preauth)# group <i>server-group</i>	Specifies the AAA RADIUS server group to use for preauthentication.
Step 3	Router(config-preauth)# clid [if-avail required] [accept-stop] [password <i>string</i>]	Preauthenticates calls on the basis of the CLID number.

	Command	Purpose
Step 4	Router(config-preauth)# ctype [if-avail required] [accept-stop] [password <i>string</i>]	Preauthenticates calls on the basis of the call type.
Step 5	Router(config-preauth)# dnis [if-avail required] [accept-stop] [password <i>string</i>]	Preauthenticates calls on the basis of the DNIS number.
Step 6	Router(config-preauth)# dnis bypass { <i>dnis-group-name</i> }	Specifies a group of DNIS numbers that will be bypassed for preauthentication.

To configure DNIS preauthentication, use the following commands beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa preauth	Enters AAA preauthentication mode.
Step 2	Router(config-preauth)# group { radius tacacs+ <i>server-group</i> }	(Optional) Selects the security server to use for AAA preauthentication requests. The default is RADIUS.
Step 3	Router(config-preauth)# dnis [password <i>string</i>]	Enables preauthentication using DNIS and optionally specifies a password to use in Access-Request packets.

In addition to configuring preauthentication on your Cisco router, you must set up the preauthentication profiles on the RADIUS server. For information on setting up the preauthentication profiles, see the following sections:

- [Setting Up the RADIUS Profile for DNIS or CLID Preauthentication](#)
- [Setting Up the RADIUS Profile for Call Type Preauthentication](#)
- [Setting Up the RADIUS Profile for Preauthentication Enhancements for Callback](#)
- [Setting Up the RADIUS Profile for a Remote Host Name Used for Large-Scale Dial-Out](#)
- [Setting Up the RADIUS Profile for Modem Management](#)
- [Setting Up the RADIUS Profile for Subsequent Authentication](#)
- [Setting Up the RADIUS Profile for Subsequent Authentication Type](#)
- [Setting Up the RADIUS Profile to Include the Username](#)
- [Setting Up the RADIUS Profile for Two-Way Authentication](#)
- [Setting Up the RADIUS Profile to Support Authorization](#)

Setting Up the RADIUS Profile for DNIS or CLID Preauthentication

To set up the RADIUS preauthentication profile, use the DNIS or CLID number as the username, and use the password defined in the **dnis** or **clid** command as the password.

**Note**

The preauthentication profile must have “outbound” as the service type because the password is predefined on the NAS. Setting up the preauthentication profile in this manner prevents users from trying to log in to the NAS with the username of the DNIS number, CLID number, or call type and an obvious password. The “outbound” service type is also included in the access-request packet sent to the RADIUS server.

Setting Up the RADIUS Profile for Call Type Preauthentication

To set up the RADIUS preauthentication profile, use the call type string as the username, and use the password defined in the **ctype** command as the password. The following table shows the call type strings that may be used in the preauthentication profile:

Call Type String	ISDN Bearer Capabilities
digital	Unrestricted digital, restricted digital.
speech	Speech, 3.1 kHz audio, 7 kHz audio. Note This is the only call type available for CAS.
v.110	Anything with V.110 user information layer.
v.120	Anything with V.120 user information layer.

**Note**

The preauthentication profile must have “outbound” as the service type because the password is predefined on the NAS. Setting up the preauthentication profile in this manner prevents users from trying to log in to the NAS with the username of the DNIS number, CLID number, or call type and an obvious password. The “outbound” service type is also included in the access-request packet sent to the RADIUS server and should be a check-in item if the RADIUS server supports check-in items.

Setting Up the RADIUS Profile for Preauthentication Enhancements for Callback

Callback allows remote network users such as telecommuters to dial in to the NAS without being charged. When callback is required, the NAS hangs up the current call and dials the caller back. When the NAS performs the callback, only information for the outgoing connection is applied. The rest of the attributes from the preauthentication access-accept message are discarded.

**Note**

The destination IP address is not required to be returned from the RADIUS server.

The following example shows a RADIUS profile configuration with a callback number of 555-1111 and the service type set to outbound. The cisco-avpair = “preauth:send-name=<string>” uses the string “andy” and the cisco-avpair = “preauth:send-secret=<string>” uses the password “cisco.”

```
5551111 password = "cisco", Service-Type = Outbound
  Service-Type = Callback-Framed
  Framed-Protocol = PPP,
  Dialback-No = "5551212"
  Class = "ISP12"
  cisco-avpair = "preauth:send-name=andy"
```

```
cisco-avpair = "preauth:send-secret=cisco"
```

Setting Up the RADIUS Profile for a Remote Host Name Used for Large-Scale Dial-Out

The following example adds to the previous example by protecting against accidentally calling a valid telephone number but accessing the wrong router by providing the name of the remote, for use in large-scale dial-out:

```
5551111 password = "cisco", Service-Type = Outbound
    Service-Type = Callback-Framed
    Framed-Protocol = PPP,
    Dialback-No = "5551212"
    Class = "ISP12"
    cisco-avpair = "preauth:send-name=andy"
    cisco-avpair = "preauth:send-secret=cisco"
    cisco-avpair = "preauth:remote-name=Router2"
```

Setting Up the RADIUS Profile for Modem Management

When DNIS, CLID, or call type preauthentication is used, the affirmative response from the RADIUS server may include a modem string for modem management in the NAS through vendor-specific attribute (VSA) 26. The modem management VSA has the following syntax:

```
cisco-avpair = "preauth:modem-service=modem min-speed <x> max-speed <y>
modulation <z> error-correction <a> compression <b>"
```

The modem management string within the VSA may contain the following:

Command	Argument
min-speed	<300 to 56000>, any
max-speed	<300 to 56000>, any
modulation	K56Flex, v22bis, v32bis, v34, v90, any
error-correction	lapm, mnp4
compression	mnp5, v42bis

When the modem management string is received from the RADIUS server in the form of a VSA, the information is passed to the Cisco IOS software and applied on a per-call basis. Modem ISDN channel aggregation (MICA) modems provide a control channel through which messages can be sent during the call setup time. Hence, this modem management feature is supported only with MICA modems and newer technologies. This feature is not supported with Microcom modems.

For more information on modem management, refer to the “Modem Configuration and Management” chapter of the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.2.

Setting Up the RADIUS Profile for Subsequent Authentication

If preauthentication passes, you may use vendor-proprietary RADIUS attribute 201 (Require-Auth) in the preauthentication profile to determine whether subsequent authentication is to be performed. If attribute 201, returned in the access-accept message, has a value of 0, then subsequent authentication will not be performed. If attribute 201 has a value of 1, then subsequent authentication will be performed as usual.

Attribute 201 has the following syntax:

```
cisco-avpair = "preauth:auth-required=<n>"
```

where *<n>* has the same value range as attribute 201 (that is, 0 or 1).

If attribute 201 is missing in the preauthentication profile, then a value of 1 is assumed, and subsequent authentication is performed.

**Note**

To perform subsequent authentication, you must set up a regular user profile in addition to a preauthentication profile.

Setting Up the RADIUS Profile for Subsequent Authentication Type

If you have specified subsequent authentication in the preauthentication profile, you must also specify the authentication types to be used for subsequent authentication. To specify the authentication types allowed in subsequent authentication, use the following VSA:

```
cisco-avpair = "preauth:auth-type=<string>"
```

where *<string>* can be one of the following:

String	Description
chap	Requires username and password of CHAP for PPP authentication.
ms-chap	Requires username and password of MS-CHAP for PPP authentication.
pap	Requires username and password of PAP for PPP authentication.

To specify that multiple authentication types are allowed, you can configure more than one instance of this VSA in the preauthentication profile. The sequence of the authentication type VSAs in the preauthentication profile is significant because it specifies the order of authentication types to be used in the PPP negotiation.

This VSA is a per-user attribute and replaces the authentication type list in the **ppp authentication** interface command.

**Note**

You should use this VSA only if subsequent authentication is required because it specifies the authentication type for subsequent authentication.

Setting Up the RADIUS Profile to Include the Username

If only preauthentication is used to authenticate a call, the NAS could be missing a username when it brings up the call. RADIUS may provide a username for the NAS to use through RADIUS attribute 1 (User-Name) or through a VSA returned in the access-accept packet. The VSA for specifying the username has the following syntax:

```
cisco-avpair = "preauth:username=<string>"
```

If no username is specified, the DNIS number, CLID number, or call type is used, depending on the last preauthentication command that has been configured (for example, if **clid** was the last preauthentication command configured, the CLID number will be used as the username).

If subsequent authentication is used to authenticate a call, there might be two usernames: one provided by RADIUS and one provided by the user. In this case, the username provided by the user overrides the one contained in the RADIUS preauthentication profile; the username provided by the user is used for both authentication and accounting.

Setting Up the RADIUS Profile for Two-Way Authentication

In the case of two-way authentication, the calling networking device will need to authenticate the NAS. The Password Authentication Protocol (PAP) username and password or Challenge Handshake Authentication Protocol (CHAP) username and password need not be configured locally on the NAS. Instead, username and password can be included in the access-accept messages for preauthentication.

Note

The **ppp authentication** command must be configured with the **radius** method.

To apply for PAP, do not configure the **ppp pap sent-name password** command on the interface. The vendor-specific attributes (VSAs) “preauth:send-name” and “preauth:send-secret” will be used as the PAP username and PAP password for outbound authentication.

For CHAP, “preauth:send-name” will be used not only for outbound authentication, but also for inbound authentication. For a CHAP inbound case, the NAS will use the name defined in “preauth:send-name” in the challenge packet to the caller networking device. For a CHAP outbound case, both “preauth:send-name” and “preauth:send-secret” will be used in the response packet.

The following example shows a configuration that specifies two-way authentication:

```
5551111 password = "cisco", Service-Type = Outbound
Service-Type = Framed-User
cisco-avpair = "preauth:auth-required=1"
cisco-avpair = "preauth:auth-type=pap"
cisco-avpair = "preauth:send-name=andy"
cisco-avpair = "preauth:send-secret=cisco"
class = "<some class>"
```

Note

Two-way authentication does not work when resource pooling is enabled.

Setting Up the RADIUS Profile to Support Authorization

If only preauthentication is configured, then subsequent authentication will be bypassed. Note that because the username and password are not available, authorization will also be bypassed. However, you may include authorization attributes in the preauthentication profile to apply per-user attributes and avoid having to return subsequently to RADIUS for authorization. To initiate the authorization process, you must also configure the **aaa authorization network** command on the NAS.

You may configure authorization attributes in the preauthentication profile with one exception: the service-type attribute (attribute 6). The service-type attribute must be converted to a VSA in the preauthentication profile. This VSA has the following syntax:

```
cisco-avpair = "preauth:service-type=<n>"
```

where <n> is one of the standard RFC 2138 values for attribute 6. For a list of possible Service-Type values, refer to the appendix RADIUS Attributes.

**Note**

If subsequent authentication is required, the authorization attributes in the preauthentication profile will not be applied.

Configuring a Guard Timer

Because response times for preauthentication and authentication requests can vary, the guard timer allows you to control the handling of calls. The guard timer starts when the DNIS is sent to the RADIUS server. If the NAS does not receive a response from AAA before the guard timer expires, it accepts or rejects the calls on the basis of the configuration of the timer.

To set a guard timer to accept or reject a call in the event that the RADIUS server fails to respond to an authentication or preauthentication request, use one of the following commands in interface configuration mode:

Command	Purpose
Router(config-if)# isdn guard-timer <i>milliseconds</i> [on-expiry { accept reject }]	Sets an ISDN guard timer to accept or reject a call in the event that the RADIUS server fails to respond to a preauthentication request.
Router(control-config)# call guard-timer <i>milliseconds</i> [on-expiry { accept reject }]	Sets a CAS guard timer to accept or reject a call in the event that the RADIUS server fails to respond to a preauthentication request.

Specifying RADIUS Authentication

After you have identified the RADIUS server and defined the RADIUS authentication key, you must define method lists for RADIUS authentication. Because RADIUS authentication is facilitated through AAA, you must enter the **aaa authentication** command, specifying RADIUS as the authentication method. For more information, refer to the chapter “Configuring Authentication.”

Specifying RADIUS Authorization

AAA authorization lets you set parameters that restrict a user’s access to the network. Authorization using RADIUS provides one method for remote access control, including one-time authorization or authorization for each service, per-user account list and profile, user group support, and support of IP, IPX, ARA, and Telnet. Because RADIUS authorization is facilitated through AAA, you must issue the **aaa authorization** command, specifying RADIUS as the authorization method. For more information, refer to the chapter “Configuring Authorization.”

Specifying RADIUS Accounting

The AAA accounting feature enables you to track the services users are accessing as well as the amount of network resources they are consuming. Because RADIUS accounting is facilitated through AAA, you must issue the **aaa accounting** command, specifying RADIUS as the accounting method. For more information, refer to the chapter “Configuring Accounting.”

Configuring RADIUS Login-IP-Host

To enable the network access server to attempt more than one login host when trying to connect a dial in user, you can enter as many as three Login-IP-Host entries in the user's profile on the RADIUS server. The following example shows that three Login-IP-Host instances have been configured for the user *joeuser*, and that TCP-Clear will be used for the connection:

```
joeuser      Password = xyz
             Service-Type = Login,
             Login-Service = TCP-Clear,
             Login-IP-Host = 10.0.0.0,
             Login-IP-Host = 10.2.2.2,
             Login-IP-Host = 10.255.255.255,
             Login-TCP-Port = 23
```

The order in which the hosts are entered is the order in which they are attempted. Use the **ip tcp synwait-time** command to set the number of seconds that the network access server waits before trying to connect to the next host on the list; the default is 30 seconds.

Your RADIUS server might permit more than three Login-IP-Host entries; however, the network access server supports only three hosts in access-accept packets.

Configuring RADIUS Prompt

To control whether user responses to access-challenge packets are echoed to the screen, you can configure the Prompt attribute in the user profile on the RADIUS server. This attribute is included only in access-challenge packets. The following example shows the Prompt attribute set to No-Echo, which prevents the user's responses from echoing:

```
joeuser Password = xyz
Service-Type = Login,
Login-Service = Telnet,
Prompt = No-Echo,
Login-IP-Host = 172.31.255.255
```

To allow user responses to echo, set the attribute to Echo. If the Prompt attribute is not included in the user profile, responses are echoed by default.

This attribute overrides the behavior of the **radius-server challenge-noecho** command configured on the access server. For example, if the access server is configured to suppress echoing, but the individual user profile allows echoing, then the user responses are echoed.

**Note**

To use the Prompt attribute, your RADIUS server must be configured to support access-challenge packets.

Configuring Suffix and Password in RADIUS Access Requests

Large-scale dial-out eliminates the need to configure dialer maps on every NAS for every destination. Instead, you can create remote site profiles that contain outgoing call attributes on the AAA server. The profile is downloaded by the NAS when packet traffic requires a call to be placed to a remote site.

You can configure the username in the access-request message to RADIUS. The default suffix of the username, "-out," is appended to the username. The format for composing the username attribute is IP address plus configured suffix.

To provide username configuration capability for large-scale dial-out, the **dialer aaa** command is implemented with the new **suffix** and **password** keywords.

	Command	Purpose
Step 1	Router(config)# aaa new-model	Enables the AAA access control model.
Step 2	Router(config)# aaa route download min	Enables the download static route feature and sets the amount of time between downloads.
Step 3	Router(config)# aaa authorization configuration default	Downloads static route configuration information from the AAA server using TACACS+ or RADIUS.
Step 4	Router(config)# interface dialer 1	Defines a dialer rotary group.
Step 5	Router(config-if)# dialer aaa	Allows a dialer to access the AAA server for dialing information.
Step 6	Router(config-if)# dialer aaa suffix suffix password password	Allows a dialer to access the AAA server for dialing information and specifies a suffix and nondefault password for authentication.

Monitoring and Maintaining RADIUS

To monitor and maintain RADIUS, use the following commands in privileged EXEC mode:

Command	Purpose
Router# debug radius	Displays information associated with RADIUS.
Router# show radius statistics	Displays the RADIUS statistics for accounting and authentication packets.

RADIUS Attributes

The network access server monitors the RADIUS authorization and accounting functions defined by RADIUS attributes in each user-profile. For a list of supported RADIUS attributes, refer to the appendix “RADIUS Attributes.”

This section includes the following sections:

- [Vendor-Proprietary RADIUS Attributes](#)
- [RADIUS Tunnel Attributes](#)

Vendor-Proprietary RADIUS Attributes

An Internet Engineering Task Force (IETF) draft standard for RADIUS specifies a method for communicating vendor-proprietary information between the network access server and the RADIUS server. Some vendors, nevertheless, have extended the RADIUS attribute set in a unique way. Cisco IOS software supports a subset of vendor-proprietary RADIUS attributes. For a list of supported vendor-proprietary RADIUS attributes, refer to the appendix “RADIUS Attributes.”

RADIUS Tunnel Attributes

RADIUS is a security server authentication, authorization, and accounting (AAA) protocol originally developed by Livingston, Inc. RADIUS uses attribute value (AV) pairs to communicate information between the security server and the network access server. RFC 2138 and RFC 2139 describe the basic functionality of RADIUS and the original set of Internet Engineering Task Force (IETF)-standard AV pairs used to send AAA information. Two draft IETF standards, “RADIUS Attributes for Tunnel Protocol Support” and “RADIUS Accounting Modifications for Tunnel Protocol Support,” extend the IETF-defined set of AV pairs to include attributes specific to virtual private networks (VPNs); these attributes are used to carry the tunneling information between the RADIUS server and the tunnel initiator. RFC 2865 and RFC 2868 extend the IETF-defined set of AV pairs to include attributes specific to compulsory tunneling in VPNs by allowing the user to specify authentication names for the network access server and the RADIUS server.

Cisco routers and access servers now support new RADIUS IETF-standard VPDN tunnel attributes. These new RADIUS IETF-standard attributes are listed in the “RADIUS Attributes” appendix. Refer to the following three configuration examples later in this chapter:

- [RADIUS User Profile with RADIUS Tunneling Attributes Example](#)
- [L2TP Access Concentrator Examples](#)
- [L2TP Network Server Examples](#)

For more information about L2F, L2TP, VPN, or VPDN, refer to the *Cisco IOS Dial Technologies Configuration Guide*, Release 12.2.

RADIUS Configuration Examples

The following sections provide RADIUS configuration examples:

- [RADIUS Authentication and Authorization Example](#)
- [RADIUS Authentication, Authorization, and Accounting Example](#)
- [Vendor-Proprietary RADIUS Configuration Example](#)
- [RADIUS Server with Server-Specific Values Example](#)
- [Multiple RADIUS Servers with Global and Server-Specific Values Example](#)
- [Multiple RADIUS Server Entries for the Same Server IP Address Example](#)
- [RADIUS Server Group Examples](#)
- [Multiple RADIUS Server Entries Using AAA Server Groups Example](#)
- [AAA Server Group Selection Based on DNIS Example](#)
- [AAA Preauthentication Examples](#)
- [RADIUS User Profile with RADIUS Tunneling Attributes Example](#)
- [Guard Timer Examples](#)
- [L2TP Access Concentrator Examples](#)
- [L2TP Network Server Examples](#)

RADIUS Authentication and Authorization Example

The following example shows how to configure the router to authenticate and authorize using RADIUS:

```
aaa authentication login use-radius group radius local
aaa authentication ppp user-radius if-needed group radius
aaa authorization exec default group radius
aaa authorization network default group radius
```

The lines in this sample RADIUS authentication and authorization configuration are defined as follows:

- The **aaa authentication login use-radius group radius local** command configures the router to use RADIUS for authentication at the login prompt. If RADIUS returns an error, the user is authenticated using the local database. In this example, **use-radius** is the name of the method list, which specifies RADIUS and then local authentication.
- The **aaa authentication ppp user-radius if-needed group radius** command configures the Cisco IOS software to use RADIUS authentication for lines using PPP with CHAP or PAP if the user has not already been authorized. If the EXEC facility has authenticated the user, RADIUS authentication is not performed. In this example, **user-radius** is the name of the method list defining RADIUS as the if-needed authentication method.
- The **aaa authorization exec default group radius** command sets the RADIUS information that is used for EXEC authorization, autocommands, and access lists.
- The **aaa authorization network default group radius** command sets RADIUS for network authorization, address assignment, and access lists.

RADIUS Authentication, Authorization, and Accounting Example

The following example shows a general configuration using RADIUS with the AAA command set:

```
radius-server host 123.45.1.2
radius-server key myRaDiUSpassWoRd
username root password ALongPassword
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa authentication login admins local
aaa authorization exec default local
line 1 16
  autoselect ppp
  autoselect during-login
  login authentication admins
  modem ri-is-cd
interface group-async 1
  encaps ppp
  ppp authentication pap dialins
```

The lines in this example RADIUS authentication, authorization, and accounting configuration are defined as follows:

- The **radius-server host** command defines the IP address of the RADIUS server host.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication and then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.

- The **ppp authentication pap dialins** command applies the “dialins” method list to the lines specified.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.
- The **aaa authentication login admins local** command defines another method list, “admins,” for login authentication.
- The **login authentication admins** command applies the “admins” method list for login authentication.

Vendor-Proprietary RADIUS Configuration Example

The following example shows a general configuration using vendor-proprietary RADIUS with the AAA command set:

```
radius-server host alcatraz non-standard
radius-server key myRaDiUSpassWoRd
radius-server configure-nas
username root password ALongPassword
aaa authentication ppp dialins group radius local
aaa authorization network default group radius local
aaa accounting network default start-stop group radius
aaa authentication login admins local
aaa authorization exec default local
line 1 16
autoselect ppp
autoselect during-login
login authentication admins
modem ri-is-cd
interface group-async 1
encaps ppp
ppp authentication pap dialins
```

The lines in this example RADIUS authentication, authorization, and accounting configuration are defined as follows:

- The **radius-server host non-standard** command defines the name of the RADIUS server host and identifies that this RADIUS host uses a vendor-proprietary version of RADIUS.
- The **radius-server key** command defines the shared secret text string between the network access server and the RADIUS server host.
- The **radius-server configure-nas** command defines that the Cisco router or access server will query the RADIUS server for static routes and IP pool definitions when the device first starts up.
- The **aaa authentication ppp dialins group radius local** command defines the authentication method list “dialins,” which specifies that RADIUS authentication, and then (if the RADIUS server does not respond) local authentication will be used on serial lines using PPP.
- The **ppp authentication pap dialins** command applies the “dialins” method list to the lines specified.
- The **aaa authorization network default group radius local** command is used to assign an address and other network parameters to the RADIUS user.
- The **aaa accounting network default start-stop group radius** command tracks PPP usage.

- The **aaa authentication login admins local** command defines another method list, “admins,” for login authentication.
- The **login authentication admins** command applies the “admins” method list for login authentication.

RADIUS Server with Server-Specific Values Example

The following example shows how to configure server-specific timeout, retransmit, and key values for the RADIUS server with IP address 172.31.39.46:

```
radius-server host 172.31.39.46 timeout 6 retransmit 5 key rad123
```

Multiple RADIUS Servers with Global and Server-Specific Values Example

The following example shows how to configure two RADIUS servers with specific timeout, retransmit, and key values. In this example, the **aaa new-model** command enables AAA services on the router, while specific AAA commands define the AAA services. The **radius-server retransmit** command changes the global retransmission value to 4 for all RADIUS servers. The **radius-server host** command configures specific timeout, retransmission, and key values for the RADIUS server hosts with IP addresses 172.16.1.1 and 172.29.39.46.

```
! Enable AAA services on the router and define those services.
aaa new-model
aaa authentication login default group radius
aaa authentication login console-login none
aaa authentication ppp default group radius
aaa authorization network default group radius
aaa accounting exec default start-stop group radius
aaa accounting network default start-stop group radius
enable password tryit1
!
! Change the global retransmission value for all RADIUS servers.
radius-server retransmit 4
!
! Configure per-server specific timeout, retransmission, and key values.
! Change the default auth-port and acct-port values.
radius-server host 172.16.1.1 auth-port 1612 acct-port 1616 timeout 3 retransmit 3 key
radkey
!
! Configure per-server specific timeout and key values. This server uses the global
! retransmission value.
radius-server host 172.29.39.46 timeout 6 key rad123
```

Multiple RADIUS Server Entries for the Same Server IP Address Example

The following example shows how to configure the network access server to recognize several RADIUS host entries with the same IP address. Two different host entries on the same RADIUS server are configured for the same services—authentication and accounting. The second host entry configured acts as fail-over backup to the first one. (The RADIUS host entries will be tried in the order they are configured.)

```
! This command enables AAA.
aaa new-model
! The next command configures default RADIUS parameters.
aaa authentication ppp default group radius
```

```
! The next set of commands configures multiple host entries for the same IP address.
radius-server host 172.20.0.1 auth-port 1000 acct-port 1001
radius-server host 172.20.0.1 auth-port 2000 acct-port 2000
```

RADIUS Server Group Examples

The following example shows how to create server group *radgroup1* with three different RADIUS server members, each using the default authentication port (1645) and accounting port (1646):

```
aaa group server radius radgroup1
server 172.16.1.11
server 172.17.1.21
server 172.18.1.31
```

The following example shows how to create server group *radgroup2* with three RADIUS server members, each with the same IP address but with unique authentication and accounting ports:

```
aaa group server radius radgroup2
server 172.16.1.1 auth-port 1000 acct-port 1001
server 172.16.1.1 auth-port 2000 acct-port 2001
server 172.16.1.1 auth-port 3000 acct-port 3001
```

Multiple RADIUS Server Entries Using AAA Server Groups Example

The following example shows how to configure the network access server to recognize two different RADIUS server groups. One of these groups, *group1*, has two different host entries on the same RADIUS server configured for the same services. The second host entry configured acts as failover backup to the first one. Each group is individually configured for *deadtime*; *deadtime* for group 1 is one minute, and *deadtime* for group 2 is two minutes.

Note

In cases where both global commands and server commands are used, the server command will take precedence over the global command.

```
! This command enables AAA.
aaa new-model
! The next command configures default RADIUS parameters.
aaa authentication ppp default group group1
! The following commands define the group1 RADIUS server group and associate servers
! with it and configures a deadtime of one minute.
aaa group server radius group1
server 1.1.1.1 auth-port 1645 acct-port 1646
server 2.2.2.2 auth-port 2000 acct-port 2001
deadtime 1
! The following commands define the group2 RADIUS server group and associate servers
! with it and configures a deadtime of two minutes.
aaa group server radius group2
server 2.2.2.2 auth-port 2000 acct-port 2001
server 3.3.3.3 auth-port 1645 acct-port 1646
deadtime 2
! The following set of commands configures the RADIUS attributes for each host entry
! associated with one of the defined server groups.
radius-server host 1.1.1.1 auth-port 1645 acct-port 1646
radius-server host 2.2.2.2 auth-port 2000 acct-port 2001
radius-server host 3.3.3.3 auth-port 1645 acct-port 1646
```

AAA Server Group Selection Based on DNIS Example

The following example shows how to select RADIUS server groups based on DNIS to provide specific AAA services:

```
! This command enables AAA.
aaa new-model
!
! The following set of commands configures the RADIUS attributes for each server
! that will be associated with one of the defined server groups.
radius-server host 172.16.0.1 auth-port 1645 acct-port 1646 key cisco1
radius-server host 172.17.0.1 auth-port 1645 acct-port 1646 key cisco2
radius-server host 172.18.0.1 auth-port 1645 acct-port 1646 key cisco3
radius-server host 172.19.0.1 auth-port 1645 acct-port 1646 key cisco4
radius-server host 172.20.0.1 auth-port 1645 acct-port 1646 key cisco5

! The following commands define the sg1 RADIUS server group and associate servers
! with it.
aaa group server radius sg1
  server 172.16.0.1
  server 172.17.0.1
! The following commands define the sg2 RADIUS server group and associate a server
! with it.
aaa group server radius sg2
  server 172.18.0.1
! The following commands define the sg3 RADIUS server group and associate a server
! with it.
aaa group server radius sg3
  server 172.19.0.1
! The following commands define the default-group RADIUS server group and associate
! a server with it.
aaa group server radius default-group
  server 172.20.0.1
!
! The next set of commands configures default-group RADIUS server group parameters.
aaa authentication ppp default group default-group
aaa accounting network default start-stop group default-group
!
```

```
! The next set of commands enables DNIS mapping and maps DNIS numbers to the defined
! RADIUS server groups. In this configuration, all PPP connection requests using
! DNIS 7777 are sent to the sg1 server group. The accounting records for these
! connections (specifically, start-stop records) are handled by the sg2 server group.
! Calls with a DNIS of 8888 use server group sg3 for authentication and server group
! default-group for accounting. Calls with a DNIS of 9999 use server group
! default-group for authentication and server group sg3 for accounting records
! (stop records only). All other calls with DNIS other than the ones defined use the
! server group default-group for both authentication and stop-start accounting records.
aaa dnis map enable
aaa dnis map 7777 authentication ppp group sg1
aaa dnis map 7777 accounting network start-stop group sg2
aaa dnis map 8888 authentication ppp group sg3
aaa dnis map 9999 accounting network stop-only group sg3
```

AAA Preauthentication Examples

The following example shows a simple configuration that specifies that the DNIS number be used for preauthentication:

```
aaa preauth
group radius
dnis required
```

The following example shows a configuration that specifies that both the DNIS number and the CLID number be used for preauthentication. DNIS preauthentication will be performed first, followed by CLID preauthentication.

```
aaa preauth
  group radius
  dnis required
  clid required
```

The following example specifies that preauthentication be performed on all DNIS numbers except the two DNIS numbers specified in the DNIS group called “hawaii”:

```
aaa preauth
group radius
dnis required
dnis bypass hawaii
```

```
dialer dnis group hawaii
  number 12345
  number 12346
```

The following example shows a sample AAA configuration with DNIS preauthentication:

```
aaa new-model
aaa authentication login CONSOLE none
aaa authentication login RADIUS_LIST group radius
aaa authentication login TAC_PLUS group tacacs+ enable
aaa authentication login V.120 none
aaa authentication enable default enable group tacacs+
aaa authentication ppp RADIUS_LIST if-needed group radius
aaa authorization exec RADIUS_LIST group radius if-authenticated
aaa authorization exec V.120 none
aaa authorization network default group radius if-authenticated
aaa authorization network RADIUS_LIST if-authenticated group radius
aaa authorization network V.120 group radius if-authenticated
aaa accounting suppress null-username
aaa accounting exec default start-stop group radius
aaa accounting commands 0 default start-stop group radius
```

```

aaa accounting network default start-stop group radius
aaa accounting connection default start-stop group radius
aaa accounting system default start-stop group radius
aaa preauth
  dn timer 30
aaa nas port extended
!
radius-server configure-nas
radius-server host 10.0.0.0 auth-port 1645 acct-port 1646 non-standard
radius-server host 10.255.255.255 auth-port 1645 acct-port 1646 non-standard
radius-server retransmit 2
radius-server deadtime 1
radius-server attribute nas-port format c
radius-server unique-ident 18
radius-server key MyKey

```

**Note**

To configure preauthentication, you must also set up preauthentication profiles on the RADIUS server.

RADIUS User Profile with RADIUS Tunneling Attributes Example

The following example shows a RADIUS user profile (Merit Daemon format) that includes RADIUS tunneling attributes. This entry supports two tunnels, one for L2F and the other for L2TP. The tag entries with :1 support L2F tunnels, and the tag entries with :2 support L2TP tunnels.

```

cisco.com Password = "cisco", Service-Type = Outbound
  Service-Type = Outbound,
  Tunnel-Type = :1:L2F,
  Tunnel-Medium-Type = :1:IP,
  Tunnel-Client-Endpoint = :1:"10.0.0.2",
  Tunnel-Server-Endpoint = :1:"10.0.0.3",
  Tunnel-Client-Auth-Id = :1:"l2f-cli-auth-id",
  Tunnel-Server-Auth-Id = :1:"l2f-svr-auth-id",
  Tunnel-Assignment-Id = :1:"l2f-assignment-id",
  Cisco-Avpair = "vpdn:nas-password=l2f-cli-pass",
  Cisco-Avpair = "vpdn:gw-password=l2f-svr-pass",
  Tunnel-Preference = :1:1,
  Tunnel-Type = :2:L2TP,
  Tunnel-Medium-Type = :2:IP,
  Tunnel-Client-Endpoint = :2:"10.0.0.2",
  Tunnel-Server-Endpoint = :2:"10.0.0.3",
  Tunnel-Client-Auth-Id = :2:"l2tp-cli-auth-id",
  Tunnel-Server-Auth-Id = :2:"l2tp-svr-auth-id",
  Tunnel-Assignment-Id = :2:"l2tp-assignment-id",
  Cisco-Avpair = "vpdn:l2tp-tunnel-password=l2tp-tnl-pass",
  Tunnel-Preference = :2:2

```

Guard Timer Examples

The following example shows an ISDN guard timer that is set at 8000 milliseconds. A call will be rejected if the RADIUS server has not responded to a preauthentication request when the timer expires.

```

interface serial1/0/0:23
  isdn guard-timer 8000 on-expiry reject

aaa preauth
  group radius
  dn timer 30

```

The following example shows a CAS guard timer that is set at 20,000 milliseconds. A call will be accepted if the RADIUS server has not responded to a preauthentication request when the timer expires.

```
controller T1 0
 framing esf
 clock source line primary
 linecode b8zs
 ds0-group 0 timeslots 1-24 type e&m-fgb dtmf dnis
 cas-custom 0
 call guard-timer 20000 on-expiry accept

aaa preauth
group radius
dnis required
```

L2TP Access Concentrator Examples

The following example shows a basic L2TP configuration for the L2TP access concentrator (LAC) for the topology shown in [Figure 12](#). The local name is not defined, so the host name used is the local name. Because the L2TP tunnel password is not defined, the username password is used. In this example, VPDN is configured locally on the LAC and does not take advantage of the new RADIUS tunnel attributes.

Figure 12 *Topology for Configuration Examples*

```
! Enable AAA globally.
aaa new-model
! Enable AAA authentication for PPP and list the default method to use for PPP
! authentication.
aaa authentication ppp default local
! Define the username as "DJ."
username DJ password 7 030C5E070A00781B
! Enable VPDN.
vpdn enable
! Define VPDN group number 1.
vpdn-group 1
! Allow the LAC to respond to dialin requests using L2TP from IP address 172.21.9.13
! domain "cisco.com."
request dialin
protocol l2tp
domain cisco.com
initiate-ip to 172.21.9.13
local name nas-1
```

The following example shows how to configure the LAC if RADIUS tunnel attributes are supported. In this example, there is no local VPDN configuration on the LAC; the LAC, instead, is configured to query the remote RADIUS security server.

```
! Enable global AAA securities services.
aaa new-model
```

```

! Enable AAA authentication for PPP and list RADIUS as the default method to use
! for PPP authentication.
aaa authentication ppp default group radius local
! Enable AAA (network) authorization and list RADIUS as the default method to use for
! authorization.
aaa authorization network default group radius
! Define the username as "DJ."
username DJ password 7 030C5E070A00781B
! Enable VPDN.
vpdn enable
! Configure the LAC to interface with the remote RADIUS security server.
radius host 171.69.1.1 auth-port 1645 acct-port 1646
radius-server key cisco

```

L2TP Network Server Examples

The following example shows a basic L2TP configuration with corresponding comments on the L2TP network server (LNS) for the topology shown in [Figure 12](#):

```

! Enable AAA globally.
aaa new-model
! Enable AAA authentication for PPP and list the default method to use for PPP
! authentication.
aaa authentication ppp default local
! Define the username as "partner."
username partner password 7 030C5E070A00781B
! Create virtual-template 1 and assign all values for virtual access interfaces.
interface Virtual-Template1
! Borrow the IP address from interface ethernet 1.
ip unnumbered Ethernet0
! Disable multicast fast switching.
no ip mroute-cache
! Use CHAP to authenticate PPP.
ppp authentication chap
! Enable VPDN.
vpdn enable
! Create vpdn-group number 1.
vpdn-group 1
! Accept all dialin l2tp tunnels from virtual-template 1 from remote peer DJ.
accept dialin l2tp virtual-template 1 remote DJ
protocol any
virtual-template 1
terminate-from hostname nas1
local name hgw1

```

The following example shows how to configure the LNS with a basic L2F and L2TP configuration using RADIUS tunneling attributes:

```

aaa new-model
aaa authentication login default none
aaa authentication login console none
aaa authentication ppp default local group radius
aaa authorization network default group radius if-authenticated
!
username l2f-cli-auth-id password 0 l2f-cli-pass
username l2f-svr-auth-id password 0 l2f-svr-pass
username l2tp-svr-auth-id password 0 l2tp-tnl-pass
!
vpdn enable
vpdn search-order domain
!
vpdn-group 1

```

```
accept-dialin
protocol l2f
virtual-template 1
terminate-from hostname l2f-cli-auth-id
local name l2f-svr-auth-id
!
vpdn-group 2
accept-dialin
protocol l2tp
virtual-template 2
terminate-from hostname l2tp-cli-auth-id
local name l2tp-svr-auth-id
!
interface Ethernet1/0
ip address 10.0.0.3 255.255.255.0
no ip route-cache
no ip mroute-cache
!
interface Virtual-Template1
ip unnumbered Ethernet1/0
ppp authentication pap
!
interface Virtual-Template2
ip unnumbered Ethernet1/0
ppp authentication pap
!
radius-server host 1.1.1.1 auth-port 1645 acct-port 1646
radius-server key <deleted>
!
```

AAA Dead-Server Detection

First Published: February 13, 2004

Last Updated: March 4, 2008

The AAA Dead-Server Detection feature allows you to configure the criteria that are to be used to mark a RADIUS server as dead. If no criteria are explicitly configured, the criteria will be computed dynamically on the basis of the number of outstanding transactions. Using this feature will result in less downtime and quicker packet processing.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for AAA Dead-Server Detection](#)” section on page 9.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for AAA Dead-Server Detection

- You must have access to a RADIUS server.
- You should be familiar with configuring a RADIUS server.
- You should be familiar with configuring authentication, authorization, and accounting (AAA).
- Before a server can be marked as dead, you must first configure the **radius-server deadtime** command. If this command is not configured, even if the criteria are met for the server to be marked as dead, the server state will be the “up” state.

Restrictions for AAA Dead-Server Detection

- Original transmissions are not counted in the number of consecutive timeouts that must occur on the router before the server is marked as dead—only the number of retransmissions are counted.

Information About AAA Dead-Server Detection

To configure the AAA Dead-Server Detection feature, you should understand the following concept:

- [Criteria for Marking a RADIUS Server As Dead, page 2](#)

Criteria for Marking a RADIUS Server As Dead

The AAA Dead-Server Detection feature allows you to determine the criteria that are used to mark a RADIUS server as dead. That is, you can configure the minimum amount of time, in seconds, that must elapse from the time that the router last received a valid packet from the RADIUS server to the time the server is marked as dead. If a packet has not been received since the router booted, and there is a timeout, the time criterion will be treated as though it has been met.

In addition, you can configure the number of consecutive timeouts that must occur on the router before the RADIUS server is marked as dead. If the server performs both authentication and accounting, both types of packets are included in the number. Improperly constructed packets are counted as though they are timeouts. Only retransmissions are counted, not the initial transmission. (Each timeout causes one retransmission to be sent.)

Note

Both the time criterion and the tries criterion must be met for the server to be marked as dead.

The RADIUS dead-server detection configuration will result in the prompt detection of RADIUS servers that have stopped responding. This configuration will also result in the avoidance of servers being improperly marked as dead when they are “swamped” (responding slowly) and the avoidance of the state of servers being rapidly changed from dead to live to dead again. This prompt detection of nonresponding RADIUS servers and the avoidance of swamped and dead-to-live-to-dead-again servers will result in less deadtime and quicker packet processing.

How to Configure AAA Dead-Server Detection

This section contains the following procedures:

- [Configuring AAA Dead-Server Detection, page 3](#) (required)
- [Verifying AAA Dead-Server Detection, page 4](#) (optional)

Configuring AAA Dead-Server Detection

To configure AAA Dead-Server Detection, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **radius-server deadtime** *minutes*
5. **radius-server dead-criteria** [**time** *seconds*] [**tries** *number-of-tries*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Router (config)# aaa new-model	Enables the AAA access control model.
Step 4	radius-server deadtime <i>minutes</i> Example: Router (config)# radius-server deadtime 5	Improves RADIUS response times when some servers might be unavailable and causes the unavailable servers to be skipped immediately.
Step 5	radius-server dead-criteria [<i>time seconds</i>] [<i>tries number-of-tries</i>] Example: Router (config)# radius-server dead-criteria time 5 tries 4	Forces one or both of the criteria—used to mark a RADIUS server as dead—to be the indicated constant.

Troubleshooting Tips

After you have configured AAA Dead-Server Detection, you should verify your configuration using the **show running-config** command. This verification is especially important if you have used the **no** form of the **radius-server dead-criteria** command. The output of the **show running-config** command must show the same values in the “Dead Criteria Details” field that you configured using the **radius-server dead-criteria** command.

Verifying AAA Dead-Server Detection

To verify your AAA Dead-Server Detection configuration, perform the following steps. The **show** and **debug** commands may be used in any order.

SUMMARY STEPS

1. **enable**
2. **debug aaa dead-criteria transactions**
3. **show aaa dead-criteria**
4. **show aaa servers**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	debug aaa dead-criteria transactions Example: Router# debug aaa dead-criteria transactions	Displays AAA dead-criteria transaction values.
Step 3	show aaa dead-criteria Example: Router# show aaa dead-criteria	Displays dead-criteria information for a AAA server.
Step 4	show aaa servers [private public] Example: Router# show aaa server private	Displays the status and number of packets that are sent to and received from all public and private authentication, authorization, and accounting (AAA) RADIUS servers. <ul style="list-style-type: none"> The private keyword optionally displays the AAA servers only. The public keyword optionally displays the AAA servers only.

Configuration Examples for AAA Dead-Server Detection

This section provides the following configuration examples:

- [Configuring AAA Dead-Server Detection: Example, page 5](#)
- [debug aaa dead-criteria transactions Command: Example, page 6](#)
- [show aaa dead-criteria Command: Example, page 6](#)

Configuring AAA Dead-Server Detection: Example

The following example shows that the router will be considered dead after 5 seconds and four tries:

```
Router (config)# aaa new-model
Router (config)# radius-server deadtime 5
Router (config)# radius-server dead-criteria time 5 tries 4
```

debug aaa dead-criteria transactions Command: Example

The following output example shows dead-criteria transaction information for a particular server group:

```
Router# debug aaa dead-criteria transactions
```

```
AAA Transaction debugs debugging is on
```

```
*Nov 14 23:44:17.403: AAA/SG/TRANSAC: Computed Retransmit Tries: 22, Current Max Tries: 22
*Nov 14 23:44:17.403: AAA/SG/TRANSAC: Computed Dead Detect Interval: 25s, Current Max
Interval: 25s
*Nov 14 23:44:17.403: AAA/SG/TRANSAC: Estimated Outstanding Transactions: 6, Current Max
Transactions: 6
```

show aaa dead-criteria Command: Example

The following output example shows that dead-server-detection information has been requested for a RADIUS server at the IP address 172.19.192.80:

```
Router# show aaa dead-criteria radius 172.19.192.80 radius
```

```
RADIUS Server Dead Criteria:
=====
Server Details:
  Address : 172.19.192.80
  Auth Port : 1645
  Acct Port : 1646
Server Group : radius
Dead Criteria Details:
  Configured Retransmits : 62
  Configured Timeout : 27
  Estimated Outstanding Transactions: 5
  Dead Detect Time : 25s
  Computed Retransmit Tries: 22
  Statistics Gathered Since Last Successful Transaction
=====
Max Computed Outstanding Transactions: 5
Max Computed Dead Detect Time: 25s
Max Computed Retransmits : 22
```

AAA-SERVER-MIB Set Operation

The AAA-SERVER-MIB Set Operation feature allows you to extend and expand your ability to configure authentication, authorization, and accounting (AAA) servers using the CISCO-AAA-SERVER-MIB. Using this feature, you can do the following:

- Create and add new AAA servers.
- Modify the “KEY” under the CISCO-AAA-SERVER-MIB.
- Delete the AAA server configuration.

History for the AAA-SERVER-MIB Set Operation Feature

Release	Modification
12.4(4)T	This feature was introduced.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Prerequisites for AAA-SERVER-MIB Set Operation

AAA must have been enabled on the router, that is, the **aaa new-model** command must have been configured. If this configuration has not been accomplished, the set operation fails.

Restrictions for AAA-SERVER-MIB Set Operation

Currently, the CISCO SNMP set operation is supported only for the RADIUS protocol. Therefore, only RADIUS servers in global configuration mode can be added, modified, or deleted.

Information About AAA-SERVER-MIB Set Operation

Before using the AAA-SERVER-MIB Set Operation feature, you should understand the following concepts:

- [CISCO-AAA-SERVER-MIB, page 2](#)
- [CISCO-AAA-SERVER-MIB Set Operation, page 2](#)

CISCO-AAA-SERVER-MIB

The CISCO-AAA-SERVER-MIB provides that statistics reflect both the state of the AAA server operation with the server itself and of AAA communications with external servers. The CISCO-AAA-SERVER-MIB provides the following information:

- Statistics for each AAA operation
- Status of servers that are providing AAA functions
- Identities of external AAA servers

CISCO-AAA-SERVER-MIB Set Operation

Before Cisco IOS Release 12.4(4)T, the CISCO-AAA-SERVER-MIB supported only the “get” operation. Effective with this release, the CISCO-AAA-SERVER-MIB supports the set operation. With the set operation, you can do the following:

- Create or add a new AAA server.
- Modify the KEY under the CISCO-AAA-SERVER-MIB. This “secret key” is used for secure connectivity to the AAA server, which is present with the network access server (NAS) and the AAA server.
- Delete the AAA server configuration.

How to Configure AAA-SERVER-MIB Set Operation

No special configuration is required for this feature. The Simple Network Management Protocol (SNMP) framework can be used to manage MIBs. See the section “[Additional References](#)” for a reference to configuring SNMP.

SNMP values can be verified by performing the following steps.

SUMMARY STEPS

1. **enable**
2. **show running-config | include radius-server host**
3. **show aaa servers**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	show running-config include radius-server host Example: Router# show running-config include radius-server host	Displays all the RADIUS servers that are configured in the global configuration mode.
Step 3	show aaa servers Example: Router# show aaa servers	Displays information about the number of requests sent to and received from authentication, authorization, and accounting (AAA) servers.

Configuration Examples for AAA-SERVER-MIB Set Operation

This section includes the following example:

- [RADIUS Server Configuration and Server Statistics: Example, page 4](#)

RADIUS Server Configuration and Server Statistics: Example

The following output example shows the RADIUS server configuration and server statistics before and after the set operation.

Before the Set Operation

```
Router# show running-config | include radius-server host
```

```
! The following line is for server 1.
radius-server host 172.19.192.238 auth-port 2095 acct-port 2096 key cisco2
! The following line is for server 2.
radius-server host 172.19.192.238 auth-port 1645 acct-port 1646
```

Server Statistics

```
Router# show aaa servers
```

```
RADIUS: id 2, priority 1, host 172.19.192.238, auth-port 2095, acct-port 2096
State: current UP, duration 25s, previous duration 0s
  Dead: total time 0s, count 7
Authen: request 8, timeouts 8
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 2
Author: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Account: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Elapsed time since counters last cleared: 5m

RADIUS: id 3, priority 2, host 172.19.192.238, auth-port 1645, acct-port 1646
State: current UP, duration 5s, previous duration 0s
  Dead: total time 0s, count 2
Authen: request 8, timeouts 8
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 4
Author: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Account: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Elapsed time since counters last cleared: 3m
```

SNMP Get Operation to Check the Configuration and Statistics of the RADIUS Servers

```
aaa-server5:/users/smetri> getmany 10.0.1.42 casConfigTable
casAddress.2.2 = 172.19.192.238
casAddress.2.3 = 172.19.192.238
casAuthenPort.2.2 = 2095
casAuthenPort.2.3 = 1645
casAcctPort.2.2 = 2096
casAcctPort.2.3 = 1646
casKey.2.2 =
casKey.2.3 =
! The following line shows priority for server 1.
casPriority.2.2 = 1
! The following line shows priority for server 2.
casPriority.2.3 = 2
casConfigRowStatus.2.2 = active(1)
casConfigRowStatus.2.3 = active(1)
aaa-server5:/users/smetri>
```

SNMP Set Operation

The key of the existing RADIUS server is being changed. The index "1" is being used. That index acts as a wildcard for addition, deletion, or modification of any entries.

Change the key for server 1:=>

```
aaa-server5:/users/smetri> setany -v2c 10.0.1.42 public casAddress.2.1 -a 172.19.192.238
casAuthenPort.2.1 -i 2095 casAcctPort.2.1 -i 2096 casKey.2.1 -o king
casAddress.2.1 = 172.19.192.238
casAuthenPort.2.1 = 2095
casAcctPort.2.1 = 2096
casKey.2.1 = king
aaa-server5:/users/smetri>
```

After the Set Operation

After the above SNMP set operation, the configurations on the router change. The following output shows the output after the set operation.

Router# **show running-config | include radius-server host**

```
radius-server host 172.19.192.238 auth-port 1645 acct-port 1646
! The following line shows a change in the key value to "king."
radius-server host 172.19.192.238 auth-port 2095 acct-port 2096 key king
```

Router# **show aaa servers**

```
RADIUS: id 3, priority 1, host 172.19.192.238, auth-port 1645, acct-port 1646
State: current UP, duration 189s, previous duration 0s
  Dead: total time 0s, count 2
Authen: request 8, timeouts 8
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 4
Author: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Account: request 0, timeouts 0
  Response: unexpected 0, server error 0, incorrect 0, time 0ms
  Transaction: success 0, failure 0
Elapsed time since counters last cleared: 6m

! The following line shows a new server with new statistics.
RADIUS: id 4, priority 2, host 172.19.192.238, auth-port 2095, acct-port 2096
State: current UP, duration 209s, previous duration 0s
  Dead: total time 0s, count 7

ACL Default Direction

First Published: October 15, 2001

Last Updated: February 23, 2007

The ACL Default Direction feature allows you to change the filter direction (where filter direction is not specified) to inbound packets only; that is, you can configure your server to filter packets that are coming toward the network.

History for the ACL Default Direction Feature

Release	Modification
12.2(4)T	This feature was introduced.
12.2(28)SB	This feature was integrated into Cisco IOS Release 12.2(28)SB.
12.2(31)SB3	This feature was integrated into Cisco IOS Release 12.2(31)SB3.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for ACL Default Direction

Before you can change the default direction of filters from RADIUS, you must perform the following tasks:

- Configure your network access server (NAS) for authentication, authorization, and accounting (AAA) and to accept incoming calls.

For more information, refer to the AAA chapters of the [Cisco IOS Security Configuration Guide](#), Release 12.4 and the [Cisco IOS Dial Technologies Configuration Guide](#), Release 12.4.

- Create a filter on your NAS.

For more information, refer to the section “[Configuring IP Services](#)” section of the chapter IP Addressing and Services of the [Cisco IOS IP Addressing Services Configuration Guide](#), Release 12.4.

- Add a filter definition for a RADIUS user; for example, Filter-Id = “myfilter”.

Information About ACL Default Direction

Before changing the default direction of filters for your access control lists (ACLs) from RADIUS, you should understand the following concepts:

- [The radius-server attribute 11 direction default Command, page 2](#)
- [Benefits of ACL Default Direction, page 2](#)

The radius-server attribute 11 direction default Command

The **radius-server attribute 11 direction default** command allows you to change the default direction of filters for your ACLs via RADIUS. (RADIUS attribute 11 (Filter-Id) indicates the name of the filter list for the user.) Enabling this command allows you to change the filter direction to inbound—which stops traffic from entering a router, and reduces resource consumption—rather than keeping the outbound default direction, where filtering occurs only as the traffic is about to leave the network.

Benefits of ACL Default Direction

The ACL Default Direction feature allows you to change the default direction, which is outbound, of filters for your ACLs to inbound via the **radius-server attribute 11 direction default** command.

How to Configure ACL Default Direction

This section contains the following procedures:

- [Configuring the ACL Default Direction from RADIUS via Attribute 11 \(Filter-Id\), page 3](#) (required)
- [Verifying the ACL Default Direction from RADIUS via Attribute 11 \(Filter-Id\), page 3](#) (optional)

Configuring the ACL Default Direction from RADIUS via Attribute 11 (Filter-Id)

To configure the default direction of filters from RADIUS via attribute 11, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `radius-server attribute 11 direction default [inbound | outbound]`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code> Example: Router> <code>enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	<code>configure terminal</code> Example: Router# <code>configure terminal</code>	Enters global configuration mode.
Step 3	<code>radius-server attribute 11 direction default [inbound outbound]</code> Example: Router(config)# <code>radius-server attribute 11 direction default inbound</code>	Specifies the default direction of filters from RADIUS to inbound or outbound.

Verifying the ACL Default Direction from RADIUS via Attribute 11 (Filter-Id)

To verify the default direction of filters from RADIUS and to verify that RADIUS attribute 11 is being sent in access accept requests, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `more system:running-config`
3. `debug radius`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	more system:running-config Example: Router# more system:running-config	Displays the contents of the current running configuration file.
Step 3	debug radius Example: Router# debug radius	Displays information associated with RADIUS. The output of this command shows whether attribute 11 is being sent in access accept requests.

Configuration Examples for ACL Default Direction

This section provides the following configuration examples:

- [Default Direction of Filters via RADIUS Attribute 11 \(Filter-Id\): Example, page 4](#)
- [RADIUS User Profile with Filter-Id: Example, page 4](#)

Default Direction of Filters via RADIUS Attribute 11 (Filter-Id): Example

The following example shows how to configure RADIUS attribute 11 to change the default direction of filters. In this example, the filtering is applied to inbound packets only.

radius-server attribute 11 direction default inbound

RADIUS User Profile with Filter-Id: Example

The following is an example of a RADIUS user profile (Merit Daemon format) that includes RADIUS attribute 11 (Filter-Id):

```
client Password = "password1"
    Service-Type = Framed,
    Framed-Protocol = PPP,
    Filter-Id = "myfilter.out"
```

The RADIUS user profile shown in this example produces the following reply from the NAS:

```
RADIUS: Send to unknown id 79 10.51.13.4:1645, Access-Request, len 85
RADIUS: authenticator 84 D3 B5 7D C2 5B 70 AD - 1E 5C 56 E8 3A 91 D0 6E
RADIUS: User-Name          [1]  8  "client"
RADIUS: CHAP-Password      [3]  19  *
RADIUS: NAS-Port           [5]  6  20030
RADIUS: NAS-Port-Type      [61] 6  ISDN                      [2]
RADIUS: Called-Station-Id  [30] 6  "4321"
RADIUS: Calling-Station-Id [31] 6  "1234"
RADIUS: Service-Type       [6]  6  Framed                      [2]
```

```

RADIUS: NAS-IP-Address      [4]   6   10.1.73.74

RADIUS: Received from id 79 10.51.13.4:1645, Access-Accept, len 46
RADIUS: authenticator 9C 6C 66 E2 F1 42 D6 4B - C1 7D D4 5E 9D 09 BB A1
RADIUS: Service-Type        [6]   6   Framed                      [2]
RADIUS: Framed-Protocol     [7]   6   PPP                        [1]
RADIUS: Filter-Id           [11]  14
RADIUS: 6D 79 66 69 6C 74 65 72 2E 6F 75 74      [myfilter.out]

```

Attribute Screening for Access Requests

First Published: November 19, 2003

Last Updated: December 17, 2007

The Attribute Screening for Access Requests feature allows you to configure your network access server (NAS) to filter attributes in outbound Access Requests to the RADIUS server for purposes of authentication or authorization.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Attribute Screening for Access Requests](#)” section on [page 9](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Americas Headquarters:

Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2003–2004, 2006–2007 Cisco Systems, Inc. All rights reserved.

Prerequisites for Attribute Screening for Access Requests

- You must be familiar with configuring attribute lists.

Restrictions for Attribute Screening for Access Requests

- Attributes 1 (Username), 2 (User-Password), and 3 (Chap-Password) cannot be filtered.

Information About Attribute Screening for Access Requests

To configure the Attribute Screening for Access Requests feature, you should understand the following concept:

- [Configuring an NAS to Filter Attributes in Outbound Access Requests, page 2](#)

Configuring an NAS to Filter Attributes in Outbound Access Requests

The Attribute Screening for Access Requests feature allows you to configure your NAS to filter attributes in outbound Access Requests to the RADIUS server for purposes of authentication or authorization. The filters can be configured on the NAS, or they can be downloaded via downloadable vendor-specific attributes (VSAs) from the authentication, authorization, and accounting (AAA) server.

The following are some examples of the downloadable VSAs:

```
Cisco:Cisco-Avpair="ppp-authen-type=chap"  
Cisco:Cisco-Avpair="ppp-authen-list=group 1"  
Cisco:Cisco-Avpair="ppp-author-list=group 1"  
Cisco:Cisco-Avpair="vpdn:tunnel-id=B53"  
Cisco:Cisco-Avpair="vpdn:ip-addresses=10.0.58.35"
```

**Note**

You must be aware of which attributes you want to filter. Filtering certain key attributes can result in authentication failure (for example, attribute 60 should not be filtered).

How to Configure Attribute Screening for Access Requests

This section contains the following procedures:

- [Configuring Attribute Screening for Access Requests, page 3](#)
- [Configuring a Router to Support Downloadable Filters, page 4](#)
- [Monitoring and Maintaining Attribute Filtering for Access Requests, page 5](#)

Configuring Attribute Screening for Access Requests

To configure the attribute screening for access requests, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **radius-server attribute list** *listname*
4. **attribute** *value1* [*value2* [*value3...*]]
5. **aaa group server radius** *group-name*
6. **authorization** [**request** | **reply**] [**accept** | **reject**] *listname*
or
accounting [**request** | **reply**] [**accept** | **reject**] *listname*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	radius-server attribute list <i>listname</i> Example: Router (config)# radius-server attribute list attrlist	Defines an attribute list.
Step 4	attribute <i>value1</i> [<i>value2</i> [<i>value3...</i>]] Example: Router (config)# attribute 6-10, 12	Adds attributes to an accept or reject list.
Step 5	aaa group server radius <i>group-name</i> Example: Router (config)# aaa group server radius rad1	Applies the attribute list to the AAA server group and enters server-group configuration mode.

	Command or Action	Purpose
Step 6	<p>authorization [request reply] [accept reject] <i>listname</i></p> <p>or</p> <p>accounting [request reply] [accept reject] <i>listname</i></p> <p>Example: Router (config-sg-radius)# authorization request accept attrlist</p> <p>or</p> <p>Example: Router (config-sg-radius)# accounting request accept attrlist</p>	<p>Filters attributes in outbound Access Requests to the RADIUS server for purposes of authentication or authorization.</p> <ul style="list-style-type: none"> The request keyword defines filters for outgoing authorization Access Requests. The reply keyword defines filters for incoming authorization Accept and Reject packets and for outgoing accounting requests.

Configuring a Router to Support Downloadable Filters

To configure your router to support downloadable filters, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa authorization template**
4. **aaa authorization network default group radius**
5. **radius-server attribute list** *list-name*
6. **attribute** *value1* [*value2* [*value3...*]]

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example: Router> enable</p>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example: Router# configure terminal</p>	<p>Enters global configuration mode.</p>
Step 3	<p>aaa authorization template</p> <p>Example: Router (config)# aaa authorization template</p>	<p>Enables usage of a local or remote customer template on the basis of Virtual Private Network (VPN) routing and forwarding (VRF).</p>

	Command or Action	Purpose
Step 4	aaa authorization network default group radius Example: Router (config)# aaa authorization network default group radius	Sets parameters that restrict user access to a network.
Step 5	radius-server attribute list list-name Example: Router (config)# radius-server attribute list attlist	Defines an accept or reject list name.
Step 6	attribute value1 [value2 [value3...]] Example: Router (config)# attribute 10-14, 24	Adds attributes to an accept or reject list.

Troubleshooting Tips

If attribute filtering is not working, ensure that the attribute list is properly defined.

Monitoring and Maintaining Attribute Filtering for Access Requests

To monitor and maintain attribute filtering, you can use the **debug radius** command.

SUMMARY STEPS

1. **enable**
2. **debug radius**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	debug radius Example: Router# debug radius	Displays information associated with RADIUS, including filtering information.

Configuration Examples for Attribute Filtering for Access Requests

This section provides the following configuration examples:

- [Attribute Filtering for Access Requests: Example, page 6](#)
- [Attribute Filtering User Profile: Example, page 6](#)
- [debug radius Command: Example, page 7](#)

Attribute Filtering for Access Requests: Example

The following example shows that the attributes 30-31 that are defined in “all-attr” will be rejected in all outbound Access Request messages:

```
aaa group server radius ras
 server 172.19.192.238 auth-port 1745 acct-port 1746
 authorization request reject all-attr
!
.
.
.
radius-server attribute list all-attr
 attribute 30-31
!
.
.
.
```

Attribute Filtering User Profile: Example

The following is a sample user profile after attribute filtering has been configured for Access Requests:

```
cisco.com Password = "cisco"
Service-Type = Framed,
Framed-Protocol = PPP,
Cisco:Cisco-Avpair = :1:"rad-serv=172.19.192.87 key rad123",
Cisco:Cisco-Avpair = :1:"rad-serv-filter=authorization request reject range1",
Cisco:Cisco-Avpair = :1:"rad-serv-filter=accounting request reject range1",
Cisco:Cisco-Avpair = "ppp-authen-type=chap"
Cisco:Cisco-Avpair = "ppp-authen-list=group 1",
Cisco:Cisco-Avpair = "ppp-author-list=group 1",
Cisco:Cisco-Avpair = "ppp-acct-list=start-stop group 1",
Cisco:Cisco-Avpair = "vpdn:tunnel-id=B53",
Cisco:Cisco-Avpair = "vpdn:tunnel-type=l2tp",
Cisco:Cisco-Avpair = "vpdn:ip-addresses=10.0.58.35",
Cisco:Cisco-Avpair = "vpdn:l2tp-tunnel-password=cisco"

user2@cisco.com
Service-Type = Outbound,
Cisco:Cisco-Avpair = "vpdn:tunnel-id=B53",
Cisco:Cisco-Avpair = "vpdn:tunnel-type=l2tp",
Cisco:Cisco-Avpair = "vpdn:ip-addresses=10.0.58.35",
Cisco:Cisco-Avpair = "vpdn:l2tp-tunnel-password=cisco"
```

When a session for user2@cisco.com “comes up” at the Layer 2 Tunneling Protocol (L2TP) Network Server (LNS)—as is shown above—because the **aaa authorization template** command has been configured, a RADIUS request is sent to the server for Cisco.com. The server then sends an Access Accept message if authentication is successful, along with the VSAs that are configured as part of the Cisco.com profile. If filters are configured as part of the Cisco.com profile, these filters will be parsed and applied to the RADIUS requests for user2@cisco.com.

In the above profile example, filter range1 has been applied to the authorization and accounting requests.

debug radius Command: Example

If the attribute you are trying to filter is rejected, you will see an **debug radius** output statement similar to the following:

```
RADIUS: attribute 31 rejected
```

If you try to filter an attribute that cannot be filtered, you will see an output statement similar to the following:

```
RADIUS: attribute 1 cannot be rejected
```

Enable Multilink PPP via RADIUS for Preauthentication User

Feature History

Release	Modification
12.2(11)T	This feature was introduced.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

This feature module describes the Enable Multilink PPP via RADIUS for Preauthentication User feature in Cisco IOS Release 12.2(11)T. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 3](#)
- [Supported Standards, MIBs, and RFCs, page 4](#)
- [Prerequisites, page 4](#)
- [Configuration Tasks, page 4](#)
- [Configuration Examples, page 5](#)
- [Command Reference, page 6](#)
- [Glossary, page 7](#)

Feature Overview

The Enable Multilink PPP via RADIUS for Preauthentication User feature allows you to selectively enable and disable Multilink PPP (MLP) negotiation for different users via RADIUS vendor-specific attribute (VSA) preauth:ppp-multilink=1.

Americas Headquarters:

Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

You can enable MLP by configuring the **ppp multilink** command on an interface, but then this command enables MLP negotiation for all connections and users on that interface; that is, you cannot selectively enable or disable MLP negotiation for specific connections and users on an interface.

**Note**

To enable this feature, the **ppp multilink** command should not be configured on the interface; this command will disable MLP by default. If the **ppp multilink** command is already configured on the interface, the attribute “preauth:ppp-multilink=1” will not override this command.

How MLP via RADIUS Works

Because MLP parameters are negotiated at the time of link control protocol (LCP) negotiation, RADIUS VSA `preauth:ppp-multilink=1` should only be a part of preauthentication user authorization. You should add this VSA to the preauthentication profile of the user to enable MLP. Thus, MLP will be enabled only for preauthentication users whose profiles contain this VSA; MLP will be disabled for all other users. If the MLP VSA is received during PPP user authorization (as opposed to preauthentication user authorization), it will be too late to negotiate MLP, and MLP will not be enabled.

When this VSA is received during preauthentication user authorization, MLP negotiation for the user is enabled. MLP is enabled when the VSA value is 1. All attribute values other than 1 are ignored.

Roles of the L2TP Access Server and L2TP Network Server

With this feature, you do not need to configure MLP on the interface of the L2TP access server (LAC); during preauthentication user authorization, the LAC will selectively choose to enable MLP for preauthentication users who receive `preauth:ppp-multilink=1`. On the L2TP network server (LNS), you can control the maximum number of links allowed in the multilink bundle by sending RADIUS VSA `multilink:max-links=n` during PPP user authorization.

New Vendor-Specific Attributes

This feature introduces the following new VSAs:

- Cisco-AVpair = `preauth:ppp-multilink=1`
Turns on MLP on the interface and is applied to the preauthentication profile.
- Cisco-AVpair = `multilink:max-links=n`
Restricts the maximum number of links that a user can have in a multilink bundle and is used with the `service=ppp` attribute. The range of “n” is from 1 to 255.
- Cisco-AVpair = `multilink:min-links=1`
Sets the minimum number of links for MLP. The range of “n” is from 0 to 255.
- Cisco-AVpair = `multilink:load-threshold=n`
Sets the load threshold for the caller for which additional links are added or deleted from the multilink bundle. If the load exceeds the specified value, links are added; if the load drops below the specified value, links are deleted. This attribute is used with the `service=ppp` attribute. The range of “n” is from 1 to 255.

**Note**

RADIUS VSAs multilink:max-links, multilink:min-links, and multilink:load-threshold serve the same purpose as TACACS+ per-user attributes, max-links, min-links, and load-threshold respectively.

Benefits

Selective Multilink PPP Configuration

MLP negotiation can be selectively enabled and disabled for different users by applying RADIUS VSA preauth:ppp-multilink=1 to the preauthentication profile.

Supported Platforms

- Cisco AS5300 series
- Cisco AS5350 series
- Cisco AS5400 series
- Cisco AS5800 series
- Cisco AS5850 series

Determining Platform Support Through Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Feature Navigator. Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image.

To access Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at <http://www.cisco.com/register>.

Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

Supported Standards, MIBs, and RFCs

Standards

None

MIBs

None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

RFCs

No new or modified RFCs are supported by this feature.

Prerequisites

Before enabling MLP via RADIUS VSA preauth:ppp-multilink=1, you should perform the following tasks:

- Enable the network access server (NAS) to recognize and use VSAs as defined by RADIUS IETF attribute 26 by using the **radius-server vsa send** command.

For more information about using VSAs, refer to the section “Configuring Router to Use Vendor-Specific RADIUS Attributes” of the chapter “Configuring RADIUS” in the *Cisco IOS Security Configuration Guide*, Release 12.2.

- Enable preauthentication.

For information about configuring preauthentication, refer to the section “Configuring AAA Preauthentication” of the chapter “Configuring RADIUS” in the *Cisco IOS Security Configuration Guide*, Release 12.2.

Configuration Tasks

None

Verifying MLP Negotiation via RADIUS in Preauthentication

To display bundle information for the MLP bundles, use the **show ppp multilink** EXEC command.

```
Router# show ppp multilink
```

```
Virtual-Access1, bundle name is mlpuser
Bundle up for 00:00:15
Dialer interface is Serial0:23
0 lost fragments, 0 reordered, 0 unassigned
0 discarded, 0 lost received, 1/255 load
0x0 received sequence, 0x0 sent sequence
Member links: 1 (max 7, min 1)
Serial0:22, since 00:00:15, no frags rcvd
```

Table 15 describes the significant fields shown when MLP is enabled.

Table 15 *show ppp multilink Field Descriptions*

Field	Description
Virtual-Access1	Multilink bundle virtual interface.
Bundle	Configured name of the multilink bundle.
Dialer Interface is Serial0:23	Name of the interface that dials the calls.
1/255 load	Load on the link in the range 1/255 to 255/255. (255/255 is a 100% load.)
Member links: 1	Number of child interfaces.

Configuration Examples

This section provides dialin VPDN configurations using Cisco VSA ppp-multilink examples:

- [LAC for MLP Configuration Example](#)
- [LAC RADIUS Profile for Preauthentication Example](#)
- [LNS for MLP Configuration Example](#)
- [LNS RADIUS Profile Example](#)

LAC for MLP Configuration Example

The following example is a sample configuration that can be used to configure a LAC for MLP via RADIUS:

```
! Enable preauthentication
aaa preauth
  group radius
  dnis required

!Enable VPDN
vpdn enable
!
vpdn-group 1
  request-dialin
  protocol l2tp
  dnis 56118
  initiate-to ip 10.0.1.22
  local name lac-router

! Don't need to configure multilink on the interface
! Multilink will be enabled by "ppp-multilink" attribute
interface Serial0:23
  ip address 15.0.1.7 255.0.0.0
  encapsulation ppp
  dialer-group 1
  isdn switch-type primary-5ess
  isdn calling-number 56118
  peer default ip address pool pool1
  no cdp enable
  ppp authentication chap
```

LAC RADIUS Profile for Preauthentication Example

The following example shows a LAC RADIUS profile for a preauthentication user who has applied the `preauth:ppp-multilink=1` VSA:

```
56118 Password = "cisco"
      Service-Type = Outbound,
      Framed-Protocol = PPP,
      Framed-MTU = 1500,
      Cisco-Avpair = "preauth:auth-required=1",
      Cisco-Avpair = "preauth:auth-type=chap",
      Cisco-Avpair = "preauth:username=dnis:56118",
      Cisco-Avpair = "preauth:ppp-multilink=1"
```

LNS for MLP Configuration Example

The following example is a sample configuration that can be used to configure a LNS to limit the number of links in a MLP bundle:

```
! Enable VPDN
vpdn enable
!
vpdn-group 1
 accept-dialin
 protocol any
 virtual-template 1
 terminate-from hostname lac-router
 local name lns-router
!
! Configure multilink on interface
interface Virtual-Template 1
 ip unnumbered Ethernet 0/0
 ppp authentication chap
 ppp multilink
```

LNS RADIUS Profile Example

The following example shows a LNS RADIUS profile for specifying the maximum number of links in a multilink bundle. The following multilink VSAs should be specified during PPP user authorization.

```
mascot password = "cisco"
      Service-Type = Framed,
      Framed-Protocol = PPP,
      Cisco-Avpair = "multilink:max-links=7"
      Cisco-Avpair = "multilink:min-links=1"
      Cisco-Avpair = "multilink:load-threshold=128"
```

Command Reference

This feature uses no new or modified commands. For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

Glossary

AAA—authentication, authorization, and accounting. Suite of network security services that provide the primary framework through which access control can be set up on your Cisco router or access server.

attribute—RADIUS Internet Engineering Task Force (IETF) attributes are the original set of 255 standard attributes that are used to communicate AAA information between a client and a server. Because IETF attributes are standard, the attribute data is predefined and well known; thus all clients and servers that exchange AAA information via IETF attributes must agree on attribute data such as the exact meaning of the attributes and the general bounds of the values for each attribute.

L2F—Layer 2 Forwarding. Protocol that supports the creation of secure virtual private dial-up networks over the Internet.

L2TP—Layer 2 Tunnel Protocol. A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

LAC—L2TP access concentrator. A network access server (NAS) to which the client directly connects and through which PPP frames are tunneled to the L2TP network server (LNS). The LAC need only implement the media over which L2TP is to operate to pass traffic to one or more LNSs. The LAC may tunnel any protocol carried within PPP. The LAC initiates incoming calls and receives outgoing calls. A LAC is analogous to an L2F network access server.

LNS—L2TP network server. A termination point for L2TP tunnels, and an access point where PPP frames are processed and passed to higher-layer protocols. An LNS can operate on any platform that terminates PPP. The LNS handles the server side of the L2TP protocol. L2TP relies only on the single medium over which L2TP tunnels arrive. The LNS initiates outgoing calls and receives incoming calls. An LNS is analogous to a home gateway in L2F technology.

MLP—Multilink PPP. MLP allows packets to be fragmented and the fragments to be sent at the same time over multiple point-to-point links to the same remote address. The multiple links come up in response to a defined dialer load threshold. The load can be calculated on inbound traffic, outbound traffic, or on either, as needed for the traffic between the specific sites. MLP provides bandwidth on demand and reduces transmission latency across WAN links.

MLP is designed to work over synchronous and asynchronous serial and BRI and PRI types of single or multiple interfaces that have been configured to support both dial-on-demand rotary groups and PPP encapsulation.

RADIUS—Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

VSA—Vendor-Specific Attribute. VSAs derived from one IETF attribute—vendor-specific (attribute 26). Attribute 26 allows a vendor to create and implement an additional 255 attributes. That is, a vendor can create an attribute that does not match the data of any IETF attribute and encapsulate it behind attribute 26: essentially, Vendor-Specific = “protocol:attribute=value.”

Enhanced Test Command

First Published: August 9, 2001

Last Updated: December 17, 2007

The Enhanced Test Command feature allows a named user profile to be created with calling line ID (CLID) or dialed number identification service (DNIS) attribute values. The CLID or DNIS attribute values can be associated with the RADIUS record that is sent with the user profile so that the RADIUS server can access CLID or DNIS attribute information for all incoming calls.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Enhanced Test Command”](#) section on page 6.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for the Enhanced Test Command

The **test aaa group** command does not work with TACACS+.

How to Configure the Enhanced Test Command

The following sections describe how to configure the Enhanced Test Command feature:

- [Configuring a User Profile and Associating it with the RADIUS Record](#)
- [Verifying the Enhanced Test Command Configuration](#)

Configuring a User Profile and Associating it with the RADIUS Record

This section describes how to create a named user profile with CLID or DNIS attribute values and associate it with the RADIUS record.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa user profile** *profile-name*
4. **aaa attribute** {dnis | clid} *attribute-value*
5. **exit**
6. **test aaa group** {group-name | radius} *username password new-code* [profile *profile-name*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa user profile <i>profile-name</i> Example: Router(config)# aaa user profile profilename1	Creates a user profile.
Step 4	aaa attribute {dnis clid} Example: Router# configure terminal	Adds DNIS or CLID attribute values to the user profile and enters AAA-user configuration mode.

	Command or Action	Purpose
Step 5	exit	Exit Global Configuration mode.
Step 6	Router# test aaa group {group-name radius } username password new-code [profile profile-name] Example: Router# test aaa group radius secret new-code profile profilename1	Associates a DNIS or CLID named user profile with the record sent to the RADIUS server. Note The <i>profile-name</i> must match the <i>profile-name</i> specified in the aaa user profile command.

Verifying the Enhanced Test Command Configuration

To verify the Enhanced Test Command configuration, use the following commands in privileged EXEC mode:

Command	Purpose
Router# debug radius	Displays information associated with RADIUS.
Router# more system:running-config	Displays the contents of the current running configuration file. (Note that the more system:running-config command has replaced the show running-config command.)

Configuration Example for Enhanced Test Command

This section provides the following configuration example:

- [User Profile Associated With a test aaa group command Example](#)

User Profile Associated With a test aaa group command Example

The following example shows how to configure the dnis = dnisvalue user profile “prfl1” and associate it with a **test aaa group** command. In this example, the **debug radius** command has been enabled and the output follows the configuration.

```

aaa user profile prfl1
  aaa attribute dnis
  aaa attribute dnis dnisvalue
  no aaa attribute clid
! Attribute not found.
  aaa attribute clid clidvalue
  no aaa attribute clid
exit
!
! Associate the dnis user profile with the test aaa group command.
test aaa group radius user1 pass new-code profile prfl1
!
!
! debug radius output, which shows that the dnis value has been passed to the radius
! server.
```

```

Framed-Route in RADIUS Accounting

First Published: November 3, 2003

Last Updated: December 17, 2007

The Framed-Route in RADIUS Accounting feature provides for the presence of Framed-Route (RADIUS attribute 22) information in RADIUS Accounting-Request accounting records. The Framed-Route information is returned to the RADIUS server in the Accounting-Request packets. The Framed-Route information can be used to verify that a per-user route or routes have been applied for a particular static IP customer on the network access server (NAS).

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Framed-Route in RADIUS Accounting](#)” section on [page 7](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Framed-Route in RADIUS Accounting

Be familiar with configuring authentication, authorization, and accounting (AAA), RADIUS servers, and RADIUS attribute screening.

Information About Framed-Route in RADIUS Accounting

This section includes the following concepts:

- [Framed-Route, Attribute 22, page 2](#)
- [Framed-Route in RADIUS Accounting Packets, page 2](#)

Framed-Route, Attribute 22

Framed-Route, attribute 22 as defined in Internet Engineering Task Force (IETF) standard RFC 2865, provides for routing information to be configured for the user on the NAS. The Framed-Route attribute information is usually sent from the RADIUS server to the NAS in Access-Accept packets. The attribute can appear multiple times.

Framed-Route in RADIUS Accounting Packets

The Framed-Route attribute information in RADIUS accounting packets shows per-user routes that have been applied for a particular static IP customer on the NAS. The Framed-Route attribute information is currently sent in Access-Accept packets. Effective with Cisco IOS Release 12.3(4)T, the Framed-Route attribute information is also sent in Accounting-Request packets if it was provided in the Access-Accept packets and was applied successfully. Zero or more instances of the Framed-Route attribute may be present in the Accounting-Request packets.

**Note**

If there is more than one Framed-Route attribute in an Access-Accept packet, there can also be more than one Framed-Route attribute in the Accounting-Request packet.

The Framed-Route information is returned in Stop and Interim accounting records and in Start accounting records when accounting Delay-Start is configured.

No configuration is required to have the Frame-Route attribute information returned in the RADIUS accounting packets.

How to Monitor Framed-Route in RADIUS Accounting

Use the **debug radius** command to monitor whether Framed-Route (attribute 22) information is being sent in RADIUS Accounting-Request packets.

Examples

This section provides the following example:

- [debug radius Command Output: Example, page 3](#)

debug radius Command Output: Example

In the following example, the **debug radius** command is used to verify that Framed-Route (attribute 22) information is being sent in the Accounting-Request packets (see the line 00:06:23: RADIUS: Framed-Route [22] 26 "10.80.0.1 255.255.255.255 10.60.0.1 100").

Router# **debug radius**

```
00:06:23: RADIUS: Send to unknown id 0 10.1.0.2:1645, Access-Request, len 126

Feature Overview

The Offload Server Accounting Enhancement feature allows users to configure their network access servers (NAS) to synchronize authentication and accounting information—NAS-IP-Address (attribute 4) and Class (attribute 25)—with the offload server.

An offload server interacts with a NAS via Virtual Private Network (VPN) to perform required Point-to-Point Protocol (PPP) negotiation for calls. The NAS performs call preauthentication, whereas the offload server performs user authentication. This feature allows the authentication and accounting data of the NAS to synchronize with the offload server as follows:

- During preauthentication, the NAS generates a unique session-id, adding the Acct-Session-Id (attribute 44) before the existing session-id (NAS-IP-Address), and retrieves a Class attribute. The new session-id is sent in preauthentication requests and resource accounting requests; the Class attribute is sent in resource accounting requests.

**Note**

Unique session-ids are needed when multiple NASs are being processed by one offload server.

- The NAS-IP-Address, the Acct-Session-Id, and the Class attribute are transmitted to the offload server via Layer 2 Forwarding (L2F) options.
- The offload server will include the new, unique session-id in user access requests and user session accounting requests. The Class attribute that was passed from the NAS will be included in the user access request, but a new Class attribute will be received in the user access reply; this new Class attribute should be included in user session accounting requests.

Benefits

The Offload Server Accounting Enhancement feature allows users to maintain authentication and accounting information between their NAS and offload server.

Although NASs can already synchronize information with an offload server, this feature extends the functionality to include a unique session-id, adding the Acct-Session-Id (attribute 44) before the existing session-id (NAS-IP-Address), and Class (attribute 25) information collected by the NASs.

Prerequisites

Before configuring the Offload Server Accounting Enhancement feature, you must perform the following tasks:

- Enable AAA. (For more information, refer to chapter “Configuring Authentication” of the *Cisco IOS Security Configuration Guide*)
- Enable VPN. (For more information, refer to the chapter “Configuring Virtual Private Networks” of the *Cisco IOS Dial Technologies Configuration Guide*)

Configuration Tasks

See the following sections for configuration tasks for the Offload Server Accounting Enhancement feature. Each task in the list is identified as either required or optional.

- [Configuring Unique Session IDs, page 3](#)(required)
- [Configuring Offload Server to Synchronize with NAS Clients, page 3](#)(required)
- [Verifying Offload Server Accounting, page 4](#)(optional)

Configuring Unique Session IDs

To maintain unique session IDs among NASs, use the following global configuration command. When multiple NASs are being processed by one offload server, this feature must be enabled by all NASs and by the offload server to ensure a common and unique session-id.

Command	Purpose
Router(config)# radius-server attribute 44 extend-with-addr	Adds the accounting IP address in front of the existing AAA session ID. Note The unique session-id is different from other NAS session-ids because it adds the Acct-Session-Id (attribute 44) before the existing session-id (NAS-IP-Address).

Configuring Offload Server to Synchronize with NAS Clients

To configure the offload server to synchronize accounting session information with the NAS clients, use the following global configuration command:

Command	Purpose
Router(config)# radius-server attribute 44 sync-with-client	Configures the offload server to synchronize accounting session information with the NAS clients.

Verifying Offload Server Accounting

To verify whether the NAS has synchronized authentication and accounting data with the offload server, use the following commands in privileged EXEC mode:

Command	Purpose
Router# more system:running-config	Displays the contents of the current running configuration file. (Note that the more system:running-config command has replaced the show running-config command.)
Router(config)# debug radius	Displays information associated with RADIUS. The output of this command shows whether attribute 44 is being sent in access requests. The output, however, does not show the entire value for attribute 44. To view the entire value for attribute 44, refer to your RADIUS server log.

Configuration Examples

This section provides the following configuration examples:

- [Unique Session ID Configuration Example, page 4](#)
- [Offload Server Synchronization with NAS Clients Example, page 4](#)

Unique Session ID Configuration Example

The following example shows how to configure unique session IDs among NASs:

```
aaa new-model
aaa authentication ppp default group radius
radius-server host 10.100.1.34
radius-server attribute 44 include-in-access-req
radius-server attribute 44 extend-with-addr
```

Offload Server Synchronization with NAS Clients Example

The following example shows how to configure the offload server to synchronize accounting session information with NAS clients:

```
radius-server attribute 44 sync-with-client
```

Additional References

The following sections provide references related to Offload Server Accounting Enhancement.

Glossary

AAA—authentication, authorization, and accounting. Suite of network security services that provide the primary framework through which access control can be set up on your Cisco router or access server.

Acct-Session-ID (attribute 44)—A unique accounting identifier that makes it easy to match start and stop records in a log file. Acct-Session ID numbers restart at 1 each time the router is power-cycled or the software is reloaded.

Class (attribute 25)—An accounting attribute. Arbitrary value that the network access server includes in all accounting packets for this user if the attribute is supplied by the RADIUS server.

L2F—Layer 2 Forwarding. A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

NAS—network access server. A Cisco platform (or collection of platforms, such as an AccessPath system) that interfaces between the packet world (for example, the Internet) and the circuit world (for example, the public switched telephone network).

NAS-IP Address (attribute 4)—Specifies the IP address of the network access server that is requesting authentication. The default value is 0.0.0.0/0.

PPP—Point-to-Point Protocol. Successor to SLIP that provides router-to-router and host-to-network connections over synchronous and asynchronous circuits. Whereas SLIP was designed to work with IP, PPP was designed to work with several network layer protocols, such as IP, IPX, and ARA. PPP also has built-in security mechanisms, such as CHAP and PAP. PPP relies on two protocols: LCP and NCP.

RADIUS—Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

VPN—A system that permits dial-in networks to exist remotely to home networks, while giving the appearance of being directly connected. VPNs use L2TP and L2F to terminate the Layer 2 and higher parts of the network connection at the LNS instead of the LAC.

**Note**

Per VRF AAA

First Published: June 4, 2001

Last Updated: January 15, 2008

The Per VRF AAA feature allows authentication, authorization, and accounting (AAA) on the basis of Virtual Private Network (VPN) routing and forwarding (VRF) instances. For Cisco IOS Release 12.2(15)T or later releases, you can use a customer template, which may be stored either locally or remotely, and AAA services can be performed on the information that is stored in the customer template. This feature has also been referred to as the Dynamic Per VRF AAA feature

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Per VRF AAA” section on page 30](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Per VRF AAA

Before configuring the Per VRF AAA feature, you must enable AAA. (For information on completing this task, refer to the AAA chapters of the “[Cisco IOS Security Configuration Guide](#)”, Release 12.4)

Restrictions for Per VRF AAA

- This feature is supported only for RADIUS servers.
- Operational parameters should be defined once per VRF rather than set per server group, because all functionalities must be consistent between the network access server (NAS) and the AAA servers.
- The ability to configure a customer template either locally or remotely is available only for Cisco IOS Release 12.2(15)T and later releases.

Information About Per VRF AAA

When you use the Per VRF AAA feature, AAA services can be based on VRF instances. This feature permits the Provider Edge (PE) or Virtual Home Gateway (VHG) to communicate directly with the customer’s RADIUS server, which is associated with the customer’s Virtual Private Network (VPN), without having to go through a RADIUS proxy. Thus, ISPs can scale their VPN offerings more efficiently because they no longer have to use RADIUS proxies and ISPs can also provide their customers with additional flexibility.

- [How Per VRF AAA Works, page 2](#)
- [Benefits, page 3](#)
- [AAA Accounting Records, page 3](#)
- [New Vendor-Specific Attributes, page 3](#)

How Per VRF AAA Works

To support AAA on a per customer basis, some AAA features must be made VRF aware. That is, ISPs must be able to define operational parameters—such as AAA server groups, method lists, system accounting, and protocol-specific parameters—and bind those parameters to a particular VRF instance. Defining and binding the operational parameters can be accomplished using one or more of the following methods:

- Virtual private dialup network (VPDN) virtual template or dialer interfaces that are configured for a specific customer
- Locally defined customer templates—Per VPN with customer definitions. The customer template is stored locally on the VHG. This method can be used to associate a remote user with a specific VPN based on the domain name or dialed number identification service (DNIS) and provide the VPN-specific configuration for virtual access interface and all operational parameters for the customer AAA server.

- Remotely defined customer templates—Per VPN with customer definitions that are stored on the service provider AAA server in a RADIUS profile. This method is used to associate a remote user with a specific VPN based on the domain name or DNIS and provide the VPN-specific configuration for the virtual access interface and all operational parameters for the AAA server of the customer.

**Note**

The ability to configure locally or remotely defined customer templates is available only with Cisco IOS Release 12.2(15)T and later releases.

Benefits

Configuration Support

ISPs can partition AAA services on a per VRF basis. Thus, ISPs can allow their customers to control some of their own AAA services.

Server Group List Extension

The list of servers in server groups is extended to include the definitions of private servers in addition to references to the hosts in the global configuration, allowing access to both customer servers and global service provider servers simultaneously.

AAA Accounting Records

The Cisco implementation of AAA accounting provides “start” and “stop” record support for calls that have passed user authentication. Start and stop records are necessary for users employing accounting records to manage and monitor their networks.

New Vendor-Specific Attributes

The Internet Engineering Task Force (IETF) draft standard specifies a method for communicating vendor-specific information between the network access server and the RADIUS server by using the vendor-specific attribute (VSA) attribute 26. Attribute 26 encapsulates VSAs, thereby, allowing vendors to support their own extended attributes otherwise not suitable for general use.

The Cisco RADIUS implementation supports one vendor-specific option using the format recommended in the specification. Cisco’s vendor-ID is 9, and the supported option has vendor-type 1, which is named “cisco-avpair.” The value is a string of the following format:

```
protocol : attribute sep value *
```

“Protocol” is a value of the Cisco “protocol” attribute for a particular type of authorization. “Attribute” and “value” are an appropriate attribute-value (AV) pair defined in the Cisco TACACS+ specification, and “sep” is “=” for mandatory attributes and “*” for optional attributes. This format allows the full set of features available for TACACS+ authorization to be used also for RADIUS.

[Table 1](#) summarizes the VSAs that are now supported with Per VRF AAA.

Table 1 VSAs supported with Per VRF AAA

VSA Name	Value Type	Description
Note Each VSA must have the prefix “template:” before the VSA name, unless a different prefix is explicitly stated.		
account-delay	string	This VSA must be “on.” The functionality of this VSA is equal to the aaa accounting delay-start command for the customer template.
account-send-stop	string	This VSA must be “on.” The functionality of this VSA is equal to the aaa accounting send stop-record authentication command with the failure keyword.
account-send-success-remote	string	This VSA must be “on.” The functionality of this VSA is equal to the aaa accounting send stop-record authentication command with the success keyword.
attr-44	string	This VSA must be “access-req.” The functionality of this VSA is equal to the radius-server attribute 44 include-in-access-req command.
ip-addr	string	This VSA specifies the IP address, followed by the mask that the router uses to indicate its own IP address and mask in negotiation with the client; for example, ip-addr=1.2.3.4 255.255.255.255
ip-unnumbered	string	This VSA specifies the name of an interface on the router. The functionality of this VSA is equal to the ip unnumbered command, which specifies an interface name such as “Loopback 0.”
ip-vrf	string	This VSA specifies which VRF will be used for the packets of the end user. This VRF name should match the name that is used on the router via the ip vrf forwarding command.
peer-ip-pool	string	This VSA specifies the name of an IP address pool from which an address will be allocated for the peer. This pool should be configured using the ip local pool command or should be automatically downloadable via RADIUS.
ppp-acct-list	string	<p>This VSA defines the accounting method list that is to be used for PPP sessions.</p> <p>The VSA syntax is as follows: “ppp-acct-list=[start-stop stop-only none] group X [group Y] [broadcast].” It is equal to the aaa accounting network mylist command functionality.</p> <p>The user must specify at least one of the following options: start-stop, stop-only, or none. If either start-stop or stop-only is specified, the user must specify at least one, but not more than four, group arguments. Each group name must consist of integers. The servers in the group should have already been identified in the access-accept via the VSA “rad-serv.” After each group has been specified, the user can specify the broadcast option</p>

VSA Name	Value Type	Description
ppp-authen-list	string	<p>This VSA defines which authentication method list is to be used for PPP sessions and, if more than one method is specified, in what order the methods should be used.</p> <p>The VSA syntax is as follows: “ppp-authen-list=[groupX local local-case none if-needed],” which is equal to the aaa authentication ppp mylist command functionality.</p> <p>The user must specify at least one, but no more than four, authentication methods. If a server group is specified, the group name must be an integer. The servers in the group should have already been identified in the access-accept via the VSA “rad-serv.”</p>
ppp-authen-type	string	<p>This VSA allows the end user to specify at least one of the following authentication types: pap, chap, eap, ms-chap, ms-chap-v2, any, or a combination of the available types that is separated by spaces.</p> <p>The end user will be permitted to log in using only the methods that are specified in this VSA.</p> <p>PPP will attempt these authentication methods in the order presented in the attribute.</p>
ppp-author-list	string	<p>This VSA defines the authorization method list that is to be used for PPP sessions. It indicates which methods will be used and in what order.</p> <p>The VSA syntax is as follows: “ppp-author-list=[groupX] [local] [if-authenticated] [none],” which is equal to the aaa authorization network mylist command functionality.</p> <p>The user must specify at least one, but no more than four, authorization methods. If a server group is specified, the group name must be an integer. The servers in the group should have already been identified in the access-accept via the VSA “rad-serv.”</p>
Note The RADIUS VSAs—rad-serv, rad-server-filter, rad-serv-source-if, and rad-serv-vrf—must have the prefix “aaa:” before the VSA name.		
rad-serv	string	<p>This VSA indicates the IP address, key, timeout, and retransmit number of a server, as well as the group of the server.</p> <p>The VSA syntax is as follows: “rad-serv=a.b.c.d [key SomeKey] [auth-port X] [acct-port Y] [retransmit V] [timeout W].” Other than the IP address, all parameters are optional and can be issued in any order. If the optional parameters are not specified, their default values will be used.</p> <p>The key cannot contain any spaces; for “retransmit V,” “V” can range from 1-100; for “timeout W,” the “W” can range from 1-1000.</p>

VSA Name	Value Type	Description
rad-serv-filter	string	The VSA syntax is as follows: “rad-serv-filter=authorization accounting-request reply-accept reject-filtername.” The filtername must be defined via the radius-server attribute list filtername command.
rad-serv-source-if	string	This VSA specifies the name of the interface that is used for transmitting RADIUS packets. The specified interface must match the interface configured on the router.
rad-serv-vrf	string	This VSA specifies the name of the VRF that is used for transmitting RADIUS packets. The VRF name should match the name that was specified via the ip vrf forwarding command.

How to Configure Per VRF AAA

The following sections contain procedures for possible deployment scenarios for using the Per VRF AAA feature.

- [Configuring Per VRF AAA, page 7](#) (required)
- [Configuring Per VRF AAA Using Local Customer Templates, page 12](#) (optional)
- [Configuring Per VRF AAA Using Remote Customer Templates, page 15](#) (optional)
- [Verifying VRF Routing Configurations, page 17](#) (optional)
- [Troubleshooting Per VRF AAA Configurations, page 18](#) (optional)

Configuring Per VRF AAA

This section contains the following procedures.

- [Configuring AAA, page 7](#)
- [Configuring Server Groups, page 7](#)
- [Configuring Authentication, Authorization, and Accounting for Per VRF AAA, page 8](#)
- [Configuring RADIUS-Specific Commands for Per VRF AAA, page 10](#)
- [Configuring Interface-Specific Commands for Per VRF AAA, page 11](#)

Configuring AAA

To enable AAA you need to complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Router(config)# aaa new-model	Enables AAA globally.

Configuring Server Groups

To configure server groups you need to complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa group server radius *groupname***

5. **server-private** *ip-address* [**auth-port** *port-number* | **acct-port** *port-number*] [**non-standard**] [**timeout** *seconds*] [**retransmit** *retries*] [**key** *string*]
6. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Router(config)# aaa new-model	Enables AAA globally.
Step 4	aaa group server radius <i>groupname</i> Example: Router(config)# aaa group server radius v2.44.com	Groups different RADIUS server hosts into distinct lists and distinct methods. Enters server-group configuration mode.
Step 5	server-private <i>ip-address</i> [auth-port <i>port-number</i> acct-port <i>port-number</i>] [non-standard] [timeout <i>seconds</i>] [retransmit <i>retries</i>] [key <i>string</i>] Example: Router(config-sg-radius)# server-private 10.10.130.2 auth-port 1600 key ww	Configures the IP address of the private RADIUS server for the group server. Note If private server parameters are not specified, global configurations will be used. If global configurations are not specified, default values will be used.
Step 6	exit Example: Router(config-sg-radius)# exit	Exits from server-group configuration mode; returns to global configuration mode.

Configuring Authentication, Authorization, and Accounting for Per VRF AAA

To configure authentication, authorization, and accounting for Per VRF AAA, you need to complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**

4. **aaa authentication ppp** {default | list-name} method1 [method2...]
5. **aaa authorization** {network | exec | commands level | reverse-access | configuration} {default | list-name} method1 [method2...]
6. **aaa accounting system default** [vrf vrf-name] {start-stop | stop-only | none} [broadcast] group groupname
7. **aaa accounting delay-start** [vrf vrf-name]
8. **aaa accounting send stop-record authentication** {failure | success {remote-server}} [vrf vrf-name]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Router(config)# aaa new-model	Enables AAA globally.
Step 4	aaa authentication ppp {default list-name} method1 [method2...] Example: Router(config)# aaa authentication ppp method_list_v2.44.com group v2.44.com	Specifies one or more AAA authentication methods for use on serial interfaces that are running PPP.
Step 5	aaa authorization {network exec commands level reverse-access configuration} {default list-name} method1 [method2...] Example: Router(config)# aaa authorization network method_list_v2.44.com group v2.44.com	Sets parameters that restrict user access to a network.
Step 6	aaa accounting system default [vrf vrf-name] {start-stop stop-only none} [broadcast] group groupname Example: Router(config)# aaa accounting system default vrf v2.44.com start-stop group v2.44.com	Enables AAA accounting of requested services for billing or security purposes when you use RADIUS.

	Command or Action	Purpose
Step 7	aaa accounting delay-start [vrf <i>vrf-name</i>] Example: Router(config)# aaa accounting delay-start vrf v2.44.com	Displays generation of the start accounting records until the user IP address is established.
Step 8	aaa accounting send stop-record authentication { failure success { remote-server }} [vrf <i>vrf-name</i>] Example: Router(config)# aaa accounting send stop-record authentication failure vrf v2.44.com	Generates accounting stop records. When using the failure keyword a “stop” record will be sent for calls that are rejected during authentication. When using the success keyword a “stop” record will be sent for calls that meet one of the following criteria: <ul style="list-style-type: none"> • Calls that are authenticated by a remote AAA server when the call is terminated. • Calls that are not authenticated by a remote AAA server and the start record has been sent. • Calls that are successfully established and then terminated with the “stop-only” aaa accounting configuration. Note The success and remote-server keywords are available in Cisco IOS Release 12.4(2)T and later releases.

Configuring RADIUS-Specific Commands for Per VRF AAA

To configure RADIUS-specific commands for Per VRF AAA you need to complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip radius source-interface** *subinterface-name* [**vrf** *vrf-name*]
4. **radius-server attribute 44 include-in-access-req** [**vrf** *vrf-name*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	ip radius source-interface <i>subinterface-name</i> [vrf vrf-name] Example: Router(config)# ip radius source-interface loopback55	Forces RADIUS to use the IP address of a specified interface for all outgoing RADIUS packets and enables the specification on a per-VRF basis.
Step 4	radius-server attribute 44 include-in-access-req [vrf vrf-name] Example: Router(config)# radius-server attribute 44 include-in-access-req vrf v2.44.com	Sends RADIUS attribute 44 in access request packets before user authentication and enables the specification on a per-VRF basis.

Configuring Interface-Specific Commands for Per VRF AAA

To configure interface-specific commands for Per VRF AAA, you need to complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number* [*name-tag*]
4. **ip vrf forwarding** *vrf-name*
5. **ppp authentication** {*protocol1* [*protocol2...*]} *listname*
6. **ppp authorization** *list-name*
7. **ppp accounting default**
8. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> [<i>name-tag</i>] Example: Router(config)# interface loopback11	Configures an interface type and enters interface configuration mode.

	Command or Action	Purpose
Step 4	ip vrf forwarding <i>vrf-name</i> Example: Router(config-if)# ip vrf forwarding v2.44.com	Associates a VRF with an interface.
Step 5	ppp authentication { <i>protocol1</i> [<i>protocol2...</i>]} <i>listname</i> Example: Router(config-if)# ppp authentication chap callin V2_44_com	Enables Challenge Handshake Authentication Protocol (CHAP) or Password Authentication Protocol (PAP) or both and specifies the order in which CHAP and PAP authentication are selected on the interface.
Step 6	ppp authorization <i>list-name</i> Example: Router(config-if)# ppp authorization V2_44_com	Enables AAA authorization on the selected interface.
Step 7	ppp accounting default Example: Router(config-if)# ppp accounting default	Enables AAA accounting services on the selected interface.
Step 8	exit Example: Router(config)# exit	Exits interface configuration mode.

Configuring Per VRF AAA Using Local Customer Templates

This section contains the following procedures:

- [Configuring AAA, page 12](#)
- [Configuring Server Groups, page 12](#)
- [Configuring Authentication, Authorization, and Accounting for Per VRF AAA, page 12](#)
- [Configuring Authorization for Per VRF AAA with Local Customer Templates, page 13](#)
- [Configuring Local Customer Templates, page 13](#)

Configuring AAA

Perform the tasks as outlined in the “[Configuring Per VRF AAA](#)” section on page 7.

Configuring Server Groups

Perform the tasks as outlined in the “[Configuring Server Groups](#)” section on page 7.

Configuring Authentication, Authorization, and Accounting for Per VRF AAA

Perform the tasks as outlined in the “[Configuring Authentication, Authorization, and Accounting for Per VRF AAA](#)” section on page 8.

Configuring Authorization for Per VRF AAA with Local Customer Templates

To configure authorization for Per VRF AAA with local templates, you need to complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa authorization template**
4. **aaa authorization network default local**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa authorization template Example: Router(config)# aaa authorization template	Enables the use of local or remote templates.
Step 4	aaa authorization network default local Example: Router(config)# aaa authorization network default local	Specifies local as the default method for authorization.

Configuring Local Customer Templates

To configure local customer templates, you need to complete the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **vpdn search-order domain**
4. **template name** [default | exit | multilink | no | peer | ppp]
5. **peer default ip address pool** pool-name
6. **ppp authentication** {protocol1 [protocol2...]} [if-needed] [list-name | default] [callin] [one-time]

7. **ppp authorization** [**default** | *list-name*]
8. **aaa accounting** {**auth-proxy** | **system** | **network** | **exec** | **connection** | **commands** *level*} {**default** | *list-name*} [**vrf** *vrf-name*] {**start-stop** | **stop-only** | **none**} [**broadcast**] **group** *groupname*
9. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	vpdn search-order domain Example: Router (config)# vpdn search-order domain	Looks up the profiles based on domain.
Step 4	template <i>name</i> [default exit multilink no peer ppp] Example: Router (config)# template v2.44.com	Creates a customer profile template and assigns a unique name that relates to the customer that will be receiving it. Enters template configuration mode.  Note Steps 5, 6, and 7 are optional. Enter multilink , peer , and ppp keywords appropriate to customer application requirements.
Step 5	peer default ip address pool <i>pool-name</i> Example: Router(config-template)# peer default ip address pool v2_44_com_pool	(Optional) Specifies that the customer profile to which this template is attached will use a local IP address pool with the specified name.
Step 6	ppp authentication { <i>protocol1</i> [<i>protocol2</i> ...]} [if-needed] [<i>list-name</i> default] [callin] [one-time] Example: Router(config-template)# ppp authentication chap	(Optional) Sets the PPP link authentication method.
Step 7	ppp authorization [default <i>list-name</i>] Example: Router(config-template)# ppp authorization v2_44_com	(Optional) Sets the PPP link authorization method.

	Command or Action	Purpose
Step 8	aaa accounting { <i>auth-proxy</i> <i>system</i> <i>network</i> <i>exec</i> <i>connection</i> <i>commands level</i> } { <i>default</i> <i>list-name</i> } [<i>vrf vrf-name</i>] { <i>start-stop</i> <i>stop-only</i> <i>none</i> } [<i>broadcast</i>] <i>group groupname</i> Example: Router(config-template)# aaa accounting v2_44_com	(Optional) Enables AAA operational parameters for the specified customer profile.
Step 9	exit Example: Router(config-template)# exit	Exits from template configuration mode; returns to global configuration mode.

Configuring Per VRF AAA Using Remote Customer Templates

This section contains the following procedures:

- [Configuring AAA, page 15](#)
- [Configuring Server Groups, page 15](#)
- [Configuring Authentication for Per VRF AAA with Remote Customer Profiles, page 15](#)
- [Configuring Authorization for Per VRF AAA with Remote Customer Profiles, page 16](#)
- [Configuring the RADIUS Profile on the SP RADIUS Server, page 17](#)

Configuring AAA

Perform the tasks as outlined in the “[Configuring Per VRF AAA](#)” section on page 7.

Configuring Server Groups

Perform the tasks as outlined in the “[Configuring Server Groups](#)” section on page 12.

Configuring Authentication for Per VRF AAA with Remote Customer Profiles

To configure authentication for Per VRF AAA with remote customer profiles, you need to perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa authentication ppp** {*default* | *list-name*} *method1* [*method2...*]
4. **aaa authorization** {*network* | *exec* | *commands level* | *reverse-access* | *configuration*} {*default* | *list-name*} [[*method1* [*method2...*]]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa authentication ppp { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>] Example: Router(config)# ppp authentication ppp default group radius	Specifies one or more authentication, authorization, and accounting (AAA) authentication methods for use on serial interfaces that are running PPP.
Step 4	aaa authorization { network exec commands <i>level</i> reverse-access configuration } { default <i>list-name</i> } [[<i>method1</i> [<i>method2...</i>]] Example: Router(config)# aaa authorization network default group sp	Sets parameters that restrict user access to a network.

Configuring Authorization for Per VRF AAA with Remote Customer Profiles

To configuring authorization for Per VRF AAA with remote customer profiles, you need to perform the following step.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa authorization template**
4. **aaa authorization** {**network** | **exec** | **commands** *level* | **reverse-access** | **configuration**} {**default** | *list-name*} [[*method1* [*method2...*]]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa authorization template Example: Router(config)# aaa authorization template	Enables use of local or remote templates.
Step 4	aaa authorization {network exec commands level reverse-access configuration} {default list-name} [[method1 [method2...]] Example: Router(config)# aaa authorization network default sp	Specifies the server group that is named as the default method for authorization.

Configuring the RADIUS Profile on the SP RADIUS Server

Configure the RADIUS profile on the SP RADIUS server. See the “[Per VRF AAA Using a Remote RADIUS Customer Template: Example](#)” for an example of how to update the RADIUS profile.

Verifying VRF Routing Configurations

To verify VRF routing configurations, you need to complete the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **show ip route vrf *vrf-name***

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	show ip route vrf vrf-name Example: Router(config)# show ip route vrf northvrf	Displays the IP routing table associated with a VRF.

Troubleshooting Per VRF AAA Configurations

To troubleshoot the Per VRF AAA feature, use at least one of the following commands in EXEC mode:

Command	Purpose
Router# debug aaa accounting	Displays information on accountable events as they occur.
Router# debug aaa authentication	Displays information on AAA authentication.
Router# debug aaa authorization	Displays information on AAA authorization.
Router# debug ppp negotiation	Displays information on traffic and exchanges in an internetwork implementing PPP.
Router# debug radius	Displays information associated with RADIUS.
Router# debug vpdn event	Displays Layer 2 Transport Protocol (L2TP) errors and events that are a part of normal tunnel establishment or shutdown for VPNs.
Router# debug vpdn error	Displays debug traces for VPN.

Configuration Examples for Per VRF AAA

This section provides the following configuration examples:

- [Per VRF Configuration: Examples, page 19](#)
- [Customer Template: Examples, page 20](#)
- [AAA Accounting Stop Records: Examples, page 22](#)

Per VRF Configuration: Examples

This section provides the following configuration examples:

- [Per VRF AAA: Example, page 19](#)
- [Per VRF AAA Using a Locally Defined Customer Template: Example, page 19](#)
- [Per VRF AAA Using a Remote RADIUS Customer Template: Example, page 20](#)

Per VRF AAA: Example

The following example shows how to configure the Per VRF AAA feature using a AAA server group with associated private servers:

```
aaa new-model

aaa authentication ppp method_list_v1.55.com group v1.55.com
aaa authorization network method_list_v1.55.com group v1.55.com
aaa accounting network method_list_v1.55.com start-stop group v1.55.com
aaa accounting system default vrf v1.55.com start-stop group v1.55.com
aaa accounting delay-start vrf v1.55.com
aaa accounting send stop-record authentication failure vrf v1.55.com

aaa group server radius v1.55.com
    server-private 10.10.132.4 auth-port 1645 acct-port 1646 key ww
    ip vrf forwarding v1.55.com

ip radius source-interface loopback55
radius-server attribute 44 include-in-access-req vrf v1.55.com
```

Per VRF AAA Using a Locally Defined Customer Template: Example

The following example shows how to configure the Per VRF AAA feature using a locally defined customer template with a AAA server group that has associated private servers:

```
aaa new-model
aaa authentication ppp method_list_v1.55.com group v1.55.com
aaa authorization network method_list_v1.55.com group v1.55.com
aaa authorization network default local
aaa authorization template
aaa accounting network method_list_v1.55.com start-stop group v1.55.com
aaa accounting system default vrf v1.55.com start-stop group v1.55.com

aaa group server radius V1_55_com
    server-private 10.10.132.4 auth-port 1645 acct-port 1646 key ww
    ip vrf forwarding V1.55.com

template V1.55.com
    peer default ip address pool V1_55_com_pool
    ppp authentication chap callin V1_55_com
    ppp authorization V1_55_com
    ppp accounting V1_55_com
    aaa accounting delay-start
    aaa accounting send stop-record authentication failure
    radius-server attribute 44 include-in-access-req
    ip vrf forwarding v1.55.com
    ip radius source-interface Loopback55
```

Per VRF AAA Using a Remote RADIUS Customer Template: Example

The following examples shows how to configure the Per VRF AAA feature using a remotely defined customer template on the SP RADIUS server with a AAA server group that has associated private servers:

```
aaa new-model
aaa authentication ppp default group radius
aaa authorization template
aaa authorization network default group sp

aaa group server radius sp
  server 10.3.3.3

radius-server host 10.3.3.3 auth-port 1645 acct-port 1646 key sp_key
```

The following RADIUS server profile is configured on the SP RADIUS server:

```
cisco-avpair = "aaa:rad-serv#1=10.10.132.4 key ww"
cisco-avpair = "aaa:rad-serv-vrf#1=V1.55.com"
cisco-avpair = "aaa:rad-serv-source-if#1=Loopback 55"
cisco-avpair = "template:ppp-authen-list=group 1"
cisco-avpair = "template:ppp-author-list=group 1"
cisco-avpair = "template:ppp-acct-list= start-stop group 1"
cisco-avpair = "template:account-delay=on"
cisco-avpair = "template:account-send-stop=on"
cisco-avpair = "template:rad-attr44=access-req"
cisco-avpair = "template:peer-ip-pool=V1.55-pool"
cisco-avpair = "template:ip-vrf=V1.55.com"
cisco-avpair = "template:ip-unnumbered=Loopback 55"
framed-protocol = ppp
service-type = framed
```

Customer Template: Examples

This section provides the following configuration examples:

- [Locally Configured Customer Template with RADIUS Attribute Screening and Broadcast Accounting: Example, page 20](#)
- [Remotely Configured Customer Template with RADIUS Attribute Screening and Broadcast Accounting: Example, page 21](#)

Locally Configured Customer Template with RADIUS Attribute Screening and Broadcast Accounting: Example

The following example shows how to create a locally configured template for a single customer, configuring additional features including RADIUS attribute screening and broadcast accounting:

```
aaa authentication ppp default local group radius
aaa authentication ppp V1_55_com group V1_55_com
aaa authorization template
aaa authorization network default local group radius
aaa authorization network V1_55_com group V1_55_com
aaa accounting network V1_55_com start-stop broadcast group V1_55_com group SP_AAA_server

aaa group server radius SP_AAA_server
  server 10.10.100.7 auth-port 1645 acct-port 1646
```

```

aaa group server radius V1_55_com
  server-private 10.10.132.4 auth-port 1645 acct-port 1646
  authorization accept min-author
  accounting accept usage-only
  ip vrf forwarding V1.55.com

ip vrf V1.55.com
  rd 1:55
  route-target export 1:55
  route-target import 1:55

template V1.55.com
  peer default ip address pool V1.55-pool
  ppp authentication chap callin V1_55_com
  ppp authorization V1_55_com
  ppp accounting V1_55_com
  aaa accounting delay-start
  aaa accounting send stop-record authentication failure
  radius-server attribute 44 include-in-access-req

vpdn-group V1.55
  accept-dialin
  protocol l2tp
  virtual-template 13
  terminate-from hostname lac-lb-V1.55
  source-ip 10.10.104.12
  lcp renegotiation always
  l2tp tunnel password 7 060506324F41

interface Virtual-Template13
  ip vrf forwarding V1.55.com
  ip unnumbered Loopback55
  ppp authentication chap callin
  ppp multilink

ip local pool V1.55-pool 10.1.55.10 10.1.55.19 group V1.55-group

ip radius source-interface Loopback0
ip radius source-interface Loopback55 vrf V1.55.com

radius-server attribute list min-author
  attribute 6-7,22,27-28,242
radius-server attribute list usage-only
  attribute 1,40,42-43,46

radius-server host 10.10.100.7 auth-port 1645 acct-port 1646 key ww
radius-server host 10.10.132.4 auth-port 1645 acct-port 1646 key ww

```

Remotely Configured Customer Template with RADIUS Attribute Screening and Broadcast Accounting: Example

The following example shows how to create a remotely configured template for a single customer, configuring additional features including RADIUS attribute screening and broadcast accounting:

```

aaa authentication ppp default local group radius
aaa authorization template
aaa authorization network default local group radius

ip vrf V1.55.com
  rd 1:55

```

```

route-target export 1:55
route-target import 1:55

vpdn-group V1.55
accept-dialin
protocol l2tp
virtual-template 13
terminate-from hostname lac-lb-V1.55
source-ip 10.10.104.12
lcp renegotiation always
l2tp tunnel password 7 060506324F41

interface Virtual-Template13
no ip address
ppp authentication chap callin
ppp multilink

ip local pool V1.55-pool 10.1.55.10 10.1.55.19 group V1.55-group

radius-server attribute list min-author
attribute 6-7,22,27-28,242

AAA Accounting Stop Records: Examples

The following AAA accounting stop record examples show how to configure the **aaa accounting send stop-record authentication** command to control the generation of “stop” records when the **aaa accounting** command is issued with the **start-stop** or **stop-only** keyword.

Note

The **success** and **remote-server** keywords are available in Cisco IOS Release 12.4(2)T and later releases.

This section provides the following configuration examples:

- [AAA Accounting Stop Record and Successful Call: Example, page 23](#)
- [AAA Accounting Stop Record and Rejected Call: Example, page 25](#)

AAA Accounting Stop Record and Successful Call: Example

The following example shows “start” and “stop” records being sent for a successful call when the **aaa accounting send stop-record authentication** command is issued with the **failure** keyword.

```
Router# show running config | include aaa
.
.
.
aaa new-model
aaa authentication ppp default group radius
aaa authorization network default local
aaa accounting send stop-record authentication failure
aaa accounting network default start-stop group radius
.

AAA Accounting Stop Record and Rejected Call: Example

The following example shows the “stop” record being sent for a rejected call during authentication when the **aaa accounting send stop-record authentication** command is issued with the **success** keyword.

```

Router# show running config | include aaa
.
.
.
aaa new-model
aaa authentication ppp default group radius
aaa authorization network default local
aaa accounting send stop-record authentication success remote-server
aaa accounting network default start-stop group radius

Feature Information for Per VRF AAA

Table 2 lists the release history for this feature. Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 2 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

This feature has also been referred to as the Dynamic Per VRF AAA feature.

Table 2 Feature Information for Per VRF AAA

Feature Name	Releases	Feature Information
Per VRF AAA	12.2(1)DX 12.2(2)DD 12.2(4)B 12.2(13)T 12.2(15)T 12.4(2)T 12.2(28)SB 12.2(33)SRC	<p>The Per VRF AAA feature allows authentication, authorization, and accounting (AAA) on the basis of Virtual Private Network (VPN) routing and forwarding (VRF) instances. For Cisco IOS Release 12.2(15)T or later releases, you can use a customer template, which may be stored either locally or remotely, and AAA services can be performed on the information that is stored in the customer template.</p> <p>In 12.2(1)DX, this feature was introduced on the Cisco 7200 series and the Cisco 7401ASR.</p> <p>In 12.2(2)DD, the ip vrf forwarding and radius-server domain-stripping commands were added.</p> <p>In 12.2(15)T, the aaa authorization template command was added.</p> <p>In 12.4(2)T, the aaa accounting send stop-record authentication command was updated with additional support for AAA accounting stop records.</p> <p>In 12.2(33)SRC dynamic configuration of AAA was introduced.</p>
Per VRF AAA	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Glossary

AAA—authentication, authorization, and accounting. A framework of security services that provide the method for identifying users (authentication), for remote access control (authorization), and for collecting and sending security server information used for billing, auditing, and reporting (accounting).

L2TP—Layer 2 Tunnel Protocol. A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

PE—Provider Edge. Networking devices that are located on the edge of a service provider network.

RADIUS—Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

SP—service provider.

VHG—Virtual Home Gateway.

VPDN—virtual private dialup network.

VPN—Virtual Private Network. A system that permits dial-in networks to exist remotely to home networks, while giving the appearance of being directly connected. VPNs use L2TP and L2F to terminate the Layer 2 and higher parts of the network connection at the LNS instead of the LAC.

VRF—Virtual Route Forwarding. Initially, a router has only one global default routing/forwarding table. VRFs can be viewed as multiple disjointed routing/forwarding tables, where the routes of a user have no correlation with the routes of another user.

**Note**

See [Internetworking Terms and Acronyms](#) for terms not included in this glossary.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

RFC-2867 RADIUS Tunnel Accounting

The RFC-2867 RADIUS Tunnel Accounting introduces six new RADIUS accounting types that are used with the RADIUS accounting attribute Acct-Status-Type (attribute 40), which indicates whether an accounting request marks the beginning of user service (start) or the end (stop).

This feature also introduces two new virtual private virtual private dialup network (VPDN) commands that help users better troubleshoot VPDN session events.

History for RFC-2867 RADIUS Tunnel Accounting

Release	Modification
12.2(15)B	This feature was introduced on the Cisco 6400 series, Cisco 7200 series, and the Cisco 7400 series routers.
12.3(4)T	This feature was integrated into Cisco IOS Release 12.3(4)T.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Restrictions for RFC-2867 RADIUS Tunnel Accounting

RADIUS tunnel accounting works only with L2TP tunnel support.

Information About RFC-2867 RADIUS Tunnel Accounting

To use RADIUS tunnel attributes and commands, you should understand the following concepts:

- [Benefits of RFC-2867 RADIUS Tunnel Accounting, page 2](#)
- [RADIUS Attributes Support for RADIUS Tunnel Accounting, page 2](#)

Benefits of RFC-2867 RADIUS Tunnel Accounting

Without RADIUS tunnel accounting support, VPDN with network accounting, which allows users to determine tunnel-link status changes, did not report all possible attributes to the accounting record file. Now that all possible attributes can be displayed, users can better verify accounting records with their Internet Service Providers (ISPs).

RADIUS Attributes Support for RADIUS Tunnel Accounting

[Table 1](#) outlines the new RADIUS accounting types that are designed to support the provision of compulsory tunneling in dialup networks; that is, these attribute types allow you to better track tunnel status changes.

**Note**

The accounting types are divided into two separate tunnel types so users can decide if they want tunnel type, tunnel-link type, or both types of accounting.

Table 1 **RADIUS Accounting Types for the Acct-Status-Type Attribute**

Type-Name	Number	Description	Additional Attributes ¹
Tunnel-Start	9	Marks the beginning of a tunnel setup with another node.	<ul style="list-style-type: none"> • User-Name (1)—from client • NAS-IP-Address (4)—from AAA • Acct-Delay-Time (41)—from AAA • Event-Timestamp (55)—from AAA • Tunnel-Type (64)—from client • Tunnel-Medium-Type (65)—from client • Tunnel-Client-Endpoint (66)—from client • Tunnel-Server-Endpoint (67)—from client • Acct-Tunnel-Connection (68)—from client
Tunnel-Stop	10	Marks the end of a tunnel connection to or from another node.	<ul style="list-style-type: none"> • User-Name (1)—from client • NAS-IP-Address (4)—from AAA • Acct-Delay-Time (41)—from AAA • Acct-Input-Octets (42)—from AAA • Acct-Output-Octets (43)—from AAA • Acct-Session-Id (44)—from AAA • Acct-Session-Time (46)—from AAA • Acct-Input-Packets (47)—from AAA • Acct-Output-Packets (48)—from AAA • Acct-Terminate-Cause (49)—from AAA • Acct-Multi-Session-Id (51)—from AAA • Event-Timestamp (55)—from AAA • Tunnel-Type (64)—from client • Tunnel-Medium-Type (65)—from client • Tunnel-Client-Endpoint (66)—from client • Tunnel-Server-Endpoint (67)—from client • Acct-Tunnel-Connection (68)—from client • Acct-Tunnel-Packets-Lost (86)—from client

Table 1 *RADIUS Accounting Types for the Acct-Status-Type Attribute (continued)*

Type-Name	Number	Description	Additional Attributes ¹
Tunnel-Reject	11	Marks the rejection of a tunnel setup with another node.	<ul style="list-style-type: none"> • User-Name (1)—from client • NAS-IP-Address (4)—from AAA • Acct-Delay-Time (41)—from AAA • Acct-Terminate-Cause (49)—from client • Event-Timestamp (55)—from AAA • Tunnel-Type (64)—from client • Tunnel-Medium-Type (65)—from client • Tunnel-Client-Endpoint (66)—from client • Tunnel-Server-Endpoint (67)—from client • Acct-Tunnel-Connection (68)—from client
Tunnel-Link-Start	12	Marks the creation of a tunnel link. Only some tunnel types (Layer 2 Transport Protocol [L2TP]) support the multiple links per tunnel; this value should be included only in accounting packets for tunnel types that support multiple links per tunnel.	<ul style="list-style-type: none"> • User-Name (1)—from client • NAS-IP-Address (4)—from AAA • NAS-Port (5)—from AAA • Acct-Delay-Time (41)—from AAA • Event-Timestamp (55)—from AAA • Tunnel-Type (64)—from client • Tunnel-Medium-Type (65)—from client • Tunnel-Client-Endpoint (66)—from client • Tunnel-Server-Endpoint (67)—from client • Acct-Tunnel-Connection (68)—from client

Table 1 **RADIUS Accounting Types for the Acct-Status-Type Attribute (continued)**

Type-Name	Number	Description	Additional Attributes ¹
Tunnel-Link-Stop	13	Marks the end of a tunnel link. Only some tunnel types (L2TP) support the multiple links per tunnel; this value should be included only in accounting packets for tunnel types that support multiple links per tunnel.	<ul style="list-style-type: none"> • User-Name (1)—from client • NAS-IP-Address (4)—from AAA • NAS-Port (5)—from AAA • Acct-Delay-Time (41)—from AAA • Acct-Input-Octets (42)—from AAA • Acct-Output-Octets (43)—from AAA • Acct-Session-Id (44)—from AAA • Acct-Session-Time (46)—from AAA • Acct-Input-Packets (47)—from AAA • Acct-Output-Packets (48)—from AAA • Acct-Terminate-Cause (49)—from AAA • Acct-Multi-Session-Id (51)—from AAA • Event-Timestamp (55)—from AAA • NAS-Port-Type (61)—from AAA • Tunnel-Type (64)—from client • Tunnel-Medium-Type (65)—from client • Tunnel-Client-Endpoint (66)—from client • Tunnel-Server-Endpoint (67)—from client • Acct-Tunnel-Connection (68)—from client • Acct-Tunnel-Packets-Lost (86)—from client
Tunnel-Link-Reject	14	Marks the rejection of a tunnel setup for a new link in an existing tunnel. Only some tunnel types (L2TP) support the multiple links per tunnel; this value should be included only in accounting packets for tunnel types that support multiple links per tunnel.	<ul style="list-style-type: none"> • User-Name (1)—from client • NAS-IP-Address (4)—from AAA • Acct-Delay-Time (41)—from AAA • Acct-Terminate-Cause (49)—from AAA • Event-Timestamp (55)—from AAA • Tunnel-Type (64)—from client • Tunnel-Medium-Type (65)—from client • Tunnel-Client-Endpoint (66)—from client • Tunnel-Server-Endpoint (67)—from client • Acct-Tunnel-Connection (68)—from client

1. If the specified tunnel type is used, these attributes should also be included in the accounting request packet.

How to Configure RADIUS Tunnel Accounting

This section contains the following procedures

- [Enabling Tunnel Type Accounting Records, page 6](#)
- [Verifying RADIUS Tunnel Accounting, page 8](#)

Enabling Tunnel Type Accounting Records

Use this task to configure your LAC to send tunnel and tunnel-link accounting records to be sent to the RADIUS server.

VPDN Tunnel Events

Two new command line interfaces (CLIs)—vpdn session accounting network (tunnel-link-type records) and vpdn tunnel accounting network (tunnel-type records)—are supported to help identify the following events:

- A VPDN tunnel is brought up or destroyed
- A request to create a VPDN tunnel is rejected
- A user session within a VPDN tunnel is brought up or brought down
- A user session create request is rejected

**Note**

The first two events are tunnel-type accounting records: authentication, authorization, and accounting (AAA) sends Tunnel-Start, Tunnel-Stop, or Tunnel-Reject accounting records to the RADIUS server. The next two events are tunnel-link-type accounting records: AAA sends Tunnel-Link-Start, Tunnel-Link-Stop, or Tunnel-Link-Reject accounting records to the RADIUS server.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa accounting network {default | list-name} {start-stop | stop-only | wait-start | none} group groupname**
4. **vpdn enable**
5. **vpdn tunnel accounting network list-name**
6. **vpdn session accounting network list-name**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	Router(config)# aaa accounting network { default <i>list-name</i> } { start-stop stop-only wait-start none } group <i>groupname</i>	Enables network accounting. <ul style="list-style-type: none"> default—If the default network accounting method-list is configured and no additional accounting configurations are enabled on the interface, network accounting is enabled by default. If either the vpdn session accounting network command or the vpdn tunnel accounting network command is linked to the default method-list, all tunnel and tunnel-link accounting records are enabled for those sessions. <i>list-name</i>—The <i>list-name</i> defined in the aaa accounting command must be the same as the <i>list-name</i> defined in the VPDN command; otherwise, accounting will not occur.
Step 4	Router(config)# vpdn enable	Enables virtual private dialup networking on the router and informs the router to look for tunnel definitions in a local database and on a remote authorization server (if applicable).
Step 5	Router(config)# vpdn tunnel accounting network <i>list-name</i>	Enables Tunnel-Start, Tunnel-Stop, and Tunnel-Reject accounting records. <ul style="list-style-type: none"> <i>list-name</i>—The <i>list-name</i> must match the <i>list-name</i> defined in the aaa accounting command; otherwise, network accounting will not occur.
Step 6	Router(config)# vpdn session accounting network <i>list-name</i>	Enables Tunnel-Link-Start, Tunnel-Link-Stop, and Tunnel-Link-Reject accounting records. <ul style="list-style-type: none"> <i>list-name</i>—The <i>list-name</i> must match the <i>list-name</i> defined in the aaa accounting command; otherwise, network accounting will not occur.

What To Do Next

After you have enabled RADIUS tunnel accounting, you can verify your configuration via the following optional task “[Verifying RADIUS Tunnel Accounting](#).”

Verifying RADIUS Tunnel Accounting

Use either one or both of the following optional steps to verify your RADIUS tunnel accounting configuration.

SUMMARY STEPS

1. `enable`
2. `show accounting`
3. `show vpdn [session | tunnel]`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code> Example: Router> <code>enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	Router# <code>show accounting</code>	Displays the active accountable events on the network and helps collect information in the event of a data loss on the accounting server.
Step 3	Router# <code>show vpdn [session] [tunnel]</code>	Displays information about active L2TP tunnel and message identifiers in a VPDN. <ul style="list-style-type: none">• session—Displays a summary of the status of all active tunnels.• tunnel—Displays information about all active L2TP tunnels in summary-style format.

Configuration Examples for RADIUS Tunnel Accounting

This section provides the following configuration examples:

- [Configuring RADIUS Tunnel Accounting on LAC: Example, page 8](#)
- [Configuring RADIUS Tunnel Accounting on LNS: Example, page 10](#)

Configuring RADIUS Tunnel Accounting on LAC: Example

The following example shows how to configure your L2TP access concentrator (LAC) to send tunnel and tunnel-link accounting records to the RADIUS server:

```
aaa new-model
!
!
aaa authentication ppp default group radius
aaa authorization network default local
aaa accounting network m1 start-stop group radius
aaa accounting network m2 stop-only group radius

RADIUS Attribute Screening

First Published: May 18, 2001

Last Published: December 17, 2007

The RADIUS Attribute Screening feature allows users to configure a list of “accept” or “reject” RADIUS attributes on the network access server (NAS) for purposes such as authorization or accounting.

If a NAS accepts and processes *all* RADIUS attributes received in an Access-Accept packet, unwanted attributes may be processed, creating a problem for wholesale providers who do not control their customers’ authentication, authorization, and accounting (AAA) servers. For example, there may be attributes that specify services to which the customer has not subscribed, or there may be attributes that may degrade service for other wholesale dial users. The ability to configure the NAS to restrict the use of specific attributes has therefore become a requirement for many users.

The RADIUS Attribute Screening feature should be implemented in one of the following ways:

- To allow the NAS to accept and process all standard RADIUS attributes for a particular purpose, except for those on a configured reject list
- To allow the NAS to reject (filter out) all standard RADIUS attributes for a particular purpose, except for those on a configured accept list

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for RADIUS Attribute Screening” section on page 10](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Additional References, page 8](#)
- [Feature Information for RADIUS Attribute Screening, page 10](#)
- [Glossary, page 11](#)

Prerequisites for RADIUS Attribute Screening

Before configuring a RADIUS accept or reject list, you must enable AAA.

For more information, refer to the [AAA](#) chapters in the *Cisco IOS Security Configuration Guide*, Release 12.2.

Restrictions for RADIUS Attribute Screening

NAS Requirements

To enable this feature, your NAS should be configured for authorization with RADIUS groups.

Accept or Reject Lists Limitations

The two filters used to configure accept or reject lists are mutually exclusive; therefore, a user can configure only one access list or one reject list for each purpose, per server group.

Vendor-Specific Attributes

This feature does not support vendor-specific attribute (VSA) screening; however, a user can specify attribute 26 (Vendor-Specific) in an accept or reject list, which accepts or rejects all VSAs.

Required Attributes Screening Recommendation

It is recommended that users do not reject the following required attributes:

- For authorization:
 - 6 (Service-Type)
 - 7 (Framed-Protocol)
- For accounting:
 - 4 (NAS-IP-Address)
 - 40 (Acct-Status-Type)
 - 41 (Acct-Delay-Time)
 - 44 (Acct-Session-ID)

If an attribute is required, the rejection is refused, and the attribute is allowed to pass through.

Note

The user does not receive an error at the point of configuring a reject list for required attributes because the list does not specify a purpose—authorization or accounting. The server determines whether an attribute is required when it is known what the attribute is to be used for.

Information About RADIUS Attribute Screening

The RADIUS Attribute Screening feature provides the following benefits:

- Users can configure an accept or reject list consisting of a selection of attributes on the NAS for a specific purpose so unwanted attributes are not accepted and processed.
- Users may wish to configure an accept list that includes only relevant accounting attributes, thereby reducing unnecessary traffic and allowing users to customize their accounting data.

How to Screen RADIUS Attributes

The following sections describe how RADIUS attributes are screened and verified:

- [Configuring RADIUS Attribute Screening](#)
- [Verifying RADIUS Attribute Screening](#)

Configuring RADIUS Attribute Screening

To configure a RADIUS attribute accept or reject list for authorization or accounting, use the following commands:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa authentication ppp default group *group-name***

4. **aaa authorization network default group** *group-name*
5. **aaa group server radius** *group-name*
6. **server** *ip-address*
7. **authorization** [**accept** | **reject**] *listname* - or - **accounting** [**accept** | **reject**] *listname*
8. **exit**
9. **radius-server host** {*hostname* | *ip-address*} [**key string**]
10. **radius-server attribute list** *listname*
11. **attribute** *value1* [*value2* [*value3...*]]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	Router(config)# aaa authentication ppp default group group-name	Specifies one or more AAA authentication methods for use on serial interfaces running PPP.
Step 4	Router(config)# aaa authorization network default group group-name	Sets parameters that restrict network access to the user.
Step 5	Router(config)# aaa group server radius group-name	Groups different RADIUS server hosts into distinct lists and distinct methods.
Step 6	Router(config-sg-radius)# server ip-address	Configures the IP address of the RADIUS server for the group server,
Step 7	Router(config-sg-radius)# authorization [accept reject] listname and/or Router(config-sg-radius)# accounting [accept reject] listname	Specifies a filter for the attributes that are returned in an Access-Accept packet from the RADIUS server. and/or Specifies a filter for the attributes that are to be sent to the RADIUS server in an accounting request. Note The accept keyword indicates that all attributes are rejected except for the attributes specified in the <i>listname</i> . The reject keyword indicates that all attributes are accepted except for the attributes specified in the <i>listname</i> and all standard attributes.
Step 8	Router(config-sg-radius)# exit	Exits server-group configuration mode.
Step 9	Router(config)# radius-server host {hostname ip-address} [key string]	Specifies a RADIUS server host.
Step 10	Router(config)# radius-server attribute list listname	Defines the list name given to the set of attributes defined in the attribute command. Note The <i>listname</i> must be the same as the <i>listname</i> defined in Step 5.
Step 11	Router(config-sg-radius)# attribute value1 [value2 [value3...]]	Adds attributes to the configured accept or reject list. Note This command can be used multiple times to add attributes to an accept or reject list.

Verifying RADIUS Attribute Screening

To verify an accept or reject list, use one of the following commands in privileged EXEC mode:

Command	Purpose
Router# debug aaa accounting	Displays information on accountable events as they occur.
Router# debug aaa authentication	Displays information on AAA authentication.
Router# show radius statistics	Displays the RADIUS statistics for accounting and authentication packets.

Configuration Examples for RADIUS Attribute Screening

This section provides the following configuration examples:

- [Authorization Accept: Example](#)
- [Accounting Reject: Example](#)
- [Authorization Reject and Accounting Accept: Example](#)
- [Rejecting Required Attributes: Example](#)

Authorization Accept: Example

The following example shows how to configure an accept list for attribute 6 (Service-Type) and attribute 7 (Framed-Protocol); all other attributes (including VSAs) are rejected for RADIUS authorization.

```
aaa new-model
aaa authentication ppp default group radius-sg
aaa authorization network default group radius-sg
aaa group server radius radius-sg
    server 10.1.1.1
    authorization accept min-author
!
radius-server host 10.1.1.1 key mykey1
radius-server attribute list min-author
    attribute 6-7
```

Accounting Reject: Example

The following example shows how to configure a reject list for attribute 66 (Tunnel-Client-Endpoint) and attribute 67 (Tunnel-Server-Endpoint); all other attributes (including VSAs) are accepted for RADIUS accounting.

```
aaa new-model
aaa authentication ppp default group radius-sg
aaa authorization network default group radius-sg
aaa group server radius radius-sg
    server 10.1.1.1
    accounting reject tnl-x-endpoint
!
radius-server host 10.1.1.1 key mykey1
radius-server attribute list tnl-x-endpoint
    attribute 66-67
```

Authorization Reject and Accounting Accept: Example

The following example shows how to configure a reject list for RADIUS authorization and configure an accept list for RADIUS accounting. Although you cannot configure more than one accept or reject list per server group for authorization or accounting, you can configure one list for authorization and one list for accounting per server group.

```
aaa new-model
aaa authentication ppp default group radius-sg
aaa authorization network default group radius-sg
aaa group server radius radius-sg
    server 10.1.1.1
    authorization reject bad-author
    accounting accept usage-only
!
radius-server host 10.1.1.1 key mykey1
radius-server attribute list usage-only
    attribute 1,40,42-43,46
!
radius-server attribute list bad-author
    attribute 22,27-28,56-59
```

Rejecting Required Attributes: Example

The following example shows debug output for the **debug aaa accounting** command. In this example, required attributes 44, 40, and 41 have been added to the reject list “standard.”

Router# **debug aaa authorization**

```
AAA/ACCT(6): Accounting method=radius-sg (radius)
RADIUS: attribute 44 cannot be rejected
RADIUS: attribute 61 rejected
RADIUS: attribute 31 rejected
RADIUS: attribute 40 cannot be rejected
RADIUS: attribute 41 cannot be rejected
```

Glossary

AAA—authentication, authorization, and accounting. Suite of network security services that provide the primary framework through which access control can be set up on your Cisco router or access server.

attribute—RADIUS Internet Engineering Task Force (IETF) attributes are the original set of 255 standard attributes that are used to communicate AAA information between a client and a server. Because IETF attributes are standard, the attribute data is predefined and well known; thus all clients and servers who exchange AAA information via IETF attributes must agree on attribute data such as the exact meaning of the attributes and the general bounds of the values for each attribute.

NAS—network access server. A Cisco platform (or collection of platforms, such as an AccessPath system) that interfaces between the packet world (for example, the Internet) and the circuit world (for example, the Public Switched Telephone Network).

RADIUS—Remote Authentication Dial-In User Service. RADIUS is a distributed client/server system that secures networks against unauthorized access. In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

VSA—vendor-specific attribute. VSAs are derived from one IETF attribute—vendor-specific (attribute 26). Attribute 26 allows a vendor to create and implement an additional 255 attributes. That is, a vendor can create an attribute that does not match the data of any IETF attribute and encapsulate it behind attribute 26: essentially, Vendor-Specific = "protocol:attribute=value".

RADIUS Centralized Filter Management

First Published: November 25, 2002

Last Updated: December 17, 2007

The RADIUS Centralized Filter Management feature introduces a filter-server to simplify ACL configuration and management. This filter-server serves as a centralized RADIUS repository and administration point, which users can centrally manage and configure access control list (ACL) filters.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for RADIUS Centralized Filter Management](#)” section on [page 10](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Feature Information for RADIUS Centralized Filter Management, page 10](#)

Prerequisites for RADIUS Centralized Filter Management

- You may need to add a dictionary file to your server if it does not support the new RADIUS VSAs. For a sample dictionary and vendors file, see the section “[RADIUS Dictionary and Vendors File: Example](#)” later in this document.
If you need to add a dictionary file, ensure that your RADIUS server is nonstandard and that it can send the newly introduced VSAs.
- You want to set up RADIUS network authentication so a remote user can dial in and get IP connectivity.

Restrictions for RADIUS Centralized Filter Management

Multiple method lists are not supported in this feature; only a single global filter method list can be configured.

Information About RADIUS Centralized Filter Management

Before the RADIUS Centralized Filter Management feature, wholesale providers (who provide premium charges for customer services such as access control lists [ACLs]) were unable to prevent customers from applying exhaustive ACLs, which could impact router performance and other customers. This feature introduces a centralized administration point—a filter server—for ACL management. The filter server acts as a centralized RADIUS repository for ACL configuration.

Whether or not the RADIUS server that is used as the filter server is the same server that is used for access authentication, the network access server (NAS) will initiate a second access request to the filter server. If configured, the NAS will use the filter-ID name as the authentication username and the filter server password for the second access request. The RADIUS server will attempt to authenticate the filter-ID name, returning any required filtering configuration in the access-accept response.

Because downloading ACLs is time consuming, a local cache is maintained on the NAS. If an ACL name exists on the local cache, that configuration will be used without consulting the filter server.

Note

An appropriately configured cache should minimize delays; however, the first dialin user to require a filter will always experience a longer delay because the ACL configuration is retrieved for the first time.

Cache Management

A global filter cache is maintained on the NAS of recently downloaded ACLs; thus, users no longer have to repeatedly request the same ACL configuration information from a potentially overloaded RADIUS server. Users are required to flush the cache when the following criteria have been met:

- After an entry becomes associated with a newly active call, the idle timer that is associated with that entry will be reset, if configured to do so.
- After the idle-time stamp of an entry expires, the entry will be removed.

- After the global cache of entries reaches a specified maximum number, the entry whose idle-timer is closest to the idle time limit will be removed.

A single timer is responsible for managing all cache entries. The timer is started after the first cache entry is created, and it runs periodically until reboot. The period of the timer will correspond to the minimum granularity offered when configuring cache idle timers, which is one expiration per minute. A single timer prevents users from having to manage individual timers per cache entry.

**Note**

The single timer introduces a lack of precision in timer expiration. There is an average error of approximately 50 percent of the timer granularity. Although decreasing the timer granularity will decrease the average error, the decreased timer granularity will negatively impact performance. Because precise timing is not required for cache management, the error delay should be acceptable.

New Vendor-Specific Attribute Support

This feature introduces support for three new vendor-specific attributes (VSAs), which can be divided into the following two categories:

- User profile extensions
 - Filter-Required (50)—Specifies whether the call should be permitted if the specified filter is not found. If present, this attribute will be applied after any authentication, authorization, and accounting (AAA) filter method-list.
- Pseudo-user profile extensions
 - Cache-Refresh (56)—Specifies whether cache entries should be refreshed each time an entry is referenced by a new session. This attribute corresponds to the **cache refresh** command.
 - Cache-Time (57)—Specifies the idle time out, in minutes, for cache entries. This attribute corresponds to the **cache clear age** command.

**Note**

All RADIUS attributes will override any command-line interface (CLI) configurations.

How to Configure Centralized Filter Management for RADIUS

Use the following sections to configure the Centralized Filter Management feature.

- [Configuring the RADIUS ACL Filter Server](#)
- [Configuring the Filter Cache](#)
- [Verifying the Filter Cache](#)

Configuring the RADIUS ACL Filter Server

To enable the RADIUS ACL filter server, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa authorization cache filterserver default <i>methodlist[methodlist2...]</i>	Enables AAA authorization caches and the downloading of an ACL configuration from a RADIUS filter server. <ul style="list-style-type: none"> default—The default authorization list. <i>methodlist [methodlist2...]</i>—One of the keywords listed on the password command page.

Configuring the Filter Cache

Follow the steps in this section to configure the AAA filter cache.

SUMMARY STEPS

- enable**
- configure terminal**
- aaa cache filter**
- password {0 | 7} password**
- cache disable**
- cache clear age minutes**
- cache refresh**
- cache max number**

	Command	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	Router(config)# aaa cache filter	Enables filter cache configuration and enters AAA filter configuration mode.

	Command	Purpose
Step 4	Router(config-aaa-filter)# password {0 7} <i>password</i>	(Optional) Specifies the optional password that is to be used for filter server authentication requests. 0—Specifies that an unencrypted password will follow. 7—Specifies that a hidden password will follow. <i>password</i> —The unencrypted (clear text) password. Note If a password is not specified, the default password (“cisco”) is enabled.
Step 5	Router(config-aaa-filter)# cache disable	(Optional) Disables the cache.
Step 6	Router(config-aaa-filter)# cache clear age <i>minutes</i>	(Optional) Specifies, in minutes, when cache entries expire and the cache is cleared. <i>minutes</i> —Any value between 0 to 4294967295. Note If a time is not specified, the default (1400 minutes [1 day]) is enabled.
Step 7	Router(config-aaa-filter)# cache refresh	(Optional) Refreshes a cache entry when a new session begins. This command is enabled by default. To disable this functionality, use the no cache refresh command.
Step 8	Router(config-aaa-filter)# cache max <i>number</i>	(Optional) Limits the absolute number of entries the cache can maintain for a particular server. <i>number</i> —The maximum number of entries the cache can contain. Any value between 0 to 4294967295. Note If a number is not specified, the default (100 entries) is enabled.

Verifying the Filter Cache

To display the cache status, use the **show aaa cache filterserver** EXEC command. The following is sample output for the **show aaa cache filterserver** command:

```
Router# show aaa cache filterserver
```

```

Filter      Server      Age Expires Refresh Access-Control-Lists

msn2        10.4.3.4      N/A   Never    2 ip in tcp drop
vone        10.5.3.4      N/A   Never    0 ip in tcp drop

```

Note

The **show aaa cache filterserver** command shows how many times a particular filter has been referenced or refreshed. This function may be used in administration to determine which filters are actually being used.

Troubleshooting Tips

To help troubleshoot your filter cache configurations, use the privileged EXEC **debug aaa cache filterserver** command. To view sample output for the **debug aaa cache filterserver** command, refer to the section “[Debug Output: Example](#)” later in this document.

Monitoring and Maintaining the Filter Cache

To monitor and maintain filter caches, use at least one of the following EXEC commands:

Command	Purpose
Router# clear aaa cache filterserver acl [<i>filter-name</i>]	Clears the cache status for a particular filter or all filters.
Router# show aaa cache filterserver	Displays the cache status.

Configuration Examples for RADIUS Centralized Filter Management

This section provides the following configuration examples:

- [NAS Configuration: Example, page 6](#)
- [RADIUS Server Configuration: Example, page 7](#)
- [RADIUS Dictionary and Vendors File: Example, page 7](#)
- [Debug Output: Example, page 7](#)

NAS Configuration: Example

The following example shows how to configure the NAS for cache filtering. In this example, the server group “mygroup” is contacted first. If there is no response, the default RADIUS server will then be contacted. If there still is no response, the local filters are contacted. Finally, the call is accepted if the filter cannot be resolved.

```
aaa authorization cache filterserver group mygroup group radius local none
!
aaa group server radius mygroup
 server 10.2.3.4
 server 10.2.3.5
!
radius-server host 10.1.3.4
!
aaa cache filter
 password mycisco
 no cache refresh
 cache max 100
!
```

RADIUS Server Configuration: Example

The following example is a sample RADIUS configuration that is for a remote user “user1” dialing into the NAS:

```
myfilter Password = "cisco"
    Service-Type = Outbound,
    Ascend:Ascend-Call-Filter = "ip in drop srcip 10.0.0.1/32 dstip 10.0.0.10/32
    icmp",
    Ascend:Ascend-Call-Filter = "ip in drop srcip 10.0.0.1/32 dstip 10.0.0.10/32 tcp
    dstport = telnet",
    Ascend:Ascend-Cache-Refresh = Refresh-No,
    Ascend:Ascend-Cache-Time = 15

user1 Password = "cisco"
    Service-Type = Framed,
    Filter-Id = "myfilter",
    Ascend:Ascend-Filter-Required = Filter-Required-Yes,
```

RADIUS Dictionary and Vendors File: Example

The following example is a sample RADIUS dictionary file for the new VSAs. In this example, the dictionary file is for a Merit server.

```
dictionary file:
Ascend.attr Ascend-Filter-Required 50 integer (*, 0, NOENCAPS)
Ascend.attr Ascend-Cache-Refresh 56 integer (*, 0, NOENCAPS)
Ascend.attr Ascend-Cache-Time 57 integer (*, 0, NOENCAPS)

Ascend.value Ascend-Cache-Refresh Refresh-No 0
Ascend.value Ascend-Cache-Refresh Refresh-Yes 1

Ascend.value Ascend-Filter-Required Filter-Required-No 0
Ascend.value Ascend-Filter-Required Filter-Required-Yes 1

vendors file:
50 50
56 56
57 57
```

Debug Output: Example

The following is sample output from the **debug aaa cache filterserver** command:

```
Router# debug aaa cache filterserver

AAA/FLTSV: need "myfilter" (fetch), call 0x612DAC64
AAA/FLTSV: send req, call 0x612DAC50
AAA/FLTSV: method SERVER_GROUP myradius
AAA/FLTSV: recv reply, call 0x612DAC50 (PASS)
AAA/FLTSV: create cache
AAA/FLTSV: add attr "call-inacl"
AAA/FLTSV: add attr "call-inacl"
AAA/FLTSV: add attr "call-inacl"
AAA/FLTSV: skip attr "filter-cache-refresh"
AAA/FLTSV: skip attr "filter-cache-time"
AAA/CACHE: set "AAA filtserv cache" entry "myfilter" refresh? no
```

```

AAA/CACHE: set "AAA filtserv cache" entry "myfilter" cachetime 15
AAA/FLTSV: add attr to list "call-inacl" call 0x612DAC64
AAA/FLTSV: add attr to list "call-inacl" call 0x612DAC64
AAA/FLTSV: add attr to list "call-inacl" call 0x612DAC64
AAA/FLTSV: PASS call 0x612DAC64
AAA/CACHE: timer "AAA filtserv cache", next in 10 secs (0 entries)
AAA/CACHE: timer "AAA filtserv cache", next in 10 secs (1 entry)
AAA/CACHE: destroy "AAA filtserv cache" entry "myfilter"
AAA/CACHE: timer "AAA filtserv cache", next in 10 secs (0 entries)

```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **aaa authorization cache filterserver**
- **aaa cache filter**
- **cache clear age**
- **cache disable**
- **cache refresh**
- **clear aaa cache filterserver acl**
- **debug aaa cache filterserver**
- **password**
- **show aaa cache filterserver**

Feature Information for RADIUS Centralized Filter Management

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for RADIUS Centralized Filter Management

Feature Name	Releases	Feature Information
RADIUS Centralized Filter Management	12.2(13)T 12.2(28)SB 12.2(33)SRC Cisco IOS XE Release 2.1	<p>The RADIUS Centralized Filter Management feature introduces a filter-server to simplify ACL configuration and management. This filter-server serves as a centralized RADIUS repository and administration point, which users can centrally manage and configure access control list (ACL) filters.</p> <p>This feature was introduced in Cisco IOS Release 12.2(13)T.</p> <p>This feature was integrated into Cisco IOS Release 12.2(28)SB.</p> <p>This feature was integrated into Cisco IOS Release 12.2(33)SRC.</p> <p>In Cisco IOS Release 2.1, this feature was introduced on Cisco ASR 1000 Series Routers.</p> <p>The following commands were introduced or modified by this feature: aaa authorization cache filterserver, aaa cache filter, cache clear age, cache disable, cache refresh, clear aaa cache filterserver acl, debug aaa cache filterserver, password, show aaa cache filterserver.</p>

RADIUS Debug Enhancements

Feature History

Release	Modification
12.2(11)T	This feature was introduced on the Cisco 1400 series, Cisco 1600 series, Cisco 1700 series, Cisco 2500 series, Cisco 2600 series, Cisco 3600 series, Cisco 7100, Cisco 7200, Cisco 7500, Cisco AS5300, Cisco AS5800, Cisco Catalyst 5000, Cisco MC3810, and Cisco MGX8850 platforms.

This document describes the Remote Authentication Dial-In User Services (RADIUS) Debug Enhancements feature in Cisco IOS Release 12.2(11)T. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 2](#)
- [Supported Standards, MIBs, and RFCs, page 3](#)
- [Prerequisites, page 4](#)
- [Configuration Tasks, page 4](#)
- [Configuration Examples, page 7](#)
- [Command Reference, page 9](#)
- [Glossary, page 10](#)

Feature Overview

This document details the RADIUS Debug Enhancements feature. RADIUS is a distributed client/server system that provides the following functionality:

- secures networks against unauthorized access
- enables authorization of specific service limits
- provides accounting information so that services can be billed

In the Cisco implementation, RADIUS clients run on Cisco routers and send authentication requests to a central RADIUS server that contains all user authentication and network service access information.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

The **debug radius** command displays information associated with RADIUS. Prior to the RADIUS Debug Enhancements feature, **debug radius** output was available only in an expanded, hexadecimal string format, resulting in displays that were difficult to interpret and analyze. Moreover, attribute value displays were truncated, particularly for vendor-specific attributes (VSAs).

The new feature provides enhanced RADIUS display including the following:

- Packet dump in a more readable, user-friendly ASCII format than before
- Complete display of attribute values without truncation
- Ability to select a brief RADIUS **debug** output display

Benefits

- Provides RADIUS debug display in a user-friendly format
- Supports complete RADIUS debug information
- Provides the default display of packet dump in ASCII format
- Allows a compact debugging output option that is useful for high-traffic, operational environments

Restrictions

Only Internet Engineering Task Force (IETF) attributes and Cisco VSAs used in voice applications are supported. For unsupported attributes, “undebuggable” is displayed.

Related Features and Technologies

- Cisco IOS security
- RADIUS authentication, authorization, and accounting (AAA)
- Cisco Voice over IP (VoIP)

Supported Platforms

- Cisco 1400 series
- Cisco 1600 series
- Cisco 1700 series
- Cisco 2500 series

- Cisco 2600 series
- Cisco 3600 series
- Cisco 7100 series
- Cisco 7200 series
- Cisco 7500 series
- Cisco AS5300
- Cisco AS5800
- Cisco Catalyst 5000
- Cisco MC3810
- Cisco MGX8850

Availability of Cisco IOS Software Images

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

Supported Standards, MIBs, and RFCs

Standards

No new or modified standards are supported by this feature.

MIBs

To locate and download MIBs for selected platforms, Cisco IOS releases, and feature sets, use Cisco MIB Locator found at the following URL:

<http://tools.cisco.com/ITDIT/MIBS/servlet/index>

If Cisco MIB Locator does not support the MIB information that you need, you can also obtain a list of supported MIBs and download MIBs from the Cisco MIBs page at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

To access Cisco MIB Locator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions found at this URL:

<http://www.cisco.com/register>

RFCs

No new or modified RFCs are supported by this feature.

Prerequisites

- Establish a working IP network. For more information about configuring IP, refer to the part “IP Overview,” and the “Configuring IP Addressing,” and “Configuring IP Services” chapters in the Cisco IOS Release 12.0 *Network Protocols Configuration Guide, Part 1*.
- Configure VoIP. For more information about configuring VoIP, refer to *Cisco IOS Voice, Video, and Fax Configuration Guide*, Release 12.2.
- Configure the gateway as a RADIUS client. Refer to the chapter “Configuring the RADIUS Client Gateway” in the *RADIUS Vendor-Specific Attributes Voice Implementation Guide*, Release 12.1.
- Be familiar with IETF RFC 2138.

Configuration Tasks

See the following sections for configuration tasks for the RADIUS Debug Enhancements feature. Each task in the list is identified as either required or optional.

- [Configuring Default Debug ASCII Display](#) (optional)
- [Configuring Debug Display in Brief Format](#) (optional)
- [Configuring Debug Display in Hex Format](#) (optional)
- [Verifying the debug radius Command](#) (optional)

Configuring Default Debug ASCII Display

The complete ASCII format debug display with no truncation is enabled by default; no configuration tasks are required to enable this feature. To reenable the feature if it was disabled by using the **no debug radius** command, use the following command in privileged EXEC mode:

Command	Purpose
Router# debug radius	Enables RADIUS debugging output.

**Note**

Prior to Cisco IOS Release 12.2(11)T, the **debug radius** command enabled truncated debugging output in hexadecimal notation, rather than ASCII. To enable debugging output in hex format, use the **debug radius hex** command.

Configuring Debug Display in Brief Format

Debugging output is available in a compact output that displays only basic information. To enable this display option, use the following command in privileged EXEC mode:

Command	Purpose
Router# debug radius brief	Enables RADIUS debugging output displaying only the client/server interaction and minimum packet information.

Configuring Debug Display in Hex Format

Debugging output is available in hexadecimal notation. To enable this display option, use the following command in privileged EXEC mode:

Command	Purpose
Router# debug radius hex	Enables RADIUS debugging output in hexadecimal notation.

Verifying the debug radius Command

Use the **show debug** command to verify RADIUS output options.

```
5300# show debug
```

```
Radius protocol debugging is on
Radius packet hex dump debugging is on

Configuration Examples

This section provides the following configuration examples:

- [Default debug radius Command Example](#)
- [Compact Debugging Output Example](#)

Default debug radius Command Example

The following sample output shows the default RADIUS output in ASCII notation, generated by the **debug radius** command:

Note

The following output displays the internal information that is found inside a RADIUS protocol message. For more information about RADIUS protocol messages, see IETF RFC 2138.

```

router# debug radius

Radius protocol debugging is on
Radius packet hex dump debugging is off

```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **debug radius**

Glossary

AAA — authentication, authorization, and accounting. Pronounced “triple a.”

ASCII — American Standard Code for Information Interchange. 8-bit code for character representation (7 bits plus parity).

attribute — Form of information items provided by the X.500 Directory Service. The directory information base consists of entries, each containing one or more attributes. Each attribute consists of a type identifier together with one or more values.

IETF — Internet Engineering Task Force. Task force consisting of over 80 working groups responsible for developing Internet standards. The IETF operates under the auspices of ISOC.

RADIUS — Remote Authentication Dial-In User Service. Database for authenticating modem and ISDN connections and for tracking connection time.

VoIP — Voice over IP. The capability to carry normal telephony-style voice over an IP-based internet with POTS-like functionality, reliability, and voice quality. VoIP enables a router to carry voice traffic (for example, telephone calls and faxes) over an IP network. In VoIP, the DSP segments the voice signal into frames, which then are coupled in groups of two and stored in voice packets. These voice packets are transported using IP in compliance with ITU-T specification H.323.

VSA — vendor-specific attribute. An attribute that has been implemented by a particular vendor. It uses the attribute Vendor-Specific to encapsulate the resulting AV pair: essentially, Vendor-Specific = protocol:attribute = value.

RADIUS Logical Line ID

First Published: November 25, 2002

Last Updated: December 17, 2007

The RADIUS Logical Line ID feature, also known as the Logical Line Identification (LLID) Blocking feature enables administrators to track their customers on the basis of the physical lines on which customer calls originate. Administrators use a virtual port that does not change as customers move from one physical line to another. This virtual port facilitates the maintenance of the administrator's customer profile database and allows the administrator to do additional security checks on customers.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for RADIUS Logical Line ID” section on page 9](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for RADIUS Logical Line ID

Although this feature can be used with any RADIUS server, some RADIUS servers may require modifications to their dictionary files to allow the Calling-Station-ID attribute to be returned in Access-Accept messages. For example, the Merit RADIUS server does not support LLID downloading unless you modify its dictionary as follows: “ATTRIBUTE Calling-Station-Id 31 string (*, *)”

Restrictions for RADIUS Logical Line ID

The RADIUS Logical Line ID feature supports RADIUS only. TACACS+ is not supported.

This feature can be applied only toward PPP over Ethernet over ATM (PPPoEoATM) and PPP over Ethernet over VLAN (PPPoEoVLAN) (Dot1Q) calls; no other calls, such as ISDN, can be used.

Information About RADIUS Logical Line ID

LLID is an alphanumeric string (which must be a minimum of one character and a maximum of 253 characters) that is a logical identification of a subscriber line. LLID is maintained in a customer profile database on a RADIUS server. When the customer profile database receives a preauthorization request from the access router, the RADIUS server sends the LLID to the router as the Calling-Station-ID attribute (attribute 31).

The Layer 2 Tunneling Protocol (L2TP) access concentrator (LAC) sends a preauthorization request to the customer profile database when the LAC is configured for preauthorization. Configure the LAC for preauthorization using the **subscriber access** command.

Note

Downloading the LLID is referred to as “preauthorization” because it occurs before either service (domain) authorization or user authentication and authorization occur.

The customer profile database on the RADIUS server consists of user profiles for each physical network access server (NAS) port that is connected to the router. Each user profile contains a profile matched to a username (attribute 1) representing the physical port on the router. When the router is configured for preauthorization, it queries the customer profile database using a username representative of the physical NAS port making the connection to the router. When a match is found in the customer profile database, the customer profile database returns an Access-Accept message containing the LLID in the user profile. The LLID is defined in the Access-Accept record as the Calling-Station-ID attribute.

The preauthorization process can also provide the real username being used for authentication to the RADIUS server. Because the physical NAS port information is being used as the username (attribute 1), RADIUS attribute 77 (Connect-Info) can be configured to contain the authentication username. This configuration allows the RADIUS server to provide additional validation on the authorization request if it chooses, such as analyzing the username for privacy rules, before returning an LLID back to the router.

How to Configure RADIUS Logical Line ID

See the following sections for configuration tasks for the RADIUS Logical Line ID feature. Each task in the list is identified as either required or optional.

- [Configuring Preauthorization, page 3](#) (required)
- [Configuring the LLID in a RADIUS User Profile, page 4](#) (required)
- [Verifying Logical Line ID, page 4](#) (optional)

Configuring Preauthorization

To download the LLID and configure the LAC for preauthorization, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip radius source-interface** *interface-name*
4. **subscriber access {pppoe | pppoa} pre-authorize nas-port-id [default | list-name][send username]**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip radius source-interface <i>interface-name</i> Example: Router (config)# ip radius source-interface Loopback1	Specifies the IP address portion of the username for the preauthorization request.
Step 4	subscriber access {pppoe pppoa} pre-authorize nas-port-id [default list-name][send username] Example: Router (config)# subscriber access pppoe pre-authorize nas-port-id mlist_llid send username	Enables the LLID to be downloaded so the router can be configured for preauthorization. The send username option specifies that you include the authentication username of the session inside the Connect-Info (attribute 77) in the Access-Request message.

Configuring the LLID in a RADIUS User Profile

To configure the user profile for preauthorization, add a NAS port user to the customer profile database and add RADIUS Internet Engineering Task Force (IETF) attribute 31 (Calling-Station-ID) to the user profile.

SUMMARY STEPS

1. `UserName=nas_port: ip-address:slot/module/port/vpi.vci`
2. `UserName=nas-port: ip-address:slot/module/port/vlan-id`
3. `Calling-Station-Id = "string (*,*)"`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>UserName=nas_port: ip-address:slot/module/port/vpi.vci</code>	(Optional) Adds a PPPoE over ATM NAS port user.
Step 2	<code>User-Name=nas-port: ip-address:slot/module/port/vlan-id</code>	(Optional) Adds a PPPoE over VLAN NAS port user.
Step 3	<code>Calling-Station-Id = "string (*,*)"</code>	Adds attribute 31 to the user profile. <ul style="list-style-type: none"> • String—One or more octets, containing the phone number from which the user placed the call.

Verifying Logical Line ID

To verify feature functionality, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `debug radius`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code> Example: <code>Router> enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<code>debug radius</code> Example: <code>Router# debug radius</code>	Checks to see that RADIUS attribute 31 is the LLID in the Accounting-Request on LAC and in the Access-Request and Accounting-Request on the LNS.

Configuration Examples for RADIUS Logical Line ID

This section provides the following configuration examples:

- [LAC for Preauthorization Configuration: Example, page 5](#)
- [RADIUS User Profile for LLID: Example, page 6](#)

LAC for Preauthorization Configuration: Example

The following example shows how to configure your LAC for preauthorization by downloading the LLID:

```

RADIUS NAS-IP-Address Attribute Configurability

First Published: November 19, 2003

Last Updated: December 3, 2007

The RADIUS NAS-IP-Address Attribute Configurability feature allows an arbitrary IP address to be configured and used as RADIUS attribute 4, NAS-IP-Address, without changing the source IP address in the IP header of the RADIUS packets. This feature may be used for situations in which service providers are using a cluster of small network access servers (NASs) to simulate a large NAS to improve scalability. This feature allows the NASs to behave as a single RADIUS client from the perspective of the RADIUS server.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for RADIUS NAS-IP-Address Attribute Configurability” section on page 8](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Command Reference, page 7](#)
- [Feature Information for RADIUS NAS-IP-Address Attribute Configurability, page 8](#)

Prerequisites for RADIUS NAS-IP-Address Attribute Configurability

The following requirements are necessary before configuring this feature:

- Experience with IP Security (IPSec) and configuring both RADIUS servers and authentication, authorization, and accounting (AAA) is necessary.
- RADIUS server and AAA lists must be configured.

Restrictions for RADIUS NAS-IP-Address Attribute Configurability

The following restrictions apply if a cluster of RADIUS clients are being used to simulate a single RADIUS client for scalability. Solutions, or workarounds, to the restrictions are also provided.

- RADIUS attribute 44, Acct-Session-Id, may overlap among sessions from different NASs.

There are two solutions. Either the **radius-server attribute 44 extend-with-addr** or **radius-server unique-ident** command can be used on NAS routers to specify different prepending numbers for different NAS routers.

- RADIUS server-based IP address pool for different NASs must be managed.

The solution is to configure different IP address pool profiles for different NASs on the RADIUS server. Different NASs use different pool usernames to retrieve them.

- RADIUS request message for sessions from different NASs must be differentiated.

One of the solutions is to configure different format strings for RADIUS attribute 32, NAS-Identifier, using the **radius-server attribute 32 include-in-access-req** command on different NASs.

Information About RADIUS NAS-IP-Address Attribute Configurability

To simulate a large NAS RADIUS client using a cluster of small NAS RADIUS clients, as shown in [Figure 1](#), a Network Address Translation (NAT) or Port Address Translation (PAT) device is inserted in a network. The device is placed between a cluster of NASs and the IP cloud that is connected to a RADIUS server. When RADIUS traffic from different NASs goes through the NAT or PAT device, the source IP addresses of the RADIUS packets are translated to a single IP address, most likely an IP address on a loopback interface on the NAT or PAT device. Different User Datagram Protocol (UDP) source ports are assigned to RADIUS packets from different NASs. When the RADIUS reply comes

back from the server, the NAT or PAT device receives it, uses the destination UDP port to translate the destination IP address back to the IP address of the NAS, and forwards the reply to the corresponding NAS.

Figure 1 demonstrates how the source IP addresses of several NASs are translated to a single IP address as they pass through the NAT or PAT device on the way to the IP cloud.

Figure 1 NAS Addresses Translated to a Single IP Address

RADIUS servers normally check the source IP address in the IP header of the RADIUS packets to track the source of the RADIUS requests and to maintain security. The NAT or PAT solution satisfies these requirements because only a single source IP address is used even though RADIUS packets come from different NAS routers.

However, when retrieving accounting records from the RADIUS database, some billing systems use RADIUS attribute 4, NAS-IP-Address, in the accounting records. The value of this attribute is recorded on the NAS routers as their own IP addresses. The NAS routers are not aware of the NAT or PAT that runs between them and the RADIUS server; therefore, different RADIUS attribute 4 addresses will be recorded in the accounting records for users from the different NAS routers. These addresses eventually expose different NAS routers to the RADIUS server and to the corresponding billing systems.

Using the RADIUS NAS-IP-Address Attribute Configurability Feature

The RADIUS NAS-IP-Address Attribute Configurability feature allows you to freely configure an arbitrary IP address as RADIUS NAS-IP-Address, RADIUS attribute 4. By manually configuring the same IP address, most likely the IP address on the loopback interface of the NAT or PAT device, for all the routers, you can hide a cluster of NAS routers behind the NAT or PAT device from the RADIUS server.

How to Configure RADIUS NAS-IP-Address Attribute Configurability

This section contains the following procedures:

- [Configuring RADIUS NAS-IP-Address Attribute Configurability, page 4](#)
- [Monitoring and Maintaining RADIUS NAS-IP-Address Attribute Configurability, page 4](#)

Configuring RADIUS NAS-IP-Address Attribute Configurability

Before configuring the RADIUS NAS-IP-Address Attribute Configurability feature, you must have configured the RADIUS servers or server groups and AAA method lists.

To configure the RADIUS NAS-IP-Address Attribute Configurability feature, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **radius-server attribute 4 ip-address**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	radius-server attribute 4 ip-address Example: Router (config)# radius-server attribute 4 10.2.1.1	Configures an IP address to be used as the RADIUS NAS-IP-Address, attribute 4.

Monitoring and Maintaining RADIUS NAS-IP-Address Attribute Configurability

To monitor the RADIUS attribute 4 address that is being used inside the RADIUS packets, use the **debug radius** command.

SUMMARY STEPS

1. **enable**
2. **debug radius**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example: Router> enable	<ul style="list-style-type: none"> Enter your password if prompted.
Step 2	debug radius	Displays information associated with RADIUS.
	Example: Router# debug radius	

Examples

The following sample output is from the **debug radius** command:

```
Router# debug radius

RADIUS/ENCODE(0000001C): acct_session_id: 29
RADIUS(0000001C): sending

RADIUS: Framed-Protocol      [7]  6  PPP                               [1]
RADIUS(0000001C): Received from id 21645/17
```

Configuration Examples for RADIUS NAS-IP-Address Attribute Configurability

This section provides the following configuration example:

- [Configuring a RADIUS NAS-IP-Address Attribute Configurability: Example, page 5](#)

Configuring a RADIUS NAS-IP-Address Attribute Configurability: Example

The following example shows that IP address 10.0.0.21 has been configured as the RADIUS NAS-IP-Address attribute:

```
radius-server attribute 4 10.0.0.21
radius-server host 10.0.0.10 auth-port 1645 acct-port 1646 key cisco
```

RADIUS Route Download

First Published: February 25, 2002

Last Updated: December 17, 2007

The RADIUS Route Download feature allows users to configure their network access server (NAS) to direct RADIUS authorization. Users configure a separate named method list (in addition to the default method list) for static route download requests sent by their NAS to authorization, authentication, and accounting (AAA) servers.

Before this feature, RADIUS authorization for static route download requests was sent only to AAA servers specified by the default method list.

This feature extends the functionality of the **aaa route download** command to allow users to specify the name of the method list that will be used to direct static route download requests to the AAA servers. The **aaa route download** command may be used to specify a separate method list for downloading static routes. This method list can be added by using the **aaa authorization configuration** command.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for RADIUS Route Download](#)” section on page 6.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Americas Headquarters:

Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

Contents

- [Prerequisites, page 2](#)
- [Configuration Tasks, page 2](#)
- [Configuration Examples, page 3](#)
- [Additional References, page 4](#)
- [Command Reference, page 5](#)
- [Feature Information for RADIUS Route Download, page 6](#)

Prerequisites

AAA network security must be enabled before you perform the tasks in this feature. For information about enabling AAA, refer to the AAA section in the *Cisco IOS Security Configuration Guide*, Release 12.4.

Configuration Tasks

Use the following sections to configure the RADIUS Route Download feature.

- [Configuring RADIUS Route Download](#)
- [Verifying RADIUS Route Download](#)

Configuring RADIUS Route Download

To configure the NAS to send static route download requests to the servers specified by a named method list, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa authorization configuration <i>method-name</i> [radius tacacs+ group <i>group-name</i>]	Downloads static route configuration information from the AAA server using RADIUS.
Step 2	Router(config)# aaa route download [<i>time</i>] [authorization <i>method-list</i>]	Enables the static route download feature. Use the authorization <i>method-list</i> attributes to specify a named method list to which RADIUS authorization requests for static route downloads are sent.

Verifying RADIUS Route Download

To verify the routes that are installed, use the **show ip route** command in EXEC mode.

To display information that is associated with RADIUS, use the **debug radius** command in privileged EXEC mode.

Configuration Examples

This section provides the following configuration examples:

- [RADIUS Route Download Configuration Example](#)

RADIUS Route Download Configuration Example

The following example shows how to configure the NAS to send static route download requests to the servers specified by the method list named “list1”:

```
aaa new-model
aaa group server radius rad1
    server 10.2.2.2 auth-port 1645 acct-port 1646
!
aaa group server tacacs+ tac1
    server 172.17.3.3
!
aaa authorization configuration default group radius
aaa authorization configuration list1 group rad1 group tac1
aaa route download 1 authorization list1

tacacs-server host 172.17.3.3
tacacs-server key cisco
tacacs-server administration
!
radius-server host 10.2.2.2 auth-port 1645 acct-port 1646
radius-server key cisco
```

RADIUS Server Load Balancing

First Published: March 20, 2006
Last Updated: December 17, 2007

The RADIUS Server Load Balancing feature distributes authentication, authorization, and accounting (AAA) authentication and accounting transactions across servers in a server group. These servers can then share the transaction load, resulting in faster responses to incoming requests by optimally using available servers.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for RADIUS Server Load Balancing](#)” section on page 19.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for RADIUS Server Load Balancing

- AAA must be configured on your RADIUS server.
- RADIUS must be configured for functions such as authentication, accounting, or static route download.
- AAA RADIUS server groups must be established.

Restrictions for RADIUS Server Load Balancing

- Load balancing is not supported on proxy RADIUS servers.
- Incoming RADIUS requests, such as Packet of Disconnect (POD) requests, are not supported.
- Load balancing is not supported for private server-groups.

Information About RADIUS Server Load Balancing

To configure the RADIUS Server Load Balancing feature, you must understand the following concepts:

- [How RADIUS Server Load Balancing Works, page 2](#)
- [How Transactions Are Load-Balanced Across RADIUS Server Groups, page 3](#)
- [RADIUS Server Status and Automated Testing, page 3](#)

How RADIUS Server Load Balancing Works

Load balancing distributes batches of transactions to servers within a server group. It assigns each batch of transactions to the server with the lowest number of outstanding transactions in its queue. The process of assigning a batch of transactions is as follows:

- The first transaction is received for a new batch.
- All server transaction queues are checked.
- The server with the lowest number of outstanding transactions is identified.
- The identified server is assigned the next batch of transactions.

Batch size is a user configured parameter. Changes in batch size may impact CPU load and network throughput. As batch size increases, CPU load decreases and network throughput increases. However, if a large batch size is used, all available server resources may not be fully utilized. As batch size decreases, CPU load increases, and network throughput decreases. It is recommended that the default batch size, 25, be used because it is optimal for high throughput, without adversely impacting CPU load.

**Note**

There is no set number for large or small batch sizes. As a frame of reference, a batch size greater than 50 is considered large and a batch size less than 25 is considered small.

**Note**

If you have ten or more servers in a server group, it is recommended that a high batch size be set in order to reduce CPU load.

How Transactions Are Load-Balanced Across RADIUS Server Groups

You can configure load balancing either per named RADIUS server group or for the global RADIUS server group. This server group must be referred to as “radius” in the AAA method lists. All public servers that are part of this server group will then be load balanced.

Authentication and accounting can be configured to use the same server or different servers. In some cases, the same server is used for preauthentication, authentication, or accounting transactions for a session. The preferred server, which is an internal setting and set as default, tells AAA to use same server for the start and stop record for a session regardless of server cost. When using the preferred server setting, it is expected that the server used for the initial transaction (for example, authentication), the preferred server, should also be part of any other server group that is used for a subsequent transaction (for example, accounting).

The preferred server is used unless one of the following states is true:

- The **ignore-preferred-server** keyword is used.
- The preferred server is dead.
- The preferred server is in quarantine.
- The want server flag has been set, overriding the preferred server setting.

The want server flag, an internal setting, is used when the same server must be used for all stages of a multistage transaction regardless of server cost. If the want server is not available, the transaction fails.

You may want to use the **ignore-preferred-server** keyword if you have either of the following configurations:

- Dedicated authentication server and a separate dedicated accounting server.
- Network where you can track all call record statistics and call record details, including start- and stop-records, and those records are stored on separate servers.

Also, if you have a configuration where your authentication servers are a superset of your accounting servers, then the preferred server will not be used.

RADIUS Server Status and Automated Testing

The RADIUS Server Load Balancing feature takes server status into account when assigning batches. Only servers that are verified alive are sent transaction batches. It is recommended that you test the status all RADIUS load-balanced servers, including low usage servers (for example, backup servers).

Transactions are not sent to a server that is marked dead. A server is marked dead until its timer expires, at which time it is in quarantine. A server is in quarantine until it is verified alive by the RADIUS automated tester functionality.

The RADIUS automated tester uses the following steps to determine if a server is alive and available to process transactions:

- A request is sent periodically to the server for a test user ID.
- If an Access-Reject message is returned from the server, the server is alive.
- If no message is returned from the server, it is not alive; that is, the server is either dead or quarantined.

If transactions have been sent to a server that is not responding, before it is marked dead, that transaction is failed over to the next available server. It is recommended that the retry reorder mode for failed transactions be used.

When using the RADIUS automated tester, verify that the test packets being sent by the network access server (NAS) to the AAA servers are being responded to. If the servers are not configured correctly, the packets may be dropped and the server erroneously marked dead.

**Caution**

It is recommended that a test user, one that is not defined on the RADIUS server, be used for RADIUS server automated testing to protect against security issues that may arise if the test user is not correctly configured.

**Note**

If you want to check load balancing transactions at a specific point in time, you can use the **test aaa group** command.

How to Configure RADIUS Server Load Balancing

This section contains the following procedures that allow you to configure load balancing:

- [Enabling Load Balancing for Named RADIUS Server Group, page 4](#)
- [Enabling Load Balancing for Global RADIUS Server Group, page 5](#)
- [Troubleshooting RADIUS Server Load Balancing, page 6](#)

Enabling Load Balancing for Named RADIUS Server Group

Use the following task to enable RADIUS Server Load Balancing for a named server group.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **radius-server host** {*hostname* | *ip-address*} [**test username** *user-name*] [**auth-port** *port-number*] [**ignore-auth-port**] [**acct-port** *port-number*] [**ignore-acct-port**] [**idle-time** *seconds*]
4. **aaa group server radius** *group-name*
5. **load-balance method least-outstanding** [**batch-size** *number*] [**ignore-preferred-server**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	radius-server host {hostname ip-address} [test username user-name] [auth-port port-number] [ignore-auth-port] [acct-port port-number] [ignore-acct-port] [idle-time seconds] Example: Router(config)# radius-server host 192.0.2.1 test username test1 idle-time 1	Enables RADIUS automated testing. <ul style="list-style-type: none"> The test username keyword must be used to enable RADIUS automated testing, followed by the value for the <i>user-name</i> argument. By default, auth-port is tested using port 1645. Use ignore-auth-port to turn off testing of the authentication port. By default, acct-port is tested using port 1645. Use ignore-acct-port to turn off testing of the accounting port. By default, the idle-time is 3600 seconds. The range is 1 – 35791.
Step 4	aaa group server radius group-name Example: Router(config)# aaa group server radius rad-sg	Enters server group configuration mode.
Step 5	load-balance method least-outstanding [batch-size number] [ignore-preferred-server] Example: Router(config-sg)# load-balance method least-outstanding batch-size 30	Enables least-outstanding load balancing for a server group. <ul style="list-style-type: none"> By default, the batch-size is set to 25. A range of 1 – 2147483647 may be used. By default, the preferred server is enabled. If you want to disable the preferred-server setting, use the keyword ignore-preferred-server.

Enabling Load Balancing for Global RADIUS Server Group

Use the following task to enable RADIUS Server Load Balancing for the global RADIUS server group. This is the group referred to as “radius” in the AAA method lists.

SUMMARY STEPS

- enable
- configure terminal

3. **radius-server host** {*hostname* | *ip-address*} [**test username** *user-name*] [**auth-port** *port-number*] [**ignore-auth-port**] [**acct-port** *port-number*] [**ignore-acct-port**] [**idle-time** *seconds*]
4. **radius-server load-balance method least-outstanding** [**batch-size** *number*] [**ignore-preferred-server**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	radius-server host { <i>hostname</i> <i>ip-address</i> } [test username <i>user-name</i>] [auth-port <i>port-number</i>] [ignore-auth-port] [acct-port <i>port-number</i>] [ignore-acct-port] [idle-time <i>seconds</i>] Example: Router(config)# radius-server host 192.0.2.1 test username test1 idle-time 1	Enables RADIUS automated testing. <ul style="list-style-type: none"> The test username keyword must be used to enable RADIUS automated testing, followed by the value for the <i>user-name</i> argument. By default, auth-port is tested using port 1645. Use ignore-auth-port to turn off testing of the authentication port. By default, acct-port is tested using port 1645. Use ignore-acct-port to turn off testing of the accounting port. By default, the idle-time is 3600 seconds. The range is 1 – 35791.
Step 4	radius-server load-balance method least-outstanding [batch-size <i>number</i>] [ignore-preferred-server] Example: Router(config)# radius-server load-balance method least-outstanding	Enables least-outstanding load balancing for the global RADIUS server group. <ul style="list-style-type: none"> By default, the batch-size is set to 25. A range of 1 – 2147483647 may be used. By default, the preferred server is enabled. If you want to disable the preferred server setting, use the ignore-preferred-server keyword.

Troubleshooting RADIUS Server Load Balancing

After configuring the RADIUS Server Load Balancing feature, you may monitor the idle timer, dead timer, load balancing server selection, or issue a manual test command to verify server status.

Use the following commands as appropriate for troubleshooting the RADIUS Server Load Balancing feature:

- The **debug aaa test** command can be used to determine when the idle timer or dead timer has expired, when test packets are sent, the status of the server, or to verify server state.

- The **debug aaa sg-server selection** command can be used to examine which server is being selected for load balancing.
- The **test aaa group** command can be used to manually verify RADIUS load-balanced server status.

SUMMARY STEPS

1. **debug aaa test**
2. **debug aaa sg-server selection**
3. **test aaa group group-name username password new-code**

DETAILED STEPS

Step 1 The idle timer is used to check the server status and is updated with or without any incoming requests. It is useful to monitor the idle timer to determine if there are nonresponsive servers and to keep your RADIUS server status updated in order to efficiently utilize your available resources. For instance, an updated idle timer would help ensure that incoming requests are being sent to servers that are alive.

The dead timer is used either to determine that a server is dead or to update a dead server's status appropriately.

Monitoring server selection can help you determine how often the server selection changes. This is effective in analyzing if there is a bottleneck, a large number of queued up requests, or if only specific servers are processing incoming requests.

For example, the following debug output shows when the idle-timer has expired:

```
Router# debug aaa test
```

```
Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) quarantined.
Jul 16 00:07:01: AAA/SG/TEST: Sending test request(s) to server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Sending 1 Access-Requests, 1 Accounting-Requests in current batch.
Jul 16 00:07:01: AAA/SG/TEST(Req#: 1): Sending test AAA Access-Request.
Jul 16 00:07:01: AAA/SG/TEST(Req#: 1): Sending test AAA Accounting-Request.
Jul 16 00:07:01: AAA/SG/TEST: Obtained Test response from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Obtained Test response from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Necessary responses received from server (192.0.2.245:1700,1701)
Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) marked ALIVE. Idle timer set for 60 sec(s).
Jul 16 00:07:01: AAA/SG/TEST: Server (192.0.2.245:1700,1701) removed from quarantine.
```

Step 2 For example, the following debug output shows 5 access requests being sent to a server group with a batch size of 3:

```
Router# debug aaa sg-server selection
```

```
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [3] transactions remaining in batch. Reusing server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [2] transactions remaining in batch. Reusing server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [1] transactions remaining in batch. Reusing server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
```

```

Jul 16 03:15:05: AAA/SG/SERVER_SELECT: No more transactions in batch. Obtaining a new
server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining a new least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[0] load: 3
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[1] load: 0
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Server[2] load: 0
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Selected Server[1] with load 0
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [3] transactions remaining in batch.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: Obtaining least loaded server.
Jul 16 03:15:05: AAA/SG/SERVER_SELECT: [2] transactions remaining in batch. Reusing
server.

```

Step 3 The following example shows the response from a load-balanced RADIUS server that is alive when the username “test” does not match a user profile. The server is verified alive when it issues an Access-Reject response to a AAA packet generated by the **test aaa group** command.

```
Router# test aaa group SG1 test lab new-code
```

```

00:06:07: RADIUS/ENCODE(00000000):Orig. component type = INVALID

Configuration Examples for RADIUS Server Load Balancing

This section provides the following RADIUS Server Load Balancing feature configuration examples:

- [Global RADIUS Server Group: Examples, page 9](#)
- [Named RADIUS Server Group: Examples, page 11](#)
- [Idle Timer Monitoring: Examples, page 13](#)
- [Preferred Server with the Same Authentication and Authorization Server: Example](#)
- [Preferred Server with Different Authentication and Authorization Servers: Example](#)
- [Preferred Server with Overlapping Authentication and Authorization Servers: Example](#)
- [Preferred Server with Authentication Servers As a Subset of Authorization Servers: Example](#)
- [Preferred Server with Authentication Servers As a Superset of Authorization Servers: Example](#)

Global RADIUS Server Group: Examples

The following example shows how to enable load balancing for global RADIUS server groups. It is shown in three parts: the current configuration of RADIUS command output, debug output, and AAA server status information. You can use the delimiting characters to display only the relevant parts of the configuration.

Server Configuration and Enabling Load Balancing for Global RADIUS Server Group: Example

The following shows the relevant RADIUS configuration.

```
Router# show running-config | include radius
```

```
aaa authentication ppp default group radius
aaa accounting network default start-stop group radius
radius-server host 192.0.2.238 auth-port 2095 acct-port 2096 key cisco
radius-server host 192.0.2.238 auth-port 2015 acct-port 2016 key cisco
radius-server load-balance method least-outstanding batch-size 5
```

The lines in the current configuration of RADIUS command output above are defined as follows:

- The **aaa authentication ppp** command authenticates all PPP users using RADIUS.
- The **aaa accounting** command enables the sending of all accounting requests to the AAA server once the client is authenticated and after the disconnect using the keyword **start-stop**.
- The **radius-server host** command defines the IP address of the RADIUS server host with the authorization and accounting ports specified and the authentication and encryption key identified.
- The **radius-server load-balance** command enables load balancing for the global radius server groups with the batch size specified.

Debug Output for Global RADIUS Server Group: Example

The debug output below shows the selection of preferred server and processing of requests for the configuration above.

```
Router# show debug
```

```
General OS:
```

```
AAA server group server selection debugging is on
```

```
#
```

```
<sending 10 pppoe requests>
```

```
Router#
```

```

```

The output shows the status of two RADIUS servers. Both servers are up and, in the last 2 minutes, have successfully processed:

- 5 out of 6 authentication requests
- 5 out of 5 accounting requests

Named RADIUS Server Group: Examples

The following example shows load balancing enabled for a named RADIUS server group. It is shown in three parts: the current configuration of RADIUS command output, debug output, and AAA server status information.

Server Configuration and Enabling Load Balancing for Named RADIUS Server Group: Example

The following shows the relevant RADIUS configuration.

```

Router# show running-config
.
.
.
aaa group server radius server-group1
  server 192.0.2.238 auth-port 2095 acct-port 2096
  server 192.0.2.238 auth-port 2015 acct-port 2016
  load-balance method least-outstanding batch-size 5
!
aaa authentication ppp default group server-group1
aaa accounting network default start-stop group server-group1
.
.
.

```

The lines in the current configuration of RADIUS command output above are defined as follows:

- The **aaa group server radius** command shows the configuration of a server group with two member servers.
- The **load-balance** command enables load balancing for the global radius server groups with the batch size specified.
- The **aaa authentication ppp** command authenticates all PPP users using RADIUS.
- The **aaa accounting** command enables the sending of all accounting requests to the AAA server once the client is authenticated and after the disconnect using the **start-stop** keyword.

Debug Output for Named RADIUS Server Group: Example

The debug output below shows the selection of preferred server and processing of requests for the configuration above.

```

Router#

```

```

*Feb 28 13:51:16.019:AAA/SG/SERVER_SELECT(0000002C):No preferred server available.

```

Server Status Information for Named RADIUS Server Group Example

The output below shows the AAA server status for the named RADIUS server group configuration example.

```
Router# show aaa servers
```

```

RADIUS:id 8, priority 1, host 192.0.2.238, auth-port 2095, acct-port 2096
State:current UP, duration 3781s, previous duration 0s

```

```

Dead:total time 0s, count 0
Quarantined:No
Authen:request 0, timeouts 0
      Response:unexpected 0, server error 0, incorrect 0, time 0ms
      Transaction:success 0, failure 0
Author:request 0, timeouts 0
      Response:unexpected 0, server error 0, incorrect 0, time 0ms
      Transaction:success 0, failure 0
Account:request 0, timeouts 0
      Response:unexpected 0, server error 0, incorrect 0, time 0ms
      Transaction:success 0, failure 0
Elapsed time since counters last cleared:0m

RADIUS:id 9, priority 2, host 192.0.2.238, auth-port 2015, acct-port 2016
State:current UP, duration 3781s, previous duration 0s
Dead:total time 0s, count 0
Quarantined:No
Authen:request 0, timeouts 0
      Response:unexpected 0, server error 0, incorrect 0, time 0ms
      Transaction:success 0, failure 0
Author:request 0, timeouts 0
      Response:unexpected 0, server error 0, incorrect 0, time 0ms
      Transaction:success 0, failure 0
Account:request 0, timeouts 0
      Response:unexpected 0, server error 0, incorrect 0, time 0ms
      Transaction:success 0, failure 0
Elapsed time since counters last cleared:0m

```

The output shows the status of two RADIUS servers. Both servers are alive, and no requests have been processed since the counters were cleared 0 minutes ago.

Idle Timer Monitoring: Examples

The following example shows idle timer and related server state for load balancing enabled for a named RADIUS server group. It is shown in two parts: the current configuration of RADIUS command output and debug output.

Server Configuration and Enabling Load Balancing for Idle Timer Monitoring: Example

The following shows the relevant RADIUS configuration.

```

Router# show running-config | include radius

aaa group server radius server-group1
radius-server host 192.0.2.238 auth-port 2095 acct-port 2096 test username junk1 idle-time
1 key cisco
radius-server host 192.0.2.238 auth-port 2015 acct-port 2016 test username junk1 idle-time
1 key cisco
radius-server load-balance method least-outstanding batch-size 5

```

The lines in the current configuration of RADIUS command output above are defined as follows:

- The **aaa group server radius** command shows the configuration of a server group.
- The **radius-server host** command defines the IP address of the RADIUS server host with the authorization and accounting ports specified and the authentication and encryption key identified.

- The **radius-server load-balance** command enables load balancing for the radius server with the batch size specified.

Debug Output for Idle Timer Monitoring: Example

The debug output below shows the test requests being sent to servers. The response to the test request sent to the server is received, the server is removed from quarantine as appropriate, marked alive, and then the idle timer is reset.

```
Router#
*Feb 28 13:52:20.835:AAA/SG/TEST:Server (192.0.2.238:2015,2016) quarantined.
*Feb 28 13:52:20.835:AAA/SG/TEST:Sending test request(s) to server (192.0.2.238:2015,2016)
*Feb 28 13:52:20.835:AAA/SG/TEST:Sending 1 Access-Requests, 1 Accounting-Requests in
current batch.
*Feb 28 13:52:20.835:AAA/SG/TEST(Req#:1):Sending test AAA Access-Request.
*Feb 28 13:52:20.835:AAA/SG/TEST(Req#:1):Sending test AAA Accounting-Request.
*Feb 28 13:52:21.087:AAA/SG/TEST:Obtained Test response from server
(192.0.2.238:2015,2016)
*Feb 28 13:52:22.651:AAA/SG/TEST:Obtained Test response from server
(192.0.2.238:2015,2016)
*Feb 28 13:52:22.651:AAA/SG/TEST:Necessary responses received from server
(192.0.2.238:2015,2016)
*Feb 28 13:52:22.651:AAA/SG/TEST:Server (192.0.2.238:2015,2016) marked ALIVE. Idle timer
set for 60 secs(s).
*Feb 28 13:52:22.651:AAA/SG/TEST:Server (192.0.2.238:2015,2016) removed from quarantine.
.
.
.
```

Preferred Server with the Same Authentication and Authorization Server: Example

The following example shows an authentication server group and an authorization server group that use the same servers, 209.165.200.225 and 209.165.200.226. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2

aaa group server radius accounting-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
```

Once a preferred server is selected for a session, all transactions for that session will continue to use the original preferred server. The servers 209.165.200.225 and 209.165.200.226 will be load balanced based on sessions rather than transactions.

Preferred Server with Different Authentication and Authorization Servers: Example

The following example shows an authentication server group that uses servers 209.165.200.225 and 209.165.200.226 and an authorization server group that uses servers 209.165.201.1 and 209.165.201.2. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
server 209.165.200.225 key radkey1
server 209.165.200.226 key radkey2
```

```
aaa group server radius accounting-group
server 209.165.201.1 key radkey3
server 209.165.201.2 key radkey4
```

The authentication server group and the accounting server group do not share any common servers. A preferred server will never be found for accounting transactions, therefore, authentication and accounting servers will be load balanced based on transactions. Start and stop records will be sent to the same server for a session.

Preferred Server with Overlapping Authentication and Authorization Servers: Example

The following example shows an authentication server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1 and an accounting server group that uses servers 209.165.201.1 and 209.165.201.2. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
server 209.165.200.225 key radkey1
server 209.165.200.226 key radkey2
server 209.165.201.1 key radkey3
```

```
aaa group server radius accounting-group
server 209.165.201.1 key radkey3
server 209.165.201.2 key radkey4
```

If all servers have equal transaction processing capability, one-third of all authentication transactions will be directed towards server 209.165.201.1. Therefore, one-third of all accounting transactions will also be directed towards server 209.165.201.1. The remaining two-thirds accounting transactions will be load balanced equally between servers 209.165.201.1 and 209.165.201.2. The server 209.165.201.1 will receive fewer authentication transactions since server 209.165.201.1 will have outstanding accounting transactions.

Preferred Server with Authentication Servers As a Subset of Authorization Servers: Example

The following example shows an authentication server group that uses servers 209.165.200.225 and 209.165.200.226 and an authorization server group that uses servers 209.165.200.225, 209.165.200.226, and 209.165.201.1. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2

aaa group server radius accounting-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
  server 209.165.201.1 key radkey3
```

One-half of all authentication transactions will be sent to server 209.165.200.225 and the other half to server 209.165.200.226. Servers 209.165.200.225 and 209.165.200.226 will be the preferred servers for authentication and accounting transaction, therefore there will be an equal distribution of authentication and accounting transactions across servers 209.165.200.225 and 209.165.200.226. Server 209.165.201.1 will be relatively unused.

Preferred Server with Authentication Servers As a Superset of Authorization Servers: Example

The following example shows an authentication server group that uses servers 209.165.200.225 and 209.165.200.226, and 209.165.201.1 and an authorization server group that uses servers 209.165.200.225 and 209.165.200.226. Both server groups have the preferred server flag enabled.

```
aaa group server radius authentication-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
  server 209.165.201.1 key radkey3

aaa group server radius accounting-group
  server 209.165.200.225 key radkey1
  server 209.165.200.226 key radkey2
```

Initially, one-third of authentication transactions will be assigned to each server in the authorization server group. As accounting transactions are generated for more sessions, the accounting transactions will only be sent to servers 209.165.200.225 and 209.165.200.226, since the preferred server flag is on. As servers 209.165.200.225 and 209.165.200.226 begin to process more transactions, authentication transactions will start to be sent to server 209.165.201.1. The transaction requests authenticated by server 209.165.201.1, will not have any preferred server setting and will be split between servers 209.165.200.225 and 209.165.200.226, which negates the use of the preferred server flag. This configuration should be used cautiously.

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **debug aaa sg-server selection**
- **debug aaa test**
- **load-balance (server-group)**
- **radius-server host**
- **radius-server load-balance**
- **test aaa group**

Feature Information for RADIUS Server Load Balancing

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for RADIUS Server Load Balancing

Feature Name	Releases	Feature Information
RADIUS Server Load Balancing	12.2(28)SB 12.4(11)T 12.2(33)SRC	The RADIUS Server Load Balancing feature distributes authentication, authorization, and accounting (AAA) authentication and accounting transactions across servers in a server group. These servers can then share the transaction load, resulting in faster responses to incoming requests by optimally using available servers. This feature was integrated into Cisco IOS Release 12.2(28)SB. This feature was integrated into Cisco IOS Release 12.4(11)T. This feature was integrated into Cisco IOS Release 12.2(33)SRC.
RADIUS Server Load Balancing porting	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

RADIUS Support of 56-Bit Acct Session-Id

The RADIUS Support of 56-Bit Acct Session-Id feature introduces a new 32-bit authentication, authorization, and accounting (AAA) variable, acct-session-id-count. The first eight bits of the acct-session-id-count variable are reserved for the unique identifier variable, a unique number assigned to the accounting session which is preserved between reloads. The acct-session-id-count variable is used in addition to the existing 32-bit acct-session-id variable, RADIUS attribute 44, providing a total of 56 bits of to represent the actual Accounting Session Identifier (ID). Benefits of this feature include the following:

- The 8-bit unique identifier variable allows accounting sessionIDs to be identified if a reload occurs.
- The additional space provided by the acct-session-id-count variable can keep track of acct-session-id wrapping when there is a high volume of traffic, such as voice calls. By incrementing each time the acct-session-id variable wraps, the acct-session-id-count variable preserves accounting information.

Feature Specifications for RADIUS Support of 56-Bit Acct Session-Id

Feature History

Release	Modification
12.3(2)T	This feature was introduced.

Supported Platforms

Cisco AS5300, Cisco AS5350, Cisco AS5400, Cisco AS5800, Cisco AS5850

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Prerequisites for RADIUS Support of 56-Bit Acct Session-Id

AAA accounting must be configured. For more information about configuring AAA accounting, refer to the “*Configuring Accounting*” chapter in the [Cisco IOS Security Configuration Guide](#), Release 12.2.

Information About RADIUS Support of 56-Bit Acct Session-Id

To configure the RADIUS Support of 56-bit Acct Session-Id feature, you must understand the following concepts:

- [Acct-Session-Id Attribute](#), page 2
- [Acct-Session-Id-Count Attribute](#), page 2
- [Benefits of RADIUS Support of 56-Bit Acct Session-Id](#), page 3

Acct-Session-Id Attribute

RADIUS attribute 44, Accounting Session ID, is a unique accounting identifier that makes it easy to match start and stop records in a log file. Accounting session ID numbers restart at 1 each time the router is power-cycled or the software is reloaded. RADIUS attribute 44 is automatically enabled when AAA accounting is configured.

The acct-session-id variable is a 32-bit variable that can take on values from 00000000–FFFFFFFF.

Acct-Session-Id-Count Attribute

The new acct-session-id-count variable is a 32-bit variable. The first eight bits of the variable are reserved for the unique identifier variable, an identifier that allows the RADIUS server to identify an accounting session if a reload occurs. The remaining 24 bits of the acct-session-id-count variable acts as a counter variable. When the first acct-session-id variable is assigned, this counter variable is set to 1. The variable increments by 1 every time the acct-session-id variable wraps, preventing the loss of accounting information.

The acct-session-id-count variable can take on values from ##000000–##FFFFFF, where ## represents the eight bits that are reserved for the unique identifier variable.

The acct-session-id-count and acct-session-id variables are concatenated before being sent to the RADIUS server, resulting in the acct-session variable being represented as the following:

##000000 00000000–##FFFFFF FFFFFFFF

This allows a total of 56 bits to be used for acct-session-id space.

Benefits of RADIUS Support of 56-Bit Acct Session-Id

Allows RADIUS Servers to Identify Accounting Sessions After a Reload

The 8-bit unique identifier variable allows accounting session identities to be identified if a reload occurs.

Provides Accounting Information Space for High Volume Traffic

The additional space provided by the acct-session-id-count variable can keep track of acct-session-id wrapping when there is a high volume of traffic, such as voice calls. By incrementing each time the acct-session-id variable wraps, the acct-session-id-count variable preserves accounting information.

How to Configure RADIUS Support of 56-Bit Acct Session-Id

This section contains the following procedure:

- [Configuring RADIUS Support of 56-Bit Acct Session-Id, page 3](#)

Configuring RADIUS Support of 56-Bit Acct Session-Id

This task enables the acct-session-id-count variable containing the unique identifier variable.

SUMMARY STEPS

1. `enable`
2. `radius-server unique-ident id`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	radius-server unique-ident <i>id</i> Example: Router(config)# radius-server unique-ident 5	Enables the acct-session-id-count variable containing the unique identifier variable. <ul style="list-style-type: none">• The <i>id</i> argument specifies the unique identifier represented by the first eight bits of the acct-session-id-count variable. Valid values range from 0 to 255.

Configuration Examples for RADIUS Support of 56-Bit Acct Session-Id

This section contains the following configuration example:

- [Configuring RADIUS Support of 56-Bit Acct Session-Id Example, page 4](#)

Configuring RADIUS Support of 56-Bit Acct Session-Id Example

The following example configures AAA authentication, enables RADIUS attribute 44 in access request packets, and enables the acct-session-id-count variable and sets the unique identifier variable to 5:

```
aaa new-model
aaa authentication ppp default group radius
radius-server host 10.100.1.34
radius-server unique-ident 5
```

RADIUS Tunnel Preference for Load Balancing and Fail-Over

Feature History

Release	Modification
12.2(4)T	This feature was introduced.

This document describes the RADIUS Tunnel Preference for Load Balancing and Fail-Over feature in Cisco IOS Release 12.2(4)T. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 4](#)
- [Supported Standards, MIBs, and RFCs, page 5](#)
- [Prerequisites, page 5](#)
- [Configuration Tasks, page 5](#)
- [Configuration Example, page 6](#)
- [Command Reference, page 6](#)
- [Glossary, page 6](#)

Feature Overview

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature provides load balancing and fail-over virtual private dialup network (VPDN) home gateway (HGW) groups in a standardized fashion. This feature introduces new software functionality; no new command is associated with this feature.

Industry-Standard Rather Than Proprietary Attributes

Until Cisco IOS Release 12.2(4)T, load balancing and fail-over functionality for a Layer 2 Tunnel Protocol network server (LNS) was provided by the Cisco proprietary Vendor Specific Attribute (VSA). In a multivendor network environment, using VSA on a RADIUS server can cause interoperability issues

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

among network access servers (NASs) manufactured by different vendors. Even though some RADIUS server implementations can send VSAs that the requesting NAS can understand, the user still must maintain different VSAs for the same purpose in a single-service profile.

A consensus regarding the tunnel attributes that are to be used in a multivendor network environment is defined in RFC 2868. In RFC 2868, Tunnel-Server-Endpoint, in conjunction with the Tunnel-Medium-Type, specifies the address to which the NAS should initiate a new session. If multiple Tunnel-Server-Endpoint attributes are defined in one tagged attribute group, they are interpreted as equal-cost load-balancing HGWs.

The Tunnel-Preference attribute defined in RFC 2868 can be used as a measure to form load balancing and fail-over HGW groups. When the Tunnel-Preference values of different tagged attribute groups are the same, the Tunnel-Server-Endpoint of those attribute groups is considered to have the same priority unless otherwise specified. When the Tunnel-Preference values of some attribute groups are higher (they have a lower preference) than other attribute groups, their Tunnel-Server-Endpoint attributes will have higher priority values. When an attribute group has a higher priority value, that attribute group will be used for fail-over in case the attribute groups with lower priority values are unavailable for the connections.

Until Cisco IOS Release 12.2(4)T, a specially formatted string would be transported within a Cisco VSA “vpdn:ip-addresses” string to a NAS for the purpose of HGW load balancing and fail-over. For example, 10.0.0.1 10.0.0.2 10.0.0.3/2.0.0.1 2.0.0.2 would be interpreted as IP addresses 10.0.0.1, 10.0.0.2, and 10.0.0.3 for the first group for load balancing. New sessions are projected to these three addresses based on the least-load-first algorithm. This algorithm uses its local knowledge to select an HGW that has the least load to initiate the new session. In this example, the addresses 2.0.0.1 and 2.0.0.2 in the second group have a lower priority and are applicable only when all HGWs specified in the first group fail to respond to the new connection request, thereby making 2.0.0.1 and 2.0.0.2 the fail-over addresses. See the section “[Configuration Example](#)” for an example of how to configure these fail-over addresses in a RADIUS tunnel profile.

Load Balancing and Fail-Over in a Multivendor Network

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature was designed for large multivendor networks that use VPDN Layer 2 tunnels over WAN links such as ATM and Ethernet, such as the configuration shown in [Figure 1](#).

Figure 1 Typical Load Balancing and Fail-Over in a Multivendor Network

In the configuration shown in [Figure 1](#), the NAS uses tunnel profiles downloaded from the RADIUS server to establish VPDN Layer 2 tunnels for load balancing and fail-over. The Point-to-Point over Ethernet (PPPoE) protocol is used as the client to generate PPP sessions.

Benefits

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature provides industry-standard load balancing and fail-over functionality for an LNS, rather than requiring the use of a Cisco proprietary VSA. The feature conforms to the tunnel attributes that are to be used in a multivendor network environment as defined in RFC 2868, thereby eliminating interoperability issues among NASs manufactured by different vendors.

Restrictions

The following restrictions and limitations apply to the RADIUS Tunnel Preference for Load Balancing and Fail-Over feature:

- This feature does not support VPDN dial-out networks; it is designed only for dial-in applications.
- The maximum number of LNSs allowed in the network is 1550, which is 50 per tag attribute group and a limit of 31 tags.
- This feature requires a RADIUS server implementation to support RFC 2868.

Related Features and Technologies

The RADIUS Tunnel Preference for Load Balancing and Fail-Over feature is used in VPDNs. Additionally, familiarity with the following technologies and protocols is recommended:

- ATM
- Ethernet
- L2TP and L2F
- PPP and PPPoE
- RADIUS servers

See the next section for a list of documentation that describes these technologies and protocols.

Supported Platforms

This feature is platform independent and was either developed for or tested on the following Cisco routers:

- Cisco 800 series
- Cisco 1600 series
- Cisco 1700 series
- Cisco 2600 series
- Cisco 3600 series
- Cisco 7100 series
- Cisco 7200 series

See the next section for information about Feature Navigator and how to use this tool to determine the platforms and software images in which this feature is available.

Determining Platform Support Through Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Feature Navigator. Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image.

To access Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at <http://www.cisco.com/register>.

Feature Navigator is updated when major Cisco IOS software releases and technology releases occur. As of May 2001, Feature Navigator supports M, T, E, S, and ST releases. You can access Feature Navigator at the following URL:

<http://www.cisco.com/go/fn>

Supported Standards, MIBs, and RFCs

Standards

None

MIBs

None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

RFCs

RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*

Prerequisites

Configuring VPDNs and HGW groups is beyond the scope of this document. Refer to the documentation listed in the section “[Related Documents](#)” for the tasks and commands to configure these types of networks.

Configuration Tasks

This feature has no new configuration commands; however, see the next section for an example of how to implement the RADIUS Tunnel Preference for Load Balancing and Fail-Over feature in a RADIUS tunnel profile.

Configuration Example

The following example shows how to create RADIUS tunnel profiles:

```
net3 Password = "cisco" Service-Type = Outbound
    Tunnel-Type = :0:L2TP,
    Tunnel-Medium-Type = :0:IP,
    Tunnel-Server-Endpoint = :0:"1.1.3.1",
    Tunnel-Assignment-Id = :0:"1",
    Tunnel-Preference = :0:1,
    Tunnel-Password = :0:"welcome"

    Tunnel-Type = :1:L2TP,
    Tunnel-Medium-Type = :1:IP,
    Tunnel-Server-Endpoint = :1:"1.1.5.1",
    Tunnel-Assignment-Id = :1:"1",
    Tunnel-Preference = :1:1,
    Tunnel-Password = :1:"welcome"

    Tunnel-Type = :2:L2TP,
    Tunnel-Medium-Type = :2:IP,
    Tunnel-Server-Endpoint = :2:"1.1.4.1",
    Tunnel-Assignment-Id = :2:"1",
    Tunnel-Preference = :2:1,
    Tunnel-Password = :2:"welcome"

    Tunnel-Type = :3:L2TP,
    Tunnel-Medium-Type = :3:IP,
    Tunnel-Server-Endpoint = :3:"1.1.6.1",
    Tunnel-Assignment-Id = :3:"1",
    Tunnel-Preference = :3:1,
    Tunnel-Password = :3:"welcome"
```

The section [“Feature Overview”](#) describes how fail-over addresses are selected in these profiles. The section [“Related Documents”](#) lists documentation that describes how to create RADIUS tunnel profiles.

Command Reference

None

Glossary

HGW—home gateway. A gateway that terminates Layer 2 tunneling protocols such as L2TP.

home gateway—See HGW.

L2TP—Layer 2 Tunnel Protocol. An Internet Engineering Task Force (IETF) standards track protocol defined in RFC 2661 that provides tunneling of PPP. Based upon the best features of L2F and PPTP, L2TP provides an industry-wide interoperable method of implementing VPDN.

L2TP network server—See LNS.

Layer 2 Tunnel Protocol—See L2TP.

LNS—L2TP network server. A node that acts as one side of an L2TP tunnel endpoint and is a peer to the NAS or L2TP access concentrator (LAC). The LNS is the logical termination point of a PPP session that is being tunneled from the remote system by the access server. Analogous to the Layer 2 Forwarding (L2F) HGW.

NAS—network access server. Cisco platform or collection of platforms that interfaces between the packet world (the Internet, for example) and the circuit world (the public switched telephone network, for example).

network access server—See NAS.

Request for Comments—See RFCs.

RFCs—Request for Comments. A series of notes about the Internet collected by the Internet Engineering Task Force (IETF). Started in 1969, the IETF is a large open international community of network designers, operators, vendors, and researchers concerned with the evolution of the Internet architecture. RFCs define many aspects of computer communication, focusing on networking protocols, procedures, programs, and concepts.

virtual private dialup network—See VPDN.

VPDN—virtual private dialup network. Enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic from one network to another.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

RADIUS Server Reorder on Failure

First Published: May 19, 2003

Last Updated: December 17, 2007

The RADIUS Server Reorder on Failure feature provides for failover to another server in the server group during periods of high load or when server failure occurs. Subsequent to the failure, all RADIUS traffic is directed to the new server. Traffic is switched from the new server to another server in the server group only if the new server also fails. Traffic is not automatically switched back to the first server.

By spreading the RADIUS transactions across multiple servers, authentication and accounting requests are serviced more quickly.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your Cisco IOS software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for RADIUS Server Reorder on Failure](#)” section on [page 12](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

© 2003, 2006–2007 Cisco Systems, Inc. All rights reserved.

- [Feature Information for RADIUS Server Reorder on Failure, page 12](#)

Prerequisites for RADIUS Server Reorder on Failure

- Before you can configure your RADIUS server to perform reorder on failure, you must enable authentication, authorization, and accounting (AAA) by using the **aaa new-model** command. (Refer to the chapter “[AAA Overview](#)” in the *Cisco IOS Security Configuration Guide*, Release 12.3.)
- You must also have RADIUS configured, for functions such as authentication, accounting, or static route download.

Restrictions for RADIUS Server Reorder on Failure

- An additional 4 bytes of memory is required per server group. However, because most server configurations have only a small number of server groups configured, the additional 4 bytes should have a minimal impact on performance.
- Some RADIUS features within the Cisco IOS software set may not be capable of using this feature. If a RADIUS feature cannot use the RADIUS Server Reorder on Failure feature, your server behaves as though the reorder feature is not configured.

Information About RADIUS Server Reorder on Failure

To configure the RADIUS Server Reorder on Failure feature, you must understand the following concepts:

- [RADIUS Server Failure, page 2](#)
- [How the RADIUS Server Reorder on Failure Feature Works, page 3](#)

RADIUS Server Failure

If the RADIUS Server Reorder on Failure feature is not configured and server failure occurs:

1. A new RADIUS transaction has to be performed.
2. A RADIUS packet for the transaction is sent to the first server in the group that is not marked dead (as per the configured deadtime) and is retransmitted for the configured number of retransmissions.
3. If all of those retransmits time out (as per the configured timeout), the router transmits the packet to the next nondead server in the list for the configured number of retransmissions.
4. Step 3 is repeated until the specified maximum number of transmissions per transaction have been made. If the end of the list is reached before the maximum number of transmissions has been reached, the router goes back to the beginning of the list and continue from there.

If at any time during this process, a server meets the dead-server detection criteria (not configurable; it varies depending on the version of Cisco IOS software being used), the server is marked as dead for the configured deadtime.

How the RADIUS Server Reorder on Failure Feature Works

If you have configured the RADIUS Server Reorder on Failure feature, the decision about which RADIUS server to use as the initial server is as follows:

- The network access server (NAS) maintains the status of “flagged” server, which is the first server to which a transmission is sent.
- After the transmission is sent to the flagged server, the transmission is sent to the flagged server again for the configured number of retransmissions.
- The NAS then sequentially sends the transmission through the list of nondead servers in the server group, starting with the one listed after the flagged server, until the configured transaction maximum tries is reached or until a response is received.
- At boot time, the flagged server is the first server in the server group list as was established using the **radius-server host** command.
- If the flagged server is marked as dead (even if the dead time is zero), the first nondead server listed after the flagged server becomes the flagged server.
- If the flagged server is the last server in the list, and it is marked as dead, the flagged server becomes the first server in the list that is not marked as dead.
- If all servers are marked as dead, the transaction fails, and no change is made to the flagged server.
- If the flagged server is marked as dead, and the dead timer expires, nothing happens.

**Note**

Some types of transmissions (for example, Challenge Handshake Authentication Protocol [CHAP], Microsoft CHAP [MS-CHAP], and Extensible Authentication Protocol [EAP]) require multiple roundtrips to a single server. For these special transactions, the entire sequence of roundtrips to the server are treated as though they were one transmission.

When RADIUS Servers Are Dead

A server can be marked as dead if the criteria in 1 and 2 are met:

1. The server has not responded to at least the configured number of retransmissions as specified by the **radius-server transaction max-tries** command.
2. The server has not responded to any request for at least the configured timeout. The server is marked dead only if both criteria (this and the one listed above) are met. The marking of a server as dead, even if the dead time is zero, is significant for the RADIUS server retry method reorder system.

How to Configure RADIUS Server Reorder on Failure

This section contains the following procedures.

- [Configuring a RADIUS Server to Reorder on Failure, page 4](#) (required)
- [Monitoring RADIUS Server Reorder on Failure, page 5](#) (optional)

Configuring a RADIUS Server to Reorder on Failure

Perform this task to configure a server in a server group to direct traffic to another server in the server group when the first server fails.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **radius-server retry method reorder**
5. **radius-server retransmit {retries}**
6. **radius-server transaction max-tries {number}**
1. **radius-server host {hostname | ip-address} [key string]**
2. **radius-server host {hostname | ip-address} [key string]**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Router (config)# aaa new-model	Enables the AAA access control model.
Step 4	radius-server retry method reorder Example: Router (config)# radius-server retry method reorder	Specifies the reordering of RADIUS traffic retries among a server group.
Step 5	radius-server retransmit {retries} Example: Router (config)# radius-server retransmit 1	Specifies the number of times the Cisco IOS software searches the list of RADIUS server hosts before giving up. The <i>retries</i> argument is the maximum number of retransmission attempts. The default is 3 attempts.

	Command or Action	Purpose
Step 6	radius-server transaction max-tries <i>{number}</i> Example: Router (config)# radius-server transaction max-tries 3	Specifies the maximum number of transmissions per transaction that may be retried on a RADIUS server. The <i>number</i> argument is the total number of transmissions per transaction. If this command is not configured, the default is eight transmissions. Note This command is global across all RADIUS servers for a given transaction.
Step 7	radius-server host <i>{hostname ip-address}</i> [key <i>string</i>] Example: Router (config)# radius-server host 10.2.3.4 key radi23	Specifies a RADIUS server host. Note You can also configure a global key for all RADIUS servers that do not have a per-server key configured by issuing the radius-server key command.
Step 8	radius-server host <i>{hostname ip-address}</i> [key <i>string</i>] Example: Router (config)# radius-server host 10.5.6.7 key rad234	Specifies a RADIUS server host. Note At least two servers must be configured.

Monitoring RADIUS Server Reorder on Failure

To monitor the server-reorder-on-failure process on your router, use the following commands:

SUMMARY STEPS

1. **enable**
2. **debug aaa sg-server selection**
3. **debug radius**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	debug aaa sg-server selection Example: Router# debug aaa sg-server selection	Displays information about why the RADIUS and TACAC+ server group system in the router is choosing a particular server.
Step 3	debug radius Example: Router# debug radius	Displays information about why the router is choosing a particular RADIUS server.

Examples

The following two debug outputs display the behavior of the RADIUS Server Reorder on Failure feature:

Debug 1

In the following sample output, the RADIUS Server Reorder on Failure feature is configured. The server retransmits are set to 0 (so each server is tried just one time before failover to the next configured server), and the transmissions per transaction are set to 4 (the transmissions stop on the third failover). The third server in the server group (10.107.164.118) has accepted the transaction on the third transmission (second failover).

Configuration Examples for RADIUS Server Reorder on Failure

This section provides the following configuration examples:

- [Configuring a RADIUS Server to Reorder on Failure Example, page 8](#)
- [Determining Transmission Order When RADIUS Servers Are Dead, page 8](#)

Configuring a RADIUS Server to Reorder on Failure Example

The following configuration example shows that a RADIUS server is configured to reorder on failure. The maximum number of transmissions per transaction that may be retried on the RADIUS server is six.

```
aaa new-model
radius-server retry method reorder
radius-server retransmit 0
radius-server transaction max-tries 6
radius-server host 10.2.3.4 key rad123
radius-server host 10.5.6.7 key rad123
```

Determining Transmission Order When RADIUS Servers Are Dead

If at boot time you have configured the following:

```
aaa new-model
radius-server retry method reorder
radius-server retransmit 0
radius-server transaction max-tries 6
radius-server host 10.2.3.4
radius-server host 10.5.6.7
```

and both servers are down, but not yet marked dead, for the first transaction you would see the transmissions as follows:

```
10.2.3.4
10.5.6.7
10.2.3.4
10.5.6.7
10.2.3.4
10.5.6.7
```

If you configure the reorder as follows:

```
aaa new-model
radius-server retry method reorder
radius-server retransmit 1
radius-server transaction max-tries 3
radius-server host 10.2.3.4
radius-server host 10.4.5.6
```

and both RADIUS servers are not responding to RADIUS packets but are not yet marked dead (as after the NAS boots), the transmissions for the first transaction are as follows:

```
10.2.3.4
10.2.3.4
10.4.5.6
```

Subsequent transactions may be transmitted according to a different pattern. The transmissions depend on whether the criteria for marking one (or both) servers as dead have been met, and as per the server flagging pattern already described.

If you configure the reorder as follows:

```
aaa new-model
radius-server retry method reorder
radius-server retransmit 1
radius-server max-tries-per-transaction 8
radius-server host 10.1.1.1
radius-server host 10.2.2.2
radius-server host 10.3.3.3
radius-server timeout 3
```

And the RADIUS server 10.1.1.1 is not responding to RADIUS packets but is not yet marked as dead, and the remaining two RADIUS servers are live, you see the following:

For the first transaction:

```
10.1.1.1
10.1.1.1
10.2.2.2
```

For any additional transaction initiated for any transmissions before the server is marked as dead:

```
10.1.1.1
10.1.1.1
10.2.2.2
```

For transactions initiated thereafter:

```
10.2.2.2
```

If servers 10.2.2.2 and 10.3.3.3 then go down as well, you see the following transmissions until servers 10.2.2.2 and 10.3.3.3 meet the criteria for being marked as dead:

```
10.2.2.2
10.2.2.2
10.3.3.3
10.3.3.3
10.1.1.1
10.1.1.1
10.2.2.2
10.2.2.2
```

The above is followed by the failure of the transmission and by the next method in the method list being used (if any).

If servers 10.2.2.2 and 10.3.3.3 go down but server 10.1.1.1 comes up at the same time, you see the following:

```
10.2.2.2
10.2.2.2
10.3.3.3
10.3.3.3
10.1.1.1
```

When servers 10.2.2.2 and 10.3.3.3 are then marked as dead, you see the following:

```
10.1.1.1
```

- **radius-server transaction max-tries**

Feature Information for RADIUS Server Reorder on Failure

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for RADIUS Server Reorder on Failure

Feature Name	Releases	Feature Information
RADIUS Server Reorder on Failure	12.3(1) 12.2(28)SB 12.2(33)SRC Cisco IOS XE Release 2.1	The RADIUS Server Reorder on Failure feature provides for failover to another server in the server group during periods of high load or when server failure occurs. This feature was introduced in 12.3(1). This feature was integrated into Cisco IOS Release 12.2(28)SB. This feature was integrated into Cisco IOS Release 12.2(33)SRC. In Cisco IOS XE Release 2.1, this feature was introduced on Cisco ASR 1000 Series Routers. The following commands were introduced or modified by this feature: debug aaa sg-server selection, radius-server retry method reorder, radius-server transaction max-tries.

Feature Overview

The Tunnel Authentication via RADIUS on Tunnel Terminator feature allows the Layer 2 Tunneling Protocol (L2TP) network server (LNS) to perform remote authentication and authorization with RADIUS on incoming L2TP access concentrator (LAC) dialin connection requests. This feature also allows the L2TP LAC to perform remote authentication and authorization with RADIUS on incoming L2TP LNS dialout connection requests.

Before the introduction of this feature, the LNS could only perform L2TP tunnel authentication and authorization locally. These processes can be difficult to maintain across numerous LNSs, especially if the number of virtual private dialup network (VPDN) groups is large, because the LAC information must be configured under the VPDN group configurations of the LNS. Remote RADIUS authentication and authorization allows users to store the LAC configurations on the RADIUS server, thereby avoiding the

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

need to store information locally. Thus, the new LAC information can be added to the RADIUS server as necessary, and the group of LNSs can authenticate and authorize by using a common user database on RADIUS.

Figure 1 and the corresponding steps explain how this feature works.

Figure 1 *LNS Remote RADIUS Tunnel Authentication and Authorization for L2TP Dialin Calls Topology*

- After the LNS receives a start-control-connection request (SCCRQ), it starts tunnel authentication and submits a request to RADIUS with the LAC hostname and the dummy password “cisco.” (If the LNS determines that authorization should be performed locally, it will search the VPDN group configurations.)

Note To change the dummy password, use the **vpdn tunnel authorization password** command.

- If the password sent by the LNS matches the password that is configured in the RADIUS server, the server will return attribute 90 (Tunnel-Client-Auth-ID) and attribute 69 (Tunnel-Password) after the LAC information is located. Otherwise, the RADIUS server replies back with an access-reject, and the LNS drops the tunnel.
- The LNS will check for the following attribute information from the RADIUS reply:
 - Attribute 90 (Tunnel-Client-Auth-ID), which is used as the LAC hostname. If this attribute does not match the LAC hostname, the tunnel will be dropped.
 - Attribute 69 (Tunnel-Password), which is used for the L2TP CHAP-like authentication shared secret. This attribute is compared against the LAC challenge attribute-value pair (AVP) that was received in the SCCRQ. If this attribute does not match the AVP, the tunnel will be dropped.
- If both attributes match, the L2TP tunnel will be established. Thereafter, you can proceed with PPP negotiation and authentication with the remote client.

Note PPP remote authentication is done to a potential different customer RADIUS server by a separate access-request/access-accept sequence. The tunnel authorization may be done by a different tunnel RADIUS server.

New RADIUS Attributes

To help implement this feature, the following two new Cisco-specific RADIUS attributes have been introduced:

- Cisco:Cisco-Avpair = “vpdn:dout-dialer = <LAC dialer number>”—Specifies which LAC dialer to use on the LAC for a dialout configuration.
- Cisco:Cisco-Avpair = “vpdn:vpdn-vtemplate = <vtemplate number>”—Specifies the virtual template number that will be used for cloning on the LNS for a dialin configuration. (This attribute is the RADIUS counterpart for the virtual-template under the vpdn-group configuration.)

**Note**

The service-type in the RADIUS user’s profile for the tunnel initiator should always be set to “Outbound.”

Benefits

This feature allows tunnel authentication and authorization to occur via a remote RADIUS server instead of local configuration on the tunnel terminator. Thus, users no longer have to configure LAC or LNS data in a VPDN group when an LNS or LAC is configured for incoming dialin or dialout L2TP tunnel termination; this information can now be added to a remote RADIUS server, providing a more manageable and scalable solution for L2TP tunnel authentication and authorization on the tunnel terminator.

Restrictions

This is applicable only to L2TP; that is, protocols such as (Layer 2 Forwarding) L2F and Point-to-Point Tunneling Protocol (PPTP) are not supported.

Supported Platforms

- Cisco 6400 series
- Cisco 7200 series
- Cisco 7400 series

Availability of Cisco IOS Software Images

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

Supported Standards, MIBs, and RFCs

Standards

None

MIBs

None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

RFCs

RFC 2868, *RADIUS Attributes for Tunnel Protocol Support*

Prerequisites

Before configuring this feature, you should define a RADIUS server group. For information on completing this task, refer to the chapter “Configuring RADIUS” in the *Cisco IOS Security Configuration Guide*, Release 12.2.

Configuration Tasks

See the following sections for configuration tasks for the Tunnel Authentication via RADIUS on Tunnel Terminator feature. Each task in the list is identified as either required or optional.

- [Configuring the LNS or LAC for Remote RADIUS Tunnel Authentication and Authorization](#) (required)
- [Verifying Remote RADIUS Tunnel Authentication and Authorization Configurations](#) (optional)

Configuring the LNS or LAC for Remote RADIUS Tunnel Authentication and Authorization

To configure an LNS or LAC for incoming dialin or dialout L2TP tunnel termination, use the following commands in global configuration:

	Command	Purpose
Step 1	Router(config)# aaa authorization network { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]	Defines an AAA authorization method list for network services.
Step 2	Router(config)# vpdn tunnel authorization network { <i>method-list-name</i> default }	Specifies the AAA authorization method list that will be used for remote tunnel hostname-based authorization. <ul style="list-style-type: none"> If the <i>list-name</i> argument was specified in the aaa authorization command, you use that list name here. If the default keyword was specified in the aaa authorization command, you must choose that keyword, which specifies the default authorization methods that are listed with the aaa authorization command here.
Step 3	Router(config)# vpdn tunnel authorization virtual-template <i>vtemplate-number</i>	(Optional) Selects the default virtual template from which to clone virtual access interfaces.
Step 4	Router(config)# vpdn tunnel authorization password <i>password</i>	(Optional) Configures a “dummy” password for the RADIUS authorization request to retrieve the tunnel configuration that is based on the remote tunnel hostname. <p>Note If this command is not enabled, the password will always be “cisco.”</p>

Verifying Remote RADIUS Tunnel Authentication and Authorization Configurations

To verify that the L2TP tunnel is up, use the **show vpdn tunnel** command in EXEC mode. One tunnel and one session must be set up.

```
Router# show vpdn tunnel
```

```
L2TP Tunnel and Session Information Total tunnels 1 sessions 1
LocID RemID Remote Name  State Remote Address  Port  Sessions VPDN Group
4571  61568 csidtw13 est    10.0.195.4      1701  1         ?
```

```
LocID RemID TunID Intf      Username                      State Last Chg
4      11      4571 Vi4.1      csidtw9@cisco.com            est   00:02:29
```

```
%No active L2F tunnels
%No active PPTP tunnels
%No active PPPoE tunnels
```

To verify that the AAA authorization RADIUS server is configured on the LNS and that the LNS can receive attributes 90 and 69 from the RADIUS server, perform the following steps:

Step 1 Enable the **debug radius** command on the LNS.

Step 2 Enable the **show logging** command on the LNS and ensure that “access-accept” is in the output and that attributes 90 and 69 can be seen in the RADIUS reply.

```
00:32:56: RADIUS: Received from id 21645/5 172.19.192.50:1645, Access-Accept, len 81
00:32:56: RADIUS:  authenticator 73 2B 1B C2 33 71 93 19 - 62 AC 3E BE 0D 13 14 85
00:32:56: RADIUS:  Service-Type      [6]  6  Outbound                               [5]
00:32:56: RADIUS:  Tunnel-Type      [64]  6  00:L2TP                               [3]
00:32:56: RADIUS:  Tunnel-Medium-Type [65]  6  00:IPv4                               [1]
```

```

00:32:56: RADIUS: Tunnel-Client-Auth-I[90] 6 00:"csidtwl3"
00:32:56: RADIUS: Tunnel-Password [69] 8 *
00:32:56: RADIUS: Vendor, Cisco [26] 29
00:32:56: RADIUS: Cisco AVpair [1] 23 "vpdn:vpdn-vtemplate=1"

```

To verify that the L2TP tunnel has been established and that the LNS can perform PPP negotiation and authentication with the remote client, perform the following steps:

-
- Step 1** Enable the **debug ppp negotiation** and **debug ppp authentication** commands on LNS.
- Step 2** Enable the **show logging** command on LNS and observe that LNS receives a PPP CHAP challenge and then sends a PPP CHAP “SUCCESS” to the client.

```

00:38:50: ppp3 PPP: Received LOGIN Response from AAA = PASS
00:38:50: ppp3 PPP: Phase is FORWARDING, Attempting Forward
00:38:50: Vi4.1 Tnl/Sn4571/4 L2TP: Session state change from wait-for-service-selection
to established
00:38:50: Vi4.1 PPP: Phase is AUTHENTICATING, Authenticated User
00:38:50: Vi4.1 CHAP: O SUCCESS id 1 len 4

```

- Step 3** After PPP authentication is successful, observe from the debug output that PPP negotiation has started, that the LNS has received LCP (IPCP) packets, and that negotiation is successful.

```

00:38:50: Vi4.1 IPCP: State is Open
00:38:50: Vi4.1 IPCP: Install route to 200.1.1.4

```

Configuration Examples

This section provides the following configuration examples:

- [L2TP Network Server \(LNS\) Configuration Example](#)
- [RADIUS User Profile for Remote RADIUS Tunnel Authentication Example](#)

L2TP Network Server (LNS) Configuration Example

The following example shows how to configure the LNS to enable remote RADIUS tunnel authentication and authorization:

```

! Define a RADIUS server group
aaa group server radius VPDN-group
 server 64.102.48.91 auth-port 1645 acct-port 1646
!
! RADIUS configurations only
aaa authorization network mymethodlist group VPDN-Group
vpdn tunnel authorization network mymethodlist
vpdn tunnel authorization virtual-template 10

```

RADIUS User Profile for Remote RADIUS Tunnel Authentication Example

The following are examples of RADIUS user profiles for the LNS to terminate L2TP tunnels from a LAC. In the first user profile, the final line is optional if the **vpdn tunnel authorization virtual-template** command is used. Also, the first RADIUS user profile is for L2TP dialin, and the second RADIUS user profile is for L2TP dialout.

The service-type in the RADIUS user's profile for the tunnel initiator should always be set to "Outbound."

```
csidtw13 Password = "cisco"
        Service-Type = Outbound,
        Tunnel-Type = :0:L2TP,
        Tunnel-Medium-Type = :0:IP,
        Tunnel-Client-Auth-ID = :0:"csidtw13",
        Tunnel-Password = :0:"cisco"
        Cisco:Cisco-Avpair = "vpdn:vpdn-vtemplate=1"

csidtw1 Password = "cisco"
        Service-Type = Outbound,
        Tunnel-Type = :0:L2TP,
        Tunnel-Medium-Type = :0:IP,
        Tunnel-Client-Auth-ID = :0:"csidtw1",
        Tunnel-Password = :0:"cisco"
        Cisco:Cisco-Avpair = "vpdn:dout-dialer=2"
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **vpdn tunnel authorization network**
- **vpdn tunnel authorization password**
- **vpdn tunnel authorization virtual-template**

Glossary

L2TP—Layer 2 Tunnel Protocol. A Layer 2 tunneling protocol that enables an ISP or other access service to create a virtual tunnel to link customer remote sites or remote users with corporate home networks. In particular, a network access server (NAS) at the ISP point of presence (POP) exchanges PPP messages with the remote users and communicates by L2F or L2TP requests and responses with the customer tunnel server to set up tunnels.

LAC—L2TP access concentrator. A network access server (NAS) to which the client directly connects and through which PPP frames are tunneled to the L2TP network server (LNS). The LAC need only implement the media over which L2TP is to operate to pass traffic to one or more LNSs. The LAC may tunnel any protocol carried within PPP. The LAC initiates incoming calls and receives outgoing calls. A LAC is analogous to an L2F network access server.

LNS—L2TP network server. A termination point for L2TP tunnels and an access point where PPP frames are processed and passed to higher layer protocols. An LNS can operate on any platform that terminates PPP. The LNS handles the server side of the L2TP protocol. L2TP relies only on the single medium over which L2TP tunnels arrive. The LNS initiates outgoing calls and receives incoming calls. An LNS is analogous to a home gateway in L2F technology.

TACACS+

Configuring TACACS+

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This chapter discusses how to enable and configure TACACS+, which provides detailed accounting information and flexible administrative control over authentication and authorization processes. TACACS+ is facilitated through AAA and can be enabled only through AAA commands.

For a complete description of the TACACS+ commands used in this chapter, refer to the chapter “TACACS+ Commands” in the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature, or refer to the software release notes for a specific release. For more information, see the section “Identifying Supported Platforms” in the chapter “Using Cisco IOS Software.”

In This Chapter

About TACACS+

TACACS+ is a security application that provides centralized validation of users attempting to gain access to a router or network access server. TACACS+ services are maintained in a database on a TACACS+ daemon running, typically, on a UNIX or Windows NT workstation. You must have access to and must configure a TACACS+ server before the configured TACACS+ features on your network access server are available.

TACACS+ provides for separate and modular authentication, authorization, and accounting facilities. TACACS+ allows for a single access control server (the TACACS+ daemon) to provide each service—authentication, authorization, and accounting—independently. Each service can be tied into its own database to take advantage of other services available on that server or on the network, depending on the capabilities of the daemon.

The goal of TACACS+ is to provide a methodology for managing multiple network access points from a single management service. The Cisco family of access servers and routers and the Cisco IOS user interface (for both routers and access servers) can be network access servers.

Network access points enable traditional “dumb” terminals, terminal emulators, workstations, personal computers (PCs), and routers in conjunction with suitable adapters (for example, modems or ISDN adapters) to communicate using protocols such as Point-to-Point Protocol (PPP), Serial Line Internet Protocol (SLIP), Compressed SLIP (CSLIP), or AppleTalk Remote Access (ARA) protocol. In other words, a network access server provides connections to a single user, to a network or subnetwork, and to interconnected networks. The entities connected to the network through a network access server are called *network access clients*; for example, a PC running PPP over a voice-grade circuit is a network access client. TACACS+, administered through the AAA security services, can provide the following services:

- **Authentication**—Provides complete control of authentication through login and password dialog, challenge and response, messaging support.

The authentication facility provides the ability to conduct an arbitrary dialog with the user (for example, after a login and password are provided, to challenge a user with a number of questions, like home address, mother’s maiden name, service type, and social security number). In addition, the TACACS+ authentication service supports sending messages to user screens. For example, a message could notify users that their passwords must be changed because of the company’s password aging policy.
- **Authorization**—Provides fine-grained control over user capabilities for the duration of the user’s session, including but not limited to setting autocommands, access control, session duration, or protocol support. You can also enforce restrictions on what commands a user may execute with the TACACS+ authorization feature.
- **Accounting**—Collects and sends information used for billing, auditing, and reporting to the TACACS+ daemon. Network managers can use the accounting facility to track user activity for a security audit or to provide information for user billing. Accounting records include user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

The TACACS+ protocol provides authentication between the network access server and the TACACS+ daemon, and it ensures confidentiality because all protocol exchanges between a network access server and a TACACS+ daemon are encrypted.

You need a system running TACACS+ daemon software to use the TACACS+ functionality on your network access server.

Cisco makes the TACACS+ protocol specification available as a draft RFC for those customers interested in developing their own TACACS+ software.

TACACS+ Operation

When a user attempts a simple ASCII login by authenticating to a network access server using TACACS+, the following process typically occurs:

1. When the connection is established, the network access server will contact the TACACS+ daemon to obtain a username prompt, which is then displayed to the user. The user enters a username and the network access server then contacts the TACACS+ daemon to obtain a password prompt. The network access server displays the password prompt to the user, the user enters a password, and the password is then sent to the TACACS+ daemon.

**Note**

TACACS+ allows an arbitrary conversation to be held between the daemon and the user until the daemon receives enough information to authenticate the user. This is usually done by prompting for a username and password combination, but may include other items, such as mother's maiden name, all under the control of the TACACS+ daemon.

2. The network access server will eventually receive one of the following responses from the TACACS+ daemon:
 - a. **ACCEPT**—The user is authenticated and service may begin. If the network access server is configured to require authorization, authorization will begin at this time.
 - b. **REJECT**—The user has failed to authenticate. The user may be denied further access, or will be prompted to retry the login sequence depending on the TACACS+ daemon.
 - c. **ERROR**—An error occurred at some time during authentication. This can be either at the daemon or in the network connection between the daemon and the network access server. If an **ERROR** response is received, the network access server will typically try to use an alternative method for authenticating the user.
 - d. **CONTINUE**—The user is prompted for additional authentication information.
3. A PAP login is similar to an ASCII login, except that the username and password arrive at the network access server in a PAP protocol packet instead of being typed in by the user, so the user is not prompted. PPP CHAP logins are also similar in principle.

Following authentication, the user will also be required to undergo an additional authorization phase, if authorization has been enabled on the network access server. Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

4. If TACACS+ authorization is required, the TACACS+ daemon is again contacted and it returns an **ACCEPT** or **REJECT** authorization response. If an **ACCEPT** response is returned, the response will contain data in the form of attributes that are used to direct the **EXEC** or **NETWORK** session for that user, determining services that the user can access.

Services include the following:

- a. Telnet, rlogin, Point-to-Point Protocol (PPP), Serial Line Internet Protocol (SLIP), or EXEC services
- b. Connection parameters, including the host or client IP address, access list, and user timeouts

TACACS+ Configuration Task List

To configure your router to support TACACS+, you must perform the following tasks:

- Use the **aaa new-model** global configuration command to enable AAA. AAA must be configured if you plan to use TACACS+. For more information about using the **aaa new-model** command, refer to the chapter “AAA Overview”.
- Use the **tacacs-server host** command to specify the IP address of one or more TACACS+ daemons. Use the **tacacs-server key** command to specify an encryption key that will be used to encrypt all exchanges between the network access server and the TACACS+ daemon. This same key must also be configured on the TACACS+ daemon.
- Use the **aaa authentication** global configuration command to define method lists that use TACACS+ for authentication. For more information about using the **aaa authentication** command, refer to the chapter “Configuring Authentication”.
- Use **line** and **interface** commands to apply the defined method lists to various interfaces. For more information, refer to the chapter “Configuring Authentication”.
- If needed, use the **aaa authorization** global command to configure authorization for the network access server. Unlike authentication, which can be configured per line or per interface, authorization is configured globally for the entire network access server. For more information about using the **aaa authorization** command, refer to the “Configuring Authorization” chapter.
- If needed, use the **aaa accounting** command to enable accounting for TACACS+ connections. For more information about using the **aaa accounting** command, refer to the “Configuring Accounting” chapter.

To configure TACACS+, perform the tasks in the following sections:

- [Identifying the TACACS+ Server Host](#) (Required)
- [Setting the TACACS+ Authentication Key](#) (Optional)
- [Configuring AAA Server Groups](#) (Optional)
- [Configuring AAA Server Group Selection Based on DNIS](#) (Optional)
- [Specifying TACACS+ Authentication](#) (Required)
- [Specifying TACACS+ Authorization](#) (Optional)
- [Specifying TACACS+ Accounting](#) (Optional)

For TACACS+ configuration examples using the commands in this chapter, refer to the “[TACACS+ Configuration Examples](#)” section at the end of this chapter.

Identifying the TACACS+ Server Host

The **tacacs-server host** command enables you to specify the names of the IP host or hosts maintaining a TACACS+ server. Because the TACACS+ software searches for the hosts in the order specified, this feature can be useful for setting up a list of preferred daemons.

To specify a TACACS+ host, use the following command in global configuration mode:

Command	Purpose
Router(config)# tacacs-server host <i>hostname</i> [single-connection] [port <i>integer</i>] [timeout <i>integer</i>] [key <i>string</i>]	Specifies a TACACS+ host.

Using the **tacacs-server host** command, you can also configure the following options:

- Use the **single-connection** keyword to specify single-connection (only valid with CiscoSecure Release 1.0.1 or later). Rather than have the router open and close a TCP connection to the daemon each time it must communicate, the single-connection option maintains a single open connection between the router and the daemon. This is more efficient because it allows the daemon to handle a higher number of TACACS operations.

Note The daemon must support single-connection mode for this to be effective, otherwise the connection between the network access server and the daemon will lock up or you will receive spurious errors.

- Use the **port** *integer* argument to specify the TCP port number to be used when making connections to the TACACS+ daemon. The default port number is 49.
- Use the **timeout** *integer* argument to specify the period of time (in seconds) the router will wait for a response from the daemon before it times out and declares an error.

Note Specifying the timeout value with the **tacacs-server host** command overrides the default timeout value set with the **tacacs-server timeout** command for this server only.

- Use the **key** *string* argument to specify an encryption key for encrypting and decrypting all traffic between the network access server and the TACACS+ daemon.

Note Specifying the encryption key with the **tacacs-server host** command overrides the default key set by the global configuration **tacacs-server key** command for this server only.

Because some of the parameters of the **tacacs-server host** command override global settings made by the **tacacs-server timeout** and **tacacs-server key** commands, you can use this command to enhance security on your network by uniquely configuring individual TACACS+ connections.

Setting the TACACS+ Authentication Key

To set the global TACACS+ authentication key and encryption key, use the following command in global configuration mode:

Command	Purpose
Router(config)# tacacs-server key <i>key</i>	Sets the encryption key to match that used on the TACACS+ daemon.

Note You must configure the same key on the TACACS+ daemon for encryption to be successful.

Configuring AAA Server Groups

Configuring the router to use AAA server groups provides a way to group existing server hosts. This allows you to select a subset of the configured server hosts and use them for a particular service. A server group is used in conjunction with a global server-host list. The server group lists the IP addresses of the selected server hosts.

Server groups can include multiple host entries as long as each entry has a unique IP address. If two different host entries in the server group are configured for the same service—for example, accounting—the second host entry configured acts as fail-over backup to the first one. Using this example, if the first host entry fails to provide accounting services, the network access server will try the second host entry for accounting services. (The TACACS+ host entries will be tried in the order in which they are configured.)

To define a server host with a server group name, enter the following commands starting in global configuration mode. The listed server must exist in global configuration mode:

	Command	Purpose
Step 1	Router(config)# tacacs-server host <i>name</i> [single-connection] [port <i>integer</i>] [timeout <i>integer</i>] [key <i>string</i>]	Specifies and defines the IP address of the server host before configuring the AAA server-group. Refer to the “ Identifying the TACACS+ Server Host ” section of this chapter for more information on the tacacs-server host command.
Step 2	Router(config-if)# aaa group server { radius tacacs+ } <i>group-name</i>	Defines the AAA server-group with a group name. All members of a group must be the same type; that is, RADIUS or TACACS+. This command puts the router in server group subconfiguration mode.
Step 3	Router(config-sg)# server <i>ip-address</i> [auth-port <i>port-number</i>] [acct-port <i>port-number</i>]	Associates a particular TACACS+ server with the defined server group. Use the auth-port <i>port-number</i> option to configure a specific UDP port solely for authentication. Use the acct-port <i>port-number</i> option to configure a specific UDP port solely for accounting. Repeat this step for each TACACS+ server in the AAA server group. Note Each server in the group must be defined previously using the tacacs-server host command.

Configuring AAA Server Group Selection Based on DNIS

Cisco IOS software allows you to authenticate users to a particular AAA server group based on the Dialed Number Identification Service (DNIS) number of the session. Any phone line (a regular home phone or a commercial T1/PRI line) can be associated with several phone numbers. The DNIS number identifies the number that was called to reach you.

For example, suppose you want to share the same phone number with several customers, but you want to know which customer is calling before you pick up the phone. You can customize how you answer the phone because DNIS allows you to know which customer is calling when you answer.

Cisco routers with either ISDN or internal modems can receive the DNIS number. This functionality allows users to assign different TACACS+ server groups for different customers (that is, different TACACS+ servers for different DNIS numbers). Additionally, using server groups you can specify the same server group for AAA services or a separate server group for each AAA service.

Cisco IOS software provides the flexibility to implement authentication and accounting services in several ways:

- Globally—AAA services are defined using global configuration access list commands and applied in general to all interfaces on a specific network access server.
- Per interface—AAA services are defined using interface configuration commands and applied specifically to the interface being configured on a specific network access server.
- DNIS mapping—You can use DNIS to specify an AAA server to supply AAA services.

Because AAA configuration methods can be configured simultaneously, Cisco has established an order of precedence to determine which server or groups of servers provide AAA services. The order of precedence is as follows:

- Per DNIS—If you configure the network access server to use DNIS to identify which server group provides AAA services, then this method takes precedence over any additional AAA selection method.
- Per interface—If you configure the network access server per interface to use access lists to determine how a server provides AAA services, this method takes precedence over any global configuration AAA access lists.
- Globally—If you configure the network access server by using global AAA access lists to determine how the security server provides AAA services, this method has the lowest precedence.

Note

Prior to configuring AAA Server Group Selection Based on DNIS, you must configure the remote security servers associated with each AAA server group. See the sections [“Identifying the TACACS+ Server Host”](#) and [“Configuring AAA Server Groups”](#) in this chapter.

To configure the router to select a particular AAA server group based on the DNIS of the server group, configure DNIS mapping. To map a server group with a group name with DNIS number, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# aaa dnis map enable	Enables DNIS mapping.
Step 2	Router(config)# aaa dnis map <i>dnis-number</i> authentication ppp group <i>server-group-name</i>	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for authentication.
Step 3	Router(config)# aaa dnis map <i>dnis-number</i> accounting network [none start-stop stop-only] group <i>server-group-name</i>	Maps a DNIS number to a defined AAA server group; the servers in this server group are being used for accounting.

Specifying TACACS+ Authentication

After you have identified the TACACS+ daemon and defined an associated TACACS+ encryption key, you must define method lists for TACACS+ authentication. Because TACACS+ authentication is operated via AAA, you need to issue the **aaa authentication** command, specifying TACACS+ as the authentication method. For more information, refer to the chapter “Configuring Authentication.”

Specifying TACACS+ Authorization

AAA authorization enables you to set parameters that restrict a user’s access to the network. Authorization via TACACS+ may be applied to commands, network connections, and EXEC sessions. Because TACACS+ authorization is facilitated through AAA, you must issue the **aaa authorization** command, specifying TACACS+ as the authorization method. For more information, refer to the chapter “Configuring Authorization.”

Specifying TACACS+ Accounting

AAA accounting enables you to track the services users are accessing as well as the amount of network resources they are consuming. Because TACACS+ accounting is facilitated through AAA, you must issue the **aaa accounting** command, specifying TACACS+ as the accounting method. For more information, refer to the chapter “Configuring Accounting.”

TACACS+ AV Pairs

The network access server implements TACACS+ authorization and accounting functions by transmitting and receiving TACACS+ attribute-value (AV) pairs for each user session. For a list of supported TACACS+ AV pairs, refer to the appendix “TACACS+ Attribute-Value Pairs.”

TACACS+ Configuration Examples

The following sections provide TACACS+ configuration examples:

- [TACACS+ Authentication Examples](#)
- [TACACS+ Authorization Example](#)
- [TACACS+ Accounting Example](#)
- [TACACS+ Server Group Example](#)
- [AAA Server Group Selection Based on DNIS Example](#)
- [TACACS+ Daemon Configuration Example](#)

TACACS+ Authentication Examples

The following example shows how to configure TACACS+ as the security protocol for PPP authentication:

```
aaa new-model
```

```
aaa authentication ppp test group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
 ppp authentication chap pap test
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “test,” to be used on serial interfaces running PPP. The keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the test method list to this line.

The following example shows how to configure TACACS+ as the security protocol for PPP authentication, but instead of the “test” method list, the “default” method list is used.

```
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
 ppp authentication chap default
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

The following example shows how to create the same authentication algorithm for PAP, but it calls the method list “MIS-access” instead of “default”:

```
aaa new-model
aaa authentication pap MIS-access if-needed group tacacs+ local
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
 ppp authentication pap MIS-access
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.

- The **aaa authentication** command defines a method list, “MIS-access,” to be used on serial interfaces running PPP. The method list, “MIS-access,” means that PPP authentication is applied to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

The following example shows the configuration for a TACACS+ daemon with an IP address of 10.2.3.4 and an encryption key of “apple”:

```
aaa new-model
aaa authentication login default group tacacs+ local
tacacs-server host 10.2.3.4
tacacs-server key apple
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines the default method list. Incoming ASCII logins on all interfaces (by default) will use TACACS+ for authentication. If no TACACS+ server responds, then the network access server will use the information contained in the local username database for authentication.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.2.3.4. The **tacacs-server key** command defines the shared encryption key to be “apple.”

TACACS+ Authorization Example

The following example shows how to configure TACACS+ as the security protocol for PPP authentication using the default method list; it also shows how to configure network authorization via TACACS+:

```
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
aaa authorization network default group tacacs+
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
  ppp authentication chap default
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done

through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.

- The **aaa authorization** command configures network authorization via TACACS+. Unlike authentication lists, this authorization list always applies to all incoming network connections made to the network access server.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

TACACS+ Accounting Example

The following example shows how to configure TACACS+ as the security protocol for PPP authentication using the default method list; it also shows how to configure accounting via TACACS+:

```
aaa new-model
aaa authentication ppp default if-needed group tacacs+ local
aaa accounting network default stop-only group tacacs+
tacacs-server host 10.1.2.3
tacacs-server key goaway
interface serial 0
  ppp authentication chap default
```

The lines in the preceding sample configuration are defined as follows:

- The **aaa new-model** command enables the AAA security services.
- The **aaa authentication** command defines a method list, “default,” to be used on serial interfaces running PPP. The keyword **default** means that PPP authentication is applied by default to all interfaces. The **if-needed** keyword means that if the user has already authenticated by going through the ASCII login procedure, then PPP authentication is not necessary and can be skipped. If authentication is needed, the keyword **group tacacs+** means that authentication will be done through TACACS+. If TACACS+ returns an ERROR of some sort during authentication, the keyword **local** indicates that authentication will be attempted using the local database on the network access server.
- The **aaa accounting** command configures network accounting via TACACS+. In this example, accounting records describing the session that just terminated will be sent to the TACACS+ daemon whenever a network connection terminates.
- The **tacacs-server host** command identifies the TACACS+ daemon as having an IP address of 10.1.2.3. The **tacacs-server key** command defines the shared encryption key to be “goaway.”
- The **interface** command selects the line, and the **ppp authentication** command applies the default method list to this line.

TACACS+ Server Group Example

The following example shows how to create a server group with three different TACACS+ servers members:

```
aaa group server tacacs tacgroup1
  server 172.16.1.1
  server 172.16.1.21
```

```
server 172.16.1.31
```

AAA Server Group Selection Based on DNIS Example

The following example shows how to select TACACS+ server groups based on DNIS to provide specific AAA services:

```
! This command enables AAA.
aaa new-model
!
! The following set of commands configures the TACACS+ servers that will be associated
! with one of the defined server groups.
tacacs-server host 172.16.0.1
tacacs-server host 172.17.0.1
tacacs-server host 172.18.0.1
tacacs-server host 172.19.0.1
tacacs-server host 172.20.0.1
tacacs-server key abcdefg

! The following commands define the sg1 TACACS+ server group and associate servers
! with it.
aaa group server tacacs sg1
    server 172.16.0.1
    server 172.17.0.1
! The following commands define the sg2 TACACS+ server group and associate a server
! with it.
aaa group server tacacs sg2
    server 172.18.0.1
! The following commands define the sg3 TACACS+ server group and associate a server
! with it.
aaa group server tacacs sg3
    server 172.19.0.1
! The following commands define the default-group TACACS+ server group and associate
! a server with it.
aaa group server tacacs default-group
    server 172.20.0.1
!
! The next set of commands configures default-group tacacs server group parameters.
aaa authentication ppp default group default-group
aaa accounting network default start-stop group default-group
!
! The next set of commands enables DNIS mapping and maps DNIS numbers to the defined
! RADIUS server groups. In this configuration, all PPP connection requests using DNIS
! 7777 are sent to the sg1 server group. The accounting records for these connections
! (specifically, start-stop records) are handled by the sg2 server group. Calls with a
! DNIS of 8888 use server group sg3 for authentication and server group default-group
! for accounting. Calls with a DNIS of 9999 use server group default-group for
! authentication and server group sg3 for accounting records (stop records only). All
! other calls with DNIS other than the ones defined use the server group default-group
! for both authentication and stop-start accounting records.
aaa dnis map enable
aaa dnis map 7777 authentication ppp group sg1
aaa dnis map 7777 accounting network start-stop group sg2
aaa dnis map 8888 authentication ppp group sg3
aaa dnis map 9999 accounting network stop-only group sg3
```

TACACS+ Daemon Configuration Example

The following example shows a sample configuration of the TACACS+ daemon. The precise syntax used by your TACACS+ daemon may be different from what is included in this example.

```
user = mci_customer1 {  
  chap = cleartext "some chap password"  
  service = ppp protocol = ip {  
    inacl#1="permit ip any any precedence immediate"  
    inacl#2="deny igrp 0.0.1.2 255.255.0.0 any"  
  }  
}
```

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

REVIEW DRAFT - CISCO CONFIDENTIAL

Per VRF for TACACS+ Servers

First Published: March 1, 2004

Last Updated: September 30, 2008

The Per VRF for TACACS+ Servers feature allows per virtual route forwarding (per VRF) to be configured for authentication, authorization, and accounting (AAA) on TACACS+ servers.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Per VRF for TACACS+ Servers”](#) section on page 8.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

REVIEW DRAFT – CISCO CONFIDENTIAL

Prerequisites for Per VRF for TACACS+ Servers

- TACACS+ server access is required.
- Experience configuring TACACS+, AAA and per VRF AAA, and group servers is necessary.

Restrictions for Per VRF for TACACS+ Servers

- The VRF instance must be specified before per VRF for a TACACS+ server is configured.

Information About Per VRF for TACACS+ Servers

To configure the Per VRF for TACACS+ Servers feature, the following concept should be understood:

- [Per VRF for TACACS+ Servers Overview, page 2](#)

Per VRF for TACACS+ Servers Overview

The Per VRF for TACACS+ Servers feature allows per VRF AAA to be configured on TACACS+ servers. Prior to Cisco IOS Release 12.3(7)T, this functionality was available only on RADIUS servers.

How to Configure Per VRF for TACACS+ Servers

This section contains the following procedures:

- [Configuring Per VRF on a TACACS+ Server, page 2](#) (required)
- [Verifying Per VRF for TACACS+ Servers, page 4](#) (optional)

Configuring Per VRF on a TACACS+ Server

The initial steps in this procedure are used to configure AAA and a server group, create a VRF routing table, and configure an interface. Steps 10 through 13 are used to configure the per VRF on a TACACS+ server feature:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip vrf *vrf-name***
4. **rd *route-distinguisher***
5. **exit**
6. **interface *interface-name***
7. **ip vrf forwarding *vrf-name***

REVIEW DRAFT – CISCO CONFIDENTIAL

8. **ip address** *ip-address mask* [**secondary**]
9. **exit**
10. **aaa group server tacacs+** *group-name*
11. **server-private** {*ip-address* | *name*} [**nat**] [**single-connection**] [**port** *port-number*] [**timeout** *seconds*] [**key** [**0** | **7**] *string*]
12. **ip vrf forwarding** *vrf-name*
13. **ip tacacs source-interface** *subinterface-name*
14. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip vrf <i>vrf-name</i> Example: Router (config)# ip vrf cisco	Configures a VRF table and enters VRF configuration mode.
Step 4	rd <i>route-distinguisher</i> Example: Router (config-vrf)# rd 100:1	Creates routing and forwarding tables for a VRF instance.
Step 5	exit Example: Router (config-vrf)# exit	Exits VRF configuration mode.
Step 6	interface <i>interface-name</i> Example: Router (config)# interface Loopback0	Configures an interface and enters interface configuration mode.
Step 7	ip vrf forwarding <i>vrf-name</i> Example: Router (config-if)# ip vrf forwarding cisco	Configures a VRF for the interface.
Step 8	ip address <i>ip-address mask</i> [secondary] Example: Router (config-if)# ip address 10.0.0.2 255.0.0.0	Sets a primary or secondary IP address for an interface.

REVIEW DRAFT—CISCO CONFIDENTIAL

	Command or Action	Purpose
Step 9	exit Example: Router (config-if)# exit	Exits interface configuration mode.
Step 10	aaa group server tacacs+ group-name Example: Router (config)# aaa group server tacacs+ tacacs1	Groups different TACACS+ server hosts into distinct lists and distinct methods and enters server-group configuration mode.
Step 11	server-private {ip-address name} [nat] [single-connection] [port port-number] [timeout seconds] [key [0 7] string] Example: Router (config-sg-tacacs+)# server-private 10.1.1.1 port 19 key cisco	Configures the IP address of the private TACACS+ server for the group server.
Step 12	ip vrf forwarding vrf-name Example: Router (config-sg-tacacs+)# ip vrf forwarding cisco	Configures the VRF reference of a AAA TACACS+ server group.
Step 13	ip tacacs source-interface subinterface-name Example: Router (config-sg-tacacs+)# ip tacacs source-interface Loopback0	Uses the IP address of a specified interface for all outgoing TACACS+ packets.
Step 14	exit Example: Router (config-sg-tacacs)# exit	Exits server-group configuration mode.

Verifying Per VRF for TACACS+ Servers

To verify the per VRF TACACS+ configuration, perform the following steps:

**Note**

The **debug** commands may be used in any order.

SUMMARY STEPS

1. **enable**
2. **debug tacacs authentication**
3. **debug tacacs authorization**
4. **debug tacacs accounting**
5. **debug tacacs packets**

REVIEW DRAFT – CISCO CONFIDENTIAL**DETAILED STEPS**

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	debug tacacs authentication Example: Router# debug tacacs authentication	Displays information about AAA/TACACS+ authentication.
Step 3	debug tacacs authorization Example: Router# debug tacacs authorization	Displays information about AAA/TACACS+ authorization.
Step 4	debug tacacs accounting Example: Router# debug tacacs accounting	Displays information about accountable events as they occur.
Step 5	debug tacacs packets Example: Router# debug tacacs packets	Displays information about TACACS+ packets.

Configuration Examples for Per VRF for TACACS+ Servers

This section includes the following configuration example:

- [Configuring Per VRF for TACACS+ Servers: Example, page 5](#)

Configuring Per VRF for TACACS+ Servers: Example

The following output example shows that the group server **tacacs1** is configured for per VRF AAA services:

```

aaa group server tacacs+ tacacs1
  server-private 10.1.1.1 port 19 key cisco
  ip vrf forwarding cisco
  ip tacacs source-interface Loopback0

ip vrf cisco
rd 100:1

interface Loopback0
ip address 10.0.0.2 255.0.0.0
ip vrf forwarding cisco

```

Configuring Kerberos

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This chapter describes the Kerberos security system. For a complete description of the Kerberos commands used in this chapter, refer to the “Kerberos Commands” chapter in the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature, or refer to the software release notes for a specific release. For more information, see the section “Identifying Supported Platforms” in the chapter “Using Cisco IOS Software.”

In This Chapter

This chapter includes the following topics and tasks:

- [About Kerberos](#)
- [Kerberos Client Support Operation](#)
- [Kerberos Configuration Task List](#)
- [Kerberos Configuration Examples](#)

About Kerberos

Kerberos is a secret-key network authentication protocol, developed at the Massachusetts Institute of Technology (MIT), that uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication. Kerberos was designed to authenticate requests for network resources.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Kerberos, like other secret-key systems, is based on the concept of a trusted third party that performs secure verification of users and services. In the Kerberos protocol, this trusted third party is called the key distribution center (KDC).

The primary use of Kerberos is to verify that users and the network services they use are really who and what they claim to be. To accomplish this, a trusted Kerberos server issues tickets to users. These tickets, which have a limited lifespan, are stored in a user's credential cache and can be used in place of the standard username-and-password authentication mechanism.

The Kerberos credential scheme embodies a concept called "single logon." This process requires authenticating a user once, and then allows secure authentication (without encrypting another password) wherever that user's credential is accepted.

Starting with Cisco IOS Release 11.2, Cisco IOS software includes Kerberos 5 support, which allows organizations already deploying Kerberos 5 to use the same Kerberos authentication database on their routers that they are already using on their other network hosts (such as UNIX servers and PCs).

The following network services are supported by the Kerberos authentication capabilities in Cisco IOS software:

- Telnet
- rlogin
- rsh
- rcp

Note

Cisco Systems' implementation of Kerberos client support is based on code developed by CyberSafe, which was derived from the MIT code. As a result, the Cisco Kerberos implementation has successfully undergone full compatibility testing with the CyberSafe Challenger commercial Kerberos server and MIT's server code, which is freely distributed.

[Table 20](#) lists common Kerberos-related terms and their definitions.

Table 20 ***Kerberos Terminology***

Term	Definition
authentication	A process by which a user or service identifies itself to another service. For example, a client can authenticate to a router or a router can authenticate to another router.
authorization	A means by which the router determines what privileges you have in a network or on the router and what actions you can perform.
credential	A general term that refers to authentication tickets, such as ticket granting tickets (TGTs) and service credentials. Kerberos credentials verify the identity of a user or service. If a network service decides to trust the Kerberos server that issued a ticket, it can be used in place of retyping in a username and password. Credentials have a default lifespan of eight hours.

Table 20 **Kerberos Terminology (continued)**

Term	Definition
instance	An authorization level label for Kerberos principals. Most Kerberos principals are of the form user@REALM (for example, smith@EXAMPLE.COM). A Kerberos principal with a Kerberos instance has the form user/instance@REALM (for example, smith/admin@EXAMPLE.COM). The Kerberos instance can be used to specify the authorization level for the user if authentication is successful. It is up to the server of each network service to implement and enforce the authorization mappings of Kerberos instances. Note that the Kerberos realm name must be in uppercase characters.
Kerberized	Applications and services that have been modified to support the Kerberos credential infrastructure.
Kerberos realm	A domain consisting of users, hosts, and network services that are registered to a Kerberos server. The Kerberos server is trusted to verify the identity of a user or network service to another user or network service. Kerberos realms must always be in uppercase characters.
Kerberos server	A daemon running on a network host. Users and network services register their identity with the Kerberos server. Network services query the Kerberos server to authenticate to other network services.
key distribution center (KDC)	A Kerberos server and database program running on a network host.
principal	Also known as a Kerberos identity, this is who you are or what a service is according to the Kerberos server.
service credential	A credential for a network service. When issued from the KDC, this credential is encrypted with the password shared by the network service and the KDC, and with the user's TGT.
SRVTAB	A password that a network service shares with the KDC. The network service authenticates an encrypted service credential by using the SRVTAB (also known as a KEYTAB) to decrypt it.
ticket granting ticket (TGT)	A credential that the key distribution center (KDC) issues to authenticated users. When users receive a TGT, they can authenticate to network services within the Kerberos realm represented by the KDC.

Kerberos Client Support Operation

This section describes how the Kerberos security system works with a Cisco router functioning as the security server. Although (for convenience or technical reasons) you can customize Kerberos in a number of ways, remote users attempting to access network services must pass through three layers of security before they can access network services.

This section includes the following sections:

- [Authenticating to the Boundary Router](#)
- [Obtaining a TGT from a KDC](#)
- [Authenticating to Network Services](#)

Authenticating to the Boundary Router

This section describes the first layer of security that remote users must pass through when they attempt to access a network. The first step in the Kerberos authentication process is for users to authenticate themselves to the boundary router. The following process describes how users authenticate to a boundary router:

1. The remote user opens a PPP connection to the corporate site router.
2. The router prompts the user for a username and password.
3. The router requests a TGT from the KDC for this particular user.
4. The KDC sends an encrypted TGT to the router that includes (among other things) the user's identity.
5. The router attempts to decrypt the TGT using the password the user entered. If the decryption is successful, the remote user is authenticated to the router.

A remote user who successfully initiates a PPP session and authenticates to the boundary router is inside the firewall but still must authenticate to the KDC directly before being allowed to access network services. This is because the TGT issued by the KDC is stored on the router and is not useful for additional authentication unless the user physically logs on to the router.

Obtaining a TGT from a KDC

This section describes how remote users who are authenticated to the boundary router authenticate themselves to a KDC.

When a remote user authenticates to a boundary router, that user technically becomes part of the network; that is, the network is extended to include the remote user and the user's machine or network. To gain access to network services, however, the remote user must obtain a TGT from the KDC. The following process describes how remote users authenticate to the KDC:

1. The remote user, at a workstation on a remote site, launches the KINIT program (part of the client software provided with the Kerberos protocol).
2. The KINIT program finds the user's identity and requests a TGT from the KDC.
3. The KDC creates a TGT, which contains the identity of the user, the identity of the KDC, and the expiration time of the TGT.
4. Using the user's password as a key, the KDC encrypts the TGT and sends the TGT to the workstation.
5. When the KINIT program receives the encrypted TGT, it prompts the user for a password (this is the password that is defined for the user in the KDC).
6. If the KINIT program can decrypt the TGT with the password the user enters, the user is authenticated to the KDC, and the KINIT program stores the TGT in the user's credential cache.

At this point, the user has a TGT and can communicate securely with the KDC. In turn, the TGT allows the user to authenticate to other network services.

Authenticating to Network Services

The following process describes how a remote user with a TGT authenticates to network services within a given Kerberos realm. Assume the user is on a remote workstation (Host A) and wants to log in to Host B.

1. The user on Host A initiates a Kerberized application (such as Telnet) to Host B.
2. The Kerberized application builds a service credential request and sends it to the KDC. The service credential request includes (among other things) the user's identity and the identity of the desired network service. The TGT is used to encrypt the service credential request.
3. The KDC tries to decrypt the service credential request with the TGT it issued to the user on Host A. If the KDC can decrypt the packet, it is assured that the authenticated user on Host A sent the request.
4. The KDC notes the network service identity in the service credential request.
5. The KDC builds a service credential for the appropriate network service on Host B on behalf of the user on Host A. The service credential contains the client's identity and the desired network service's identity.
6. The KDC then encrypts the service credential twice. It first encrypts the credential with the SRVTAB that it shares with the network service identified in the credential. It then encrypts the resulting packet with the TGT of the user (who, in this case, is on Host A).
7. The KDC sends the twice-encrypted credential to Host A.
8. Host A attempts to decrypt the service credential with the user's TGT. If Host A can decrypt the service credential, it is assured the credential came from the real KDC.
9. Host A sends the service credential to the desired network service. Note that the credential is still encrypted with the SRVTAB shared by the KDC and the network service.
10. The network service attempts to decrypt the service credential using its SRVTAB.
11. If the network service can decrypt the credential, it is assured the credential was in fact issued from the KDC. Note that the network service trusts anything it can decrypt from the KDC, even if it receives it indirectly from a user. This is because the user first authenticated with the KDC.

At this point, the user is authenticated to the network service on Host B. This process is repeated each time a user wants to access a network service in the Kerberos realm.

Kerberos Configuration Task List

For hosts and the KDC in your Kerberos realm to communicate and mutually authenticate, you must identify them to each other. To do this, you add entries for the hosts to the Kerberos database on the KDC and add SRVTAB files generated by the KDC to all hosts in the Kerberos realm. You also make entries for users in the KDC database.

This section describes how to set up a Kerberos-authenticated server-client system and contains the following topics:

- [Configuring the KDC Using Kerberos Commands](#)
- [Configuring the Router to Use the Kerberos Protocol](#)

This section assumes that you have installed the Kerberos administrative programs on a UNIX host, known as the KDC, initialized the database, and selected a Kerberos realm name and password. For instructions about completing these tasks, refer to documentation that came with your Kerberos software.

**Note**

Write down the host name or IP address of the KDC, the port number you want the KDC to monitor for queries, and the name of the Kerberos realm it will serve. You need this information to configure the router.

Configuring the KDC Using Kerberos Commands

After you set up a host to function as the KDC in your Kerberos realm, you must make entries to the KDC database for all principals in the realm. Principals can be network services on Cisco routers and hosts or they can be users.

To use Kerberos commands to add services to the KDC database (and to modify existing database information), complete the tasks in the following sections:

- [Adding Users to the KDC Database](#)
- [Creating SRVTABs on the KDC](#)
- [Extracting SRVTABs](#)

**Note**

All Kerberos command examples are based on Kerberos 5 Beta 5 of the original MIT implementation. Later versions use a slightly different interface.

Adding Users to the KDC Database

To add users to the KDC and create privileged instances of those users, use the **su** command to become root on the host running the KDC and use the `kdb5_edit` program to use the following commands in privileged EXEC mode:

	Command	Purpose
Step 1	Router# ank <i>username@REALM</i>	Use the ank (add new key) command to add a user to the KDC. This command prompts for a password, which the user must enter to authenticate to the router.
Step 2	Router# ank <i>username/instance@REALM</i>	Use the ank command to add a privileged instance of a user.

For example, to add user *loki* of Kerberos realm CISCO.COM, enter the following Kerberos command:

```
ank loki@CISCO.COM
```

**Note**

The Kerberos realm name must be in uppercase characters.

You might want to create privileged instances to allow network administrators to connect to the router at the enable level, for example, so that they need not enter a clear text password (and compromise security) to enter enable mode.

To add an instance of *loki* with additional privileges (in this case, *enable*, although it could be anything) enter the following Kerberos command:

```
ank loki/enable@CISCO.COM
```

In each of these examples, you are prompted to enter a password, which you must give to user *loki* to use at login.

The “[Enabling Kerberos Instance Mapping](#)” section describes how to map Kerberos instances to various Cisco IOS privilege levels.

Creating SRVTABs on the KDC

All routers that you want to authenticate to use the Kerberos protocol must have an SRVTAB. This section and the “[Extracting SRVTABs](#)” section describe how to create and extract SRVTABs for a router called *router1*. The section “[Copying SRVTAB Files](#)” describes how to copy SRVTAB files to the router.

To make SRVTAB entries on the KDC, use the following command in privileged EXEC mode:

Command	Purpose
Router# ark SERVICE/HOSTNAME@REALM	Use the ark (add random key) command to add a network service supported by a host or router to the KDC.

For example, to add a Kerberized authentication service for a Cisco router called *router1* to the Kerberos realm CISCO.COM, enter the following Kerberos command:

```
ark host/router1.cisco.com@CISCO.COM
```

Make entries for all network services on all Kerberized hosts that use this KDC for authentication.

Extracting SRVTABs

SRVTABs contain (among other things) the passwords or randomly generated keys for the service principals you entered into the KDC database. Service principal keys must be shared with the host running that service. To do this, you must save the SRVTAB entries to a file, then copy the file to the router and all hosts in the Kerberos realm. Saving SRVTAB entries to a file is called *extracting* SRVTABs. To extract SRVTABs, use the following command in privileged EXEC mode:

Command	Purpose
Router# xst router-name host	Use the kdb5_edit command xst to write an SRVTAB entry to a file.

For example, to write the host/router1.cisco.com@CISCO.COM SRVTAB to a file, enter the following Kerberos command:

```
xst router1.cisco.com@CISCO.COM host
```

Use the **quit** command to exit the kdb5_edit program.

Configuring the Router to Use the Kerberos Protocol

To configure a Cisco router to function as a network security server and authenticate users using the Kerberos protocol, complete the tasks in the following sections:

- [Defining a Kerberos Realm](#)
- [Copying SRVTAB Files](#)
- [Specifying Kerberos Authentication](#)
- [Enabling Credentials Forwarding](#)
- [Opening a Telnet Session to the Router](#)
- [Establishing an Encrypted Kerberized Telnet Session](#)
- [Enabling Mandatory Kerberos Authentication](#)
- [Enabling Kerberos Instance Mapping](#)
- [Monitoring and Maintaining Kerberos](#)

Defining a Kerberos Realm

For a router to authenticate a user defined in the Kerberos database, it must know the host name or IP address of the host running the KDC, the name of the Kerberos realm and, optionally, be able to map the host name or Domain Name System (DNS) domain to the Kerberos realm.

To configure the router to authenticate to a specified KDC in a specified Kerberos realm, use the following commands in global configuration mode. Note that DNS domain names must begin with a leading dot (.):

	Command	Purpose
Step 1	Router(config)# kerberos local-realm <i>kerberos-realm</i>	Defines the default realm for the router.
Step 2	Router(config)# kerberos server <i>kerberos-realm</i> { <i>hostname</i> <i>ip-address</i> } [<i>port-number</i>]	Specifies to the router which KDC to use in a given Kerberos realm and, optionally, the port number that the KDC is monitoring. (The default is 88.)
Step 3	Router(config)# kerberos realm { <i>dns-domain</i> <i>host</i> } <i>kerberos-realm</i>	(Optional) Maps a host name or DNS domain to a Kerberos realm.

Note

Because the machine running the KDC and all Kerberized hosts must interact within a 5-minute window or authentication fails, all Kerberized machines, and especially the KDC, should be running the Network Time Protocol (NTP).

The **kerberos local-realm**, **kerberos realm**, and **kerberos server** commands are equivalent to the UNIX *krb.conf* file. [Table 21](#) identifies mappings from the Cisco IOS configuration commands to a Kerberos 5 configuration file (*krb5.conf*).

Table 21 **Kerberos 5 Configuration File and Commands**

krb5.conf File	Cisco IOS Configuration Command
[libdefaults] default_realm = DOMAIN.COM	(in configuration mode) kerberos local-realm DOMAIN.COM
[domain_realm] .domain.com = DOMAIN.COM domain.com = DOMAIN.COM	(in configuration mode) kerberos realm.domain.com DOMAIN.COM kerberos realm domain.com DOMAIN.COM
[realms] kdc = DOMAIN.PIL.COM:750 admin_server = DOMAIN.PIL.COM default_domain = DOMAIN.COM	(in configuration mode) kerberos server DOMAIN.COM 172.65.44.2 (172.65.44.2 is the example IP address for DOMAIN.PIL.COM)

For an example of defining a Kerberos realm, see the section “[Defining a Kerberos Realm](#)” later in this chapter.

Copying SRVTAB Files

To make it possible for remote users to authenticate to the router using Kerberos credentials, the router must share a secret key with the KDC. To do this, you must give the router a copy of the SRVTAB you extracted on the KDC.

The most secure method to copy SRVTAB files to the hosts in your Kerberos realm is to copy them onto physical media and go to each host in turn and manually copy the files onto the system. To copy SRVTAB files to the router, which does not have a physical media drive, you must transfer them via the network using TFTP.

To remotely copy SRVTAB files to the router from the KDC, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos srvtab remote {hostname ip-address} {filename}	Retrieves an SRVTAB file from the KDC.

When you copy the SRVTAB file from the router to the KDC, the **kerberos srvtab remote** command parses the information in this file and stores it in the router’s running configuration in the **kerberos srvtab entry** format. To ensure that the SRVTAB is available (does not need to be acquired from the KDC) when you reboot the router, use the **write memory** configuration command to write your running configuration (which contains the parsed SRVTAB file) to NVRAM.

For an example of copying SRVTAB files, see the section “[SRVTAB File Copying Example](#)” later in this chapter.

Specifying Kerberos Authentication

You have now configured Kerberos on your router. This makes it possible for the router to authenticate using Kerberos. The next step is to tell it to do so. Because Kerberos authentication is facilitated through AAA, you need to enter the **aaa authentication** command, specifying Kerberos as the authentication method. For more information, refer to the chapter “Configuring Authentication”.

Enabling Credentials Forwarding

With Kerberos configured thus far, a user authenticated to a Kerberized router has a TGT and can use it to authenticate to a host on the network. However, if the user tries to list credentials after authenticating to a host, the output will show no Kerberos credentials present.

You can optionally configure the router to forward users' TGTs with them as they authenticate from the router to Kerberized remote hosts on the network when using Kerberized Telnet, rcp, rsh, and rlogin (with the appropriate flags).

To force all clients to forward users' credentials as they connect to other hosts in the Kerberos realm, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos credentials forward	Forces all clients to forward user credentials upon successful Kerberos authentication.

With credentials forwarding enabled, users' TGTs are automatically forwarded to the next host they authenticate to. In this way, users can connect to multiple hosts in the Kerberos realm without running the KINIT program each time to get a new TGT.

Opening a Telnet Session to the Router

To use Kerberos to authenticate users opening a Telnet session to the router from within the network, use the following command in global configuration mode:

Command	Purpose
Router(config)# aaa authentication login {default list-name} krb5_telnet	Sets login authentication to use the Kerberos 5 Telnet authentication protocol when using Telnet to connect to the router.

Although Telnet sessions to the router are authenticated, users must still enter a clear text password if they want to enter enable mode. The **kerberos instance map** command, discussed in a later section, allows them to authenticate to the router at a predefined privilege level.

Establishing an Encrypted Kerberized Telnet Session

Another way for users to open a secure Telnet session is to use Encrypted Kerberized Telnet. With Encrypted Kerberized Telnet, users are authenticated by their Kerberos credentials before a Telnet session is established. The Telnet session is encrypted using 56-bit Data Encryption Standard (DES) encryption with 64-bit Cipher Feedback (CFB). Because data sent or received is encrypted, not clear text, the integrity of the dialed router or access server can be more easily controlled.

Note

This feature is available only if you have the 56-bit encryption image. 56-bit DES encryption is subject to U.S. Government export control regulations.

To establish an encrypted Kerberized Telnet session from a router to a remote host, use either of the following commands in EXEC command mode:

Command	Purpose
Router(config)# connect <i>host</i> [<i>port</i>] / encrypt kerberos	Establishes an encrypted Telnet session.
OR	
Router(config)# telnet <i>host</i> [<i>port</i>] / encrypt kerberos	

When a user opens a Telnet session from a Cisco router to a remote host, the router and remote host negotiate to authenticate the user using Kerberos credentials. If this authentication is successful, the router and remote host then negotiate whether or not to use encryption. If this negotiation is successful, both inbound and outbound traffic is encrypted using 56-bit DES encryption with 64-bit CFB.

When a user dials in from a remote host to a Cisco router configured for Kerberos authentication, the host and router will attempt to negotiate whether or not to use encryption for the Telnet session. If this negotiation is successful, the router will encrypt all outbound data during the Telnet session.

If encryption is not successfully negotiated, the session will be terminated and the user will receive a message stating that the encrypted Telnet session was not successfully established.

For information about enabling bidirectional encryption from a remote host, refer to the documentation specific to the remote host device.

For an example of using encrypted Kerberized Telnet to open a secure Telnet session, see the section “[Encrypted Telnet Session Example](#)” later in this chapter.

Enabling Mandatory Kerberos Authentication

As an added layer of security, you can optionally configure the router so that, after remote users authenticate to it, these users can authenticate to other services on the network only with Kerberized Telnet, rlogin, rsh, and rcp. If you do not make Kerberos authentication mandatory and Kerberos authentication fails, the application attempts to authenticate users using the default method of authentication for that network service; for example, Telnet and rlogin prompt for a password, and rsh attempts to authenticate using the local rhost file.

To make Kerberos authentication mandatory, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos clients mandatory	Sets Telnet, rlogin, rsh, and rcp to fail if they cannot negotiate the Kerberos protocol with the remote server.

Enabling Kerberos Instance Mapping

As mentioned in the section “[Creating SRVTABs on the KDC](#),” you can create administrative instances of users in the KDC database. The **kerberos instance map** command allows you to map those instances to Cisco IOS privilege levels so that users can open secure Telnet sessions to the router at a predefined privilege level, obviating the need to enter a clear text password to enter enable mode.

To map a Kerberos instance to a Cisco IOS privilege level, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos instance map <i>instance privilege-level</i>	Maps a Kerberos instance to a Cisco IOS privilege level.

If there is a Kerberos instance for user *loki* in the KDC database (for example, *loki/admin*), user *loki* can now open a Telnet session to the router as *loki/admin* and authenticate automatically at privilege level 15, assuming instance “admin” is mapped to privilege level 15. (See the section “[Adding Users to the KDC Database](#)” earlier in this chapter.)

Cisco IOS commands can be set to various privilege levels using the **privilege level** command.

After you map a Kerberos instance to a Cisco IOS privilege level, you must configure the router to check for Kerberos instances each time a user logs in. To run authorization to determine if a user is allowed to run an EXEC shell based on a mapped Kerberos instance, use the **aaa authorization** command with the **krb5-instance** keyword. For more information, refer to the chapter “Configuring Authorization.”

Monitoring and Maintaining Kerberos

To display or remove a current user’s credentials, use the following commands in EXEC mode:

	Command	Purpose
Step 1	Router# show kerberos creds	Lists the credentials in a current user’s credentials cache.
Step 2	Router# clear kerberos creds	Destroys all credentials in a current user’s credentials cache, including those forwarded.

For an example of Kerberos configuration, see the section “[Kerberos Configuration Examples](#)”.

Kerberos Configuration Examples

The following sections provide Kerberos configuration examples:

- [Kerberos Realm Definition Examples](#)
- [SRVTAB File Copying Example](#)
- [Kerberos Configuration Examples](#)
- [Encrypted Telnet Session Example](#)

Kerberos Realm Definition Examples

To define CISCO.COM as the default Kerberos realm, use the following command:

```
kerberos local-realm CISCO.COM
```

To tell the router that the CISCO.COM KDC is running on host 10.2.3.4 at port number 170, use the following Kerberos command:

```
kerberos server CISCO.COM 10.2.3.4 170
```

To map the DNS domain cisco.com to the Kerberos realm CISCO.COM, use the following command:

```
kerberos realm.cisco.com CISCO.COM
```

SRVTAB File Copying Example

To copy over the SRVTAB file on a host named `host123.cisco.com` for a router named `router1.cisco.com`, the command would look like this:

```
kerberos srvtab remote host123.cisco.com router1.cisco.com-new-srvtab
```

Kerberos Configuration Examples

This section provides a typical non-Kerberos router configuration and shows output for this configuration from the **write term** command, then builds on this configuration by adding optional Kerberos functionality. Output for each configuration is presented for comparison against the previous configuration.

This example shows how to use the `kdb5_edit` program to perform the following configuration tasks:

- Adding user `chet` to the Kerberos database
- Adding a privileged Kerberos instance of user `chet` (`chet/admin`) to the Kerberos database
- Adding a restricted instance of `chet` (`chet/restricted`) to the Kerberos database
- Adding workstation `chet-ss20.cisco.com`
- Adding router `chet-2500.cisco.com` to the Kerberos database
- Adding workstation `chet-ss20.cisco.com` to the Kerberos database
- Extracting SRVTABs for the router and workstations
- Listing the contents of the KDC database (with the **ldb** command)

Note that, in this sample configuration, host `chet-ss20` is also the KDC:

```
chet-ss20# sbin/kdb5_edit
kdb5_edit: ank chet
Enter password:
Re-enter password for verification:
kdb5_edit: ank chet/admin
Enter password:
Re-enter password for verification:
kdb5_edit: ank chet/restricted
Enter password:
Re-enter password for verification:
kdb5_edit: ark host/chet-ss20.cisco.com
kdb5_edit: ark host/chet-2500.cisco.com
kdb5_edit: xst chet-ss20.cisco.com host
'host/chet-ss20.cisco.com@CISCO.COM' added to keytab
'WRFILE:chet-ss20.cisco.com-new-srvtab'
kdb5_edit: xst chet-2500.cisco.com host
'host/chet-2500.cisco.com@CISCO.COM' added to keytab
'WRFILE:chet-2500.cisco.com-new-srvtab'
kdb5_edit: ldb
entry: host/chet-2500.cisco.com@CISCO.COM
entry: chet/restricted@CISCO.COM
entry: chet@CISCO.COM
entry: K/M@CISCO.COM
entry: host/chet-ss20.cisco.com@CISCO.COM
entry: krbtgt/CISCO.COM@CISCO.COM
entry: chet/admin@CISCO.COM
```

```
kdb5_edit:  q
chet-ss20#
```

The following example shows output from a **write term** command, which displays the configuration of router chet-2500. This is a typical configuration with no Kerberos authentication.

```
chet-2500# write term

The following example shows how to enable user authentication on the router via the Kerberos database. To enable user authentication via the Kerberos database, you would perform the following tasks:

- Entering configuration mode
- Defining the Kerberos local realm
- Identifying the machine hosting the KDC
- Enabling credentials forwarding
- Specifying Kerberos as the method of authentication for login
- Exiting configuration mode (CTL-Z)
- Writing the new configuration to the terminal

```

chet-2500# configure term
Enter configuration commands, one per line. End with CNTL/Z.
chet-2500(config)# kerberos local-realm CISCO.COM
chet-2500(config)# kerberos server CISCO.COM chet-ss20

Traffic Filtering, Firewalls, and Virus Detection

Automatic Signature Extraction

First Published: July 19, 2007

The Automatic Signature Extraction (ASE) feature helps shorten the response time for identifying malware by dynamically extracting signatures of unknown viruses and worms traversing the network without the need for human intervention.

Before Cisco IOS Release 12.4(15)T, network protection from malware such as botnets, viruses, and worms was accomplished by deploying solutions that rely on manual signatures to identify the malware. Normally, security professionals require approximately 8 to 12 hours to generate a signature for a new piece of malware. This time interval had been acceptable for thwarting malware, but is no longer acceptable nor scalable due to the exponential increase in malware that is seen on networks.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for](#)” section on page 12.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for

The following prerequisites apply for the ASE collector.

See the “[Collector Operation](#)” section on [page 4](#) for more information on the ASE collector.

- The ASE collector runs on an x86-based Linux PC and must have IP connectivity to the network and ASE sensors. Threat Information Distribution Protocol (TIDP) is the communication protocol used between the Linux-based ASE collector and Cisco IOS-based ASE sensors.
- It is recommended that the ASE collector software image run on RedHat Enterprise Linux AS Release 3 or a later release.

**Note**

Contact your Cisco representative for more information about installing the ASE collector functionality on your network.

Restrictions for

Contact your Cisco representative for any restrictions concerning the ASE collector or ASE sensor implementation.

Information About

The following sections describe how the ASE feature works and how ASE is implemented on a WAN:

- [Overview, page 3](#)
- [Sensor Operation, page 3](#)
- [Collector Operation, page 4](#)
- [Automatic Signature Extraction Implementation on a Network, page 5](#)

Overview

The Automatic Signature Extraction feature is used to identify and define potential worms and viruses found in network traffic based on the following characteristics:

- Content invariance identifies that all worms have some code that remains unchanged through the infection.
- Content prevalence identifies if packet payloads were observed frequently in the network. Because worms are designed to spread, the unchanged portion of a worm's content appears frequently on a network as it spreads or attempts to spread.
- Address dispersion identifies whether the same payload is sent to and from a large number of source and destination IP address pairs.

**Note**

The ASE feature can detect e-mail viruses but is disabled by default. This feature can be enabled on the ASE collector. Contact your Cisco representative for more information.

When the ASE sensor extracts a malware signature, the ASE sensor sends the signature to the collector using the TIDP Threat Mitigation Service (TMS) to contain and mitigate the malware outbreak among TMS consumers spread across the network. The TMS framework rapidly and efficiently distributes threat information to devices on the network and generates actions to TMS consumers to either drop or redirect the packets containing the malware signature.

**Note**

See the [“Sensor Operation” section on page 3](#) for more information on this feature.

See [TIDP Based Mitigation Services](#) for more information on TMS operation.

Sensor Operation

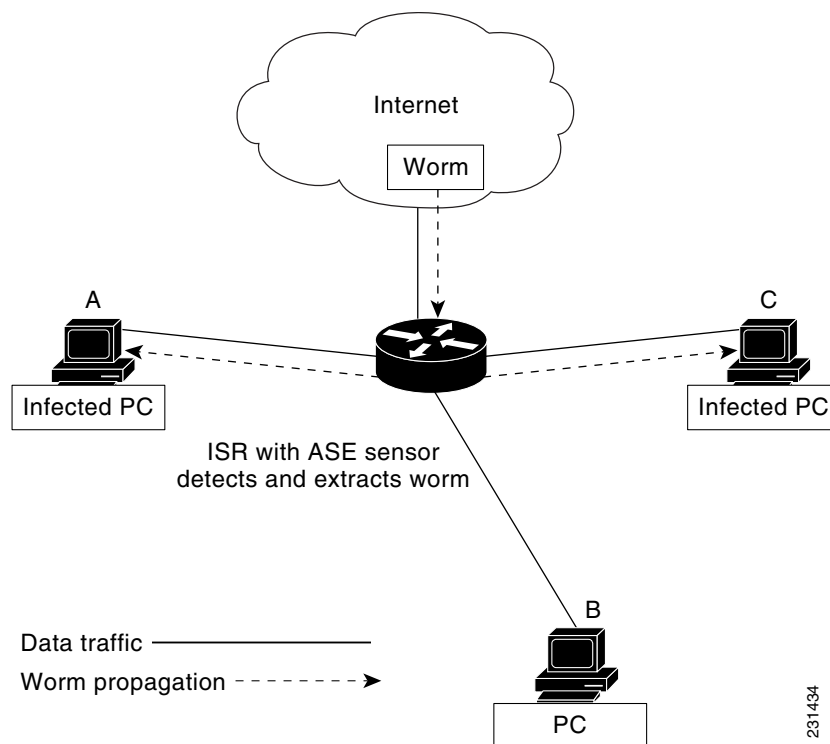

The ASE feature has two main components: a sensor and collector. The ASE sensor sifts through the contents of network traffic to reduce the number of different source and destination addresses seen in packets. To minimize the impact on the device, sensing can be enabled or disabled on a per-interface basis and traffic designated as ASE traffic can be specified. The ASE sensor observes the same traffic as the router can observe after an access list is applied.

**Note**

The sensor is unable to extract signatures from within encrypted traffic passing through a router.

[Figure 1, Cisco IOS Signature Extraction](#), shows that devices A and C are infected with the same worm. As traffic crosses the Cisco IOS router running the ASE sensor, the router extracts the worm's signature based on its address dispersion and content prevalence. Then the router sends this information to the ASE collector for further processing.

Figure 1 Cisco IOS Signature Extraction

Collector Operation

The ASE collector, which runs on a Linux-based PC, performs the following functions:

- Processes signatures it receives from the ASE sensor.
- Initiates the mitigation of signatures.
- Coordinates detection between multiple ASE sensors.
- Manages and distributes entry information and files on the network.
- Collects signatures and packets sent by the sensor.
- Analyzes extracted signatures to determine what the best signature is for a malicious packet to correctly identify a threat.
- Performs post processing of signatures to reduce false alarms.
- Maintains a signature database.
- Reduces false positives in signatures through classification.
- Manages sensor configuration such as thresholds, scanning criteria, and other parameters.
- Generates a report or reports on collected signatures.

Note

Contact your Cisco representative for more information about installing the ASE collector functionality on your network.

Automatic Signature Extraction Implementation on a Network

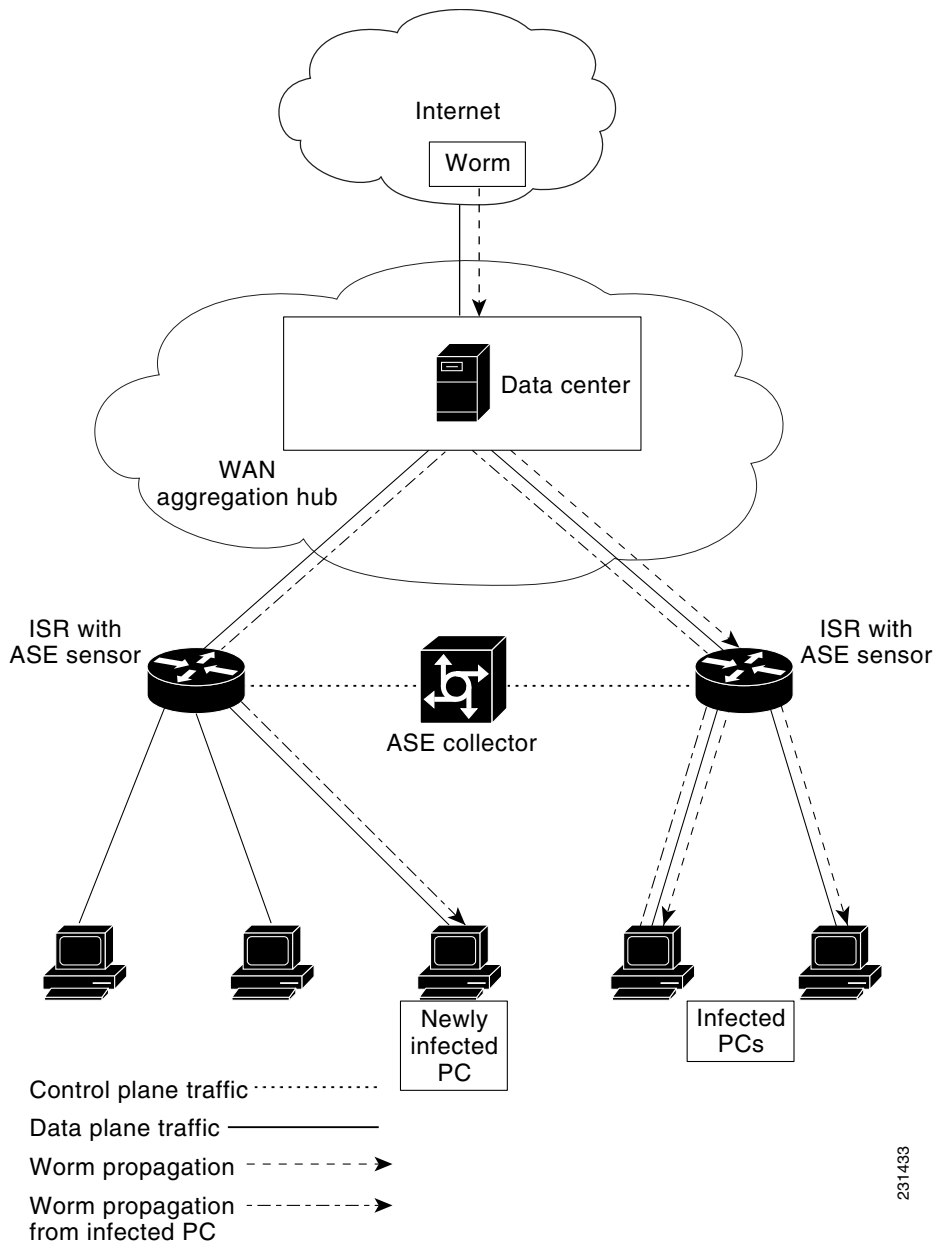

Self-propagating worms continue to grow and affect the security of hosts and networks. These malicious malware attacks often target specific victims or subnets within an enterprise organization. Specifically, a worm can affect and saturate the local network (including all hosts), the branch router, and the local WAN connection or both. The optimal location to detect, contain, and mitigate these worms is on the gateway network connection to prevent the worms from spreading to the entire network, including all connected branches.

Using the WAN Aggregation Model to Contain Malware

The ASE sensor is typically deployed on the Customer Premises Equipment (CPE) WAN so that worms closest to the source can be extracted and prevented from spreading to other areas of the enterprise network.

The WAN aggregation model refers to the traditional deployment scenario in which CPEs are terminated over WAN links to an aggregation HUB. In this model, the CPEs would serve as ASE sensors, and the aggregation HUB would provide ASE Collector functionality. [Figure 2, WAN Aggregation Model](#), shows how worm signatures are extracted at the CPEs and the HUB site with the ASE sensor and shows how the ASE sensor uses this signature information with the ASE collector to contain the outbreak.

Figure 2 WAN Aggregation Model

How to Configure

This section contains the following task:

- [Configuring](#)

Configuring

This section describes how to configure the Automatic Signature Extraction sensor feature on an ISR router.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ase group** *TIDP-group-number*
4. **ase collector** *ip-address*
5. **ase signature extraction**
6. **interface** *interface-type number*
7. **ase enable**
8. **end**
9. **show ase**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ase group <i>TIDP-group-number</i> Example: Router(config)# ase group 10	The group number range is between 1 and 65535, which identifies the TIDP group number used for exchange between the ASE sensor and ASE collector. Note See the Threat Information Distribution Protocol feature documentation for more information on TIDP groups.
Step 4	ase collector <i>ip-address</i> Example: Router(config)# ase collector 10.10.10.3	Enters the destination IP address of the ASE collector server so that the ASE sensor has IP connectivity to the ASE collector.
Step 5	ase signature extraction Example: Router(config)# ase signature extraction	Enables the ASE feature globally on the router.
Step 6	interface <i>interface-type number</i> Example: Router(config)# interface GigabitEthernet0/1	Enters the interface for the ASE feature, and enters interface configuration mode.
Step 7	ase enable Example: Router(config-if)# ase enable	Enables the ASE feature on this interface.

	Command or Action	Purpose
Step 8	end Example: Router(config-if)# end	Returns to privileged EXEC mode.
Step 9	show ase Example: Router# show ase	Displays the ASE run-time status. The four states are: <ul style="list-style-type: none">• Not Enabled—(Not displayed) The ASE feature is not enabled in global configuration mode.• Enabled—The ASE feature is enabled in global configuration mode, but the ASE sensor has not connected with the ASE collector.• Connected—The ASE sensor has connected with the ASE collector, but it has not completed initialization.• Online—The ASE is ready for inspecting traffic.

What to Do Next

Start the ASE collector. The ASE collector, which runs on a Linux-based PC, provides the ASE sensor software on the Cisco IOS with entries and analysis on extracted signatures.

Note

Contact your Cisco representative for more information about installing the ASE collector on your network.

After the ASE collector is started, the ASE run-time status information can be displayed by using the **show ase** command, as shown below:

Note

The ASE collector must be started in order for the ASE run-time status information to be displayed.

```
Router# show ase
ASE Information:

Collector IP: 10.10.10.3
TIDP Group   : 10
Status       : Online

Packets inspected: 1105071
Address Dispersion Threshold: 20
Prevalence Threshold: 10
Sampling set to: 1 in 64
Address Dispersion Inactivity Timer: 3600s
Prevalence Table Refresh Time: 60s
```

Feature Information for

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for

Feature Name	Releases	Feature Information
	12.4(15)T	<p>The Automatic Signature Extraction feature helps shorten the response time for identifying malware by dynamically extracting signatures for unknown viruses and worms traversing the network without the need for human intervention.</p> <p>This feature was introduced on the Cisco 1800, 2800, and 7200 series routers, Cisco 7301 router, and Integrated Services Routers (ISRs) as ASE sensors.</p>

Glossary

botnet—Slang term for a collection of software robots, or bots, which run autonomously or to a network of compromised “zombie” computers running distributed programs, which are usually referred to as worms, Trojan horses, or backdoors, under a common command and control infrastructure.

CPE—Customer Premises Equipment. Terminating equipment, such as a router installed at a customer site, and connected to a WAN.

ISR—Integrated Services Router. Router that supports integrated or multimedia services, including traffic management mechanisms.

malware—Detrimental software designed to infiltrate or damage a computer system without the owner's informed consent. Examples of malware include viruses, worms, botnets, spam, adware, etc.

signature—The 40 bytes of packet data that can be used to identify a piece of malware.

TIDP—Threat Information Distribution Protocol. Communication protocol used between the Linux-based Automatic Signature Extraction collector and Cisco IOS-based ASE sensors.

TMS—Threat Mitigation Service. TMS is used with the TIDP protocol to contain and mitigate the malware outbreak among TMS consumers on a network.

Virus—Hidden, self-replicating section of computer software, usually malicious logic, that propagates by infecting—that is, inserting a copy of itself into and becoming part of—another program. A virus cannot run by itself; it requires that its host program be run to make the virus active.

WAN—wide-area network. Data communications network that serves users across a broad geographic area and often uses transmission devices provided by common carriers. Frame Relay, SMDS, and X.25 are examples of WANs.

worm—Computer program that can run independently, can propagate a complete working version of itself onto other hosts on a network, and can consume computer resources destructively.

Access Control Lists (ACLs)

IP Access List Features Roadmap

First Published: August 18, 2006

Last Updated: August 18, 2006

This roadmap lists the access list features documented in the *Cisco IOS Security Configuration Guide* and maps them to the modules in which they appear.

Feature and Release Support

[Table 1](#) lists access list feature support for the Cisco IOS software releases 12.2S, 12.3T, and 12.4T.

Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table. *Not all features may be supported in your Cisco IOS software release*

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 **Supported Access List Features**

Release	Feature Name	Feature Description	Where Documented
Cisco IOS Releases 12.2S, 12.3T, and 12.4T			
12.2(25)S	ACL Support for Filtering IP Options	This feature allows you to filter packets having IP Options, in order to prevent routers from becoming saturated with spurious packets.	Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values

Americas Headquarters:

Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Supported Access List Features (continued)

12.3(4)T 12.2(25)S	ACL TCP Flags Filtering	This feature provides a flexible mechanism for filtering on TCP flags. Before Cisco IOS Release 12.3(4)T, an incoming packet was matched as long as any TCP flag in the packet matched a flag specified in the access control entry (ACE). This behavior allows for a security loophole, because packets with all flags set could get past the access control list (ACL). The ACL TCP Flags Filtering feature allows you to select any combination of flags on which to filter. The ability to match on a flag set and on a flag not set gives you a greater degree of control for filtering on TCP flags, thus enhancing security.	Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values
12.3(7)T 12.2(25)S	ACL—Named ACL Support for Noncontiguous Ports on an Access Control Entry	This feature allows you to specify noncontiguous ports in a single access control entry, which greatly reduces the number of entries required in an access control list when several entries have the same source address, destination address, and protocol, but differ only in the ports.	Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values
12.4(2)T	ACL Support for Filtering on TTL Value	You may use extended IP access lists (named or numbered) to filter packets based on their time-to-live (TTL) value, from 0 to 255. This filtering enhances your control over which packets reach a router.	Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values
12.4(6)T	ACL Manageability	The ACL Manageability feature enables users to display and clear Access Control Entry (ACE) statistics per interface and per incoming or outgoing traffic direction for access control lists (ACLs).	Displaying and Clearing IP Access List Data Using ACL Manageability http://lbgj/push_targets1/ucdit/cc/td/doc/product/software/ios124/124tcg/sec_c/tsaclsho.htm

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and

IP Access List Overview

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

First Published: August 18, 2006

Last Updated: August 18, 2006

Access control lists (ACLs) perform packet filtering to control which packets move through the network and where. Such control provides security by helping to limit network traffic, restrict the access of users and devices to the network, and prevent traffic from leaving a network. IP access lists can reduce the chance of spoofing and denial-of-service attacks and allow dynamic, temporary user access through a firewall.

IP access lists can also be used for purposes other than security, such as bandwidth control, restricting the content of routing updates, redistributing routes, triggering dial-on-demand (DDR) calls, limiting debug output, and identifying or classifying traffic for quality of service (QoS) features. This module provides an overview of IP access lists.

- [Additional IP Access List Features, page 10](#)
- [Time-Based and Distributed Time-Based Access Lists, page 11](#)
- [Types of IP Access Lists, page 11](#)
- [Where to Apply an Access List, page 11](#)

Benefits of IP Access Lists

Access control lists (ACLs) perform packet filtering to control which packets move through the network and where. Such control can restrict the access of users and devices to the network, providing a measure of security. Access lists can save network resources by reducing traffic. Access lists provide diverse benefits, depending on how they are used. Many of the benefits fall into the following categories:

Block Unwanted Traffic or Users

Access lists can filter incoming or outgoing packets on an interface, thereby controlling access based on source addresses, destination addresses, or user authentication. You can also use access lists to determine which types of traffic are forwarded or blocked at the router interfaces. For example, you can permit e-mail traffic to be routed, but at the same time block all Telnet traffic.

Reduce the Chance of DOS Attacks

There are a number of ways to reduce the chance of denial-of-service attacks. For example, by specifying IP source addresses, you can control whether traffic from hosts, networks, or users access your network. You can filter on specific time-to-live (TTL) values in packets to control how many hops a packet can take before reaching a router in your network. By configuring the TCP Intercept feature, you can prevent servers from being flooded with requests for a connection.

Control Access to Virtual Terminal Lines

You can place an access list on inbound vty (Telnet) line access from certain nodes or networks. You can also place an access list on outbound vty access, blocking or permitting Telnet access to other devices.

Restrict the Content of Routing Updates

Access lists can control routing updates being sent, received, or redistributed.

Provide Bandwidth Control

An access list on a slow link can prevent excess traffic.

Identify or Classify Traffic for QoS Features

Access lists can provide congestion avoidance by setting IP precedence for WRED or CAR. It can provide congestion management for class-based weighted fair queuing (WFQ), priority queuing, and custom queuing.

Trigger Dial-on-Demand (DDR) Calls

An access list can enforce dialing and disconnect criteria.

Limit Debug Command Output

An access list can limit debug output based on an address or protocol.

Provide NAT Control

Access lists can control which addresses are translated by Network Address Translation (NAT).

Authenticate Incoming RSH and RCP Requests

To enable the Cisco IOS software to receive incoming remote shell (rsh) protocol and remote copy (rcp) protocol requests, customers must configure an authentication database to control access to the router. Access lists can simplify the identification of local users, remote hosts, and remote users in the database authentication configuration.

Border Routers and Firewall Routers Should Use Access Lists

There are many reasons to configure access lists; for example, you can use access lists to restrict contents of routing updates or to provide traffic flow control. One of the most important reasons to configure access lists is to provide a basic level of security for your network by controlling access to it. If you do not configure access lists on your router, all packets passing through the router could be allowed onto all parts of your network.

An access list can allow one host to access a part of your network and prevent another host from accessing the same area. In [Figure 1](#), by applying an appropriate access list to the interfaces of the router, Host A is allowed to access the Human Resources network and Host B is prevented from accessing the Human Resources network.

Figure 1 *Traffic Filters to Prevent Traffic from Being Routed to a Network*

Access lists should be used in firewall routers, which are often positioned between your internal network and an external network such as the Internet. You can also use access lists on a router positioned between two parts of your network, to control traffic entering or exiting a specific part of your internal network.

To provide some security benefits of access lists, you should at least configure access lists on border routers—routers located at the edges of your networks. Such an access list provides a basic buffer from the outside network or from a less controlled area of your own network into a more sensitive area of your network. On these border routers, you should configure access lists for each network protocol configured on the router interfaces. You can configure access lists so that inbound traffic or outbound traffic or both are filtered on an interface.

Access lists are defined on a per-protocol basis. In other words, you should define access lists for every protocol enabled on an interface if you want to control traffic flow for that protocol.

Definition of an Access List

An access list is a sequential list consisting of at least one **permit** statement and possibly one or more **deny** statements. In the case of IP access lists, the statements can apply to IP addresses, upper-layer IP protocols, or other fields in IP packets. The access list is identified and referenced by a name or a number. The access list acts as a packet filter, filtering packets based on the criteria defined in the access list.

An access list may be configured, but it does not take effect until the access list is either applied to an interface (with the **ip access-group** command), a virtual terminal line (vty) (with the **access-class** command), or referenced by some other command that accepts an access list. Access lists have many uses, and therefore many Cisco IOS software commands accept a reference to an access list in their command syntax. Multiple commands can reference the same access list.

In the following configuration excerpt, the first three lines are an example of an IP access list named `branchoffices`, which is applied to serial interface 0 on incoming packets. No sources other than those on the networks specified by each source address and mask pair can access this interface. The destinations for packets coming from sources on network 172.20.7.0 are unrestricted. The destination for packets coming from sources on network 172.29.2.0 must be 172.25.5.4.

```
ip access-list extended branchoffices
 10 permit 172.20.7.0 0.0.0.3 any
 20 permit 172.29.2.0 0.0.0.255 host 172.25.5.4
```

```
!  
interface serial 0  
 ip access-group branchoffices in
```

Software Processing of an Access List

The following general steps describe how the Cisco IOS software processes an access list when it is applied to an interface, a vty, or referenced by some other Cisco IOS command. These steps apply to an access list that has 13 or fewer access list entries.

- The software receives an IP packet and tests parts of each packet being filtered against the conditions in the access list, one condition (**permit** or **deny** statement) at a time. For example, the software tests the source and destination addresses of the packet against the source and destination addresses in a **permit** or **deny** statement.
- If a packet does not match an access list statement, the packet is then tested against the next statement in the list.
- If a packet and an access list statement match, the rest of the statements in the list are skipped and the packet is permitted or denied as specified in the matched statement. The first entry that the packet matches determines whether the software permits or denies the packet. That is, after the first match, no subsequent entries are considered.
- If the access list denies a packet, the software discards the packet and returns an ICMP Host Unreachable message.
- If no conditions match, the software drops the packet. This is because each access list ends with an unwritten, implicit **deny** statement. That is, if the packet has not been permitted by the time it was tested against each statement, it is denied.

In later Cisco IOS releases such as Release 12.4, 12.2S, and 12.0S, by default, an access list that has more than 13 access list entries is processed differently from one that has 13 or fewer entries. In order to be more efficient, an access list with more than 13 entries is processed using a trie-based lookup algorithm. This process will happen automatically; it does not need to be configured.

Access List Rules

Keep the following rules and characteristics of access lists in mind when creating one:

- Only one access list per interface, per protocol, per direction is allowed.
- The access list must contain at least one **permit** statement or else all packets are denied.
- Because the software stops testing conditions after the first match, the order of the conditions is critical. The same **permit** or **deny** statements specified in a different order could result in a packet being passed under one circumstance and denied in another circumstance.
- If an access list is referenced by name in a command, but the access list does not exist, all packets pass. That is, an interface or command with an empty access list applied to it permits all traffic.
- Standard access lists and extended access lists cannot have the same name.
- Inbound access lists process packets arriving at the router. Incoming packets are processed before being routed to an outbound interface. An inbound access list is efficient because it saves the overhead of routing lookups if the packet is to be discarded because it is denied by the filtering tests. If the packet is permitted by the tests, it is then processed for routing. For inbound lists, **permit** means continue to process the packet after receiving it on an inbound interface; **deny** means discard the packet.

- Outbound access lists process packets before they leave the router. Incoming packets are routed to the outbound interface and then processed through the outbound access list. For outbound lists, **permit** means send it to the output buffer; **deny** means discard the packet.
- An access list can control traffic arriving at the router or leaving the router, but not traffic originating at the router.

Helpful Hints for Creating IP Access Lists

The following tips will help you avoid unintended consequences and help you create more efficient, useful access lists.

- Create the access list before applying it to an interface (or elsewhere), because if you apply a nonexistent access list to an interface and then proceed to configure the access list, the first statement is put into effect, and the implicit **deny** statement that follows could cause you immediate access problems.
- Another reason to configure an access list before applying it is because an interface with an empty access list applied to it permits all traffic.
- All access lists need at least one **permit** statement; otherwise, all packets are denied and no traffic passes.
- Because the software stops testing conditions after it encounters the first match (to either a **permit** or **deny** statement), you will reduce processing time and resources if you put the statements that packets are most likely to match at the beginning of the access list. Place more frequently occurring conditions before less frequent conditions.
- Organize your access list so that more specific references in a network or subnet appear before more general ones.
- Use the statement **permit any any** if you want to allow all other packets not already denied. Using the statement **permit any any** in effect avoids denying all other packets with the implicit deny statement at the end of an access list. Do not make your first access list entry **permit any any** because all traffic will get through; no packets will reach the subsequent testing. In fact, once you specify **permit any any**, all traffic not already denied will get through.
- Although all access lists end with an implicit **deny** statement, we recommend use of an explicit **deny** statement (for example, **deny ip any any**). On most platforms, you can display the count of packets denied by issuing the **show access-list** command, thus finding out more information about who your access list is disallowing. Only packets denied by explicit **deny** statements are counted, which is why the explicit **deny** statement will yield more complete data for you.
- While you are creating an access list or after it is created, you might want to delete an entry.
 - You cannot delete an entry from a *numbered* access list; trying to do so will delete the entire access list. If you need to delete an entry, you need to delete the entire access list and start over.
 - You can delete an entry from a *named* access list. Use the **no permit** or **no deny** command to delete the appropriate entry.
- In order to make the purpose of individual statements more scannable and easily understood at a glance, you can write a helpful remark before or after any statement by using the **remark** command.
- If you want to deny access to a particular host or network and find out if someone from that network or host is attempting to gain access, include the **log** keyword with the corresponding **deny** statement so that the packets denied from that source are logged for you.

- This hint applies to the placement of your access list. When trying to save resources, remember that an inbound access list applies the filter conditions *before* the routing table lookup. An outbound access list applies the filter conditions *after* the routing table lookup.

Named or Numbered Access Lists

All access lists must be identified by a name or a number. Named and numbered access lists have different command syntax. Named access lists are compatible with Cisco IOS Release 11.2 and later. Named access lists are more convenient than numbered access lists because you can specify a meaningful name that is easier to remember and associate with a purpose. You may reorder statements in or add statements to a named access list.

Named access list are newer than numbered access lists and support the following features that are not supported in numbered access lists:

- TCP flag filtering
- IP option filtering
- noncontiguous ports
- reflexive access lists
- ability to delete entries with the **no permit** or **no deny** command

Not all commands that accept a numbered access list will accept a named access list. For example, virtual terminal lines use only numbered access lists.

Standard or Extended Access Lists

All access lists are either standard or extended access lists. If you only intend to filter on a source address, the simpler standard access list is sufficient. For filtering on anything other than a source address, an extended access list is necessary.

- Named access lists are specified as standard or extended based on the keyword **standard** or **extended** in the **ip access-list** command syntax.
- Numbered access lists are specified as standard or extended based on their number in the **access-list** command syntax. Standard IP access lists are numbered 1 to 99 or 1300 to 1999; extended IP access lists are numbered 100 to 199 or 2000 to 2699. The range of standard IP access lists was initially only 1 to 99, and was subsequently expanded with the range 1300 to 1999 (the intervening numbers were assigned to other protocols). The extended access list range was similarly expanded.

Standard Access Lists

Standard IP access lists test only source addresses of packets (except for two exceptions). Because standard access lists test source addresses, they are very efficient at blocking traffic close to a destination. There are two exceptions when the address in a standard access list is not a source address:

- On outbound VTY access lists, when someone is trying to telnet, the address in the access list entry is used as a destination address rather than a source address.
- When filtering routes, you are filtering the network being advertised to you rather than a source address.

Extended Access Lists

Extended access lists are good for blocking traffic anywhere. Extended access lists test source and destination addresses and other IP packet data, such as protocols, TCP or UDP port numbers, type of service (ToS), precedence, TCP flags, IP options, and TTL value. Extended access lists can also provide capabilities that standard access lists cannot, such as the following:

- Filtering IP Options
- Filtering TCP flags
- Filtering noninitial fragments of packets (see the module “Refining an IP Access List”)
- Time-based entries (see the [“Time-Based and Distributed Time-Based Access Lists”](#) section on page 11 and the module “Refining an IP Access List”)
- Dynamic access lists (see the section [“Types of IP Access Lists”](#) section on page 11)
- Reflexive access lists (see the section [“Types of IP Access Lists”](#) section on page 11 and the module “Configuring IP Session Filtering [Reflexive Access Lists])

**Note**

Packets that are subject to an extended access list will not be autonomous switched.

IP Packet Fields You Can Filter to Control Access

You can use an extended access list to filter on any of the following fields in an IP packet. Source address and destination address are the two most frequently specified fields on which to base an access list:

- Source address—Specifies a source address to control packets coming from certain networking devices or hosts.
- Destination address—Specifies a destination address to control packets being sent to certain networking devices or hosts.
- Protocol—Specifies an IP protocol indicated by the keyword **eigrp**, **gre**, **icmp**, **igmp**, **ip**, **ipinip**, **nos**, **ospf**, **tcp**, or **udp**, or indicated by an integer in the range from 0 to 255 (representing an Internet protocol). If you specify a transport layer protocol (**icmp**, **igmp**, **tcp**, or **udp**), the command has a specific syntax.
 - Ports and non-contiguous ports—Specifies TCP or UDP ports by a port name or port number. The port numbers can be noncontiguous port numbers. Port numbers can be useful to filter Telnet traffic or HTTP traffic, for example.
 - TCP flags—Specifies that packets match any flag or all flags set in TCP packets. Filtering on specific TCP flags can help prevent false synchronization packets.
- IP options—Specifies IP options; one reason to filter on IP options is to prevent routers from being saturated with spurious packets containing them.
- TTL value—Specifies TTL values indicated by an operator and possibly a range of values. Filtering on TTL value can control who can reach an interface based on how many hops away the source is. Such filtering can also prevent packets from reaching the process level.

Wildcard Mask for Addresses in an Access List

Address filtering uses wildcard masking to indicate to the software whether to check or ignore corresponding IP address bits when comparing the address bits in an access list entry to a packet being submitted to the access list. By carefully setting wildcard masks, you can specify one or more IP addresses for permit or deny tests.

Wildcard masking for IP address bits uses the number 1 and the number 0 to specify how the software treats the corresponding IP address bits. A wildcard mask is sometimes referred to as an inverted mask because a 1 and 0 mean the opposite of what they mean in a subnet (network) mask.

- A wildcard mask bit 0 means *check* the corresponding bit value; they must match.
- A wildcard mask bit 1 means *ignore* that corresponding bit value; they need not match.

If you do not supply a wildcard mask with a source or destination address in an access list statement, the software assumes an implicit wildcard mask of 0.0.0.0, meaning all values must match.

Unlike subnet masks, which require contiguous bits indicating network and subnet to be ones, wildcard masks allow noncontiguous bits in the mask.

Table 1 shows examples of IP addresses and masks from an access list, along with the corresponding addresses that are considered a match.

Table 1 **Sample IP Addresses, Wildcard Masks, and Match Results**

Address	Wildcard Mask	Match Results
0.0.0.0	255.255.255.255	All addresses will match the access list conditions.
172.18.0.0/16	0.0.255.255	Network 172.18.0.0
172.18.5.2/16	0.0.0.0	Only host 172.18.5.2 matches
172.18.8.0	0.0.0.7	Only subnet 172.18.8.0/29 matches
172.18.8.8	0.0.0.7	Only subnet 172.18.8.8/29 matches
172.18.8.15	0.0.0.3	Only subnet 172.18.8.15/30 matches
10.1.2.0	0.0.252.255 (noncontiguous bits in mask)	Matches any even-numbered network in the range of 10.1.2.0 to 10.1.254.0

Access List Sequence Numbers

The ability to apply sequence numbers to IP access list entries simplifies access list changes. Prior to the IP Access List Entry Sequence Numbering feature, there was no way to specify the position of an entry within an access list. If you wanted to insert an entry in the middle of an existing list, all of the entries after the desired position had to be removed, then the new entry was added, and then all the removed entries had to be reentered. This method was cumbersome and error prone.

This feature allows users to add sequence numbers to access list entries and resequence them. When you add a new entry, you specify the sequence number so that it is in a desired position in the access list. If necessary, entries currently in the access list can be resequenced to create room to insert the new entry.

Access List Logging

The Cisco IOS software can provide logging messages about packets permitted or denied by a single standard or extended IP access list entry. That is, any packet that matches the entry will cause an informational logging message about the packet to be sent to the console. The level of messages logged to the console is controlled by the **logging console** global configuration command.

The first packet that triggers the access list entry causes an immediate logging message, and subsequent packets are collected over 5-minute intervals before they are displayed or logged. The logging message includes the access list number, whether the packet was permitted or denied, the source IP address of the packet, and the number of packets from that source permitted or denied in the prior 5-minute interval.

However, you can use the **ip access-list log-update** command to set the number of packets that, when match an access list (and are permitted or denied), cause the system to generate a log message. You might want to do this to receive log messages more frequently than at 5-minute intervals.

Caution

If you set the *number-of-matches* argument to 1, a log message is sent right away, rather than caching it; every packet that matches an access list causes a log message. A setting of 1 is not recommended because the volume of log messages could overwhelm the system.

Even if you use the **ip access-list log-update** command, the 5-minute timer remains in effect, so each cache is emptied at the end of 5 minutes, regardless of the count of messages in each cache. Regardless of when the log message is sent, the cache is flushed and the count reset to 0 for that message the same way it is when a threshold is not specified.

Note

The logging facility might drop some logging message packets if there are too many to be handled or if there is more than one logging message to be handled in 1 second. This behavior prevents the router from crashing due to too many logging packets. Therefore, the logging facility should not be used as a billing tool or an accurate source of the number of matches to an access list.

Alternative to Access List Logging

Packets matching an entry in an ACL with a log option are process switched. It is not recommended to use the log option on ACLs, but rather use NetFlow export and match on a destination interface of Null0. This is done in the CEF path. The destination interface of Null0 is set for any packet that is dropped by the ACL.

Additional IP Access List Features

Beyond the basic steps to create a standard or extended access list, you can enhance your access lists as mentioned below. Each of these methods is described completely in the module entitled “[Refining an Access List](#).”

- You can impose dates and times when **permit** or **deny** statements in an extended access list are in effect, making your access list more granular and specific to an absolute or periodic time period.
- After you create a named access list, you might want to add entries or change the order of the entries, known as resequencing an access list.
- You can achieve finer granularity when filtering packets by filtering on noninitial fragments of packets.

Time-Based and Distributed Time-Based Access Lists

Time-based access lists implement access list entries based on particular times of the day or week. This is an advantage when you don't want access list entries always in effect or in effect as soon as they are applied. Use time-based access lists to make the enforcement of permit or deny conditions granular, based on time and date.

Distributed time-based access lists are those that are supported on line cards for the Cisco 7500 series routers. Packets destined for an interface configured with time-based access lists are distributed switched through the line card.

Types of IP Access Lists

There are several types of access lists that are distinct because of how they are triggered, their temporary nature, or how their behavior differs from an ordinary access list.

Authentication Proxy

Authentication proxy provides dynamic, per-user authentication and authorization, authenticating users against industry standard TACACS+ and RADIUS authentication protocols. Authenticating and authorizing connections by users provides more robust protection against network attacks.

Context-Based Access Control

Context-based access control (CBAC) examines not only network layer and transport layer information, but also the application-layer protocol information (such as FTP information) to learn about the state of TCP and UDP connections. CBAC maintains connection state information for individual connections. This state information is used to make intelligent decisions about whether packets should be permitted or denied, and dynamically creates and deletes temporary openings in the firewall.

Dynamic Access Lists with the Lock-and-Key Feature

Dynamic access lists provide temporary access to designated users who are using Telnet to reach designated hosts through a firewall. Dynamic access lists involve user authentication and authorization.

Reflexive Access Lists

Reflexive access lists provide filtering on upper-layer IP protocol sessions. They contain temporary entries that are automatically created when a new IP session begins. They are nested within extended, named IP access lists that are applied to an interface. Reflexive access lists are typically configured on border routers, which pass traffic between an internal and external network. These are often firewall routers. Reflexive access lists do not end with an implicit deny statement because they are nested within an access list and the subsequent statements need to be examined.

Where to Apply an Access List

If you are applying an access list to an interface, carefully consider whether to specify it as **in** (inbound) or **out** (outbound). Applying an access list to an incoming or outgoing interface controls the traffic that will enter or leave the router's interface or process level (in the case of filtering on TTL values).

- When an inbound access list is applied to an interface, after the software receives a packet, the software checks the packet against the access list statements. If the access list permits the packet, the software continues to process the packet. Therefore, filtering on incoming packets can save router resources because filtered packets will not go through the router.

- Access lists that apply to outbound packets are filtering packets that have already gone through the router. Packets that pass the access list are transmitted (sent) out the interface.
- The TCP ACL splitting feature of Rate-Based Satellite Control Protocol (RBSCP) is an example of a feature that can be used on an outgoing interface. The access list controls which packets are subject to TCP ACK splitting.

Access lists can be used in ways other than applying them to interfaces. The following are additional places to apply an access list.

- To restrict incoming and outgoing connections between a particular vty (into a Cisco device) and the network devices at addresses in an access list, apply an access list to a line. See the “[Controlling Access to a Virtual Terminal Line](#)” module.
- Referencing an access list from a **debug** command limits the amount of information displayed to only the information permitted by the access list, such as sources, destinations, or protocols, for example.
- Access lists can be used to control routing updates, to control dial-on-demand routing (DDR), and to control quality of service (QoS) features, for example. See the appropriate configuration chapters for using access lists with these features.

Where to Go Next

You must first decide what you want to restrict, and then select the type of access list that achieves your goal. Next, you will create an access list that permits or denies packets based on values in the fields you specify, and finally, you will apply the access list (which determines its placement).

Assuming you have decided what you want to restrict and what type of access list you need, your next step is to create an access list. Creating an access list based on source address, destination address, or protocol is described in the “[Creating an IP Access List and Applying It to an Interface](#)” module. You could create an access list that filters on other fields, as described in “[Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values](#).” If you want to control access to a virtual line, see “Controlling Access to a Virtual Terminal Line.” If the purpose of your access list is to control routing updates or QoS features, for example, see the appropriate technology chapter.

Creating an IP Access List and Applying It to an Interface

First Published: August 18, 2006

Last Updated: August 18, 2006

IP access lists provide many benefits for securing a network and achieving nonsecurity goals, such as determining quality of service (QoS) factors or limiting **debug** command output. This module describes how to create standard, extended, named, and numbered IP access lists. An access list can be referenced by a name or a number. Standard access lists filter on only the source address in IP packets. Extended access lists can filter on source address, destination address, and other fields in an IP packet.

After you create an access list, you must apply it to something in order for it to have any effect. This module describes how to apply an access list to an interface. However, there are many other uses for an access list, which are referenced in this module and described in other modules and in other configuration guides for various technologies.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Creating IP Access Lists](#)” section on page 24.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Creating an IP Access List and Applying It to an Interface

Before you create or apply an IP access list, you should understand the concepts in the “IP Access List Overview” module. You should also have IP running in your network.

Information About Creating an IP Access List and Applying It to an Interface

You should understand the following concepts before creating an IP access list.

- [Helpful Hints for Creating IP Access Lists, page 2](#)
- [Access List Remarks, page 3](#)
- [Additional IP Access List Features, page 3](#)

Helpful Hints for Creating IP Access Lists

The following tips will help you avoid unintended consequences and help you create more efficient access lists.

- Create the access list before applying it to an interface (or elsewhere), because if you apply a nonexistent access list to an interface and then proceed to configure the access list, the first statement is put into effect, and the implicit **deny** statement that follows could cause you immediate access problems.
- Another reason to configure an access list before applying it is because an interface with an empty access list applied to it permits all traffic.
- All access lists need at least one **permit** statement; otherwise, all packets are denied and no traffic passes.
- Because the software stops testing conditions after it encounters the first match (to either a **permit** or **deny** statement), you will reduce processing time and resources if you put the statements that packets are most likely to match at the beginning of the access list. Place more frequently occurring conditions before less frequent conditions.
- Organize your access list so that more specific references in a network or subnet appear before more general ones.
- Use the statement **permit any any** if you want to allow all other packets not already denied. Using the statement **permit any any** in effect avoids denying all other packets with the implicit deny statement at the end of an access list. Do not make your first access list entry **permit any any** because all traffic will get through; no packets will reach the subsequent testing. In fact, once you specify **permit any any**, all traffic not already denied will get through.

- Although all access lists end with an implicit **deny** statement, we recommend use of an explicit **deny** statement (for example, **deny ip any any**). On most platforms, you can display the count of packets denied by issuing the **show access-list** command, thus finding out more information about who your access list is disallowing. Only packets denied by explicit **deny** statements are counted, which is why the explicit **deny** statement will yield more complete data for you.
- While you are creating an access list or after it is created, you might want to delete an entry.
 - You cannot delete an entry from a *numbered* access list; trying to do so will delete the entire access list. If you need to delete an entry, you need to delete the entire access list and start over.
 - You can delete an entry from a *named* access list. Use the **no permit** or **no deny** command to delete the appropriate entry.
- In order to make the purpose of individual statements more scannable and easily understood at a glance, you can write a helpful remark before or after any statement by using the **remark** command.
- If you want to deny access to a particular host or network and find out if someone from that network or host is attempting to gain access, include the **log** keyword with the corresponding **deny** statement so that the packets denied from that source are logged for you.
- This hint applies to the placement of your access list. When trying to save resources, remember that an inbound access list applies the filter conditions *before* the routing table lookup. An outbound access list applies the filter conditions *after* the routing table lookup.

Access List Remarks

You can include comments (remarks) about entries in a named IP access list. An access list remark is an optional comment before or after an access list entry that describes the entry for you at a glance, so you do not have to interpret the purpose of the entry by its command syntax. Each remark is limited to 100 characters.

The remark can go before or after a **permit** or **deny** statement. You should be consistent about where you put your remarks so that it is clear which remark describes which statement. It could be confusing to have some remarks before the associated **permit** or **deny** statements and some remarks after the associated statements.

The following example of a remark is a user-friendly description of what the subsequent **deny** statement does.

```
ip access-list extended telnetting
remark Do not allow host1 subnet to telnet out
deny tcp host 172.69.2.88 any eq telnet
```

Additional IP Access List Features

Beyond the basic steps to create a standard or extended access list, you can enhance your access lists as mentioned below. Each of these methods is described completely in the module entitled “[Refining an Access List](#).”

- You can impose dates and times when **permit** or **deny** statements in an extended access list are in effect, making your access list more granular and specific to an absolute or periodic time period.
- After you create a named or numbered access list, you might want to add entries or change the order of the entries, known as resequencing an access list.
- You can achieve finer granularity when filtering packets by filtering on noninitial fragments of packets.

How to Create an IP Access List and Apply It to an Interface

This section describes the general ways to create a standard or extended access list using either a name or a number. Access lists are very flexible; the tasks simply illustrate one **permit** command and one **deny** command to provide you the command syntax of each. Only you can determine how many **permit** and **deny** commands you need and their order.

Note

The first two tasks in this module create an access list; you must apply the access list in order for it to function. If you want to apply the access list to an interface, perform the task [“Applying the Access List to an Interface” section on page 16](#).

If you don’t intend to apply the access list to an interface, see the [“Where to Go Next” section on page 21](#) for pointers to modules that describe other ways to apply access lists.

- [Creating a Standard Access List to Filter on Source Address, page 4](#)
- [Creating an Extended Access List, page 10](#)
- [Applying the Access List to an Interface, page 16](#)

Creating a Standard Access List to Filter on Source Address

If you want to filter on source address only, a standard access list is simple and sufficient. There are two alternative types of standard access list: named and numbered. Named access lists allow you to identify your access lists with a more intuitive name rather than a number, and they also support more features than numbered access lists.

- [Creating a Named Access List to Filter on Source Address, page 4](#)
- [Creating a Numbered Access List to Filter on Source Address, page 7](#)

Creating a Named Access List to Filter on Source Address

Use a standard, named access list if you need to filter on source address only. This task illustrates one **permit** statement and one **deny** statement, but the actual statements you use and their order depend on what you want to filter or allow. Define your **permit** and **deny** statements in the order that achieves your filtering goals.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list standard** *name*
4. **remark** *remark*
5. **deny** {*source* [*source-wildcard*] | **any**} [**log**]
6. **remark** *remark*
7. **permit** {*source* [*source-wildcard*] | **any**} [**log**]
8. Repeat some combination of Steps 4 through 7 until you have specified the source networks and hosts on which you want to base your access list.

9. `end`
10. `show ip access-list`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list standard name Example: Router(config)# ip access-list standard R&D	Defines a standard IP access list using a name and enters standard named access list configuration mode.
Step 4	remark remark Example: Router(config-std-nacl)# remark deny Sales network	(Optional) Adds a user-friendly comment about an access list entry. <ul style="list-style-type: none"> A remark can precede or follow an access list entry. In this example, the remark reminds the network administrator that the subsequent entry denies the Sales network access to the interface (assuming this access list is later applied to an interface).
Step 5	deny {source [source-wildcard] any} [log] Example: Router(config-std-nacl)# deny 172.16.0.0 0.0.255.255 log	(Optional) Denies the specified source based on a source address and wildcard mask. <ul style="list-style-type: none"> If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. In this example, all hosts on network 172.16.0.0 are denied passing the access list. Because this example explicitly denies a source address and the log keyword is specified, any packets from that source are logged when they are denied. This is a way to be notified that someone on a network or host is trying to gain access.
Step 6	remark remark Example: Router(config-std-nacl)# remark Give access to Tester's host	(Optional) Adds a user-friendly comment about an access list entry. <ul style="list-style-type: none"> A remark can precede or follow an access list entry. This remark reminds the network administrator that the subsequent entry allows the Tester's host access to the interface.

	Command or Action	Purpose
Step 7	<p>permit {<i>source</i> [<i>source-wildcard</i>] any} [log]</p> <p>Example: Router(config-std-nacl)# permit 172.18.5.22 0.0.0.0</p>	<p>Permits the specified source based on a source address and wildcard mask.</p> <ul style="list-style-type: none"> Every access list needs at least one permit statement; it need not be the first entry. If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. In this example, host 172.18.5.22 is allowed to pass the access list.
Step 8	Repeat some combination of Steps 4 through 7 until you have specified the sources on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 9	<p>end</p> <p>Example: Router(config-std-nacl)# end</p>	Ends configuration mode and brings the system to privileged EXEC mode.
Step 10	<p>show ip access-list</p> <p>Example: Router# show ip access-list</p>	(Optional) Displays the contents of all current IP access lists.

What to Do Next

The access list you created is not in effect until you apply it to an interface, a vty line, or reference it from a command that uses an access list. See the [“Applying the Access List to an Interface”](#) section on page 16 or the [“Where to Go Next”](#) section on page 21 for pointers to modules that describe other ways to use access lists.

Creating a Numbered Access List to Filter on Source Address

Configure a standard, numbered access list if you need to filter on source address only and you prefer not to use a named access list.

IP standard access lists are numbered 1 to 99 or 1300 to 1999. This task illustrates one **permit** statement and one **deny** statement, but the actual statements you use and their order depend on what you want to filter or allow. Define your **permit** and **deny** statements in the order that achieves your filtering goals.

SUMMARY STEPS

- enable**
- configure terminal**
- access-list** *access-list-number* **remark** *remark*
- access-list** *access-list-number* **permit** {*source* [*source-wildcard*] | **any**} [**log**]

5. **access-list** *access-list-number* **remark** *remark*
6. **access-list** *access-list-number* **deny** {*source* [*source-wildcard*] | **any**} [**log**]
7. Repeat some combination of Steps 3 through 6 until you have specified the sources on which you want to base your access list.
8. **end**
9. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list access-list-number remark remark Example: Router(config)# access-list 1 remark Give access to Jones	(Optional) Adds a user-friendly comment about an access list entry. <ul style="list-style-type: none"> A remark of up to 100 characters can precede or follow an access list entry.
Step 4	access-list access-list-number permit {source [source-wildcard] any} [log] Example: Router(config)# access-list 1 permit 172.16.5.22 0.0.0.0	Permits the specified source based on a source address and wildcard mask. <ul style="list-style-type: none"> Every access list needs at least one permit statement; it need not be the first entry. Standard IP access lists are numbered 1 to 99 or 1300 to 1999. If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. In this example, host 172.16.5.22 is allowed to pass the access list.
Step 5	access-list access-list-number remark remark Example: Router(config)# access-list 1 remark Don't give access to Johnson and log any attempts	(Optional) Adds a user-friendly comment about an access list entry. <ul style="list-style-type: none"> A remark of up to 100 characters can precede or follow an access list entry.
Step 6	access-list access-list-number deny {source [source-wildcard] any} [log] Example: Router(config)# access-list 1 deny 172.16.7.34 0.0.0.0	Denies the specified source based on a source address and wildcard mask. <ul style="list-style-type: none"> If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. Optionally use the abbreviation any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. In this example, host 172.16.7.34 is denied passing the access list.

	Command or Action	Purpose
Step 7	Repeat some combination of Steps 3 through 6 until you have specified the sources on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 8	end Example: Router(config-std-nacl)# end	Ends configuration mode and brings the system to privileged EXEC mode.
Step 9	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.

What to Do Next

The access list you created is not in effect until you apply it to an interface, a vty line, or reference it from a command that uses an access list. See the [“Applying the Access List to an Interface” section on page 16](#) or the [“Where to Go Next” section on page 21](#) for pointers to modules that describe other ways to use access lists.

Creating an Extended Access List

If you want to filter on anything other than source address, you need to create an extended access list. There are two alternative types of extended access list: named and numbered. Named access lists allow you to identify your access lists with a more intuitive name rather than a number, and they also support more features.

For details on how to filter something other than source or destination address, see the syntax descriptions in the command reference documentation.

- [Creating a Named Extended Access List, page 10](#)
- [Creating a Numbered Extended Access List, page 13](#)

Creating a Named Extended Access List

Create a named extended access list if you want to filter on source and destination address, or a combination of addresses and other IP fields.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *name*
4. **remark** *remark*
5. **deny** *protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log | log-input] [time-range time-range-name] [fragments]*

6. **remark** *remark*
7. **permit** *protocol source [source-wildcard] destination [destination-wildcard]* [**option** *option-name*] [**precedence** *precedence*] [**tos** *tos*] [**established**] [**log** | **log-input**] [**time-range** *time-range-name*] [**fragments**]
8. Repeat some combination of Steps 4 through 7 until you have specified the fields and values on which you want to base your access list.
9. **end**
10. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended name Example: Router(config)# ip access-list extended nomarketing	Defines an extended IP access list using a name and enters extended named access list configuration mode.
Step 4	remark remark Example: Router(config-ext-nacl)# remark protect server by denying access from the Marketing network	(Optional) Adds a user-friendly comment about an access list entry. <ul style="list-style-type: none"> A remark can precede or follow an access list entry. In this example, the remark reminds the network administrator that the subsequent entry denies the Sales network access to the interface.
Step 5	deny protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log log-input] [time-range time-range-name] [fragments] Example: Router(config-ext-nacl)# deny ip 172.18.0.0 0.0.255.255 host 172.16.40.10 log	(Optional) Denies any packet that matches all of the conditions specified in the statement. <ul style="list-style-type: none"> If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255. Optionally use the keyword host source to indicate a source and source wildcard of <i>source</i> 0.0.0.0 or the abbreviation host destination to indicate a destination and destination wildcard of <i>destination</i> 0.0.0.0. In this example, packets from all sources are denied access to the destination network 172.18.0.0. Logging messages about packets permitted or denied by the access list are sent to the facility configured by the logging facility command (for example, console, terminal, or syslog). That is, any packet that matches the access list will cause an informational logging message about the packet to be sent to the configured facility. The level of messages logged to the console is controlled by the logging console command.

	Command or Action	Purpose
Step 6	remark <i>remark</i> Example: Router(config-ext-nacl)# remark allow TCP from any source to any destination	(Optional) Adds a user-friendly comment about an access list entry. <ul style="list-style-type: none"> A remark can precede or follow an access list entry.
Step 7	permit <i>protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log log-input] [time-range time-range-name] [fragments]</i> Example: Router(config-ext-nacl)# permit tcp any any	Permits any packet that matches all of the conditions specified in the statement. <ul style="list-style-type: none"> Every access list needs at least one permit statement. If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255. In this example, TCP packets are allowed from any source to any destination. Use the log-input keyword to include input interface, source MAC address, or virtual circuit in the logging output.
Step 8	Repeat some combination of Steps 4 through 7 until you have specified the fields and values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 9	end Example: Router(config-ext-nacl)# end	Ends configuration mode and brings the system to privileged EXEC mode.
Step 10	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.

What to Do Next

The access list you created is not in effect until you apply it to an interface, a vty line, or reference it from a command that uses an access list. See the [“Applying the Access List to an Interface”](#) section on page 16 or the [“Where to Go Next”](#) section on page 21 for pointers to modules that describe other ways to use access lists.

Creating a Numbered Extended Access List

Create a numbered extended access list if you want to filter on source and destination address, or a combination of addresses and other IP fields, and you prefer not to use a name. Extended IP access lists are numbered 100 to 199 or 2000 to 2699.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list** *access-list-number* **remark** *remark*
4. **access-list** *access-list-number* **permit** *protocol* { *source* [*source-wildcard*] | **any** } { *destination* [*destination-wildcard*] | **any** } [**precedence** *precedence*] [**tos** *tos*] [**established**] [**log** | **log-input**] [**time-range** *time-range-name*] [**fragments**]
5. **access-list** *access-list-number* **remark** *remark*
6. **access-list** *access-list-number* **deny** *protocol* { *source* [*source-wildcard*] | **any** } { *destination* [*destination-wildcard*] | **any** } [**precedence** *precedence*] [**tos** *tos*] [**established**] [**log** | **log-input**] [**time-range** *time-range-name*] [**fragments**]
7. Repeat some combination of Steps 3 through 6 until you have specified the fields and values on which you want to base your access list.
8. **end**
9. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example: Router> enable</p>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example: Router# configure terminal</p>	<p>Enters global configuration mode.</p>
Step 3	<p>access-list <i>access-list-number</i> remark <i>remark</i></p> <p>Example: Router(config)# access-list 107 remark allow Telnet packets from any source to network 173.69.0.0 (headquarters)</p>	<p>(Optional) Adds a user-friendly comment about an access list entry.</p> <ul style="list-style-type: none"> A remark of up to 100 characters can precede or follow an access list entry.
Step 4	<p>access-list <i>access-list-number</i> permit <i>protocol</i> [<i>source</i> [<i>source-wildcard</i>] any] [<i>destination</i> [<i>destination-wildcard</i>] any] [precedence <i>precedence</i>] [tos <i>tos</i>] [established] [log log-input] [time-range <i>time-range-name</i>] [fragments]</p> <p>Example: Router(config)# access-list 107 permit tcp any 173.69.0.0 0.0.255.255 eq telnet</p>	<p>Permits any packet that matches all of the conditions specified in the statement.</p> <ul style="list-style-type: none"> Every access list needs at least one permit statement; it need not be the first entry. Extended IP access lists are numbered 100 to 199 or 2000 to 2699. If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255. TCP and other protocols have additional syntax available. See the access-list command in the command reference for complete syntax.
Step 5	<p>access-list <i>access-list-number</i> remark <i>remark</i></p> <p>Example: Router(config)# access-list 107 remark deny all other TCP packets</p>	<p>(Optional) Adds a user-friendly comment about an access list entry.</p> <ul style="list-style-type: none"> A remark of up to 100 characters can precede or follow an access list entry.

	Command or Action	Purpose
Step 6	<p>access-list <i>access-list-number</i> deny <i>protocol</i> {<i>source</i> [<i>source-wildcard</i>] any} {<i>destination</i> [<i>destination-wildcard</i>] any} [precedence <i>precedence</i>] [tos <i>tos</i>] [established] [log log-input] [time-range <i>time-range-name</i>] [fragments]</p> <p>Example: Router(config)# access-list 107 deny tcp any any</p>	<p>Denies any packet that matches all of the conditions specified in the statement.</p> <ul style="list-style-type: none"> If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255.
Step 7	Repeat some combination of Steps 3 through 6 until you have specified the fields and values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 8	<p>end</p> <p>Example: Router(config)# end</p>	Ends configuration mode and brings the system to privileged EXEC mode.
Step 9	<p>show ip access-list</p> <p>Example: Router# show ip access-list</p>	(Optional) Displays the contents of all current IP access lists.

Applying the Access List to an Interface

Perform this task to apply an access list to an interface.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip access-group** {*access-list-number* | *access-list-name*} {**in** | **out**}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: Router(config)# interface ethernet 0	Specifies an interface and enters interface configuration mode.
Step 4	ip access-group { <i>access-list-number</i> <i>access-list-name</i> } { in out } Example: Router(config-if)# ip access-group noncorp in	Applies the specified access list to the incoming or outgoing interface. <ul style="list-style-type: none"> When you are filtering on source addresses, you typically apply the access list to an incoming interface. Filtering on source addresses is most efficient when applied near the destination.

What to Do Next

The access list you created is not in effect until you apply it to an interface, a vty line, or reference it from a command that uses an access list. See the [“Applying the Access List to an Interface”](#) section on page 16 or the [“Where to Go Next”](#) section on page 21 for pointers to modules that describe other ways to use access lists.

Configuration Examples for IP Access Lists

This section contains the following examples of named and numbered, standard and extended IP access lists that are applied to an interface or referenced by a command:

- [Filtering on Source Address \(Hosts\): Example, page 18](#)
- [Filtering on Source Address \(Subnet\): Example, page 18](#)
- [Filtering on Source Address, Destination Address, and IP Protocols: Example, page 18](#)
- [Filtering on Source Address \(Host and Subnets\) Using a Numbered Access List: Example, page 19](#)
- [Preventing Telnet Access to a Subnet: Example, page 19](#)
- [Filtering on TCP and ICMP Using Port Numbers: Example, page 19](#)
- [Allowing SMTP \(E-mail\) and Established TCP Connections: Example, page 19](#)
- [Preventing Access to the Web By Filtering on Port Name: Example, page 20](#)
- [Filtering on Source Address and Logging the Packets Permitted and Denied: Example, page 20](#)
- [Limiting Debug Output: Example, page 21](#)

Filtering on Source Address (Hosts): Example

In the following example, the workstation belonging to Jones is allowed access to Ethernet interface 0 and the workstation belonging to Smith is not allowed access:

```
interface ethernet 0
 ip access-group workstations in
!
ip access-list standard workstations
 remark Permit only Jones workstation through
 permit 172.16.2.88
 remark Do not allow Smith workstation through
 deny 172.16.3.13
```

Filtering on Source Address (Subnet): Example

In the following example, the Jones subnet is not allowed access to Ethernet interface 0, but the Main subnet is allowed access:

```
interface ethernet 0
 ip access-group prevention in
!
ip access-list standard prevention
 remark Do not allow Jones subnet through
 deny 172.22.0.0 0.0.255.255
 remark Allow Main subnet
 permit 172.25.0.0 0.0.255.255
```

Filtering on Source Address, Destination Address, and IP Protocols: Example

The following configuration example shows an interface with two access lists, one applied to outgoing packets and one applied to incoming packets. The standard access list named Internet_filter filters outgoing packets on source address. The only packets allowed out the interface must be from source 172.16.3.4.

The extended access list named marketing_group filters incoming packets. The access list permits Telnet packets from any source to network 172.26.0.0 and denies all other TCP packets. It permits any ICMP packets. It denies UDP packets from any source to network 172.26.0.0 on port numbers less than 1024. Finally, the access list denies all other IP packets and performs logging of packets passed or denied by that entry.

```
interface Ethernet0/5
 ip address 172.20.5.1 255.255.255.0
 ip access-group Internet_filter out
 ip access-group marketing_group in
!
ip access-list standard Internet_filter
 permit 172.16.3.4
ip access-list extended marketing_group
 permit tcp any 172.26.0.0 0.0.255.255 eq telnet
 deny tcp any any
 permit icmp any any
 deny udp any 172.26.0.0 0.0.255.255 lt 1024
 deny ip any any
```

Filtering on Source Address (Host and Subnets) Using a Numbered Access List: Example

In the following example, network 10.0.0.0 is a Class A network whose second octet specifies a subnet; that is, its subnet mask is 255.255.0.0. The third and fourth octets of a network 10.0.0.0 address specify a particular host. Using access list 2, the Cisco IOS software would accept one address on subnet 48 and reject all others on that subnet. The last line of the list shows that the software would accept addresses on all other network 10.0.0.0 subnets.

```
interface ethernet 0
  ip access-group 2 in
!
access-list 2 permit 10.48.0.3
access-list 2 deny 10.48.0.0 0.0.255.255
access-list 2 permit 10.0.0.0 0.255.255.255
```

Preventing Telnet Access to a Subnet: Example

In the following example, the Jones subnet is not allowed to Telnet out Ethernet interface 0:

```
interface ethernet 0
  ip access-group telnetting out
!
ip access-list extended telnetting
  remark Do not allow Jones subnet to telnet out
  deny tcp 172.20.0.0 0.0.255.255 any eq telnet
  remark Allow Top subnet to telnet out
  permit tcp 172.33.0.0 0.0.255.255 any eq telnet
```

Filtering on TCP and ICMP Using Port Numbers: Example

In the following example, the first line of the extended access list named goodports permits any incoming TCP connections with destination ports greater than 1023. The second line permits incoming TCP connections to the Simple Mail Transfer Protocol (SMTP) port of host 172.28.1.2. The last line permits incoming ICMP messages for error feedback.

```
interface ethernet 0
  ip access-group goodports in
!
ip access-list extended goodports
  permit tcp any 172.28.0.0 0.0.255.255 gt 1023
  permit tcp any host 172.28.1.2 eq 25
  permit icmp any 172.28.0.0 255.255.255.255
```

Allowing SMTP (E-mail) and Established TCP Connections: Example

Suppose you have a network connected to the Internet, and you want any host on an Ethernet to be able to form TCP connections to any host on the Internet. However, you do not want IP hosts to be able to form TCP connections to hosts on the Ethernet except to the mail (SMTP) port of a dedicated mail host.

SMTP uses TCP port 25 on one end of the connection and a random port number on the other end. The same two port numbers are used throughout the life of the connection. Mail packets coming in from the Internet will have a destination port of 25. Outbound packets will have the port numbers reversed. The

fact that the secure system behind the router always will accept mail connections on port 25 is what makes possible separate control of incoming and outgoing services. The access list can be configured on either the outbound or inbound interface.

In the following example, the Ethernet network is a Class B network with the address 172.18.0.0, and the address of the mail host is 172.18.1.2. The **established** keyword is used only for the TCP protocol to indicate an established connection. A match occurs if the TCP datagram has the ACK or RST bits set, which indicate that the packet belongs to an existing connection.

```
interface ethernet 0
  ip access-group 102 in
!
access-list 102 permit tcp any 172.18.0.0 0.0.255.255 established
access-list 102 permit tcp any host 172.18.1.2 eq 25
```

Preventing Access to the Web By Filtering on Port Name: Example

In the following example, the Winter and Smith workstations are not allowed web access; other hosts on network 172.20.0.0 are allowed web access:

```
interface ethernet 0
  ip access-group no_web out
!
ip access-list extended no_web
  remark Do not allow Winter to browse the web
  deny host 172.20.3.85 any eq http
  remark Do not allow Smith to browse the web
  deny host 172.20.3.13 any eq http
  remark Allow others on our network to browse the web
  permit 172.20.0.0 0.0.255.255 any eq http
```

Filtering on Source Address and Logging the Packets Permitted and Denied: Example

The following example defines access lists 1 and 2, both of which have logging enabled:

```
interface ethernet 0
  ip address 172.16.1.1 255.0.0.0
  ip access-group 1 in
  ip access-group 2 out
!
access-list 1 permit 172.25.0.0 0.0.255.255 log
access-list 1 deny 172.30.0.0 0.0.255.255 log
!
access-list 2 permit 172.27.3.4 log
access-list 2 deny 172.17.0.0 0.0.255.255 log
```

If the interface receives 10 packets from 172.25.7.7 and 14 packets from 172.17.23.21, the first log will look like the following:

```
list 1 permit 172.25.7.7 1 packet
list 2 deny 172.17.23.21 1 packet
```

Five minutes later, the console will receive the following log:

```
list 1 permit 172.25.7.7 9 packets
list 2 deny 172.17.23.21 13 packets
```

Limiting Debug Output: Example

The following example configuration example uses an access list to limit the **debug** command output displayed. Limiting debug output narrows the volume of data to what you are interested in, saving you time and resources.

```
ip access-list idaho
  remark Displays only advertisements for LDP peer in idaho
  permit host 10.0.0.44

Router# debug mpls ldp advertisements peer-acl idaho

tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 172.17.0.33
tagcon: peer 10.0.0.44:0 (pp 0x60E105BC): advertise 172.16.0.31

Where to Go Next

This module describes how to create an access list that permits or denies packets based on source or destination address or protocol. However, there are other fields you could filter on, and other ways to use access lists. If you want to create an access list that filters on other fields or if you want to apply an access list to something other than an interface, you should decide what you want to restrict in your network and determine the type of access list that achieves your goal.

See the following table for references to other fields to filter and other ways to use an IP access list.

Feature Information for Creating IP Access Lists

[Table 1](#) lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

For information on a feature in this technology that is not documented here, see the IP Access List Roadmap.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

[Table 1](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 *Feature Information for Creating IP Access Lists*

Feature Name	Releases	Feature Configuration Information
—	Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Commented IP Access List Entries	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
Standard IP Access List Logging	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values

First Published: August 18, 2006
Last Updated: August 18, 2006

This module describes how to use an IP access list to filter IP packets that contain certain IP Options, TCP flags, noncontiguous ports, or time-to-live (TTL) values.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Using an IP Access List to Filter Packets](#)” section on page 21.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values

Before you perform any of the tasks in this module, you should be familiar with the information in the following modules:

- “IP Access List Overview”
- “Creating an IP Access List and Applying It to an Interface”

How to Create an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values

This section includes the following optional tasks:

- [Filtering Packets That Contain IP Options, page 2](#)
- [Filtering Packets That Contain TCP Flags, page 5](#)
- [Configuring an Access Control Entry with Noncontiguous Ports, page 8](#)
- [Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry, page 10](#)
- [Filtering Packets Based on TTL Value, page 12](#)
- [Enabling Control Plane Policing to Filter on TTL Values 0 and 1, page 15](#)

Filtering Packets That Contain IP Options

The task in this section configures an access list to filter packets that contain IP Options and verifies that the access list has been configured correctly.

IP Options

IP uses four key mechanisms in providing its service: Type of Service, Time to Live, Options, and Header Checksum.

The Options, commonly referred to as IP Options, provide for control functions that are required in some situations but unnecessary for the most common communications. IP Options include provisions for time stamps, security, and special routing.

IP Options may or may not appear in datagrams. They must be implemented by all IP modules (host and gateways). What is optional is their transmission in any particular datagram, not their implementation. In some environments the security option may be required in all datagrams.

The option field is variable in length. There may be zero or more options. IP Options can have one of two formats:

- Format 1: A single octet of option-type.
- Format 2: An option-type octet, an option-length octet, and the actual option-data octets.

The option-length octet counts the option-type octet, the option-length octet, and the option-data octets.

The option-type octet is viewed as having three fields: a 1-bit copied flag, a 2-bit option class, and a 5-bit option number. These fields form an 8-bit value for the option type field. IP Options are commonly referred to by their 8-bit value.

For a complete list and description of IP Options, refer to RFC 791, *Internet Protocol* at the following URL:

<http://www.faqs.org/rfcs/rfc791.html>

Benefits of Filtering IP Options

- Filtering of packets that contain IP Options from the network relieves downstream routers and hosts of the load from options packets.
- This feature also minimizes load to the Route Processor (RP) for packets with IP Options that require RP processing on distributed systems. Previously, the packets were always routed to or processed by the RP CPU. Filtering the packets prevents them from impacting the RP.

Restrictions

- The ACL Support for Filtering IP Options feature can be used only with named, extended ACLs.
- Resource Reservation Protocol (RSVP) Multiprotocol Label Switching Traffic Engineering (MPLS TE), Internet Group Management Protocol Version 2 (IGMPV2), and other protocols that use IP Options packets may not function in drop or ignore mode if this feature is configured.
- On most Cisco routers, a packet with IP Options is not switched in hardware, but requires control plane software processing (primarily because there is a need to process the options and rewrite the IP header), so all IP packets with IP Options will be filtered and switched in software.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *access-list-name*
4. [*sequence-number*] **deny** *protocol source source-wildcard destination destination-wildcard* [**option** *option-value*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]
5. [*sequence-number*] **permit** *protocol source source-wildcard destination destination-wildcard* [**option** *option-value*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]
6. Repeat Step 4 or Step 5 as necessary.
7. **end**
8. **show ip access-lists** *access-list-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended access-list-name Example: Router(config)# ip access-list extended mylist1	Specifies the IP access list by name and enters named access list configuration mode. Note The ACL Support for Filtering IP Options feature works only with named, extended ACLs.
Step 4	<pre>[sequence-number] deny protocol source source-wildcard destination destination-wildcard [option option-value] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</pre> Example: Router(config-ext-nacl)# deny ip any any option traceroute	(Optional) Specifies a deny statement in named IP access list mode. <ul style="list-style-type: none"> This access list happens to use a deny statement first, but a permit statement could appear first, depending on the order of statements you need. Use the option keyword and <i>option-value</i> argument to filter packets that contain a particular IP Option. In this example, any packet that contains the traceroute IP Option will be filtered out. Use the no sequence-number form of this command to delete an entry.
Step 5	<pre>[sequence-number] permit protocol source source-wildcard destination destination-wildcard [option option-value] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</pre> Example: Router(config-ext-nacl)# permit ip any any option security	Specifies a permit statement in named IP access list mode. <ul style="list-style-type: none"> In this example, any packet (not already filtered) that contains the security IP Option will be permitted. Use the no sequence-number form of this command to delete an entry.
Step 6	Repeat Step 4 or Step 5 as necessary.	Allows you to revise the access list.
Step 7	end Example: Router(config-ext-nacl)# end	(Optional) Exits the configuration mode and returns to privileged EXEC mode.
Step 8	show ip access-lists access-list-name Example: Router# show ip access-lists mylist1	(Optional) Displays the contents of the IP access list. <ul style="list-style-type: none"> Review the output to verify that the access list includes the new entry.

What to Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Note

To effectively eliminate all packets that contain IP Options, we recommend that you configure the global **ip options drop** command.

Filtering Packets That Contain TCP Flags

The task in this section configures an access list to filter packets that contain TCP flags and verifies that the access list has been configured correctly.

Benefits of Filtering on TCP Flags

The ACL TCP Flags Filtering feature provides a flexible mechanism for filtering on TCP flags. Before Cisco IOS Release 12.3(4)T, an incoming packet was matched as long as any TCP flag in the packet matched a flag specified in the access control entry (ACE). This behavior allows for a security loophole, because packets with all flags set could get past the access control list (ACL). The ACL TCP Flags Filtering feature allows you to select any combination of flags on which to filter. The ability to match on a flag set and on a flag not set gives you a greater degree of control for filtering on TCP flags, thus enhancing security.

Because TCP packets can be sent as false synchronization packets that can be accepted by a listening port, it is recommended that administrators of firewall devices set up some filtering rules to drop false TCP packets.

The ACEs that make up an access list can be configured to detect and drop unauthorized TCP packets by allowing only the packets that have a very specific group of TCP flags set or not set. The ACL TCP Flags Filtering feature gives users a greater degree of packet-filtering control in the following ways:

- Users can select any desired combination of TCP flags on which to filter TCP packets.
- Users can configure ACEs in order to allow matching on a flag that is set, as well as on a flag that is not set.

TCP Flags

[Table 1](#) lists the TCP flags, which are further described in RFC 793, *Transmission Control Protocol*.

Table 1 TCP Flags

TCP Flag	Purpose
ACK	Acknowledge flag—Indicates that the acknowledgment field of a segment specifies the next sequence number the sender of this segment is expecting to receive.
FIN	Finish flag—Used to clear connections.
PSH	Push flag— Indicates the data in the call should be immediately pushed through to the receiving user.
RST	Reset flag—Indicates that the receiver should delete the connection without further interaction.

Table 1 *TCP Flags (continued)*

TCP Flag	Purpose
SYN	Synchronize flag—Used to establish connections.
URG	Urgent flag—Indicates that the urgent field is meaningful and must be added to the segment sequence number.

Restrictions

- TCP flag filtering can be used only with named, extended ACLs.
- The ACL TCP Flags Filtering feature is supported only for Cisco IOS ACLs.
- Before Cisco IOS Release 12.3(4)T, the following command-line interface (CLI) format could be used to configure a TCP flag-checking mechanism:

permit tcp any any rst

The following format that represents the same ACE can be used with Cisco IOS Release 12.3(4)T and later releases:

permit tcp any any match-any +rst

Both the CLI formats are accepted; however, if the new keywords **match-all** or **match-any** are chosen, they must be followed by the new flags that are prefixed with “+” or “-”. It is advisable to use only the old format or the new format in a single ACL. You cannot mix and match the old and new CLI formats.

Caution

If a router having ACEs with the new syntax format is reloaded with an older version of Cisco IOS software that does not support the ACL TCP Flags Filtering feature, the ACEs will not be applied, leading to possible security loopholes.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended *access-list-name***
4. *[sequence-number] permit tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established | {match-any | match-all} {+ | -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]*
5. *[sequence-number] deny tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established | {match-any | match-all} {+ | -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]*
6. Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the **no sequence-number** command to delete an entry.
7. **end**
8. **show ip access-lists *access-list-name***

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example: Router> enable</p>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example: Router# configure terminal</p>	<p>Enters global configuration mode.</p>
Step 3	<p>ip access-list extended access-list-name</p> <p>Example: Router(config)# ip access-list extended kmd1</p>	<p>Specifies the IP access list by name and enters named access list configuration mode.</p> <p>Note The ACL TCP Flags Filtering feature works only with named, extended ACLs.</p>
Step 4	<p>[sequence-number] permit tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established {match-any match-all} {+ -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</p> <p>Example: Router(config-ext-nacl)# permit tcp any any match-any +rst</p>	<p>Specifies a permit statement in named IP access list mode.</p> <ul style="list-style-type: none"> This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. Use the TCP command syntax of the permit command. Any packet with the RST TCP header flag set will be matched and allowed to pass the named access list kmd1 in Step 3.
Step 5	<p>[sequence-number] deny tcp source source-wildcard [operator [port]] destination destination-wildcard [operator [port]] [established {match-any match-all} {+ -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</p> <p>Example: Router(config-ext-nacl)# deny tcp any any match-all -ack -fin</p>	<p>(Optional) Specifies a deny statement in named IP access list mode.</p> <ul style="list-style-type: none"> This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. Use the TCP command syntax of the deny command. Any packet that does not have the ACK flag set, and also does not have the FIN flag set, will not be allowed to pass the named access list kmd1 in Step 3. See the deny (IP) command for additional command syntax to permit upper-layer protocols (ICMP, IGMP, TCP, and UDP).
Step 6	<p>Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the no sequence-number command to delete an entry.</p>	<p>Allows you to revise the access list.</p>

	Command or Action	Purpose
Step 7	end Example: Router(config-ext-nacl)# end	(Optional) Exits the configuration mode and returns to privileged EXEC mode.
Step 8	show ip access-lists <i>access-list-name</i> Example: Router# show ip access-lists kmd1	(Optional) Displays the contents of the IP access list. <ul style="list-style-type: none"> Review the output to confirm that the access list includes the new entry.

What to Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Configuring an Access Control Entry with Noncontiguous Ports

Perform this task to create access list entries that use noncontiguous TCP or UDP port numbers. Although this task uses TCP ports, you could use the UDP syntax of the **permit** and **deny** commands to filter noncontiguous UDP ports.

Although this task uses a **permit** command first, use the **permit** and **deny** commands in the order that achieves your filtering goals.

Benefits of Using the ACL—Named ACL Support for Noncontiguous Ports on an Access Control Entry Feature

This feature greatly reduces the number of ACEs required in an access control list to handle multiple entries for the same source address, destination address, and protocol. If you maintain large numbers of ACEs, we recommend that you use this feature to consolidate existing groups of access list entries wherever it is possible and also when you create new access list entries. When you configure access list entries with noncontiguous ports, you will have fewer access list entries to maintain.

Restrictions

The ACL—Named ACL Support for Noncontiguous Ports on an Access Control Entry feature can be used only with named, extended ACLs.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *access-list-name*
4. [*sequence-number*] **permit tcp** *source source-wildcard* [*operator port* [*port*]] *destination destination-wildcard* [*operator* [*port*]] [**established** | {**match-any** | **match-all**} {+ | -} *flag-name*] [**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]

5. `[sequence-number] deny tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established | {match-any | match-all} {+ | -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]`
6. Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the `no sequence-number` command to delete an entry.
7. `end`
8. `show ip access-lists access-list-name`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example: Router> enable</p>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	<p><code>configure terminal</code></p> <p>Example: Router# configure terminal</p>	<p>Enters global configuration mode.</p>
Step 3	<p><code>ip access-list extended access-list-name</code></p> <p>Example: Router(config)# ip access-list extended kmd1</p>	<p>Specifies the IP access list by name and enters named access list configuration mode.</p>
Step 4	<p><code>[sequence-number] permit tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established {match-any match-all} {+ -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</code></p> <p>Example: Router(config-ext-nacl)# permit tcp any eq telnet ftp any eq 450 679</p>	<p>Specifies a permit statement in named IP access list configuration mode.</p> <ul style="list-style-type: none"> Operators include lt (less than), gt (greater than), eq (equal), neq (not equal), and range (inclusive range). If the operator is positioned after the source and source-wildcard arguments, it must match the source port. If the operator is positioned after the destination and destination-wildcard arguments, it must match the destination port. The range operator requires two port numbers. You can configure up to 10 ports after the eq and neq operators. All other operators require one port number. To filter UDP ports, use the UDP syntax of this command.

	Command or Action	Purpose
Step 5	<pre>[sequence-number] deny tcp source source-wildcard [operator port [port]] destination destination-wildcard [operator [port]] [established {match-any match-all} {+ -} flag-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</pre> <p>Example: Router(config-ext-nacl)# deny tcp any neq 45 565 632</p>	<p>(Optional) Specifies a deny statement in named access list configuration mode.</p> <ul style="list-style-type: none"> Operators include lt (less than), gt (greater than), eq (equal), neq (not equal), and range (inclusive range). If the <i>operator</i> is positioned after the <i>source</i> and <i>source-wildcard</i> arguments, it must match the source port. If the <i>operator</i> is positioned after the <i>destination</i> and <i>destination-wildcard</i> arguments, it must match the destination port. The range operator requires two port numbers. You can configure up to 10 ports after the eq and neq operators. All other operators require one port number. To filter UDP ports, use the UDP syntax of this command.
Step 6	Repeat Step 4 or Step 5 as necessary, adding statements by sequence number where you planned. Use the no sequence-number command to delete an entry.	Allows you to revise the access list.
Step 7	<p>end</p> <p>Example: Router(config-ext-nacl)# end</p>	(Optional) Exits named access list configuration mode and returns to privileged EXEC mode.
Step 8	<pre>show ip access-lists access-list-name</pre> <p>Example: Router# show ip access-lists kmd1</p>	<p>(Optional) Displays the contents of the access list.</p> <ul style="list-style-type: none"> Review the output to verify that the access list displays the new entries that you created.

Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry

Perform this task to consolidate a group of access list entries with noncontiguous ports into one access list entry.

Although this task uses TCP ports, you could use the UDP syntax of the **permit** and **deny** commands to filter noncontiguous UDP ports.

Although this task uses a **permit** command first, use the **permit** and **deny** commands in the order that achieves your filtering goals.

SUMMARY STEPS

1. **enable**
2. **show ip access-lists access-list-name**
3. **configure terminal**
4. **ip access-list extended access-list-name**

5. **no** *[sequence-number]* **permit** *protocol source source-wildcard destination destination-wildcard* **[option option-name]** **[precedence precedence]** **[tos tos]** **[log]** **[time-range time-range-name]** **[fragments]**
6. *[sequence-number]* **permit** *protocol source source-wildcard [operator port [port]] destination destination-wildcard [operator port [port]]* **[option option-name]** **[precedence precedence]** **[tos tos]** **[log]** **[time-range time-range-name]** **[fragments]**
7. Repeat Steps 5 and 6 as necessary, adding **permit** or **deny** statements to consolidate access list entries where possible. Use the **no sequence-number** command to delete an entry.
8. **end**
9. **show ip access-lists** *access-list-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	show ip access-lists <i>access-list-name</i> Example: Router# show ip access-lists mylist1	(Optional) Displays the contents of the IP access list. <ul style="list-style-type: none"> Review the output to see if you can consolidate any access list entries.
Step 3	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 4	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended mylist1	Specifies the IP access list by name and enters named access list configuration mode.
Step 5	no <i>[sequence-number]</i> permit <i>protocol source source-wildcard destination destination-wildcard</i> [option option-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments] Example: Router(config-ext-nacl)# no 10	Removes the redundant access list entry that can be consolidated. <ul style="list-style-type: none"> Repeat this step to remove entries to be consolidated because only the port numbers differ. After this step is repeated to remove the access list entries 20, 30, and 40, for example, those entries are removed because they will be consolidated into one permit statement. If a <i>sequence-number</i> is specified, the rest of the command syntax is optional.

	Command or Action	Purpose
Step 6	<pre>[sequence-number] permit protocol source source-wildcard [operator port [port]] destination destination-wildcard [operator port [port]] [option option-name] [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</pre> <p>Example: Router(config-ext-nacl)# permit tcp any neq 45 565 632 any eq 23 45 34 43</p>	<p>Specifies a permit statement in named access list configuration mode.</p> <ul style="list-style-type: none"> In this instance, a group of access list entries with noncontiguous ports was consolidated into one permit statement. You can configure up to 10 ports after the eq and neq operators.
Step 7	Repeat Steps 5 and 6 as necessary, adding permit or deny statements to consolidate access list entries where possible. Use the no sequence-number command to delete an entry.	Allows you to revise the access list.
Step 8	<p>end</p> <p>Example: Router(config-std-nacl)# end</p>	(Optional) Exits named access list configuration mode and returns to privileged EXEC mode.
Step 9	<p>show ip access-lists access-list-name</p> <p>Example: Router# show ip access-lists mylist1</p>	<p>(Optional) Displays the contents of the access list.</p> <ul style="list-style-type: none"> Review the output to verify that the redundant access list entries have been replaced with your new consolidated entries.

What To Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Filtering Packets Based on TTL Value

Because access lists are very flexible, it is not possible to define only one combination of **permit** and **deny** commands to filter packets based on the TTL value. This task illustrates just one example that achieves TTL filtering. Configure the appropriate **permit** and **deny** statements that will accomplish your filtering plan.

How Filtering on TTL Works

IP extended named and numbered access lists may filter on the TTL value of packets arriving at or leaving an interface. Packets with any possible TTL values 0 through 255 may be permitted or denied (filtered). Like filtering on other fields, such as source or destination address, the **ip access-group** command specifies **in** or **out**, which makes the access list ingress or egress and applies it to incoming or outgoing packets, respectively. The TTL value is checked in conjunction with the specified protocol, application, and any other settings in the access list entry, and all conditions must be met.

Special Handling for Packets with TTL of 0 or 1 Arriving on Ingress Interface

The software switching paths—distributed Cisco Express Forwarding (dCEF), CEF, fast switching, and process switching—will usually permit or discard the packets based on the access list statements. However, when the TTL value of packets arriving on an *ingress* interface have a TTL of 0 or 1, special

handling is required. The packets with a TTL of 0 or 1 get sent to the process level before the ingress access list is checked in CEF, dCEF, or fast switching paths. The ingress access list is applied to packets with TTL values 2 through 255 and a permit or deny decision is made.

Packets with a TTL value of 0 or 1 are sent to the process level because they will never be forwarded out of the device; the process level must check whether each packet is destined for the router or not and whether an Internet Control Message Protocol (ICMP) TTL Expire message needs to be sent back or not. This means that even if an ACL with TTL value 0 or 1 filtering is configured on the ingress interface with the intention to drop packets with a TTL of 0 or 1, the dropping of the packets will not happen in the faster paths. It will instead happen in the process level when the process applies the ACL. This is also true for hardware switching platforms. Packets with TTL 0 or 1 are sent to the process level of the route processor (RP) or Multilayer Switch Feature Card (MSFC).

On egress interfaces, access list filtering on TTL work just like other access list features. The check will happen in the fastest switching path enabled in the device. This is because the faster switching paths handle all the TTL values (0-255) equally on the egress interface.

Control Plane Policing for Filtering TTL Values 0 and 1

The special behavior for packets with a TTL of 0 or 1 results in higher CPU usage for the device. If you are filtering on TTL value 0 or 1, you should use control plane policing (CPP) to protect the CPU from being overwhelmed. In order to leverage CPP, you must configure an access list especially for filtering TTL values 0 and 1 and apply the access list through CPP. This access list will be a separate access list from any interface access lists. Because CPP works for the entire system, not just on individual interfaces, you would need to configure only one such special access list for the entire device. This task is described in the section [“Enabling Control Plane Policing to Filter on TTL Values 0 and 1”](#) section on page 15.

Benefits of Filtering on TTL

- Filtering on TTL provides a way to control which packets are allowed to reach the router or prevented from reaching the router. By looking at your network layout, you can choose whether to accept or deny packets from a certain router based on how many hops away it is. For example, in a small network, you can deny packets from a location more than three hops away. Filtering on TTL allows you to validate if the traffic originated from a neighboring device, as follows. You can accept only packets that reach you in one hop, for example, by accepting only packets with a TTL of one less than the initial TTL value of a particular protocol.
- Many control plane protocols communicate only with their neighbors, but receive packets from everyone. By applying to receiving routers an access list that filters on TTL, you can block unwanted packets.
- The Cisco IOS software sends all packets with a TTL of 0 or 1 to the process level to be processed. The device must then send an ICMP TTL expire message to the source. By filtering packets that have a TTL of 0 through 2, you can reduce the load on the process level.

Restrictions

- When the access list specifies the operation EQ or NEQ, routers running Cisco IOS Release 12.2S can have that access list specify up to ten TTL values. However, for Release 12.0S, only one TTL value can be specified.

SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **ip access-list extended** *access-list-name*
4. [*sequence-number*] **permit** *protocol source source-wildcard destination destination-wildcard* [**option** *option-name*] [**precedence** *precedence*] [**tos** *tos*] [**ttl** *operator value*] [**log**] [**time-range** *time-range-name*] [**fragments**]
5. Continue to add **permit** or **deny** statements to achieve the filtering you want.
6. **exit**
7. **interface** *type number*
8. **ip access-group** *access-list-name* {**in** | **out**}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended ttlfilter	Defines an IP access list by name. <ul style="list-style-type: none">An access list that filters on TTL value must be an extended access list.
Step 4	[<i>sequence-number</i>] permit <i>protocol source source-wildcard destination destination-wildcard</i> [option <i>option-name</i>] [precedence <i>precedence</i>] [tos <i>tos</i>] [ttl <i>operator value</i>] [log] [time-range <i>time-range-name</i>] [fragments] Example: Router(config-ext-nacl)# permit ip host 172.16.1.1 any ttl lt 2	Sets conditions to allow a packet to pass a named IP access list. <ul style="list-style-type: none">Every access list must have at least one permit statement.This example permits packets from source 172.16.1.1 to any destination with a TTL value less than 2.
Step 5	Continue to add permit or deny statements to achieve the filtering you want.	—
Step 6	exit Example: Router(config-ext-nacl)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.

	Command or Action	Purpose
Step 7	<code>interface type number</code> Example: Router(config)# interface ethernet 0	Configures an interface type and enters interface configuration mode.
Step 8	<code>ip access-group access-list-name {in out}</code> Example: Router(config-if)# ip access-group ttlfilter in	Applies the access list to an interface.

Enabling Control Plane Policing to Filter on TTL Values 0 and 1

Perform this task if you want to filter IP packets based on a TTL value of 0 or 1 and you want to protect the CPU from being overwhelmed. This task configures an access list for classification on TTL 0 and 1, configures Modular QoS CLI (MQC), and applies the policy map to the control plane. Any packets that pass the access list are dropped. This special access list is separate from any interface access lists.

Because access lists are very flexible, it is not possible to define only one combination of **permit** and **deny** commands to filter packets based on the TTL value. This task illustrates just one example that achieves TTL filtering. Configure the appropriate **permit** and **deny** statements that will accomplish your filtering plan.

SUMMARY STEPS

- `enable`
- `configure terminal`
- `ip access-list extended access-list-name`
- `[sequence-number] permit protocol source source-wildcard destination destination-wildcard ttl operator value`
- Continue to add **permit** or **deny** statements to achieve the filtering you want.
- `exit`
- `class-map class-map-name [match-all | match-any]`
- `match access-group {access-group | name access-group-name}`
- `exit`
- `policy-map policy-map-name`
- `class {class-name | class-default}`
- `drop`
- `exit`
- `exit`
- `control-plane`
- `service-policy {input | output} policy-map-name`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended ttlfilter	Defines an IP access list by name. <ul style="list-style-type: none">An access list that filters on a TTL value must be an extended access list.
Step 4	[<i>sequence-number</i>] permit <i>protocol source source-wildcard destination destination-wildcard</i> ttl <i>operator value</i> Example: Router(config-ext-nacl)# permit ip host 172.16.1.1 any ttl lt 2	Sets conditions to allow a packet to pass a named IP access list. <ul style="list-style-type: none">Every access list must have at least one permit statement.This example permits packets from source 172.16.1.1 to any destination with a TTL value less than 2.
Step 5	Continue to add permit or deny statements to achieve the filtering you want.	The packets that pass the access list will be dropped.
Step 6	exit Example: Router(config-ext-nacl)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.
Step 7	class-map <i>class-map-name</i> [match-all match-any] Example: Router(config)# class-map acl-filtering	Creates a class map to be used for matching packets to a specified class.
Step 8	match access-group { <i>access-group</i> name <i>access-group-name</i> } Example: Router(config-cmap)# match access-group name ttlfilter	Configures the match criteria for a class map on the basis of the specified access control list.
Step 9	exit Example: Router(config-cmap)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.

	Command or Action	Purpose
Step 10	policy-map <i>policy-map-name</i> Example: Router(config)# policy-map acl-filter	Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy.
Step 11	class { <i>class-name</i> class-default } Example: Router(config-pmap)# class acl-filter-class	Specifies the name of the class whose policy you want to create or change or to specify the default class (commonly known as the class-default class) before you configure its policy.
Step 12	drop Example: Router(config-pmap-c)# drop	Configures a traffic class to discard packets belonging to a specific class.
Step 13	exit Example: Router(config-pmap-c)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.
Step 14	exit Example: Router(config-pmap)# exit	Exits any configuration mode to the next highest mode in the CLI mode hierarchy.
Step 15	control-plane Example: Router(config)# control-plane	Associates or modifies attributes or parameters that are associated with the control plane of the device.
Step 16	service-policy { input output } <i>policy-map-name</i> Example: Router(config-cp)# service-policy input acl-filter	Attaches a policy map to a control plane for aggregate control plane services.

Configuration Examples for Filtering IP Options, TCP Flags, Noncontiguous Ports, and TTL Values

This section provides the following configuration examples:

- [Filtering Packets That Contain IP Options: Example, page 18](#)
- [Filtering Packets That Contain TCP Flags: Example, page 18](#)
- [Creating an Access List Entry with Noncontiguous Ports: Example, page 18](#)
- [Consolidating Some Existing Access List Entries into One Access List Entry with Noncontiguous Ports: Example, page 19](#)
- [Filtering on TTL Value: Example, page 19](#)
- [Control Plane Policing to Filter on TTL Values 0 and 1: Example, page 20](#)

Filtering Packets That Contain IP Options: Example

The following example shows an extended access list named `mylist2` that contains access list entries (ACEs) that are configured to permit TCP packets only if they contain the IP Options that are specified in the ACEs:

```
ip access-list extended mylist2
 10 permit ip any any option eool
 20 permit ip any any option record-route
 30 permit ip any any option zsu
 40 permit ip any any option mtup
```

The **show access-list** command has been entered to show how many packets were matched and therefore permitted:

```
Router# show ip access-list mylist2

Extended IP access list test
10 permit ip any any option eool (1 match)
20 permit ip any any option record-route (1 match)
30 permit ip any any option zsu (1 match)
40 permit ip any any option mtup (1 match)
```

Filtering Packets That Contain TCP Flags: Example

The following access list allows TCP packets only if the TCP flags ACK and SYN are set and the FIN flag is not set:

```
ip access-list extended aaa
 permit tcp any any match-all +ack +syn -fin
end
```

The **show access-list** command has been entered to display the ACL:

```
Router# show access-list aaa

Extended IP access list aaa
 10 permit tcp any any match-all +ack +syn -fin
```

Creating an Access List Entry with Noncontiguous Ports: Example

The following access list entry can be created because up to ten ports can be entered after the **eq** and **neq** operators:

```
ip access-list extended aaa
 permit tcp any eq telnet ftp any eq 23 45 34
end
```

Enter the **show access-lists** command to display the newly created access list entry.

```
Router# show access-lists aaa

Extended IP access list aaa
 10 permit tcp any eq telnet ftp any eq 23 45 34
```

Consolidating Some Existing Access List Entries into One Access List Entry with Noncontiguous Ports: Example

The **show access-lists** command is used to display a group of access list entries for the access list named abc:

```
Router# show access-lists abc
```

```
Extended IP access list abc
 10 permit tcp any eq telnet any eq 450
 20 permit tcp any eq telnet any eq 679
 30 permit tcp any eq ftp any eq 450
 40 permit tcp any eq ftp any eq 679
```

Because the entries are all for the same **permit** statement and simply show different ports, they can be consolidated into one new access list entry. The following example shows the removal of the redundant access list entries and the creation of a new access list entry that consolidates the previously displayed group of access list entries:

```
ip access-list extended abc
 no 10
 no 20
 no 30
 no 40
 permit tcp any eq telnet ftp any eq 450 679
end
```

When the **show access-lists** command is reentered, the consolidated access list entry is displayed:

```
Router# show access-lists abc
```

```
Extended IP access list abc
 10 permit tcp any eq telnet ftp any eq 450 679
```

Filtering on TTL Value: Example

The following access list filters IP packets containing type of service (ToS) level 3 with TTL values 10 and 20. It also filters IP packets with a TTL greater than 154 and applies that rule to noninitial fragments. It permits IP packets with a precedence level of flash and a TTL not equal to 1, and it sends log messages about such packets to the console. All other packets are denied.

```
ip access-list extended incomingfilter
 deny ip any any tos 3 ttl eq 10 20
 deny ip any any ttl gt 154 fragments
 permit ip any any precedence flash ttl neq 1 log
!
interface ethernet 0
ip access-group incomingfilter in
```

Control Plane Policing to Filter on TTL Values 0 and 1: Example

The following example configures a traffic class called `acl-filter-class` for use in a policy map called `acl-filter`. An access list permits IP packets from any source having a TTL of 0 or 1. Any packets matching the access list are dropped. The policy map is attached to the control plane.

```
ip access-list extended ttlfilter
  permit ip any any ttl eq 0 1
class-map acl-filter-class
  match access-group name ttlfilter
policy-map acl-filter
  class acl-filter-class
    drop
control-plane
  service-policy input acl-filter
```

Feature Information for Using an IP Access List to Filter Packets

Table 2 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for a specific command was introduced, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

Table 2 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 2 *Feature Information for Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values*

Feature Name	Releases	Feature Configuration Information
ACL Support for Filtering IP Options	12.3(4)T 12.2(25)S	This feature allows you to filter packets having IP Options, in order to prevent routers from becoming saturated with spurious packets. See the following sections: <ul style="list-style-type: none"> • Filtering Packets That Contain IP Options, page 2 • Filtering Packets That Contain IP Options: Example, page 18
ACL TCP Flags Filtering	12.3(4)T 12.2(25)S	This feature provides a flexible mechanism for filtering on TCP flags. Before Cisco IOS Release 12.3(4)T, an incoming packet was matched as long as any TCP flag in the packet matched a flag specified in the access control entry (ACE). This behavior allows for a security loophole, because packets with all flags set could get past the access control list (ACL). The ACL TCP Flags Filtering feature allows you to select any combination of flags on which to filter. The ability to match on a flag set and on a flag not set gives you a greater degree of control for filtering on TCP flags, thus enhancing security. See the following sections: <ul style="list-style-type: none"> • Filtering Packets That Contain TCP Flags, page 5 • Filtering Packets That Contain TCP Flags: Example, page 18
ACL—Named ACL Support for Noncontiguous Ports on an Access Control Entry	12.3(7)T 12.2(25)S	This feature allows you to specify noncontiguous ports in a single access control entry, which greatly reduces the number of entries required in an access control list when several entries have the same source address, destination address, and protocol, but differ only in the ports. See the following sections: <ul style="list-style-type: none"> • Configuring an Access Control Entry with Noncontiguous Ports, page 8 • Consolidating Access List Entries with Noncontiguous Ports into One Access List Entry, page 10 • Creating an Access List Entry with Noncontiguous Ports: Example, page 18 • Consolidating Some Existing Access List Entries into One Access List Entry with Noncontiguous Ports: Example, page 19

Table 2 **Feature Information for Creating an IP Access List to Filter IP Options, TCP Flags, Noncontiguous Ports, or TTL Values (continued)**

Feature Name	Releases	Feature Configuration Information
ACL Support for Filtering on TTL Value	12.4(2)T	<p>Customers may use extended IP access lists (named or numbered) to filter packets based on their time-to-live (TTL) value, from 0 to 255. This filtering enhances a customer's control over which packets reach a router. See the following sections:</p> <ul style="list-style-type: none"> • Filtering Packets Based on TTL Value, page 12 • Enabling Control Plane Policing to Filter on TTL Values 0 and 1, page 15 • Filtering on TTL Value: Example, page 19 • Control Plane Policing to Filter on TTL Values 0 and 1: Example, page 20
ACL - Named ACL Support for Noncontiguous Ports on an Access Control Entry	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
ACL - TCP Flags Filtering	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
ACL Support for Filtering IP Options	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.
Selective Drop/ Ignore of IP Options	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Refining an IP Access List

First Published: August 18, 2006
Last Updated: August 18, 2006

There are several ways to refine an access list while or after you create it. You can change the order of the entries in an access list or add entries to an access list. You can restrict access list entries to a certain time of day or week, or achieve finer granularity when filtering packets by filtering noninitial fragments of packets.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Refining an IP Access List”](#) section on page 19.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Refining an IP Access List

Before you perform any of the tasks in this module, you should be familiar with the concepts in the “IP Access List Overview” module.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

Information About Refining an IP Access List

You should understand the following concept before configuring an IP access list with sequence numbers:

- [Access List Sequence Numbers, page 2](#)

Access List Sequence Numbers

The ability to apply sequence numbers to IP access list entries simplifies access list changes. Prior to the IP Access List Entry Sequence Numbering feature, there was no way to specify the position of an entry within an access list. If you wanted to insert an entry in the middle of an existing list, all of the entries after the desired position had to be removed, then the new entry was added, and then all the removed entries had to be reentered. This method was cumbersome and error prone.

Sequence numbers allow users to add access list entries and resequence them. When you add a new entry, you specify the sequence number so that it is in a desired position in the access list. If necessary, entries currently in the access list can be resequenced to create room to insert the new entry.

How to Refine an IP Access List

The tasks in this module provide you with various ways to refine an access list if you did not already do so while you were creating it. You can change the order of the entries in an access list, add entries to an access list, restrict access list entries to a certain time of day or week, or achieve finer granularity when filtering packets by filtering on noninitial fragments of packets.

This section includes the following tasks:

- [Revising an Access List Using Sequence Numbers, page 2](#) (optional)
- [Restricting an Access List Entry to a Time of Day or Week, page 6](#) (optional)
- [Filtering Noninitial Fragments of Packets, page 11](#) (optional)

Revising an Access List Using Sequence Numbers

Perform this task if you want to add entries to an existing access list, change the order of entries, or simply number the entries in an access list to accommodate future changes.

Note

Remember that if you want to delete an entry from an access list, you can simply use the **no deny** or **no permit** form of the command, or the **no sequence-number** command if the statement already has a sequence number.

Benefits of Access List Sequence Numbers

An access list sequence number is a number at the beginning of a **permit** or **deny** command in an access list. The sequence number determines the order that the entry appears in the access list. The ability to apply sequence numbers to IP access list entries simplifies access list changes.

Prior to having sequence numbers, users could only add access list entries to the end of an access list; therefore, needing to add statements anywhere except the end of the list required reconfiguring the entire access list. There was no way to specify the position of an entry within an access list. If a user wanted to insert an entry (statement) in the middle of an existing list, all of the entries after the desired position had to be removed, then the new entry was added, and then all the removed entries had to be reentered. This method was cumbersome and error prone.

This feature allows users to add sequence numbers to access list entries and resequence them. When a user adds a new entry, the user chooses the sequence number so that it is in a desired position in the access list. If necessary, entries currently in the access list can be resequenced to create room to insert the new entry. Sequence numbers make revising an access list much easier.

Sequence Numbering Behavior

- For backward compatibility with previous releases, if entries with no sequence numbers are applied, the first entry is assigned a sequence number of 10, and successive entries are incremented by 10. The maximum sequence number is 2147483647. If the generated sequence number exceeds this maximum number, the following message is displayed:

`Exceeded maximum sequence number.`

- If the user enters an entry without a sequence number, it is assigned a sequence number that is 10 greater than the last sequence number in that access list and is placed at the end of the list.
- If the user enters an entry that matches an already existing entry (except for the sequence number), then no changes are made.
- If the user enters a sequence number that is already present, the following error message is generated:
`Duplicate sequence number.`
- If a new access list is entered from global configuration mode, then sequence numbers for that access list are generated automatically.
- Distributed support is provided so that the sequence numbers of entries in the Route Processor (RP) and line card are in synchronization at all times.
- Sequence numbers are not nvgened. That is, the sequence numbers themselves are not saved. In the event that the system is reloaded, the configured sequence numbers revert to the default sequence starting number and increment. The function is provided for backward compatibility with software releases that do not support sequence numbering.
- This feature works with named and numbered, standard and extended IP access lists.

Restrictions

- Access list sequence numbers do not support dynamic, reflexive, or firewall access lists.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list resequence** *access-list-name starting-sequence-number increment*
4. **ip access-list {standard | extended}** *access-list-name*
5. *sequence-number permit source source-wildcard*

or

sequence-number **permit** *protocol source source-wildcard destination destination-wildcard*
[**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]

6. *sequence-number* **deny** *source source-wildcard*

or

sequence-number **deny** *protocol source source-wildcard destination destination-wildcard*
[**precedence** *precedence*] [**tos** *tos*] [**log**] [**time-range** *time-range-name*] [**fragments**]

7. Repeat Step 5 and Step 6 as necessary, adding statements by sequence number where you planned. Use the **no** *sequence-number* command to delete an entry.
8. **end**
9. **show ip access-lists** *access-list-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list resequence <i>access-list-name</i> <i>starting-sequence-number</i> <i>increment</i> Example: Router(config)# ip access-list resequence kmd1 100 15	Resequences the specified IP access list using the starting sequence number and the increment of sequence numbers. <ul style="list-style-type: none"> This example resequences an access list named kmd1. The starting sequence number is 100 and the increment is 15.
Step 4	ip access-list { standard extended } <i>access-list-name</i> Example: Router(config)# ip access-list standard xyz123	Specifies the IP access list by name and enters named access list configuration mode. <ul style="list-style-type: none"> If you specify standard, make sure you specify subsequent permit and deny statements using the standard access list syntax. If you specify extended, make sure you specify subsequent permit and deny statements using the extended access list syntax.
Step 5	<i>sequence-number</i> permit <i>source</i> <i>source-wildcard</i> or <i>sequence-number</i> permit <i>protocol</i> <i>source</i> <i>source-wildcard</i> <i>destination</i> <i>destination-wildcard</i> [precedence <i>precedence</i>] [tos <i>tos</i>] [log] [time-range <i>time-range-name</i>] [fragments] Example: Router(config-std-nacl)# 105 permit 10.5.5.5 0.0.0.255	Specifies a permit statement in named IP access list mode. <ul style="list-style-type: none"> This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. See the permit (IP) command for additional command syntax to permit upper layer protocols (ICMP, IGMP, TCP, and UDP). Use the no <i>sequence-number</i> command to delete an entry. As the prompt indicates, this access list was a standard access list. If you had specified extended in Step 4, the prompt for this step would be Router(config-ext-nacl)# and you would use the extended permit command syntax.

	Command or Action	Purpose
Step 6	<p><code>sequence-number deny source source-wildcard</code></p> <p>or</p> <p><code>sequence-number deny protocol source source-wildcard destination destination-wildcard [precedence precedence] [tos tos] [log] [time-range time-range-name] [fragments]</code></p> <p>Example: Router(config-std-nacl)# 110 deny 10.6.6.7 0.0.0.255</p>	<p>(Optional) Specifies a deny statement in named IP access list mode.</p> <ul style="list-style-type: none"> This access list happens to use a permit statement first, but a deny statement could appear first, depending on the order of statements you need. See the deny (IP) command for additional command syntax to permit upper layer protocols (ICMP, IGMP, TCP, and UDP). Use the no sequence-number command to delete an entry. As the prompt indicates, this access list was a standard access list. If you had specified extended in Step 4, the prompt for this step would be Router(config-ext-nacl)# and you would use the extended deny command syntax.
Step 7	Repeat Step 5 and Step 6 as necessary, adding statements by sequence number where you planned. Use the no sequence-number command to delete an entry.	Allows you to revise the access list.
Step 8	<p>end</p> <p>Example: Router(config-std-nacl)# end</p>	(Optional) Exits the configuration mode and returns to privileged EXEC mode.
Step 9	<p>show ip access-lists access-list-name</p> <p>Example: Router# show ip access-lists xyz123</p>	<p>(Optional) Displays the contents of the IP access list.</p> <ul style="list-style-type: none"> Review the output to see that the access list includes the new entry.

Examples

The following is sample output from the **show ip access-lists** command when the **xyz123** access list is specified.

```
Router# show ip access-lists xyz123

Standard IP access list xyz123
100 permit 10.4.4.0, wildcard bits 0.0.0.255
105 permit 10.5.5.5, wildcard bits 0.0.0.255
115 permit 10.0.0.0, wildcard bits 0.0.0.255
130 permit 10.5.5.0, wildcard bits 0.0.0.255
145 permit 10.0.0.0, wildcard bits 0.0.0.255
```

Restricting an Access List Entry to a Time of Day or Week

By default, access list statements are always in effect once they are applied. However, you can define the times of the day or week that **permit** or **deny** statements are in effect by defining a time range, and then referencing the time range by name in an individual access list statement. IP and Internetwork Packet Exchange (IPX) named or numbered extended access lists can use time ranges.

Benefits of Time Ranges

Benefits and possible uses of time ranges include the following:

- The network administrator has more control over permitting or denying a user access to resources. These resources could be an application (identified by an IP address/mask pair and a port number), policy routing, or an on-demand link (identified as interesting traffic to the dialer).
- Network administrators can set time-based security policy, including the following:
 - Perimeter security using the Cisco IOS Firewall feature set or access lists
 - Data confidentiality with Cisco Encryption Technology or IP Security Protocol (IPSec)
- Policy-based routing (PBR) and queueing functions are enhanced.
- When provider access rates vary by time of day, it is possible to automatically reroute traffic cost effectively.
- Service providers can dynamically change a committed access rate (CAR) configuration to support the quality of service (QoS) service level agreements (SLAs) that are negotiated for certain times of day.
- Network administrators can control logging messages. Access list entries can log traffic at certain times of the day, but not constantly. Therefore, administrators can simply deny access without needing to analyze many logs generated during peak hours.

Distributed Time-Based Access Lists

Before the introduction of the Distributed Time-Based Access Lists feature, time-based access lists were not supported on line cards for the Cisco 7500 series routers. If time-based access lists were configured, they behaved as normal access lists. If an interface on a line card were configured with a time-based access list, the packets switched into the interface were not distributed switched through the line card, but were forwarded to the Route Processor for processing.

The Distributed Time-Based Access Lists feature allows packets destined for an interface configured with a time-based access list to be distributed switched through the line card.

For this functionality to work, the software clock must remain synchronized between the Route Processor and the line card. This synchronization occurs through an exchange of interprocess communications (IPC) messages from the Route Processor to the line card. When a time range or a time-range entry is changed, added, or deleted, an IPC message is sent by the Route Processor to the line card.

There is no difference between how the user configures a time-based access list and a distributed time-based access list.

Prerequisites

The time range relies on the software clock of the routing device. For the time range feature to work the way you intend, you need a reliable clock source. We recommend that you use Network Time Protocol (NTP) to synchronize the software clock of the routing device.

Restrictions

The Distributed Time-Based Access Lists feature is supported on Cisco 7500 series routers with a Versatile Interface Processor (VIP) enabled.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **time-range** *time-range-name*
4. **periodic** *days-of-the-week hh:mm to [days-of-the-week] hh:mm*
5. Repeat Step 4 if you want more than one period of time applied to an access list statement.
6. **absolute** [*start time date*] [*end time date*]
7. **exit**
8. Repeat Steps 3 through 7 if you want different time ranges to apply to **permit** or **deny** statements.
9. **ip access-list extended** *name*
10. **deny** *protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log | log-input] time-range time-range-name*
11. **permit** *protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log | log-input] time-range time-range-name*
12. Optionally repeat some combination of Steps 10 and 11 until you have specified the values on which you want to base your access list.
13. **end**
14. **show ip access-list**
15. **show time-range**
16. **show time-range ipc**
17. **clear time-range ipc**
18. **debug time-range ipc**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	time-range <i>time-range-name</i> Example: Router(config)# time-range limit_http	Defines a time range and enters time-range configuration mode. <ul style="list-style-type: none"> The name cannot contain a space or quotation mark, and must begin with a letter. Multiple time ranges can occur in a single access list.
Step 4	periodic <i>days-of-the-week hh:mm to [days-of-the-week] hh:mm</i> Example: Router(config-time-range)# periodic Monday 6:00 to Wednesday 19:00	(Optional) Specifies a recurring (weekly) time range. <ul style="list-style-type: none"> The first occurrence of <i>days-of-the-week</i> is the starting day or day of the week that the associated time range is in effect. The second occurrence is the ending day or day of the week the associated statement is in effect. The <i>days-of-the-week</i> argument can be any single day or combinations of days: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday. Other possible values are: <ul style="list-style-type: none"> daily—Monday through Sunday weekdays—Monday through Friday weekend—Saturday and Sunday If the ending days of the week are the same as the starting days of the week, they can be omitted. The first occurrence of <i>hh:mm</i> is the starting hours:minutes that the associated time range is in effect. The second occurrence is the ending hours:minutes the associated statement is in effect. The hours:minutes are expressed in a 24-hour clock. For example, 8:00 is 8:00 a.m. and 20:00 is 8:00 p.m.
Step 5	Repeat Step 4 if you want more than one period of time applied to an access list statement.	(Optional) Multiple periodic commands are allowed in a time range.

	Command or Action	Purpose
Step 6	<p>absolute [start <i>time date</i>] [end <i>time date</i>]</p> <p>Example: Router(config-time-range)# absolute start 6:00 1 August 2005 end 18:00 31 October 2005</p>	<p>(Optional) Specifies an absolute time when a time range is in effect.</p> <ul style="list-style-type: none"> Only one absolute command is allowed in a time range. The time is expressed in 24-hour notation, in the form of hours:minutes. For example, 8:00 is 8:00 a.m. and 20:00 is 8:00 p.m. The date is expressed in the format <i>day month year</i>. The minimum start is 00:00 1 January 1993. If no start time and date are specified, the permit or deny statement is in effect immediately. Absolute time and date that the permit or deny statement of the associated access list is no longer in effect. Same time and date format as described for the start keyword. The end time and date must be after the start time and date. The maximum end time is 23:59 31 December 2035. If no end time and date are specified, the associated permit or deny statement is in effect indefinitely.
Step 7	<p>exit</p> <p>Example: Router(config-time-range)# exit</p>	Exits to the next highest mode.
Step 8	Repeat Steps 3 through 7 if you want different time ranges to apply to permit or deny statements.	—
Step 9	<p>ip access-list extended <i>name</i></p> <p>Example: Router(config)# ip access-list extended autumn</p>	Defines an extended IP access list using a name and enters extended named access list configuration mode.
Step 10	<p>deny <i>protocol source</i> [<i>source-wildcard</i>] [<i>destination</i> [<i>destination-wildcard</i>] [option <i>option-name</i>] [precedence <i>precedence</i>] [tos <i>tos</i>] [established] [log log-input] time-range <i>time-range-name</i></p> <p>Example: Router(config-ext-nacl)# deny tcp 172.16.22.23 any eq http time-range limit_http</p>	<p>(Optional) Denies any packet that matches all of the conditions specified in the statement.</p> <ul style="list-style-type: none"> Specify the time range you created in Step 3. In this example, one host is denied HTTP access during the time defined by the time range called “limit_http.”
Step 11	<p>permit <i>protocol source</i> [<i>source-wildcard</i>] [<i>destination</i> [<i>destination-wildcard</i>] [option <i>option-name</i>] [precedence <i>precedence</i>] [tos <i>tos</i>] [established] [log log-input] time-range <i>time-range-name</i></p> <p>Example: Router(config-ext-nacl)# permit tcp any any eq http time-range limit_http</p>	<p>Permits any packet that matches all of the conditions specified in the statement.</p> <ul style="list-style-type: none"> You can specify the time range you created in Step 3 or in a different instance of Step 3, depending on whether you want the time ranges for your statements to be the same or different. In this example, all other sources are given access to HTTP during the time defined by the time range called “limit_http.”

	Command or Action	Purpose
Step 12	Optionally repeat some combination of Steps 10 and 11 until you have specified the values on which you want to base your access list.	—
Step 13	end Example: Router(config-ext-nacl)# end	Ends configuration mode and returns the system to privileged EXEC mode.
Step 14	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.
Step 15	show time-range Example: Router# show time-range	(Optional) Displays the time ranges that are set.
Step 16	show time-range ipc Example: Router# show time-range ipc	(Optional) Displays the statistics about the time-range IPC messages between the Route Processor and line card on the Cisco 7500 series router.
Step 17	clear time-range ipc Example: Router# clear time-range ipc	(Optional) Clears the time-range IPC message statistics and counters between the Route Processor and line card on the Cisco 7500 series router.
Step 18	debug time-range ipc Example: Router# debug time-range ipc	(Optional) Enables debugging output for monitoring the time-range IPC messages between the Route Processor and line card on the Cisco 7500 series router.

What to Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Filtering Noninitial Fragments of Packets

Filter noninitial fragments of packets with an extended access list if you want to block more of the traffic you intended to block, not just the initial fragment of such packets. You should first understand the following concepts.

Benefits of Filtering Noninitial Fragments of Packets

If the **fragments** keyword is used in additional IP access list entries that deny fragments, the fragment control feature provides the following benefits:

Additional Security

You are able to block more of the traffic you intended to block, not just the initial fragment of such packets. The unwanted fragments no longer linger at the receiver until the reassembly timeout is reached because they are blocked before being sent to the receiver. Blocking a greater portion of unwanted traffic improves security and reduces the risk from potential hackers.

Reduced Cost

By blocking unwanted noninitial fragments of packets, you are not paying for traffic you intended to block.

Reduced Storage

By blocking unwanted noninitial fragments of packets from ever reaching the receiver, that destination does not have to store the fragments until the reassembly timeout period is reached.

Expected Behavior Is Achieved

The noninitial fragments will be handled in the same way as the initial fragment, which is what you would expect. There are fewer unexpected policy routing results and fewer fragments of packets being routed when they should not be.

Access List Processing of Fragments

The behavior of access list entries regarding the use or lack of use of the **fragments** keyword can be summarized as follows:

If the Access-List Entry Has...	Then...
...no fragments keyword (the default), and assuming all of the access-list entry information matches,	<p>For an access list entry that contains only Layer 3 information:</p> <ul style="list-style-type: none"> The entry is applied to nonfragmented packets, initial fragments, and noninitial fragments. <p>For an access list entry that contains Layer 3 and Layer 4 information:</p> <ul style="list-style-type: none"> The entry is applied to nonfragmented packets and initial fragments. <ul style="list-style-type: none"> If the entry is a permit statement, then the packet or fragment is permitted. If the entry is a deny statement, then the packet or fragment is denied. The entry is also applied to noninitial fragments in the following manner. Because noninitial fragments contain only Layer 3 information, only the Layer 3 portion of an access list entry can be applied. If the Layer 3 portion of the access list entry matches, and <ul style="list-style-type: none"> If the entry is a permit statement, then the noninitial fragment is permitted. If the entry is a deny statement, then the next access list entry is processed. <p>Note The deny statements are handled differently for noninitial fragments versus nonfragmented or initial fragments.</p>
...the fragments keyword, and assuming all of the access-list entry information matches,	<p>The access list entry is applied only to noninitial fragments.</p> <p>The fragments keyword cannot be configured for an access list entry that contains any Layer 4 information.</p>

Be aware that you should not add the **fragments** keyword to every access list entry because the first fragment of the IP packet is considered a nonfragment and is treated independently of the subsequent fragments. An initial fragment will not match an access list **permit** or **deny** entry that contains the **fragments** keyword. The packet is compared to the next access list entry, and so on, until it is either permitted or denied by an access list entry that does not contain the **fragments** keyword. Therefore, you may need two access list entries for every **deny** entry. The first **deny** entry of the pair will not include the **fragments** keyword and applies to the initial fragment. The second **deny** entry of the pair will include the **fragments** keyword and applies to the subsequent fragments. In the cases in which there are multiple **deny** entries for the same host but with different Layer 4 ports, a single **deny** access list entry with the **fragments** keyword for that host is all that needs to be added. Thus all the fragments of a packet are handled in the same manner by the access list.

Packet fragments of IP datagrams are considered individual packets, and each counts individually as a packet in access list accounting and access list violation counts.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *name*
4. *[sequence-number] deny protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard][operator port [port]]*
5. *[sequence-number] deny protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]] [fragments]*
6. *[sequence-number] permit protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]]*
7. Repeat some combination of Steps 4 through 6 until you have specified the values on which you want to base your access list.
8. **end**
9. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended name Example: Router(config)# ip access-list extended rstrct4	Defines an extended IP access list using a name and enters extended named access list configuration mode.
Step 4	[sequence-number] deny protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]] Example: Router(config-ext-nacl)# deny ip any 172.20.1.1	(Optional) Denies any packet that matches all of the conditions specified in the statement. <ul style="list-style-type: none"> This statement will apply to nonfragmented packets and initial fragments.
Step 5	[sequence-number] deny protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]] fragments Example: Router(config-ext-nacl)# deny ip any 172.20.1.1 fragments	(Optional) Denies any packet that matches all of the conditions specified in the statement <ul style="list-style-type: none"> This statement will apply to noninitial fragments.
Step 6	[sequence-number] permit protocol source [source-wildcard] [operator port [port]] destination [destination-wildcard] [operator port [port]] Example: Router(config-ext-nacl)# permit tcp any any	Permits any packet that matches all of the conditions specified in the statement. <ul style="list-style-type: none"> Every access list needs at least one permit statement. If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255.
Step 7	Repeat some combination of Steps 4 through 6 until you have specified the values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.

	Command or Action	Purpose
Step 8	end Example: Router(config-ext-nacl)# end	Ends configuration mode and returns the system to privileged EXEC mode.
Step 9	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.

What to Do Next

Apply the access list to an interface or reference it from a command that accepts an access list.

Configuration Examples for Refining an IP Access List

This section provides the following configuration examples:

- [Resequencing Entries in an Access List: Example, page 16](#)
- [Adding an Entry with a Sequence Number: Example, page 17](#)
- [Adding an Entry with No Sequence Number: Example, page 17](#)
- [Time Ranges Applied to IP Access List Entries: Example, page 18](#)
- [Filtering IP Packet Fragments: Example, page 18](#)

Resequencing Entries in an Access List: Example

The following example shows an access list before and after resequencing. The starting value is 1, and increment value is 2. The subsequent entries are ordered based on the increment values that users provide, and the range is from 1 to 2147483647.

When an entry with no sequence number is entered, by default it has a sequence number of 10 more than the last entry in the access list.

```
Router# show access-list carls
```

```
Extended IP access list carls
 10 permit ip host 10.3.3.3 host 172.16.5.34
 20 permit icmp any any
 30 permit tcp any host 10.3.3.3
 40 permit ip host 10.4.4.4 any
 50 Dynamic test permit ip any any
 60 permit ip host 172.16.2.2 host 10.3.3.12
 70 permit ip host 10.3.3.3 any log
 80 permit tcp host 10.3.3.3 host 10.1.2.2
 90 permit ip host 10.3.3.3 any
100 permit ip any any
```

```
Router(config)# ip access-list extended carls
Router(config)# ip access-list resequence carls 1 2
Router(config)# end
```

```
Router# show access-list carls

Extended IP access list carls
 1 permit ip host 10.3.3.3 host 172.16.5.34
 3 permit icmp any any
 5 permit tcp any host 10.3.3.3
 7 permit ip host 10.4.4.4 any
 9 Dynamic test permit ip any any
11 permit ip host 172.16.2.2 host 10.3.3.12
13 permit ip host 10.3.3.3 any log
15 permit tcp host 10.3.3.3 host 10.1.2.2
17 permit ip host 10.3.3.3 any
19 permit ip any any
```

Adding an Entry with a Sequence Number: Example

In the following example, a new entry (sequence number 15) is added to an access list:

```
Router# show ip access-list

Standard IP access list tryon
 2 permit 10.4.4.2, wildcard bits 0.0.255.255
 5 permit 10.0.0.44, wildcard bits 0.0.0.255
10 permit 10.0.0.1, wildcard bits 0.0.0.255
20 permit 10.0.0.2, wildcard bits 0.0.0.255

Router(config)# ip access-list standard tryon

Router(config-std-nacl)# 15 permit 10.5.5.5 0.0.0.255

Router# show ip access-list

Standard IP access list tryon
 2 permit 10.4.0.0, wildcard bits 0.0.255.255
 5 permit 10.0.0.0, wildcard bits 0.0.0.255
10 permit 10.0.0.0, wildcard bits 0.0.0.255
15 permit 10.5.5.0, wildcard bits 0.0.0.255
20 permit 10.0.0.0, wildcard bits 0.0.0.255
```

Adding an Entry with No Sequence Number: Example

The following example shows how an entry with no specified sequence number is added to the end of an access list. When an entry is added without a sequence number, it is automatically given a sequence number that puts it at the end of the access list. Because the default increment is 10, the entry will have a sequence number 10 higher than the last entry in the existing access list.

```
Router(config)# ip access-list standard resources

Router(config-std-nacl)# permit 10.1.1.1 0.0.0.255
Router(config-std-nacl)# permit 10.2.2.2 0.0.0.255
Router(config-std-nacl)# permit 10.3.3.3 0.0.0.255

Router# show access-list

Standard IP access list resources
10 permit 10.1.1.1, wildcard bits 0.0.0.255
20 permit 10.2.2.2, wildcard bits 0.0.0.255
30 permit 10.3.3.3, wildcard bits 0.0.0.255

Router(config)# ip access-list standard resources
```

```
Router(config-std-nacl)# permit 10.4.4.4 0.0.0.255
Router(config-std-nacl)# end

Router# show access-list

Standard IP access list resources
10 permit 10.1.1.1, wildcard bits 0.0.0.255
20 permit 10.2.2.2, wildcard bits 0.0.0.255
30 permit 10.3.3.3, wildcard bits 0.0.0.255
40 permit 10.4.4.4, wildcard bits 0.0.0.255
```

Time Ranges Applied to IP Access List Entries: Example

The following example creates a time range called no-http, which extends from Monday to Friday from 8:00 a.m. to 6:00 p.m. That time range is applied to the **deny** statement, thereby denying HTTP traffic on Monday through Friday from 8:00 a.m. to 6:00 p.m.

The time range called udp-yes defines weekends from noon to 8:00 p.m. That time range is applied to the **permit** statement, thereby allowing UDP traffic on Saturday and Sunday from noon to 8:00 p.m. only. The access list containing both statements is applied to inbound packets on Ethernet interface 0.

```
time-range no-http
  periodic weekdays 8:00 to 18:00
!
time-range udp-yes
  periodic weekend 12:00 to 20:00
!
ip access-list extended strict
  deny tcp any any eq http time-range no-http
  permit udp any any time-range udp-yes
!
interface ethernet 0
  ip access-group strict in
```

Filtering IP Packet Fragments: Example

In the following access list, the first statement will deny only noninitial fragments destined for host 172.16.1.1. The second statement will permit only the remaining nonfragmented and initial fragments that are destined for host 172.16.1.1 TCP port 80. The third statement will deny all other traffic. In order to block noninitial fragments for any TCP port, we must block noninitial fragments for all TCP ports, including port 80 for host 172.16.1.1. That is, non-initial fragments will not contain Layer 4 port information, so, in order to block such traffic for a given port, we have to block fragments for all ports.

```
access-list 101 deny ip any host 172.16.1.1 fragments
access-list 101 permit tcp any host 172.16.1.1 eq 80
access-list 101 deny ip any any
```

Additional References

The following sections provide references related to access list entry resequencing, time-based access lists, or IP fragment filtering.

Feature Information for Refining an IP Access List

[Table 1](#) lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Release 12.2(1) or a later release appear in the table.

Not all commands may be available in your Cisco IOS software release. For details on when support for a specific command was introduced, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

**Note**

[Table 1](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 *Feature Information for Refining an IP Access List*

Feature Name	Releases	Feature Configuration Information
Distributed Time-Based Access Lists	12.2(2)T	<p>Before the introduction of this feature, time-based access lists were not supported on line cards for the Cisco 7500 series routers. If time-based access lists were configured, they behaved as normal access lists. If an interface on a line card were configured with a time-based access list, the packets switched into the interface were not distributed switched through the line card, but were forwarded to the Route Processor for processing.</p> <p>The Distributed Time-Based Access Lists feature allows packets destined for an interface configured with a time-based access list to be distributed switched through the line card. See the following section:</p> <ul style="list-style-type: none"> • Distributed Time-Based Access Lists, page 7
Time-Based Access Lists	Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Object Groups for ACLs

First Published: July 11, 2008

Last Updated: July 11, 2008

The Object Groups for ACLs feature lets you classify users, devices, or protocols into groups and apply them to access control lists (ACLs) to create access control policies for those groups. This feature lets you use object groups instead of individual IP addresses, protocols, and ports, which are used in conventional ACLs. This feature allows multiple access control entries (ACEs), but now you can use each ACE to allow an entire group of users to access a group of servers or services or to deny them from doing so.

In large networks, the number of ACLs can be large (hundreds of lines) and difficult to configure and manage, especially if the ACLs frequently change. Object group-based ACLs are smaller, more readable, and easier to configure and manage than conventional ACLs, which simplifies static and dynamic ACL deployments for large user access environments on Cisco IOS routers.

Cisco IOS Firewall benefits from object groups, because they simplify policy creation (for example, group A has access to group A services).

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Object Groups for ACLs”](#) section on page 18.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for Object Groups for ACLs

- You can use object groups only in extended and named (not numbered) ACLs.
- Object group-based ACLs support only IPv4 addresses.
- Object group-based ACLs support only Layer 3 interfaces (such as routed interfaces and VLAN interfaces). Object group-based ACLs do not support Layer 2 features such as VLAN ACLs (VACLs) or port ACLs (PACLs).

Information About Object Groups for ACLs

You can configure conventional ACEs and ACEs that refer to object groups in the same ACL.

You can use object group-based ACLs with QoS match criteria, Cisco IOS Firewall, IPSec, DHCP, and any other features that use extended ACLs. In addition, you can use object group-based ACLs with multicast traffic.

When there are many inbound and outbound packets, using object group-based ACLs increases performance when compared to conventional ACLs. Also, in large configurations, this feature reduces the storage needed in NVRAM, because using object groups in ACEs means that you do not need to define an individual ACE for every address and protocol pairing.

To configure the Object Groups for ACLs feature, you should understand the following concepts:

- [Object Groups, page 2](#)
- [ACLs Based on Object Groups, page 3](#)

Object Groups

An object group can contain a single object (such as a single IP address, network, or subnet) or multiple objects (such as a combination of multiple IP addresses, networks, or subnets)

A typical ACE could allow a group of users to have access only to a specific group of servers. In an object group-based ACL, you can create a single ACE that uses an object group name instead of creating many ACEs (which would require each one to have a different IP address). A similar object group (such as a protocol port group) can be extended to provide access only to a set of applications for a user group to a server group. ACEs can have object groups for the source only, destination only, none, or both.

You can use object groups to separate the ownership of the components of an ACE. For example, each department in an organization could control its group membership, and the administrator could own the ACE itself to control which departments can contact each other.

You can use object groups as members (children) of other object groups. For example, you can create an ENG-ALL address group that contains the ENG-EAST and ENG-WEST address groups. You can use an unlimited number of levels of nested (child) object groups (however, a maximum of two levels is recommended).

You can use object groups in features that use Cisco Policy Language (CPL) class maps.

This feature supports two types of object group for grouping ACL parameters: network object groups and service object groups. These object groups can be used to group IP addresses, protocols, protocol services (ports), and ICMP types.

Objects Allowed in Network Object Groups

A network object group is a group of any of the following objects:

- Hostnames
- Host IP addresses
- Subnets
- Ranges of IP addresses
- Other network object groups

Objects Allowed in Service Object Groups

A service object group is a group of any of the following objects:

- Source and destination protocol ports (such as Telnet or SNMP)
- ICMP types (such as echo, echo-reply, or host-unreachable)
- Top-level protocols (such as TCP, UDP, or ESP)
- Other service object groups

ACLs Based on Object Groups

All features that use or reference conventional ACLs are compatible with object group-based ACLs, and feature interactions for conventional ACLs are the same with object group-based ACLs. This feature extends the conventional ACL syntax to support object group-based ACLs and also adds new keywords along with the source and destination addresses and ports.

You can apply object group-based ACLs to interfaces that are configured in a VPN routing/forwarding (VRF) instance or features that are used within a VRF context.

How to Configure Object Group-Based ACLs

You can add to, delete from, or change objects in an object group membership list dynamically (meaning without deleting and redefining the object group). Also, you can add to, delete from, or change objects in an object group membership list without redefining the ACL ACE that is using the object group (meaning without deleting the ACE before changing the object group and then redefining the ACE after the change). You can add objects to groups and delete them from groups and then ensure that the changes are properly functioning within the object group-based ACL without re-applying it to the interface.

You can configure an object group-based ACL multiple times with source group only, destination group only, or source and destination groups.

You cannot delete an object group that is being used within an ACL or a CPL policy.

To configure the Object Groups for ACLs feature, you first create one or more object groups. These can be any combination of network object groups (containing objects such as host addresses and network addresses) or service object groups (which use operators such as **lt**, **eq**, **gt**, **neq**, and **range** with port numbers). Then, you create ACEs that apply a policy (such as **permit** or **deny**) to those object groups.

This section contains the following procedures:

- [Creating a Network Object Group, page 5](#) (optional)
- [Creating a Service Object Group, page 7](#) (optional)
- [Creating an Object Group-Based ACL, page 8](#) (required)
- [Applying an Object Group-Based ACL to an Interface, page 12](#) (required)
- [Verifying Object Groups for ACLs, page 13](#) (optional)

Creating a Network Object Group

To create a network object group, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **object-group network** *object-group-name*
4. **description** *description-text*
5. **host** {*host-address* | *host-name*}
6. *network-address* [*network-mask*]
7. **range** *host-address1* *host-address2*
8. **group-object** *nested-object-group-name*
9. Repeat some combination of Steps 5. through 8. until you have specified the objects on which you want to base your object group.
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	Router(config)# object-group network <i>object-group-name</i> Example: Router(config)# object-group network my_network_object_group	Defines the object group name and enters network object-group configuration mode.
Step 4	Router(config-network-group)# description <i>description-text</i> Example: Router(config-network-group)# description San Jose engineers	(Optional) Specifies a description of the object group. You can use up to 200 characters.
Step 5	Router(config-network-group)# host { <i>host-address</i> <i>host-name</i> } Example: Router(config-network-group)# host 10.20.20.1	(Optional) Specifies the IP address or name of a host. If you specify a host address, you must use an IPv4 address.

	Command or Action	Purpose
Step 6	<pre>Router(config-network-group)# <i>network-address</i> [<i>network-mask</i>]</pre> <p>Example:</p> <pre>Router(config-network-group)# 10.30.0.0 255.255.0.0</pre>	(Optional) Specifies a subnet object. You must specify an IPv4 address for the network address. The default network mask is 255.255.255.255.
Step 7	<pre>Router(config-network-group)# range <i>host-address1</i> <i>host-address2</i></pre> <p>Example:</p> <pre>Router(config-network-group)# range 172.23.56.195 172.23.56.196</pre>	(Optional) Specifies a range of host IP addresses. A mask of 255.255.255.0 is implicit.
Step 8	<pre>Router(config-network-group)# group-object <i>nested-object-group-name</i></pre> <p>Example:</p> <pre>Router(config-network-group)# group-object my_nested_object_group</pre>	<p>(Optional) Specifies a nested (child) object group to be included in the current (parent) object group.</p> <p>The type of child object group must match that of the parent (for example, if you are creating a network object group, you must specify another network object group as the child).</p> <p>You can use duplicated objects in an object group if it is because of the inclusion of group objects. For example, if object 1 is in both group A and group B, you can define a group C that includes both A and B. However, you cannot include a group object that causes the group hierarchy to become circular (for example, you cannot include group A in group B and then also include group B in group A).</p> <p>You can use an unlimited number of levels of nested object groups (however, a maximum of two levels is recommended).</p>
Step 9	Repeat some combination of Steps 5 through 8 until you have specified the objects on which you want to base your object group.	
Step 10	<pre>Router(config-network-group)# end</pre> <p>Example:</p> <pre>Router(config-network-group)# end</pre>	Returns to privileged EXEC mode.

Creating a Service Object Group

To create a service object group, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **object-group service** *object-group-name*
4. **description** *description-text*
5. *protocol*
6. **[tcp | udp | tcp-udp]** **[source** { **[eq | lt | gt]** *port1* | **range** *port1 port2* } } **[{ [eq | lt | gt]** *port1* | **range** *port1 port2* }]
7. **icmp** *icmp-type*
8. **group-object** *nested-object-group-name*
9. Repeat some combination of Steps 5. through 8. until you have specified the objects on which you want to base your object group.
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	Router(config)# object-group service <i>object-group-name</i> Example: Router(config)# object-group service my_service_object_group	Defines the object group name and enters service object-group configuration mode.
Step 4	Router(config-service-group)# description <i>description-text</i> Example: Router(config-service-group)# description Milpitas engineers	(Optional) Specifies a description of the object group. You can use up to 200 characters.
Step 5	Router(config-service-group)# <i>protocol</i> Example: Router(config-service-group)# ahp	(Optional) Specifies an IP protocol number or name.

	Command or Action	Purpose
Step 6	<pre>Router(config-service-group)# tcp udp tcp-udp [source {[eq] lt gt} <i>port1</i> range <i>port1 port2</i>]} [{[eq] lt gt} <i>port1</i> range <i>port1 port2</i>}]</pre> <p>Example:</p> <pre>Router(config-service-group)# tcp-udp range 2000 2005</pre>	(Optional) Specifies TCP, UDP, or both.
Step 7	<pre>Router(config-service-group)# icmp <i>icmp-type</i></pre> <p>Example:</p> <pre>Router(config-service-group)# conversion-error</pre>	(Optional) Specifies the decimal number or name of an ICMP type.
Step 8	<pre>Router(config-service-group)# group-object <i>nested-object-group-name</i></pre> <p>Example:</p> <pre>Router(config-service-group)# group-object my_nested_object_group</pre>	<p>(Optional) Specifies a nested (child) object group to be included in the current (parent) object group.</p> <p>The type of child object group must match that of the parent (for example, if you are creating a network object group, you must specify another network object group as the child).</p> <p>You can use duplicated objects in an object group if it is because of the inclusion of group objects. For example, if object 1 is in both group A and group B, you can define a group C that includes both A and B. However, you cannot include a group object that causes the group hierarchy to become circular (for example, you cannot include group A in group B and then also include group B in group A).</p> <p>You can use an unlimited number of levels of nested object groups (however, a maximum of two levels is recommended).</p>
Step 9	Repeat some combination of Steps 5 through 8 until you have specified the objects on which you want to base your object group.	
Step 10	<pre>Router(config-service-group)# end</pre> <p>Example:</p> <pre>Router(config-service-group)# end</pre>	Returns to privileged EXEC mode.

Creating an Object Group-Based ACL

When creating an object group-based ACL, you configure an ACL that references one or more object groups. As with regular ACLs, you can associate the same access policy with one or more interfaces.

You can define multiple ACEs that reference object groups within the same object group-based ACL. Also, you can reuse a specific object group in multiple ACEs.

To create an object group-based ACL, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *access-list-name*
4. **remark** *remark*
5. **deny protocol source** [*source-wildcard*] *destination* [*destination-wildcard*] [**option** *option-name*] [**precedence** *precedence*] [**tos** *tos*] [**established**] [**log** | **log-input**] [**time-range** *time-range-name*] [**fragments**]
6. **remark** *remark*
7. **permit protocol source** [*source-wildcard*] *destination* [*destination-wildcard*] [**option** *option-name*] [**precedence** *precedence*] [**tos** *tos*] [**established**] [**log** | **log-input**] [**time-range** *time-range-name*] [**fragments**]
8. Repeat some combination of Steps 4. through 7. until you have specified the fields and values on which you want to base your access list.
9. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended nomarketing	Defines an extended IP access list using a name and enters extended named access list configuration mode.
Step 4	remark <i>remark</i> Example: Router(config-ext-nacl)# remark protect server by denying access from the Marketing network	(Optional) Adds a user-friendly comment about an access list entry. <ul style="list-style-type: none">• A remark can precede or follow an access list entry.• In this example, the remark reminds the network administrator that the subsequent entry denies the Sales network access to the interface.

	Command or Action	Purpose
Step 5	<p>deny <i>protocol</i> <i>source</i> [<i>source-wildcard</i>] <i>destination</i> [<i>destination-wildcard</i>] [option <i>option-name</i>] [precedence <i>precedence</i>] [tos <i>tos</i>] [established] [log log-input] [time-range <i>time-range-name</i>] [fragments]</p> <p>Example: Router(config-ext-nacl)# deny ip 172.18.0.0 0.0.255.255 host 172.16.40.10 log</p>	<p>(Optional) Denies any packet that matches all of the conditions specified in the statement.</p> <ul style="list-style-type: none"> Optionally use the keyword and argument object-group <i>service-object-group-name</i> as a substitute for the <i>protocol</i>. Optionally use the keyword and argument object-group <i>source-network-object-group-name</i> as a substitute for the <i>source source-wildcard</i>. Optionally use the keyword and argument object-group <i>destination-network-object-group-name</i> as a substitute for the <i>destination destination-wildcard</i>. If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255. Optionally use the keyword host <i>source</i> to indicate a source and source wildcard of <i>source</i> 0.0.0.0 or the abbreviation host <i>destination</i> to indicate a destination and destination wildcard of <i>destination</i> 0.0.0.0. In this example, packets from all sources are denied access to the destination network 172.18.0.0. Logging messages about packets permitted or denied by the access list are sent to the facility configured by the logging facility command (for example, console, terminal, or syslog). That is, any packet that matches the access list will cause an informational logging message about the packet to be sent to the configured facility. The level of messages logged to the console is controlled by the logging console command.
Step 6	<p>remark <i>remark</i></p> <p>Example: Router(config-ext-nacl)# remark allow TCP from any source to any destination</p>	<p>(Optional) Adds a user-friendly comment about an access list entry.</p> <ul style="list-style-type: none"> A remark can precede or follow an access list entry.

	Command or Action	Purpose
Step 7	<p>permit <i>protocol source [source-wildcard] destination [destination-wildcard] [option option-name] [precedence precedence] [tos tos] [established] [log log-input] [time-range time-range-name] [fragments]</i></p> <p>Example: Router(config-ext-nacl)# permit tcp any any</p>	<p>Permits any packet that matches all of the conditions specified in the statement.</p> <ul style="list-style-type: none"> • Every access list needs at least one permit statement. • Optionally use the keyword and argument object-group <i>service-object-group-name</i> as a substitute for the <i>protocol</i>. • Optionally use the keyword and argument object-group <i>source-network-object-group-name</i> as a substitute for the <i>source source-wildcard</i>. • Optionally use the keyword and argument object-group <i>destination-network-object-group-name</i> as a substitute for the <i>destination destination-wildcard</i>. • If the <i>source-wildcard</i> or <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source or destination address, respectively. • Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> or <i>destination destination-wildcard</i> to specify the address and wildcard of 0.0.0.0 255.255.255.255. • In this example, TCP packets are allowed from any source to any destination. • Use the log-input keyword to include input interface, source MAC address, or virtual circuit in the logging output.
Step 8	Repeat some combination of Steps 4 through 7 until you have specified the fields and values on which you want to base your access list.	Remember that all sources not specifically permitted are denied by an implicit deny statement at the end of the access list.
Step 9	<p>end</p> <p>Example: Router(config-ext-nacl)# end</p>	Returns to privileged EXEC mode.

Applying an Object Group-Based ACL to an Interface

You use the **ip access-group** command to apply an object group-based ACL to an interface. The command syntax and usage are the same as for conventional ACLs.

To apply an object group-based ACL to an interface, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip access-group** {*access-list-name* | *access-list-number*} {**in** | **out**}
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: Router(config-if# interface vlan 100	Specifies the interface type and number and enters interface configuration mode.
Step 4	ip access-group { <i>access-list-name</i> <i>access-list-number</i> } { in out } Example: Router(config-if)# ip access-group my_ogacl_policy in	Applies the ACL to the interface and specifies whether to filter inbound or outbound packets.
Step 5	Router(config-if)# end Example: Router(config-if)# end	Returns to privileged EXEC mode.

Verifying Object Groups for ACLs

To verify object groups for ACLs, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **show object-group** [*object-group-name*]
3. **show ip access-list** [*access-list-name*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	Router# show object-group [<i>object-group-name</i>]	Displays the configuration in the named object group (or in all object groups if no name is entered).
Step 3	Router# show ip access-list [<i>access-list-name</i>]	Displays the contents of the named access list or object group-based ACL (or for all access lists and object group-based ACLs if no name is entered).

Configuration Examples for Object Groups for ACLs

This section provides the following configuration examples:

- [Creating a Network Object Group: Example, page 13](#)
- [Creating a Service Object Group: Example, page 14](#)
- [Creating an Object Group-Based ACL: Example, page 14](#)
- [Applying an Object Group-Based ACL to an Interface: Example, page 14](#)
- [Verifying Object Groups for ACLs: Example, page 15](#)

Creating a Network Object Group: Example

The following example shows how to create a network object group named `my_network_object_group`, which contains two hosts, a range of IP addresses, and a subnet as objects.

```
Router> enable
Router# configure terminal
Router(config)# object-group network my_network_object_group
Router(config-network-group)# host 10.20.20.1
Router(config-network-group)# host 10.20.20.5
Router(config-network-group)# range 10.50.1.23 10.50.1.45
Router(config-network-group)# 10.30.0.0 255.255.0.0
```

The following example shows how to create a network object group named `sjc_ftp_servers`, which contains two hosts, a subnet, and an existing object group (child) named `sjc_eng_ftp_servers` as objects.

```
Router> enable
Router# configure terminal
Router(config)# object-group network sjc_ftp_servers
Router(config-network-group)# host sjc.eng.ftp
Router(config-network-group)# host 172.23.56.195
Router(config-network-group)# 193.1.1.0 255.255.255.224
Router(config-network-group)# group-object sjc_eng_ftp_servers
```

Creating a Service Object Group: Example

The following example shows how to create a service object group named `my_service_object_group`, which contains several ICMP, TCP, UDP, and TCP-UDP protocols and an existing object group (child) named `sjc_eng_svcs` as objects.

```
Router> enable
Router# configure terminal
Router(config)# object-group service my_service_object_group
(config-service-group)# icmp echo
(config-service-group)# tcp smtp
(config-service-group)# tcp telnet
(config-service-group)# tcp source range 1 65535 snmp
(config-service-group)# udp domain
(config-service-group)# tcp-udp range 2000 2005
(config-service-group)# group-object sjc_eng_svcs
```

Creating an Object Group-Based ACL: Example

The following example shows how to create an object group-based ACL that permits packets from the users in `my_network_object_group` if the protocol ports match the ports specified in `my_service_object_group`.

```
Router> enable
Router# configure terminal
Router(config)# ip access-list extended my_ogacl_policy
Router(config-ext-nacl)# permit tcp object-group my_network_object_group object-group
my_service_object_group any
Router(config-ext-nacl)# deny tcp any any
Router(config-ext-nacl)# exit
Router(config)# exit
```

Applying an Object Group-Based ACL to an Interface: Example

The following example shows how to apply an object group-based ACL to an interface. In this example, an object group-based ACL named `my_ogacl_policy` is applied to VLAN interface 100:

```
Router> enable
Router# configure terminal
Router(config)# interface vlan 100
Router(config-if)# ip access-group my_ogacl_policy in
Router(config-if)# end
```

Verifying Object Groups for ACLs: Example

The following example shows how to display all object groups.

```
Router> enable
Router#
Network object group auth_proxy_acl_deny_dest
  host 171.68.225.134

Service object group auth_proxy_acl_deny_services
  tcp eq www
  tcp eq 443

Network object group auth_proxy_acl_permit_dest
  10.34.250.96 255.255.255.224
  171.68.0.0 255.252.0.0
  172.16.0.0 255.240.0.0
  128.107.0.0 255.255.0.0
  10.0.0.0 255.0.0.0
  64.100.0.0 255.253.0.0
  64.104.0.0 255.255.0.0
  144.254.0.0 255.255.0.0
  161.44.0.0 255.255.0.0
  192.168.0.0 255.255.0.0

Service object group auth_proxy_acl_permit_services
  tcp eq www
  tcp eq 443
```

The following example shows how to display information about specific object group-based ACLs.

```
Router# show ip access-list my_ogacl_policy
Extended IP access list my_ogacl_policy
10 permit object-group eng_service any any
```

Feature Information for Object Groups for ACLs

Table 1 lists the features in this module and provides links to specific configuration information. Only features that were introduced or modified in Cisco IOS Releases 12.2(1), 12.0(3)S, 12.2(33)SRA, 12.2(33)SXH, or later releases appear in the table.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for Object Groups for ACLs

Feature Name	Releases	Feature Information
Object Groups for ACLs	12.4(20)T	<p>The Object Groups for ACLs feature lets you classify users, devices, or protocols into groups and apply them to access control lists (ACLs) to create access control policies for those groups. This feature lets you use object groups instead of individual IP addresses, protocols, and ports, which are used in conventional ACLs. This feature allows multiple access control entries (ACEs), but now you can use each ACE to allow an entire group of users to access a group of servers or services or to deny them from doing so.</p> <p>The following sections provide information about this feature:</p> <ul style="list-style-type: none"> • ACLs Based on Object Groups, page 3 • Object Groups, page 2 • Creating a Network Object Group, page 5 • Creating a Service Object Group, page 7 • Creating an Object Group-Based ACL, page 8 • Applying an Object Group-Based ACL to an Interface, page 12 • Verifying Object Groups for ACLs, page 13 <p>The following commands were introduced or modified: deny, ip access-group, ip access-list, object-group network, object-group service, permit, show ip access-list, show object-group.</p>

Displaying and Clearing IP Access List Data Using ACL Manageability

First Published: August 18, 2006

Last Updated: August 18, 2006

This module describes how to display the entries in an IP access list and the number of packets that have matched each entry. Users can get these statistics globally, or per interface and per incoming or outgoing traffic direction, by using the ACL Manageability feature. Viewing details of incoming and outgoing traffic patterns on various interfaces of a network device can help secure devices against attacks coming in on a particular interface. This module also describes how to clear counters so that the count of packets matching an access list entry will restart from zero.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module.

[“Feature Information for Displaying IP Access List Information and Clearing Counters” section on page 8.](#)

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Information About IP Access List Data

Before displaying or clearing IP access list data, you should understand the following concepts:

- [Benefits of ACL Manageability, page 2](#)
- [Support for Interface-Level ACL Statistics, page 2](#)

Benefits of ACL Manageability

Prior to Cisco IOS Release 12.4(6)T, the ACL infrastructure in Cisco IOS software maintained only global statistics for each ACE in an ACL. With this method, if an ACL is applied to multiple interfaces, the maintained ACE statistics are the sum of incoming and outgoing packet matches (hits) on all the interfaces on which that ACL is applied.

However, if ACE statistics are maintained per interface and per incoming or outgoing traffic direction, users can view specific details of incoming and outgoing traffic patterns and the effectiveness of ACEs on the various interfaces of a network device. This type of information is useful for securing devices against attacks coming in on a particular interface.

Support for Interface-Level ACL Statistics

Displaying Global IP ACL Statistics

SUMMARY STEPS

1. `enable`
`show ip access-list [access-list-number | access-list-name]`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code>	Enables privileged EXEC mode. Enter your password if prompted.
	Example: Router> <code>enable</code>	
	<code>show ip access-list [access-list-number access-list-name]</code> Router# <code>show ip access-list limited</code>	

This section describes how to display IP ACE statistics per interface and per incoming or outgoing traffic direction for ACLs. This feature is known as ACL Manageability.

Restrictions for ACL Manageability

-

–

–

–

–

interface

in out

	Enables privileged EXEC mode. Enter your password if prompted.
<pre>in out interface interface-name Router# show ip access-list interface FastEthernet 0/0 in</pre>	

Clearing the Access List Counters

The system counts how many packets match (hit) each line of an access list; the counters are displayed by the EXEC command. Perform this task to clear the counters of an access list. You might do this if you are trying to determine a more recent count of packets that match an access list, starting from zero.

{ | }

Router> enable	
{ access-list-name}	
Router# clear access-list counters corpmark	

Display and Clear IP ACL Data Examples

Displaying Global IP ACL Statistics: Example

The following example displays global statistics for ACL 150:

```
show ip access-list 150
```

```
Extended IP access list 150
 10 permit ip host 10.1.1.1 any (3 matches)
 30 permit ip host 10.2.2.2 any (27 matches)
```

```
Router# show ip access-list interface FastEthernet 0/1 in
```

Displaying Output Statistics: Example

```
show ip access-list interface FastEthernet 0/0 out
```

```
10 permit udp any any eq snmp (6 matches)
```

Displaying Input and Output Statistics: Example

Note

```
Router#

Extended IP access list 150 in
 10 permit ip host 10.1.1.1 any
 30 permit ip host 10.2.2.2 any (15 matches)
Extended IP access list myacl out
 5 deny ip any 10.1.0.0 0.0.255.255
```

Controlling Access to a Virtual Terminal Line

First Published: August 18, 2006

Last Updated: August 18, 2006

You can control who can access the virtual terminal lines (vty) to a router by applying an access list to inbound vtys. You can also control the destinations that the vtys from a router can reach by applying an access list to outbound vtys.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Controlling Access to a Virtual Terminal Line”](#) section on page 9.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for Controlling Access to a Virtual Terminal Line

When you apply an access list to a vty (by using the **access-class** command), the access list must be a numbered access list, not a named access list.

Information About Controlling Access to a Virtual Terminal Line

Before you control access to a vty, you should understand the following concepts:

- [Benefits of Controlling Access to a Virtual Terminal Line, page 2](#)

Benefits of Controlling Access to a Virtual Terminal Line

By applying an access list to an inbound vty, you can control who can access the lines to a router. By applying an access list to an outbound vty, you can control the destinations that the lines from a router can reach.

How to Control Access to a Virtual Terminal Line

This section contains the following procedures:

- [Controlling Inbound Access to a vty, page 2](#)
- [Controlling Outbound Access to a vty, page 4](#)

Controlling Inbound Access to a vty

Perform this task when you want to control access to a vty coming into the router by using an access list. Access lists are very flexible; this task illustrates one **access-list deny** command and one **access-list permit** command. You will decide how many of each command you should use and their order to achieve the restrictions you want.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list** *access-list-number* **deny** {*source* [*source-wildcard*] | **any**} [**log**]
4. **access-list** *access-list-number* **permit** {*source* [*source-wildcard*] | **any**} [**log**]
5. **line vty** *line-number* [*ending-line-number*]
6. **access-class** *access-list-number* **in** [**vrf-also**]
7. **exit**
8. Repeat Steps 5 and 6 for each line to set identical restrictions on all the virtual terminal lines because a user can connect to any of them.
9. **end**
10. **show line** [*line-number* | **summary**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list access-list-number deny {source [source-wildcard] any} [log] Example: Router(config)# access-list 1 deny 172.16.7.34	(Optional) Denies the specified source based on a source address and wildcard mask. <ul style="list-style-type: none"> If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. In this example, host 172.16.7.34 is denied passing the access list.
Step 4	access-list access-list-number permit {source [source-wildcard] any} [log] Example: Router(config)# access-list 1 permit 172.16.0.0 0.0.255.255	Permits the specified source based on a source address and wildcard mask. <ul style="list-style-type: none"> If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. In this example, hosts on network 172.16.0.0 (other than the host denied in the prior step) pass the access list, meaning they can access the vtys identified in the line command.
Step 5	line vty line-number [ending-line-number] Example: Router(config)# line vty 5 10	Identifies a specific line for configuration and enters line configuration mode. <ul style="list-style-type: none"> Entering the line command with the optional line type vtty designates the line number as a relative line number. You also can use the line command without specifying a line type. In this case, the line number is treated as an absolute line number.

	Command or Action	Purpose
Step 6	access-class <i>access-list-number</i> in [vrf-also] Example: Router(config-line)# access-class 1 in vrf-also	Restricts incoming connections between a particular vty (into a Cisco device) and the networking devices associated with addresses in the access list. <ul style="list-style-type: none"> If you do not specify the vrf-also keyword, incoming Telnet connections from interfaces that are part of a VPN routing and forwarding (VRF) instance are rejected.
Step 7	exit Example: Router(config-line)# exit	Returns the user to the next highest configuration mode.
Step 8	Repeat Steps 5 and 6 for each line to set identical restrictions on all the vtys because a user can connect to any of them.	If you indicated the full range of vty lines in Step 5 with the line command, you do not need to repeat Steps 5 and 6.
Step 9	end Example: Router(config-line)# end	Returns the user to privileged EXEC mode.
Step 10	show line [<i>line-number</i> summary] Example: Router# show line 5	Displays parameters of a terminal line.

Controlling Outbound Access to a vty

Perform this task when you want to control access from a vty to a destination. Access lists are very flexible; this task illustrates one **access-list deny** command and one **access-list permit** command. You will decide how many of each command you should use and their order to achieve the restrictions you want.

Outbound Access List on a Line Specifies a Destination Address

When a standard access list is applied to a line with the **access-class out** command, the address specified in the access list is not a source address (as it is in an access list applied to an interface), but a destination address.

SUMMARY STEPS

- enable**
- configure terminal**
- access-list** *access-list-number* **deny** {*destination* [*destination-wildcard*] | **any**} [**log**]
- access-list** *access-list-number* **permit** {*destination* [*destination-wildcard*] | **any**} [**log**]
- line vty** *line-number* [*ending-line-number*]
- access-class** *access-list-number* **out**

7. **exit**
8. Repeat Steps 5 and 6 for each line to set identical restrictions on all the virtual terminal lines because a user can connect to any of them.
9. **end**
10. **show line** [*line-number* | **summary**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list access-list-number deny {destination [destination-wildcard] any} [log] Example: Router(config)# access-list 2 deny 172.16.7.34	Denies line access to the specified destination based on a destination address and wildcard mask. <ul style="list-style-type: none"> If the <i>destination-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. Optionally use the keyword any as a substitute for the <i>destination destination-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. In this example, host 172.16.7.34 is denied passing the access list, meaning the line cannot connect to it.
Step 4	access-list access-list-number permit {source [source-wildcard] any} [log] Example: Router(config)# access-list 2 permit 172.16.0.0 0.0.255.255	Permits the specified source based on a source address and wildcard mask. <ul style="list-style-type: none"> If the <i>source-wildcard</i> is omitted, a wildcard mask of 0.0.0.0 is assumed, meaning match on all bits of the source address. Optionally use the keyword any as a substitute for the <i>source source-wildcard</i> to specify the source and source wildcard of 0.0.0.0 255.255.255.255. In this example, hosts on network 172.16.0.0 (other than the host denied in the prior step) pass the access list, meaning they can be connected to by the vty identified in the line command.
Step 5	line vty line-number [ending-line-number] Example: Router(config)# line vty 5 10	Identifies a specific line for configuration and enter line configuration mode. <ul style="list-style-type: none"> Entering the line command with the optional line type vty designates the line number as a relative line number. You also can use the line command without specifying a line type. In this case, the line number is treated as an absolute line number.
Step 6	access-class access-list-number out Example: Router(config-line)# access-class 2 out	Restricts connections between a particular vty (into a Cisco device) out to the networking devices associated with addresses in the access list.

	Command or Action	Purpose
Step 7	exit Example: Router(config-line)# exit	Returns the user to the next highest configuration mode.
Step 8	Repeat Steps 5 and 6 for each line to set identical restrictions on all the vtys because a user can connect to any of them.	If you indicated the full range of vtys in Step 5 with the line command, you do not need to repeat Steps 5 and 6.
Step 9	end Example: Router(config-line)# end	Returns the user to privileged EXEC mode.
Step 10	show line [<i>line-number</i> summary] Example: Router# show line 5	Displays parameters of a terminal line.

Configuration Examples for Controlling Access to a Virtual Terminal Line

This section provides the following configuration examples:

- [Controlling Inbound Access on vtys: Example, page 7](#)
- [Controlling Outbound Access on vtys: Example, page 7](#)

Controlling Inbound Access on vtys: Example

The following example defines an access list that permits only hosts on network 172.19.5.0 to connect to the virtual terminal lines 1 through 5 on the router. Because the **vty** keyword is omitted from the **line** command, the line numbers 1 through 5 are absolute line numbers.

```
access-list 12 permit 172.19.5.0 0.0.0.255
line 1 5
access-class 12 in
```

Controlling Outbound Access on vtys: Example

The following example defines an access list that denies connections to networks other than network 171.20.0.0 on terminal lines 1 through 5. Because the **vty** keyword is omitted from the **line** command, the line numbers 1 through 5 are absolute line numbers.

```
access-list 10 permit 172.20.0.0 0.0.255.255
line 1 5
access-class 10 out
```

Where to Go Next

You can further secure a vty by configuring a password with the **password** line configuration command. See the **password** (line configuration) command in the [Cisco IOS Security Command Reference](#), Release 12.4.

Cisco IOS Firewall Overview

This chapter describes how you can configure your Cisco networking device to function as a firewall, using Cisco IOS Firewall security features.

This chapter has the following sections:

- [About Firewalls](#)
- [The Cisco IOS Firewall Solution](#)
- [Creating a Customized Firewall](#)
[Other Guidelines for Configuring Your Firewall](#)

About Firewalls

Firewalls are networking devices that control access to your organization's network assets. Firewalls are positioned at the entrance points into your network. If your network has multiple entrance points, you must position a firewall at each point to provide effective network access control.

Firewalls are often placed in between the internal network and an external network such as the Internet. With a firewall between your network and the Internet, all traffic coming from the Internet must pass through the firewall before entering your network.

Firewalls can also be used to control access to a specific part of your network. For example, you can position firewalls at all the entry points into a research and development network to prevent unauthorized access to proprietary information.

The most basic function of a firewall is to monitor and filter traffic. Firewalls can be simple or elaborate, depending on your network requirements. Simple firewalls are usually easier to configure and manage. However, you might require the flexibility of a more elaborate firewall.

The Cisco IOS Firewall Solution

firewall functionality are listed in the [“Creating a Customized Firewall”](#) section.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

The Cisco IOS Firewall Feature Set

The Cisco IOS Firewall feature set combines existing Cisco IOS firewall technology and Context-based Access Control (CBAC). When you configure the Cisco IOS Firewall on your Cisco router, you turn your router into an effective, robust firewall.

The Cisco IOS Firewall features are designed to prevent unauthorized external individuals from gaining access to your internal network and to block attacks on your network, while at the same time allowing authorized users to access network resources.

You can use the Cisco IOS Firewall features to configure your Cisco IOS router as one of the following:

- An Internet firewall or part of an Internet firewall
- A firewall between groups in your internal network
- A firewall providing secure connections to or from branch offices
- A firewall between your company's network and your company's partners' networks

The Cisco IOS Firewall features provide the following benefits:

- Protection of internal networks from intrusion
- Monitoring of traffic through network perimeters
- Enabling of network commerce via the World Wide Web

Creating a Customized Firewall

- Standard Access Lists and Static Extended Access Lists
- Reflexive Access Lists
- Lock-and-Key (Dynamic Access Lists)
- TCP Intercept
- Context-based Access Control
- Intrusion Prevention System (IPS) (formerly known as Cisco IOS Firewall Intrusion Detection System)
- Authentication Proxy
- Port to Application Mapping
- Security Server Support
- Network Address Translation
- IPSec Network Security
- Neighbor Router Authentication

User Authentication and Authorization

In addition to configuring these features, you should follow the guidelines listed in the “[Other Guidelines for Configuring Your Firewall](#)” section. This section outlines important security practices to protect your firewall and network. [Table 23](#) describes Cisco IOS security features.

Table 23 *Cisco IOS Features for a Robust Firewall*

Feature	Chapter	Comments
		through your firewall, such as IP, IPX, AppleTalk, and so forth.
Lock-and-Key (Dynamic Access Lists)	“Configuring Lock-and-Key Security (Dynamic Access Lists)”	Lock-and-Key provides traffic filtering with the ability to allow temporary access through the firewall for certain individuals. These individuals must first be authenticated (by a username/password mechanism) before the firewall allows their traffic through the firewall. Afterwards, the firewall closes the temporary opening. This provides tighter control over traffic at the firewall than with standard or static extended access lists.
Reflexive Access Lists	“Configuring IP Session Filtering (Reflexive Access Lists)”	Reflexive access lists filter IP traffic so that TCP or UDP “session” traffic is only permitted through the firewall if the session originated from within the internal network. You would only configure Reflexive Access Lists when not using Context-based Access Control.
TCP Intercept	“Configuring TCP Intercept (Preventing Denial-of-Service Attacks)”	TCP Intercept protects TCP servers within your network from TCP SYN-flooding attacks, a type of denial-of-service attack. You would only configure TCP Intercept when not using Context-based Access Control.

	<p>“Configuring TACACS+,” “Configuring RADIUS,” and “Configuring Kerberos”</p>	<p>The Cisco IOS Firewall feature set can be configured as a client of the following supported security servers:</p> <p style="padding-left: 40px;">TACACS+ (including CiscoSecure)</p> <p style="padding-left: 40px;">RADIUS</p> <p style="padding-left: 40px;">Kerberos</p> <p>You can use any of these security servers to store a database of user profiles. To gain access into your firewall or to gain access through the firewall into another network, users must enter authentication information (such as a username and password), which is matched against the information on the security server. When users pass authentication, they are granted access according to their specified privileges.</p>
Network Address Translation	<p>“Configuring NAT for IP Address Conservation”</p>	<p>You can use Network Address Translation (NAT) to hide internal IP network addresses from the world outside the firewall.</p> <p>NAT was designed to provide IP address conservation and for internal IP networks that have unregistered (not globally unique) IP addresses: NAT translates these unregistered IP addresses into legal addresses at the firewall. NAT can also be configured to advertise only one address for the entire internal network to the outside world. This provides security by effectively hiding the entire internal network from the world.</p> <p>NAT gives you limited spoof protection because internal addresses are hidden. Additionally, NAT removes all your internal services from the external name space.</p> <p>NAT does not work with the application-layer protocols RPC, VDOLive, or SQL*Net “Redirected.” (NAT does work with SQL*Net “Bequeathed.”) Do not configure NAT with networks that will carry traffic for these incompatible protocols.</p>

Configuring Lock-and-Key Security (Dynamic Access Lists)

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This chapter describes how to configure lock-and-key security at your router. Lock-and-key is a traffic filtering security feature available for the IP protocol.

For a complete description of lock-and-key commands, refer to the “Lock-and-Key Commands” chapter of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

- [Verifying Lock-and-Key Configuration](#)
- [Maintaining Lock-and-Key](#)
- [Lock-and-Key Configuration Examples](#)

About Lock-and-Key

Lock-and-key is a traffic filtering security feature that dynamically filters IP protocol traffic. Lock-and-key is configured using IP dynamic extended access lists. Lock-and-key can be used in conjunction with other standard access lists and static extended access lists.

When lock-and-key is configured, designated users whose IP traffic is normally blocked at a router can gain temporary access through the router. When triggered, lock-and-key reconfigures the interface's existing IP access list to permit designated users to reach their designated host(s). Afterwards, lock-and-key reconfigures the interface back to its original state.

For a user to gain access to a host through a router with lock-and-key configured, the user must first open a Telnet session to the router. When a user initiates a standard Telnet session to the router, lock-and-key automatically attempts to authenticate the user. If the user is authenticated, they will then gain temporary access through the router and be able to reach their destination host.

This section has the following sections:

- [Benefits of Lock-and-Key](#)
- [When to Use Lock-and-Key](#)
- [How Lock-and-Key Works](#)

Benefits of Lock-and-Key

Lock-and-key provides the same benefits as standard and static extended access lists (these benefits are discussed in the chapter "Access Control Lists: Overview and Guidelines"). However, lock-and-key also has the following security benefits over standard and static extended access lists:

- Lock-and-key uses a challenge mechanism to authenticate individual users.
- Lock-and-key provides simpler management in large internetworks.
- In many cases, lock-and-key reduces the amount of router processing required for access lists.
- Lock-and-key reduces the opportunity for network break-ins by network hackers.

With lock-and-key, you can specify which users are permitted access to which source and destination hosts. These users must pass a user authentication process before they are permitted access to their designated hosts. Lock-and-key creates dynamic user access through a firewall, without compromising other configured security restrictions.

When to Use Lock-and-Key

Two examples of when you might use lock-and-key follow:

- When you want a specific remote user (or group of remote users) to be able to access a host within your network, connecting from their remote hosts via the Internet. Lock-and-key authenticates the user, then permits limited access through your firewall router for the individual's host or subnet, for a finite period of time.

- When you want a subset of hosts on a local network to access a host on a remote network protected by a firewall. With lock-and-key, you can enable access to the remote host only for the desired set of local user's hosts. Lock-and-key require the users to authenticate through a TACACS+ server, or other security server, before allowing their hosts to access the remote hosts.

How Lock-and-Key Works

The following process describes the lock-and-key access operation:

1. A user opens a Telnet session to a border (firewall) router configured for lock-and-key. The user connects via the virtual terminal port on the router.
2. The Cisco IOS software receives the Telnet packet, opens a Telnet session, prompts for a password, and performs a user authentication process. The user must pass authentication before access through the router is allowed. The authentication process can be done by the router or by a central access security server such as a TACACS+ or RADIUS server.
3. When the user passes authentication, they are logged out of the Telnet session, and the software creates a temporary entry in the dynamic access list. (Per your configuration, this temporary entry can limit the range of networks to which the user is given temporary access.)
4. The user exchanges data through the firewall.
5. The software deletes the temporary access list entry when a configured timeout is reached, or when the system administrator manually clears it. The configured timeout can either be an idle timeout or an absolute timeout.

Note

The temporary access list entry is not automatically deleted when the user terminates a session. The temporary access list entry remains until a configured timeout is reached or until it is cleared by the system administrator.

Compatibility with Releases Before Cisco IOS Release 11.1

Enhancements to the **access-list** command are used for lock-and-key. These enhancements are backward compatible—if you migrate from a release before Cisco IOS Release 11.1 to a newer release, your access lists will be automatically converted to reflect the enhancements. However, if you try to use lock-and-key with a release before Cisco IOS Release 11.1, you might encounter problems as described in the following caution paragraph:

Caution

Cisco IOS releases before Release 11.1 are not upwardly compatible with the lock-and-key access list enhancements. Therefore, if you save an access list with software older than Release 11.1, and then use this software, the resulting access list will not be interpreted correctly. *This could cause you severe security problems.* You must save your old configuration files with Cisco IOS Release 11.1 or later software before booting an image with these files.

Risk of Spoofing with Lock-and-Key

**Caution**

Lock-and-key access allows an external event (a Telnet session) to place an opening in the firewall. While this opening exists, the router is susceptible to source address spoofing.

When lock-and-key is triggered, it creates a dynamic opening in the firewall by temporarily reconfiguring an interface to allow user access. While this opening exists, another host might spoof the authenticated user's address to gain access behind the firewall. Lock-and-key does not cause the address spoofing problem; the problem is only identified here as a concern to the user. Spoofing is a problem inherent to all access lists, and lock-and-key does not specifically address this problem.

To prevent spoofing, configure encryption so that traffic from the remote host is encrypted at a secured remote router, and decrypted locally at the router interface providing lock-and-key. You want to ensure that all traffic using lock-and-key will be encrypted when entering the router; this way no hackers can spoof the source address, because they will be unable to duplicate the encryption or to be authenticated as is a required part of the encryption setup process.

Router Performance Impacts with Lock-and-Key

When lock-and-key is configured, router performance can be affected in the following ways:

- When lock-and-key is triggered, the dynamic access list forces an access list rebuild on the silicon switching engine (SSE). This causes the SSE switching path to slow down momentarily.
- Dynamic access lists require the idle timeout facility (even if the timeout is left to default) and therefore cannot be SSE switched. These entries must be handled in the protocol fast-switching path.
- When remote users trigger lock-and-key at a border router, additional access list entries are created on the border router interface. The interface's access list will grow and shrink dynamically. Entries are dynamically removed from the list after either the idle-timeout or max-timeout period expires. Large access lists can degrade packet switching performance, so if you notice performance problems, you should look at the border router configuration to see if you should remove temporary access list entries generated by lock-and-key.

Prerequisites to Configuring Lock-and-Key

Lock-and-key uses IP extended access lists. You must have a solid understanding of how access lists are used to filter traffic, before you attempt to configure lock-and-key. Access lists are described in the chapter "Access Control Lists: Overview and Guidelines."

Lock-and-key employs user authentication and authorization as implemented in Cisco's authentication, authorization, and accounting (AAA) paradigm. You must understand how to configure AAA user authentication and authorization before you configure lock-and-key. User authentication and authorization is explained in the "Authentication, Authorization, and Accounting (AAA)" part of this document.

Lock-and-key uses the **autocommand** command, which you should understand. This command is described in the "Modem Support and Asynchronous Device Commands" chapter of the *Cisco IOS Dial Technologies Command Reference*.

Configuring Lock-and-Key

To configure lock-and-key, use the following commands beginning in global configuration mode. While completing these steps, be sure to follow the guidelines listed in the “[Lock-and-Key Configuration Guidelines](#)” section of this chapter.

	Command	Purpose
Step 1	Router(config)# access-list <i>access-list-number</i> [dynamic <i>dynamic-name</i> [timeout <i>minutes</i>]] { deny permit } telnet <i>source source-wildcard destination destination-wildcard</i> [precedence <i>precedence</i>] [tos <i>tos</i>] [established] [log]	Configures a dynamic access list, which serves as a template and placeholder for temporary access list entries.
Step 2	Router(config)# access-list dynamic-extend	(Optional) Extends the absolute timer of the dynamic ACL by six minutes when you open another Telnet session into the router to re-authenticate yourself using lock-and-key. Use this command if your job will run past the ACL’s absolute timer.
Step 3	Router(config)# interface <i>type number</i>	Configures an interface and enters interface configuration mode.
Step 4	Router(config-if)# ip access-group <i>access-list-number</i>	Applies the access list to the interface.
Step 5	Router(config-if)# exit	Exits interface configuration mode and enters global configuration mode.
Step 6	Router(config)# line vty <i>line-number</i> [<i>ending-line-number</i>]	Defines one or more virtual terminal (VTY) ports and enters line configuration mode. If you specify multiple VTY ports, they must all be configured identically because the software hunts for available VTY ports on a round-robin basis. If you do not want to configure all your VTY ports for lock-and-key access, you can specify a group of VTY ports for lock-and-key support only.
Step 7	Router(config-line)# login tacacs or Router(config-line)# password <i>password</i> or Router(config-line)# login local or Router(config-line)# exit then Router(config)# username <i>name</i> password <i>secret</i>	Configures user authentication in line or global configuration mode.
Step 8	Router(config-line)# autocommand access-enable [host] [timeout <i>minutes</i>] or Router(config)# autocommand access-enable [host] [timeout <i>minutes</i>]	Enables the creation of temporary access list entries in line or global configuration mode. If the optional host keyword is <i>not</i> specified, all hosts on the entire network are allowed to set up a temporary access list entry. The dynamic access list contains the network mask to enable the new network connection.

For an example of a lock-and-key configuration, see the section “[Lock-and-Key Configuration Examples](#)” later in this chapter.

Lock-and-Key Configuration Guidelines

Before you configure lock-and-key, you should understand the guidelines discussed in the following sections:

- [Dynamic Access Lists](#)
- [Lock-and-Key Authentication](#)
- [The autocommand Command](#)

Dynamic Access Lists

Use the following guidelines for configuring dynamic access lists:

- Do *not* create more than one dynamic access list for any one access list. The software only refers to the first dynamic access list defined.
- Do *not* assign the same *dynamic-name* to another access list. Doing so instructs the software to reuse the existing list. All named entries must be globally unique within the configuration.
- Assign attributes to the dynamic access list in the same way you assign attributes for a static access list. The temporary access list entries inherit the attributes assigned to this list.
- Configure Telnet as the protocol so that users must open a Telnet session into the router to be authenticated before they can gain access through the router.
- Either define an idle timeout now with the **timeout** keyword in the **access-enable** command in the **autocommand** command, or define an absolute timeout value later with the **access-list** command. You must define either an idle timeout or an absolute timeout—otherwise, the temporary access list entry will remain configured indefinitely on the interface (even after the user has terminated their session) until the entry is removed manually by an administrator. (You could configure both idle and absolute timeouts if you wish.)
- If you configure an idle timeout, the idle timeout value should be equal to the WAN idle timeout value.
- If you configure both idle and absolute timeouts, the idle timeout value must be less than the absolute timeout value.
- If you realize that a job will run past the ACL's absolute timer, use the **access-list dynamic-extend** command to extend the absolute timer of the dynamic ACL by six minutes. This command allows you to open a new Telnet session into the router to re-authentication yourself using lock-and-key.
- The only values replaced in the temporary entry are the source or destination address, depending whether the access list was in the input access list or output access list. All other attributes, such as port, are inherited from the main dynamic access list.
- Each addition to the dynamic list is always put at the beginning of the dynamic list. You cannot specify the order of temporary access list entries.
- Temporary access list entries are never written to NVRAM.
- To manually clear or to display dynamic access lists, refer to the section "[Maintaining Lock-and-Key](#)" later in this chapter.

Lock-and-Key Authentication

There are three possible methods to configure an authentication query process. These three methods are described in this section.

**Note**

Cisco recommends that you use the TACACS+ server for your authentication query process. TACACS+ provides authentication, authorization, and accounting services. It also provides protocol support, protocol specification, and a centralized security database. Using a TACACS+ server is described in the next section, “[Method 1—Configuring a Security Server](#).”

Method 1—Configuring a Security Server

Use a network access security server such as TACACS+ server. This method requires additional configuration steps on the TACACS+ server but allows for stricter authentication queries and more sophisticated tracking capabilities.

```
Router(config-line)# login tacacs
```

Method 2—Configuring the username Command

Use the **username** command. This method is more effective because authentication is determined on a user basis.

```
Router(config)# username name {nopassword | password {mutual-password | encryption-type encryption-password}}
```

Method 3—Configuring the password and login Commands

Use the **password** and **login** commands. This method is less effective because the password is configured for the port, not for the user. Therefore, any user who knows the password can authenticate successfully.

```
Router(config-line)# password password
Router(config-line)# login local
```

The autocommand Command

Use the following guidelines for configuring the **autocommand** command:

- If you use a TACACS+ server to authenticate the user, you should configure the **autocommand** command on the TACACS+ server as a per-user autocommand. If you use local authentication, use the **autocommand** command on the line.
- Configure all virtual terminal (VTY) ports with the same **autocommand** command. Omitting an **autocommand** command on a VTY port allows a random host to gain EXEC mode access to the router and does not create a temporary access list entry in the dynamic access list.
- If you did not previously define an idle timeout with the **autocommand access-enable** command, you must define an absolute timeout now with the **access-list** command. You must define either an idle timeout or an absolute timeout—otherwise, the temporary access list entry will remain configured indefinitely on the interface (even after the user has terminated their session) until the entry is removed manually by an administrator. (You could configure both idle and absolute timeouts if you wish.)
- If you configure both idle and absolute timeouts, the absolute timeout value must be greater than the idle timeout value.

Verifying Lock-and-Key Configuration

You can verify that lock-and-key is successfully configured on the router by asking a user to test the connection. The user should be at a host that is permitted in the dynamic access list, and the user should have AAA authentication and authorization configured.

To test the connection, the user should Telnet to the router, allow the Telnet session to close, and then attempt to access a host on the other side of the router. This host must be one that is permitted by the dynamic access list. The user should access the host with an application that uses the IP protocol.

The following sample display illustrates what end-users might see if they are successfully authenticated. Notice that the Telnet connection is closed immediately after the password is entered and authenticated. The temporary access list entry is then created, and the host that initiated the Telnet session now has access inside the firewall.

```
Router% telnet corporate
Trying 172.21.52.1 ...
Connected to corporate.example.com.
Escape character is '^]'.
User Access Verification
Password:Connection closed by foreign host.
```

You can then use the **show access-lists** command at the router to view the dynamic access lists, which should include an additional entry permitting the user access through the router.

Maintaining Lock-and-Key

When lock-and-key is in use, dynamic access lists will dynamically grow and shrink as entries are added and deleted. You need to make sure that entries are being deleted in a timely way, because while entries exist, the risk of a spoofing attack is present. Also, the more entries there are, the bigger the router performance impact will be.

If you do not have an idle or absolute timeout configured, entries will remain in the dynamic access list until you manually remove them. If this is the case, make sure that you are extremely vigilant about removing entries.

Displaying Dynamic Access List Entries

You can display temporary access list entries when they are in use. After a temporary access list entry is cleared by you or by the absolute or idle timeout parameter, it can no longer be displayed. The number of matches displayed indicates the number of times the access list entry was hit.

To view dynamic access lists and any temporary access list entries that are currently established, use the following command in privileged EXEC mode:

Command	Purpose
Router# show access-lists [<i>access-list-number</i>]	Displays dynamic access lists and temporary access list entries.

Manually Deleting Dynamic Access List Entries

To manually delete a temporary access list entry, use the following command in privileged EXEC mode:

Command	Purpose
Router# clear access-template [<i>access-list-number</i> <i>name</i>] [<i>dynamic-name</i>] [<i>source</i>] [<i>destination</i>]	Deletes a dynamic access list.

Lock-and-Key Configuration Examples

The following sections provide lock-and-key configuration examples:

- [Lock-and-Key with Local Authentication Example](#)
- [Lock-and-Key with TACACS+ Authentication Example](#)

Cisco recommends that you use a TACACS+ server for authentication, as shown in the second example.

Lock-and-Key with Local Authentication Example

This example shows how to configure lock-and-key access, with authentication occurring locally at the router. Lock-and-key is configured on the Ethernet 0 interface.

```
interface ethernet0
 ip address 172.18.23.9 255.255.255.0
 ip access-group 101 in

access-list 101 permit tcp any host 172.18.21.2 eq telnet
access-list 101 dynamic mytestlist timeout 120 permit ip any any

line vty 0
 login local
 autocommand access-enable timeout 5
```

The first access-list entry allows only Telnet into the router. The second access-list entry is always ignored until lock-and-key is triggered.

In the **access-list** command, the timeout is the absolute timeout. In this example, the lifetime of the mytestlist ACL is 120 minutes; that is, when a user logs in and enable the **access-enable** command, a dynamic ACL is created for 120 minutes (the maximum absolute time). The session is closed after 120 minutes, whether or not anyone is using it.

In the **autocommand** command, the timeout is the idle timeout. In this example, each time the user logs in or authenticates there is a 5-minute session. If there is no activity, the session closes in 5 minutes and the user has to reauthenticate. If the user uses the connection, the absolute time takes affect and the session closes in 120 minutes.

After a user opens a Telnet session into the router, the router will attempt to authenticate the user. If authentication is successful, the **autocommand** executes and the Telnet session terminates. The **autocommand** creates a temporary inbound access list entry at the Ethernet 0 interface, based on the second access-list entry (mytestlist). This temporary entry will expire after 5 minutes, as specified by the timeout.

Lock-and-Key with TACACS+ Authentication Example

The following example shows how to configure lock-and-key access, with authentication on a TACACS+ server. Lock-and-key access is configured on the BRI0 interface. Four VTY ports are defined with the password “cisco”.

```

Configuring IP Session Filtering (Reflexive Access Lists)

This chapter describes how to configure reflexive access lists on your router. Reflexive access lists provide the ability to filter network traffic at a router, based on IP upper-layer protocol “session” information.

For a complete description of reflexive access list commands, refer to the “Reflexive Access List Commands” chapter of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

In This Chapter

This chapter has the following sections:

- [About Reflexive Access Lists](#)
- [Pework: Before You Configure Reflexive Access Lists](#)
- [Reflexive Access Lists Configuration Task List](#)
- [Reflexive Access List Configuration Examples](#)

About Reflexive Access Lists

Reflexive access lists allow IP packets to be filtered based on upper-layer session information. You can use reflexive access lists to permit IP traffic for sessions originating from within your network but to deny IP traffic for sessions originating from outside your network. This is accomplished by reflexive filtering, a kind of session filtering.

Reflexive access lists can be defined with extended named IP access lists only. You cannot define reflexive access lists with numbered or standard named IP access lists or with other protocol access lists.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

You can use reflexive access lists in conjunction with other standard access lists and static extended access lists.

This section has the following sections:

- [Benefits of Reflexive Access Lists](#)
- [What Is a Reflexive Access List?](#)
- [How Reflexive Access Lists Implement Session Filtering](#)
- [Where to Configure Reflexive Access Lists](#)
- [How Reflexive Access Lists Work](#)
- [Restrictions on Using Reflexive Access Lists](#)

Benefits of Reflexive Access Lists

Reflexive access lists are an important part of securing your network against network hackers, and can be included in a firewall defense. Reflexive access lists provide a level of security against spoofing and certain denial-of-service attacks. Reflexive access lists are simple to use, and, compared to basic access lists, provide greater control over which packets enter your network.

What Is a Reflexive Access List?

Reflexive access lists are similar in many ways to other access lists. Reflexive access lists contain condition statements (entries) that define criteria for permitting IP packets. These entries are evaluated in order, and when a match occurs, no more entries are evaluated.

However, reflexive access lists have significant differences from other types of access lists. Reflexive access lists contain only temporary entries; these entries are automatically created when a new IP session begins (for example, with an outbound packet), and the entries are removed when the session ends. Reflexive access lists are not themselves applied directly to an interface, but are “nested” within an extended named IP access list that is applied to the interface. (For more information about this, see the section “[Reflexive Access Lists Configuration Task List](#)” later in this chapter.) Also, reflexive access lists do not have the usual implicit “deny all traffic” statement at the end of the list, because of the nesting.

How Reflexive Access Lists Implement Session Filtering

This section compares session filtering with basic access lists to session filtering with reflexive access lists. This section contains the following sections:

- [With Basic Access Lists](#)
- [With Reflexive Access Lists](#)

With Basic Access Lists

With basic standard and static extended access lists, you can approximate session filtering by using the **established** keyword with the **permit** command. The **established** keyword filters TCP packets based on whether the ACK or RST bits are set. (Set ACK or RST bits indicate that the packet is not the first in the session, and therefore, that the packet belongs to an established session.) This filter criterion would be part of an access list applied permanently to an interface.

With Reflexive Access Lists

Reflexive access lists, however, provide a truer form of session filtering, which is much harder to spoof because more filter criteria must be matched before a packet is permitted through. (For example, source and destination addresses and port numbers are checked, not just ACK and RST bits.) Also, session filtering uses temporary filters which are removed when a session is over. This limits the hacker's attack opportunity to a smaller time window.

Moreover, the previous method of using the **established** keyword was available only for the TCP upper-layer protocol. So, for the other upper-layer protocols (such as UDP, ICMP, and so forth), you would have to either permit all incoming traffic or define all possible permissible source/destination host/port address pairs for each protocol. (Besides being an unmanageable task, this could exhaust NVRAM space.)

Where to Configure Reflexive Access Lists

Configure reflexive access lists on border routers—routers that pass traffic between an internal and external network. Often, these are firewall routers.

Note

In this chapter, the words “within your network” and “internal network” refer to a network that is controlled (secured), such as your organization's intranet, or to a part of your organization's internal network that has higher security requirements than another part. “Outside your network” and “external network” refer to a network that is uncontrolled (unsecured) such as the Internet or to a part of your organization's network that is not as highly secured.

How Reflexive Access Lists Work

A reflexive access list is triggered when a new IP upper-layer session (such as TCP or UDP) is initiated from inside your network, with a packet traveling to the external network. When triggered, the reflexive access list generates a new, temporary entry. This entry will permit traffic to enter your network if the traffic is part of the session, but will not permit traffic to enter your network if the traffic is not part of the session.

For example, if an outbound TCP packet is forwarded to outside of your network, and this packet is the first packet of a TCP session, then a new, temporary reflexive access list entry will be created. This entry is added to the reflexive access list, which applies to inbound traffic. The temporary entry has characteristics as described next.

This section contains the following sections:

- [Temporary Access List Entry Characteristics](#)
- [When the Session Ends](#)

Temporary Access List Entry Characteristics

- The entry is always a **permit** entry.
- The entry specifies the same protocol (TCP) as the original outbound TCP packet.
- The entry specifies the same source and destination addresses as the original outbound TCP packet, except the addresses are swapped.
- The entry specifies the same source and destination port numbers as the original outbound TCP packet, except the port numbers are swapped.
(This entry characteristic applies only for TCP and UDP packets. Other protocols, such as ICMP and IGMP, do not have port numbers, and other criteria are specified. For example, for ICMP, type numbers are used instead.)
- Inbound TCP traffic will be evaluated against the entry, until the entry expires. If an inbound TCP packet matches the entry, the inbound packet will be forwarded into your network.
- The entry will expire (be removed) after the last packet of the session passes through the interface.
- If no packets belonging to the session are detected for a configurable length of time (the timeout period), the entry will expire.

When the Session Ends

Temporary reflexive access list entries are removed at the end of the session. For TCP sessions, the entry is removed 5 seconds after two set FIN bits are detected, or immediately after matching a TCP packet with the RST bit set. (Two set FIN bits in a session indicate that the session is about to end; the 5-second window allows the session to close gracefully. A set RST bit indicates an abrupt session close.) Or, the temporary entry is removed after no packets of the session have been detected for a configurable length of time (the timeout period).

For UDP and other protocols, the end of the session is determined differently than for TCP. Because other protocols are considered to be connectionless (sessionless) services, there is no session tracking information embedded in packets. Therefore, the end of a session is considered to be when no packets of the session have been detected for a configurable length of time (the timeout period).

Restrictions on Using Reflexive Access Lists

Reflexive access lists do not work with some applications that use port numbers that change during a session. For example, if the port numbers for a return packet are different from the originating packet, the return packet will be denied, even if the packet is actually part of the same session.

The TCP application of FTP is an example of an application with changing port numbers. With reflexive access lists, if you start an FTP request from within your network, the request will not complete. Instead, you must use Passive FTP when originating requests from within your network.

Prework: Before You Configure Reflexive Access Lists

Before you configure reflexive access lists, you must decide whether to configure reflexive access lists on an internal or external interface, as described in the next section, “[Choosing an Interface: Internal or External](#).”

You should also be sure that you have a basic understanding of the IP protocol and of access lists; specifically, you should know how to configure extended named IP access lists. To learn about configuring IP extended access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Configuration Guide*.

Choosing an Interface: Internal or External

Reflexive access lists are most commonly used with one of two basic network topologies. Determining which of these topologies is most like your own can help you decide whether to use reflexive access lists with an internal interface or with an external interface (the interface connecting to an internal network, or the interface connecting to an external network).

The first topology is shown in [Figure 18](#). In this simple topology, reflexive access lists are configured for the *external* interface Serial 1. This prevents IP traffic from entering the router and the internal network, unless the traffic is part of a session already established from within the internal network.

Figure 18 Simple Topology—Reflexive Access Lists Configured at the External Interface

The second topology is shown in [Figure 19](#). In this topology, reflexive access lists are configured for the *internal* interface Ethernet 0. This allows external traffic to access the services in the Demilitarized Zone (DMZ), such as DNS services, but prevents IP traffic from entering your internal network—unless the traffic is part of a session already established from within the internal network.

Figure 19 DMZ Topology—Reflexive Access Lists Configured at the Internal Interface

Use these two example topologies to help you decide whether to configure reflexive access lists for an internal or external interface.

Reflexive Access Lists Configuration Task List

In the previous section, “[Prework: Before You Configure Reflexive Access Lists](#),” you decided whether to configure reflexive access lists for an internal or external interface.

Now, complete the tasks in one of the following configuration task lists:

- [External Interface Configuration Task List](#)
- [Internal Interface Configuration Task List](#)

For configuration examples, refer to the “[Reflexive Access List Configuration Examples](#)” section at the end of this chapter.

External Interface Configuration Task List

To configure reflexive access lists for an external interface, perform the following tasks:

1. Defining the reflexive access list(s) in an *outbound* IP extended named access list
2. Nesting the reflexive access list(s) in an *inbound* IP extended named access list
3. Setting a global timeout value

These tasks are described in the sections following the “[Internal Interface Configuration Task List](#)” section.

**Note**

The defined (outbound) reflexive access list evaluates traffic traveling out of your network: if the defined reflexive access list is matched, temporary entries are created in the nested (inbound) reflexive access list. These temporary entries will then be applied to traffic traveling into your network.

Internal Interface Configuration Task List

To configure reflexive access lists for an internal interface, perform the following tasks:

1. Defining the reflexive access list(s) in an *inbound* IP extended named access list
2. Nesting the reflexive access list(s) in an *outbound* IP extended named access list
3. Setting a global timeout value

These tasks are described in the next sections.

**Note**

The defined (inbound) reflexive access list is used to evaluate traffic traveling out of your network: if the defined reflexive access list is matched, temporary entries are created in the nested (outbound) reflexive access list. These temporary entries will then be applied to traffic traveling into your network.

Defining the Reflexive Access List(s)

To define a reflexive access list, you use an entry in an extended named IP access list. This entry must use the **reflect** keyword.

- If you are configuring reflexive access lists for an external interface, the extended named IP access list should be one that is applied to outbound traffic.

- If you are configuring reflexive access lists for an internal interface, the extended named IP access list should be one that is applied to inbound traffic.

To define reflexive access lists, use the following commands, beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip access-list extended <i>name</i>	External interface: Specifies the outbound access list. or Internal interface: Specifies the inbound access list. (This command enters access-list configuration mode.)
Step 2	Router(config-ext-nacl)# permit <i>protocol any any</i> reflect <i>name [timeout seconds]</i>	Defines the reflexive access list using the reflexive permit entry. Repeat this step for each IP upper-layer protocol; for example, you can define reflexive filtering for TCP sessions and also for UDP sessions. You can use the same <i>name</i> for multiple protocols. For additional guidelines for this task, see the following section, “ Mixing Reflexive Access List Statements with Other Permit and Deny Entries .”

If the extended named IP access list you just specified has never been applied to the interface, you must also apply the extended named IP access list to the interface.

To apply the extended named IP access list to the interface, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# ip access-group <i>name out</i>	External interface: Applies the extended access list to the interface’s outbound traffic.
or	
Router(config-if)# ip access-group <i>name in</i>	Internal interface: Applies the extended access list to the interface’s inbound traffic.

Mixing Reflexive Access List Statements with Other Permit and Deny Entries

The extended IP access list that contains the reflexive access list **permit** statement can also contain other normal **permit** and **deny** statements (entries). However, as with all access lists, the order of entries is important, as explained in the next few paragraphs.

If you configure reflexive access lists for an external interface, when an outbound IP packet reaches the interface, the packet will be evaluated sequentially by each entry in the outbound access list until a match occurs.

If the packet matches an entry prior to the reflexive **permit** entry, the packet will not be evaluated by the reflexive **permit** entry, and no temporary entry will be created for the reflexive access list (reflexive filtering will not be triggered).

The outbound packet will be evaluated by the reflexive **permit** entry only if no other match occurs first. Then, if the packet matches the protocol specified in the reflexive **permit** entry, the packet is forwarded out of the interface and a corresponding temporary entry is created in the inbound reflexive access list (unless the corresponding entry already exists, indicating the outbound packet belongs to a session in progress). The temporary entry specifies criteria that permits inbound traffic only for the same session.

Nesting the Reflexive Access List(s)

After you define a reflexive access list in one IP extended access list, you must “nest” the reflexive access list within a different extended named IP access list.

- If you are configuring reflexive access lists for an external interface, nest the reflexive access list within an extended named IP access list applied to inbound traffic.
- If you are configuring reflexive access lists for an internal interface, nest the reflexive access list within an extended named IP access list applied to outbound traffic.

After you nest a reflexive access list, packets heading into your internal network can be evaluated against any reflexive access list temporary entries, along with the other entries in the extended named IP access list.

To nest reflexive access lists, use the following commands, beginning in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip access-list extended <i>name</i>	External interface: Specifies the inbound access list. or Internal interface: Specifies the outbound access list. (This command enters access-list configuration mode.)
Step 2	Router(config-ext-nacl)# evaluate <i>name</i>	Adds an entry that “points” to the reflexive access list. Adds an entry for each reflexive access list <i>name</i> previously defined.

Again, the order of entries is important. Normally, when a packet is evaluated against entries in an access list, the entries are evaluated in sequential order, and when a match occurs, no more entries are evaluated. With a reflexive access list nested in an extended access list, the extended access list entries are evaluated sequentially up to the nested entry, then the reflexive access list entries are evaluated sequentially, and then the remaining entries in the extended access list are evaluated sequentially. As usual, after a packet matches *any* of these entries, no more entries will be evaluated.

If the extended named IP access list you just specified has never been applied to the interface, you must also apply the extended named IP access list to the interface.

To apply the extended named IP access list to the interface, use one of the following commands in interface configuration mode:

Command	Purpose
Router(config-if)# ip access-group <i>name</i> in	External interface: Applies the extended access list to the interface's inbound traffic.
OR	
Router(config-if)# ip access-group <i>name</i> out	Internal interface: Applies the extended access list to the interface's outbound traffic.

Setting a Global Timeout Value

Reflexive access list entries expire after no packets in the session have been detected for a certain length of time (the “timeout” period). You can specify the timeout for a particular reflexive access list when you define the reflexive access list. But if you do not specify the timeout for a given reflexive access list, the list will use the global timeout value instead.

The global timeout value is 300 seconds by default. But, you can change the global timeout to a different value at any time.

To change the global timeout value, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip reflexive-list timeout <i>seconds</i>	Changes the global timeout value for temporary reflexive access list entries. Use a positive integer from 0 to 2,147,483.

Reflexive Access List Configuration Examples

The following sections provide reflexive access list configuration examples:

- [External Interface Configuration Example](#)
- [Internal Interface Configuration Example](#)

External Interface Configuration Example

This example shows reflexive access lists configured for an external interface, for a topology similar to the one in [Figure 18](#) (shown earlier in this chapter).

This configuration example permits both inbound and outbound TCP traffic at interface Serial 1, but only if the first packet (in a given session) originated from inside your network. The interface Serial 1 connects to the Internet.

Define the interface where the session-filtering configuration is to be applied:

```
interface serial 1
description Access to the Internet via this interface
```

Apply access lists to the interface, for inbound traffic and for outbound traffic:

```
ip access-group inboundfilters in
ip access-group outboundfilters out
```

Define the outbound access list. This is the access list that evaluates all outbound traffic on interface Serial 1.

```
ip access-list extended outboundfilters
```

Define the reflexive access list *tcptraffic*. This entry permits *all* outbound TCP traffic and creates a new access list named *tcptraffic*. Also, when an outbound TCP packet is the first in a new session, a corresponding temporary entry will be automatically created in the reflexive access list *tcptraffic*.

```
permit tcp any any reflect tcptraffic
```

Define the inbound access list. This is the access list that evaluates all inbound traffic on interface Serial 1.

```
ip access-list extended inboundfilters
```

Define the inbound access list entries. This example shows Enhanced IGRP permitted on the interface. Also, no ICMP traffic is permitted. The last entry points to the reflexive access list. If a packet does not match the first two entries, the packet will be evaluated against all the entries in the reflexive access list *tcptraffic*.

```
permit eigrp any any
deny icmp any any
evaluate tcptraffic
```

Define the global idle timeout value for all reflexive access lists. In this example, when the reflexive access list *tcptraffic* was defined, no timeout was specified, so *tcptraffic* uses the global timeout. Therefore, if for 120 seconds there is no TCP traffic that is part of an established session, the corresponding reflexive access list entry will be removed.

```
ip reflexive-list timeout 120
```

The example configuration looks as follows:

```
interface Serial 1
description Access to the Internet via this interface
ip access-group inboundfilters in
ip access-group outboundfilters out
!
ip reflexive-list timeout 120
!
ip access-list extended outboundfilters
permit tcp any any reflect tcptraffic
!
ip access-list extended inboundfilters
permit eigrp any any
deny icmp any any
evaluate tcptraffic
```

With this configuration, before any TCP sessions have been initiated the **show access-list EXEC** command displays the following:

```
Extended IP access list inboundfilters
permit eigrp any any
deny icmp any any
evaluate tcptraffic
Extended IP access list outboundfilters
permit tcp any any reflect tcptraffic
```

Notice that the reflexive access list does not appear in this output. This is because before any TCP sessions have been initiated, no traffic has triggered the reflexive access list, and the list is empty (has no entries). When empty, reflexive access lists do not show up in **show access-list** output.

After a Telnet connection is initiated from within your network to a destination outside of your network, the **show access-list EXEC** command displays the following:

```
Extended IP access list inboundfilters
  permit eigrp any any
  deny icmp any any
  evaluate tcptraffic
Extended IP access list outboundfilters
  permit tcp any any reflect tcptraffic
Reflexive IP access list tcptraffic
  permit tcp host 172.19.99.67 eq telnet host 192.168.60.185 eq 11005 (5 matches) (time
left 115 seconds)
```

Notice that the reflexive access list *tcptraffic* now appears and displays the temporary entry generated when the Telnet session initiated with an outbound packet.

Internal Interface Configuration Example

This is an example configuration for reflexive access lists configured for an internal interface. This example has a topology similar to the one in [Figure 19](#) (shown earlier in this chapter).

This example is similar to the previous example; the only difference between this example and the previous example is that the entries for the outbound and inbound access lists are swapped. Please refer to the previous example for more details and descriptions.

```
interface Ethernet 0
  description Access from the I-net to our Internal Network via this interface
  ip access-group inboundfilters in
  ip access-group outboundfilters out
  !
ip reflexive-list timeout 120
!
ip access-list extended outboundfilters
  permit eigrp any any
  deny icmp any any
  evaluate tcptraffic
!
ip access-list extended inboundfilters
  permit tcp any any reflect tcptraffic
```

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Configuring TCP Intercept (Preventing Denial-of-Service Attacks)

Feature History

Release	Modification
Cisco IOS	For information about feature support in Cisco IOS software, use Cisco Feature Navigator.
Cisco IOS XE Release 2.1	This feature was introduced on Cisco ASR 1000 Series Routers.

This chapter describes how to configure your router to protect TCP servers from TCP SYN-flooding attacks, a type of denial-of-service attack. This is accomplished by configuring the Cisco IOS feature known as TCP Intercept.

For a complete description of TCP Intercept commands, refer to the “TCP Intercept Commands” chapter of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter “Identifying Supported Platforms” section in the “Using Cisco IOS Software.”

In This Chapter

This chapter has the following sections:

- [About TCP Intercept](#)
- [TCP Intercept Configuration Task List](#)
- [TCP Intercept Configuration Example](#)

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

About TCP Intercept

The TCP intercept feature implements software to protect TCP servers from TCP SYN-flooding attacks, which are a type of denial-of-service attack.

A SYN-flooding attack occurs when a hacker floods a server with a barrage of requests for connection. Because these messages have unreachable return addresses, the connections cannot be established. The resulting volume of unresolved open connections eventually overwhelms the server and can cause it to deny service to valid requests, thereby preventing legitimate users from connecting to a web site, accessing e-mail, using FTP service, and so on.

The TCP intercept feature helps prevent SYN-flooding attacks by intercepting and validating TCP connection requests. In intercept mode, the TCP intercept software intercepts TCP synchronization (SYN) packets from clients to servers that match an extended access list. The software establishes a connection with the client on behalf of the destination server, and if successful, establishes the connection with the server on behalf of the client and knits the two half-connections together transparently. Thus, connection attempts from unreachable hosts will never reach the server. The software continues to intercept and forward packets throughout the duration of the connection. The number of SYNs per second and the number of concurrent connections proxied depends on the platform, memory, processor, and other factors.

In the case of illegitimate requests, the software's aggressive timeouts on half-open connections and its thresholds on TCP connection requests protect destination servers while still allowing valid requests.

When establishing your security policy using TCP intercept, you can choose to intercept all requests or only those coming from specific networks or destined for specific servers. You can also configure the connection rate and threshold of outstanding connections.

You can choose to operate TCP intercept in watch mode, as opposed to intercept mode. In watch mode, the software passively watches the connection requests flowing through the router. If a connection fails to get established in a configurable interval, the software intervenes and terminates the connection attempt.

TCP options that are negotiated on handshake (such as RFC 1323 on window scaling) will not be negotiated because the TCP intercept software does not know what the server can do or will negotiate.

TCP Intercept Configuration Task List

To configure TCP intercept, perform the tasks in the following sections. The first task is required; the rest are optional.

- [Enabling TCP Intercept](#) (Required)
- [Setting the TCP Intercept Mode](#) (Optional)
- [Setting the TCP Intercept Drop Mode](#) (Optional)
- [Changing the TCP Intercept Timers](#) (Optional)
- [Changing the TCP Intercept Aggressive Thresholds](#) (Optional)
- [Monitoring and Maintaining TCP Intercept](#) (Optional)

For TCP intercept configuration examples using the commands in this chapter, refer to the “[TCP Intercept Configuration Example](#)” section at the end of this chapter.

Enabling TCP Intercept

To enable TCP intercept, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# access-list <i>access-list-number</i> { deny permit } tcp any <i>destination destination-wildcard</i>	Defines an IP extended access list.
Step 2	Router(config)# ip tcp intercept list <i>access-list-number</i>	Enables TCP intercept.

You can define an access list to intercept all requests or only those coming from specific networks or destined for specific servers. Typically the access list will define the source as **any** and define specific destination networks or servers. That is, you do not attempt to filter on the source addresses because you do not necessarily know who to intercept packets from. You identify the destination in order to protect destination servers.

If no access list match is found, the router allows the request to pass with no further action.

Setting the TCP Intercept Mode

The TCP intercept can operate in either active intercept mode or passive watch mode. The default is intercept mode.

In intercept mode, the software actively intercepts each incoming connection request (SYN) and responds on behalf of the server with an SYN-ACK, then waits for an ACK from the client. When that ACK is received, the original SYN is sent to the server and the software performs a three-way handshake with the server. When this is complete, the two half-connections are joined.

In watch mode, connection requests are allowed to pass through the router to the server but are watched until they become established. If they fail to become established within 30 seconds (configurable with the **ip tcp intercept watch-timeout** command), the software sends a Reset to the server to clear up its state.

To set the TCP intercept mode, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept mode { intercept watch }	Sets the TCP intercept mode.

Setting the TCP Intercept Drop Mode

When under attack, the TCP intercept feature becomes more aggressive in its protective behavior. If the number of incomplete connections exceeds 1100 or the number of connections arriving in the last one minute exceeds 1100, each new arriving connection causes the oldest partial connection to be deleted. Also, the initial retransmission timeout is reduced by half to 0.5 seconds (so the total time trying to establish a connection is cut in half).

By default, the software drops the oldest partial connection. Alternatively, you can configure the software to drop a random connection. To set the drop mode, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept drop-mode {oldest random}	Sets the drop mode.

Changing the TCP Intercept Timers

By default, the software waits for 30 seconds for a watched connection to reach established state before sending a Reset to the server. To change this value, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept watch-timeout <i>seconds</i>	Changes the time allowed to reach established state.

By default, the software waits for 5 seconds from receipt of a reset or FIN-exchange before it ceases to manage the connection. To change this value, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept finrst-timeout <i>seconds</i>	Changes the time between receipt of a reset or FIN-exchange and dropping the connection.

By default, the software still manages a connection for 24 hours after no activity. To change this value, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip tcp intercept connection-timeout <i>seconds</i>	Changes the time the software will manage a connection after no activity.

Changing the TCP Intercept Aggressive Thresholds

Two factors determine when aggressive behavior begins and ends: total incomplete connections and connection requests during the last one-minute sample period. Both thresholds have default values that can be redefined.

When a threshold is exceeded, the TCP intercept assumes the server is under attack and goes into aggressive mode. When in aggressive mode, the following occurs:

- Each new arriving connection causes the oldest partial connection to be deleted. (You can change to a random drop mode.)
- The initial retransmission timeout is reduced by half to 0.5 seconds, and so the total time trying to establish the connection is cut in half. (When not in aggressive mode, the code does exponential back-off on its retransmissions of SYN segments. The initial retransmission timeout is 1 second. The subsequent timeouts are 2 seconds, 4 seconds, 8 seconds, and 16 seconds. The code retransmits 4 times before giving up, so it gives up after 31 seconds of no acknowledgment.)
- If in watch mode, the watch timeout is reduced by half. (If the default is in place, the watch timeout becomes 15 seconds.)

The drop strategy can be changed from the oldest connection to a random connection with the **ip tcp intercept drop-mode** command.

**Note**

The two factors that determine aggressive behavior are related and work together. When *either* of the **high** values is exceeded, aggressive behavior begins. When *both* quantities fall below the **low** value, aggressive behavior ends.

You can change the threshold for triggering aggressive mode based on the total number of incomplete connections. The default values for **low** and **high** are 900 and 1100 incomplete connections, respectively. To change these values, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip tcp intercept max-incomplete low number	Sets the threshold for stopping aggressive mode.
Step 2	Router(config)# ip tcp intercept max-incomplete high number	Sets the threshold for triggering aggressive mode.

You can also change the threshold for triggering aggressive mode based on the number of connection requests received in the last 1-minute sample period. The default values for **low** and **high** are 900 and 1100 connection requests, respectively. To change these values, use the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# ip tcp intercept one-minute low number	Sets the threshold for stopping aggressive mode.
Step 2	Router(config)# ip tcp intercept one-minute high number	Sets the threshold for triggering aggressive mode.

Monitoring and Maintaining TCP Intercept

To display TCP intercept information, use either of the following commands in EXEC mode:

Command	Purpose
Router# show tcp intercept connections	Displays incomplete connections and established connections.
Router# show tcp intercept statistics	Displays TCP intercept statistics.

TCP Intercept Configuration Example

The following configuration defines extended IP access list 101, causing the software to intercept packets for all TCP servers on the 192.168.1.0/24 subnet:

```
ip tcp intercept list 101
!
access-list 101 permit tcp any 192.168.1.0 0.0.0.255
```

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. Any use of actual IP addresses in illustrative content is unintentional and coincidental.

Context-Based Access Control

Configuring Context-Based Access Control

This chapter describes how to configure Context-based Access Control (CBAC). CBAC provides advanced traffic filtering functionality and can be used as an integral part of your network's firewall. For more information regarding firewalls, refer to the chapter "Cisco IOS Firewall Overview."

For a complete description of the CBAC commands used in this chapter, refer to the "Context-Based Access Control Commands" chapter in the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the chapter "Identifying Supported Platforms" section in the "Using Cisco IOS Software."

In This Chapter

This chapter has the following sections:

- [About Context-Based Access Control](#)
- [CBAC Configuration Task List](#)
- [Monitoring and Maintaining CBAC](#)
- [CBAC Configuration Examples](#)

About Context-Based Access Control

This section describes CBAC features and functions:

- [What CBAC Does](#)
- [What CBAC Does Not Do](#)
- [How CBAC Works](#)
- [When and Where to Configure CBAC](#)
- [The CBAC Process](#)

- [Supported Protocols](#)
- [Restrictions](#)
- [Memory and Performance Impact](#)

What CBAC Does

CBAC works to provide network protection on multiple levels using the following functions:

- [Traffic Filtering](#)
- [Traffic Inspection](#)
- [Alerts and Audit Trails](#)
- [Intrusion Prevention](#)

Traffic Filtering

CBAC intelligently filters TCP and UDP packets based on application-layer protocol session information. You can configure CBAC to permit specified TCP and UDP traffic through a firewall only when the connection is initiated from within the network you want to protect. CBAC can inspect traffic for sessions that originate from either side of the firewall, and CBAC can be used for intranet, extranet, and Internet perimeters of your network.

Without CBAC, traffic filtering is limited to access list implementations that examine packets at the network layer, or at most, the transport layer. However, CBAC examines not only network layer and transport layer information but also examines the application-layer protocol information (such as FTP connection information) to learn about the state of the session. This allows support of protocols that involve multiple channels created as a result of negotiations in the control channel. Most of the multimedia protocols as well as some other protocols (such as FTP, RPC, and SQL*Net) involve multiple channels.

Using CBAC, Java blocking can be configured to filter HTTP traffic based on the server address or to completely deny access to Java applets that are not embedded in an archived or compressed file. With Java, you must protect against the risk of users inadvertently downloading destructive applets into your network. To protect against this risk, you could require all users to disable Java in their browser. If this is not an acceptable solution, you can create a CBAC inspection rule to filter Java applets at the firewall, which allows users to download only applets residing within the firewall and trusted applets from outside the firewall. For extensive content filtering of Java, Active-X, or virus scanning, you might want to consider purchasing a dedicated content filtering product.

Traffic Inspection

CBAC inspects traffic that travels through the firewall to discover and manage state information for TCP and UDP sessions. This state information is used to create temporary openings in the firewall's access lists to allow return traffic and additional data connections for permissible sessions.

Inspecting packets at the application layer, and maintaining TCP and UDP session information, provides CBAC with the ability to detect and prevent certain types of network attacks such as SYN-flooding. A SYN-flood attack occurs when a network attacker floods a server with a barrage of requests for connection and does not complete the connection. The resulting volume of half-open connections can overwhelm the server, causing it to deny service to valid requests. Network attacks that deny access to a network device are called denial-of-service (DoS) attacks.

CBAC helps to protect against DoS attacks in other ways. CBAC inspects packet sequence numbers in TCP connections to see if they are within expected ranges—CBAC drops any suspicious packets. You can also configure CBAC to drop half-open connections, which require firewall processing and memory resources to maintain. Additionally, CBAC can detect unusually high rates of new connections and issue alert messages.

CBAC can help by protecting against certain DoS attacks involving fragmented IP packets. Even though the firewall prevents an attacker from making actual connections to a given host, the attacker can disrupt services provided by that host. This is done by sending many non-initial IP fragments or by sending complete fragmented packets through a router with an ACL that filters the first fragment of a fragmented packet. These fragments can tie up resources on the target host as it tries to reassemble the incomplete packets.

Alerts and Audit Trails

CBAC also generates real-time alerts and audit trails. Enhanced audit trail features use SYSLOG to track all network transactions; recording time stamps, source host, destination host, ports used, and the total number of transmitted bytes, for advanced, session-based reporting. Real-time alerts send SYSLOG error messages to central management consoles upon detecting suspicious activity. Using CBAC inspection rules, you can configure alerts and audit trail information on a per-application protocol basis. For example, if you want to generate audit trail information for HTTP traffic, you can specify that in the CBAC rule covering HTTP inspection.

Intrusion Prevention

CBAC provides a limited amount of intrusion detection to protect against specific SMTP attacks. With intrusion detection, SYSLOG messages are reviewed and monitored for specific “attack signatures.” Certain types of network attacks have specific characteristics, or signatures. When CBAC detects an attacks, it resets the offending connections and sends SYSLOG information to the SYSLOG server. Refer to the section [“Interpreting Syslog and Console Messages Generated by CBAC”](#) later in this chapter for a list of supported signatures.

In addition to the limited intrusion detection offered by CBAC, the Cisco IOS Firewall feature set offers intrusion detection technology for mid-range and high-end router platforms using the Cisco IOS Intrusion Prevention System (IPS). Cisco IOS IPS restructures and replaces the existing Cisco IOS Intrusion Detection System (IDS). It is ideal for any network perimeter, and especially for locations in which a router is being deployed and additional security between network segments is required. It also can protect intranet and extranet connections where additional security is mandated, and branch-office sites connecting to the corporate office or Internet.

The Cisco IOS IPS acts as an in-line intrusion detection sensor, watching packets and sessions as they flow through the router and scanning each packet to match any of the Cisco IOS IPS signatures. When Cisco IOS IPS detects suspicious activity, it responds before network security can be compromised and logs the event through Cisco IOS syslog messages or Security Device Event Exchange (SDEE).

For more information about Cisco IOS IPS, refer to the module “Configuring Cisco IOS Intrusion Prevention System (IPS).”

What CBAC Does Not Do

CBAC does not provide intelligent filtering for all protocols; it only works for the protocols that you specify. If you do not specify a certain protocol for CBAC, the existing access lists will determine how that protocol is filtered. No temporary openings will be created for protocols not specified for CBAC inspection.

CBAC does not protect against attacks originating from within the protected network unless that traffic travels through a router that has the Cisco IOS Firewall feature set deployed on it. CBAC only detects and protects against attacks that travel through the firewall. This is a scenario in which you might want to deploy CBAC on an intranet-based router.

CBAC protects against certain types of attacks, but not every type of attack. CBAC should not be considered a perfect, impenetrable defense. Determined, skilled attackers might be able to launch effective attacks. While there is no such thing as a perfect defense, CBAC detects and prevents most of the popular attacks on your network.

How CBAC Works

You should understand the material in this section before you configure CBAC. If you do not understand how CBAC works, you might inadvertently introduce security risks by configuring CBAC inappropriately. This section contains the following sections:

- [How CBAC Works—Overview](#)
- [How CBAC Works—Details](#)

How CBAC Works—Overview

CBAC creates temporary openings in access lists at firewall interfaces. These openings are created when specified traffic exits your internal network through the firewall. The openings allow returning traffic (that would normally be blocked) and additional data channels to enter your internal network back through the firewall. The traffic is allowed back through the firewall only if it is part of the same session as the original traffic that triggered CBAC when exiting through the firewall.

Throughout this chapter, the terms “inbound” and “outbound” are used to describe the direction of traffic relative to the router interface on which CBAC is applied. For example, if a CBAC rule is applied inbound on interface E0, then packets entering interface E0 from the network will be inspected. If a CBAC rule is applied outbound on interface E0, then packets leaving interface E0 to the network will be inspected. This is similar to the way ACLs work.

For example, consider a CBAC inspection rule named *hqusers*, and suppose that rule is applied inbound at interface E0:

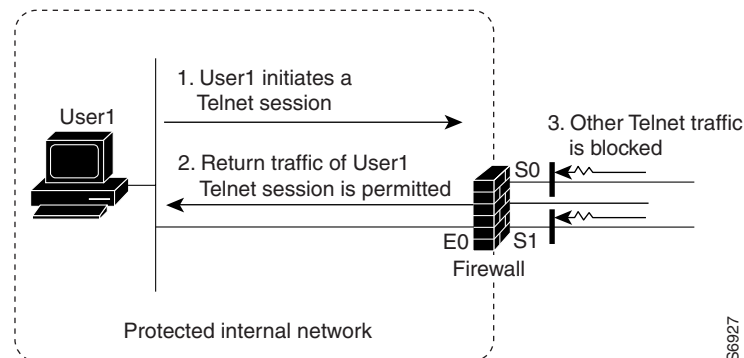

```
router (config-if)# ip inspect hqusers in
```

This command causes CBAC to inspect the packets coming into this interface from the network. If a packet is attempting to initiate a session, CBAC will then determine if this protocol is allowed, create a CBAC session, add the appropriate ACLs to allow return traffic and do any needed content inspection on any future packets for this session.

The terms “input” and “output” are used to describe the interfaces at which network traffic enters or exits the firewall router. A packet enters the firewall router via the input interface, is inspected by the firewall software and then exits the router via the output interface.

In [Figure 20](#), the inbound access lists at S0 and S1 are configured to block Telnet traffic, and there is no outbound access list configured at E0. When the connection request for User1's Telnet session passes through the firewall, CBAC creates a temporary opening in the inbound access list at S0 to permit returning Telnet traffic for User1's Telnet session. (If the same access list is applied to both S0 and S1, the same opening would appear at both interfaces.) If necessary, CBAC would also have created a similar opening in an outbound access list at E0 to permit return traffic.

Figure 20 *CBAC Opens Temporary Holes in Firewall Access Lists*

How CBAC Works—Details

This section describes how CBAC inspects packets and maintains state information about sessions to provide intelligent filtering.

Packets Are Inspected

With CBAC, you specify which protocols you want to be inspected, and you specify an interface and interface direction (in or out) where inspection originates. Only specified protocols will be inspected by CBAC.

Packets entering the firewall are inspected by CBAC only if they first pass the inbound access list at the input interface and outbound access list at the output interface. If a packet is denied by the access list, the packet is simply dropped and not inspected by CBAC.

CBAC inspection tracks sequence numbers in all TCP packets, and drops those packets with sequence numbers that are not within expected ranges.

CBAC inspection recognizes application-specific commands (such as illegal SMTP commands) in the control channel, and detects and prevents certain application-level attacks.

When CBAC suspects an attack, the DoS feature can take several actions:

- Generate alert messages
- Protect system resources that could impede performance
- Block packets from suspected attackers

CBAC uses timeout and threshold values to manage session state information, helping to determine when to drop sessions that do not become fully established. Setting timeout values for network sessions helps prevent DoS attacks by freeing up system resources, dropping sessions after a specified amount of time. Setting threshold values for network sessions helps prevent DoS attacks by controlling the number of half-open sessions, which limits the amount of system resources applied to half-open sessions. When a

session is dropped, CBAC sends a reset message to the devices at both end points (source and destination) of the session. When the system under DoS attack receives a reset command, it releases, or frees up, processes and resources related to that incomplete session.

CBAC provides three thresholds against DoS attacks:

- The total number of half-open TCP or UDP sessions
- The number of half-open sessions based upon time
- The number of half-open TCP-only sessions per host

If a threshold is exceeded, CBAC has two options:

- Send a reset message to the end points of the oldest half-open session, making resources available to service newly arriving SYN packets.
- In the case of half open TCP only sessions, CBAC blocks all SYN packets temporarily for the duration configured by the threshold value. When the router blocks a SYN packet, the TCP three-way handshake is never initiated, which prevents the router from using memory and processing resources needed for valid connections.

DoS detection and prevention requires that you create a CBAC inspection rule and apply that rule on an interface. The inspection rule must include the protocols that you want to monitor against DoS attacks. For example, if you have TCP inspection enabled on the inspection rule, then CBAC can track all TCP connections to watch for DoS attacks. If the inspection rule includes FTP protocol inspection but not TCP inspection, CBAC tracks only FTP connections for DoS attacks.

For detailed information about setting timeout and threshold values in CBAC to detect and prevent DoS attacks, refer in the [“Configuring Global Timeouts and Thresholds”](#) section.

A State Table Maintains Session State Information

Whenever a packet is inspected, a state table is updated to include information about the state of the session.

Return traffic will only be permitted back through the firewall if the state table contains information indicating that the packet belongs to a permissible session. CBAC controls the traffic that belongs to a valid session. When return traffic is inspected, the state table information is updated as necessary.

UDP “Sessions” Are Approximated

With UDP—a connectionless service—there are no actual sessions, so the software approximates sessions by examining the information in the packet and determining if the packet is similar to other UDP packets (for example, same source/destination addresses and port numbers) and if the packet was detected soon after another similar UDP packet. “Soon” means within the configurable UDP idle timeout period.

Access List Entries Are Dynamically Created and Deleted to Permit Return Traffic and Additional Data Connections

CBAC dynamically creates and deletes access list entries at the firewall interfaces, according to the information maintained in the state tables. These access list entries are applied to the interfaces to examine traffic flowing back into the internal network. These entries create temporary openings in the firewall to permit only traffic that is part of a permissible session.

The temporary access list entries are never saved to NVRAM.

When and Where to Configure CBAC

Configure CBAC at firewalls protecting internal networks. Such firewalls should be Cisco routers with the Cisco IOS Firewall feature set configured as described previously in the section “Cisco IOS Firewall.”

Use CBAC when the firewall will be passing traffic such as the following:

- Standard TCP and UDP Internet applications
- Multimedia applications
- Oracle support

Use CBAC for these applications if you want the application’s traffic to be permitted through the firewall only when the traffic session is initiated from a particular side of the firewall (usually from the protected internal network).

In many cases, you will configure CBAC in one direction only at a single interface, which causes traffic to be permitted back into the internal network only if the traffic is part of a permissible (valid, existing) session. This is a typical configuration for protecting your internal networks from traffic that originates on the Internet.

You can also configure CBAC in two directions at one or more interfaces. CBAC is configured in two directions when the networks on both sides of the firewall should be protected, such as with extranet or intranet configurations, and to protect against DoS attacks. For example, if the firewall is situated between two partner companies’ networks, you might wish to restrict traffic in one direction for certain applications, and restrict traffic in the opposite direction for other applications.

The CBAC Process

This section describes a sample sequence of events that occurs when CBAC is configured at an external interface that connects to an external network such as the Internet.

In this example, a TCP packet exits the internal network through the firewall’s external interface. The TCP packet is the first packet of a Telnet session, and TCP is configured for CBAC inspection.

1. The packet reaches the firewall’s external interface.
2. The packet is evaluated against the interface’s existing outbound access list, and the packet is permitted. (A denied packet would simply be dropped at this point.)
3. The packet is inspected by CBAC to determine and record information about the state of the packet’s connection. This information is recorded in a new state table entry created for the new connection.

(If the packet’s application—Telnet—was not configured for CBAC inspection, the packet would simply be forwarded out the interface at this point without being inspected by CBAC. See the section “[Defining an Inspection Rule](#)” later in this chapter for information about configuring CBAC inspection.)

4. Based on the obtained state information, CBAC creates a temporary access list entry which is inserted at the beginning of the external interface’s inbound extended access list. This temporary access list entry is designed to permit inbound packets that are part of the same connection as the outbound packet just inspected.
5. The outbound packet is forwarded out the interface.
6. Later, an inbound packet reaches the interface. This packet is part of the same Telnet connection previously established with the outbound packet. The inbound packet is evaluated against the inbound access list, and it is permitted because of the temporary access list entry previously created.

7. The permitted inbound packet is inspected by CBAC, and the connection's state table entry is updated as necessary. Based on the updated state information, the inbound extended access list temporary entries might be modified in order to permit only packets that are valid for the current state of the connection.
8. Any additional inbound or outbound packets that belong to the connection are inspected to update the state table entry and to modify the temporary inbound access list entries as required, and they are forwarded through the interface.
9. When the connection terminates or times out, the connection's state table entry is deleted, and the connection's temporary inbound access list entries are deleted.

In the sample process just described, the firewall access lists are configured as follows:

- An outbound IP access list (standard or extended) is applied to the external interface. This access list permits all packets that you want to allow to exit the network, including packets you want to be inspected by CBAC. In this case, Telnet packets are permitted.
- An inbound extended IP access list is applied to the external interface. This access list denies any traffic to be inspected by CBAC—including Telnet packets. When CBAC is triggered with an outbound packet, CBAC creates a temporary opening in the inbound access list to permit only traffic that is part of a valid, existing session.

If the inbound access list had been configured to permit *all* traffic, CBAC would be creating pointless openings in the firewall for packets that would be permitted anyway.

Supported Protocols

This section provides a list of CBAC supported protocols and includes a more detailed look at support for multimedia applications, specifically RTSP and H.323.

CBAC Supported Protocols

You can configure CBAC to inspect the following types of sessions:

- All TCP sessions, regardless of the application-layer protocol (sometimes called “single-channel” or “generic” TCP inspection)
- All UDP sessions, regardless of the application-layer protocol (sometimes called “single-channel” or “generic” UDP inspection)

You can also configure CBAC to specifically inspect certain application-layer protocols. The following application-layer protocols can all be configured for CBAC:

- CU-SeeMe (only the White Pine version)
- FTP
- H.323 (such as NetMeeting, ProShare)
- HTTP (Java blocking)
- Microsoft NetShow
- UNIX R-commands (such as rlogin, rexec, and rsh)
- RealAudio
- RTSP (Real Time Streaming Protocol)
- RPC (Sun RPC, not DCE RPC)

- SMTP (Simple Mail Transport Protocol)

**Note**

CBAC can be configured to inspect SMTP but not ESMTP (Extended Simple Mail Transport Protocol). SMTP is described in RFC 821. CBAC SMTP inspect does not inspect the ESMTP session or command sequence. Configuring SMTP inspection is not useful for ESMTP, and it can cause problems.

To determine whether a mail-server is doing SMTP or ESMTP, contact your mail-server software vendor, or telnet to the mail-server port 25 and observe the banner to see if it reports SMTP or ESMTP.

- SQL*Net
- StreamWorks
- TFTP
- VDOLive

When a protocol is configured for CBAC, that protocol traffic is inspected, state information is maintained, and in general, packets are allowed back through the firewall only if they belong to a permissible session.

RTSP and H.323 Protocol Support for Multimedia Applications

CBAC supports a number of protocols for multimedia applications that require delivery of data with real-time properties such as audio and video conferencing. This support includes the following multimedia application protocols:

- Real Time Streaming Protocol (RTSP)
- H.323 Version 2 (H.323 V2)

RTSP and H.323 V2 inspection allows clients on a protected network to receive data associated with a multimedia session from a server on an unprotected network.

RTSP Support

RTSP is the IETF standards-based protocol (RFC 2326) for control over the delivery of data with real-time properties such as audio and video streams. It is useful for large-scale broadcasts and audio or video on demand streaming, and is supported by a variety of vendor products of streaming audio and video multimedia, including Cisco IP/TV, RealNetworks RealAudio G2 Player, and Apple QuickTime 4 software.

RFC 2326 allows RTSP to run over either UDP or TCP, though CBAC currently supports only TCP-based RTSP. RTSP establishes a TCP-based control connection, or channel, between the multimedia client and server. RTSP uses this channel to control commands such as “play” and “pause” between the client and server. These control commands and responses are text-based and are similar to HTTP.

RTSP typically relies on a UDP-based data transport protocol such as standard Real-Time Transport Protocol (RTP) to open separate channels for data and for RTP Control Protocol (RTCP) messages. RTP and RTCP channels occur in pairs, with RTP being an even numbered port and RTCP being the next consecutive port. Understanding the relationship of RTP and RTCP is important for verifying session information using CBAC **show** commands.

The RTSP client uses TCP port 554 or 8554 to open a multimedia connection with a server. The data channel or data control channel (using RTCP) between the client and the server is dynamically negotiated between the client and the server using any of the high UDP ports (1024 to 65536).

CBAC uses this port information along with connection information from the client to create dynamic access control list (ACL) entries in the firewall. As TCP or UDP connections are terminated, CBAC removes these dynamic entries from the appropriate ACLs.

CBAC support for RTSP includes the following data transport modes:

- **Standard Real-Time Transport Protocol (RTP)**
RTP is an IETF standard (RFC 1889) supporting delivery of real-time data such as audio and video. RTP uses the RTP Control Protocol (RTCP) for managing the delivery of the multimedia data stream. This is the normal mode of operation for Cisco IP/TV and Apple QuickTime 4 software.
- **RealNetworks Real Data Transport (RDT)**
RDT is a proprietary protocol developed by RealNetworks for data transport. This mode uses RTSP for communication control and uses RDT for the data connection and retransmission of lost packets. This is the normal mode of operation for the RealServer G2 from RealNetworks.
- **Interleaved (Tunnel Mode)**
In this mode, RTSP uses the control channel to tunnel RTP or RDT traffic.
- **Synchronized Multimedia Integration Language (SMIL)**
SMIL is a layout language that enables the creation of multimedia presentations consisting of multiple elements of music, voice, images, text, video and graphics. This involves multiple RTSP control and data streams between the player and the servers. This mode is available only using RTSP and RDT. SMIL is a proposed specification of the World Wide Web Consortium (W3C). The RealNetworks RealServer and RealServer G2 provide support for SMIL—Cisco IP/TV and Apple QuickTime 4 do not.

H.323 Support

CBAC support for H.323 inspection includes H.323 Version 2 and H.323 Version 1. H.323 V2 provides additional options over H.323 V1, including a “fast start” option. The fast start option minimizes the delay between the time that a user initiates a connection and the time that the user gets the data (voice, video). H.323 V2 inspection is backward compatible with H.323 V1.

With H.323 V1, after a TCP connection is established between the client and server (H.225 Channel), a separate channel for media control (H.245 Channel) is opened through which multimedia channels for audit and video are further negotiated.

The H.323 V2 client opens a connection to server which is listening on port 1720. The data channel between the client and the server is dynamically negotiated using any of the high UDP ports (1024 to 65536).

CBAC uses this port information along with connection information from the client to create dynamic access control list (ACL) entries in the firewall. As TCP or UDP connections are terminated, CBAC removes these dynamic entries from the appropriate ACLs.

Restrictions

CBAC has the following restrictions:

- CBAC is available only for IP protocol traffic. Only TCP and UDP packets are inspected. (Other IP traffic, such as ICMP, cannot be inspected with CBAC and should be filtered with basic access lists instead.)
- If you reconfigure your access lists when you configure CBAC, be aware that if your access lists block TFTP traffic into an interface, you will not be able to netboot over that interface. (This is not a CBAC-specific limitation, but is part of existing access list functionality.)
- Packets with the firewall as the source or destination address are not inspected by CBAC.
- CBAC ignores ICMP Unreachable messages.
- H.323 V2 and RTSP protocol inspection supports only the following multimedia client-server applications: Cisco IP/TV, RealNetworks RealAudio G2 Player, Apple QuickTime 4.

You can use CBAC together with all the other firewall features mentioned previously in the “Cisco IOS Firewall Overview” chapter.

CBAC works with fast switching and process switching.

This section also discusses restrictions concerning:

- [FTP Traffic and CBAC](#)
- [IPSec and CBAC Compatibility](#)

FTP Traffic and CBAC

- With FTP, CBAC does not allow third-party connections (three-way FTP transfer).
- When CBAC inspects FTP traffic, it only allows data channels with the destination port in the range of 1024 to 65535.
- CBAC will not open a data channel if the FTP client-server authentication fails.

IPSec and CBAC Compatibility

When CBAC and IPSec are enabled on the same router, and the firewall router is an endpoint for IPSec for the particular flow, then IPSec is compatible with CBAC (that is, CBAC can do its normal inspection processing on the flow).

If the router is not an IPSec endpoint, but the packet is an IPSec packet, then CBAC will not inspect the packets because the protocol number in the IP header of the IPSec packet is not TCP or UDP. CBAC only inspects UDP and TCP packets.

Memory and Performance Impact

CBAC uses less than approximately 600 bytes of memory per connection. Because of the memory usage, you should use CBAC only when you need to. There is also a slight amount of additional processing that occurs whenever packets are inspected.

Sometimes CBAC must evaluate long access lists, which might have presented a negative impact to performance. However, this impact is avoided, because CBAC evaluates access lists using an accelerated method (CBAC hashes access lists and evaluates the hash).

CBAC Configuration Task List

To configure CBAC, perform the tasks described in the following sections. The tasks in the first seven sections are required; the task of verifying the CBAC configuration is optional.

- [Picking an Interface: Internal or External](#) (Required)
- [Configuring IP Access Lists at the Interface](#) (Required)
- [Configuring Global Timeouts and Thresholds](#) (Required)
- [Defining an Inspection Rule](#) (Required)
- [Applying the Inspection Rule to an Interface](#) (Required)
- [Configuring Logging and Audit Trail](#) (Required)
- [Other Guidelines for Configuring a Firewall](#) (Required)
- [Verifying CBAC](#) (Optional)

Following CBAC configuration, you can monitor and maintain CBAC using the information in this section.

**Note**

If you try to configure Context-based Access Control (CBAC) but do not have a good understanding of how CBAC works, you might inadvertently introduce security risks to the firewall and to the protected network. You should be sure you understand what CBAC does before you configure CBAC.

**Note**

As with all networking devices, protect access into the firewall by configuring passwords as described in the “Configuring Passwords and Privileges” chapter. You should also consider configuring user authentication, authorization, and accounting as described in the “Authentication, Authorization, and Accounting (AAA)” part of this guide. Additional guidelines to help you establish a good security policy can be found in the “Cisco IOS Firewall Overview” chapter.

For CBAC configuration examples, refer to the “[CBAC Configuration Examples](#)” section at the end of this chapter.

Picking an Interface: Internal or External

You must decide whether to configure CBAC on an internal or external interface of your firewall.

“Internal” refers to the side where sessions must originate for their traffic to be permitted through the firewall. “External” refers to the side where sessions cannot originate (sessions originating from the external side will be blocked).

If you will be configuring CBAC in two directions, you should configure CBAC in one direction first, using the appropriate “internal” and “external” interface designations. When you configure CBAC in the other direction, the interface designations will be swapped. (CBAC can be configured in two directions at one or more interfaces. Configure CBAC in two directions when the networks on both sides of the firewall require protection, such as with extranet or intranet configurations, and for protection against DoS attacks.)

The firewall is most commonly used with one of two basic network topologies. Determining which of these topologies is most like your own can help you decide whether to configure CBAC on an internal interface or on an external interface.

The first topology is shown in [Figure 21](#). In this simple topology, CBAC is configured for the *external* interface Serial 1. This prevents specified protocol traffic from entering the firewall and the internal network, unless the traffic is part of a session initiated from within the internal network.

Figure 21 Simple Topology—CBAC Configured at the External Interface

The second topology is shown in [Figure 22](#). In this topology, CBAC is configured for the *internal* interface Ethernet 0. This allows external traffic to access the services in the Demilitarized Zone (DMZ), such as DNS services, but prevents specified protocol traffic from entering your internal network—unless the traffic is part of a session initiated from within the internal network.

Figure 22 DMZ Topology—CBAC Configured at the Internal Interface

Using these two sample topologies, decide whether to configure CBAC on an internal or external interface.

To view various firewall configuration scenarios, see the [“CBAC Configuration Examples”](#) section at the end of this chapter.

Configuring IP Access Lists at the Interface

For CBAC to work properly, you need to make sure that you have IP access lists configured appropriately at the interface.

Follow these three general rules when evaluating your IP access lists at the firewall:

- Start with a basic configuration.

If you try to configure access lists without a good understanding of how access lists work, you might inadvertently introduce security risks to the firewall and to the protected network. You should be sure you understand what access lists do before you configure your firewall. For more information about access control lists, refer to the “Access Control Lists: Overview and Guidelines” chapter.

A basic initial configuration allows all network traffic to flow from the protected networks to the unprotected networks, while blocking network traffic from any unprotected networks.

- Permit CBAC traffic to leave the network through the firewall.

All access lists that evaluate traffic leaving the protected network should permit traffic that will be inspected by CBAC. For example, if Telnet will be inspected by CBAC, then Telnet traffic should be permitted on all access lists that apply to traffic leaving the network.

- Use extended access lists to deny CBAC return traffic entering the network through the firewall.

For temporary openings to be created in an access list, the access list must be an extended access list. So wherever you have access lists that will be applied to returning traffic, you must use extended access lists. The access lists should deny CBAC return traffic because CBAC will open up temporary holes in the access lists. (You want traffic to be normally blocked when it enters your network.)

Note

If your firewall only has two connections, one to the internal network and one to the external network, using all inbound access lists works well because packets are stopped before they get a chance to affect the router itself.

This section contains the following sections:

- [Basic Configuration](#)
- [External Interface](#)
- [Internal Interface](#)

Basic Configuration

The first time you configure the Cisco IOS Firewall, it is helpful to start with a basic access list configuration that makes the operation of the firewall easy to understand without compromising security. The basic configuration allows all network traffic from the protected networks access to the unprotected networks, while blocking all network traffic (with some exceptions) from the unprotected networks to the protected networks.

Any firewall configuration depends on your site security policy. If the basic configuration does not meet your initial site security requirements, configure the firewall to meet your policy. If you are unfamiliar with that policy or need help with the configuration, contact your network administration group for assistance. For additional guidelines on configuring a firewall, refer to the “[Other Guidelines for Configuring a Firewall](#)” section in this chapter.

Use the following guidelines for configuring the initial firewall access lists:

- Do not configure an access list for traffic from the protected networks to the unprotected networks, meaning that all traffic from the protected networks can flow through the interface.

This helps to simplify firewall management by reducing the number of access lists applied at the interfaces. Of course this assumes a high level of trust for the users on the protected networks, and it assumes there are no malicious users on the protected networks who might launch attacks from the “inside.” You can fine tune network access for users on the protected networks as you gain experience with access list configuration and the operation of the firewall.

- Configure an access list that includes entries permitting certain ICMP traffic from unprotected networks.

While an access list that denies all IP traffic not part of a connection inspected by CBAC seems most secure, it is not practical for normal operation of the router. The router expects to see ICMP traffic from other routers in the network. Additionally, ICMP traffic is not inspected by CBAC, meaning specific entries are needed in the access list to permit return traffic for ICMP commands. For example, a user on a protected network uses the **ping** command to get the status of a host on an unprotected network; without entries in the access list that permit **echo reply** messages, the user on the protected network gets no response to the **ping** command.

Include access list entries to permit the following ICMP messages:

Message	Description
echo reply	Outgoing ping commands require echo-reply messages to come back.
time-exceeded	Outgoing traceroute commands require time-exceeded messages to come back.
packet-too-big	Path MTU discovery requires “too-big” messages to come back.
traceroute	Allow an incoming traceroute.
unreachable	Permit all “unreachable” messages to come back. If a router cannot forward or deliver a datagram, it sends an ICMP unreachable message back to the source and drops the datagram.

- Add an access list entry denying any network traffic from a source address matching an address on the protected network.

This is known as anti-spoofing protection because it prevents traffic from an unprotected network from assuming the identity of a device on the protected network.

- Add an entry denying broadcast messages with a source address of 255.255.255.255.

This entry helps to prevent broadcast attacks.

- By default, the last entry in an extended access list is an implicit denial of all IP traffic not specifically allowed by other entries in the access list.

Although this is the default setting, this final deny statement is not shown by default in an access list. Optionally, you can add an entry to the access list denying IP traffic with any source or destination address with no undesired effects.

For complete information about how to configure IP access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Addressing Services Configuration Guide*.

For tips on applying access lists at an external or internal interface, review the sections “[External Interface](#)” and “[Internal Interface](#)” in this chapter.

External Interface

Here are some guidelines for your access lists when you will be configuring CBAC on an external interface:

- If you have an outbound IP access list at the external interface, the access list can be a standard or extended access list. This outbound access list should permit traffic that you want to be inspected by CBAC. If traffic is not permitted, it will not be inspected by CBAC, but will be simply dropped.

- The inbound IP access list at the external interface must be an extended access list. This inbound access list should deny traffic that you want to be inspected by CBAC. (CBAC will create temporary openings in this inbound access list as appropriate to permit only return traffic that is part of a valid, existing session.)
- For complete information about how to configure IP access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Addressing Services Configuration Guide*.

Internal Interface

Here are some tips for your access lists when you will be configuring CBAC on an internal interface:

- If you have an inbound IP access list at the internal interface or an outbound IP access list at external interface(s), these access lists can be either a standard or extended access list. These access lists should permit traffic that you want to be inspected by CBAC. If traffic is not permitted, it will not be inspected by CBAC, but will be simply dropped.
- The outbound IP access list at the internal interface and the inbound IP access list at the external interface must be extended access lists. These outbound access lists should deny traffic that you want to be inspected by CBAC. (CBAC will create temporary openings in these outbound access lists as appropriate to permit only return traffic that is part of a valid, existing session.) You do not necessarily need to configure an extended access list at both the outbound internal interface and the inbound external interface, but at least one is necessary to restrict traffic flowing through the firewall into the internal protected network.
- For complete information about how to configure IP access lists, refer to the “Configuring IP Services” chapter of the *Cisco IOS IP Addressing Services Configuration Guide*.

Configuring Global Timeouts and Thresholds

CBAC uses timeouts and thresholds to determine how long to manage state information for a session, and to determine when to drop sessions that do not become fully established. These timeouts and thresholds apply globally to all sessions.

You can use the default timeout and threshold values, or you can change to values more suitable to your security requirements. You should make any changes to the timeout and threshold values before you continue configuring CBAC.

Note

If you want to enable the more aggressive TCP host-specific denial-of-service prevention that includes the blocking of connection initiation to a host, you must set the **block-time** specified in the **ip inspect tcp max-incomplete host** command (see the last row in [Table 24](#)).

All the available CBAC timeouts and thresholds are listed in [Table 24](#), along with the corresponding command and default value. To change a global timeout or threshold listed in the “Timeout or Threshold Value to Change” column, use the global configuration command in the “Command” column:

Table 24 **Timeout and Threshold Values**

Timeout or Threshold Value to Change	Command	Default
The length of time the software waits for a TCP session to reach the established state before dropping the session.	ip inspect tcp synwait-time <i>seconds</i>	30 seconds
The length of time a TCP session will still be managed after the firewall detects a FIN-exchange.	ip inspect tcp finwait-time <i>seconds</i>	5 seconds
The length of time a TCP session will still be managed after no activity (the TCP idle timeout). ¹	ip inspect tcp idle-time <i>seconds</i>	3600 seconds (1 hour)
The length of time a UDP session will still be managed after no activity (the UDP idle timeout). ¹	ip inspect udp idle-time <i>seconds</i>	30 seconds
The length of time a DNS name lookup session will still be managed after no activity.	ip inspect dns-timeout <i>seconds</i>	5 seconds
The number of existing half-open sessions that will cause the software to start deleting half-open sessions. ²	ip inspect max-incomplete high <i>number</i>	500 existing half-open sessions
The number of existing half-open sessions that will cause the software to stop deleting half-open sessions. ²	ip inspect max-incomplete low <i>number</i>	400 existing half-open sessions
The rate of new sessions that will cause the software to start deleting half-open sessions. ²	ip inspect one-minute high <i>number</i>	500 half-open sessions per minute
The rate of new sessions that will cause the software to stop deleting half-open sessions. ²	ip inspect one-minute low <i>number</i>	400 half-open sessions per minute
The number of existing half-open TCP sessions with the same destination host address that will cause the software to start dropping half-open sessions to the same destination host address. ³	ip inspect tcp max-incomplete host <i>number</i> block-time <i>minutes</i>	50 existing half-open TCP sessions; 0 minutes

1. The global TCP and UDP idle timeouts can be overridden for specified application-layer protocols' sessions as described in the **ip inspect name** (global configuration) command description, found in the "Context-Based Access Control Commands" chapter of the *Cisco IOS Security Command Reference*.
2. See the following section, "Half-Open Sessions," for more information.
3. Whenever the **max-incomplete host** threshold is exceeded, the software will drop half-open sessions differently depending on whether the **block-time** timeout is zero or a positive non-zero number. If the **block-time** timeout is zero, the software will delete the oldest existing half-open session for the host for every new connection request to the host and will let the SYN packet through. If the **block-time** timeout is greater than zero, the software will delete all existing half-open sessions for the host, and then block all new connection requests to the host. The software will continue to block all new connection requests until the **block-time** expires.

To reset any threshold or timeout to the default value, use the **no** form of the command in [Table 24](#).

Half-Open Sessions

An unusually high number of half-open sessions (either absolute or measured as the arrival rate) could indicate that a denial-of-service attack is occurring. For TCP, "half-open" means that the session has not reached the established state—the TCP three-way handshake has not yet been completed. For UDP, "half-open" means that the firewall has detected no return traffic.

CBAC measures both the total number of existing half-open sessions and the rate of session establishment attempts. Both TCP and UDP half-open sessions are counted in the total number and rate measurements. Rate measurements are made several times per minute.

When the number of existing half-open sessions rises above a threshold (the **max-incomplete high** number), the software will delete half-open sessions as required to accommodate new connection requests. The software will continue to delete half-open requests as necessary, until the number of existing half-open sessions drops below another threshold (the **max-incomplete low** number).

When the rate of new connection attempts rises above a threshold (the **one-minute high** number), the software will delete half-open sessions as required to accommodate new connection attempts. The software will continue to delete half-open sessions as necessary, until the rate of new connection attempts drops below another threshold (the **one-minute low** number). The rate thresholds are measured as the number of new session connection attempts detected in the last one-minute sample period.

Defining an Inspection Rule

After you configure global timeouts and thresholds, you must define an inspection rule. This rule specifies what IP traffic (which application-layer protocols) will be inspected by CBAC at an interface.

Normally, you define only one inspection rule. The only exception might occur if you want to enable CBAC in two directions as described earlier in the section “When and Where to Configure CBAC.” For CBAC configured in both directions at a single firewall interface, you should configure two rules, one for each direction.

An inspection rule should specify each desired application-layer protocol as well as generic TCP or generic UDP if desired. The inspection rule consists of a series of statements each listing a protocol and specifying the same inspection rule name.

Inspection rules include options for controlling alert and audit trail messages and for checking IP packet fragmentation.

To define an inspection rule, follow the instructions in the following sections:

- [Configuring Application-Layer Protocol Inspection](#)
- [Configuring Generic TCP and UDP Inspection](#)

Configuring Application-Layer Protocol Inspection

This section provides instructions for configuring CBAC with the following inspection information:

- [Configuring Application-Layer Protocols](#)
- [Configuring Java Blocking](#)
- [Configuring IP Packet Fragmentation Inspection](#)

Note

For CBAC inspection to work with NetMeeting 2.0 traffic (an H.323 application-layer protocol), you must also configure inspection for TCP, as described later in the “[Configuring Generic TCP and UDP Inspection](#)” section. This requirement exists because NetMeeting 2.0 uses an additional TCP channel not defined in the H.323 specification.

Configuring Application-Layer Protocols

To configure CBAC inspection for an application-layer protocol, use one or both of the following commands in global configuration mode:

Command	Purpose
Router(config)# ip inspect name <i>inspection-name</i> <i>protocol</i> [alert { on off }] [audit-trail { on off }] [timeout <i>seconds</i>]	Configures CBAC inspection for an application-layer protocol (except for RPC and Java). Use one of the protocol keywords defined in Table 25 . Repeat this command for each desired protocol. Use the same <i>inspection-name</i> value to create a single inspection rule.
Router(config)# ip inspect name <i>inspection-name</i> rpc program-number <i>number</i> [wait-time <i>minutes</i>] [alert { on off }] [audit-trail { on off }] [timeout <i>seconds</i>]	Enables CBAC inspection for the RPC application-layer protocol. You can specify multiple RPC program numbers by repeating this command for each program number. Use the same <i>inspection-name</i> value to create a single inspection rule.

Refer to the description of the **ip inspect name** global configuration command in the “Context-Based Access Control Commands” chapter of the *Cisco IOS Security Command Reference* for more information about how the command works with each application-layer protocol.

To enable CBAC inspection for Java blocking, see the following section, “[Configuring Java Blocking](#).” [Table 25](#) identifies application protocol keywords for the **ip inspect name** command.

Table 25 Application Protocol Keywords for the **ip inspect name** Command

Application Protocol	Protocol Keyword
CU-SeeMe	cuseeme
FTP	ftp
H.323	h323
Microsoft NetShow	netshow
UNIX R commands (rlogin, rexec, rsh)	rcmd
RealAudio	realaudio
SMTP	smtp
SQL*Net	sqlnet
StreamWorks	streamworks
TFTP	tftp
VDOLive	vdolive

Configuring Java Blocking

Java applet filtering distinguishes between trusted and untrusted applets by relying on a list of external sites that you designate as “friendly.” If an applet is from a friendly site, the firewall allows the applet through. If the applet is not from a friendly site, the applet will be blocked. (Alternately, you could permit applets from all external sites except for those you specifically designate as hostile.)

**Note**

Java blocking forces a strict order on TCP packets. To properly verify that Java applets are not in the response, a firewall will drop any TCP packet that is out of order. Because the network—not the firewall—determines how packets are routed, the firewall cannot control the order of the packets; the firewall can only drop and retransmit all TCP packets that are not in order.

To block all Java applets except for applets from friendly locations, use the following commands in global configuration mode:

	Command	Purpose
Step 1	<pre>Router(config)# ip access-list standard name permit ... deny ... (Use permit and deny statements as appropriate.) or Router(config)# access-list access-list-number {deny permit} protocol source [source-wildcard] eq www destination [destination-wildcard]</pre>	<p>Creates a standard access list that permits traffic only from friendly sites, and denies traffic from hostile sites.</p> <p>Use the any keyword for the destination as appropriate—but be careful to not misuse the any keyword to inadvertently allow all applets through.</p>
Step 2	<pre>Router(config)# ip inspect name inspection-name http [java-list access-list] [alert {on off}] [audit-trail {on off}] [timeout seconds]</pre>	<p>Blocks all Java applets except for applets from the friendly sites defined previously in the access list. Java blocking only works with numbered standard access lists.</p> <p>To create a single inspection rule, use the same <i>inspection-name</i> value as when you specified other protocols.</p>

**Caution**

CBAC does not detect or block encapsulated Java applets. Therefore, Java applets that are wrapped or encapsulated, such as applets in .zip or .jar format, are *not* blocked at the firewall. CBAC also does not detect or block applets loaded from FTP, gopher, HTTP on a nonstandard port, and so forth.

Configuring IP Packet Fragmentation Inspection

CBAC inspection rules can help protect hosts against certain DoS attacks involving fragmented IP packets.

Using fragmentation inspection, the firewall maintains an *interfragment state* (structure) for IP traffic. Non-initial fragments are discarded unless the corresponding initial fragment was permitted to pass through the firewall. Non-initial fragments received before the corresponding initial fragments are discarded.

**Note**

Fragmentation inspection can have undesirable effects in certain cases, because it can result in the firewall discarding any packet whose fragments arrive out of order. There are many circumstances that can cause out-of-order delivery of legitimate fragments. Applying fragmentation inspection in situations where legitimate fragments, which are likely to arrive out of order, might have a severe performance impact.

Because routers running Cisco IOS software are used in a large variety of networks, and because the CBAC feature is often used to isolate parts of internal networks from one another, the fragmentation inspection feature is disabled by default. Fragmentation detection must be explicitly enabled for an inspection rule using the **ip inspect name** command. Unfragmented traffic is never discarded because it lacks a fragment state. Even when the system is under heavy attack with fragmented packets, legitimate fragmented traffic, if any, gets some fraction of the firewall's fragment state resources, and legitimate, unfragmented traffic can flow through the firewall unimpeded.

Configuring Generic TCP and UDP Inspection

You can configure TCP and UDP inspection to permit TCP and UDP packets to enter the internal network through the firewall, even if the application-layer protocol is not configured to be inspected. However, TCP and UDP inspection do not recognize application-specific commands, and therefore might not permit all return packets for an application, particularly if the return packets have a different port number than the previous exiting packet.

Any application-layer protocol that is inspected will take precedence over the TCP or UDP packet inspection. For example, if inspection is configured for FTP, all control channel information will be recorded in the state table, and all FTP traffic will be permitted back through the firewall if the control channel information is valid for the state of the FTP session. The fact that TCP inspection is configured is irrelevant to the FTP state information.

With TCP and UDP inspection, packets entering the network must exactly match the corresponding packet that previously exited the network. The entering packets must have the same source/destination addresses and source/destination port numbers as the exiting packet (but reversed); otherwise, the entering packets will be blocked at the interface. Also, all TCP packets with a sequence number outside of the window are dropped.

With UDP inspection configured, replies will only be permitted back in through the firewall if they are received within a configurable time after the last request was sent out. (This time is configured with the **ip inspect udp idle-time** command.)

To configure CBAC inspection for TCP or UDP packets, use one or both of the following commands in global configuration mode:

Command	Purpose
Router(config)# ip inspect name <i>inspection-name</i> tcp [alert {on off}] [audit-trail {on off}] [timeout <i>seconds</i>]	Enables CBAC inspection for TCP packets. To create a single inspection rule, use the same <i>inspection-name</i> value as when you specified other protocols.
Router(config)# ip inspect name <i>inspection-name</i> udp [alert {on off}] [audit-trail {on off}] [timeout <i>seconds</i>]	Enables CBAC inspection for UDP packets. To create a single inspection rule, use the same <i>inspection-name</i> value as when you specified other protocols.

Applying the Inspection Rule to an Interface

After you define an inspection rule, you apply this rule to an interface.

Normally, you apply only one inspection rule to one interface. The only exception might occur if you want to enable CBAC in two directions as described earlier in the section “When and Where to Configure CBAC.” For CBAC configured in both directions at a single firewall interface, you should apply two rules, one for each direction.

If you are configuring CBAC on an external interface, apply the rule to outbound traffic.

If you are configuring CBAC on an internal interface, apply the rule to inbound traffic.

To apply an inspection rule to an interface, use the following command in interface configuration mode:

Command	Purpose
Router(config-if)# ip inspect <i>inspection-name</i> {in out}	Applies an inspection rule to an interface.

Configuring Logging and Audit Trail

Turn on logging and audit trail to provide a record of network access through the firewall, including illegitimate access attempts, and inbound and outbound services. To configure logging and audit trail functions, enter the following commands in global configuration mode:

	Command	Purpose
Step 1	Router(config)# service timestamps log datetime	Adds the date and time to syslog and audit trail messages.
Step 2	Router(config)# logging host	Specifies the host name or IP address of the host where you want to send syslog messages.
Step 3	Router(config)# logging facility <i>facility-type</i>	Configures the syslog facility in which error messages are sent.
Step 4	Router(config)# logging trap level	(Optional) Uses this command to limit messages logged to the syslog servers based on severity. The default is level 7 (informational).
Step 5	Router(config)# ip inspect audit-trail	Turns on CBAC audit trail messages.

For information on how to interpret the syslog and audit trail messages, refer to the “[Interpreting Syslog and Console Messages Generated by CBAC](#)” section.

To configure audit trail functions on a per-application basis, refer to the “[Defining an Inspection Rule](#)” section for more information.

For complete information about how to configure logging, refer to the “Troubleshooting the Router” chapter of the *Cisco IOS Network Management Configuration Guide*.

Other Guidelines for Configuring a Firewall

As with all networking devices, you should always protect access into the firewall by configuring passwords as described in the module “Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices.” You should also consider configuring user authentication, authorization, and accounting as described in the “Authentication, Authorization, and Accounting (AAA)” part of this guide.

You should also consider the following recommendations:

- When setting passwords for privileged access to the firewall, use the **enable secret** command rather than the **enable password** command, which does not have as strong an encryption algorithm.

- Put a password on the console port. In authentication, authorization, and accounting (AAA) environments, use the same authentication for the console as for elsewhere. In a non-AAA environment, at a minimum configure the **login** and **password password** commands.
- Think about access control *before* you connect a console port to the network in any way, including attaching a modem to the port. Be aware that a *break* on the console port might give total control of the firewall, even with access control configured.
- Apply access lists and password protection to all virtual terminal ports. Use access lists to limit who can Telnet into your router.
- Do not enable any local service (such as SNMP or NTP) that you do not use. Cisco Discovery Protocol (CDP) and Network Time Protocol (NTP) are on by default, and you should turn these off if you do not need them.

To turn off CDP, enter the **no cdp run** global configuration command. To turn off NTP, enter the **ntp disable** interface configuration command on each interface not using NTP.

If you must run NTP, configure NTP only on required interfaces, and configure NTP to listen only to certain peers.

Any enabled service could present a potential security risk. A determined, hostile party might be able to find creative ways to misuse the enabled services to access the firewall or the network.

For local services that are enabled, protect against misuse. Protect by configuring the services to communicate only with specific peers, and protect by configuring access lists to deny packets for the services at specific interfaces.

- Protect against spoofing: protect the networks on both sides of the firewall from being spoofed from the other side. You could protect against spoofing by configuring input access lists at all interfaces to pass only traffic from expected source addresses, and to deny all other traffic.

You should also disable source routing. For IP, enter the **no ip source-route** global configuration command. Disabling source routing at *all* routers can also help prevent spoofing.

You should also disable minor services. For IP, enter the **no service tcp-small-servers** and **no service udp-small-servers** global configuration commands. In Cisco IOS Release 12.0 and later, these services are disabled by default.

- Prevent the firewall from being used as a relay by configuring access lists on any asynchronous Telnet ports.
- Normally, you should disable directed broadcasts for all applicable protocols on your firewall and on all your other routers. For IP, use the **no ip directed-broadcast** command. Rarely, some IP networks do require directed broadcasts; if this is the case, do not disable directed broadcasts.

Directed broadcasts can be misused to multiply the power of denial-of-service attacks, because every denial-of-service packet sent is broadcast to every host on a subnet. Furthermore, some hosts have other intrinsic security risks present when handling broadcasts.
- Configure the **no proxy-arp** command to prevent internal addresses from being revealed. (This is important to do if you do not already have NAT configured to prevent internal addresses from being revealed.)
- Keep the firewall in a secured (locked) room.

Verifying CBAC

You can view and verify CBAC configuration, status, statistics, and session information by using one or more of the following commands in EXEC mode:

Command	Purpose
Router# show ip access-lists	Displays the contents of all current IP access lists.
Router# show ip inspect name <i>inspection-name</i>	Shows a particular configured inspection rule.
Router# show ip inspect config	Shows the complete CBAC inspection configuration.
Router# show ip inspect interfaces	Shows interface configuration with regards to applied inspection rules and access lists.
Router# show ip inspect session [<i>detail</i>]	Shows existing sessions that are currently being tracked and inspected by CBAC.
Router# show ip inspect all	Shows all CBAC configuration and all existing sessions that are currently being tracked and inspected by CBAC.

In most cases, you can tell whether CBAC is inspecting network traffic properly because network applications are working as expected. In some cases, however, you might want to verify CBAC operation. For example, to verify RTSP or H.323 inspection, initiate an RTSP- or H.323-based application through the firewall. Use the **show ip inspect session** and **show ip access lists** commands to verify CBAC operation. These commands display the dynamic ACL entries and the established connections for a multimedia session.

In the case of RTSP inspection, session output can vary based on the multimedia protocol and the transport mode. This section uses examples of RTSP and H.323 V2 sessions to illustrate verification procedures and to illustrate how session information, and the interpretation of that session information, varies based on the protocol being inspected. This section provides the following sample session output:

- [RTSP with RDT](#)
- [RTSP with TCP Only \(Interleaved Mode\)](#)
- [RTSP with SMIL](#)
- [RTSP with RTP \(IP/TV\)](#)
- [H.323 V2](#)

RTSP with RDT

The following example illustrates the result of the **show ip inspect session** command. It shows that a control channel (rtsp) and data channel (rtsp-data) are open between hosts 192.168.155.2 and 192.168.35.1.

```
router# show ip inspect session
Established Sessions
  Session 616B4F1C (192.168.155.2:7548)=>(192.168.35.1:6970) rtsp-data SIS_OPEN
  Session 611E2904 (192.168.35.1:1221)=>(192.168.155.2:554) rtsp SIS_OPEN
```

The following example illustrates the result of the **show ip access-list** command. It shows that two dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1221 on the server. The UDP entry creates a dynamic opening between data port 7548 on the client and data port 6970 on the server.

```
router# show ip access-list
Extended IP access list 100
  permit udp host 192.168.155.2 eq 7548 host 192.168.35.1 eq 6970 (31 matches)
  permit tcp host 192.168.155.2 eq 554 host 192.168.35.1 eq 1221 (27 matches)
```

After closing the multimedia session, review the session output using the **show** commands to verify the firewall software has removed the dynamic entries from the configuration.

RTSP with TCP Only (Interleaved Mode)

The following example illustrates the result of the **show ip inspect session** command. It shows that only a single control channel (rtsp) is open between hosts 192.168.155.2 and 192.168.35.1. In this mode, data is tunneled through the firewall using the TCP connection to interleave RDT or RTP data.

```
router# show ip inspect session
Established Sessions
  Session 611E2904 (192.168.35.1:1228)=>(192.168.155.2:554) rtsp SIS_OPEN
```

The following example illustrates the result of the **show ip access-list** command. It shows that a single dynamic entry (permit statement) was added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1228 on the server.

```
router# show ip access-lists
Extended IP access list 100
  permit tcp host 192.168.155.2 eq 554 host 192.168.35.1 eq 1228 (391 matches)
```

After closing the multimedia session, review the session output using the **show** commands to verify the firewall software has removed the dynamic entries from the configuration.

RTSP with SMIL

The following example illustrates the result of the **show ip inspect session** command for RTSP using Synchronized Multimedia Integration Language (SMIL). It shows that a single control channel (rtsp) and multiple data channels (rtsp-data) are open between hosts 192.168.155.2 and 192.168.35.1. The data channels appear as half open sessions because the UDP data flows in one direction only, which is from the server to the client.

```
router# show ip inspect session
Established Sessions
  Session 616CA914 (192.168.155.2:30616)=>(192.168.35.1:6974) rtsp-data SIS_OPEN
  Session 616B4E78 (192.168.35.1:1230)=>(192.168.155.2:554) rtsp SIS_OPEN
  Session 614AB61C (192.168.155.2:29704)=>(192.168.35.1:6976) rtsp-data SIS_OPEN
  Session 616CAA88 (192.168.155.2:26764)=>(192.168.35.1:6972) rtsp-data SIS_OPEN
Half-open Sessions
  Session 614AAEF0 (192.168.155.2:15520)=>(192.168.35.1:6970) rtsp-data SIS_OPENING
```

The following example illustrates the result of the **show ip access-lists** command. It shows that multiple dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1230 on the server. The UDP entries create dynamic openings between negotiated data ports on the client (192.168.155.2) and the server (192.168.35.1).

```
router# show ip access-list
Extended IP access list 100
  permit udp host 192.168.155.2 eq 29704 host 192.168.35.1 eq 6976 (182 matches)
  permit udp host 192.168.155.2 eq 30616 host 192.168.35.1 eq 6974 (268 matches)
  permit udp host 192.168.155.2 eq 26764 host 192.168.35.1 eq 6972 (4 matches)
  permit udp host 192.168.155.2 eq 15520 host 192.168.35.1 eq 6970 (12 matches)
  permit tcp host 192.168.155.2 eq 554 host 192.168.35.1 eq 1230 (41 matches)
```

After closing the multimedia session, review the session output using the **show** commands to verify the firewall software has removed the dynamic entries from the configuration.

RTSP with RTP (IP/TV)

The following example illustrates the result of the **show ip inspect session** command for RTSP with the Cisco IP/TV application. The output shows that a single control channel (rtsp) and multiple data channels (rtsp-data) are open between hosts 192.168.2.15 and 192.168.102.23. The data channels appear as half-open sessions because the UDP data flows in one direction only, which is from the server to the client.

```
router# show ip inspect session
Established Sessions
  Session 611493C0 (192.168.2.15:2571)=>(192.168.102.23:8554) rtsp SIS_OPEN
Half-open Sessions
  Session 6114A22C (192.168.102.23:2428)=>(192.168.2.15:20112) rtsp-data SIS_OPENING
  Session 61149F44 (192.168.102.23:2428)=>(192.168.2.15:20113) rtsp-data SIS_OPENING
  Session 6114A0B8 (192.168.102.23:2429)=>(192.168.2.15:20115) rtsp-data SIS_OPENING
  Session 6114A3A0 (192.168.102.23:2429)=>(192.168.2.15:20114) rtsp-data SIS_OPENING
```

The following example illustrates the result of the **show ip access-lists** command. It shows that multiple dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 554 (RTSP protocol port) on the client and port 1230 on the server. The UDP entries create dynamic openings between negotiated data ports on the client (192.168.2.15) and the server (192.168.102.23).

```
router# show ip access-lists
Extended IP access list 100
  permit udp host 192.168.102.23 eq 2428 host 192.168.2.15 eq 20113 (11 matches)
  permit udp host 192.168.102.23 eq 2428 host 192.168.2.15 eq 20112 (256 matches)
  permit udp host 192.168.102.23 eq 2429 host 192.168.2.15 eq 20115 (11 matches)
  permit udp host 192.168.102.23 eq 2429 host 192.168.2.15 eq 20114 (4598 matches)
  permit tcp host 192.168.102.23 eq 8554 host 192.168.2.15 eq 2571 (22 matches)
```

After closing the multimedia session, review the session output using the **show** commands to verify that the firewall software has removed the dynamic entries from the configuration.

H.323 V2

The following example illustrates the result of the **show ip inspect session** command for H.323 V2. It shows a single H.323 control channel, an RTP Control Protocol channel for both audio and video data, and an RTP data channel between hosts 192.168.155.2 and 192.168.35.1.

```
Session 615E2688 (192.168.35.1:49609)=>(192.168.155.1:49609) H323-RTCP-audio SIS_OPEN
Session 615E2688 (192.168.35.1:49508)=>(192.168.155.1:49508) H323-RTP-audio SIS_OPEN
Session 615E2688 (192.168.35.1:49410)=>(192.168.155.1:49410) H323-RTP-video SIS_OPEN
Session 615E2688 (192.168.35.1:49611)=>(192.168.155.1:49611) H323-RTCP-video SIS_OPEN
Session 615E1640 (192.168.35.1:4414)=>(192.168.155.1:1720) H323 SIS_OPEN
```

The following example illustrates the result of the **show ip access-lists** command. It shows that multiple dynamic entries (permit statements) were added to ACL 100 for the multimedia session. The TCP entry creates a dynamic opening through the firewall between port 1720 (H.323 V2 protocol port) on the client and port 4414 on the server. The UDP entries create dynamic openings between negotiated data ports on the client (192.168.155.1) and the server (192.168.35.1).

```
router# show ip access-lists
Extended IP access list 100
  permit udp host 192.168.155.1 eq 49609 host 192.168.35.1 eq 49609 (11 matches)
  permit udp host 192.168.155.1 eq 49508 host 192.168.35.1 eq 49508 (256 matches)
  permit udp host 192.168.155.1 eq 49411 host 192.168.35.1 eq 49411 (11 matches)
  permit udp host 192.168.155.1 eq 49610 host 192.168.35.1 eq 49610 (4598 matches)
  permit tcp host 192.168.155.1 eq 1720 host 192.168.35.1 eq 4414 (22 matches)
```

Monitoring and Maintaining CBAC

You can watch for network attacks and investigate network problems using debug commands and system messages. This section has the following sections:

- [Debugging Context-Based Access Control](#)
- [Interpreting Syslog and Console Messages Generated by CBAC](#)
- [Turning Off CBAC](#)

Debugging Context-Based Access Control

To assist CBAC debugging, you can turn on audit trail messages that will be displayed on the console after each CBAC session closes. Audit trail information is also configurable on a per-application basis using the CBAC inspection rules.

To turn on audit trail messages, use the following command in global configuration mode:

Command	Purpose
Router(config)# ip inspect audit-trail	Turns on CBAC audit trail messages.

If required, you can also use the CBAC **debug** commands listed in this section. (Debugging can be turned off for each of the commands in this section by using the **no** form of the command. To disable all debugging, use the privileged EXEC commands **no debug all** or **undebg all**.)

The following **debug** commands are available:

- [Generic Debug Commands](#)
- [Transport Level Debug Commands](#)
- [Application Protocol Debug Commands](#)

For a complete description of the debug commands, refer to the *Cisco IOS Debug Command Reference*.

Note

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

Generic Debug Commands

You can use the following generic **debug** commands, entered in privileged EXEC mode:

Command	Purpose
Router# debug ip inspect function-trace	Displays messages about software functions called by CBAC.
Router# debug ip inspect object-creation	Displays messages about software objects being created by CBAC. Object creation corresponds to the beginning of CBAC-inspected sessions.
Router# debug ip inspect object-deletion	Displays messages about software objects being deleted by CBAC. Object deletion corresponds to the closing of CBAC-inspected sessions.

Command	Purpose
Router# debug ip inspect events	Displays messages about CBAC software events, including information about CBAC packet processing.
Router# debug ip inspect timers	Displays messages about CBAC timer events such as when a CBAC idle timeout is reached.
Router# debug ip inspect detail	Enables the detailed option, which can be used in combination with other options to get additional information.

Transport Level Debug Commands

You can use the following transport-level **debug** commands, entered in privileged EXEC mode:

Command	Purpose
Router# debug ip inspect tcp	Displays messages about CBAC-inspected TCP events, including details about TCP packets.
Router# debug ip inspect udp	Displays messages about CBAC-inspected UDP events, including details about UDP packets.

Application Protocol Debug Commands

You can use the following application protocol **debug** command, entered in privileged EXEC mode:

Command	Purpose
Router# debug ip inspect protocol	Displays messages about CBAC-inspected protocol events, including details about the protocol's packets. Refer to Table 26 to determine the protocol keyword.

[Table 26](#) identifies application protocol keywords for the **debug ip inspect** command.

Table 26 Application Protocol Keywords for the **debug ip inspect** Command

Application Protocol	Protocol Keyword
CU-SeeMe	cuseeme
FTP commands and responses	ftp-cmd
FTP token (enables tracing of the FTP tokens parsed)	ftp-token
H.323	h323
HTTP (Java applets)	http
Microsoft NetShow	netshow
UNIX R commands (rlogin, rexec, rsh)	rcmd
RealAudio	realaudio
RPC	rpc
SMTP	smtp

Table 26 **Application Protocol Keywords for the debug ip inspect Command (continued)**

Application Protocol	Protocol Keyword
SQL*Net	sqlnet
StreamWorks	streamworks
TFTP	tftp
VDOLive	vdolive

Interpreting Syslog and Console Messages Generated by CBAC

CBAC provides syslog messages, console alert messages, and audit trail messages. These messages are useful because they can alert you to network attacks and because they provide an audit trail that provides details about sessions inspected by CBAC. While they are generally referred to as error messages, not all error messages indicate problems with your system.

Audit trail and alert information is configurable on a per-application basis using the CBAC inspection rules.

The following types of messages can be generated by CBAC:

- [Denial-of-Service Attack Detection Error Messages](#)
- [SMTP Attack Detection Error Messages](#)
- [Java Blocking Error Messages](#)
- [FTP Error Messages](#)
- [Audit Trail Messages](#)

For explanations and recommended actions related to the error messages mentioned in this section, refer to the *Cisco IOS System Error Messages*.

Denial-of-Service Attack Detection Error Messages

CBAC detects and blocks denial-of-service attacks and notifies you when denial-of-service attacks occur. Error messages such as the following may indicate that denial-of-service attacks have occurred:

```
%FW-4-ALERT_ON: getting aggressive, count (550/500) current 1-min rate: 250
%FW-4-ALERT_OFF: calming down, count (0/400) current 1-min rate: 0
```

When %FW-4-ALERT_ON and %FW-4-ALERT_OFF error messages appear together, each “aggressive/calming” pair of messages indicates a separate attack. The preceding example shows one separate attack.

Error messages such as the following may indicate that a denial-of-service attack has occurred on a specific TCP host:

```
%FW-4-HOST_TCP_ALERT_ON: Max tcp half-open connections (50) exceeded for host
172.21.127.242.
%FW-4-BLOCK_HOST: Blocking new TCP connections to host 172.21.127.242 for 2 minutes
(half-open count 50 exceeded)
%FW-4-UNBLOCK_HOST: New TCP connections to host 172.21.127.242 no longer blocked
```

SMTP Attack Detection Error Messages

CBAC detects and blocks SMTP attacks (illegal SMTP commands) and notifies you when SMTP attacks occur. Error messages such as the following may indicate that an SMTP attack has occurred:

```
%FW-4-SMTP_INVALID_COMMAND: Invalid SMTP command from initiator (192.168.12.3:52419)
```

CBAC also detects a limited number of SMTP attack signatures. A signature in a SYSLOG message indicates a possible attack against the protected network, such as the detection of illegal SMTP commands in a packet. Whenever a signature is detected, the connection will be reset.

The Cisco IOS Firewall supports the following SMTP attack signatures:

Signature	Description
Mail: bad rcpt	Triggers on any mail message with a “pipe” () symbol in the recipient field.
Mail: bad from	Triggers on any mail message with a “pipe” () symbol in the “From:” field.
Mail: old attack	Triggers when “wiz” or “debug” commands are sent to the SMTP port.
Mail: decode	Triggers on any mail message with a “:decode@” in the header.
Majordomo	A bug in the Majordomo program will allow remote users to execute arbitrary commands at the privilege level of the server.

The following is a sample SMTP attack signature message:

```
02:04:55: %FW-4-TCP_MAJORDOMO_EXEC_BUG: Sig:3107:Majordomo Execute Attack - from
192.168.25.1 to 192.168.205.1:
```

Java Blocking Error Messages

CBAC detects and selectively blocks Java applets and notifies you when a Java applet has been blocked. Error messages such as the following may indicate that a Java applet has been blocked:

```
%FW-4-HTTP_JAVA_BLOCK: JAVA applet is blocked from (172.21.127.218:80) to
(172.16.57.30:44673).
```

FTP Error Messages

CBAC detects and prevents certain FTP attacks and notifies you when this occurs. Error messages such as the following may appear when CBAC detects these FTP attacks:

```
%FW-3-FTP_PRIV_PORT: Privileged port 1000 used in PORT command -- FTP client 10.0.0.1 FTP
server 10.1.0.1
%FW-3-FTP_SESSION_NOT_AUTHENTICATED: Command issued before the session is authenticated
-- FTP client 10.0.0.1
%FW-3-FTP_NON_MATCHING_IP_ADDR: Non-matching address 172.19.148.154 used in PORT command
-- FTP client 172.19.54.143 FTP server 172.16.127.242
```

Audit Trail Messages

CBAC provides audit trail messages to record details about inspected sessions. Audit trail information is configurable on a per-application basis using the CBAC inspection rules. To determine which protocol was inspected, use the responder's port number. The port number follows the responder's address. The following are sample audit trail messages:

```
%FW-6-SESS_AUDIT_TRAIL: tcp session initiator (192.168.1.13:33192) sent 22 bytes --  
responder (192.168.129.11:25) sent 208 bytes  
%FW-6-SESS_AUDIT_TRAIL: http session initiator (172.16.57.30:44673) sent 1599 bytes --  
responder (172.21.127.218:80) sent 93124 bytes
```

Turning Off CBAC

You can turn off CBAC using the **no ip inspect** global configuration command.

**Note**

The **no ip inspect** command removes all CBAC configuration entries and resets all CBAC global timeouts and thresholds to the defaults. All existing sessions are deleted and their associated access lists removed.

In most situations, turning off CBAC has no negative security impact because CBAC creates “permit” access lists. Without CBAC configured, no “permit” access lists are maintained. Therefore, no derived traffic (returning traffic or traffic from the data channels) can go through the firewall. The exception is SMTP and Java blocking. With CBAC turned off, unacceptable SMTP commands or Java applets may go through the firewall.

CBAC Configuration Examples

The following sections provide CBAC configuration examples:

- [Ethernet Interface Configuration Example](#)
- [ATM Interface Configuration Example](#)
- [Remote Office to ISP Configuration Example](#)
- [Remote Office to Branch Office Configuration Example](#)
- [Two-Interface Branch Office Configuration Example](#)
- [Multiple-Interface Branch Office Configuration Example](#)

The first example develops a CBAC inspection rule for specific protocols and a supporting access control list (ACL). This example focuses how to configure CBAC; it does not provide a complete router configuration and does not describe other elements of the configuration.

The next example develops a CBAC inspection rule for sites that might have remote traffic through an ATM interface. This example further illustrates on how to configure CBAC and emphasizes the application of the configuration rule at the interface, whatever that interface might be. This example does not provide a complete router configuration and does not describe other elements of the configuration.

The remote-office examples also focus on the firewall configuration but do not provide detailed descriptions of other configuration elements, such as the Basic Rate Interface (BRI) and dialer interface configurations.

Other examples provide more complete firewall configurations, further illustrating ways in which to apply CBAC.

In each example, configuring protocol inspection using CBAC has four components:

- Defining an access list with the appropriate permissions.
- Applying the ACL at an interface where you want to control access.
- Defining an inspection rule that includes the protocol that you want to inspect.
- Applying the inspection rule at an interface where you want to inspect traffic.

Ethernet Interface Configuration Example

This example looks at each of these four components. For this example, CBAC is being configured to inspect RTSP and H.323 protocol traffic inbound from the protected network on a router with two Ethernet interfaces. Interface Ethernet1/0 is the protected network and interface Ethernet1/1 is the unprotected network. The security policy for the protected site uses access control lists (ACLs) to restrict inbound traffic on the unprotected interface to specific ICMP protocol traffic, denying inbound access for TCP and UDP protocol traffic. Inbound access for specific protocol traffic is provided through dynamic access lists, which are generated according to CBAC inspection rules.

ACL 100 denies TCP and UDP traffic from any source or destination while permitting specific ICMP protocol traffic. The final deny statement is not required, but is included for explicitness—the final entry in any ACL is an implicit denial of all IP protocol traffic.

```
Router(config)# access-list 100 deny tcp any any
Router(config)# access-list 100 deny udp any any
Router(config)# access-list 100 permit icmp any any echo-reply
Router(config)# access-list 100 permit icmp any any time-exceeded
Router(config)# access-list 100 permit icmp any any packet-too-big
Router(config)# access-list 100 permit icmp any any traceroute
Router(config)# access-list 100 permit icmp any any unreachable
Router(config)# access-list 100 deny ip any any
```

ACL 100 is applied inbound at interface Ethernet1/1 to block all access from the unprotected network to the protected network.

```
Router(config)# interface Ethernet1/1
Router(config-if)# ip access-group 100 in
```

An inspection rule is created for “hquers” that covers two protocols: RTSP and H.323.

```
Router(config)# ip inspect name hquers rtsp
Router(config)# ip inspect name hquers h323
```

The inspection rule is applied inbound at interface Ethernet1/0 to inspect traffic from users on the protected network. When CBAC detects multimedia traffic from the protected network, CBAC creates dynamic entries in access list 100 to allow return traffic for multimedia sessions.

```
Router(config)# interface Ethernet1/0
Router(config-if)# ip inspect hquers in
```

ATM Interface Configuration Example

In this example, CBAC inspection (firewall protection) is required against inbound traffic on an ATM interface. This example might apply to sites where local hosts require access to hosts or services on a remote network. The security policy for this site uses access control lists (ACLs) to restrict inbound

traffic on the ATM interface to specific ICMP protocol traffic, denying inbound access for TCP and UDP protocol traffic. Inbound access for specific TCP and UDP protocol traffic is provided through dynamic access lists, which are generated according to CBAC inspection rules.

For information on how to select the interface on which to apply CBAC, refer to the [“Picking an Interface: Internal or External”](#) section.

Note

For Frame Relay or ATM interfaces, you can apply CBAC inspection rules separately on each sub-interface, even though the subinterfaces are physically connected through one interface.

```

! -----
! Create the Inspection Rule
! -----
!
! Create the CBAC inspection rule "test", allowing inspection of the protocol traffic
! specified by the rule. This inspection rule sets the timeout value to 30 seconds for
! each protocol (except for RPC). The timeout value defines the maximum time that a
! connection for a given protocol can remain active without any traffic passing through
! the router. When these timeouts are reached, the dynamic ACLs that are inserted to
! permit the returning traffic are removed, and subsequent packets (possibly even valid
! ones) are not permitted.
ip inspect name test cuseeme timeout 30
ip inspect name test ftp timeout 30
ip inspect name test h323 timeout 30
ip inspect name test realaudio timeout 30
ip inspect name test rpc program-number 100000
ip inspect name test streamworks timeout 30
ip inspect name test vdolive timeout 30
!
! -----
! Create the Access Control List
! -----
!
! In this example, ACL 105 denies all TCP and UDP protocol traffic. ICMP traffic from
! subnet 192.168.1.0 is permitted to allow access for routing and control traffic.
! ACL 105 specifies that only the return traffic for protocols defined in the
! inspection rule is allow access through the interface where this rule is applied. The
! final deny statement is added for explicitness.
access-list 105 deny TCP any any
access-list 105 deny UDP any any
access-list 105 permit icmp any any echo-reply
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 time-exceeded
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 packet-too-big
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 traceroute
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 unreachable
access-list 105 deny ip any any
!
! -----
! Apply the Inspection Rule and ACL
! -----
!
! In this example, the inspection rule "test" is applied to traffic at interface ATM3/0
! for connections initiated in the outbound direction; that is, from hosts that are
! located on a local network. CBAC creates dynamic access list entries for traffic
! initiated by local hosts. These dynamic entries allow inbound (returning) traffic for
! that connection. ACL 105 is applied at interface ATM3/0 in the inbound direction to
! block traffic initiated from hosts on a remote network that is not part of an
! existing connection.
interface ATM3/0
    ip address 10.1.10.1 255.0.0.0
    ip access-group 105 in

```

```

no ip directed-broadcast
ip inspect test out
no shutdown
atm clock INTERNAL
atm pvc 7 7 7 aal5snap
map-group atm

```

Remote Office to ISP Configuration Example

This example describes one possible Cisco IOS Firewall configuration for a remote office router connected to an Internet service provider (ISP). In this configuration, the site security policy allows hosts on the local network to initiate traffic to the ISP while traffic inbound to the router from the ISP is blocked at the ISDN interface. Specific ICMP control message traffic is permitted through the firewall. No mail or Web services are available from the local network. [Figure 23](#) illustrates this example.

Figure 23 Remote Office to ISP Sample Configuration

The firewall has two interfaces:

- An Ethernet interface connects to the internal protected network.
Interface Ethernet0 has no ACL applied to it, meaning that all traffic initiated on the LAN is allowed access to the ISP. In this configuration example, Network Address Translation (NAT) is not turned on, and the addresses on interface Ethernet0 are reserved IP addresses. In a production environment, addresses on Ethernet0 either must be registered network addresses, or you must turn on NAT to hide these inside addresses from being visible on the Internet.
- An ISDN Basic Rate Interface (BRI) connects the router to the ISP. In this example, a dialer profile is used to control the BRI interface. This means that the ACL and CBAC inspection rules are applied at the dialer interface, not directly at the physical ISDN (BRI) interface using a dialer map.

```

! -----
! General Cisco IOS Firewall Guidelines
! -----
! The following global configuration entries illustrate good security practices.
enable secret 5 <elided>
no ip source-route
no cdp run
!
! -----
! Create the CBAC inspection rule
! -----
! Create the CBAC inspection rule STOP to allow inspection of the protocol traffic
! specified by the rule.
ip inspect name STOP tcp
ip inspect name STOP ftp
ip inspect name STOP smtp

```

```

ip inspect name STOP h323
ip inspect name STOP rcmd
!
! -----
! Create Access Control List 105
! -----
! ACL 105 denies all IP protocol traffic except for specific ICMP control traffic.
! This means that only the return traffic for protocols defined in the
! inspection rule and the specified ICMP traffic is allowed access through the
! interface where this rule is applied.
!
! Deny broadcast messages with a source address of 255.255.255.255; this helps to
! prevent broadcast attacks.
access-list 105 deny ip host 255.255.255.255 any
!
! Add anti-spoofing protection by denying traffic with a source address matching a host
! on the Ethernet interface.
acl 105 deny ip 192.168.1.0 0.0.0.255 any
!
! ICMP traffic is not inspected by CBAC. To control the type of ICMP traffic at the
! interface, add static access list entries. This example has the following ICMP
! requirements: outgoing ping commands require echo-reply messages to come back,
! outgoing traceroute commands require time-exceeded messages to come back, path MTU
! discovery requires "too-big" messages to come back, and incoming traceroute
! messages must be allowed. Additionally, permit all "unreachable" messages to come
! back; that is, if a router cannot forward or deliver a datagram, it sends an ICMP
! unreachable message back to the source and drops the datagram.
access-list 105 permit icmp any any echo-reply
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 time-exceeded
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 packet-too-big
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 traceroute
access-list 105 permit icmp any 192.168.1.0 0.0.0.255 unreachable
!
! Final deny for explicitness. This entry is not required but helps complete the access
! list picture. By default, the final entry in any access list is an implicit deny of
! IP protocol traffic. This ensures that the firewall blocks any traffic not explicitly
! permitted by the access list.
access-list 105 deny ip any any
!
! -----
! Configure the interface
! -----
! In this example, no ACLs or inspection rules are applied at interface Ethernet0,
! meaning that all traffic on the local network is allowed to go out. This assumes a
! high-level of trust for the users on the local network.
interface Ethernet0
    ip address 192.168.1.104 255.255.255.0
!
no ip directed-broadcast
!
! This example uses a dialer profile, so the ACL and CBAC inspection rules are applied
! at the dialer interface, not the physical BRI interface. The dialer pool-member
! command is used to associate the physical interface with a dialer profile.
interface BRI0
    no ip address
    no ip directed-broadcast
    encapsulation ppp
    dialer pool-member 1
    isdn switch-type basic-5ess
!
! -----
! Create the dialer profile.
! -----
! Through the dialer profile, the ACL and CBAC inspection rules are

```

```

! applied to every pool member. In this example, the ACL is applied in, meaning that it
! applies to traffic inbound from the ISP. The CBAC inspection rule STOP is applied
! out, meaning that CBAC monitors the traffic through the interface and controls return
! traffic to the router for an existing connection.
interface Dialer0
    ip address negotiated
    ip access-group 105 in
    no ip directed-broadcast
    ip inspect STOP out
    encapsulation ppp
    dialer remote-name <ISP router>

! Route traffic to the dialer interface.
ip route 0.0.0.0 0.0.0.0 Dialer0
! Include a dialer list protocol entry to specify the protocol that triggers dialing.
dialer-list 1 protocol ip permit
! Add a user name (name of the router your are configuring) and password for caller
! identification and password authentication with the ISP router.
username <router host name> password 5 <elided>

```

Remote Office to Branch Office Configuration Example

This example describes one possible Cisco IOS Firewall configuration for a remote office router connected to a branch office. In this configuration, the site security policy allows hosts on the local network to initiate traffic to the branch office. Mail or Web services are available from a server on the local network, and access to these services is available from the branch office. Traffic from the branch office, except for mail and Web traffic, is blocked at the outside interface. Specific ICMP control message traffic is permitted through the firewall. [Figure 24](#) illustrates this example.

Figure 24 Remote Office to Branch Office Sample Configuration

The firewall has two interfaces:

- An Ethernet interface connects to the internal protected network.

23076

Interface Ethernet0 has no ACL applied to it, meaning that all traffic initiated from the LAN is allowed access through the firewall.

- An ISDN Basic Rate Interface (BRI) connects the router to the branch office. In this example, a dialer profile is used to control the BRI interface. This means that the ACL and CBAC inspection rules are applied at dialer interface, not directly at the physical ISDN (BRI) interface.

```

enable secret 5 <elided>
no ip source-route
no cdp run
!
! -----
! Create the Inspection Rule
! -----
! Create the CBAC inspection rule STOP to allow inspection of the specified protocol
! traffic. Create the inspection rule GO to allow inspection of SMTP traffic.
ip inspect name STOP tcp
ip inspect name STOP ftp
ip inspect name STOP smtp
ip inspect name STOP h323
ip inspect name GO smtp
!
! -----
! Create Access Control Lists 106 and 51
! -----
! ACL 106 permits mail and Web traffic from any host to the specified server. ACL 106
! denies all other ip protocol traffic except for specific ICMP control traffic.
! This means that only the return traffic for protocols defined in the
! inspection rule and the specified ICMP traffic is allowed access through the
! interface where this rule is applied.
!
! Deny broadcast messages with a source address of 255.255.255.255; this helps to
! prevent broadcast attacks.
access-list 106 deny ip host 255.255.255.255 any
!
! Add anti-spoofing protection by denying traffic with a source address matching a host
! on the Ethernet interface.
access-list 106 deny ip 192.168.1.0 0.0.0.255 any
!
! ICMP traffic is not inspected by CBAC. To control the type of ICMP traffic at the
! interface, add static access list entries. This example has the following ICMP
! requirements: outgoing ping commands require echo-reply messages to come back,
! outgoing traceroute commands require time-exceeded messages to come back, path MTU
! discovery requires "too-big" messages to come back, and incoming traceroute must be
! allowed. Additionally, permit all "unreachable" messages to come back; that is, if a
! router cannot forward or deliver a datagram, it sends an ICMP unreachable message
! back to the source and drops the datagram.
access-list 106 permit icmp any any echo-reply
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 time-exceeded
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 packet-too-big
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 traceroute
access-list 106 permit icmp any 192.168.1.0 0.0.0.255 unreachable
!
! Permit mail and Web access to a specific server.
access-list 106 permit tcp any host 192.168.1.20 eq smtp
access-list 106 permit tcp any host 192.168.1.20 eq www
!
! Final deny for explicitness. This entry is not required but helps complete the access
! list picture. By default, the final entry in any access list is an implicit deny of
! IP protocol traffic. This ensures that the firewall blocks any traffic not explicitly
```

```

! permitted by the access list.
access-list 106 deny ip any any
!
! -----
! Configure the interface.
! -----
! In this example, no ACLs or inspection rules are applied at interface Ethernet0,
! meaning that all traffic on the local network is allowed to go out. This assumes a
! high-level of trust for the users on the local network.
interface Ethernet0
    ip address 192.168.1.104 255.255.255.0
    no ip directed-broadcast
!
! This example uses a dialer profile, so the ACL and CBAC inspection rules are applied
! at the dialer interface, not the physical BRI interface. The dialer pool-member
! command is used to associate the physical interface with a dialer profile.
interface BRI0
    no ip address
    no ip directed-broadcast
    encapsulation ppp
    dialer pool-member 1
    isdn switch-type basic-5ess
!
! -----
! Apply the ACL and CBAC inspection rules at the dialer interface.
! -----
! Through the dialer profile, the ACL and CBAC inspection rules are
! applied to every pool member. In this example, the ACL is applied in, meaning that it
! applies to traffic inbound from the branch office. The CBAC inspection rule STOP is
! applied out, meaning that CBAC monitors the traffic and controls return traffic to
! the router for an existing connection. The CBAC inspection rule GO is applied in,
! protecting against certain types of DoS attacks as described in this document. Note
! that the GO inspection rule does not control return traffic because there is no ACL
! blocking traffic in that direction; however, it does monitor the connections.
interface Dialer0
    ip address <ISDN interface address>

ip classless
! Route traffic to the dialer interface.
ip route 0.0.0.0 0.0.0.0 Dialer0
! Include a dialer list protocol entry to specify the protocol that triggers dialing.
dialer-list 1 protocol ip permit
! Add a user name (name of the router your are configuring) and password for caller
! identification and password authentication with the ISP router.
username <router host name> password 5 <elided>

```

Two-Interface Branch Office Configuration Example

This sample configuration file describes a firewall configured with CBAC. The firewall is positioned between a protected field office's internal network and a WAN connection to the corporate headquarters. CBAC is configured on the firewall in order to protect the internal network from potential network threats coming from the WAN side.

The firewall has two interfaces configured:

- Interface Ethernet0 connects to the internal protected network
- Interface Serial0 connects to the WAN with Frame Relay

```
! -----
! This first section contains some configuration that is not required for CBAC,
! but illustrates good security practices. Note that there are no
! services on the Ethernet side. Email is picked up via POP from a server on the
! corporate side.
! -----
!
hostname user1-examplecorp-fr
!
boot system flash c1600-fw1600-1
enable secret 5 <elided>
!
username user1 password <elided>
ip subnet-zero
no ip source-route
ip domain-name example.com
ip name-server 172.19.2.132
ip name-server 198.92.30.32
!
!
! -----
! The next section includes configuration required specifically for CBAC.
! -----
!
! The following commands define the inspection rule "myfw", allowing
! the specified protocols to be inspected. Note that Java applets will be permitted
! according to access list 51, defined later in this configuration.
ip inspect name myfw cuseeme timeout 3600
ip inspect name myfw ftp timeout 3600
ip inspect name myfw http java-list 51 timeout 30
ip inspect name myfw rcmd timeout 3600
ip inspect name myfw realaudio timeout 3600
ip inspect name myfw smtp timeout 3600
ip inspect name myfw tftp timeout 30
ip inspect name myfw udp timeout 15
ip inspect name myfw tcp timeout 3600
!
! The following interface configuration applies the "myfw" inspection rule to
! inbound traffic at Ethernet 0. Since this interface is on the internal network
! side of the firewall, traffic entering Ethernet 0 is actually
! exiting the internal network. Applying the inspection rule to this interface causes
! inbound traffic (which is exiting the network) to be inspected; return traffic will
! only be permitted back through the firewall if part of a session which began from
! within the network.
! Also note that access list 101 is applied to inbound traffic at Ethernet 0.
! (Traffic blocked by the access list will not be inspected.)
interface Ethernet0
description ExampleCorp Ethernet chez user1
ip address 172.19.139.1 255.255.255.248
ip broadcast-address 172.19.131.7
```

```

no ip directed-broadcast
no ip proxy-arp
ip inspect myfw in
ip access-group 101 in
no cdp enable
!
interface Serial0
description Frame Relay (Telco ID 22RTQQ062438-001) to ExampleCorp HQ
no ip address
ip broadcast-address 0.0.0.0
encapsulation frame-relay IETF
no arp frame-relay
bandwidth 56
service-module 56k clock source line
service-module 56k network-type dds
frame-relay lmi-type ansi
!
! Note that the following interface configuration applies access list 111 to
! inbound traffic at the external serial interface. (Inbound traffic is
! entering the network.) When CBAC inspection occurs on traffic exiting the
! network, temporary openings will be added to access list 111 to allow returning
! traffic that is part of existing sessions.
!
interface Serial0.1 point-to-point
ip unnumbered Ethernet0
ip access-group 111 in
bandwidth 56
no cdp enable
frame-relay interface-dlci 16
!
ip classless
ip route 0.0.0.0 0.0.0.0 Serial0.1
!
! The following access list defines "friendly" and "hostile" sites for Java
! applet blocking. Because Java applet blocking is defined in the inspection
! rule "myfw" and references access list 51, applets will be actively denied
! if they are from any of the "deny" addresses and allowed only if they are from
! either of the two "permit" networks.
!
access-list 51 deny    172.19.1.203
access-list 51 deny    172.19.2.147
access-list 51 permit 172.18.0.0 0.1.255.255
access-list 51 permit 192.168.1.0 0.0.0.255
access-list 51 deny    any
!
! The following access list 101 is applied to interface Ethernet 0 above.
! This access list permits all traffic that should be CBAC inspected, and also
! provides anti-spoofing. The access list is deliberately set up to deny unknown
! IP protocols, because no such unknown protocols will be in legitimate use.
!
access-list 101 permit tcp 172.19.139.0 0.0.0.7 any
access-list 101 permit udp 172.19.139.0 0.0.0.7 any
access-list 101 permit icmp 172.19.139.0 0.0.0.7 any
access-list 101 deny    ip any any
!
! The following access list 111 is applied to interface Serial 0.1 above.
! This access list filters traffic coming in from the external side. When
! CBAC inspection occurs, temporary openings will be added to the beginning of
! this access list to allow return traffic back into the internal network.
! This access list should restrict traffic that will be inspected by
! CBAC. (Remember that CBAC will open holes as necessary to permit returning traffic.)
! Comments precede each access list entry. These entries are not all specifically
! related to CBAC, but are created to provide general good security.
!

```

```
! Anti-spoofing.
access-list 111 deny ip 172.19.139.0 0.0.0.7 any
! Sometimes EIGRP is run on the Frame Relay link. When you use an
! input access list, you have to explicitly allow even control traffic.
! This could be more restrictive, but there would have to be entries
! for the EIGRP multicast as well as for the office's own unicast address.
access-list 111 permit igrp any any
!
! These are the ICMP types actually used...
! administratively-prohibited is useful when you are trying to figure out why
! you cannot reach something you think you should be able to reach.
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 administratively-prohibited
!
! This allows network admins at headquarters to ping hosts at the field office:
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 echo
!
! This allows the field office to do outgoing pings
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 echo-reply
!
! Path MTU discovery requires too-big messages
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 packet-too-big
!
! Outgoing traceroute requires time-exceeded messages to come back
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 time-exceeded
!
! Incoming traceroute
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 traceroute
!
! Permits all unreachable because if you are trying to debug
! things from the remote office, you want to see them. If nobody ever did
! any debugging from the network, it would be more appropriate to permit only
! port unreachable or no unreachable at all.
access-list 111 permit icmp any 172.19.139.0 0.0.0.7 unreachable
!
!
! These next two entries permit users on most ExampleCorp networks to Telnet to
! a host in the field office. This is for remote administration by the network admins.
access-list 111 permit tcp 172.18.0.0 0.1.255.255 host 172.19.139.1 eq telnet
access-list 111 permit tcp 192.168.1.0 0.0.0.255 host 172.19.139.1 eq telnet
!

Multiple-Interface Branch Office Configuration Example

In this configuration example, a single Cisco 3600 series firewall router is positioned at a branch office. It has four internal networks and two WAN connections to the corporate headquarters. CBAC is configured on the firewall to protect two of the internal networks from potential network threats coming from the WAN side and from less secure internal networks. Anti-spoofing protection is added at each interface with client systems. [Figure 25](#) illustrates this configuration.

**Note**

This example shows a moderately high level of trust by the administrators toward the expected users. Additional protection could be added to this configuration for a situation in a lower level of trust. That configuration would include ICMP filtering statements, significantly more protocol and address control through the use of more restrictive access control lists, and anti-spoofing applied everywhere. This configuration does not contain those additional restrictions because that would detract from the CBAC example.

Figure 25 Sample Cisco IOS Firewall Application Environment

The branch office has this sample network configuration:

- Ethernet interface 0/0 supports the Human Resources department servers. This network includes an email (SMTP and POP3) host and a Windows NT server. The Windows NT server is the Primary Domain Controller (PDC) for the Human Resources domain and has a trust relationship with the rest of the company; however, it contains applications and databases that must not be accessed by the rest of the company or the other groups in the branch office. The devices on this LAN are accessible only by users in the Human Resources department on Ethernet interface 0/1. The Mail server must be able to send and receive email (through SMTP sessions) with all other devices. The Windows 95 machines can use this machine as their email server (for sending email through SMTP sessions) and as a repository for accumulating email that they can then download through POP3 sessions. No one else in the company is allowed to form POP3 sessions to any machine on this LAN.
- Ethernet interface 0/1 supports the Windows 95 computers in the Human Resources department. These users must have access to the Human Resources mail servers located on Ethernet interface 0/0 as well as access to the rest of the company. Access to the Windows NT server resources are controlled through the Windows NT permissions assigned to each user in the Windows NT domain.
- Ethernet interface 1/0 supports the branch office web servers, which can be accessed by everyone in the company. These servers use TCP ports 80 (HTTP) and 443 (SHTTP) for inbound Web access. This network also includes a backup domain controller (BDC) for the overall domain that is also used as file, print, and service server.

Ethernet interface 1/1 supports all users who are not in the Human Resources department. These users have no access to the Human Resources department servers, but they can access the other network interfaces and the serial interfaces for WAN connectivity. Serial interface 0/0 and 0/1 connect to the WAN with T1 links (links to corporate headquarters). In this sample configuration, the Domain Name System (DNS) servers are located somewhere within the rest of the company.

Additionally, network management (SNMP) and Telnet sessions are limited to the management network (192.168.55.0), which is located somewhere within the rest of the company across the serial interface.

```
! -----
! This first section contains some configuration that is not required
! for CBAC, but illustrates good security practices.
! -----
! Add this line to get timestamps on the syslog messages.
service timestamps log datetime localtime show-timezone
!
hostname Router1
!
boot system flash c3600-fw3600-1
!
! Configure AAA user authentication.
aaa new-model
aaa authentication login lista group tacacs+ enable
!
enable secret 5 <elided>
ip subnet-zero
!
! Disable source routing to help prevent spoofing.
no ip source-route
!
! Set up the domain name and server IP addresses.
ip domain-name example.com
ip name-server 192.168.55.132
ip name-server 192.168.27.32
!
! The audit-trail command enables the delivery of specific CBAC messages
! through the syslog notification process.
ip inspect audit-trail
!
! Establish the time-out values for DNS queries. When this idle-timer expires,
! the dynamic ACL entries that were created to permit the reply to a DNS request
! will be removed and any subsequent packets will be denied.
ip inspect dns-timeout 10
!
! -----
! The next section includes configuration statements required specifically for CBAC.
! -----
! Define the CBAC inspection rule "inspect1", allowing the specified protocols to be
! inspected. The first rule enables SMTP specific inspection. SMTP inspection causes
! the exchange of the SMTP session to be inspected for illegal commands. Any packets
! with illegal commands are dropped, and the SMTP session will hang and eventually
! time out.
ip inspect name inspect1 smtp timeout 30
!
! In the next two lines of inspect1, define the maximum time that each of the UDP and
! TCP sessions are allowed to continue without any traffic passing
! through the router. When these timeouts are reached, the dynamic ACLs that
! are inserted to permit the returning traffic are removed and subsequent packets
! (possibly even valid ones) will not be permitted.
ip inspect name inspect1 udp timeout 30
ip inspect name inspect1 tcp timeout 30
!
```

```

! Define the CBAC inspection rule "inspect2", allowing the specified protocols to be
! inspected. These rules are similar to those used in the inspection rule "inspect1,"
! except that on the interfaces where this rule is applied, SMTP sessions are not
! expected to go through; therefore, the SMTP rule element is not applied here.
ip inspect name inspect2 udp timeout 30
ip inspect name inspect2 tcp timeout 30
!
! -----
! The next section shows the Ethernet interface configuration statements for each
! interface, including access lists and inspections rules.
! -----
! Apply the "inspect1" inspection rule to sessions that are initiated in the outbound
! direction (toward the LAN) at Ethernet interface 0/0. All packets in these sessions
! will be inspected by CBAC. Provided that network traffic passes the Access Control
! List (ACL) restrictions, traffic is then inspected by CBAC for access through the
! Cisco Secure Integrated Software. Traffic blocked by the access list is not inspected
! by CBAC. Access list 110 is applied to outbound traffic on this interface.
interface Ethernet0/0
    description HR_Server Ethernet
    ip address 172.16.110.1 255.255.255.0

Application Firewall—Instant Message Traffic Enforcement

The Application Firewall—Instant Message Traffic Enforcement feature enables users to define and enforce a policy that specifies which instant messenger traffic types are allowed into the network. Thus, the following additional functionality can also be enforced:

- Configuration of firewall inspection rules
- Deep packet inspection of the payload, looking for services such as text chat

History for the Application Firewall—Instant Message Traffic Enforcement Feature

Release	Modification
12.4(4)T	This feature was introduced.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Restrictions for Application Firewall—Instant Message Traffic Enforcement

If an instant messenger traffic enforcement policy is configured on a Cisco IOS router with a server command, traffic destined to other services (such as Telnet, FTP, SMTP) that is running on the instant message server's IP address will also be treated as IM traffic by the Cisco IOS router. Thus, access to the other services is prevented through the Cisco IOS firewall; however, this limitation is not a problem for most IM application users who are connecting from a user's network.

Information About Application Firewall—Instant Message Traffic Enforcement

Before creating an application firewall policy for instant message traffic enforcement, you should understand the following concept:

- [What Is an Application Policy?, page 2](#)
- [Instant Messenger Application Policy Overview, page 2](#)

What Is an Application Policy?

The application firewall uses an application policy, which consists of a collection of static signatures, to detect security violations. A static signature is a collection of parameters that specify protocol conditions that must be met before an action is taken. These protocol conditions and reactions are defined by the end user via the command-line interface (CLI) to form an application policy.

Instant Messenger Application Policy Overview

Cisco IOS application firewall has been enhanced to support instant native messenger application policies. Thus, the Cisco IOS firewall can now detect and prohibit user connections to instant messenger servers for the AOL Instant Messenger (AIM), Yahoo! Messenger, and MSN Messenger instant messaging services. This functionality controls all connections for supported services, including text, voice, video, and file-transfer capabilities. The three applications can be individually denied or permitted. Each service may be individually controlled so that text-chat service is allowed, and voice, file transfer, video, and other services are restricted. This functionality augments existing Application Inspection capability to control IM application traffic that has been disguised as HTTP (web) traffic.

**Note**

If an instant messenger application is blocked, the connection will be reset and a syslog message will be generated, as appropriate.

How to Define and Apply an Application Policy to a Firewall for Inspection

This section contains the following procedures:

- [Defining an Application Policy to Permit or Deny Instant Messenger Traffic, page 3](#)
- [Applying an Instant Messenger Traffic Application Policy to a Firewall for Inspection, page 6](#)

Defining an Application Policy to Permit or Deny Instant Messenger Traffic

Use this task to create an instant messenger application firewall policy.

Prerequisites

Before defining and enabling an application policy for instant messenger traffic, you must have already properly configured your router with a Domain Name System (DNS) server IP address via the **ip domain lookup** command and the **ip name-server** command.

The IP address of the DNS server configured on the Cisco IOS router must be the same as that configured on all PCs connecting to the IM servers from behind the Cisco IOS firewall.

Note

If at least one DNS name was not specified for resolution under any of the application policies for IM protocols (AOL, Yahoo, or MSN), you do not need to configure the DNS server IP address in the Cisco IOS router.

Restrictions

Although application firewall policies are defined in global configuration mode, only one global policy for a given protocol is allowed per interface.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **appfw policy-name** *policy-name*
4. **application** *protocol*
5. **audit-trail** {on | off}
6. **server** {permit | deny} {name *string* | ip-address {*ip-address* | range *ip-address-start ip-address-end*}
7. **timeout** *seconds*
8. **service** {default | text-chat} **action** {allow [alarm] | reset [alarm] | alarm}
9. **alert** {on | off}
10. **exit**
11. **show appfw** {configuration | dns cache} [*policy policy-name*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	appfw policy-name <i>policy-name</i> Example: Router(config)# appfw policy-name my_policy	Defines an application firewall policy and enters application firewall policy configuration mode.
Step 4	application <i>protocol</i> Example: Router(cfg-appfw-policy)# application im aol	Allows you to configure inspection parameters for a given protocol. <ul style="list-style-type: none"> <i>protocol</i>— One of the following options: <ul style="list-style-type: none"> http (HTTP traffic will be inspected) im {aol yahoo msn} (Traffic for the specified instant messenger application will be inspected) This command puts the router in appfw-policy-protocol configuration mode, where “protocol” is dependent upon the specified protocol.
Step 5	audit-trail {on off} Example: Router(cfg-appfw-policy-aim)# audit-trail on	(Optional) Enables message logging for established or torn-down connections. If this command is not issued, the default value specified via the ip inspect audit-trail command will be used.
Step 6	server {permit deny} {name <i>string</i> ip-address {ip-address range ip-address-start ip-address-end} Example: Router(cfg-appfw-policy-aim)# server permit name login.cat.aol.com	Controls access to instant messenger servers. Note The server command helps the instant messenger application engine to recognize the port-hopping instant messenger traffic and to enforce the security policy for that instant messenger application; thus, if this command is not issued, the security policy cannot be enforced if IM applications use port-hopping techniques. To deploy IM traffic enforcement policies effectively, it is recommended that you issue the appropriate server command.

	Command or Action	Purpose
Step 7	<p>timeout <i>seconds</i></p> <p>Example: Router(cfg-appfw-policy-aim)# timeout 30</p>	<p>(Optional) Specifies the elapsed length of time before an inactive connection is torn down.</p> <ul style="list-style-type: none"> <i>seconds</i>—Available timeout range: 5 to 43200 (12 hours). <p>If this command is not issued, the default value specified via the ip inspect tcp idle-time command will be used.</p> <p>Note Some IM applications continue to send “keepalive-like” packets that effectively prevent timeout even when the user is idle.</p>
Step 8	<p>service {default text-chat} action {allow [alarm] reset [alarm] alarm}</p> <p>Example: Router(cfg-appfw-policy-aim)# service default action reset</p>	<p>(Optional) Specifies an action when a specific service is detected in the instant messenger traffic.</p> <ul style="list-style-type: none"> If a specific action is not specified for a service, the service default command will be performed. If the service default command is not specified for an application, the action is considered “reset” by the system.
Step 9	<p>alert {on off}</p> <p>Example: Router(cfg-appfw-policy-aim)# alert on</p>	<p>(Optional) Enables message logging when events, such as the start of a text-chat, begin.</p> <p>If this parameter is not configured, the global setting for the ip inspect alert-off command will take effect.</p>
Step 10	<p>exit</p> <p>Example: Router(cfg-appfw-policy-aim)# exit</p> <p>Example: Router(cfg-appfw-policy)# exit</p> <p>Example: Router(config)# exit</p>	<p>(Optional) Exits application firewall policy <i>protocol</i> configuration mode, application firewall policy configuration mode, and global configuration mode.</p>
Step 11	<p>show appfw {configuration dns cache} [policy <i>policy-name</i>]</p> <p>Example: Router# show appfw dns cache policy abc</p>	<p>(Optional) Displays the IP addresses that have been resolved by the DNS server and stored in the DNS cache of the IM traffic policy enforcement component of the Cisco IOS router.</p> <ul style="list-style-type: none"> If you don’t indicate a specific policy via the policy <i>policy-name</i> option, IP addresses gathered for all DNS names for all policies are displayed.

Troubleshooting Tips

Resolved IP addresses are never “timed out” and not automatically removed from the DNS cache. Thus, if you find an obsolete IP address in the instant messenger database (DNS cache), you can issue the **clear appfw dns cache** command to remove the IP address and prevent the address from being interpreted by the router as that of an IM server.

Always allow a couple of minutes for the DNS cache to populate after configuring the **server** command (with the **name string** option) in an application firewall policy for IM applications.

If you do not want the DNS resolver to send periodic queries, do not use the **server** command (with the **name string** option); instead, use the **server** command (with the **ip address** option).

If you issue the **server** command (with the **name string** option), ensure that you specify the name of every DNS server for an IM application in your policy. Always be alert to new names.

What to Do Next

After you have successfully defined an application policy for instant message traffic inspection, you must apply the policy to an inspection rule. Thereafter, the inspection rule must be applied to an interface. For information on completing this task, see the section “[Applying an Instant Messenger Traffic Application Policy to a Firewall for Inspection](#).”

Applying an Instant Messenger Traffic Application Policy to a Firewall for Inspection

Use this task to apply an IM application policy to an inspection rule, followed by applying the inspection rule to an interface.

Prerequisites

You must have already defined an application policy (as shown in the section “[Defining an Application Policy to Permit or Deny Instant Messenger Traffic](#)”).

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect name** *inspection-name* **appfw** *policy-name*
4. **interface** *type number*
5. **ip inspect** *inspection-name* {**in** | **out**}
6. **exit**
7. **exit**
8. **show appfw configuration** [*name*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name inspection-name appfw policy-name Example: Router(config)# ip inspect name firewall appfw mypolicy	Defines a set of inspection rules for the application policy. <ul style="list-style-type: none"> <i>policy-name</i>—Must match the policy name specified via the appfw policy-name command.
Step 4	interface type number Example: Router#(config)# interface FastEthernet0/0	Configures an interface type and enters interface configuration mode.
Step 5	ip inspect inspection-name {in out} Example: Router#(config-if)# ip inspect firewall in	Applies the inspection rules (defined in Step 3) to all traffic entering the specified interface. <ul style="list-style-type: none"> The <i>inspection-name</i> argument must match the inspection name defined via the ip inspect name command.
Step 6	exit Example: Router#(config-if)# exit	Exits interface configuration mode.
Step 7	exit Example: Router(config)# exit	Exits global configuration mode.
Step 8	show appfw configuration [name] Example: Router# show appfw configuration	(Optional) Displays application firewall policy configuration information.

Configuration Examples for Setting Up an Instant Messenger Traffic Inspection Engine

This section contains the following configuration example:

- [Instant Messenger Application Policy Configuration: Example, page 8](#)

Instant Messenger Application Policy Configuration: Example

The following example shows to configure application policy “my-im-policy,” which allows text-chat for Yahoo! instant messenger users and blocks instant messenger traffic for all other users:

```
appfw policy-name my-im-policy
  application http
  port-misuse im reset
!
  application im yahoo
  server permit name scs.msg.yahoo.com
  server permit name scsa.msg.yahoo.com
  server permit name scsb.msg.yahoo.com
  server permit name scsc.msg.yahoo.com
  service text-chat action allow
  service default action reset
!
  application im aol
  server deny name login.oscar.aol.com
!
  application im msn
  server deny name messenger.hotmail.com
!
ip inspect name test appfw my-im-policy

interface FastEthernet0/0
  description Inside interface
  ip inspect test in
```

The **port-misuse im** command blocks all the three IM applications going through the HTTP protocol. It is always recommended that you block IM activity through HTTP and allow IM traffic to pass, if at all, through its native port.

The **server permit** commands help to identify all the servers for Yahoo! messenger services. A connection to any one of the specified servers will be recognized by the firewall as a Yahoo! IM session—even if the Yahoo! client uses port-hopping techniques (which can be accomplished by using server port-numbers such as 25 instead of the standard 5050.)

If a **server permit** command is not issued within the **application im yahoo** command, the Cisco IOS firewall will classify only the traffic going to server port 5050 as Yahoo! messenger traffic. Because the port classification scheme breaks if any of the Yahoo! clients are configured to use a port other than 5050, it is more reliable to have **server permit** command entries instead of relying on the port classification method.

The **server deny** commands under other IM applications deny connection to respective servers. This action operates at the network layer connection level—not at the application session level. When traffic is denied, the TCP connection to the server is denied, no data traffic is allowed, and all packets are dropped in the firewall.

Cisco IOS Firewall MIB

First Published: February 27, 2006

Last Updated: February 27, 2006

The Cisco IOS Firewall MIB feature introduces support for the Cisco Unified Firewall MIB, which helps to manage and monitor firewall performance via Simple Network Management Protocol (SNMP). Statistics can be collected and monitored via standards-based SNMP techniques for firewall features such as stateful packet inspection and URL filtering.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for Cisco IOS Firewall MIB](#)” section on [page 19](#).

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Prerequisites

Before you can provide firewall connection and URL filtering statistics via SNMP, you must set up the firewall by performing the following tasks:

- Configure a firewall policy via the **ip inspect name** command.
- Enable the firewall by applying the firewall on a target via the **interface** command followed by the **ip inspect** command.
- Enable URL filtering, if applicable, via the **ip urlfilter server vendor** command.

You must also enable SNMP on the router. For more information on enabling SNMP, see the section [“Enabling SNMP for Firewall Sessions”](#) later in this document.

Restrictions for Cisco IOS Firewall MIB

- Cisco does not support all of the MIB variables that are defined in the Cisco Unified Firewall MIB. For a list of variables that are supported by this feature, see [Table 1](#), [Table 2](#), and [Table 3](#).
- MIB statistics are not provided when the firewall is configured using CPL.

Memory and Performance Impact

Depending on the number of targets that have a configured firewall and the number of configured URL filtering servers, the MIB functionality can create an adverse impact on memory. For each firewall policy that is configured on your system, more memory is required to store SNMP statistics.

The following information defines the minimum memory requirements for connection statistics only:

- Global connection statistics: approximately 64 bytes.
- Protocol-specific statistics: multiply the number of configured protocols by 56 to determine the minimum memory requirement.
- Policy-target-protocol statistics: multiply the number of configured protocols and the number of targets for which the firewall policies are configured by 48 to determine the minimum memory requirement.

The following information defines the minimum memory requirements for URL filtering statistics only:

- Global URL filtering statistics: approximately 96 bytes.
- URL filtering server-specific statistics: multiply the number of configured URL filtering servers by 40 to determine the minimum memory requirement.

Information About Cisco IOS Firewall MIB

To use Cisco IOS Firewall MIBs to monitor firewall performance, you should understand the following concepts:

- [Connection Statistics, page 3](#)
- [URL Filtering Statistics, page 4](#)

Connection Statistics

Connection statistics are a record of the firewall traffic streams that have attempted to flow through the firewall system. Connection statistics can be displayed on a global basis (that is, an aggregate of all connection statistics for the entire router), protocol-specific basis, or a firewall-policy-specific basis. The Firewall can allow, drop, or deny the connection based on firewall policies and firewall resources.

[Table 1](#) lists all supported connection statistics—global, protocol-specific¹, or firewall-policy-specific²—that are available via SNMP.

Table 1 *Connection Statistics*

Statistic Type	Connection Type	Description
<ul style="list-style-type: none"> Global Protocol-specific Firewall-policy-specific 	Aborted	Number of connections that were abnormally terminated after successful establishment
<ul style="list-style-type: none"> Global Protocol-specific Firewall-policy-specific 	Active	Number of connections that are currently active
<ul style="list-style-type: none"> Global Protocol-specific Firewall-policy-specific 	Attempted	Number of connection attempts sent to the firewall system
Global	Embryonic	Number of embryonic-application-layer connections
Global	Expired	Number of connections that were active but have since been terminated normally
<ul style="list-style-type: none"> Global Protocol-specific 	Five-Minute Connection Rate	Number of connection attempts that were established per second, averaged over the last 300 seconds
<ul style="list-style-type: none"> Global Protocol-specific Firewall-policy-specific 	Half-Open	Number of connections that are currently in the process of being established (half-open)
<ul style="list-style-type: none"> Global Protocol-specific 	One-Minute Connection Rate	Number of connection attempts that were establish per second, averaged over the last 60 seconds

1. All protocol-based statistics can be accessed with the following index—protocol, which is the protocol of interest such as ICMP, UDP, TCP, HTTP, and FTP. The protocols, which are a predefined static list, must be specified
2. All firewall-policy-specific statistics can be accessed with the following indexes: Policy, which is the name of the firewall security policy of interest. (The policy name is specified via the `ip inspect name` command.) Policy target type, which is the type of physical or virtual target that has the policy name applied to it. Currently, only include interface targets are supported.

Table 1 *Connection Statistics (continued)*

Statistic Type	Connection Type	Description
<ul style="list-style-type: none"> Global Protocol-specific Firewall-policy-specific 	Policy Declined	Number of connection attempts that were declined due to application of a firewall security policy
<ul style="list-style-type: none"> Global Protocol-specific Firewall-policy-specific 	Resource Declined	Number of connection attempts that were declined due to firewall resource constraints

URL Filtering Statistics

URL Filtering feature provides an Internet management application that allows you to control web traffic for a given host or user on the basis of a specified security policy. URL filtering statistics include the status of distinct URL filtering servers that are configured on the firewall and the impact of the performance of the URL filtering servers on the latency and throughput of the firewall.

[Table 2](#) and [Table 3](#) list all supported URL filtering statistics—on a global basis or per server—that are available via SNMP.

Table 2 *Global URL Filtering Statistics (across all servers)*

Connection Type	Description
Five minute URL Filtering Requests Declined Rate	Rate at which URL access requests were declined by the firewall via the URL filtering server or the firewall exclusive domain configuration, averaged over the last 300 seconds.
Five minute URL Filtering Requests Resource Dropped Rate	Rate at which URL access requests were dropped by the firewall due to firewall resource constraints, averaged over the last 300 seconds.
One minute URL Filtering Requests Declined Rate	Rate at which URL access requests were declined by the firewall via the URL filtering server or the firewall exclusive domain configuration, averaged over the last 60 seconds.
One minute URL Filtering Requests Resource Dropped Rate	Rate at which URL access requests were dropped by the firewall due to firewall resource constraints, averaged over the last 60 seconds.
URL Filtering Allow Mode On	Displays whether the firewall has allowed or discarded URL requests when the URL filtering server is not available. Returns a “true” statistics if the firewall allows all requested URLs to be retrieved from the remote host when the URL server is not available; returns a “false” statistic if the firewall discards all URL.
URL Filtering Allow Mode Requests Allowed	Number of URL access requests that were allowed by the firewall when the URL filtering server was not available.

Table 2 **Global URL Filtering Statistics (across all servers) (continued)**

Connection Type	Description
URL Filtering Allow Mode Requests Denied	Number of URL access requests that were denied by the firewall when the URL filtering server was not available.
URL Filtering Enabled	Displays whether or not URL filtering is enabled. Returns a “false” statistic if the firewall will not perform URL filtering, even if the system contains configuration information that pertains to other aspects of URL filtering.
URL Filtering Late Responses	Number of responses from the URL filtering server that were received after the original URL access request was dropped by the Firewall.
URL Filtering Requests Allowed	Number of URL access requests allowed by the firewall via the use of the URL filtering server or the firewall exclusive domain configuration.
URL Filtering Requests Declined	Number of URL access requests that were declined by the firewall via the URL filtering server or the firewall exclusive domain configuration.
URL Filtering Requests Processed	Number of URL access requests that were processed by the firewall.
URL Filtering Request Process Rate	Number of URL access requests that were processed per second by the firewall, averaged over the last 300 seconds.
URL Filtering Requests Resource Dropped	Number of incoming URL access requests that were dropped by the Firewall due to firewall resource constraints.
URL Filtering Responses Resource Dropped	Number of responses to URL access requests from remote hosts that were dropped by the firewall due to resource constraints while the firewall was waiting for a response from the URL filtering server.
URL Filtering Server Timeouts	Number of times the firewall did not receive a response from the URL Filtering server.

Table 3 *Per server URL Filtering Statistics*

Connection Type	Description
URL Filtering Protocol Version	Version of the transport protocol that is used by the firewall to communicate with the URL filtering server. For TCP, valid version values are 1 and 4. For UDP, 1 is the only valid version.
URL Filtering Server Late Responses	Number of URL access responses received by the firewall from the URL filtering server after the original URL access request was dropped by the firewall.
URL Filtering Server Requests	Number of URL access requests forwarded by the firewall to the URL filtering server.
URL Filtering Server Requests Allowed	Number of URL access requests allowed by the URL filtering server. The count does not include late responses.
URL Filtering Server Requests Declined	Number of URL access requests declined by the URL filtering server. The count does not include late responses.
URL Filtering Server Responses	Number of URL access responses received by the firewall from the URL filtering server. The count does not include late responses.
URL Filtering Server Response Time Rate	Average round-trip response time of the URL filtering server, averaged over the last 300 seconds. A value of zero indicates that there was insufficient data to compute this value over the last time interval.
URL Filtering Server Status	Status of the URL filtering server: ONLINE or OFFLINE.
URL Filtering Server Timeouts	Number of times the URL filtering server failed to respond to URL access requests sent by the firewall.
URL Filtering Server Transport Protocol	Transport protocol that is used by the firewall to communicate with the URL filtering server. The protocol will be TCP, UDP, or DEFAULT. DEFAULT is used in implementations that do not explicitly specify a transport protocol.
URL Filtering Server Vendor	Vendor who provided the URL filtering server. Currently only Websense and N2H2 servers are supported.

A URL filtering server is identified by the following items, which also form the indexes into the URL filtering server statistics table:

- URL Filtering Server Address Type—Type of IP address of the URL filtering server. For example, IPv4 or IPv6.
- URL Filtering Server Address—IP address of the URL filtering server.

- URL Filtering Server Port—Port number that the URL filtering server uses to receive filtering requests.

How to Use Firewall MIBs

This section contains the following task:

- [Enabling SNMP for Firewall Sessions, page 7](#)
- [Verifying Firewall Connection and URL Filtering Statistics, page 8](#)

Enabling SNMP for Firewall Sessions

Use this task to enable SNMP for firewall-related session management.

Prerequisites

Before you can begin monitoring firewall performance via SNMP, you must set up the firewall by performing the following tasks:

- Configure a firewall policy via the **ip inspect name** command.

Note Statistics are collected only for protocols that are specified via the **ip inspect name** command.

- Enable the firewall by applying the firewall on a target via the **interface** command followed by the **ip inspect** command.
- Enable URL filtering, if applicable, via the **ip urlfilter server vendor** command.

Firewall MIB Traps

To receive firewall MIB traps, you need a management station, and you must enable the **snmp-server enable trap firewall serverstatuschange** command (as shown in the configuration task table below).

Output for the SNMP trap fields, which are displayed on the management station, are as follows:

- Server IP Address Type (IPv4 or IPv6)
- Server IP Address Type Length. (4 for IPv4 and 16 for IPv6)
- Server IP Address
- Server Port

Note

Only IPv4 is currently supported.

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **snmp-server community** *string*
4. **snmp-server host** *hostname community-string*
5. **snmp-server enable traps firewall** [serverstatuschange]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	snmp-server community <i>string</i> Example: Router(config)# snmp-server community public	Sets up the community access string to permit access to the SNMP.
Step 4	snmp-server host <i>hostname community-string</i> Example: Router(config)# snmp-server host 192.168.1.1 version 2c public	Specifies the recipient of the firewall-related SNMP notifications.
Step 5	snmp-server enable traps firewall [serverstatuschange] Example: Router(config)# snmp-server enable traps firewall serverstatuschange	Enables firewall-related SNMP notifications.

What to Do Next

After the firewall and SNMP have been properly enabled, statistics will begin to accumulate after the traffic flow starts. To verify whether statistics are being collected and view MIB counters, you can perform at least one of the steps in the task “[Verifying Firewall Connection and URL Filtering Statistics](#).”

Verifying Firewall Connection and URL Filtering Statistics

Use this task to verify firewall connection and URL filtering statistics via command-line interface (CLI). (These statistics can also be collected via any SNMP-capable client.)

Note

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

SUMMARY STEPS

1. **enable**
2. **show ip inspect mib connection-statistics** {global | l4-protocol {all | icmp | tcp | udp} | l7-protocol {all | other | telnet | ftp} | policy *policy-name* target *target name* {l4-protocol {all | icmp | tcp | udp} | l7-protocol {all | other | telnet | ftp}}}
3. **show ip urlfilter** [mib] statistics {global | server {ip-address [port] | all}}
4. **debug ip inspect mib** {object-creation | object-deletion | events | retrieval | update}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show ip inspect mib connection-statistics {global l4-protocol {all icmp tcp udp} l7-protocol {all other telnet ftp} policy <i>policy-name</i> target <i>target name</i> {l4-protocol {all icmp tcp udp} l7-protocol {all other telnet ftp}}} Example: Router# show ip inspect mib connection-statistics global	Displays firewall performance summary statistics that are monitored via SNMP. <ul style="list-style-type: none"> • global—Provides global connection statistics. • l4-protocol—Provides Layer 4 statistics for a specified protocol. • l7-protocol—Provides Layer 7 statistics for a specified protocol. • policy <i>policy-name</i> target <i>target-name</i>—Provides statistics on a per-policy target basis. For example, per firewall policy name and the interface on which the firewall is configured.
Step 3	show ip urlfilter [mib] statistics [{global server {ip-address [port] all}}] Example: Router# show ip urlfilter mib statistics global	Displays URL filtering statistics for firewall-related MIB events.
Step 4	debug ip inspect mib {object-creation object-deletion events retrieval update} Example: Router# debug ip inspect mib events	Displays messages about firewall MIB events.

Troubleshooting Tips

All statistics are accumulated since the last reboot of the firewall system. Thus, you must reboot the system to clear MIB connection statistics from your system.

Configuration Examples for Cisco IOS Firewall MIB Monitoring

This section contains the following examples:

- [Sample Cisco IOS Firewall Configuration: Example, page 10](#)
- [Sample URL Filtering Configuration: Example, page 12](#)
- [show ip inspect mib Output: Examples, page 14](#)
- [show ip urlfilter mib statistics command output: Examples, page 15](#)

Sample Cisco IOS Firewall Configuration: Example

The following output from the show running-config command shows how to configure a Cisco IOS Firewall:

```
Router# show running-config

- **show ip inspect**
- **show ip urlfilter statistics**
- **snmp-server enable traps firewall**

Feature Information for Cisco IOS Firewall MIB

Table 4 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Cisco IOS software images are specific to a Cisco IOS software release, a feature set, and a platform. Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

**Note**

Table 4 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 4 Feature Information for Cisco IOS Firewall MIB

Feature Name	Releases	Feature Information
Cisco IOS Firewall MIB	12.4(6)T	Introduces support for the Cisco Unified Firewall MIB, which helps to manage and monitor firewall performance via SNMP. Statistics can be collected and monitored via standards-based SNMP techniques for firewall features such as stateful packet inspection and URL filtering.

Cisco IOS Firewall Performance Improvements

Feature History

Release	Modification
12.2(8)T	This feature was introduced.

This document describes the Cisco IOS Firewall Performance Improvements feature in Cisco IOS Release 12.2(8)T. It includes the following sections:

- [Feature Overview, page 1](#)
- [Supported Platforms, page 3](#)
- [Supported Standards, MIBs, and RFCs, page 4](#)
- [Configuration Tasks, page 5](#)
- [Configuration Examples, page 5](#)
- [Command Reference, page 6](#)

Feature Overview

The Cisco IOS Firewall Performance Improvements feature introduces three performance metrics for Context-Based Access Control (CBAC)—[Throughput Improvement](#), [Connections Per Second Improvement](#), and [CPU Utilization Improvement](#).

CBAC is a context-based firewall that performs the following:

- Inspects traffic in one direction for network, transport, and application layer information
- Extracts relevant port information
- Dynamically creates access list entries for return traffic
- Closes ports at the end of a connection

CBAC also forces protocol conformance for some protocols, has a limited vulnerability signature detection mechanism, and extensive denial-of-service (DOS) prevention mechanisms. However, many of these features are CPU intensive, thereby, adversely affecting the performance of the router. The router is also affected during times of heavy traffic due to the processing of the base engine itself. With this feature, the performance of the router running CBAC is no longer subdued.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

Throughput Improvement

Throughput is a metric defined by the number of packets transferred from the input interface to the output interface within 1 second by a router running CBAC. When the CBAC base engine inspects packets that belong to an existing session, it must find out which session the packet belongs to; thus, the base engine implements a hash table to search for the session of the packet.

Collisions in a hash table result in poor hash function distribution because many entries are hashed into the same bucket for certain patterns of addresses. Even if a hash function distribution evenly dispenses the input across all of the buckets, a small hashtable size will not scale well if there are a large number of sessions. As the number of sessions increase, the collisions increase, which increases the length of the linked lists, thereby, deteriorating the throughput performance.

The Cisco IOS Firewall Performance Improvements feature allows users to dynamically change the size of the session hash table without reloading the router by using the **ip inspect hashtable** command. By increasing the size of the hash table, the number of sessions per hash bucket can be reduced, which improves the throughput performance of the base engine.

Connections Per Second Improvement

Connections per second is a metric defined by the number of short-lived connections that can be created and deleted within 1 second by a router running CBAC. (These connections apply only to TCP connections because UDP is a connectionless protocol.)

Initially, CBAC had several restrictions that limited the connections per second metric. While a packet was being processed for connection setup and connection teardown of TCP connections, the base engine (which allocates and de-allocates memory while processing packets) would “bump up” several packets to the process switching path. Bumping up these packets drastically slowed down their processing. Also, the base engine had to process each packet again when it was bumped up into the process switching path, which also contributed to the degrading performance.

The Cisco IOS Firewall Performance Improvements feature prevents these restrictions by allowing only the first packet of any connection to be bumped up to the process switching path while the remaining packets are processed by the base engine in the fast path. Thus, the base engine is no longer slowed down by bumping up several packets or by processing packets twice.

**Note**

In this document, a connection is defined as creating a session, sending a data packet, and immediately deleting a session.

CPU Utilization Improvement

The CPU utilization of the router running CBAC can be measured while a specific throughput or connections per second metric is maintained. This improvement is used in conjunction with the throughput and connections per second metrics.

Benefits

Layer 4 Processing Performance Improvement

This enhancement improves the connections per second metric and the CPU utilization. The code path for connection initiation and teardown was rewritten, thereby, enabling quicker creation of the connections per second metric, which reduces CPU utilization per connection.

Hash Table Function Performance Improvement

With this enhancement, the hash function has been rewritten to ensure better distribution. This newly improved feature allows users to dynamically configure the size of the session hash table from 1K to 8K. When a packet belonging to an existing session comes into the router, a hash table is used to map the packet to an existing firewall session. As the number of sessions increases, the number of sessions hashing into the same bucket increases if the size of the hash table is fixed. By allowing the user to change the size of the hash table when the number of concurrent sessions increases or to reduce the search time for the session, the throughput performance of the base engine is greatly improved.

Application Module Tuning Performance Improvement

This enhancement makes changes to application modules, ensuring that only the connection-initiating packet from all the packets belonging to the connection initiation and teardown is bumped up to the process switching path. Thus, the connections per second metric is significantly improved.

Restrictions

To benefit from the performance enhancements, your router must be running CBAC.

Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that support specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to quickly determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at <http://www.cisco.com/register>.

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

Supported Standards, MIBs, and RFCs

Standards

None

MIBs

None

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

RFCs

None

Configuration Tasks

See the following sections for configuration tasks for the Cisco IOS Firewall Performance Improvements feature. Each task in the list is identified as either required or optional.

- [Changing the Size of the Hash Table](#) (required)
- [Verifying CBAC Configurations](#) (optional)

Changing the Size of the Hash Table

You can increase the hash table to improve packet distribution. To change the size of the session hash table, use the following command in global configuration mode:

Command	Purpose
Router# ip inspect hashtable <i>number</i>	<p>Changes the size of the hash table.</p> <p><i>number</i> specifies the size of the hash table in terms of buckets. Possible values for the hash table are 1024, 2048, 4096, and 8192; the default value is 1024.</p> <p>Note You should increase the hash table size when the total number of sessions running through the CBAC router is approximately twice the current hash size; decrease the hash table size when the total number of sessions is reduced to approximately half the current hash size. Essentially, try to maintain a 1:1 ratio between the number of sessions and the size of the hash table.</p>

Verifying CBAC Configurations

To verify all CBAC configurations and all existing sessions that are currently being tracked and inspected by CBAC, use the **show ip inspect all** command in EXEC mode.

Configuration Examples

This section provides the following configuration example:

- [Changing the Size of the Hash Table Example](#)

Changing the Size of the Hash Table Example

The following example shows how to change the size of the hash table to 2048 buckets:

```
ip inspect hashtable 2048
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **ip inspect hashtable**

Cisco IOS Firewall—SIP Enhancements: ALG and AIC

First Published: April 14, 2008

Last Updated: July 11, 2008

Enhanced Session Initiation Protocol (SIP) inspection in the Cisco IOS firewall provides basic SIP inspect functionality (SIP packet inspection and pinholes opening) as well as protocol conformance and application security. These enhancements give the user a more control than in previous releases on what policies and security checks to apply to SIP traffic and the capability to filter out unwanted messages or users.

The development of additional SIP functionality in Cisco IOS provides increased support for Cisco Call Manager (CCM), Cisco Call Manager Express (CCME), and Cisco IP-IP Gateway based voice/video systems. Application Layer Gateway (ALG), and Application Inspection and Control (AIC) SIP enhancements also support RFC 3261 and its extensions.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Cisco IOS Firewall—SIP Enhancements: ALG and AIC” section on page 21](#).

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Cisco IOS Firewall—SIP Enhancements: ALG and AIC

The following prerequisites apply to the configuration of Cisco IOS Firewall—SIP Enhancements: ALG and AIC.

Hardware Requirements

- A platform, which can be any of the following:
 - Cisco 861, Cisco 881, or Cisco 881G routers
 - Cisco 1700 routers
 - Cisco 1800 routers
 - Cisco 2600 routers
 - Cisco 2800 routers

Software Requirements

- Cisco IOS Release 12.4(15)XZ or a later release.

Restrictions for Cisco IOS Firewall—SIP Enhancements: ALG and AIC

DNS Name Resolution

Although SIP methods can have Domain Name System (DNS) names instead of raw IP addresses, this feature currently does not support DNS names.

Earlier Releases of Cisco IOS

Some Cisco IOS releases earlier than Release 12.4(15)XZ may accept the configuration commands for SIP that are shown in this document; however, those earlier versions will not function properly.

Information About Cisco IOS Firewall—SIP Enhancements: ALG and AIC

To configure the Cisco IOS Firewall—SIP Enhancements: ALG and AIC feature, you must understand the following concepts:

- [Firewall and SIP Overviews, page 3](#)
- [Firewall for SIP Functionality Description, page 3](#)
- [SIP Inspection, page 4](#)

Firewall and SIP Overviews

Cisco IOS Firewall

The Cisco IOS firewall extends the concept of static access control lists (ACLs) by introducing dynamic ACL entries that open on the basis of the necessary application ports on a specific application and close these ports at the end of the application session. The Cisco IOS firewall achieves this functionality by inspecting the application data, checking for conformance of the application protocol, extracting the relevant port information to create the dynamic ACL entries, and closing these ports at the end of the session. The Cisco IOS firewall is designed to easily allow a new application inspection whenever support is needed.

Session Initiation Protocol

SIP is an application-layer control (signaling) protocol for creating, modifying, and terminating sessions with one or more participants. These sessions could include Internet telephone calls, multimedia distribution, and multimedia conferences. SIP is based on an HTTP-like request/response transaction model. Each transaction consists of a request that invokes a particular method or function on the server and at least one response.

SIP invitations used to create sessions carry session descriptions that allow participants to agree on a set of compatible media types. SIP makes use of elements called proxy servers to help route requests to the user's current location, authenticate and authorize users for services, implement provider call-routing policies, and provide features to users. SIP also provides a registration function that allows users to upload their current locations for use by proxy servers. SIP runs on top of several different transport protocols.

Firewall for SIP Functionality Description

The firewall for SIP support feature allows SIP signaling requests to traverse directly between gateways or through a series of proxies to the destination gateway or phone. After the initial request, if the Record-Route header field is not used, subsequent requests can traverse directly to the destination gateway address as specified in the Contact header field. Thus, the Cisco IOS firewall is aware of all surrounding proxies and gateways and allows the following functionality:

- SIP signaling responses can travel the same path as SIP signaling requests.
- Subsequent signaling requests can travel directly to the endpoint (destination gateway).
- Media endpoints can exchange data between each other.

SIP UDP and TCP Support

RFC 3261 is the current RFC for SIP, which replaces RFC 2543. This feature supports the SIP User Datagram Protocol (UDP) and the TCP format for signaling.

SIP Inspection

This section describes the deployment scenarios supported by the Cisco IOS Firewall—SIP, ALG, and AIC Enhancements feature.

Cisco IOS Firewall Between SIP Phones and CCM

The Cisco IOS firewall is located between CCM or CCME and SIP phones. SIP phones are registered to CCM or CCME through the firewall, and any SIP calls from or to the SIP phones pass through the firewall.

Cisco IOS Firewall Between SIP Gateways

The Cisco IOS firewall is located between two SIP gateways, which can be CCM, CCME, or a SIP proxy. Phones are registered with SIP gateways directly. The firewall sees the SIP session or traffic only when there is a SIP call between phones registered to different SIP gateways. In some scenarios an IP-IP gateway can also be configured on the same device as the firewall. With this scenario all the calls between the SIP gateways are terminated in the IP-IP gateway.

Cisco IOS Firewall with Local CCME and Remote CCME/CCCM

The Cisco IOS firewall is located between two SIP gateways, which can be CCM, CCME, or a SIP proxy. One of the gateways is configured on the same device as the firewall. All the phones registered to this gateway are locally inspected by the firewall. The firewall also inspects SIP sessions between the two gateways when there is a SIP call between them. With this scenario the firewall locally inspects SIP phones on one side and SIP gateways on the other side.

Cisco IOS Firewall with Local CCME

The Cisco IOS firewall and CCME is configured on the same device. All the phones registered to the CCME are locally inspected by the firewall. Any SIP call between any of the phones registered will also be inspected by the Cisco IOS firewall.

How to Configure Cisco IOS Firewall—SIP Enhancements: ALG and AIC

Perform the following tasks to configure Cisco IOS Firewall—SIP Enhancements: ALG and AIC:

- [Configuring a Policy to Allow RFC 3261 Methods, page 5](#)
- [Configuring a Policy to Block Messages, page 7](#)
- [Configuring a 403 Response Alarm, page 9](#)
- [Limiting Application Messages, page 11](#)
- [Limiting Application Messages for a Particular Proxy, page 13](#)

Configuring a Policy to Allow RFC 3261 Methods

To configure a policy to allow basic RFC 3261 methods and block extension methods, perform the steps in this section.

Note

The Cisco IOS Firewall—SIP Enhancements: ALG and AIC feature provides essential support for the new SIP methods such as UPDATE and PRACK, as CCM 5.x and CCME 4.x also use these methods.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **class-map type inspect** *protocol-name* **match-any** *class-map-name*
4. **match request method** *method-name*
5. **exit**
6. **class-map type inspect** *protocol-name* **match-any** *class-map-name*
7. **match request method** *method-name*
8. **exit**
9. **policy-map type inspect** *protocol-name* *policy-map-name*
10. **class type inspect** *protocol-name* *class-map-name*
11. **allow**
12. **exit**
13. **class type inspect** *protocol-name* *class-map-name*
14. **reset**
15. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	class-map type inspect <i>protocol-name</i> match-any <i>class-map-name</i> Example: Router(config)# class-map type inspect sip match-any sip_class1	Creates an inspect type class map and enters class-map configuration mode.

	Command or Action	Purpose
Step 4	match request method <i>method-name</i> Example: Router(config-cmap)# match request method invite	Matches RFC 3261 methods. Methods include the following: <ul style="list-style-type: none"> ack, bye, cancel, info, invite, message, notify, options, prack, refer, register, subscribe, update.
Step 5	exit Example: Router(config-cmap)# exit	Exits class-map configuration mode.
Step 6	class-map type inspect <i>protocol-name</i> match-any <i>class-map-name</i> Example: Router(config)# class-map type inspect sip match-any sip_class2	Creates an inspect type class map and enters class-map configuration mode.
Step 7	match request method <i>method-name</i> Example: Router(config-cmap)# match request method message	Matches RFC 3261 methods, which include the following: <ul style="list-style-type: none"> ack, bye, cancel, info, invite, message, notify, options, prack, refer, register, subscribe, update.
Step 8	exit Example: Router(config-cmap)# exit	Exits class-map configuration mode.
Step 9	policy-map type inspect <i>protocol-name</i> <i>policy-map-name</i> Example: Router(config)# policy-map type inspect sip sip_policy	Creates an inspect type policy map and enters policy-map configuration mode.
Step 10	class type inspect <i>protocol-name</i> <i>class-map-name</i> Example: Router(config-pmap)# class type inspect sip sip_class1	Specifies the class on which the action is performed and enters policy-map-class configuration mode.
Step 11	allow Example: Router(config-pmap-c)# allow	Allows SIP inspection.
Step 12	exit Example: Router(config-pmap-c)# exit	Exits policy-map-class configuration mode.

	Command or Action	Purpose
Step 13	class type inspect <i>protocol-name class-map-name</i> Example: Router(config-pmap)# class type inspect sip sip_class2	Specifies the class on which the action is performed and enters policy-map-class configuration mode.
Step 14	reset Example: Router(config-pmap-c)# reset	Resets the class map.
Step 15	exit Example: Router(config-pmap-c)# exit	Exits policy-map-class configuration mode.

Configuring a Policy to Block Messages

To configure a policy to block SIP messages coming from a particular proxy device, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **parameter-map type regex** *parameter-map-name*
4. **pattern** *url-pattern*
5. **exit**
6. **class-map type inspect** *protocol-name class-map-name*
7. **match request header** *field* **regex** *regex-parameter-map*
8. **exit**
9. **policy-map type inspect** *protocol-name policy-map-name*
10. **class type inspect** *protocol-name class-map-name*
11. **reset**
12. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	parameter-map type regex <i>parameter-map-name</i> Example: Router(config)# parameter-map type regex unsecure_proxy	Configures a parameter-map type to match a specific traffic pattern and enters profile configuration mode.
Step 4	pattern url-pattern Example: Router(config-profile)# pattern "compromised.server.com"	Matches a call based on the SIP uniform resource identifier (URI).
Step 5	exit Example: Router(config-profile)# exit	Exits profile configuration mode.
Step 6	class-map type inspect <i>protocol-name</i> <i>class-map-name</i> Example: Router(config)# class-map type inspect sip sip_class	Creates an inspect type class map and enters class-map configuration mode.
Step 7	match request header <i>field</i> regex <i>regex-param-map</i> Example: Router(config-cmap)# match request header Via regex unsecure_proxy	Configures a class-map type to match a specific request header pattern.
Step 8	exit Example: Router(config-cmap)# exit	Exits class-map configuration mode.
Step 9	policy-map type inspect <i>protocol-name</i> <i>policy-map-name</i> Example: Router(config)# policy-map type inspect sip sip_policy	Creates an inspect type policy map and enters policy-map configuration mode.

	Command or Action	Purpose
Step 10	class type inspect <i>protocol-name class-map-name</i> Example: Router(config-pmap)# class type inspect sip sip_class	Specifies the class on which the action is performed and enters policy-map-class configuration mode.
Step 11	reset Example: Router(config-pmap-c)# reset	Resets the class map.
Step 12	exit Example: Router(config-pmap-c)# exit	Exits policy-map-class configuration mode.

Configuring a 403 Response Alarm

To configure a policy to generate an alarm whenever a 403 response is returned, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **parameter-map type regex** *parameter-map-name*
4. **pattern** *url-pattern*
5. **exit**
6. **class-map type inspect** *protocol-name class-map-name*
7. **match response status regex** *regex-parameter-map*
8. **exit**
9. **policy-map type inspect** *protocol-name policy-map-name*
10. **class type inspect** *protocol-name class-map-name*
11. **log**
12. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	parameter-map type regex <i>parameter-map-name</i> Example: Router(config)# parameter-map type regex allowed_im_users	Configures a parameter-map type to match a specific traffic pattern and enters profile configuration mode.
Step 4	pattern <i>url-pattern</i> Example: Router(config-profile)# pattern "+403"	Matches a call based on the SIP URI.
Step 5	exit Example: Router(config-profile)# exit	Exits profile configuration mode.
Step 6	class-map type inspect <i>protocol-name</i> <i>class-map-name</i> Example: Router(config)# class-map type inspect sip sip_class	Creates an inspect type class map and enters class-map configuration mode.
Step 7	match response status regex <i>regex-parameter-map</i> Example: Router(config-cmap)# match response status regex allowed_im_users	Configures a class-map type to match a specific response pattern.
Step 8	exit Example: Router(config-cmap)# exit	Exits class-map configuration mode.
Step 9	policy-map type inspect <i>protocol-name</i> <i>policy-map-name</i> Example: Router(config)# policy-map type inspect sip sip_policy	Creates an inspect type policy map and enters policy-map configuration mode.

	Command or Action	Purpose
Step 10	class type inspect <i>protocol-name class-map-name</i> Example: Router(config-pmap)# class type inspect sip sip_class	Specifies the class on which the action is performed and enters policy-map-class configuration mode.
Step 11	log Example: Router(config-pmap-c) # log	Generates a log of messages.
Step 12	exit Example: Router(config)# exit	Exits policy-map-class configuration mode.

Limiting Application Messages

To configure a policy to rate-limit INVITE messages, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **class-map type inspect** *protocol-name match-any class-map-name*
4. **match request method** *method-name*
5. **exit**
6. **policy-map type inspect** *protocol-name policy-map-name*
7. **class type inspect** *protocol-name class-map-name*
8. **rate-limit** *limit-number*
9. **exit**
10. **class-map type inspect** *protocol-name match-any class-map-name*
11. **match protocol** *protocol-name*
12. **exit**
13. **policy-map type inspect** *protocol-name policy-map-name*
14. **class type inspect** *protocol-name class-map-name*
15. **inspect**
16. **service-policy** *policy-map-name*
17. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	class-map type inspect protocol-name match-any class-map-name Example: Router(config)# class-map type inspect sip match-any class_2	Creates an inspect type class map and enters class-map configuration mode.
Step 4	match request method method-name Example: Router(config-cmap)# match request method invite	Matches RFC 3261 methods. Methods include the following: <ul style="list-style-type: none"> ack, bye, cancel, info, invite, message, notify, options, prack, refer, register, subscribe, update.
Step 5	exit Example: Router(config-cmap)# exit	Exits class-map configuration mode.
Step 6	policy-map type inspect protocol-name policy-map-name Example: Router(config)# policy-map type inspect sip policy_2	Creates an inspect type policy map and enters policy-map configuration mode.
Step 7	class type inspect protocol-name class-map-name Example: Router(config-pmap)# class type inspect sip class_2	Specifies the class on which the action is performed and enters policy-map-class configuration mode.
Step 8	rate-limit limit-number Example: Router(config-pmap-c)# rate-limit 16	Limits the number of SIP messages that strike the Cisco IOS firewall every second.
Step 9	exit Example: Router(config-pmap-c)# exit	Exits policy-map-class configuration mode.

	Command or Action	Purpose
Step 10	class-map type inspect <i>protocol-name</i> match-any <i>class-map-name</i> Example: Router(config)# class-map type inspect sip match-any class_1	Creates an inspect type class map and enters class-map configuration mode.
Step 11	match protocol <i>protocol-name</i> Example: Router(config-cmap)# match protocol sip	Configures the match criterion for a class map on the basis of the specified protocol.
Step 12	exit Example: Router(config-cmap)# exit	Exits class-map configuration mode.
Step 13	policy-map type inspect <i>protocol-name</i> <i>policy-map-name</i> Example: Router(config)# policy-map type inspect sip policy_1	Creates an inspect type policy map and enters policy-map configuration mode.
Step 14	class type inspect <i>protocol-name</i> <i>class-map-name</i> Example: Router(config-pmap)# class type inspect sip class_1	Specifies the class on which the action is performed and enters policy-map-class configuration mode.
Step 15	inspect Example: Router(config-pmap-c)# inspect	Enables stateful packet inspection.
Step 16	service-policy <i>policy-map-name</i> Example: Router(config-pmap-c)# service-policy policy_2	Attaches the policy map to the service policy for the interface or virtual circuit.
Step 17	exit Example: Router(config-pmap-c)# exit	Exits policy-map-class configuration mode.

Limiting Application Messages for a Particular Proxy

To configure a policy to rate-limit INVITE messages coming for a particular proxy, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **parameter-map type regex** *parameter-map-name*
4. **pattern** *url-pattern*
5. **exit**
6. **class-map type inspect** *protocol-name* **match-any** *class-map-name*
7. **match request method** *method-name*
8. **match request header field regex** *regex-parameter-map*
9. **exit**
10. **policy-map type inspect** *protocol-name* *policy-map-name*
11. **class type inspect** *protocol-name* *class-map-name*
12. **rate-limit** *limit-number*
13. **exit**
14. **class-map type inspect** *protocol-name* **match-any** *class-map-name*
15. **match protocol** *protocol-name*
16. **exit**
17. **policy-map type inspect** *protocol-name* *policy-map-name*
18. **class type inspect** *protocol-name* *class-map-name*
19. **inspect**
20. **service-policy** *policy-map-name*
21. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example: Router> enable	<ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	
Step 3	parameter-map type regex <i>parameter-map-name</i>	Configures a parameter-map type to match a specific traffic pattern and enters profile configuration mode.
	Example: Router(config)# parameter-map type regex rate_limited_proxy	

	Command or Action	Purpose
Step 4	pattern <i>url-pattern</i> Example: Router(config-profile)# pattern "compromised.server.com"	Matches a call based on the SIP URI.
Step 5	exit Example: Router(config-cmap)# exit	Exits profile configuration mode.
Step 6	class-map type inspect <i>protocol-name</i> match-any <i>class-map-name</i> Example: Router(config)# class-map type inspect sip match-all class_2	Creates an inspect type class map and enters class-map configuration mode.
Step 7	match request method <i>method-name</i> Example: Router(config-cmap)# match request method invite	Matches RFC 3261 methods. Methods include the following: <ul style="list-style-type: none"> ack, bye, cancel, info, invite, message, notify, options, prack, refer, register, subscribe, update.
Step 8	match request header <i>field</i> regex <i>regex-param-map</i> Example: Router(config-cmap)# match request header Via regex rate_limited_proxy	Configures a class-map type to match a specific request header pattern.
Step 9	exit Example: Router(config-cmap)# exit	Exits class-map configuration mode.
Step 10	policy-map type inspect <i>protocol-name</i> <i>policy-map-name</i> Example: Router(config)# policy-map type inspect sip policy_2	Creates an inspect type policy map and enters policy-map configuration mode.
Step 11	class type inspect <i>protocol-name</i> <i>class-map-name</i> Example: Router(config-pmap)# class type inspect sip class_2	Specifies the class on which the action is performed and enters policy-map-class configuration mode.
Step 12	rate-limit <i>limit-number</i> Example: Router(config-pmap-c)# rate-limit 16	Limits the number of SIP messages that strike the Cisco IOS firewall every second.

	Command or Action	Purpose
Step 13	exit Example: Router(config-pmap-c)# exit	Exits policy-map-class configuration mode.
Step 14	class-map type inspect <i>protocol-name</i> match-any <i>class-map-name</i> Example: Router(config)# class-map type inspect sip match-any class_1	Creates an inspect type class map and enters class-map configuration mode.
Step 15	match protocol <i>protocol-name</i> Example: Router(config-cmap)# match protocol sip	Configures the match criterion for a class map on the basis of the specified protocol.
Step 16	exit Example: Router(config-cmap)# exit	Exits class-map configuration mode.
Step 17	policy-map type inspect <i>protocol-name</i> <i>policy-map-name</i> Example: Router(config)# policy-map type inspect sip policy_1	Creates an inspect type policy map and enters policy-map configuration mode.
Step 18	class type inspect <i>protocol-name</i> <i>class-map-name</i> Example: Router(config-pmap)# class type inspect sip class_1	Specifies the class on which the action is performed and enters policy-map-class configuration mode.
Step 19	inspect Example: Router(config-pmap-c)# inspect	Enables stateful packet inspection.
Step 20	service-policy <i>policy-map-name</i> Example: Router(config-pmap-c)# service-policy policy_2	Attaches the policy map to the service policy for the interface or virtual circuit.
Step 21	exit Example: Router(config-pmap-c)# exit	Exits policy-map-class configuration mode.

Troubleshooting Tips

The following commands can be used to troubleshoot Cisco IOS Firewall—SIP Enhancements: ALG and AIC:

- **clear zone-pair**
- **debug cce**
- **debug ip inspect**
- **debug policy-map type inspect**
- **show policy-map type inspect zone-pair**
- **show zone-pair security**

Note

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

Examples

show policy-map type inspect zone-pair

The following example shows sample output of the **show policy-map type inspect zone-pair** command when the **session** keyword is used.

```
Router# show policy-map type inspect zone-pair session
```

```
policy exists on zp zp_test_out_self
Zone-pair: zp_test_out_self
Service-policy inspect : test
Class-map: c_sip (match-any)
...
Number of Established Sessions = 2
Established Sessions
Session 6717A7A0 (192.168.105.118:62265)=>(192.168.105.2:5060) sip:udp SIS_OPEN

```

show zone-pair security

The following example shows sample output of the **show zone-pair security** command.

```
Router# show zone-pair security
```

```

Zone-pair name zp_in_out
Source-Zone inside Destination-Zone outside
service-policy test
Zone-pair name zp_in_self
Source-Zone inside Destination-Zone self
service-policy test
Zone-pair name zp_self_out
Source-Zone self Destination-Zone outside
service-policy test

```

Configuration Examples for Cisco IOS Firewall—SIP Enhancements: ALG and AIC

This section contains the following example:

- [Firewall and SIP Configuration: Example, page 18](#)

Firewall and SIP Configuration: Example

The following example shows how to configure the Cisco IOS Firewall—SIP Enhancements: ALG and AIC feature when the Cisco IOS firewall is located between two SIP gateways (CCM or CCME), as described in the [Cisco IOS Firewall Between SIP Gateways, page 4](#). Some phones are registered to the CCME inside the firewall (inside zone). Other phones are registered to another CCME / CCM outside the firewall (outside zone). Cisco IOS firewall is configured for SIP inspection when there is no IP-IP gateway configured on the firewall device.

```

class-map type inspect sip match-any sip-aic-class
match request method invite
policy-map type inspect sip sip-aic-policy
class type inspect sip sip-aic-class
rate-limit 15
!
policy-map type inspect sip-policy
class type inspect sip-traffic-class
service-policy sip sip-aic-policy
!
class-map type inspect match-any sip-traffic-class
match protocol sip
!

```

```

policy-map type inspect sip-policy
class type inspect sip-traffic-class
inspect my-parameters
!
zone security inside
zone security outside
!
interface fastethernet 0
zone-member security inside
interface fastethernet 1
zone-member security outside
!
zone-pair security in-out source inside destination outside
service-policy type inspect sip-policy
!
zone-pair security in-self source inside destination self
service-policy type inspect sip-policy

```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, use the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or a Cisco IOS master commands list.

- **class-map type inspect**
- **match protocol**
- **match protocol-violation**
- **match req-resp**
- **match request**
- **match response**
- **policy-map type inspect**
- **rate-limit (firewall)**

Feature Information for Cisco IOS Firewall—SIP Enhancements: ALG and AIC

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for Cisco IOS Firewall—SIP Enhancements: ALG and AIC

Feature Name	Releases	Feature Information
Cisco IOS Firewall—SIP Enhancements: ALG and AIC	12.4(15)XZ 12.4(20)T	<p>This feature provides voice security enhancements within the Firewall feature set in Cisco IOS software for Release 12.4(15)XZ and later releases.</p> <p>In Release 12.4(15)XZ, this feature was introduced on the Cisco 861, Cisco 881, and Cisco 881G routers.</p> <p>In Release 12.4(20)T, this feature was implemented on the Cisco 1700, Cisco 1800, Cisco 2600, Cisco 2800, Cisco 3700, Cisco 3800, Cisco 7200, and Cisco 7300 routers.</p> <p>The following commands were introduced or modified: class-map type inspect, match protocol, match protocol-violation, match req-resp, match request, match response, policy-map type inspect, rate-limit (firewall).</p>

CCDE, CCENT, Cisco Eos, Cisco Lumin, Cisco Nexus, Cisco StadiumVision, Cisco TelePresence, the Cisco logo, DCE, and Welcome to the Human Network are trademarks; Changing the Way We Work, Live, Play, and Learn and Cisco Store are service marks; and Access Registrar, Aironet, AsyncOS, Bringing the Meeting To You, Catalyst, CCDA, CCDP, CCIE, CCIP, CCNA, CCNP, CCSP, CCVP, Cisco, the Cisco Certified Internetwork Expert logo, Cisco IOS, Cisco Press, Cisco Systems, Cisco Systems Capital, the Cisco Systems logo, Cisco Unity, Collaboration Without Limitation, EtherFast, EtherSwitch, Event Center, Fast Step, Follow Me Browsing, FormShare, GigaDrive, HomeLink, Internet Quotient, IOS, iPhone, iQ Expertise, the iQ logo, iQ Net Readiness Scorecard, iQuick Study, IronPort, the IronPort logo, LightStream, Linksys, MediaTone, MeetingPlace, MeetingPlace Chime Sound, MGX, Networkers, Networking Academy, Network Registrar, PCNow, PIX, PowerPanels, ProConnect, ScriptShare, SenderBase, SMARTnet, Spectrum Expert, StackWise, The Fastest Way to Increase Your Internet Quotient, TransPath, WebEx, and the WebEx logo are registered trademarks of Cisco Systems, Inc. and/or its affiliates in the United States and certain other countries.

E-mail Inspection Engine

The E-mail Inspection Engine feature allows the Cisco IOS Firewall to inspect Post Office Protocol 3 (POP3) and Internet Message Access Protocol (IMAP) e-mail, in addition to Simple Mail Transfer Protocol (SMTP) and Extended Simple Mail Transfer Protocol (ESMTP) e-mail which were previously supported.

The **secure-login** enhancement allows people to download external POP3 e-mail only if authentication methods are secure.

Feature History for E-mail Inspection Engine

Release	Modification
12.3(14)T	This feature was introduced.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. Prerequisites for E-mail Inspection Engine

- Configure CBAC.
- Enable SSL VPN tunnels.

Restrictions for E-mail Inspection Engine

None.

Information About E-mail Inspection Engine

To configure E-mail Inspection Engine, you need to understand the following concepts:

- [E-mail Inspection Engine Operation, page 2](#)
- [Inspection, page 3](#)
- [POP3, page 3](#)
- [IMAP Protocol, page 3](#)
- [Client Command Validation, page 4](#)
- [SMTP, page 4](#)
- [SSL, page 4](#)

E-mail Inspection Engine Operation

The client/server communication is validated from the time the TCP connection is initialized until the client is authenticated. The Cisco IOS Firewall uses a state router to track each stage of authentication. After the client is authenticated, the Cisco IOS Firewall allows all the client/server commands without further L7 inspection. TCP L4 inspection continues until the connection is closed. At the end of the e-mail session when the client host quits and before the TCP connection is closed, no further client/server interaction is allowed unless the client is reauthenticated.

During the authentication, any unrecognized command causes the Cisco IOS Firewall to drop the packet and close the connection.

If encryption is negotiated between the client and server control channel, no further validation occurs.

An e-mail client logging in from a nonsecure location may need to use encryption for authentication. For information about secure logins, see the description of the **secure-login** keyword of the **ip inspect name** command.

Inspection

Context Based Access Control (CBAC) inspects traffic that travels through the firewall to discover and manage state information for TCP and User Datagram Protocol (UDP) sessions. This state information is used to create temporary openings in the firewall's access lists to allow return traffic and additional data connections for permissible sessions.

Inspecting packets at the application layer and maintaining TCP and UDP session information provides CBAC with the ability to detect and prevent certain types of network attacks such as SYN-flooding. A SYN-flood attack occurs when a network attacker floods a server with a barrage of requests for connection and does not complete the connection. The resulting volume of half-open connections can overwhelm the server, causing it to deny service to valid requests. Network attacks that deny access to a network device are called denial-of-service (DoS) attacks.

POP3

The Post Office Protocol, Version 3 (POP3) is used to receive e-mail that is stored on a mail server. Unlike IMAP, POP only retrieves mail from a remote host.

POP3 works best when there is only one computer because it supports “offline” message access where messages are downloaded and then deleted from the mail server. This mode of access is not compatible with access from multiple computers because it tends to sprinkle messages across all the computers used for mail access.

With POP3-based e-mail clients, messages are downloaded to the user's local message store and can also be deleted from the mail server. Deletion is optional in most clients. When a new voice message arrives, the subscriber's only immediate notification is the activation of the MWI on the phone. New messages are displayed in the Inbox only after the client's local message store is updated with the Exchange message store. After the subscriber downloads new messages, the message state automatically changes from “new” to “read” on the server, even though the subscriber has not actually listened to the voice messages. MWIs on the subscriber's phone are extinguished, and the message state between the TUI and the subscriber's Inbox are not synchronized.

IMAP Protocol

The Internet Message Access Protocol (IMAP) is a method of accessing electronic mail or bulletin board messages that are kept on a mail server that may be shared. It permits a “client” e-mail program to access remote messages as though they were local. For example, e-mail stored on an IMAP server can be retrieved, sent, and managed from a desktop computer at home, from a workstation at the office, or from a laptop without transferring messages or files back and forth between the computers.

Only the message header and sender information are displayed in the Inbox until the user downloads the entire message, including attachments, from the server. When a new voice message arrives, the subscriber's only immediate notification is the activation of the Message Waiting Indication (MWI) on the phone. New messages are displayed in the Inbox only after the client's local message store is updated with the Exchange message store. When the subscriber listens to a new message by using the telephone user interface (TUI), the MWI is extinguished. In this case again, the message state is not updated in the Inbox until the client's message store is refreshed. However, if the subscriber uses an installed multimedia player to listen to the WaveForm Audio (WAV) attachment from the e-mail client's Inbox, message state changes are automatically synchronized with the TUI.

How message state changes are conveyed to the Cisco Unity subscriber, and how these changes are synchronized with the TUI, depend on whether the subscriber's e-mail client is configured to use POP3 or IMAP4 to access Exchange.

Client Command Validation

The Cisco IOS Firewall authenticates an e-mail client accessing an IMAP or POP3 server before allowing complete access into the server. The firewall searches the IMAP/POP3 TCP stream for valid protocol commands. If the client's commands are outside the protocol's definition, the Cisco IOS Firewall drops the packets and resets the connection.

Client command validation is typically needed in a DeMilitarized Zone (DMZ). Client access is allowed into the DMZ only if the e-mail server validates the user authentication. After the client is authenticated, the client becomes a trusted user and access is permitted.

SMTP

The Simple Mail Transfer Protocol (SMTP) is used to transfer e-mail between servers and clients on the Internet. E-mail clients and mail servers that use protocols other than Message Application Programming Interface (MAPI) can use the SMTP protocol to transfer a message from a client to the server, and then forward it to a message recipient's server. To retrieve, send, and manage these messages from the e-mail client use POP3 or IMAP4.

Cisco Unity uses SMTP to route voice messages via the Internet Voice Connector (IVC) gateway between other Exchange servers that are not connected by using a Site Message Connector. There is an IVC gateway on either end of the SMTP connection between Exchange servers. This ensures that MAPI message attributes survive the outbound transit between SMTP connections. It also ensures that the MIME-encoded attributes survive the inbound transit, and are included with the message stored in the Exchange message store.

SSL

The Secure Socket Layer (SSL) protocol is the standard protocol that delivers secure content over the Internet. It is a point-to-point security protocol that secures communication between a client and a server. SSL usually does not require a special client (that is, a Web browser often will suffice) and it does not require any additional operating system software.

SSL includes client and server authentication and data encryption for a limited set of applications (for example, the Web, e-mail, news, and file transfer). SSL is useful for securing e-commerce transactions over the Internet, and the protocol is well suited for extranets and remote access because it is relatively simple to deploy.

How to Configure E-mail Inspection Engine

This section contains the following procedures:

- [Configuring Firewall Inspection of POP3 or IMAP E-mail, page 5](#) (required)
- [Verifying the E-mail Inspection Engine Configuration, page 6](#) (optional)

Configuring Firewall Inspection of POP3 or IMAP E-mail

To allow the Cisco IOS Firewall to inspect POP3 or IMAP e-mail, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect name** *inspection-name* *protocol* [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**reset**] [**secure-login**] [**timeout** *seconds*]
4. **interface** *type slot/port*
5. **ip inspect name** *inspection-name* {**in** | **out**}
6. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name inspection-name protocol [alert {on off}] [audit-trail {on off}] [reset] [secure-login] [timeout seconds] Example: Router(config)# ip inspect name mail-guard pop3	Defines a set of inspection rules.
Step 4	interface type slot/port Example: Router(config-if)# interface 1/0	Configures an interface type.
Step 5	ip inspect name inspection-name {in out} Example: Router(config-if)# ip inspect name mail-guard in	Enables the Cisco IOS Firewall on an interface.
Step 6	exit Example: Router(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.

Verifying the E-mail Inspection Engine Configuration

To verify the E-mail Inspection Engine configuration, perform the following steps.

**Note**

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

SUMMARY STEPS

1. **debug ip inspect imap**
2. **debug ip inspect pop3**
3. **show ip inspect { name inspection-name | config | interfaces | session [detail] | all }**

DETAILED STEPS

Step 1 **debug ip inspect imap**

Use this command to display messages about Cisco IOS Firewall events related to IMAP protocol e-mail messages.

```
Router# debug ip inspect imap
```

Step 2 **debug ip inspect pop3**

Use this command to display messages about Cisco IOS Firewall events related to POP3 protocol e-mail messages.

```
Router# debug ip inspect pop3
```

Step 3 **show ip inspect {name *inspection-name* | config | interfaces | session [detail] | all}**

Use this command to view CBAC configuration and session information.

```
Router# show ip inspect
```

```
Session audit trail is disabled
one-minute (sampling period) thresholds are [400:500] connections
max-incomplete sessions thresholds are [400:500]
max-incomplete tcp connections per host is 50. Block-time 0 minute.
tcp synwait-time is 30 sec -- tcp finwait-time is 5 sec
tcp idle-time is 3600 sec -- udp idle-time is 30 sec
dns-timeout is 5 sec
Inspection Rule Configuration
  Inspection name mail-guard
    tcp timeout 3600
    udp timeout 30
    ftp timeout 3600
```

Configuration Examples for E-mail Inspection Engine

- [Configuring IMAP and POP3 Protocol E-mail: Example, page 7](#)

Configuring IMAP and POP3 Protocol E-mail: Example

The following example configures the Cisco IOS Firewall inspection of IMAP and POP3 protocol e-mail:

```
configure terminal
ip inspect name mail-guard pop3
ip inspect name mail-guard imap
exit
```

The following commands enable this functionality on an interface:

```
configure terminal
interface 1/0
ip inspect name mail-guard in
exit
```

- **show ip inspect**

Glossary

authentication—Process during which any unrecognized command causes the Cisco IOS Firewall to drop the packet and close the connection.

CBAC—Context-Based Access Control. A Cisco IOS Firewall set feature that scrutinizes source and destination addresses to enhance security for TCP and UDP applications that use well-known ports, such as FTP and e-mail traffic.

ESMTP—Extended Simple Mail Transfer Protocol. An extended version of the Simple Mail Transfer Protocol (SMTP), which includes additional functionality, such as delivery notification and session delivery.

IMAP—Internet Message Access Protocol. A method of accessing e-mail or bulletin board messages kept on a mail server that can be shared. IMAP permits client e-mail applications to access remote message stores as if they were local without actually transferring the message.

POP—Post Office Protocol. A protocol that client e-mail applications use to retrieve mail from a mail server.

SMTP—Simple Mail Transfer Protocol. An Internet protocol providing e-mail services.

SSL—Secure Socket Layer Protocol. This protocol is used to deliver secure information over the Internet.

state router—A router that tracks the client/server commands until the client is authenticated.

TCP—Transmission Control Protocol. A connection-oriented transport layer protocol that provides reliable full-duplex data transmission. TCP is part of the TCP/IP protocol stack.

UDP—User Datagram Protocol. A connectionless transport-layer protocol for exchanging datagrams without acknowledgments or guaranteed delivery.

VPN—Virtual Private Network. A network that enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic from one network to another. A VPN network uses “tunneling” to encrypt all information at the IP level.

ESMTP Support for Cisco IOS Firewall

The ESMTP Support for Cisco IOS Firewall feature enhances the Cisco IOS Firewall to support Extended Simple Mail Transport Protocol (ESMTP), allowing customers who install mail servers behind Cisco IOS firewalls to install their servers on the basis of ESMTP (instead of Simple Mail Transport Protocol [SMTP]).

Feature History for ESMTP Support for Cisco IOS Firewall

Release	Modification
12.3(7)T	This feature was introduced.

Information About ESMTP Support for Cisco IOS Firewall

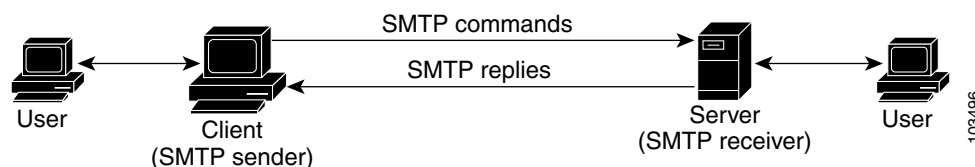

To configure a Cisco IOS firewall to inspect an ESMTP session and command sequence, you should understand the following concepts:

- [SMTP Functionality Overview, page 2](#)
- [ESMTP Overview, page 3](#)
- [SMTP Firewall and ESMTP Firewall Comparison, page 3](#)

SMTP Functionality Overview

SMTP inspection provides a basic method for exchanging e-mail messages. [Figure 26](#) and the following steps outline a basic SMTP session.

Figure 26 **Sample SMTP Exchange Topology**

After a user sends an e-mail request to the client (the “SMTP sender”), the client established a TCP channel with the server (the “SMTP receiver”). Thereafter, the client and the server exchange SMTP commands and responses until the mail transaction is complete. The steps of typical SMTP transaction are as follows:

4. The client establishes a TCP connection with the server.
5. The client sends a HELO command with its domain name. If the server can accept mail from that domain name, it responds with a 250 reply code, which allows the client to continue with the mail transaction. (If the server does not respond with a 250 reply code, the client will send a QUIT command and terminate the TCP session.)
6. The client sends the MAIL command, indicating who initiated the mail. If the server accepts the mail, it responds with an OK reply. Then, the client sends the RCPT command, identifying the recipient of the mail. If the server accepts mail for the specified recipient, it responds with an OK reply; if the server cannot accept mail for the specified recipient, it rejects the recipient but not the entire transaction. (Several recipients can be negotiated.)
7. After the list of recipients has been negotiated between the client and the server, the client sends a DATA command. If the server is ready to receive data, it responds with a 354 reply code. If the server is not ready to receive data, it responds with an error reply, and the client terminates the transaction.
8. The client sends mail data ending with a special sequence. When the server sees the end of the message, it sends a 250 code reply.
9. The client sends a QUIT command, waits for the server to respond, then terminates the session.

ESMTP Overview

Like SMTP, ESMTP inspection provides a basic method for exchanging e-mail messages. Although an ESMTP session is similar to SMTP, there is one difference—the EHLO command.

After the TCP connection has been established between the client (the ESMTP sender) and the server (the ESMTP receiver), the client sends the EHLO command (instead of the HELO command that is used for SMTP). If the server does not support ESMTP, it sends a failure reply to the client because it did not recognize the EHLO command. If it supports ESMTP, the server responds with the code 250 and a list of extensions that the server supports. (Refer to RFC 1869 for an explanation of the extensions that your server may support.)

The server may send any of the following error codes if it supports ESMTP but is unable to function as normal:

- Error code 501—The server recognizes the EHLO command but is unable to accept it.
- Error code 502—The server recognizes the EHLO command but does not implement it.
- Error code 554—The server is unable to list the service extensions it supports.

If the client receives any of these error codes, it should issue the HELO command to revert to SMTP mode or issue the QUIT command to end the session.

After the client receives a successful response to the EHLO command, it will work the same way as SMTP, except that the client may issue new extended commands, and it may add a few parameters to the MAIL FROM and REPT TO commands.

SMTP Firewall and ESMTP Firewall Comparison

Although a SMTP firewall and an ESMTP firewall support the same functionality—command inspection, session conversion, and Intrusion Detection System (IDS) detection—slight variations exist between the protocols. [Table 27](#) explains the firewall functionality and protocol-specific differences.

Table 27 *SMTP and ESMTP Firewalls Functionality Comparison*

Functionality	SMTP Firewall Description	ESMTP Firewall Description
Command Inspection	<p>The SMTP firewall inspects commands for illegal commands. Illegal commands found in a packet are modified to an “xxxx” pattern and forwarded to the server. This process causes the server to send a negative reply, forcing the client to issue a valid command.</p> <p>An illegal SMTP command is any command except the following: DATA, HELO, HELP, MAIL, NOOP, QUIT, RCPT, RSET, SAML, SEND, SOML, and VRFY.</p> <p>Note Prior to Cisco IOS Release 12.3(7)T, an SMTP firewall will reset the TCP connection upon detection of an illegal command. That is, an SMTP firewall no longer resets the TCP connection upon detecting an illegal command.</p>	<p>ESMTP command inspection is the same as SMTP command inspection, except that ESMTP supports three additional commands—AUTH, EHLO, and ETRN.</p> <p>An illegal ESMTP command is any command except the following: AUTH, DATA, EHLO, ETRN, HELO, HELP, MAIL, NOOP, QUIT, RCPT, RSET, SAML, SEND, SOML, and VRFY.</p>
Parameter Inspection	Not applicable.	<p>The ESMTP firewall inspects the following extensions by performing deeper command inspection:</p> <ul style="list-style-type: none"> • Message Size Declaration (SIZE) • Remote Queue Processing Declaration (ETRN) • Binary MIME (BINARYMIME) • Command Pipelining • Authentication • Delivery Status Notification (DSN) • Enhanced Status Code (ENHANCEDSTATUSCODE) • 8bit-MIMEtransport (8BITMIME) <p>Note All other extensions, including private extensions, are not supported.</p>

Table 27 *SMTP and ESMTP Firewalls Functionality Comparison (continued)*

Functionality	SMTP Firewall Description	ESMTP Firewall Description
EHLO Reply Inspection	Not applicable.	The ESMTP firewall inspects the EHLO reply, which contains a list of SMTP extensions that the server supports. Any unsupported extension that is found in the server's reply will be replaced with the "XXXX" pattern, which labels that extension "private." Thus, the client will no longer use the unsupported extension.
ESMTP to SMTP Session Conversion	<p>The SMTP firewall forces a client that initiates an ESMTP session to use SMTP. When a client attempts to initiate an ESMTP session by sending the ELHO command, the firewall treats the EHLO command as an illegal command and modified it to the "xxxx" pattern. This response causes the server to send a 5xx code reply, forcing the client to revert to SMTP mode.</p> <p>Note Prior to Cisco IOS Release 12.3(7)T, the firewall intercepts the EHLO command and changes it to the NOOP command. The server responds with a 250 code reply. The firewall intercepts the response and modifies it to 502 code reply, which tells the client that the EHLO command is not supported.</p>	Not applicable (because EHLO is supported in ESMTP).
IDS Signature Detection	The SMTP and ESMTP firewalls scan for a set of hard-coded IDS signatures. There are 11 signatures—6 are hard coded in the firewall and are enabled by default. The other 5 signatures remain in the IDS code and are disabled by default.	

Table 27 SMTP and ESMTP Firewalls Functionality Comparison (continued)

Functionality	SMTP Firewall Description	ESMTP Firewall Description
Command Pipelining	Not available. (The client sends a command to the server and must wait for a reply before sending another command.)	An ESMTP firewall can inspect commands that are in the pipeline. That is, commands that are sent before a response is received are inspected.
Resetting a Connection	<p>Both SMTP and ESMTP firewalls will always send a “5xx” error code and close the connection upon detection of an unsupported parameter or an IDS signature in a command. That is, the firewall sends an appropriate reply code and closes the connection with proper TCP closing sequence packets (such as FIN or FIN+ACK) so the client does not continually attempt to send the same message.</p> <p>Note Prior to Cisco IOS Release 12.3(7)T, an SMTP firewall will reset the TCP connection upon detection of an illegal command or IDS signature. This behavior causes the client to keep trying to send the same message for up to 4 days (which is when the original message is bounced back to the user).</p>	

How to Configure a Firewall to Support ESMTP

This section contains the following procedures:

- [Configuring a Firewall for ESMTP Inspection, page 6](#)

Configuring a Firewall for ESMTP Inspection

Use this task to configure a Cisco IOS Firewall to inspect an ESMTP session and command sequence.

Restrictions

SMTP and ESMTP cannot exist simultaneously. If SMTP is already configured, an attempt to configure ESMTP will result in the error message, “%ESMTP cannot coexist with SMTP, please unconfigure SMTP and try again...” If ESMTP is already configured, an attempt to configure SMTP will result in the error message, “%SMTP cannot coexist with ESMTP, please unconfigure ESMTP and try again...”

The following example illustrates how the router will react if you attempt to configure both protocols:

```
Router(config)# ip inspect name mail-guard smtp
Router(config)# ip inspect name mail-guard esmtp
ESMTP cannot coexist with SMTP, please unconfigure SMTP and try again...
Router(config)# end
Router# show running-config
.
.
.
ip inspect name mail-guard smtp
.
.
.
```

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect name** *inspection-name* {**smtp** | **esmtplib**} [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**max-data** *number*] [**timeout** *seconds*]
4. **interface** *type number*
5. **ip inspect** *inspection-name* {**in** | **out**}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name <i>inspection-name</i> { smtp esmtplib } [alert { on off }] [audit-trail { on off }] [max-data <i>number</i>] [timeout <i>seconds</i>] Example: Router(config)# ip inspect name test esmtplib	Configures inspection of a SMTP or an ESMTP session.
Step 4	interface <i>type number</i> Example: Router(config)# interface ethernet0	Configures an interface type and enters interface configuration mode.
Step 5	ip inspect <i>inspection-name</i> { in out } Example: Router(config-if)# ip inspect test in	Applies an inspection rule to an interface.

Troubleshooting Tips

To view and verify the inspection configuration, status, or session information, you can use any of the following EXEC commands:

- **show ip inspect name** *inspection-name*—Shows a particular configured inspection rule.
- **show ip inspect session**—Shows existing sessions that are currently being tracked and inspected by the firewall.
- **show ip inspect all**—Shows all inspection configuration and all existing sessions that are currently being tracked and inspected by the firewall.

Alert Messages

The existing SMTP-related alert message will not change. This message is logged every time the firewall detects an illegal or unsupported command. The message format is as follows:

```
FW-3-SMTP_INVALID_COMMAND: Invalid SMTP command (%s) (total %d chars) from initiator (%i:%d)
```

A new alert message is added. This message is logged whenever the firewall detects an illegal parameter in an SMTP command. The message includes the address and port of the sender as well as the illegal parameter. The message format is as follows:

```
FW-3-SMTP_INVALID_PARAMETER: Invalid SMTP parameter (%s) from initiator (%i:%d)
```

What to Do Next

To provide a record of network access through the firewall, including illegitimate access attempts, and inbound and outbound services, you should turn on logging and audit trail. For information on completing this task, refer to the section “Configuring Logging and Audit Trail” in the chapter “Configuring Context-Based Access Control” in the *Cisco IOS Security Configuration Guide*.

Configuration Examples for Firewall ESMTP Support

This section contains the following configuration example:

- [ESMTP Inspection Configuration: Example, page 8](#)

ESMTP Inspection Configuration: Example

The following example shows how to configure inspection of ESMTP traffic:

```
Router# configure terminal  
Router(config)# ip inspect name mail-guard esmtp timeout 30
```

Firewall ACL Bypass

The Firewall ACL Bypass feature allows a packet to avoid redundant access control list (ACL) checks by allowing the firewall to permit the packet on the basis of existing inspection sessions instead of dynamic ACLs. Thus, input and output dynamic ACLs searches are eliminated, improving the overall throughput performance of the base engine.

Feature History for Firewall ACL Bypass

Release	Modification
12.3(4)T	This feature was introduced.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Information About Firewall ACL Bypass

To better understand how dynamic ACL bypass works, you should understand the following concepts:

- [Benefits of Firewall ACL Bypass, page 2](#)

Americas Headquarters:

Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

- [Firewall ACL Bypass Functionality Overview, page 2](#)

Benefits of Firewall ACL Bypass

Because input and output dynamic ACLs are no longer necessary, the need for context-based access control (CBAC) to create dynamic ACLs on the interface is eliminated. Thus, the following benefits are now available:

- Improved connections per second performance of the firewall
- Reduced run-time memory consumption of the firewall

Firewall ACL Bypass Functionality Overview

Before ACL bypassing was implemented, a packet could be subjected to as many as three redundant searches—an input ACL search, an output ACL search, and an inspection session search. Each dynamic ACL that CBAC creates corresponds to a single inspection session. Thus, a matching dynamic ACL entry for a given packet implies that a matching inspection session exists and that the packet should be permitted through the ACL. Because a matching inspection session is often found in the beginning of IP processing, the input and output dynamic ACL searches are no longer necessary and can be eliminated.

ACL bypassing subjects the packet to one search—the inspection session search—during its processing path through the router. When a packet is subjected to a single inspection session search before the ACL checks, the packet is matched against the list of session identifiers that already exist on the interface. (Session identifiers keep track of the source and destination IP addresses and ports of the packets and on which interface the packet arrived.)

Note

Session identifiers are not created on interfaces for inspection sessions that are only Intrusion Detection Sessions (IDS).

How to Use Firewall ACL Bypass

After your firewall is configured for inspection, ACL bypassing is performed by default. That is, you should configure inspection as normal.

To configure CBAC for your firewall, see the following chapter “Configuring Context-Based Access Control” in the *Cisco IOS Security Configuration Guide*.

Configuration Examples for Verifying Firewall Session Information

After you have configured your firewall for inspection, you can use the **show ip inspect sessions detail** command to view session inspection information. The following examples show how eliminating dynamic ACLs changes the sample output:

- [Old show ip inspect CLI Output: Example, page 3](#)
- [New show ip inspect CLI Output: Example, page 3](#)

Old show ip inspect CLI Output: Example

The following is sample output from the **show ip inspect session detail** command, which shows that an outgoing ACL and an inbound ACL (dynamic ACLs) have been created to allow return traffic:

```
Router# show ip inspect session detail
```

```
Established Sessions
```

```
Session 80E87274 (192.168.1.116:32956)=>(192.168.101.115:23) tcp SIS_OPEN
Created 00:00:08, Last heard 00:00:04
Bytes sent (initiator:responder) [140:298] acl created 2
Outgoing access-list 102 applied to interface FastEthernet0/0
Inbound access-list 101 applied to interface FastEthernet0/1
```

```
Router# show access-lists
```

```
Extended IP access list 101
```

```
 permit tcp host 192.168.101.115 eq telnet host 192.168.1.116 eq 32956 (27 matches)
 deny udp any any
 deny tcp any any
 permit ip any any
```

```
Extended IP access list 102
```

```
 permit tcp host 192.168.101.115 eq telnet host 192.168.1.116 eq 32956 (27 matches)
 deny udp any any
 deny tcp any any
 permit ip any any
```

New show ip inspect CLI Output: Example

The following is sample output from the **show ip inspect session detail** command, which shows related ACL information (such as session identifiers [SID]), but does not show dynamic ACLs, which are no longer created:

```
Router# show ip inspect session detail
```

```
Established Sessions
```

```
Session 814063CC (192.168.1.116:32955)=>(192.168.101.115:23) tcp SIS_OPEN
Created 00:00:10, Last heard 00:00:06
Bytes sent (initiator:responder) [140:298]
In  SID 192.168.101.115[23:23]=>192.168.1.117[32955:32955] on ACL 101 (15 matches)
Out SID 192.168.101.115[23:23]=>192.168.1.116[32955:32955] on ACL 102
```

```
Router# show access-list
```

```
Extended IP access list 101
```

```
 deny udp any any (20229 matches)
 deny tcp any any
 permit ip any any (6 matches)
```

```
Extended IP access list 102
```

```
 deny udp any any
 deny tcp any any
 permit ip any any (1 match)
```

Firewall N2H2 Support

The Firewall N2H2 Support feature provides users with an additional option when choosing the URL filter vendor. Just like the Websense URL filtering server, N2H2 interacts with your Cisco IOS firewall (also known as Cisco Secure Integrated Software [CSIS]) to allow you to prevent users from accessing specified websites on the basis of some policy. The Cisco IOS firewall works with the N2H2 Internet Filtering Protocol (IFP) server to know whether a particular URL should be allowed or denied (blocked).

Feature Specifications for the Firewall N2H2 Support feature

Feature History

Release	Modification
12.2(11)YU	This feature was introduced.
12.2(15)T	This feature was integrated into Cisco IOS Release 12.2(15)T.

Supported Platforms

For platforms supported in Cisco IOS Release 12.2(11)YU and 12.2(15)T, consult Cisco Feature Navigator.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Restrictions for Firewall N2H2 Support

N2H2 IFP (Server) Requirement

To enable this feature, you must have at least one N2H2 server; however, two or more N2H2 servers are preferred. Although there is no limit to the number of N2H2 servers you may have, and you can configure as many servers as you wish, only one server will be active at any given time—the primary server. URL lookup requests will be sent only to the primary server.

URL Filtering Support Restriction

This feature supports only one active URL filtering scheme at a time. (Before enabling N2H2 URL filtering, you should always ensure that there is not another URL filtering scheme configured, such as Websense.)

Username Restriction

N2H2 requires the username to be supplied with the URL lookup request. Thus, the user-based policy will not work with N2H2 because the current Cisco IOS software does not retrieve the username.

Protocol Used to Communicate Between Firewall and N2H2 Server Restriction

TCP is currently the only protocol used to communicate between the Cisco IOS firewall (UNIX FileSystem [UFS]) and the N2H2 server.

Information About Cisco N2H2 Support

To configure Firewall N2H2 support, you must understand the following concepts:

- [Benefits of Firewall N2H2 Support, page 2](#)
- [Feature Design of Firewall N2H2 Support, page 4](#)
- [Supported N2H2 Filtering Methods, page 5](#)

Benefits of Firewall N2H2 Support

The Cisco IOS Firewall N2H2 Support feature provides an Internet management application that allows you to control web traffic for a given host or user on the basis of a specified security policy. In addition, the following functions are available in this feature:

Primary and Secondary Servers

When users configure multiple N2H2 servers, the firewall will use only one server at a time—the primary server; all other servers are called secondary servers. When the primary server becomes unavailable for any reason, it becomes a secondary server and one of the secondary servers becomes the primary server.

A firewall marks a primary server as down when sending a request to or receiving a response from the server fails. When a primary server goes down, the system will go to the beginning of the configured servers list and try to activate the first server on the list. If the first server on the list is unavailable, it will

try the second server on the list; the system will keep trying to activate a server until it is successful or until it reaches the end of the server list. If the system reaches the end of the server list, it will set a flag indicating that all of the servers are down, and it will enter allowmode.

When all the servers are down and the system is in allow mode, a periodic event that occurs for each minute will trace through the server list, trying to bring up a server by opening a TCP connection. If the TCP connection is successfully opened, the server is considered to be up, and the system will return to operational mode.

IP Cache Table

This function provides an IP cache table that contains the IP addresses of web servers whose underlying URLs can be accessed by all users and hosts.

The caching algorithm involves three parameters—the maximum number of IP addresses that can be cached, an idle time, and an absolute time. The algorithm also involves two timers—idle timer and absolute timer. The idle timer is a small periodic timer (1 minute) that checks to see whether the number of cached IP addresses in the cache table exceeds 80 percent of the maximum limit. If the cached IP addresses have exceeded 80 percent, it will start removing idle entries; if it has not exceeded 80 percent, it will quit and wait for the next cycle. The absolute timer is a large periodic timer (1 hour) that is used to remove all of the elapsed entries. (The age of an elapsed entry is greater than the absolute time.) An elapsed entry will also be removed during cache lookup.

The idle time value is fixed at 10 minutes. The absolute time value is taken from the N2H2 lookup response, which is often greater than 15 hours. The absolute value for cache entries made out of exclusive-domains is 12 hours. The maximum number of cache entries is configurable.

To configure cache table parameters, use the **ip urlfilter cache** command.

Packet Buffering

This function allows you to increase the maximum number of HTTP responses that a Cisco IOS firewall can hold. If the HTTP responses arrive prior to an N2H2 server reply, this buffering scheme allows your firewall to store a maximum of 200 HTTP responses. (After 200 responses have been reached, the firewall will drop further responses.) The responses will remain in the buffer until an allow or deny message is received from N2H2: if the status indicates that the URL is allowed, the firewall will release the HTTP responses in the buffer to the browser of the end user; if the status indicates that the URL is blocked, the firewall will discard the HTTP responses in the buffer and close the connection to both ends. This function prevents numerous HTTP responses from overwhelming your system.

To configure the maximum number of HTTP responses for your firewall, use the **ip urlfilter max-resp-pak** command.

Exclusive Domains

This function provides a configurable list of domain names so that the Cisco IOS firewall does not have to send a lookup request to the N2H2 server for the HTTP traffic that is destined for one of the domains in the exclusive list. Thus, the N2H2 server does not have to deal with look-up requests for HTTP traffic that is destined for a host that has already been marked as “allowed.”

Flexibility when entering domain names is also provided; that is, the user can enter the complete domain name or a partial domain name. If the user adds a complete domain name such as “www.cisco.com” to the exclusive domain list, all HTTP traffic whose URLs are destined for this domain (such as www.cisco.com/news and www.cisco.com/index) will be excluded from the N2H2 URL filtering policies and, on the basis of the configuration, the URLs will be permitted or blocked (denied).

If the user adds only a partial domain name to the exclusive domain list, such as “.cisco.com,” all URLs whose domain names end with this partial domain name (such as www.cisco.com/products and www.cisco.com/eng) will be excluded from the N2H2 URL filtering policies and, based upon the configuration, the URLs will be permitted or blocked (denied).

To configure an exclusive domain list, use the **ip urlfilter exclusive-domain** command.

Allow Mode

The system will go into allow mode when connections to all the N2H2 servers are down. The system will return to normal mode when a connection to at least one web N2H2 server is up. Allow mode directs your system to forward or drop all packets on the basis of the configurable allow mode setting. By default, allow mode is off, so all HTTP requests are forbidden if all N2H2 servers are down.

To configure allow mode for your system, use the **ip urlfilter allowmode** command.

Feature Design of Firewall N2H2 Support

Note

This feature assumes that the N2H2 server will be part of a protected network and that requests from the Cisco IOS firewall will not travel over any unprotected network to reach the N2H2 server.

Figure 27 and the corresponding steps explain a sample URL filtering network topology.

Figure 27 Cisco IOS Firewall N2H2 URL Filtering Sample Topology

1. The end user browses a page on the web server, and the browser sends an HTTP request.
2. After the Cisco IOS firewall receives this request, it forwards the request to the web server, while simultaneously extracting the URL and sending a look-up request to the N2H2 server.
3. After the N2H2 server receives the look-up request, it checks its database to see whether it should permit or deny the URL; it returns a permit or deny status via a look-up response to the Cisco IOS firewall.
4. After the Cisco IOS Firewall receives this look-up response, it performs one of the following functions:
 - If the look-up response permits the URL, it sends the HTTP response to the end user.

- If the look-up response denies the URL, the N2H2 server redirects the user to its own internal web server, which displays a message that describes the category under which the URL is blocked; thereafter, the connection is reset to both ends.

Supported N2H2 Filtering Methods

The Cisco IOS firewall supports most of the filtering methods that are supported by the N2H2 server. [Table 28](#) lists N2H2 filtering methods and identifies which methods are supported by Cisco.

Table 28 *N2H2 Filtering Methods Supported on Cisco IOS Firewall*

N2H2 Filtering Method	Description	Supported by Cisco IOS Firewall?
Client-IP-based filtering	Filtering is applied to specified client IP addresses	Yes
Global filtering	Filtering is applied to all users, groups, and IP addresses	Yes
User-based filtering	Filtering is applied to a specified user	No

How to Configure N2H2 URL Support

To configure your Cisco IOS firewall to interact with at least one N2H2 server to provide URL filtering, configure the following procedures:

- [Configuring Cisco IOS Firewall N2H2 URL Filtering, page 5](#) (required)
- [Verifying Firewall and N2H2 URL Filtering, page 10](#) (optional)
- [Maintaining the Cache Table, page 10](#) (optional)
- [Monitoring the URL Filter Subsystems, page 11](#) (optional)

Configuring Cisco IOS Firewall N2H2 URL Filtering

N2H2 is based on a pass-through filtering technology, which is the most accurate, reliable, and scalable method of Internet filtering. Pass-through filtering requires all requests for web pages to pass through an Internet control point, such as a firewall, proxy server, or caching device. N2H2 is integrated with these control points and checks each request to determine whether it should be allowed or denied. All responses are logged for reporting purposes.

Prerequisites

- Before enabling N2H2 URL filtering, you should always ensure that there is not another URL filtering scheme configured, such as Websense. If you try to enter a new filtering scheme when one already exists, the new scheme will be ignored, and the system will display an error message that says, “different URL filtering scheme cannot co-exist.”

- URL filtering does not have an interface-specific command. It relies on Cisco IOS firewall C HTTP inspection to classify the traffic that needs filtering. This makes the configuration of Cisco IOS firewall inspection mandatory for the URL filtering feature to work. For more details on Cisco IOS firewall configuration, refer to the chapter “Cisco IOS Firewall Overview” in the IOS Security Configuration Guide, Release 12.2.

Restrictions

Enabling HTTP inspection (via the **ip inspect name** command) triggers the Java applet scanner, which is very CPU intensive. The only way to stop the Java applet scanner is to specify the **java-list access-list** option and configure a standard access-list to allow any traffic. Configuring URL filtering without enabling the **java-list access-list** option will severely impact performance.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect name** *inspection-name* **http** [**urlfilter**] [**java-list** *access-list*] [**alert** {**on** | **off**}] [**timeout** *seconds*] [**audit-trail** {**on** | **off**}]
4. **ip urlfilter server vendor** {**websense** | **n2h2**} *ip-address* [**port** *port-number*] [**timeout** *seconds*] [**retransmit** *number*]
5. **ip urlfilter alert**
6. **ip urlfilter audit-trail**
7. **ip urlfilter urlf-server-log**
8. **ip urlfilter exclusive-domain** {**permit** | **deny**} *domain-name*
9. **ip urlfilter cache** *number*
10. **ip urlfilter allowmode** [**on** | **off**]
11. **ip urlfilter max-resp-pak** *number*
12. **ip urlfilter max-request** *number*
13. **interface** *type slot/port*
14. **ip inspect inspection-name** {**in** | **out**}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example: Router> enable	<ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	

	Command or Action	Purpose
Step 3	<pre>ip inspect name inspection-name http [urlfilter] [java-list access-list] [alert {on off}] [timeout seconds] [audit-trail {on off}]</pre> <p>Example: Router(config)# ip inspect name fw_urlf http urlfilter java-list 51 timeout 30</p>	<p>Turns on HTTP inspection. The urlfilter keyword associates URL filtering with HTTP inspection.</p> <p>Note You may configure two or more inspections in a router, but URL filtering will work only with the inspections in which the urlfilter keyword is enabled.</p> <p>Note Enabling HTTP inspection with or without any options triggers the Java applet scanner, which is CPU intensive. The only way to stop the Java applet scanner is to specify the java-list access-list option. Configuring URL filtering without enabling the java-list access-list option will severely impact performance.</p>
Step 4	<pre>ip urlfilter server vendor {websense n2h2} ip-address [port port-number] [timeout seconds] [retransmit number]</pre> <p>Example: Router(config)# ip urlfilter server vendor websense 10.201.6.202</p>	<p>Configures an N2H2 server to interact with the firewall to filter HTTP requests based on a specified policy.</p> <ul style="list-style-type: none"> <i>ip-address</i>—IP address of the vendor server. port port-number—Port number that the vendor server listens on. The default port number is 4005. timeout seconds—Length of time that the firewall will wait for a response from the vendor server. The default timeout is 5 minutes. retransmit number—Number of times the firewall will retransmit the request when a response does not arrive. The default value is 2 times.
Step 5	<pre>ip urlfilter alert</pre> <p>Example: Router(config)# ip urlfilter alert</p>	<p>(Optional) Enables the system alert, which displays system messages such as a server entering allow mode or going down.</p> <ul style="list-style-type: none"> The system alert is enabled by default.
Step 6	<pre>ip urlfilter audit-trail</pre> <p>Example: Router(config)# ip urlfilter audit-trail</p>	<p>(Optional) Enables the logging of messages into the syslog server of router.</p> <ul style="list-style-type: none"> This function is disabled by default.
Step 7	<pre>ip urlfilter urlf-server-log</pre> <p>Example: Router(config)# ip urlfilter urlf-server-log</p>	<p>(Optional) Enables the logging of system messages on the URL filtering server (the N2H2 server). This function is disabled by default.</p>

	Command or Action	Purpose
Step 8	<p>ip urlfilter exclusive-domain {permit deny} <i>domain-name</i></p> <p>Example: Router(config)# ip urlfilter exclusive-domain permit www.cisco.com</p>	<p>(Optional) Adds a domain name to or from the exclusive domain list so the firewall does not have to send look-up requests to the N2H2 server.</p> <ul style="list-style-type: none"> • permit—Permits all traffic destined for the specified domain name. • deny—Denies all traffic destined for the specified domain name. • <i>domain-name</i>—Domain name that is added or removed from the exclusive domain list.
Step 9	<p>ip urlfilter cache <i>number</i></p> <p>Example: Router(config)# ip urlfilter cache 4500</p>	<p>(Optional) Configures cache table parameters.</p> <ul style="list-style-type: none"> • <i>number</i>—Specifies the maximum number of destination IP addresses that can be cached into the cache table; the default is 5000.
Step 10	<p>ip urlfilter allowmode [on off]</p> <p>Example: Router(config)# ip urlfilter allowmode on</p>	<p>(Optional) Turns on the default mode of the filtering systems.</p> <ul style="list-style-type: none"> • on—Allows HTTP requests to pass to the end user if all N2H2 servers are down. • off—Blocks all HTTP requests if all N2H2 servers are down; off is the default setting.
Step 11	<p>ip urlfilter max-resp-pak <i>number</i></p> <p>Example: Router(config)# ip urlfilter max-resp-pak 150</p>	<p>(Optional) Configures the maximum number of HTTP responses that the firewall can keep in its packet buffer.</p> <ul style="list-style-type: none"> • The default value is 200. The maximum value is 20000, so you may set the max-resp-pak <i>number</i> to a value up to 20000.
Step 12	<p>ip urlfilter max-request <i>number</i></p> <p>Example: Router(config)# ip urlfilter max-request 500</p>	<p>(Optional) Sets the maximum number of outstanding requests that can exist at any given time.</p> <ul style="list-style-type: none"> • The default value is 1000.
Step 13	<p>interface <i>type slot/port</i></p> <p>Example: Router(config)# interface FastEthernet 0/0</p>	Configures an interface type and enters interface configuration mode
Step 14	<p>ip inspect inspection-name {in out}</p> <p>Example: Router(config-if)# ip inspect inspection-name out</p>	<p>Applies a set of inspection rules to an interface.</p> <ul style="list-style-type: none"> • URL filtering is associated with inspection, and inspection is an interface-specific command. Hence, the ip inspect command needs to be configured on an interface.

Troubleshooting Tips

This feature introduces the following alert messages:

- “%URLF-3-SERVER_DOWN: Connection to the URL filter server 10.92.0.9 is down”

This level three LOG_ERR-type message is displayed when a configured UFS goes down. When this happens, the firewall will mark the configured server as secondary, try to bring up one of the other secondary servers, and mark that server as the primary server. If there is no other server configured, the firewall will enter allow mode and display the “URLF-3-ALLOW_MODE” message.

- %URLF-3-ALLOW_MODE: Connection to all URL filter servers are down and ALLOW MODE is OFF

This LOG_ERR type message is displayed when all UFSs are down and the system enters allow mode.

Note Whenever the system goes into allow mode (all filter servers are down), a periodic keepalive timer will be triggered which will try to bring up a server by opening a TCP connection.

- “%URLF-5-SERVER_UP: Connection to an URL filter server 10.92.0.9 is made, the system is returning from ALLOW MODE”

This LOG_NOTICE-type message is displayed when the UFSs are detected as being up and the system is returning from allow-mode.

- “%URLF-4-URL_TOO_LONG:URL too long (more than 3072 bytes), possibly a fake packet?”

This LOG_WARNING-type message is displayed when the URL in a look-up request is too long; any URL longer than 3K will be dropped.

- “%URLF-4-MAX_REQ: The number of pending request exceeds the maximum limit <1000>”

This LOG_WARNING-type message is displayed when the number of pending requests in the system exceeds the maximum limit and all further requests are dropped.

To display these alert messages, use the **ip urlfilter alert** command.

This feature introduces the following syslog messages:

- “%URLF-6-SITE_ALLOWED: Client 10.0.0.2:12543 accessed server 10.76.82.21:8080”

This message is logged for each request whose destination IP address is found in the cache. It includes the source IP address, source port number, destination IP address, and destination port number. The URL is not logged because the IP address of the request is found in the cache, so parsing the request and extracting the URL is a waste of time.

- “%URLF-4-SITE-BLOCKED: Access denied for the site ‘www.sports.com’; client 10.54.192.6:34557 server 172.24.50.12:80”

This message is logged when a request finds a match against one of the blocked domains in the exclusive-domain list or the corresponding entry in the IP cache.

- “%URLF-6-URL_ALLOWED: Access allowed for URL http://www.n2h2.com/; client 10.54.192.6:54123 server 192.168.0.1:80”

This message is logged for each URL request that is allowed by a UFS. It includes the allowed URL, source IP address, source port number, destination IP address, and destination port number. Longer URLs will be truncated to 300 bytes and logged.

- “%URLF-6-URL_BLOCKED: Access denied URL http://www.google.com; client 10.54.192.6:54678 server 172.19.14.2:80”

This message is logged for each URL request that is blocked by a UFS. It includes the blocked URL, source IP address, source port number, destination IP address, and destination port number. Longer URLs will be truncated to 300 bytes and then logged.

To display these syslog messages, use the **ip urlfilter audit-trail** command.

Verifying Firewall and N2H2 URL Filtering

To verify that the Firewall N2H2 Support feature is working, perform any of the following optional steps:

SUMMARY STEPS

1. **enable**
2. **show ip urlfilter cache**
3. **show ip urlfilter config**

DETAILED STEPS

Command or Action	Purpose
enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
show ip urlfilter cache Example: Router# show ip urlfilter cache	Displays the destination IP addresses that are cached into the cache table.
show ip urlfilter config Example: Router# show ip urlfilter config	Displays the size of the cache, the maximum number of outstanding requests, the allow mode state, and the list of configured N2H2 servers.
show ip urlfilter statistics Example: Router# show ip urlfilter statistics	Displays information such as the number of requests that are sent to the N2H2 server, the number of responses received from the N2H2 server, the number pending requests in the system, the number of failed requests, the number of blocked URLs.

Maintaining the Cache Table

To clear the cache table of a specified or all IP addresses, perform the following optional steps:

SUMMARY STEPS

1. **enable**
2. **clear ip urlfilter cache**

DETAILED STEPS

Command or Action	Purpose
enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
clear ip urlfilter cache { <i>ip-address</i> all } Example: Router# clear ip urlfilter cache all	Clears the cache table.

Monitoring the URL Filter Subsystems

To monitor the URL filter subsystems, perform the following optional steps:

SUMMARY STEPS

1. **enable**
2. **debug ip urlfilter** {**function-trace** | **detailed** | **events**}

DETAILED STEPS

Command or Action	Purpose
enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
debug ip urlfilter { function-trace detailed events } Example: Router# debug ip urlfilter detailed	Enables debugging information of URL filter subsystems. <ul style="list-style-type: none"> function-trace—Prints a sequence of important functions that are called when configuring URL filtering. detailed—Prints detailed information about various activities that occur during URL filtering. events—Prints various events such as queue event, timer event, and socket event.

Configuration Examples for Firewall and Webserver

This section provides the following comprehensive configuration example:

- [URL Filter Client \(Firewall\) Configuration Example, page 12](#)

URL Filter Client (Firewall) Configuration Example

The following example shows how to configure the Cisco IOS firewall (also known as the URL filter client [UFC]) for N2H2 URL filtering:

Topology:

```

End User-----LAN-----Fa0/0 -- Firewall -- S2/0----- Internet ---- Web Server
                        |
                        | Router
N2H2
Server -----+

```

Router Configuration:

Example 1:

```

hostname fw9-7200b
!
!-----
! The following commands define the inspection rule "myfw," allowing
! the specified protocols to be inspected. Note that the "urlfilter"
! keyword entered for HTTP protocol enables URL filtering on HTTP
! traffic that are bound to this inspection.
!-----
!
ip inspect name myfw http urlfilter
ip inspect name myfw ftp
ip inspect name myfw smtp
ip inspect name myfw h323
!
!-----
! The following command sets the URL filtering cache table size to 12000.
!-----
ip urlfilter cache 12000
!
!-----
! The following commands configure three exclusive domains--
! two partial domains and one complete domain.
!-----
ip urlfilter exclusive-domain permit .weapons.com
ip urlfilter exclusive-domain deny .nbc.com
ip urlfilter exclusive-domain permit www.cisco.com
!
!-----
! The following two commands enable URL filtering Audit Trail and
! Alert messages.
!-----
ip urlfilter audit-trail
ip urlfilter alert
!
!-----
! The command configures the N2H2 URL filtering server installed
! on 192.168.3.1.
!-----
ip urlfilter server vendor n2h2 192.168.3.1
!
!-----
! Create Access Control List 102:
! ACL 102 denies all IP protocol traffic except for ICMP traffic.
! This means that only the return traffic for protocols defined in the
! inspection rule and the ICMP traffic is allowed access through the

```

```

! interface where this rule is applied.
!
! Note that ACL is given here for an example; it is not relevant
! to the URL filtering. The URL filtering will work without ACL also.
!-----
!
access-list 102 permit icmp any any
access-list 102 deny tcp any any
access-list 102 deny udp any any
access-list 102 deny ip any any
!
!
interface FastEthernet0/0
ip address 192.168.3.254 255.255.255.0
ip nat inside
no ip route-cache
no ip mroute-cache
!
interface Ethernet1/0
no ip route-cache
no ip mroute-cache
shutdown
duplex half
!
interface Ethernet1/1
no ip address
no ip mroute-cache
shutdown
duplex half
!
!-----
! The ACL and CBAC inspection rules are applied to the Serial2/0 interface.
! In this example, the ACL is applied IN, meaning that it applies to traffic
! inbound from the internet. The CBAC inspection rule myfw is applied OUT,
! meaning that CBAC inspects the traffic that goes out through the interface
! and controls return traffic to the router for an existing connection.
!-----
interface Serial2/0
ip address 10.6.9.7 255.255.0.0
ip access-group 102 in
ip nat outside
ip inspect myfw out
no ip directed-broadcast
no ip mroute-cache
!
ip nat inside source static 192.168.3.1 10.6.243.1
ip nat inside source static 192.168.3.2 10.6.243.2
ip nat inside source static 192.168.3.3 10.6.243.3
ip classless

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

New Commands

- **clear ip urlfilter cache**
- **debug ip urlfilter**
- **ip urlfilter alert**
- **ip urlfilter allowmode**
- **ip urlfilter audit-trail**
- **ip urlfilter cache**
- **ip urlfilter exclusive-domain**
- **ip urlfilter max-request**
- **ip urlfilter max-resp-pak**
- **ip urlfilter server vendor**
- **ip urlfilter urlf-server-log**
- **show ip urlfilter cache**
- **show ip urlfilter config**
- **show ip urlfilter statistics**

Modified Command

- `ip inspect name`

Glossary

ACL—Access Control List.

CSIS—Cisco Secure Integrated Software. CSIS is a content-based firewall that currently inspects application data, checks for protocol conformance, extracts the relevant port information to create dynamic access list entries that successfully allows return traffic, and closes the ports at the end of the session.

ICMP—Internet Control Message Protocol. ICMP is a network layer Internet protocol that reports errors and provides other information relevant to IP packet processing. ICMP is documented in RFC 792.

UFC—URL filter client. UFC is a separate process that accepts URLs from CSIS, forwards the URL to the Websense server, and process the replies from the vendor server (Websense or N2H2).

UFS—URL filter server. UFS is a generic name given to the vendor server (Websense or N2H2), which processes URLs and decides whether to allow or deny web traffic based on a given policy.

Firewall Stateful Inspection of ICMP

The Firewall Stateful Inspection of ICMP feature addresses the limitation of qualifying Internet Control Management Protocol (ICMP) messages into either a malicious or benign category by allowing the Cisco IOS firewall to use stateful inspection to “trust” ICMP messages that are generated within a private network and to permit the associated ICMP replies. Thus, network administrators can debug network issues by using ICMP without concern that possible intruders may enter the network.

Feature Specifications for the Firewall Stateful Inspection of ICMP feature

Feature History

Release	Modification
12.2(11)YU	This feature was introduced.
12.2(15)T	This feature was integrated into Cisco IOS Release 12.2(15)T.

Supported Platforms

For platforms supported in Cisco IOS Release 12.2(11)YU and 12.2(15)T, consult Cisco Feature Navigator.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

- [Glossary, page 10](#)

Restrictions for Firewall Stateful Inspection of ICMP

- To enable this feature, your Cisco IOS image must contain the Cisco IOS firewall.
- This feature does not work for the User Datagram Protocol (UDP) traceroute, in which UDP datagrams are sent instead of ICMP packets. The UDP traceroute is typically the default for UNIX systems. To use ICMP inspection with a UNIX host, use the “I” option with the traceroute command. This functionality will cause the UNIX host to generate ICMP traceroute packets, which will be inspected by the Cisco IOS firewall ICMP.

Information About Firewall Stateful Inspection of ICMP

The following sections provide information about Cisco IOS Firewall Stateful Inspection of ICMP:

- [Feature Design of Firewall Stateful Inspection of ICMP, page 2](#)
- [ICMP Inspection Checking, page 3](#)

Feature Design of Firewall Stateful Inspection of ICMP

ICMP is used to report errors and information about a network. It is a useful tool for network administrators who are trying to debug network connectivity issues. Unfortunately, intruders can also use ICMP to discover the topology of a private network. To guard against a potential intruder, ICMP messages can be blocked from entering a private network; however, a network administrator may then be unable to debug the network. Although a Cisco IOS router can be configured using access lists to selectively allow certain ICMP messages through the router, the network administrator must still guess which messages are potentially malicious and which messages are benign. With the introduction of this feature, a user can now configure a Cisco IOS firewall for stateful inspection to “trust” that the ICMP messages are generated within the private network and to permit the associated ICMP replies.

Note

Access lists can still be used to allow unsolicited error messages along with Cisco IOS firewall inspection. Access lists complement Cisco IOS firewall ICMP inspection.

Stateful inspection of ICMP packets is limited to the most common types of ICMP messages that are useful to network administrators who are trying to debug their networks. That is, ICMP messages that do not provide a valuable tool for the internal network administrator will not be allowed. For the Cisco IOS firewall-supported ICMP message request types, see [Table 29](#).

Table 29 *ICMP Packet Types Supported by CBAC*

ICMP Packet Type	Name	Description
0	Echo Reply	Reply to Echo Request (Type 8)
3	Destination Unreachable	Possible reply to any request
		Note This packet is included because it is a possible response to any ICMP packet request.

Table 29 *ICMP Packet Types Supported by CBAC*

ICMP Packet Type	Name	Description
8	Echo Request	Ping or traceroute request
11	Time Exceeded	Reply to any request if the time to live (TTL) packet is 0
13	Timestamp Request	Request
14	Timestamp Reply	Reply to Timestamp Request (type 13)

**Note**

ICMP packet types 0 and 8 are used for pinging: the source sends out an Echo Request packet, and the destination responds with an Echo Reply packet.

Packet types 0, 8, and 11 are used for ICMP traceroute: Echo Request packets are sent out starting with a TTL packet of 1, and the TTL is incremented for each hop. The intermediate hops respond to the Echo Request packet with a Time Exceeded packet; the final destination responds with an Echo Reply packet.

ICMP Inspection Checking

Return packets are checked by the inspect code, not by ACLs. The inspect code tracks each destination address from outgoing packets and checks each return packet. For ECHO REPLY and TIMESTAMP REPLY packets, the return address is checked. For UNREACHABLE and TIME EXCEEDED packets, the intended destination address is extracted from the packet data and checked.

For more information, see [Checking for ICMP Inspection Example, page 7](#).

How to Use Firewall Stateful Inspection of ICMP

This section contains the following procedures:

- [Configuring Firewall Stateful Inspection for ICMP, page 3](#)
- [Verifying Firewall and ICMP Session Information, page 4](#)
- [Monitoring Firewall and ICMP Session Information, page 5](#)

Configuring Firewall Stateful Inspection for ICMP

To enable the Cisco IOS Firewall to start inspection ICMP messages, perform the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect name *inspection-name* icmp [alert {on | off}] [audit-trail {on | off}] [timeout *seconds*]**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name <i>inspection-name</i> icmp [alert {on off}] [audit-trail {on off}] [timeout <i>seconds</i>] Example: Router(config)# ip inspect name test icmp alert on audit-trail on timeout 30	Turns on inspection for ICMP. <ul style="list-style-type: none"> alert—Alert messages are generated. This function is on by default. audit-trail—Audit trail messages are generated. This function is off by default. timeout—Overrides the global channel inactivity timeout value. The default value of the <i>seconds</i> argument is 10.

Verifying Firewall and ICMP Session Information

To display active ICMP session and IP access list information, perform the following optional steps:

SUMMARY STEPS

1. **enable**
2. **show ip inspect session [detail]**
3. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	show ip inspect session [detail] Example: Router# show ip inspect session	(Optional) Displays existing sessions that are currently being tracked and inspected by the Cisco IOS firewall. <ul style="list-style-type: none"> The optional detail keyword causes additional details about these sessions to be shown.
Step 3	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists. For a sample output example, see the section “ICMP Session Verification Example.”

Monitoring Firewall and ICMP Session Information

To monitor debugging messages related to ICMP inspection, perform the following optional steps:

Note

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

SUMMARY STEPS

1. enable
2. debug ip inspect icmp

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	debug ip inspect icmp Example: Router# debug ip inspect icmp	(Optional) Displays the operations of the ICMP inspection engine for debugging purposes. For an example of sample output, see the command debug ip inspect in the Command Reference section.

Configuration Examples for Stateful Inspection of ICMP

This section provides the following configuration examples:

- [Firewall Stateful Inspection for ICMP Configuration Example, page 6](#)
- [Checking for ICMP Inspection Example, page 7](#)
- [ICMP Session Verification Example, page 7](#)

Firewall Stateful Inspection for ICMP Configuration Example

The default ICMP timeout is deliberately short (10 seconds) due to the security hole that is opened by allowing ICMP packets with a wild-carded source address back into the inside network. The timeout will occur 10 seconds after the last outgoing packet from the originating host. For example, if you send a set of 10 ping packets spaced 1 second apart, the timeout will expire in 20 seconds or 10 seconds after the last outgoing packet. However, the timeout is not extended for return packets. If a return packet is not seen within the timeout window, the hole will be closed and the return packet will not be allowed in. Although the default timeout can be made longer if desired, it is recommended that this value be kept relatively short.

The following example shows how to configure a firewall for stateful inspection of ICMP packets:

```
no service pad
service timestamps debug uptime
service timestamps log uptime
service password-encryption
!
hostname UUT
!
ip subnet-zero
no ip domain lookup
!
ip inspect audit-trail
ip inspect name test icmp alert on audit-trail on timeout 30
!
interface Ethernet0
ip address 192.168.10.2 255.255.255.0
ip inspect test in
!
interface Ethernet1
ip address 192.168.20.2 255.255.255.0
ip access-group 101 in
!
ip classless
ip route 0.0.0.0 0.0.0.0 192.168.20.3
no ip http server
!
access-list 101 deny ip any any
!
line con 0
exec-timeout 0 0
!
end
```

Checking for ICMP Inspection Example

In the following example, three destinations were pinged. The example shows that the inspect code tracked each destination address in the inspect session information.

```
fw_1751#sh ip insp sess detail
Established Sessions
Session 813A1808 (192.168.156.5:0)=>(0.0.0.0:0) icmp SIS_OPEN
  Created 00:04:20, Last heard 00:00:00
  Destinations: 3
    Dest addr [192.168.131.3]
    Dest addr [192.168.131.7]
    Dest addr [192.168.131.31]
  Bytes sent (initiator:responder) [8456:5880] acl created 4
  Inbound access-list 102 applied to interface Ethernet0/0
  Inbound access-list 102 applied to interface Ethernet0/0
  Inbound access-list 102 applied to interface Ethernet0/0
  Inbound access-list 102 applied to interface Ethernet0/0
```

ICMP Session Verification Example

The following example is sample output from the **show ip access-list** command. In this example, Access Control Lists (ACLs) are created for an ICMP session on which only ping packets were issued from the host.

```
Router# show ip access-list 101

Extended IP access list 101
  permit icmp any host 192.168.133.3 time-exceeded
  permit icmp any host 192.168.133.3 unreachable
  permit icmp any host 192.168.133.3 timestamp-reply
  permit icmp any host 192.168.133.3 echo-reply (4 matches)
```

Command Reference

The following commands are introduced or modified in the feature or features documented in this module. For information about these commands, see the *Cisco IOS Security Command Reference* at http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html. For information about all Cisco IOS commands, go to the Command Lookup Tool at <http://tools.cisco.com/Support/CLILookup> or to the *Cisco IOS Master Commands List*.

- **debug ip inspect**
- **ip inspect name**

Glossary

ACL—access control list. An ACL is a list kept by routers to control access to or from the router for a number of services (for example, to prevent packets with a certain IP address from leaving a particular interface on the router).

CBAC—Context-Based Access Control. CBAC is the name given to the Cisco IOS Firewall subsystem.

firewall—A firewall is a networking device that controls access to the network assets of your organization. Firewalls are positioned at the entrance points into your network. If your network has multiple entrance points, you must position a firewall at each point to provide effective network access control.

The most basic function of a firewall is to monitor and filter traffic. Firewalls can be simple or elaborate, depending on your network requirements. Simple firewalls are usually easier to configure and manage. However, you might require the flexibility of a more elaborate firewall.

ICMP—Internet Control Message Protocol. An ICMP is a network layer Internet protocol that reports errors and provides other information relevant to IP packet processing.

RPC—remote-procedure call. A RPC is the technological foundation of client or server computing. RPCs are procedure calls that are built or specified by clients and are executed on servers, with the results returned over the network to the clients.

RTSP—Real Time Streaming Protocol. RTSP enables the controlled delivery of real-time data, such as audio and video. Sources of data can include both live data feeds, such as live audio and video, and stored content, such as prerecorded events. RTSP is designed to work with established protocols, such as RTP and HTTP.

SIP—Session Initiation Protocol. SIP is a protocol developed by the IETF MUSIC Working Group as an alternative to H.323. SIP features are compliant with IETF RFC 2543, published in March 1999. SIP equips platforms to signal the setup of voice and multimedia calls over IP networks.

SMTP—simple mail transfer protocol. SMTP is an Internet protocol providing e-mail services.

UDP—User Datagram Protocol. A UDP is a connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, requiring that error processing and retransmission be handled by other protocols. UDP is defined in RFC 768.

Firewall Support for SIP

The Firewall Support for SIP feature integrates Cisco IOS firewalls, Voice over IP (VoIP) protocol, and Session Initiation Protocol (SIP) within a Cisco IOS-based platform, enabling better network convergence.

Note

Some Cisco IOS versions earlier than 12.2(11)YU and 12.2(15)T may accept the configuration commands for SIP that are shown in this document; however, those earlier versions will not function properly.

Feature Specifications for Firewall Support for SIP

Feature History

Release	Modification
12.2(11)YU	This feature was introduced.
12.2(15)T	This feature was integrated into Cisco IOS Release 12.2(15)T.

Supported Platforms

For platforms supported in Cisco IOS Releases 12.2(11)YU and 12.2(15)T, consult Cisco Feature Navigator.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Restrictions for Firewall Support for SIP

DNS Name Resolution

Although SIP methods can have Domain Name System (DNS) names instead of raw IP addresses, this feature currently does not support DNS names.

SIP UDP Support Only

This feature supports only the SIP User Datagram Protocol (UDP) format for signaling; the TCP format is not supported.

SIP Abbreviated Header

This feature does not support the compact form of SIP header fields.

Earlier Versions of Cisco IOS

Some Cisco IOS versions earlier than 12.2(11)YU and 12.2(15)T may accept the configuration commands for SIP that are shown in this document; however, those earlier versions will not function properly.

Information About Firewall Support for SIP

To configure the Cisco IOS Firewall Support for SIP feature, you must understand the following concepts:

- [Firewall and SIP Overviews, page 2](#)
- [Firewall for SIP Functionality Description, page 5](#)
- [SIP Message Treatment by the Firewall, page 6](#)
- [Call Database, page 7](#)

Firewall and SIP Overviews

This section contains the following concepts:

- [Cisco IOS Firewall, page 2](#)
- [SIP \(Session Initiation Protocol\), page 3](#)

Cisco IOS Firewall

The Cisco IOS firewall extends the concept of static access control lists (ACLs) by introducing dynamic ACL entries that open on the basis of the necessary application ports on a specific application and close these ports at the end of the application session. The Cisco IOS firewall achieves this functionality by inspecting the application data, checking for conformance of the application protocol, extracting the

relevant port information to create the dynamic ACL entries, and closing these ports at the end of the session. The Cisco IOS firewall is designed to easily allow a new application inspection whenever support is needed.

SIP (Session Initiation Protocol)

SIP is an ASCII-based, application-layer control protocol that can be used to establish, maintain, and terminate calls between two or more endpoints. Like other VoIP protocols, SIP is designed to address the functions of signaling and session management within a packet telephony network. Signaling allows call information to be carried across network boundaries. Session management provides the ability to control the attributes of an end-to-end call.

SIP Messages

SIP has two types of messages—requests and responses—that have the following generic structure:

```
generic-message = Request-Line | Status-Line
                  * ( general-header | request-header
                    | response-header | entity-header )
                  CRLF
                  [ message-body]
```

Note

Any of these message components may contain embedded IP addresses.

[Table 30](#) identifies the six available SIP request messages.

Table 30 *SIP Request Messages*

SIP Message	Purpose
ACK	Confirms receipt of a final response to INVITE
BYE	Is sent by either side to end the call
CANCEL	Is sent to end a call that has not yet been connected
INVITE	Is a request from a User Agent Client (UAC) to initiate a session
OPTIONS	Are sent to query capabilities of the user agents and network servers
REGISTER	Is sent by the client to register the address with a SIP proxy

[Table 31](#) identifies the available SIP response methods.

Table 31 *SIP Response Messages*

SIP Message	Purpose
1xx Informational	<ul style="list-style-type: none"> • 100 = Trying • 180 = Ringing • 181 = Call Is Being Forwarded • 182 = Queued • 183 = Session Progress
2xx Successful	<ul style="list-style-type: none"> • 200 = OK
3xx Redirection	<ul style="list-style-type: none"> • 300 = Multiple Choices • 301 = Moved Permanently • 302 = Moved Temporarily • 303 = See Other • 305 = Use Proxy • 380 = Alternative Service
4xx Request Failure	<ul style="list-style-type: none"> • 400 = Bad Request • 401 = Unauthorized • 402 = Payment Required • 403 = Forbidden • 404 = Not Found • 405 = Method Not Allowed • 406 = Not Acceptable • 407 = Proxy Authentication Required • 408 = Request Timeout • 409 = Conflict • 410 = Gone • 411 = Length Required • 413 = Request Entity Too Large • 414 = Request URI Too Large • 415 = Unsupported Media Type • 420 = Bad Extension • 480 = Temporarily Not Available • 481 = Call Leg/Transaction Does Not Exist
4xx Request Failure (continued)	<ul style="list-style-type: none"> • 482 = Loop Detected • 483 = Too Many Hops • 484 = Address Incomplete • 485 = Ambiguous • 486 = Busy Here

Table 31 **SIP Response Messages (continued)**

SIP Message	Purpose
5xx Server Failure	<ul style="list-style-type: none">• 500 = Internal Server Error• 501 = Not Implemented• 502 = Bad Gateway• 503 = Service Unavailable• 504 = Gateway Timeout• 505 = SIP Version Not Supported
6xx Global Failure	<ul style="list-style-type: none">• 600 = Busy Anywhere• 603 = Decline• 604 = Does Not Exist Anywhere• 606 = Not Acceptable

Firewall for SIP Functionality Description

The Firewall for SIP Support feature allows SIP signaling requests to traverse directly between gateways or through a series of proxies to the destination gateway or phone. After the initial request, if the Record-Route header field is not used, subsequent requests can traverse directly to the destination gateway address as specified in the Contact header field. Thus, the Cisco IOS firewall is aware of all surrounding proxies and gateways and allows the following functionality:

- SIP signaling responses can travel the same path as SIP signaling requests.
- Subsequent signaling requests can travel directly to the endpoint (destination gateway).
- Media endpoints can exchange data between each other.

See [Figure 28](#) for a sample topology that displays these functionalities.

Figure 28 Cisco IOS Firewall for SIP Awareness Sample Topology

SIP Message Treatment by the Firewall

See [Table 32](#) for information on the treatment of SIP methods by the Cisco IOS firewall.

Table 32 Treatment of SIP Methods by the Cisco IOS Firewall

SIP Message	Purpose
200 OK	Signifies the end of the call creation phase. The packet is checked for validity against the call database, and the contact information of the server is taken from it. Temporary call-flow-based openings in the firewall are created for allowing the BYE message, which can be initiated from the inside or outside.
200 OK for BYE	Signifies the graceful termination of the call and is in response to the BYE message. The same action as the CANCEL message is taken.
ACK	Signifies that the message is passed after checking for validity.
BYE	Signifies the intent to terminate the call. The database state is updated and temporary openings in the firewall are created for response to the BYE message.
CANCEL	Signifies abnormal data termination. The signaling sessions, media sessions, pregenerated temporary openings in the firewall, and the call database entry for the call are removed.

Table 32 *Treatment of SIP Methods by the Cisco IOS Firewall (continued)*

SIP Message	Purpose
INVITE	Occurs typically at the start of the call. The firewall will create a database entry upon receipt of this method and fill the database with relevant information extracted from this message. Temporary openings in the firewall will allow for a series of responses to the INVITE request. The temporary openings will be call-flow sensitive and will allow for responses for a fixed amount of time (t = 30 secs).
NO MATCH	Signifies a signaling message that is not present in the database.
Other Methods	Signifies that the message is passed if the call ID is present in the call database.
REGISTER	Results in the creation of an entry in the call database. Time-based, flow-control ACL firewall openings will allow for the response to the REGISTER and subsequent INVITE messages.
SESSION PROGRESS	Contains a response to the INVITE message, and it is a packet during the call creation phase. The packet is checked against the call database for validity of call ID and the media ports; the server proxy information is gathered from the packet. Media channels should be created in this phase.

Call Database

A call database, which contains the details of a call leg, is maintained for all call flows. A call database is created and maintained because there can be numerous signaling sessions for each call. [Table 33](#) identifies the information available in the call database.

Table 33 *Call Database Information*

Type	Purpose
call_int_over	Checks to see whether or not call initialization is over, and if so, checks to see if the call is in the teardown phase
C con ip & C con port	Signifies the IP address and port in the contact field of the initiator; for example, "Contact:<sip:1111@172.16.0.3:5060;user=phone>"
C media ip & C media port	Signifies the IP address in the media field of the initiator; for example, "c=IN IP4 172.16.0.3"
C media port	Signifies the port in the media field of the initiator; for example, "m=audio 20758 RTP/AVP 0"
C src ip & C src port	Signifies the actual IP address and port of the initiator
C via ip & C via port	Signifies the IP address and port in the via field of the initiator (the first via line); for example, "Via: SIP/2.0/UDP 172.16.0.3:5060"
current sip state	Is the current state of the call (which helps to avoid retransmission)
from/to/callid	Is extracted from the "INVITE" SIP request message to identify the call
media header	Keeps the list of media sessions for the call

Table 33 **Call Database Information (continued)**

Type	Purpose
media opened	Signifies multiple messages that may have media information, so you need to check to see whether or not the media has been opened for the call
prev sip state	Signifies the previous state of the call (which helps to avoid retransmission)
S con ip & S con port	Signifies the IP address and port in the contact field for the responder
S media ip	Signifies the IP address in the media field for the responder
S media port	Signifies the port in the media field for the responder
S src ip & S src port	Signifies the actual IP address and port of the responder
S via ip & S via port	Signifies the IP address and port in the via field for the responder
signal header	Keeps the list of signaling sessions for the call
sip_proxy_traversed	Makes the firewall topologically aware of whether the call has traversed through proxies

How to Configure Your Firewall for SIP

To configure a Cisco IOS Firewall for SIP support, perform the following tasks:

- [Configuring Firewall for SIP Support, page 8](#) (required)
- [Verifying Firewall for SIP Support, page 9](#) (optional)
- [Monitoring Firewall for SIP Support, page 10](#) (optional)

Configuring Firewall for SIP Support

To enable a firewall to support SIP, use the following commands.

Prerequisite

Before you configure Cisco IOS firewall support for SIP on your router, you first need to configure access lists, whose purpose normally is to block SIP traffic from unprotected networks for which the firewall will create temporary openings for specific traffic. For information about configuring access lists and the **access-list** command, see the chapter “[Configuring IPsec Network Security](#)” in the *Cisco IOS Security Configuration Guide*, Release 12.2, and the *Cisco IOS Command Reference*, Release 12.2 T, respectively.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect name** *inspection-name* **sip** [**alert {on | off}**] [**audit-trail {on | off}**] [**timeout** *seconds*]
4. **interface** *type number*
5. **ip inspect** *inspection-name* **{in | out}**

6. Repeat Steps 3 through 5 (Optional)

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name inspection-name sip [alert {on off}] [audit-trail {on off}] [timeout seconds] Example: Router(config)# ip inspect name voip sip	Turns on inspection for SIP. <ul style="list-style-type: none"> alert—Alert messages are generated. This function is on by default. audit-trail—Audit trail messages are generated. This function is off by default. timeout—Overrides the global channel inactivity timeout value.
Step 4	interface type number Example: Router(config)# interface FastEthernet 0/0	Configures an interface type and enters interface configuration mode.
Step 5	ip inspect inspection-name {in out} Example: Router(config-if)# ip inspect voip in	Applies inspection configurations to an interface and for a particular traffic direction.
Step 6	If SIP calls are coming from other interfaces, repeat Steps 3 through 5 and apply SIP inspections for the calls that are coming from those interfaces.	Note The inspection of protocols other than SIP may not be desirable for traffic that comes from external networks, so it may be necessary to configure an additional inspection rule specifying only SIP.

Verifying Firewall for SIP Support

To verify Cisco IOS firewall session information, perform the following optional steps:

SUMMARY STEPS

1. **enable**
2. **show ip inspect name inspection-name**
3. **show ip inspect session [detail]**
4. **show ip access-list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	show ip inspect name <i>inspection-name</i> Example: Router# show ip inspect name voip	(Optional) Displays the configured inspection rule.
Step 3	show ip inspect session [detail] Example: Router# show ip inspect session	(Optional) Displays existing sessions that are currently being tracked and inspected by the Cisco IOS firewall. <ul style="list-style-type: none"> The optional detail keyword causes additional details about these sessions to be shown.
Step 4	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists.

Monitoring Firewall for SIP Support

To monitor firewall events, perform the following optional steps:

Note

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

SUMMARY STEPS

- enable
- debug ip inspect sip

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	debug ip inspect sip Example: Router# debug ip inspect sip	(Optional) Displays the operations of the SIP inspection engine for debugging purposes.

Configuration Examples for Firewall SIP Support

This section provides the following configuration example:

- [Firewall and SIP Configuration Example, page 11](#)

Firewall and SIP Configuration Example

The following example shows how to allow outside initiated calls and internal calls. For outside initiated calls, an ACL needs to be punched to allow for the traffic from the initial signaling packet from outside. Subsequent signaling and media channels will be allowed by the inspection module.

```
ip inspect name voip sip
interface FastEthernet0/0
  ip inspect voip in
!
!
interface FastEthernet0/1
  ip inspect voip in
  ip access-group 100 in
!
!
access-list 100 permit udp host <gw ip> any eq 5060
access-list 100 permit udp host <proxy ip> any eq 5060
access-list deny ip any any
```

Firewall Websense URL Filtering

First Published: December 23, 2002

Last Updated: July 31, 2008

The Firewall Websense URL Filtering feature enables your Cisco IOS firewall (also known as Cisco Secure Integrated Software [CSIS]) to interact with the Websense URL filtering software, thereby allowing you to prevent users from accessing specified websites on the basis of some policy. The Cisco IOS firewall works with the Websense server to know whether a particular URL should be allowed or denied (blocked).

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the [“Feature Information for Firewall Websense URL Filtering” section on page 17](#).

Use Cisco Feature Navigator to find information about platform support and Cisco IOS, Catalyst OS, and Cisco IOS XE software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for Firewall Websense URL Filtering

Websense Server Requirement

To enable this feature, you must have *at least* one Websense server; however, two or more Websense servers are preferred. Although there is no limit to the number of Websense servers you may have, and you can configure as many servers as you wish, only one server will be active at any given time—the primary server. URL look-up requests will be sent only to the primary server.

URL Filtering Support Restriction

This feature supports only one active URL filtering scheme at a time. (Before enabling Websense URL filtering, you should always ensure that there is not another URL filtering scheme configured, such as N2H2.)

Username Restriction

This feature does not pass the username and group information to the Websense server. However, the Websense server can work for user-based policies because it has another mechanism for getting the username to correspond to an IP address.

Exclusive Domain List Restriction

This feature does not resolve the domains before it searches an exclusive domain list. When a questionable URL is presented to the filtering server, this feature searches only for the value that was specified in the command-line interface (CLI). That is, if an exclusive domain list was configured via the **ip urlfilter exclusive-domain deny 198.168.1.1** command, a user entering `http://198.168.1.1` into a browser will be denied access. However, a user who is trying to access this same domain and who enters `http://www.cisco.com`, will be allowed access because 198.168.1.1 was specified via the CLI, not `www.cisco.com`.

PISA URL Filtering Restrictions — Cisco IOS Release 12.2(18)ZYA

- Only one inspection rule is supported.
- Only HTTP filtering is supported. (HTTPS and FTP filtering are not supported.)
- HTTP over ports used by static Network Based Application Recognition (NBAR) protocols are not supported.
- Context-based Access Control (CBAC) is not supported.
- Only Layer 3 SVIs, Layer 3 routed ports, and Layer 3 subinterfaces are supported.
- The **clear ip urlfilter cache** and **show ip urlfilter cache** commands are not supported.
- Only the Websense URL filtering server is supported. (N2H2/SmartFilter/Trend Micro filtering servers are not supported.)
- Usernames are not passed on from PISA to Websense.

Information About Firewall Websense URL Filtering

To configure the Firewall Websense URL Filtering feature, you should understand the following concepts:

- [Benefits of Firewall Websense URL Filtering, page 3](#)
- [Feature Design of Firewall Websense URL Filtering, page 4](#)
- [Supported Websense Server Features on a Cisco IOS Firewall, page 5](#)

Benefits of Firewall Websense URL Filtering

The Cisco IOS Firewall Websense URL Filtering feature provides an Internet management application that allows you to control web traffic for a given host or user on the basis of a specified security policy. In addition, the following functions are available in this feature:

Primary and Secondary Servers

When users configure multiple Websense servers, the firewall will use only one server at a time—the primary server; all other servers are called secondary servers. When the primary server becomes unavailable for any reason, it becomes a secondary server and one of the secondary servers becomes the primary server.

A firewall marks a primary server as down when sending a request to or receiving a response from the server fails. When a primary server goes down, the system will go to the beginning of the configured servers list and try to activate the first server on the list. If the first server on the list is unavailable, it will try the second server on the list; the system will keep trying to activate a server until it is successful or until it reaches the end of the server list. If the system reaches the end of the server list, it will set a flag indicating that all of the servers are down, and it will enter allow mode.

When all the servers are down and the system is in allow mode, a periodic event that occurs for each minute will trace through the server list, trying to bring up a server by opening a TCP connection. If the TCP connection is successfully opened, the server is considered to be up, and the system will return to operational mode.

IP Cache Table

This function provides an IP cache table that contains the IP addresses of web servers whose underlying URLs can be accessed by all users and hosts.

The caching algorithm involves three parameters—the maximum number of IP addresses that can be cached, an idle time, and an absolute time. The algorithm also involves two timers—idle timer and absolute timer. The idle timer is a small periodic timer (1 minute) that checks to see whether the number of cached IP addresses in the cache table exceeds 80 percent of the maximum limit. If the cached IP addresses have exceeded 80 percent, it will start removing idle entries; if it has not exceeded 80 percent, it will quit and wait for the next cycle. The absolute timer is a large periodic timer (1 hour) that is used to remove all of the elapsed entries. (The age of an elapsed entry is greater than the absolute time.) An elapsed entry will also be removed during cache lookup.

The idle time value is fixed at 10 minutes. The absolute time value is taken from the Websense look-up response, which is often greater than 15 hours. The absolute value for cache entry made out of exclusive-domains is 12 hours. The maximum number of cache entries is configurable.

To configure cache table parameters, use the **ip urlfilter cache** command.

Packet Buffering

This function allows you to increase the maximum number of HTTP responses that a Cisco IOS firewall can hold. If the HTTP responses arrive prior to a Websense server reply, this buffering scheme allows your firewall to store a maximum of 200 HTTP responses. (After 200 responses have been reached, the firewall will drop further responses.) The responses will remain in the buffer until an allow or deny message is received from Websense: if the status indicates that the URL is allowed, the firewall will release the HTTP responses in the buffer to the browser of the end user; if the status indicates that the URL is blocked, the firewall will discard the HTTP responses in the buffer and close the connection to both ends. This function prevents numerous HTTP responses from overwhelming your system.

To configure the maximum number of HTTP responses for your firewall, use the **ip urlfilter max-resp-pak** command.

Exclusive Domains

This function provides a configurable list of domain names so that the Cisco IOS firewall does not have to send a lookup request to the Websense server for the HTTP traffic that is destined for one of the domains in the exclusive list. Thus, the Websense server does not have to deal with look-up requests for HTTP traffic that is destined for a host that has already been marked as “allowed.”

Flexibility when entering domain names is also provided; that is, the user can enter the complete domain name or a partial domain name. If the user adds a complete domain name, such as “www.cisco.com,” to the exclusive domain list, all HTTP traffic whose URLs are destined for this domain (such as www.cisco.com/news and www.cisco.com/index) will be excluded from the Websense URL filtering policies, and based on the configuration, the URLs will be permitted or blocked (denied).

If the user adds only a partial domain name to the exclusive domain list, such as “.cisco.com,” all URLs whose domain names end with this partial domain name (such as www.cisco.com/products and www.cisco.com/eng) will be excluded from the Websense URL filtering policies, and based on the configuration, the URLs will be permitted or blocked (denied).

To configure an exclusive domain list, use the **ip urlfilter exclusive-domain** command.

Allow Mode

The system will go into allow mode when connections to all the Websense servers are down. The system will return to normal mode when a connection to at least one web Websense server is up. Allow mode directs your system to forward or drop all packets on the basis of the configurable allow mode setting. By default, allow mode is off, so all HTTP requests are forbidden if all Websense servers are down.

To configure allow mode for your system, use the **ip urlfilter allowmode** command.

Feature Design of Firewall Websense URL Filtering

Note

This feature assumes that the Websense server will be part of a protected network and that requests from the Cisco IOS firewall will not travel over any unprotected network to reach the Websense server.

[Figure 29](#) and the corresponding steps explain a sample URL filtering network topology.

Figure 29 Firewall Websense URL Filtering Sample Topology

1. The end user browses a page on the web server, and the browser sends an HTTP request.
2. After the Cisco IOS firewall receives this request, it forwards the request to the web server while simultaneously extracting the URL and sending a look-up request to the Websense server.
3. After the Websense server receives the look-up request, it checks its database to see whether it should permit or deny the URL; it returns a permit or deny status via a look-up response to the Cisco IOS firewall.
4. After the Cisco IOS firewall receives this look-up response, it performs one of the following functions:
 - If the look-up response permits the URL, it sends the HTTP response to the end user.
 - If the look-up response denies the URL, the Websense server redirects the user to its own internal web server, which displays a message that describes the category under which the URL is blocked; thereafter, the connection is reset to both ends.

Supported Websense Server Features on a Cisco IOS Firewall

The Cisco IOS firewall supports all of the filtering and user authentication methods that are supported by the Websense server.

The following filtering methods are supported:

- Global filtering, which is applied to all users, groups, and IP addresses
- User- or group-based filtering, which is applied to a specific user or group
- Keyword-based filtering, which is applied on the basis of specific keywords (for example, a user can configure a policy for which all URLs with the keyword “dog” will be denied)
- Category-based filtering, which is applied on the basis of specific categories
- Customized filtering, which allows the user to apply a policy for customized URLs

The NT LAN Manager (NTLM) and Lightweight Directory Access Protocol (LDAP) user authentication methods are supported in this feature. Websense uses these methods to authenticate the user when the firewall does not pass the authenticated username along with the look-up request.

When the username is not passed along with the look-up request, the Websense server retrieves the username through one of the following methods:

- Manual authentication—Websense redirects the user to its own internal web server, which displays a challenge or response for the username and password. (This process is similar to when a user is blocked, but in this process, an authentication message is displayed instead of a blocked message.) Thereafter, Websense checks the NTLM or LDAP directory service to see if the username and password are a match. If there is a match, Websense associates the username with the source IP address and policies can be created for that username.
- Transparent ID (XID)—Websense has an agent that automatically associates users, when they log onto a Windows network, to their IP addresses. Unlike manual authentication, this method does not require an additional logon by the user. However, this method can be used only for Windows.

**Note**

Although Websense also supports user authentication via TACACS or RADIUS, this feature currently does not support these protocols for user authentication.

How to Configure Websense URL Filtering

To configure your Cisco IOS firewall to interact with at least one Websense server to provide URL filtering, configure the following procedures:

- [Configuring Firewall Websense URL Filtering, page 6](#) (required)
- [Verifying Cisco IOS Firewall and Websense URL Filtering, page 11](#) (optional)
- [Maintaining the Cache Table, page 12](#) (optional)
- [Monitoring the URL Filter Subsystems, page 13](#) (optional)

Configuring Firewall Websense URL Filtering

Websense is a third-party filtering software that can filter HTTP requests on the basis of the following policies: destination hostname, destination IP address, keywords, and username. The software maintains a URL database of more than 20 million sites organized into more than 60 categories and subcategories.

Prerequisites

Before enabling Websense URL filtering, you should always ensure that there is not another URL filtering scheme configured, such as N2H2. If you try to enter a new filtering scheme when one already exists, the new scheme will be ignored, and the system will display an error message that says, “different URL filtering scheme cannot co-exist.”

Restrictions

Enabling HTTP inspection (via the **ip inspect name** command) triggers the Java applet scanner, which is CPU intensive. The only way to stop the Java applet scanner is to specify the **java-list access-list** keyword and argument and configure a standard access list to allow any traffic. Configuring URL filtering without enabling the **java-list access-list** keyword and argument will severely impact performance.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect name** *inspection-name* **http** [**java-list** *access-list*] [**urlfilter**] [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**timeout** *seconds*]
4. **ip inspect** *inspection-name* {**in** | **out**}
5. **ip urlfilter server vendor** {**websense** | **n2h2**} *ip-address* [**port** *port-number*] [**timeout** *seconds*] [**retransmit** *number*]
6. **ip urlfilter alert**
7. **ip urlfilter audit-trail**
8. **ip urlfilter urlf-server-log**
9. **ip urlfilter exclusive-domain** {**permit** | **deny**} *domain-name*
10. **ip urlfilter cache** *number*
11. **ip urlfilter allowmode** [**on** | **off**]
12. **ip urlfilter max-resp-pak** *number*
13. **ip urlfilter max-request** *number*
14. **ip urlfilter truncate** {**script-parameters** | **hostname**}
15. **ip urlfilter mode** {**per-session** | **per-uri** | **per-uri-proxy-only**}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
	Example: Router> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example: Router# configure terminal	

	Command or Action	Purpose
Step 3	<p>ip inspect name inspection-name http [java-list access-list] [urlfilter] [alert {on off}] [audit-trail {on off}] [timeout seconds]</p> <p>Example: Router(config)# ip inspect name fw_urlf http java-list 51 urlfilter timeout 30</p>	<p>Turns on HTTP inspection. The urlfilter keyword associates URL filtering with HTTP inspection.</p> <p>Note You may configure two or more inspections in a router, but URL filtering will work only with the inspections in which the urlfilter keyword is enabled.</p> <p>Note Enabling HTTP inspection with or without any options triggers the Java applet scanner, which is CPU intensive. The only way to stop the Java applet scanner is to specify the java-list access-list keyword and argument. Configuring URL filtering without enabling the java-list access-list keyword and argument will severely impact performance.</p>
Step 4	<p>ip inspect inspection-name {in out}</p> <p>Example: Router(config)# ip inspect fw_urlf in</p>	<p>Applies a set of inspection rules to an interface.</p> <ul style="list-style-type: none"> The in keyword applies the inspection rules to inbound traffic.
Step 5	<p>ip urlfilter server vendor {websense n2h2} ip-address [port port-number] [timeout seconds] [retransmit number]</p> <p>Example: Router(config)# ip urlfilter server vendor websense 10.201.6.202</p>	<p>Configures a Websense server to interact with the firewall to filter HTTP requests on the basis of a specified policy.</p> <ul style="list-style-type: none"> ip-address—IP address of the vendor server. port port-number—Port number that the vendor server listens on. The default port number is 15868. timeout seconds—Length of time that the firewall will wait for a response from the vendor server. The default timeout is 5 minutes. retransmit number—Number of times the firewall will retransmit the request when a response does not arrive. The default value is 2 times.
Step 6	<p>ip urlfilter alert</p> <p>Example: Router(config)# ip urlfilter alert</p>	<p>(Optional) Enables the system alert, which displays system messages such as a server entering allow mode or going down.</p> <ul style="list-style-type: none"> The system alert is enabled by default.
Step 7	<p>ip urlfilter audit-trail</p> <p>Example: Router(config)# ip urlfilter audit-trail</p>	<p>(Optional) Enables the logging of messages into the syslog server of router. This function is disabled by default.</p>
Step 8	<p>ip urlfilter urlf-server-log</p> <p>Example: Router(config)# ip urlfilter urlf-server-log</p>	<p>(Optional) Enables the logging of system messages on the URL filtering server (the Websense server).</p> <ul style="list-style-type: none"> This function is disabled by default.

	Command or Action	Purpose
Step 9	<p>ip urlfilter exclusive-domain {permit deny} <i>domain-name</i></p> <p>Example: Router(config)# ip urlfilter exclusive-domain permit www.cisco.com</p>	<p>(Optional) Adds a domain name to or from the exclusive domain list so that the firewall does not have to send look-up requests to the Websense server.</p> <ul style="list-style-type: none"> • permit—Permits all traffic destined for the specified domain name. • deny—Denies all traffic destined for the specified domain name. • <i>domain-name</i>—Domain name that is added or removed from the exclusive domain list.
Step 10	<p>ip urlfilter cache <i>number</i></p> <p>Example: Router(config)# ip urlfilter cache 4500</p>	<p>(Optional) Configures cache table parameters.</p> <ul style="list-style-type: none"> • <i>number</i>—Maximum number of destination IP addresses that can be cached into the cache table; the default is 5000.
Step 11	<p>ip urlfilter allowmode [on off]</p> <p>Example: Router(config)# ip urlfilter allowmode on</p>	<p>(Optional) Turns on the default mode of the filtering systems.</p> <ul style="list-style-type: none"> • on—Allows HTTP requests to pass to the end user if all Websense servers are down. • off—Blocks all HTTP requests if all Websense servers are down; off is the default setting.
Step 12	<p>ip urlfilter max-resp-pak <i>number</i></p> <p>Example: Router(config)# ip urlfilter max-resp-pak 150</p>	<p>(Optional) Configures the maximum number of HTTP responses that the firewall can keep in its packet buffer. The default value is 200 512-byte buffers.</p>
Step 13	<p>ip urlfilter max-request <i>number</i></p> <p>Example: Router(config)# ip urlfilter maxrequest 500</p>	<p>(Optional) Sets the maximum number of outstanding requests that can exist at any given time. If the maximum number of requests is reached, all subsequent URLs are dropped.</p> <ul style="list-style-type: none"> • The default value is 1000.

	Command or Action	Purpose
Step 14	ip urlfilter truncate {script-parameters hostname} Example: Router(config)# ip urlfilter truncate hostname	(Optional) Allows the URL filter to truncate long URLs to the server.
Step 15	ip urlfilter mode {per-session per-uri per-uri-proxy-only} Example: Router(config)# ip urlfilter mode per-uri	(Optional) Configures a URL filtering mode. <ul style="list-style-type: none"> • per-session—Filters the first URL in the HTTP session. • per-uri—Filters the first URL in each packet. • per-uri-proxy-only—Filters via the per-session keyword behavior for direct (non-proxy) requests. Filters via the per-uri keyword behavior for proxy requests. <p>Note This command is available only on the Catalyst 6500 with PISA in Cisco IOS Release 12.2(18)ZYA.</p>

Troubleshooting Tips

This feature introduces the following alert messages:

- “%URLF-3-SERVER_DOWN: Connection to the URL filter server 10.92.0.9 is down”

This level three LOG_ERR-type message is displayed when a configured UFS goes down. When this happens, the firewall will mark the configured server as secondary and try to bring up one of the other secondary servers and mark that server as the primary server. If there is no other server configured, the firewall will enter allow mode and display the “URLF-3-ALLOW_MODE” message.

- %URLF-3-ALLOW_MODE: Connection to all URL filter servers are down and ALLOW MODE is OFF

This LOG_ERR type message is displayed when all UFSs are down and the system enters allow mode.

Note Whenever the system goes into allow mode (all filter servers are down), a periodic keepalive timer will be triggered that will try to bring up a server by opening a TCP connection.

- “%URLF-5-SERVER_UP: Connection to an URL filter server 10.92.0.9 is made; the system is returning from ALLOW MODE”

This LOG_NOTICE-type message is displayed when the UFSs are detected as being up and the system is returning from allow mode.

- “%URLF-4-URL_TOO_LONG:URL too long (more than 3072 bytes), possibly a fake packet?”

This LOG_WARNING-type message is displayed when the URL in a look-up request is too long; any URL longer than 3K will be dropped.

- “%URLF-4-MAX_REQ: The number of pending request exceeds the maximum limit <1000>”

This LOG_WARNING-type message is displayed when the number of pending requests in the system exceeds the maximum limit and all further requests are dropped.

To display these alert messages, use the **ip urlfilter alert** command.

This feature introduces the following syslog messages:

- “%URLF-6-SITE_ALLOWED: Client 10.0.0.2:12543 accessed server 10.76.82.21:8080”

This message is logged for each request whose destination IP address is found in the cache. It includes the source IP address, source port number, destination IP address, and destination port number. The URL is not logged because the IP address of the request is found in the cache, so parsing the request and extracting the URL is a waste of time.

- “%URLF-4-SITE-BLOCKED: Access denied for the site ‘www.sports.com’; client 10.54.192.6:34557 server 172.24.50.12:80”

This message is logged when a request finds a match against one of the blocked domains in the exclusive-domain list or the corresponding entry in the IP cache.

- “%URLF-6-URL_ALLOWED: Access allowed for URL http://www.websense.com/; client 10.54.192.6:54123 server 192.168.0.1:80”

This message is logged for each URL request that is allowed by a UFS. It includes the allowed URL, source IP address, source port number, destination IP address, and destination port number. Longer URLs will be truncated to 300 bytes and then logged.

- “%URLF-6-URL_BLOCKED: Access denied URL http://www.google.com; client 12.54.192.6:54678 server 64.192.14.2:80”

This message is logged for each URL request that is blocked by a UFS. It includes the blocked URL, source IP address, source port number, destination IP address, and destination port number. Longer URLs will be truncated to 300 bytes and then logged.

To display these syslog messages, use the **ip urlfilter audit-trail** command.

Verifying Cisco IOS Firewall and Websense URL Filtering

To verify that the Firewall Websense URL Filtering feature is working, perform any of the following optional steps:

SUMMARY STEPS

1. **enable**
2. **show ip urlfilter cache**
3. **show ip urlfilter config**
4. **show ip urlfilter statistics**

DETAILED STEPS

Command or Action	Purpose
enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
show ip urlfilter cache Example: Router# show ip urlfilter cache	Displays the destination IP addresses that are cached into the cache table. Note This command is not supported on PISA in Cisco IOS Release 12.2(18)ZYA.
show ip urlfilter config Example: Router# show ip urlfilter config	Displays the size of the cache, the maximum number of outstanding requests, the allow mode state, and the list of configured Websense servers.
show ip urlfilter statistics Example: Router# show ip urlfilter statistics	Displays information such as the number of requests that are sent to the Websense server, the number of responses received from the Websense server, the number of pending requests in the system, the number of failed requests, the number of blocked URLs.

Maintaining the Cache Table

To clear the cache table of a specified address or of all IP addresses, perform the following optional steps.

SUMMARY STEPS

1. enable
2. clear ip urlfilter cache

DETAILED STEPS

Command or Action	Purpose
enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
clear ip urlfilter cache {ip-address all} Example: Router# clear ip urlfilter cache all	Clears the cache table. Note This command is not supported on PISA in Cisco IOS Release 12.2(18)ZYA.

Monitoring the URL Filter Subsystems

To monitor the URL filter subsystems, perform the following optional steps:

SUMMARY STEPS

1. **enable**
2. **debug ip urlfilter {func-trace | detailed | events}**

DETAILED STEPS

Command or Action	Purpose
enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
debug ip urlfilter {func-trace detailed events} Example: Router# debug ip urlfilter detailed	Enables debugging information of the URL filter subsystems. <ul style="list-style-type: none"> • func-trace—Prints a sequence of important functions that are called when configuring URL filtering. • detailed—Prints detailed information about various activities that occur during URL filtering. • events—Prints various events, such as queue event, timer event, and socket event.

Configuration Examples for the Firewall and Webserver

This section provides the following comprehensive configuration example:

- [URL Filter Client \(Firewall\) Configuration Example, page 13](#)

URL Filter Client (Firewall) Configuration Example

The following example shows how to configure the Cisco IOS firewall (also known as the URL filter client [UFC]) for Websense URL filtering:

```
hostname fw9-7200b
!

Feature Information for Firewall Websense URL Filtering

[Table 34](#) lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

[Table 34](#) lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 34 **Feature Information for Firewall Websense URL Filtering**

Feature Name	Releases	Feature Information
Firewall Websense URL Filtering	12.2(11)YU 12.2(15)T 12.2(18)ZYA	<p>This feature enables your Cisco IOS firewall to interact with the Websense URL filtering software, thereby allowing you to prevent users from accessing specified websites on the basis of some policy.</p> <p>In 12.2(18)ZYA, support was added on the Catalyst 6500 series of switches equipped with the PISA.</p> <p>The following commands were introduced or modified: clear ip urlfilter cache, debug ip urlfilter, ip inspect name, ip urlfilter alert, ip urlfilter allowmode, ip urlfilter audit-trail, ip urlfilter cache, ip urlfilter exclusive-domain, ip urlfilter max-request, ip urlfilter max-resp-pak, ip urlfilter server vendor, ip urlfilter urlf-server-log, show ip urlfilter cache, show ip urlfilter config, show ip urlfilter statistics.</p> <p>In Cisco IOS Release 12.2(18)ZYA, the following command was introduced: ip urlfilter mode</p>

Glossary

CSIS—Cisco Secure Integrated Software. CSIS is a content-based firewall that currently inspects application data, checks for protocol conformance, extracts the relevant port information to create dynamic access list entries that successfully allow return traffic, and closes the ports at the end of the session.

UFC—URL filter client. UFC is a separate process that accepts URLs from CSIS, forwards the URL to the Websense server, and processes the replies from the vendor server (Websense or N2H2).

UFS—URL filter server. UFS is a generic name given to the vendor server (Websense or N2H2), which processes URLs and decides whether to allow or deny web traffic on the basis of a given policy.

Firewall Support of Skinny Client Control Protocol (SCCP)

The Firewall Support of Skinny Client Control Protocol (SCCP) feature enables Context-Based Access Control (CBAC) inspection to support the Voice over IP (VoIP) protocol, Skinny Client Control Protocol (SCCP). That is, CBAC inspects Skinny control packets that are exchanged between a Skinny client and the Call Manager (CM); CBAC then configures the router (also known as the Cisco IOS Firewall) to enable the Skinny data channels to traverse through the router.

Feature Specifications for the Firewall Support of Skinny Client Control Protocol (SCCP) Feature

Feature History

Release	Modification
12.3(1)	This feature was introduced.

Supported Platforms

For platforms supported in Cisco IOS Release 12.3(1), consult Cisco Feature Navigator.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Prerequisites for Firewall Support of Skinny Client Control Protocol (SCCP)

The Skinny inspection module is part of the inspection subsystem; thus, your router must be running an image that has firewall support.

Restrictions for Firewall Support of Skinny Client Control Protocol (SCCP)

This feature has the following restrictions:

- Skinny inspection will inspect only the SCCP sessions that have been established after the firewall is configured with Skinny inspection. That is, any SCCP sessions that were established through the firewall before the Skinny inspection was configured will not be inspected.
- This feature does not support Music on Hold (MOH) when a device other than the CM is the music server. (This feature does support MOH when the CM is the music server.)
- This feature does not address either the multicast functionality of SCCP or the functionality of multiple active calls on a single Skinny client.

This feature does not support the following Skinny and firewall configurations:

- The firewall and CM cannot be in the same router. Skinny inspection does not support this configuration because the current firewall implementation does not inspect sessions that start or terminate at the router. Thus, Skinny inspection will work only with an external CM.
- The CM and the Skinny client cannot be on three different networks that are separated at the firewall. The current firewall implementation does not inspect sessions that have devices residing on more than two distinct networks that are segregated at the firewall. That is, if there are more than two interfaces at the firewall, session inspection is not supported.

Information About Firewall Support of Skinny Client Control Protocol (SCCP)

To configure the Firewall Support of SCCP feature, you must understand the following concepts:

- [Context-Based Access Control Overview, page 3](#)
- [Skinny Overview, page 3](#)
- [CBAC and Skinny Functionality Overview, page 3](#)

Context-Based Access Control Overview

CBAC extends the concept of static access control lists (ACLs) by introducing dynamic ACL entries that open the necessary application ports on the basis of a specific application and close these ports at the end of the application session. CBAC achieves this functionality by inspecting the application data, checking for conformance of the application protocol, extracting the relevant port information to create the dynamic ACL entries, and closing these ports at the end of the session. CBAC is designed to easily allow a new application inspection whenever support is needed.

Skinny Overview

Skinny enables voice communication between two Skinny clients through the use of a CM. Typically, the CM provides service to the Skinny clients on TCP Port 2000. Initially, a Skinny client connects to the CM by establishing a TCP connection; the client will also establish a TCP connection with a secondary CM, if available. After the TCP connection is established, the client will register with the primary CM, which will be used as the controlling CM until it reboots or there is a keepalive failure. Thus, the Skinny TCP connection between the client and the CM exists forever and is used to establish calls coming to or from the client. If a TCP connection failure is detected, the secondary CM is used. All data channels established with the previous CM remain active and will be closed after the end parties hang up the call.

[Table 1](#) lists the set of messages that are necessary for the data sessions to open and close. Skinny inspection will examine the data sessions that are deemed for opening and closing the access list pin holes.

Table 1 *Skinny Data Session Messages*

Skinny Inspection Message	Description
StationOpenReceiveChannelAckMessage	Contains the IP address and port information of the Skinny client sending this message. This message also contains the status of whether or not the client is willing to receive the voice traffic.
StationStartMediaTransmissionMessage	Contains the IP address and port information of the remote Skinny client.
StationCloseReceiveChannelMessage	CM instructs the Skinny client (on the basis of the information in this message) to close the receiving channel.
StationStopMediaTransmissionMessage	CM instructs the Skinny client (on the basis of the information in this message) to stop transmitting voice traffic.
StationStopSessionTransmissionMessage	CM instructs the Skinny client (on the basis of the information in this message) to end an indicated session.

CBAC and Skinny Functionality Overview

[Figure 1](#) depicts typical deployment solutions that are supported by CBAC inspection for Skinny. According to [Figure 1](#), a firewall with Skinny inspection can be configured on Cisco IOS Router A, Cisco IOS Router B, or both routers, thereby addressing the following three scenarios:

- A Cisco IOS router with a firewall on the customer premises equipment (CPE) side, supporting Skinny VoIP phone
- A Cisco IOS router with a firewall on the CM side
- A Cisco IOS router with a firewall at both ends of the connection

Figure 1 *CBAC Inspection for Skinny Sample Topology*

How to Configure Your Firewall for Skinny Support

To configure a Cisco IOS Firewall for SCCP support, perform the following tasks:

- [Configuring Basic Skinny CBAC Inspection, page 4](#)
- [Setting Skinny CBAC Session Timeouts, page 6](#)
- [Configuring Port to Application Mapping, page 6](#)
- [Verifying Cisco IOS Firewall for Skinny Support, page 7](#)
- [Monitoring Cisco IOS Firewall for Skinny Support, page 8](#)

Configuring Basic Skinny CBAC Inspection

Perform the following required steps to configure a basic Skinny CBAC configuration:

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **ip inspect name** *inspection-name protocol* [**alert** {on | off}] [**audit-trail** {on | off}] [**timeout** *seconds*]
4. **ip inspect name** *inspection-name protocol* [**alert** {on | off}] [**audit-trail** {on | off}] [**timeout** *seconds*] (Optional. Required if the TFTP server is outside the firewall.)
5. **interface** *type number*
6. **ip access-group** {*access-list-number*} {in | out}
7. **ip inspect** *inspection-name* {in | out}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables higher privilege levels, such as privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name <i>inspection-name protocol</i> [alert {on off}] [audit-trail {on off}] [timeout <i>seconds</i>] Example: Router(config)# ip inspect name firewall skinny	Enables CBAC Skinny inspections.
Step 4	ip inspect name <i>inspection-name protocol</i> [alert {on off}] [audit-trail {on off}] [timeout <i>seconds</i>] Example: Router(config)# ip inspect name firewall tftp	(Optional. Required if the TFTP server is outside the firewall.) Defines a set of inspection rules.
Step 5	interface <i>type number</i> Example: Router(config)# interface FastEthernet 0/0	Configures an interface type and enters interface configuration mode.
Step 6	ip access-group { <i>access-list-number</i> } {in out} Example: Router(config-if)# ip access-group 100 in	Control access to an interface. Number of the access list that is blocking incoming traffic.
Step 7	ip inspect <i>inspection-name</i> {in out} Example: Router(config-if)# ip inspect firewall out	Applies a set of inspection rules to an interface.

Setting Skinny CBAC Session Timeouts

Session timeouts are triggered when traffic is not seen on a particular session for a configured amount of time. (This value is configured via the **ip inspect name** command.) After the inactivity timeout is triggered, the firewall will clean up the session and deallocate all of the session data.

You must set the inactivity timeout value for Skinny to a greater value than the keepalive timeout value that is configured between the CM and Skinny clients. Otherwise, the Skinny connection may become inaccessible for inspection because the firewall might delete the session-related information due to inactivity.

After the inactivity timeout is triggered, the inspection module will send reset (RST packets) to both ends of the connection. Any data channels that are associated with the control channel will not be closed. After both end parties hang up, there will not be any traffic on the data channels and the connection will eventually timeout.

Note

If the inactivity timeout of the control channel that is connected to the primary CM is less than the keepalive timeout that is sent by the CM to the Skinny client, the firewall will set the inactivity timeout to three times the keepalive timeout. If a timeout is not configured, the default value of 3600 seconds will be used.

Configuring Port to Application Mapping

By default, the Skinny inspection will inspect SCCP messages to or from the CM on TCP port 2000. If you prefer to configure the CM to use a different port, the port to application mapping (PAM) feature should be used to specify the desired port to the Cisco IOS firewall. Thus, the firewall will inspect the SCCP messages in the desired port and in port 2000. To configure the CM to use a different port via PAM, use the **ip port-map** command.

Prerequisites

Before you can configure PAM, you must first configure the steps in the section, “[Configuring Basic Skinny CBAC Inspection](#).”

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip port map** *appl_name* **port** *port_num* [**list** *acl_num*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables higher privilege levels, such as privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip port map <i>appl_name</i> port <i>port_num</i> [list <i>acl_num</i>] Example: Router(config)# ip port map skinny port 2100	(Optional) Creates a port to address mapping for SCCP. This command allows you to indicate additional ports that need to be monitored for SCCP.

Verifying Cisco IOS Firewall for Skinny Support

To display active Skinny session information, perform the following optional steps:

SUMMARY STEPS

1. **enable**
2. **show ip inspect** {**name** *inspection-name* | **config** | **interfaces** | **session** [**detail**] | **all**}
3. **show ip access-list**
4. **show ip port-map** [*appl_name* | **port** *port_num*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables higher privilege levels, such as privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	show ip inspect { name <i>inspection-name</i> config interfaces session [detail] all } Example: Router# show ip inspect session detail	(Optional) Displays existing sessions that are currently being tracked and inspected by CBAC. The optional detail keyword causes additional details about these sessions to be shown.

	Command or Action	Purpose
Step 3	show ip access-list Example: Router# show ip access-list	(Optional) Displays the contents of all current IP access lists, which includes the dynamic access lists created by Skinny inspection.
Step 4	show ip port-map [appl_name port port_num] Example: Router# show ip port-map skinny	(Optional) Displays information about the active port to application mappings on the router. Use this command to view Skinny port map information. <ul style="list-style-type: none"> <i>appl_name</i>—Displays Skinny-specific PAM information. (You must specify the <i>skinny</i> argument.)

Monitoring Cisco IOS Firewall for Skinny Support

Note

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

To monitor debugging messages related to Skinny inspection, perform the following optional steps:

SUMMARY STEPS

1. **enable**
2. **debug ip inspect {sccp | detailed}**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables higher privilege levels, such as privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	debug ip inspect {sccp detailed} Example: Router# debug ip inspect sccp	(Optional) Displays and logs the debugging messages related to SCCP inspection.

Configuration Examples for Firewall Skinny Support

This section provides the following configuration example:

- [Firewall and Skinny Configuration Example, page 9](#)

Firewall and Skinny Configuration Example

Figure 2 *Skippy and CBAC Configuration*

The following is an example of how to configure a Cisco IOS firewall for Skinny support and includes PAM (see [Figure 2](#)):

```
! Define the name of the router as "CBAC-Firewall."
!
host CBAC-Firewall
!
! Create a DHCP server process to offer out 10.1.1.x addresses on the
! inside network. Option 150 is used by Cisco IP phones as where to
! look for their configuration file. A default router is required so that all
! the IP phones can talk to networks other than just to the local 10.1.1.x.
!
ip dhcp pool localnetwork
  network 10.1.1.0 255.255.255.0
  option 150 ip 192.168.1.100
  default-router 10.1.1.1
!
! Prevent the DHCP server process from assigning 10.1.1.1 -.9 as an IP
! address on the local network. This is done to hold the addresses .2 - .9 as static-
! defined addresses.
!
ip dhcp excluded-address 10.1.1.1 10.1.1.9
!
! Define firewall rules to all Skinny traffic in/out along with TFTP
! services.
!
ip inspect name fwout tftp
ip inspect name fwout skinny
!
! Prevent any traffic from coming in.
!
access-list 100 deny ip any any
!
interface ethernet 1
  ip access-group 100 in
  ip inspect firewall out
```

If the CallManager is requiring Skinny registration to happen on port tcp/2100, you will still need the above configuration plus the following additional step.

```
ip port map skinny port 2100
```

Granular Protocol Inspection

The Granular Protocol Inspection feature adds flexibility to the Cisco IOS Firewall by allowing it to perform a higher degree of inspection of TCP and User Data Protocol (UDP) traffic for most RFC 1700 application types.

Feature History for Granular Protocol Inspection

Release	Modification
12.3(14)T	This feature was introduced.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Contents

- [Prerequisites for Granular Inspection Protocol, page 1](#)

- [Configuration Examples for Granular Protocol Inspection, page 9](#)
- [Additional References, page 12](#)
- [Command Reference, page 13](#)
- [Glossary, page 14](#)

Prerequisites for Granular Inspection Protocol

- Cisco IOS Firewall software must be installed in your network.

Americas Headquarters:
Cisco Systems, Inc., 170 West Tasman Drive, San Jose, CA 95134-1706 USA

© 2007 Cisco Systems, Inc. All rights reserved.

- Access control lists (ACLs) must be applied to specified interfaces to enable the existing firewall software to function properly.

Restrictions for Granular Inspection Protocol

Port ranges cannot be specified directly in the **ip inspect name** command; use the port-to-application mapping (PAM) table.

Information About Granular Protocol Inspection

To use the Granular Protocol Inspection feature, you need to understand the following concepts:

- [Cisco IOS Firewall, page 3](#)
- [Granular Protocol Inspection, page 3](#)
- [Benefits, page 4](#)

Cisco IOS Firewall

The Cisco IOS Firewall is a security-specific option that provides inspection firewall functionality and intrusion detection for every network perimeter. By delivering state-of-the-art security features such as stateful, application-based filtering; dynamic per-user authentication and authorization; and URL filtering, the Cisco IOS Firewall adds greater depth and flexibility to existing Cisco IOS security solutions including authentication, encryption, and failover.

A firewall is a physical software or hardware barrier between one part of an internal network used to control access to and from external networks. This barrier is unique because it allows predefined traffic to pass through the firewall while being monitored for protocol anomalies. The difficult part is determining the criteria by which the packets are granted or denied access through the device.

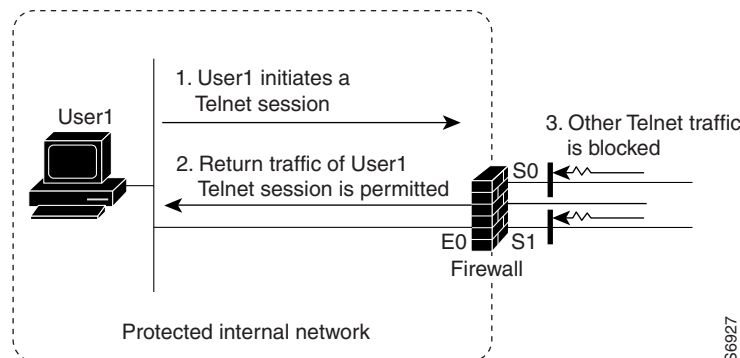

As mentioned, a firewall blocks traffic and permits other types of traffic to traverse. Firewalls are not just access control lists (ACLs); rather, they are a stateful inspection application.

Granular Protocol Inspection

The Cisco IOS Firewall performs inspections for TCP and UDP traffic. For example, TCP inspections include Telnet traffic (port 23, by default) as well as all other applications on TCP such as Hypertext Transfer Protocol (HTTP), e-mail, instant message (IM) chatter, and so on. Therefore, there is no easy way to inspect Telnet traffic alone and deny all other TCP traffic.

The Granular Protocol Inspection feature allows you to specify TCP or UDP ports using the PAM table. As a result, the Cisco IOS Firewall can restrict traffic inspections to specific applications, thereby permitting a higher degree of granularity in selecting which protocols are to be permitted and denied as shown in [Figure 32](#).

Figure 32 **Sample Topology**

Benefits

The Granular Protocol Inspection feature provides the following benefits:

- Greater flexibility by allowing more granularity in the selection of protocols to be inspected
- Ease of use by providing for group inspection of multiple ports into a single, user-defined application keyword
- Enhanced functionality with the addition of more well-known ports, user-defined applications, and user-defined port ranges
- Improved performance and reduced CPU load resulting from focused inspection selections

How to Configure Granular Protocol Inspection

This section contains the following procedures:

- [Defining Applications, page 5](#) (required)
- [Setting Up Inspection Rules, page 6](#) (required)
- [Verifying the Configuration, page 7](#) (optional)

Defining Applications

Perform the following task to define your applications in the PAM table by using the **ip port-map** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip port-map** *appl-name* **port** [**tcp** | **udp**] [*port_num* | **from** *begin_port_num* **to** *end_port_num*] [*list acl-num*] [**description** *description_string*]
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip port-map <i>appl-name</i> port [tcp udp] [<i>port_num</i> from <i>begin_port_num</i> to <i>end_port_num</i>] [list <i>acl-num</i>] [description <i>description_string</i>] Example: Router(config)# ip port-map user-10 port udp from 3400 to 3433 list 22 description "test application"	Establishes PAM entries. Note When defining a user application in the PAM table, you must enter the prefix user- ; otherwise, the following error message appears: "Unable to add port-map entry. Names for user-defined applications must start with 'user-'." Note Write the text string in the following format: " <i>C description_string C</i> ," where " <i>C</i> " is a delimiting character.
Step 4	exit Example: Router(config)# exit	Exits global configuration mode.

Setting Up Inspection Rules

Perform the following task to set up your inspection rules by using the **ip inspect name** command.

SUMMARY STEPS

- enable**
- configure terminal**
- ip inspect name** *inspection-name* *protocol* [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**timeout** *seconds*]
- exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name inspection-name protocol [alert {on off}] [audit-trail {on off}] [timeout seconds] Example: Router(config)# ip inspect name abc user-10	Defines inspection rules. Note Replace the <i>protocol</i> argument with the application (PAM entry) that you just defined in the previous step. In this example, it is <i>user-10</i> .
Step 4	exit Example: Router(config)# exit	Exits global configuration mode.

Verifying the Configuration

Perform the following task to verify your applications and inspection rules.

SUMMARY STEPS

1. enable
2. show ip port-map [appl-name | port port-num [detail]]
3. exit

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	show ip port-map [<i>appl-name</i> port <i>port-num</i> [detail]] Example: Router# show ip port-map port 70 detail	Establishes PAM entries.
Step 3	exit Example: Router# exit	(Optional) Exits privileged EXEC mode.

Configuration Examples for Granular Protocol Inspection

This section contains the following configuration examples:

- [Defining an Application for the PAM Table: Example, page 9](#)
- [Setting Up an Inspection Rule: Example, page 9](#)
- [Verifying the Configuration: Example, page 10](#)

Defining an Application for the PAM Table: Example

In the following example from the **ip port-map** command, a user-defined application named user-10 is defined in the PAM table for five ports using the TCP protocol. Standard access list 77 is applied to define host-specific port mapping and “TEST STRING” is the description.

```
Router# configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.

```
Router(config)# ip port-map user-10 port tcp 4000 5000 6000 7000 8000 list 77 description
"TEST STRING"
```

```
Router(config)# end
```

Setting Up an Inspection Rule: Example

The following example from the **ip inspect name** command, lists user-10 as an application with the description “TEST STRING.”

```
Router# configure terminal
```

Enter configuration commands, one per line. End with CNTL/Z.

```
Router(config)# ip inspect name abc ?
```

bootpc	Bootstrap Protocol Client
bootps	Bootstrap Protocol Server
cisco-fna	Cisco FNATIVE
cisco-sys	Cisco SYSMAINT
cisco-tna	Cisco TNATIVE
cuseeme	CUSEeMe Protocol
echo	Echo port
esmtpt	Extended SMTP
finger	Finger
fragment	IP fragment inspection
ftp	File Transfer Protocol
gopher	Gopher
gtpv0	GPRS Tunneling Protocol Version 0
gtpv1	GPRS Tunneling Protocol Version 1
h323	H.323 Protocol (e.g, MS NetMeeting, Intel Video Phone)
http	HTTP Protocol
icmp	ICMP Protocol
imap	IMAP Protocol
imap3	Interactive Mail Access Protocol 3
kerberos	Kerberos
ldap	Lightweight Directory Access Protocol
netbios-dgm	NETBIOS Datagram Service
netshow	Microsoft NetShow Protocol

```

nntp          Network News Transport Protocol
parameter    Specify inspection parameters
pop3         POP3 Protocol
pwdgen       Password Generator Protocol
rcmd         R commands (r-exec, r-login, r-sh)
realaudio    Real Audio Protocol
rpc          Remote Procedure Call Protocol
rtsp         Real Time Streaming Protocol
secure-http  Secure Hypertext Transfer Protocol
sip          SIP Protocol
skinny       Skinny Client Control Protocol
smtp         Simple Mail Transfer Protocol
snmp         Simple Network Management Protocol
snmptrap     SNMP Trap
sqlnet       SQL Net Protocol
sqlsrv       SQL Service
streamworks  StreamWorks Protocol
tacacs       Login Host Protocol (TACACS)
tacacs-ds    TACACS-Database Service
tcp          Transmission Control Protocol
telnet       Telnet
tftp         TFTP Protocol
udp          User Datagram Protocol
vdolive      VDOLive Protocol
user-10      TEST STRING<----- !user-defined application!

```

In the following example from the **ip inspect name** command, an inspection rule is established for user-10:

```

Router# configure terminal

Enter configuration commands, one per line.  End with CNTL/Z.

Router(config)# ip inspect name abc user-10

Router(config)# end

```

Verifying the Configuration: Example

The following example verifies your port-map configuration:

```

Router# show running-config | include port-map

ip port-map user-10 port tcp 4000 5000 6000 7000 8000 list 77 description "TEST STRING"

```

The following example verifies your inspection rule configuration:

```

Router# show running-config | include inspect

ip inspect name abc user-10

```

The following example displays information about the user-defined application called user-10.

```
Router# show ip port-map user-10
```

```
Host specific:      user-10                tcp port 4000...8000      in list 77      user defined
```

The following example displays detailed information about the user-defined application called user-10.

```
Router# show ip port-map user-10 detail
```

```
IP port-map entry for application 'user-10':
```

```
tcp 4000...8000                list 77 "TEST STRING"                user defined
```

Glossary

CBAC—Context-Based Access Control. A protocol that provides internal users with secure access control for each application and for all traffic across network perimeters. CBAC enhances security by scrutinizing both source and destination addresses and by tracking each application's connection status.

firewall—A router or access server, or several routers or access servers, designated as a buffer between any connected public networks and a private network. A firewall router uses access lists and other methods to ensure the security of the private network.

granular—Degree of componentization. Small, fine-grained components provide greater flexibility in assembling the right combination of functionality, but can be difficult to manage.

inspection rule—A rule that specifies what IP traffic (which application-layer protocols) will be inspected by CBAC at an interface.

PAM—port-to-application mapping. A flexible, per-application port mapping capability that allows the Cisco IOS Firewall to support applications running on nonstandard ports. This feature allows network administrators to customize access control for specific applications and services, in order to meet their distinct network needs.

traffic inspection—A way that CBAC inspects traffic that travels through the firewall to discover and manage state information for TCP and UDP sessions. This state information is used to create temporary openings in the firewall's access lists to allow return traffic and additional data connections for permissible sessions (sessions that originated from within the protected internal network).

UDP—User Data Protocol. A connectionless service—there are no actual sessions, so the software approximates sessions by examining the information in the packet and determining if the packet is similar to other UDP packets (for example, similar source/destination addresses and port numbers) and if the packet was detected soon after another similar UDP packet. "Soon" means within the configurable UDP idle timeout period.

H.323 RAS Support in Cisco IOS Firewall

First Published: November 17, 2006

Last Updated: November 17, 2006

This feature introduces support for H.225 Registration, Admission, and Status (RAS) signaling in Cisco IOS firewalls. RAS is a signaling protocol that is used between endpoints (such as gateways) and gatekeepers.

The H.225 standard is used by H.323 for call setup. H.255 includes RAS control, which is used to communicate with the gatekeeper. A RAS signaling channel enables connections between the gatekeeper and H.323 endpoints.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for H.323 RAS Support in Cisco IOS Firewall”](#) section on page 8.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Restrictions for H.323 RAS Support in Cisco IOS Firewall

H.225 RAS inspection is supported only with zone-based policy firewall inspection.

How to Configure a Firewall Policy for H.323 RAS Protocol Inspection

This section contains the following configuration tasks:

- [Configuring a Class Map for H.323 RAS Protocol Inspection, page 2](#)
- [Creating a Policy Map for H.323 RAS Protocol Inspection, page 3](#)

Configuring a Class Map for H.323 RAS Protocol Inspection

Use this task to configure a class map for classifying network traffic.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **class-map type inspect** [**match any** | **match all**] *class-map-name*
4. **match access-group** { *access-group* | **name** *access-group-name* }
5. **match protocol** *protocol-name* [**signature**]
6. **match class-map** *class-map-name*
7. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	class-map type inspect [match-any match-all] <i>class-map-name</i> Example: Router(config)# class-map type inspect match-all c1	Creates a Layer 3 or Layer 4 inspect type class map and enters class-map configuration mode.
Step 4	match access-group { <i>access-group</i> name <i>access-group-name</i> } Example: Router(config-cmap)# match access-group 101	(Optional) Configures the match criterion for a class map based on the access control list (ACL) name or number.
Step 5	match protocol <i>protocol-name</i> [signature] Example: Router(config-cmap)# match protocol h225ras	Configures the match criterion for a class map on the basis of a specified protocol. Note You should specify the h225ras keyword to create a class-map for H.225 RAS protocol classification. For a list of supported protocols, use the command-line interface (CLI) help option (?) on your platform.
Step 6	match class-map <i>class-map-name</i> Example: Router(config-cmap)# match class-map c1	(Optional) Specifies a previously defined class as the match criterion for a class map.
Step 7	exit Example: Router(config-cmap)# exit	Returns to global configuration mode.

Creating a Policy Map for H.323 RAS Protocol Inspection

Use this task to create a policy map for a firewall policy that will be attached to zone pairs.

**Note**

If you are creating an inspect type policy map, only the following actions are allowed: drop, inspect, police, and pass.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **policy-map type inspect** *policy-map-name*
4. **class type inspect** *class-name*
5. **inspect** [*parameter-map-name*]
6. **police rate** *bps* **burst** *size*
7. **drop** [log]
8. **pass**
9. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	policy-map type inspect <i>policy-map-name</i> Example: Router(config)# policy-map type inspect p1	Creates a Layer 3 and Layer 4 inspect type policy map and enters policy-map configuration mode.
Step 4	class type inspect <i>class-name</i> Example: Router(config-pmap)# class type inspect c1	Specifies the traffic (class) on which an action is to be performed and enters policy-map class configuration mode.
Step 5	inspect [<i>parameter-map-name</i>] Example: Router(config-pmap-c)# inspect inspect-params	Enables Cisco IOS stateful packet inspection.
Step 6	police rate <i>bps</i> <i>burst size</i> Example: Router(config-pmap-c)# police rate 2000 burst 3000	(Optional) Limits traffic matching within a firewall (inspect) policy.
Step 7	drop [log] Example: Router(config-pmap-c)# drop	(Optional) Drops packets that are matched with the defined class. Note The actions drop and pass are exclusive, and the actions inspect and drop are exclusive; that is, you cannot specify both of them.
Step 8	pass Example: Router(config-pmap-c)# pass	(Optional) Allows packets that are matched with the defined class.
Step 9	exit Example: Router(config-pmap-c)# exit	Returns to policy-map configuration mode.

What to Do Next

After configuring an H.323 RAS protocol firewall policy, you want to attach the policy to a zone pair. For information on completing this task, see the [“Zone-Based Policy Firewall”](#) module.

Configuration Examples for H.225 RAS Protocol Inspection

This section contains the following configuration example:

- [H.323 RAS Protocol Inspection Configuration: Example, page 6](#)

H.323 RAS Protocol Inspection Configuration: Example

The following example shows how to configure an H.323 RAS protocol inspection policy:

```
class-map type inspect match-any c1
  match protocol h323
  match protocol h225ras
class-map type inspect match-all c2
  match protocol icmp
!
policy-map type inspect p1
  class type inspect c1
  inspect
  class class-default
  drop
policy-map type inspect p2
  class type inspect c2
  inspect
  class class-default
  drop
!
zone security z1
  description One-Network zone
zone security z2
  description Two-Network zone
zone-pair security zp source z1 destination z2
  service-policy type inspect p1
zone-pair security zp-rev source z2 destination z1
  service-policy type inspect p2
!
interface FastEthernet1/0
  ip address 10.0.0.0 255.255.0.0
  zone-member security z1
  duplex auto
  speed auto
!
interface FastEthernet1/1
  ip address 10.0.1.1 255.255.0.0
  zone-member security z2
  duplex auto
  speed auto
```

HTTP Inspection Engine

The HTTP Inspection Engine feature allows users to configure their Cisco IOS Firewall to detect and prohibit HTTP connections—such as tunneling over port 80, unauthorized request methods, and non-HTTP compliant file transfers—that are not authorized within the scope of the security policy configuration. Tunneling unauthorized protocols through port 80 and over HTTP exposes a network to significant security risks.

The Cisco IOS Firewall can now be configured with a security policy that adheres to the following tasks:

- Allowing specific traffic targeted for port 80 to traverse the firewall. The traffic is inspected for protocol conformance and for the types of HTTP commands that are allowed or disallowed.
- Denying specific traffic targeted for port 80 that does not comply to HTTP traffic standards. The firewall is enabled to drop the packet, reset the connection, and send a syslog message, as appropriate.

Feature History for HTTP Inspection Engine

Release	Modification
12.3(14)T	This feature was introduced.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

- [Command Reference, page 12](#)

Restrictions for HTTP Inspection Engine

The Cisco 831 router with 48M RAM does not have enough memory to support this feature.

Information About HTTP Inspection Engine

Before configuring an application firewall to detect and police specific traffic targeted for port 80, you should understand the following concepts:

- [What Is a Security Policy?, page 2](#)
- [Cisco IOS HTTP Application Policy Overview, page 2](#)

What Is a Security Policy?

The application firewall uses a security policy, which consists of a collection of static signatures, to detect security violations. A static signature is a collection of parameters that specify protocol conditions that must be met before an action is taken. (For example, a signature may specify that an HTTP data stream containing the POST method must reset the connection.) These protocol conditions and reactions are defined by the end user via the command-line interface (CLI) to form a security policy.

Cisco IOS HTTP Application Policy Overview

HTTP uses port 80 to transport Internet web services, which are commonly used on the network and rarely challenged with regards to their legitimacy and conformance to standards. Because port 80 traffic is typically allowed through the network without being challenged, many application developers are leveraging HTTP traffic as an alternative transport protocol in which to enable their application to travel through or even bypass the firewall.

Most firewalls provide only packet filtering capabilities that simply permit or deny port 80 traffic without inspecting the data stream; the Cisco IOS application firewall for HTTP performs packet inspection as follows:

- Detects HTTP connections that are not authorized within the scope of the security policy configuration.
- Detects users who are tunneling applications through port 80.

If the packet is not in compliance with the HTTP protocol, it will be dropped, the connection will be reset, and a syslog message will be generated, as appropriate.

How to Define and Apply an HTTP Application Policy to a Firewall for Inspection

This section contains the following procedures:

- [Defining an HTTP Application Policy, page 3](#)

- [Applying an HTTP Application Policy to a Firewall for Inspection, page 7](#)

Defining an HTTP Application Policy

Use this task to create an HTTP application firewall policy.

Restrictions

Although application firewall policies are defined in global configuration mode, only one global policy for a given protocol is allowed per interface.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **appfw policy-name** *policy-name*
4. **application** *protocol*
5. **strict-http action** {reset | allow} [alarm]
6. **content-length** {min *bytes* max *bytes* | min *bytes* | max *bytes*} **action** {reset | allow} [alarm]
7. **content-type-verification** [match-req-resp] **action** {reset | allow} [alarm]
8. **max-header-length** {request *bytes* response *bytes*} **action** {reset | allow} [alarm]
9. **max-uri-length** *bytes* **action** {reset | allow} [alarm]
10. **request-method** {rfc *rfc-method* | extension *extension-method*} **action** {reset | allow} [alarm]
11. **port-misuse** {p2p | tunneling | im | default} **action** {reset | allow} [alarm]
12. **transfer-encoding type** {chunked | compress | deflate | gzip | identity | default} **action** {reset | allow} [alarm]
13. **timeout** *seconds*
14. **audit-trail** {on | off}
15. **exit**
16. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	appfw policy-name policy-name Example: Router(config)# appfw policy-name mypolicy	Defines an application firewall policy and puts the router in application firewall policy configuration mode.
Step 4	application protocol Example: Router(cfg-appfw-policy)# application http	Allows you to configure inspection parameters for a given protocol. Currently, only HTTP traffic can be inspected. <ul style="list-style-type: none"> <i>protocol</i> —Specify the http keyword. This command puts you in <i>appfw-policy-protocol</i> configuration mode, where “ <i>protocol</i> ” is dependent upon the specified protocol. Because only HTTP can be specified, the configuration mode is <i>appfw-policy-http</i> .
Step 5	strict-http action {reset allow} [alarm] Example: Router(cfg-appfw-policy-http)# strict-http action allow alarm	(Optional) Allows HTTP messages to pass through the firewall or resets the TCP connection when HTTP noncompliant traffic is detected.
Step 6	content-length {min bytes max bytes min bytes max bytes} action {reset allow} [alarm] Example: Router(cfg-appfw-policy-http)# content-length max 1 action allow alarm	(Optional) Permits or denies HTTP traffic through the firewall on the basis of message size. <ul style="list-style-type: none"> min max bytes—Minimum or maximum content length, in bytes, allowed per message. Number of bytes range: 0 to 65535.
Step 7	content-type-verification [match-req-resp] action {reset allow} [alarm] Example: Router(cfg-appfw-policy-http)# content-type-verification match-req-resp action allow alarm	(Optional) Permits or denies HTTP traffic through the firewall on the basis of content message type.
Step 8	max-header-length {request bytes response bytes} action {reset allow} [alarm] Example: Router(cfg-appfw-policy-http)# max-header-length request 1 response 1 action allow alarm	(Optional) Permits or denies HTTP traffic on the basis of the message header length. <ul style="list-style-type: none"> <i>bytes</i>—Number of bytes ranging from 0 to 65535.

	Command or Action	Purpose
Step 9	max-uri-length <i>bytes</i> action { reset allow } [alarm] Example: Router(cfg-appfw-policy-http)# max-uri-length 1 action allow alarm	(Optional) Permits or denies HTTP traffic on the basis of the URI length in the request message.
Step 10	request method { rfc <i>rfc-method</i> extension <i>extension-method</i> } action { reset allow } [alarm] Example: Router(cfg-appfw-policy-http)# request-method rfc default action allow alarm	(Optional) Permits or denies HTTP traffic according to either the request methods or the extension methods. <ul style="list-style-type: none"> • rfc—Specifies that the supported methods of RFC 2616, <i>Hypertext Transfer Protocol—HTTP/1.1</i>, are to be used for traffic inspection. • <i>rfc-method</i>—Any one of the following RFC 2616 methods can be specified: connect, default, delete, get, head, options, post, put, trace. • extension—Specifies that the extension methods are to be used for traffic inspection. • <i>extension-method</i>—Any one of the following extension methods can be specified: copy, default, edit, getattribute, getproperties, index, lock, mkdir, move, revadd, revlabel, revlog, save, setattribute, startrev, stoprev, unedit, unlock.
Step 11	port-misuse { p2p tunneling im default } action { reset allow } [alarm] Example: Router(cfg-appfw-policy-http)# port-misuse default action allow alarm	(Optional) Permits or denies HTTP traffic through the firewall on the basis of specified applications in the HTTP message. <ul style="list-style-type: none"> • p2p—Peer-to-peer protocol applications subject to inspection: Kazaa and Gnutella. • tunneling—Tunneling applications subject to inspection: HTTPPort/HTTPHost, GNU Httptunnel, GotoMyPC, Firethru, Http-tunnel.com Client • im—Instant messaging protocol applications subject to inspection: Yahoo Messenger. • default—All applications are subject to inspection.

	Command or Action	Purpose
Step 12	<p>transfer-encoding type {chunked compress deflate gzip identity default} action {reset allow} [alarm]</p> <p>Example: Router(cfg-appfw-policy-http)# transfer-encoding type default action allow alarm</p>	<p>(Optional) Permits or denies HTTP traffic according to the specified transfer-encoding of the message.</p> <ul style="list-style-type: none"> • chunked—Encoding format (specified in RFC 2616, <i>Hypertext Transfer Protocol—HTTP/1</i>) in which the body of the message is transferred in a series of chunks; each chunk contains its own size indicator. • compress—Encoding format produced by the UNIX “compress” utility. • deflate—“ZLIB” format defined in RFC 1950, <i>ZLIB Compressed Data Format Specification version 3.3</i>, combined with the “deflate” compression mechanism described in RFC 1951, <i>DEFLATE Compressed Data Format Specification version 1.3</i>. • gzip—Encoding format produced by the “gzip” (GNU zip) program. • identity—Default encoding, which indicates that no encoding has been performed. • default—All of the transfer encoding types.
Step 13	<p>timeout <i>seconds</i></p> <p>Example: Router(cfg-appfw-policy-http)# timeout 60</p>	<p>(Optional) Overrides the global TCP idle timeout value for HTTP traffic.</p> <p>Note If this command is not issued, the default value specified via the ip inspect tcp idle-time command will be used.</p>
Step 14	<p>audit-trail {on off}</p> <p>Example: Router(cfg-appfw-policy-http)# audit-trail on</p>	<p>(Optional) Turns audit trail messages on or off.</p> <p>Note If this command is not issued, the default value specified via the ip inspect audit-trail command will be used.</p>
Step 15	<p>exit</p> <p>Example: Router(cfg-appfw-policy-http)# exit</p>	Exits cfg-appfw-policy-http configuration mode.
Step 16	<p>exit</p> <p>Example: Router(cfg-appfw-policy)# exit</p>	Exits cfg-appfw-policy configuration mode.

What to Do Next

After you have successfully defined an application policy for HTTP traffic inspection, you must apply the policy to an inspection rule. Thereafter, the inspection rule must be applied to an interface. For information on completing this task, see the section “[Applying an HTTP Application Policy to a Firewall for Inspection.](#)”

Applying an HTTP Application Policy to a Firewall for Inspection

Use this task to apply an HTTP application policy to an inspection rule, followed by applying the inspection rule to an interface.

**Note**

An application policy can coexist with other inspection protocols (for example, an HTTP policy and an FTP policy can coexist).

Prerequisites

You must have already defined an application policy (as shown in the section “[Defining an HTTP Application Policy](#)”).

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect name** *inspection-name* **appfw** *policy-name*
4. **ip inspect name** *inspection-name* **http** [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**timeout** *seconds*]
5. **interface** *type number*
6. **ip inspect** *inspection-name* {**in** | **out**}
7. **exit**
8. **exit**
9. **show appfw configuration** [*name*]
or
show ip inspect {**name** *inspection-name* | **config** | **interfaces** | **session** [**detail**] | **statistics** | **all**}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name inspection-name appfw policy-name Example: Router(config)# ip inspect name firewall appfw mypolicy	Defines a set of inspection rules for the application policy. <ul style="list-style-type: none"> <i>policy-name</i>—Must match the policy name specified via the appfw policy-name command.
Step 4	ip inspect name inspection-name http [alert {on off}] [audit-trail {on off}] [timeout seconds] Example: Router(config)# ip inspect name firewall http	Defines a set of inspection rules that is to be applied to all HTTP traffic. <ul style="list-style-type: none"> The <i>inspection-name</i> argument must match the <i>inspection-name</i> argument specified in Step 3.
Step 5	interface type number Example: Router#(config)# interface FastEthernet0/0	Configures an interface type and enters interface configuration mode.
Step 6	ip inspect inspection-name {in out} Example: Router#(config-if)# ip inspect firewall in	Applies the inspection rules (defined in Step 3 and Step 4) to all traffic entering the specified interface. <ul style="list-style-type: none"> The <i>inspection-name</i> argument must match the inspection name defined via the ip inspect name command.
Step 7	exit Example: Router#(config-if)# exit	Exits interface configuration mode.

	Command or Action	Purpose
Step 8	exit Example: Router(config)# exit	Exits global configuration mode.
Step 9	show appfw configuration [name] Example: Router# show appfw configuration or show ip inspect {name inspection-name config interfaces session [detail] statistics all} Example: Router# show ip inspect config	(Optional) Displays application firewall policy configuration information. (Optional) Displays firewall-related configuration information.

Troubleshooting Tips

To help troubleshoot the application firewall configuration, issue the following application-firewall specific debug command: **debug appfw {application protocol | function-trace | object-creation | object-deletion | events | timers | detailed}**.

The following sample configuration shows how to configure an HTTP policy with application firewall debugging enabled:

```
Router(config)# appfw policy-name myPolicyAPPPFW FUNC:appfw_policy_find
APPPFW FUNC:appfw_policy_find -- Policy myPolicy is not found
APPPFW FUNC:appfw_policy_alloc
APPPFW FUNC:appfw_policy_alloc -- policy_alloc 0x65727278
APPPFW FUNC:appfw_policy_alloc -- Policy 0x65727278 is set to valid
APPPFW FUNC:appfw_policy_alloc -- Policy myPolicy has been created
APPPFW FUNC:appfw_policy_command -- memlock policy 0x65727278

! Debugging sample for application (HTTP) creation

Router(cfg-appfw-policy)# application httpAPPPFW FUNC:appfw_http_command
APPPFW FUNC:appfw_http_appl_find
APPPFW FUNC:appfw_http_appl_find -- Application not found
APPPFW FUNC:appfw_http_appl_alloc
APPPFW FUNC:appfw_http_appl_alloc -- appl_http 0x64D7A25C
APPPFW FUNC:appfw_http_appl_alloc -- Application HTTP parser structure 64D7A25C created

! Debugging sample for HTTP-specific application inspection
Router(cfg-appfw-policy-http)#
Router(cfg-appfw-policy-http)# strict-http action reset alarm
APPPFW FUNC:appfw_http_subcommand
APPPFW FUNC:appfw_http_subcommand -- strict-http cmd turned on

Router# debug appfw detailed

APPPFW Detailed Debug debugging is on
fw7-7206a#debug appfw object-creation
APPPFW Object Creations debugging is on
fw7-7206a#debug appfw object-deletion
APPPFW Object Deletions debugging is on
```

Configuration Examples for Setting Up an HTTP Inspection Engine

This section contains the following configuration example:

- [Setting Up and Verifying an HTTP Inspection Engine: Example, page 10](#)

Setting Up and Verifying an HTTP Inspection Engine: Example

The following example show how to define the HTTP application firewall policy “mypolicy.” This policy includes all supported HTTP policy rules. This example also includes sample output from the **show appfw configuration** and **show ip inspect config** commands, which allow you to verify the configured setting for the application policy.

```
! Define the HTTP policy.
appfw policy-name mypolicy
  application http
    strict-http action allow alarm
    content-length maximum 1 action allow alarm
    content-type-verification match-req-rsp action allow alarm
    max-header-length request 1 response 1 action allow alarm
    max-uri-length 1 action allow alarm
    port-misuse default action allow alarm
    request-method rfc put action allow alarm
    transfer-encoding type default action allow alarm
!
!
! Apply the policy to an inspection rule.
ip inspect name firewall appfw mypolicy
ip inspect name firewall http
!
!
! Apply the inspection rule to all HTTP traffic entering the FastEthernet0/0 interface.
interface FastEthernet0/0
  ip inspect firewall in
!
!
! Issue the show appfw configuration command and the show ip inspect config command after
the inspection rule “mypolicy” is applied to all incoming HTTP traffic on the
FastEthernet0/0 interface.
!
Router# show appfw configuration

Application Firewall Rule configuration
Application Policy name mypolicy
  Application http
    strict-http action allow alarm
    content-length minimum 0 maximum 1 action allow alarm
    content-type-verification match-req-rsp action allow alarm
    max-header-length request length 1 response length 1 action allow alarm
    max-uri-length 1 action allow alarm
    port-misuse default action allow alarm
    request-method rfc put action allow alarm
    transfer-encoding default action allow alarm

Router# show ip inspect config

Session audit trail is disabled
Session alert is enabled
```

```
one-minute (sampling period) thresholds are [400:500] connections
max-incomplete sessions thresholds are [400:500]
max-incomplete tcp connections per host is 50. Block-time 0 minute.
tcp synwait-time is 30 sec -- tcp finwait-time is 5 sec
tcp idle-time is 3600 sec -- udp idle-time is 30 sec
dns-timeout is 5 sec
Inspection Rule Configuration
Inspection name firewall
http alert is on audit-trail is off timeout 3600
```

Inspection of Router-Generated Traffic

The Inspection of Router-Generated Traffic feature allows Context-Based Access Control (CBAC) to inspect traffic that is originated by or destined to the router on which CBAC is configured. Previously, inspection of Transmission Control Protocol (TCP), User Datagram Protocol (UDP), and H.323 connections initiated by or destined to the router were allowed.

Feature History for Inspection of Router-Generated Traffic

Release	Modification
12.3(14)T	This feature was introduced.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Prerequisites for Inspection of Router-Generated Traffic

- Configure CBAC.
- Configure Cisco Call Manager Express (CCME) or H.323 Gateway to configure the inspection of H.323 connections to and from the router.

Restrictions for Inspection of Router-Generated Traffic

- Inspection of router-generated traffic is supported only on the following protocols: H.323, TCP, and UDP.
- The Cisco IOS Firewall supports only Version 2 of the H.323 protocol. If CCME or the H.323 Gateway has inspection of H.323 router traffic enabled, enter the following commands so that it is configured to support only Version 2 features:

```
voice service voip
h323
session transport tcp calls-per-connection 1
h245 tunnel disable
h245 caps mode restricted
h225 timeout tcp call-idle value 0
```

Information About Inspection of Router-Generated Traffic

To configure Inspection of Router-Generated Traffic, you need to understand the following concepts:

- [CBAC, page 2](#)
- [Inspection of Router-Generated Traffic Overview, page 3](#)

CBAC

CBAC is a Cisco IOS Firewall set feature that provides network protection by using the following functions:

- [Traffic Filtering](#)
- [Traffic Inspection](#)
- [Alerts and Audit Trails](#)
- [Intrusion Detection](#)

Traffic Filtering

CBAC filters TCP and UDP packets based on application-layer protocol session information. You can configure CBAC to permit specified TCP and UDP traffic through a firewall only when the connection is initiated from within the network you want to protect. CBAC can inspect traffic for sessions that originate from either side of the firewall, and CBAC can be used for intranet, extranet, and Internet perimeters of your network.

Traffic Inspection

CBAC inspects traffic that travels through the firewall to discover and manage state information for TCP and UDP sessions. This state information is used to create temporary openings in the firewall's access lists to allow return traffic and additional data connections for permissible sessions.

Alerts and Audit Trails

CBAC generates real-time alerts and audit trails. Enhanced audit trail features use SYSLOG to track all network transactions; it records time stamps, the source host, the destination host, the ports used, and the total number of transmitted bytes, for advanced, session-based reporting. Real-time alerts send SYSLOG error messages to central management consoles upon detecting suspicious activity.

Using CBAC inspection rules, you can configure alerts and audit trail information on a per-application protocol basis. For example, if you want to generate audit trail information for HTTP traffic, you can specify that in the CBAC rule covering HTTP inspection.

Intrusion Detection

CBAC provides a limited amount of intrusion detection to protect against specific Simple Mail Transfer Protocol (SMTP) attacks. With intrusion detection, SYSLOG messages are reviewed and monitored for specific “attack signatures.” Certain types of network attacks have specific characteristics, or signatures. When CBAC detects an attack, it resets the offending connections and sends SYSLOG information to the SYSLOG server.

Inspection of Router-Generated Traffic Overview

Inspection of Router-Generated Traffic enhances CBAC's functionality to inspect TCP, UDP, and H.323 connections that have a router or firewall as one of the connection endpoints. This enables CBAC to open pinholes for TCP, UDP, and H.323 control channel connections to and from the router, and to open pinholes for data and media channels negotiated over the H.323 control channels.

Inspection of TCP and UDP channels initiated from the router enables dynamic opening of pinholes on the interface access control list (ACL) to allow return traffic. You do not have to modify the ACL when a TCP connection such as Telnet is made from the router.

Inspection of local H.323 connections enables the deployment of CCME, H.323 gateway, and the Cisco IOS Firewall on the same router. This also simplifies ACL configuration on CCME's interface through which H.323 connections are made. Before this feature, in addition to configuring ACLs to allow H.323 connections on a standard port (for example, port 1720), you had to configure ACLs to allow all dynamically negotiated data and media channels. With this feature you just configure the ACLs to allow H.323 control channels on port 1720. The Cisco IOS Firewall inspects all the traffic on the control channel and opens pinholes to allow dynamically negotiated data and media channels.

To enable Inspection of Router-Generated Traffic, specify the **router-traffic** keyword in the **ip inspect name** command of the appropriate protocol.

How to Configure Inspection of Router-Generated Traffic

This section contains the following procedures:

- [Configuring H.323 Inspection, page 4](#) (required)
- [Configuring CBAC, page 5](#) (required)
- [Verifying the CBAC Configuration, page 7](#) (optional)

Configuring H.323 Inspection

To configure the H.323 protocol, perform the following steps.

SUMMARY STEPS

- 1. **enable**
- 2. **configure terminal**
- 3. **ip inspect name** *inspection-name* {TCP | UDP | H323} [alert {on | off}] [audit-trail {on | off}][router-traffic][timeout *seconds*]
- 4. **interface** *type slot/port*
- 5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name <i>inspection-name</i> {TCP UDP H323} [alert {on off}] [audit-trail {on off}][router-traffic][timeout <i>seconds</i>] Example: Router(config)# ip inspect name test H.323 router-traffic	Defines a set of inspection rules.
Step 4	interface <i>type slot/port</i> Example: Router(config)# interface FE 0/0	Configures an interface type.
Step 5	exit Example: Router(config)# exit	Exits global configuration mode.

Configuring CBAC

To configure CBAC, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list** *access-list-number* {**deny** | **permit**} *source* [*source-wildcard*] [**log**]
4. **ip inspect name** *inspection-name* {**TCP** | **UDP** | **H323**} [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**router-traffic**] [**timeout** *seconds*]
5. **interface** *type slot/port*
6. **ip inspect** *inspection-name* {**in** | **out**}
7. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list <i>access-list-number</i> { deny permit } <i>source</i> [<i>source-wildcard</i>] [log] Example: Router(config)# access-list 121 permit tcp host 100.168.11.1 any eq 1720	Defines a standard IP access list.
Step 4	ip inspect name <i>inspection-name</i> { TCP UDP H323 } [alert { on off }] [audit-trail { on off }] [router-traffic] [timeout <i>seconds</i>] Example: Router(config)# ip inspect name here H323 router-traffic timeout 180	Defines a set of inspection rules.
Step 5	interface <i>type slot/port</i> Example: Router(config)# Serial0/3/0	Configures an interface type.

	Command or Action	Purpose
Step 6	ip inspect <i>inspection-name</i> { in out }	Enables the Cisco IOS Firewall on an interface.
	Example: Router(config-if)# ip inspect test in	
Step 7	exit	Exits global configuration mode and returns to privileged EXEC mode.
	Example: Router(config)# exit	

Verifying the CBAC Configuration

To verify the CBAC configuration, perform the following steps.

SUMMARY STEPS

1. `show ip inspect name inspection-name`
2. `show ip inspect config`
3. `show ip inspect interfaces`
4. `show ip inspect session [detail]`
5. `show ip inspect all`

DETAILED STEPS

Step 1 `show ip inspect name inspection-name`

Use this command to show a particular configured inspection rule. The following example configures the inspection rule `myinspectionrule`. **The output** shows the protocols that should be inspected by CBAC and the corresponding idle timeouts for each protocol.

```
Router# show ip inspect name myinspectionrule
```

```
Inspection Rule Configuration
```

```
Inspection name myinspectionrule
tcp timeout 3600
udp timeout 30
ftp timeout 3600
```

Step 2 `show ip inspect config`

Use this command to show the CBAC configuration, including global timeouts, thresholds, and inspection rules.

```
Router# show ip inspect config
```

```
Session audit trail is disabled
one-minute (sampling period) thresholds are [400:500] connections
max-incomplete sessions thresholds are [400:500]
max-incomplete tcp connections per host is 50. Block-time 0 minute.
tcp synwait-time is 30 sec -- tcp finwait-time is 5 sec
tcp idle-time is 3600 sec -- udp idle-time is 30 sec
dns-timeout is 5 sec
Inspection Rule Configuration
inspection name myinspectionrule
tcp timeout 3600
udp timeout 30
ftp timeout 3600
```

Step 3 show ip inspect interfaces

Use this command to show the interface configuration with respect to applied inspection rules and access lists.

```
Router# show ip inspect interfaces

Interface Configuration
Interface Ethernet0
  Inbound inspection rule is myinspectionrule
    tcp timeout 3600
    udp timeout 30
    ftp timeout 3600
  Outgoing inspection rule is not set
  Inbound access list is not set
  Outgoing access list is not set
```

Step 4 show ip inspect session detail

Use this command to display existing sessions that CBAC is currently tracking and inspecting. The following sample output shows that an outgoing ACL and an inbound ACL (dynamic ACLs) have been created to allow return traffic.

```
Router# show ip inspect session detail

Established Sessions
Session 80E87274 (192.168.1.116:32956)=>(192.168.101.115:23) tcp SIS_OPEN
  Created 00:00:08, Last heard 00:00:04
  Bytes sent (initiator:responder) [140:298] acl created 2
  Outgoing access-list 102 applied to interface FastEthernet0/0
  Inbound access-list 101 applied to interface FastEthernet0/1
```

Step 5 show ip inspect all

Use this command to show all CBAC configuration and all existing sessions that are currently being tracked and inspected by CBAC.

```
Router# show ip inspect all

Session audit trail is disabled
one-minute (sampling period) thresholds are [400:500] connections
max-incomplete sessions thresholds are [400:500]
max-incomplete tcp connections per host is 50. Block-time 0 minute.
tcp synwait-time is 30 sec -- tcp finwait-time is 5 sec
tcp idle-time is 3600 sec -- udp idle-time is 30 sec
dns-timeout is 5 sec
Inspection Rule Configuration
  Inspection name all
    tcp timeout 3600
    udp timeout 30
    ftp timeout 3600
Interface Configuration
Interface Ethernet0
  Inbound inspection rule is all
    tcp timeout 3600
    udp timeout 30
    ftp timeout 3600
  Outgoing inspection rule is not set
  Inbound access list is not set
  Outgoing access list is not set
Established Sessions
Session 25A6E1C (30.0.0.1:46065)=>(40.0.0.1:21) ftp SIS_OPEN
Session 25A34A0 (40.0.0.1:20)=>(30.0.0.1:46072) ftp-data SIS_OPEN
```

Configuration Examples for Inspection of Router-Generated Traffic

This section provides the following configuration examples:

- [Configuring CBAC with Inspection of H.323 Traffic: Example, page 9](#)

Configuring CBAC with Inspection of H.323 Traffic: Example

These commands create the ACL. In this example, TCP traffic from subnet 100.168.11.1, 192.168.11.50, and 192.168.100.1 is permitted.

```
access-list 120 permit tcp host 100.168.11.1 any eq 1720
access-list 121 permit tcp host 192.168.11.50 host 100.168.11.1 eq 1720
access-list 121 permit tcp host 192.168.100.1 host 100.168.11.1 eq 1720
```

These commands create the CBAC inspection rule LOCAL-H323, allowing inspection of the protocol traffic specified by the rule. This inspection rule sets the timeout value to 180 seconds for each protocol (except for RPC). The timeout value defines the maximum time that a connection for a given protocol can remain active without any traffic passing through the router. When these timeouts are reached, the dynamic ACLs that are inserted to permit the returning traffic are removed, and subsequent packets (possibly even valid ones) are not permitted.

```
ip inspect name LOCAL-H323 tftp timeout 180
ip inspect name LOCAL-H323 h323 router-traffic timeout 180
```

These commands apply the inspection rule and ACL. In this example, the inspection rule LOCAL-H323 is applied to traffic at interface Serial0/3/0.

```
interface Serial0/3/0
 ip address 11.168.11.2 255.255.255.0
 ip access-group 121 in
 ip access-group 120 out
 ip inspect LOCAL-H323 in
 ip inspect LOCAL-H323 out
 encapsulation frame-relay
 frame-relay map ip 11.168.11.1 168 broadcast
 no frame-relay inverse-arp
 frame-relay intf-type dce
```

Glossary

CBAC—Context-Based Access Control. Scrutinizes source and destination addresses to enhance security for TCP and UDP applications that use well-known ports, such as FTP and e-mail traffic.

firewall—One or more router or access servers designated as a buffer between any connected public networks and a private network. A firewall router uses access lists and other methods to ensure the security of the private network.

FTP—File Transfer Protocol. An application protocol, part of the TCP/IP protocol stack, for transferring files between network nodes.

H.323—A multimedia conferencing protocol that includes voice, video, and data conferencing for use over packet-switched networks. H.323 allows dissimilar communication devices to communicate with each other by using a standardized communication protocol.

IMAP—Internet Message Access Protocol. A method of accessing e-mail or bulletin board messages kept on a mail server that can be shared. IMAP permits client e-mail applications to access remote message stores as if they were local without actually transferring the message.

IP—Internet Protocol. Connectionless protocol at the network layer (Layer 3) of the OSI reference model. Provides features for addressing, type-of-service specification, fragmentation and reassemble, and security. IP works with TCP and is usually identified as TCP/IP.

POP—Post Office Protocol. A protocol that client e-mail applications use to retrieve mail from a mail server.

SMTP—Simple Mail Transfer Protocol. A simple ASCII protocol that describes the exchange of e-mail between two message-transfer agents using TCP/IP.

TCP—Transmission Control Protocol. A connection-oriented transport-layer protocol that provides reliable full-duplex data transmissions.

TCP/IP—Transmission Control Protocol/Internet Protocol. Common name for the suite of protocols developed by the U.S. Department of Defense in the 1970s to support the construction of worldwide internetworks. TCP and IP are the two best-known protocols in the suite.

UDP—User Datagram Protocol. A connectionless transport-layer protocol for exchanging datagrams without acknowledgments or guaranteed delivery.

VoIP—Voice over IP. Capability of carrying normal telephony-style voice over an IP network with circuit-based telephone-like functionality, reliability, and voice quality. VoIP generally refers to the Cisco standards-based (H.323 and so forth) approach to IP voice traffic.

TCP Out-of-Order Packet Support for Cisco IOS Firewall and Cisco IOS IPS

First Published: November 17, 2006

Last Updated: November 17, 2006

This feature allows out-of-order packets in TCP streams to be cached and reassembled before they are inspected by Cisco IOS Intrusion Prevention System (IPS) or Cisco IOS Firewall.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the “[Feature Information for TCP Out-of-Order Packet Support for Cisco IOS Firewall and IPS](#)” section on page 8.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for TCP Out-of-Order Packet Support for Cisco IOS Firewall and Cisco IOS IPS

Cisco IOS IPS or Cisco IOS Firewall must be configured on your router.

Restrictions for TCP Out-of-Order Packet Support for Cisco IOS Firewall and Cisco IOS IPS

- The feature is enabled by default. The user must explicitly disable it. To disable TCP out-of-order packet buffering and reassembly, issue the **ip inspect tcp reassembly queue length 0** command.
- Zone-based policy firewall is not supported. Only Cisco IOS IPS and Cisco IOS Firewall application inspection can support out-of-order TCP packets.

Information About TCP Out-of-Order Packet Support for Cisco IOS Firewall and Cisco IOS IPS

Before reassembling TCP out-of-order packets, you should understand the following concept:

- [How TCP Out-of-Order Packet Support Works, page 2](#)

How TCP Out-of-Order Packet Support Works

Cisco IOS Firewall and IPS track packets in TCP connections. If configured to look into the application data of the packets, Cisco IOS Firewall and IPS expect the TCP packets to arrive in the correct order because some data items are split across segments. When packets arrive out of order, they are dropped by the firewall or IPS. Dropping out-of-order packets can cause significant delays in end applications because packets are dropped only after the retransmission timer expires (on behalf of the sender).

Out-of-order TCP packet support enables Cisco IOS Firewall and IPS to hold a copy of the out-of-order packet in a buffer (whose size is configurable with a maximum of 1024 packets per session). The original packet passes through the router and reaches its destination, but the firewall or IPS do not execute on the packet. When the next packet arrives, the firewall or IPS look for that packet to “fill the hole,” providing a consecutive sequence of segments. If this packet does not fulfill that requirement, it is processed as an out-of-order packet; when another packet arrives and provides a consecutive sequence of segments, it is processed by the firewall or IPS.

How to Configure Cisco IOS Firewall or IPS to Handle TCP Out-of-Order Packets

This section contains the following procedure:

- [Changing Default TCP Out-of-Order Packet Parameters, page 3](#)

Changing Default TCP Out-of-Order Packet Parameters

Use this task to change any of the predefined parameters that instruct Cisco IOS Firewall application inspection or Cisco IOS IPS how to handle out-of-order TCP packets.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect tcp reassembly** {[*queue length packet-number*] [*timeout seconds*] [*memory limit size-in-kb*] [*alarm {on | off}*]}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect tcp reassembly {[queue length <i>packet-number</i>] [timeout <i>seconds</i>] [memory limit <i>size-in-kb</i>] [alarm { on off }]} Example: Router(config)# ip inspect tcp reassembly queue length 10 timeout 8	Sets parameters that define how a Cisco IOS IPS handles out-of-order TCP packets. <ul style="list-style-type: none"> queue length <i>packet-number</i>—Maximum number of out-of-order packets that can be held per queue (buffer). Note that there are 2 queues per session. Available value range: 0 to 1024. Default value: 16. If the queue length is set to 0, all out-of-order packets are dropped. timeout <i>seconds</i>—Number of seconds the TCP reassembly module will hold out-of-order segments waiting for the first segment missing in the sequence. After the timeout timer has expired, a retry timer is started. The value for the retry timer is four times the configured timeout value. memory limit <i>size-in-kb</i>—Maximum allowed memory use by the TCP reassembly module. alarm {on off}—If enabled, a syslog message is generated when an out-of-order packet is dropped. Default value: on

Configuration Examples for TCP Out-of-Order Packet Parameters

This sections contains the following configuration example:

- [Verifying TCP Out-of-Order Packets: Example, page 4](#)

Verifying TCP Out-of-Order Packets: Example

The following example shows how to instruct Cisco IOS IPS how to handle out of order packets for TCP connections:

```
Router(config)# ip inspect tcp reassembly queue length 18
Router(config)# ip inspect tcp reassembly memory limit 200
```

The following sample output displays the configured out-of-order packet parameters:

```
Router# show ip ips statistics
```

```
Signature Statistics [process switch:fast switch]
Signature 1000: 324 packets checked: [124:200]
Signature 1024: 100 packets checked: [0:100]
Interfaces configured for ips 0
Session creations since subsystem startup or last reset 0
Current session counts (estab/half-open/terminating) [0:0:0]
Maxever session counts (estab/half-open/terminating) [0:0:0]
Last session created never
Last statistic reset never
TCP reassembly statistics
received 200 packets out-of-order; dropped 25
peak memory usage; 200 KB; current usage: 154 KB
peak queue length 18
```

Transparent Cisco IOS Firewall

The Transparent Cisco IOS Firewall feature allows users to “drop” a Cisco IOS Firewall in front of their existing network without changing the statically defined IP addresses of their network-connected devices. Thus, users can allow selected devices from a subnet to traverse the firewall while access to other devices on the same subnet is denied.

Feature History for Transparent Cisco IOS Firewall

Release	Modification
12.3(7)T	This feature was introduced.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://www.cisco.com/go/fn>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

Restrictions for Transparent Cisco IOS Firewall

Layer 3 IP Packet Support Only

Only IP packets (TCP, User Datagram Protocol [UDP], and Internet Control Message Protocol [ICMP]) are subjected to inspection by the transparent firewall. Non-IP traffic is bridged as usual without interference from the transparent firewall. However, if users wish to block non-IP traffic, the MAC access control lists (ACLs) can be applied on interfaces to filter out non-IP traffic and allow only IP traffic.

The following example shows how to configure an ACL that permits all IP packets (0x0800) into the Ethernet interface but denies all Internetwork Packet Exchange (IPX) packets (0x8137):

```
Router(config)# access-list 201 permit 0x0800
Router(config)# access-list 201 deny 0x8137
Router(config)# interface ethernet 0
Router(config-if)# bridge-group 1 input-type-list 201
```

VLAN Trunk Bridging

Bridging between VLAN trunks works only for dot1q encapsulation; Inter-Switch Link (ISL) encapsulation will not work. (However, ISL VLANs will work if subinterfaces are created and placed in a bridge group.)

Information About Transparent Cisco IOS Firewall

To use a transparent Cisco IOS Firewall in your network, you should understand the following concepts:

- [Benefit of the Transparent Firewall, page 2](#)
- [Transparent Firewall Overview, page 2](#)
- [Layer 2 and Layer 3 Firewalls Configured on the Same Router, page 3](#)

Benefit of the Transparent Firewall

Added Security with Minimum Configuration

Users can simply drop a transparent Cisco IOS Firewall into an existing network without having to reconfigure their statically defined devices. Thus, the tedious and costly overhead that is required to renumber devices on the trusted network is eliminated.

Transparent Firewall Overview

A typical Cisco IOS Firewall is a Layer 3 device with trusted and untrusted interfaces on different IP subnets. A Layer 3 firewall works well with Cisco IOS devices that function as routers with preexisting subnet separations. However, when a Layer 3 firewall is placed in an existing network, the network IP addresses must be reconfigured to accommodate the firewall.

A transparent Cisco IOS firewall acts as a Layer 2 transparent bridge with context-based access control (CBAC) and ACLs configured on the bridged interface. Because the Layer 2 firewall intercepts packets at Layer 2 and is “transparent” to the existing network, Layer 3 firewall limitations are not applicable.

Transparent Bridging Overview

If configured for bridging, a Cisco IOS device can bridge any number of interfaces. The device can complete basic bridging tasks such as learning MAC addresses on ports to restrict collision domains and running Spanning Tree Protocol (STP) to prevent looping in the topology.

Within bridging, a user can configure Integrated Routed Bridging (IRB), which allows a device to bridge on some interfaces while a Layer 3 Bridged Virtual Interface (BVI) is presented for routing. The bridge can determine whether the packet is to be bridged or routed on the basis of the destination of the Layer 2 or Layer 3 IP address in the packet. Configured with an IP address, the BVI can manage the device even if there is no interface configured for routing.

Layer 2 and Layer 3 Firewalls Configured on the Same Router

A transparent firewall supports a BVI for routing, so a packet that comes in on a bridged interface can be bridged or routed out of the BVI. This functionality allows a Layer 2 (transparent) firewall and a Layer 3 firewall to be configured on the same router: The transparent firewall operates on the bridged packets while the “normal” firewall operates on the routed packets. For example, if you have six interfaces on your router and two of them are in a bridge group, you can simultaneously configure and run normal inspection on the remaining four interfaces.

How to Configure a Transparent Cisco IOS Firewall

You configure a transparent firewall just as you would configure a Layer 3 firewall (via the **ip inspect** command, which can be configured on any of the bridged interfaces for the transparent firewall). Also, you configure transparent bridging for a firewall just as you would for any other Cisco IOS device.

This section contains the following procedures:

- [Configuring a Bridge Group, page 3](#) (required)
- [Configuring Inspection and ACLs, page 6](#) (required)
- [Forwarding DHCP Traffic, page 8](#) (optional)
- [Monitoring Transparent Firewall Events, page 8](#) (optional)

Configuring a Bridge Group

Use this task to configure a bridge group and to associate interfaces or subinterfaces in the configured bridge group.

BVI Configuration Requirements

- If a BVI is not configured, you must disable IP routing (via the **no ip routing** command) for the bridging operation to take effect.
- If configured, a BVI must be configured with an IP address in the same subnet.
- You *must* configure a BVI if more than two interfaces are placed in a bridge group.

Restrictions

- If more than two interfaces are assigned to a bridge group, any routers that are acting as first-hop gateways to hosts that are in the bridged network (the bridge group) must allow ICMP time-to-live (TTL) exceeded messages to pass.
- Spanning Tree Bridge Protocol Data Units (BPDU) and packets that are to be routed out of the bridge, if IRB is configured, are not inspected.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **bridge *bridge-group* protocol {dec | ibm | ieee | vlan-bridge}**
4. **interface *type number***
5. **bridge-group *bridge-group***
6. **exit**
7. **bridge irb**
8. **bridge *bridge-group* route protocol**
9. **interface *type number***
10. **ip address *ip-address mask***
11. **no shutdown**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	bridge <i>bridge-group</i> protocol {dec ibm ieee vlan-bridge} Example: Router(config)# bridge 1 protocol ieee	Defines the type of Spanning Tree Protocol (STP).
Step 4	interface <i>type number</i> Example: Router(config)# interface Ethernet0	Configures an interface type and enters interface configuration mode.

	Command or Action	Purpose
Step 5	bridge-group <i>bridge-group</i> Example: Router(config-if)# bridge-group 1	Assigns each network interface to a bridge group. Note Complete Step 4 and Step 5 for each interface you want to assign to a bridge group. Note You can also assign subinterfaces to a bridge group to control bridging between VLANs.
Step 6	exit	Exits interface configuration mode.
Step 7	bridge irb Example: Router(config)# bridge irb	Enables the Cisco IOS software to route a given protocol between routed interfaces and bridge groups or to route a given protocol between bridge groups. Note Step 7 through Step 11 are necessary only if you want to configure a BVI.
Step 8	bridge <i>bridge-group</i> route <i>protocol</i> Example: Router(config)# bridge 1 route ip	Enables the routing of a specified protocol in a specified bridge group.
Step 9	interface <i>type number</i> Example: Router(config)# interface BVI1	Configures a BVI and enters interface configuration mode.
Step 10	ip address <i>ip-address mask</i> Example: Router(config-if) ip address 10.1.1.1 255.255.255.0	Sets a primary IP address for an interface.
Step 11	no shutdown Example: Router(config-if)# no shutdown	Restarts a disabled interface.

Examples

The following example shows how to configure interfaces “ethernet0” and “ethernet1” in a bridge group. These interfaces are associated with the BVI interface “BVI1,” which can be reached from any host on either of the interfaces via the IP address 10.1.1.1.

```
Router(config)# bridge 1 protocol ieee
Router(config)# interface ethernet0
Router(config-if)# bridge-group 1
Router(config-if)# interface ethernet1
Router(config-if)# bridge-group 1
Router(config-if)# exit
! Configure the BVI.
Router(config)# bridge irb
Router(config)# bridge 1 route ip
Router(config)# interface BVI1
Router(config-if)# ip address 10.1.1.1 255.255.255.0
Router(config-if)# no shutdown
```

Troubleshooting Tips

To display the status of each bridge group, use the **show bridge-group** command or to display entries in the bridge table, use the **show bridge** command.

What to Do Next

After you have configured the bridge group, you must configure an inspection rule and at least one IP ACL. To complete this task, refer to the following section, “[Configuring Inspection and ACLs](#).”

Note

If inspection is not configured on any interface in the bridge group, IP ACLs on bridged interfaces will not be active.

Configuring Inspection and ACLs

Use this task to configure an inspection rule and apply it on the appropriate interface. Also, use this task to configure at least one ACL and apply it on one or more of the interfaces that you configured in the bridge group.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect name** *protocol* [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**timeout** *seconds*]
4. **interface** *type number*
5. **ip inspect** *inspection-name* {**in** | **out**}
6. **exit**
7. **access-list** *access-list-number* {**permit** | **deny**} {*type-code wild-mask* | *address mask*}
8. **interface** *type number*
9. **ip access-group** {*access-list-number* | *access-list-name*} {**in** | **out**}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	ip inspect name protocol [alert {on off}] [audit-trail {on off}] [timeout seconds] Example: Router(config)# ip inspect name test tcp	Defines a set of inspection rules.
Step 4	interface type number Example: Router(config)# interface Ethernet0	Configures an interface type and enters interface configuration mode.
Step 5	ip inspect inspection-name {in out} Example: Router(config-if)# ip inspect test in	Applies a set of inspection rules to an interface.
Step 6	exit	Exits interface configuration mode.
Step 7	access-list access-list-number {permit deny} {type-code wild-mask address mask} Example: Router(config)# access-list 156 permit 10.1.1.0 0.0.0.255 any	Configures the ACL. Note Repeat this step for each ACL that you want to configure.
Step 8	interface type number Example: Router(config)# interface Ethernet0	Configures an interface type and enters interface configuration mode. Note Repeat Steps 8 and 9 for each ACL that you want to apply to inbound packets from a specific interface.
Step 9	ip access-group {access-list-number access-list-name} {in out} Example: Router(config-if) ip access-group 156 in	Controls access to an interface.

Examples

The following example shows how to configure an inspection rule on interface “ethernet0,” which is the inside interface. Policies can be specified via ACL 156 or 101; for example, ACL 156 can be used to specify that rlogin and rsh are not allowed for the internal users, and ACL 101 can be used to specify that an external host requires connectivity to a particular host in the internal domain.

```
Router(config)# ip inspect name test tcp
Router(config)# interface ethernet0
Router(config-if)# ip inspect test in
Router(config-if)# exit
!
! Configure the ACLs.
Router(config)# access-list 101 deny ip any any
Router(config)# access-list 156 permit 10.1.1.0 0.0.0.255 any
Router(config)# access-list 156 deny ip any any

Router(config)# interface ethernet0
Router(config-if) ip access-group 156 in
```

```
Router(config)# interface ethernet1
Router(config-if) ip access-group 101 in
```

Forwarding DHCP Traffic

Use this task to enable a transparent firewall to forward DHCP packets across the bridge without inspection; that is, the **ip inspect L2-transparent dhcp-passthrough** command overrides the ACL for DHCP packets, so DHCP packets will be forwarded even if the ACL is configured to deny all IP packets. Thus, clients on one side of the bridge can get an IP address from a DHCP server on the opposite side of the bridge.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip inspect L2-transparent dhcp-passthrough**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect L2-transparent dhcp-passthrough Example: Router#(config) ip inspect L2-transparent dhcp-passthrough	Allows a transparent firewall to forward DHCP passthrough traffic.

Monitoring Transparent Firewall Events

Use either of these optional steps to monitor the activity of the transparent firewall.

Note

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

SUMMARY STEPS

1. **enable**
2. **debug ip inspect L2-transparent {packet | dhcp-passthrough}**

3. `show ip inspect {name inspection-name | config | interfaces | session [detail] | all}`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	debug ip inspect L2-transparent {packet dhcp-passthrough} Example: Router# debug ip inspect L2-transparent dhcp-passthrough	Enables debugging messages for transparent firewall events. <ul style="list-style-type: none"> packet—Displays messages for all debug packets that are inspected by the transparent firewall. dhcp-passthrough—Displays debug messages only for DHCP pass-through traffic that the transparent firewall forwards across the bridge.
Step 3	show ip inspect {name <i>inspection-name</i> config interfaces session [detail] all} Example: Router# show ip inspect all	Displays Cisco IOS Firewall configuration and session information. <ul style="list-style-type: none"> If the transparent firewall is configured, use the all keyword to display the bridging interface in the interface configuration section of the output.

Examples

The following sample output is a portion of the **show ip inspect all** command that shows the bridging interface:

```
Router# show ip inspect all
.
.
.
Interface Configuration
! Below is the bridging interface.
Interface Ethernet1
Inbound inspection rule is test
tcp alert is on audit-trail is off timeout 3600
ftp alert is on audit-trail is off timeout 3600
Outgoing inspection rule is not set
Inbound access list is not set
Outgoing access list is 156
.
.
.
```

Configuration Examples for Transparent Cisco IOS Firewall

This section contains the following configuration examples:

- [Comprehensive Transparent Firewall Configuration: Example, page 10](#)
- [Monitoring Telnet Connections via debug and show Output: Examples, page 12](#)

- [Configuring and Verifying DHCP Pass-Through Traffic: Examples, page 16](#)

Comprehensive Transparent Firewall Configuration: Example

The following example and sample topology (see [Figure 1](#)) illustrate how to configure and debug a transparent Cisco IOS Firewall configuration between a client, a firewall, and a server. This example also includes **show** command output for additional configuration verification. After you have configured a transparent firewall, you can Telnet from the client to the server through the firewall. (See the section “[Monitoring Telnet Connections via debug and show Output: Examples.](#)”

Figure 1 Sample Topology for Transparent Firewall Configuration

Note

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

```

Monitoring Telnet Connections via debug and show Output: Examples

The following examples shows how to monitor established Telnet connections from the client to the server through the firewall (see [Figure 1](#)) and from the server to the client. In these example, the **debug ip inspect L2-transparent packet** command has been issued to generate the debug messages. Relevant **show** commands are also issued for additional verification.

**Note**

Effective with Cisco IOS Release 12.4(20)T, the **debug ip inspect** command is replaced by the **debug policy-firewall** command. See the *Cisco IOS Debug Command Reference* for more information.

- [Telnet Connection from the Client \(97.0.0.2\) to the Server \(97.0.0.23\), page 13](#)
- [Telnet Connection from the Server \(97.0.0.23\) to the Client \(97.0.0.2\), page 15](#)

Telnet Connection from the Client (97.0.0.2) to the Server (97.0.0.23)

The following example is output from the initial Telnet connection between the client and the server. A subsequent connection is established to highlight differences in the debug output. Explanations are given inline.

```
! A packet is received by the firewall in the flood path because the bridge-table is
! initially empty. However, the client seems to have the server's mac-address in its ARP
! cache, so the bridge floods the packet and it appears in the firewall's "flood" path.

```

Configuring and Verifying DHCP Pass-Through Traffic: Examples

The following examples show how to verify (via debug messages) DHCP pass-through that has been allowed and traffic that has not been allowed.

- [Allowing DHCP Pass-Through Traffic: Example, page 16](#)
- [Denying DHCP Pass-Through Traffic: Example, page 17](#)

Allowing DHCP Pass-Through Traffic: Example

In this example, the static IP address of the client is removed and the address is acquired via DHCP using the **ip address dhcp** command on the interface that is connected to the transparent firewall.

```
Router# show debug
ARP:
  ARP packet debugging is on
L2 Inspection:
  INSPECT L2 firewall debugging is on
  INSPECT L2 firewall DHCP debugging is on
Router#
Router#
! Configure DHCP passthrough
Router(config)# ip insp L2-transparent dhcp-passthrough
! The DHCP discover broadcast packet arrives from the client. Since this packet is a
! broadcast (255.255.255.255), it arrives in the flood path
*Mar 1 00:35:01.299:L2FW:insp_l2_flood:input is Ethernet0 output is Ethernet1

Denying DHCP Pass-Through Traffic: Example

In this example, DHCP pass-through traffic is not allowed (via the **no ip inspect L2-transparent dhcp-passthrough** command). The client is denied when it attempts to acquire a DHCP address from the server.

```
! Deny DHCP pass-through traffic
Router(config)# no ip inspect L2-transparent dhcp-passthrough
! The DHCP discover broadcast packet arrives from the client
*Mar  1 00:36:40.003:L2FW:insp_l2_flood:input is Ethernet0 output is Ethernet1
*Mar  1 00:36:40.003:L2FW*:Src 0.0.0.0 dst 255.255.255.255 protocol udp
*Mar  1 00:36:40.003:L2FW:udp ports src 68 dst 67
*Mar  1 00:36:40.007:L2FW:src 0.0.0.0 dst 255.255.255.255
! The pass-through flag is checked
*Mar  1 00:36:40.007:L2FW:DHCP packet seen. Pass-through flag denies the packet
! The packet is dropped because the flag does not allow DHCP passthrough traffic. Thus,
! the client cannot acquire an address, and it times out
*Mar  1 00:36:40.007:L2FW:FLOOD Dropping the packet after ACL check.
Router#
```

User-Based Firewall Support

First Published: July 11, 2008

Last Updated: July 11, 2008

Firewalls traditionally apply rules based on source and destination IP addresses. In the new, highly dynamic mobile world, IP addresses of end systems constantly change. Therefore it becomes increasingly difficult to have a particular user group function assigned to a particular block of IP addresses. It is also difficult to apply firewall policies for a user group that is the source of the traffic. This feature allows source IP addresses to be associated with user groups. Network administrators can apply firewall policies based on user-groups, and the infrastructure can seamlessly apply these security policies.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for User-Based Firewall Support”](#) section on page 28.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

- [Command Reference, page 27](#)
- [Feature Information for User-Based Firewall Support, page 28](#)

Prerequisites for User-Based Firewall Support

The following prerequisites apply to the configuration of User-Based Firewall Support.

Hardware Requirements

- Access Control Server
- Cisco Network Access Device, which can be any of the following:
 - Cisco 7200 router
 - Cisco 1800 router
 - Cisco 2800 router
 - Cisco 3800 router

Software Requirements

- Cisco IOS Release 12.4(20)T or a later release
- An Ingress Security feature that uses the Identity Policy infrastructure for policy application

Restrictions for User-Based Firewall Support

User-group mapping is based on the end-host's source IPv4 address. The “user-group” match criterion is supported for inspect class-maps.

Authentication Proxy and IP Admission

Authentication Proxy and IP Admission is an input only feature that should be configured on all the interfaces of the source zone. The Authentication Proxy and IP Admission feature is not virtual routing and forwarding (VRF) aware; therefore, user-group Zone Policy Firewall policies cannot be applied on a per VRF basis.

Information About User-Based Firewall Support

To configure the User-Based Firewall Support feature, you should understand the following concepts:

- [Feature Design of User-Based Firewall Support, page 3](#)
- [Firewall Support, page 3](#)
- [Authentication Proxy, page 4](#)
- [Zone-Based Policy Firewall, page 4](#)

- [Tag and Template, page 4](#)
- [Access Control List Overview, page 5](#)

Feature Design of User-Based Firewall Support

The User-Based Firewall Support feature was designed to provide identity or user-group based security that provides differentiated access for different classes of users. Classification can be provided on the basis of user identity, device type (for example, IP phones), location (for example, building) and role (for example, engineer). Because of the dynamic nature of end-host access, where every user is different and the resource he or she accesses is different, it is important to associate end-user's identity, role, or location with security policies. This association prevents the need for administrators to constantly update policy filters, a cumbersome task. The end-user identity can be derived through a variety of different mechanisms. Once a user's identity is established, security policies will be aware of the user's identity, not just the source address. Individual policies can be enforced allowing for greater control.

Cisco IOS supports several features that offer dynamic, per-user authentication and authorization of network access connections. These features include 802.1X, IKE, Authentication Proxy, Network Admission Control (NAC), and so on. These features allow network administrators to enforce security policies on per-user basis. By integrating authentication features with Cisco Policy Language based features such as Zone Based Firewall, Quality of Service (QoS), and so on, the combination can provide a transparent, reliable, ease to manage and deploy security solution to dynamically authenticate and enforce policies on a per user basis.

Cisco IOS User-Based Firewall Support leverages existing authentication and validation methods to associate each source IP address to a user-group. User-group association can be achieved using two methods. The first method (Tag and Template) uses locally defined policies to achieve the association, while the second method obtains the user-group information from the access control server (ACS) and requires no further configuration on the network access device (NAD).

The User-Based Firewall Support feature leverages the Tag and Template concept where the authenticating server returns a tag-name on validating the user credentials. This tag received on the authentication device is mapped to a template. The template is a control plane policy map that refers to an identity policy configured on the device. The identity policy contains the access policies that are to be applied for the corresponding tag-name. The identity policy defines one or more user-groups to which the source IP would be associated. This mapping provides administrators with flexibility to associate the end-host with multiple user-group memberships. The scope of the user-group defined in the identity policy is local to the device. Once the end-host's user-group membership has been established, other Cisco IOS policy language based features can enforce security policies on a per user-group basis.

Match Criterion

The match user-group criterion in the inspect type class map configuration can be used to enforce security policies on a per user-group basis. The match criterion filters the traffic stream based on the client's source IP address in the specified user-group, making it independent of the authentication method that established the group membership. The match criterion in the inspect type class map enables inspection for any ingress traffic and for any protocol, thereby enabling inspection for all traffic.

Firewall Support

Cisco IOS Firewall includes multiple security features. Cisco IOS Firewall stateful packet inspection provides true firewall capabilities to protect networks against unauthorized traffic and control legitimate business-critical data. Authentication proxy controls access to hosts or networks based on user

credentials stored in an authentication, authorization, and accounting (AAA) server. Multi-VRF firewall offers firewall services on virtual routers with VRF, accommodating overlapping address space to provide multiple isolated private route spaces with a full range of security services. Transparent firewall adds stateful inspection without time-consuming, disruptive IP addressing modifications. Application inspection controls application activity to provide granular policy enforcement of application usage, protecting legitimate application protocols from rogue applications and malicious activity. For more information on firewall support see the [Cisco IOS Firewall Design Guide](#).

Authentication Proxy

The Cisco IOS Firewall Authentication Proxy feature provides dynamic, per-user authentication and authorization, authenticating users against industry standard TACACS+ and RADIUS authentication protocols. Authenticating and authorizing connections by users provides more robust protection against network attacks. See the [Authentication Proxy](#) chapter in the *Cisco IOS Security Configuration Guide* for more information about this feature.

Zone-Based Policy Firewall

Cisco IOS Zone-Based Policy Firewall can be used to deploy security policies by assigning interfaces to different zones and configuring a policy to inspect the traffic moving between these zones. The policy specifies a set of actions to be applied on the defined traffic class. For more information see the chapter “Configuring Cisco IOS Firewall” in the *Cisco IOS Security Configuration Guide*. See the [Zone-Based Firewall](#) chapter in the *Cisco IOS Security Configuration Guide* for more information about this feature.

Tag and Template

The Tag and Template feature allows network administrators to define enforcement policies on a local device and have a RADIUS server specify the policy selector to be enforced. This feature can be applied to a NAC architecture. See the [Tag and Template feature guide](#) for more information about this feature.

Network Admission Control

In a typical Network Admission Control deployment, an ACS or a RADIUS server is used for validating the user posture information and for applying the policies on the NAD. A centralized ACS can be used to support multiple NADs. This solution has inherent problems associated with it, namely:

- Version control of policies. Typically, a specific NAD that is running a Cisco IOS image may support some access control lists (ACLs), and another NAD may support a different version. Managing different versions can be a problem.
- Users connect on different interfaces to the NAD, and on the basis of the interface type, the policies that can be applied to the user can change, and the NAD can determine the policies to be applied. In the current architecture, the ACS sends the same set of policies to all the NADs when a profile is matched, which does not give enough control to the administrator to configure the policies on the basis of the NAD configuration.

Configuring the Tag and Template feature allows the ACS to map users to specific groups and associate a tag with them. For example, the Usergroup1 user group may have a tag with the name "usergroup1." When the NAD queries the ACS for the policies, the ACS can return the tag that is associated with the user group. When this tag is received at the NAD, the NAD can map the tag to a specific template that

can have a set of policies that are associated with the user group. This mapping provides administrators with the flexibility to configure the template on a NAD basis, and the policies can change from NAD to NAD even though the tag is the same.

In summary, a template must be configured on the NAD, and the template must be associated with a tag. When the ACS sends the policies back to the NAD, the template that matches the tag that was received from the ACS is used.

Access Control List Overview

Cisco provides basic traffic filtering capabilities with access control lists (also referred to as access lists). Access lists can be configured for all routed network protocols (IP, AppleTalk, and so on) to filter the packets of those protocols as the packets pass through a router. You can configure access lists at your router to control access to a network. Access lists can prevent certain traffic from entering or exiting a network. See the [Access Control List](#) guidelines in the *Cisco IOS Security Configuration Guide* for more information about this feature.

How to Configure User-Based Firewall Support

Perform the following tasks to configure User-Based Firewall Support:

- [Configuring Access Control Lists, page 5](#)
- [Configuring the Identity Policy for Tag and Template, page 6](#)
- [Configuring Control Type Tag Class-Maps or Policy-Maps for Tag and Template, page 7](#)
- [Configuring Supplicant-Group Attribute on the ACS, page 9](#)
- [Configuring Firewall Class-Maps and Policy-Maps, page 9](#)
- [Configuring Firewall Zone Security and Zone-Pair, page 11](#)
- [Configuring ACLs for Authentication Proxy, page 12](#)
- [Configuring Authentication Proxy, page 14](#)
- [Configuring AAA and RADIUS, page 17](#)

Configuring Access Control Lists

To configure ACLs, perform the steps in this section. Policy specific ACLs are defined under the identity policy.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *access-list-name*
4. **permit** *protocol* **any host** *ip-address*
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended auth_proxy_acl	Defines an IP access list and enters extended named access list configuration mode.
Step 4	permit <i>protocol</i> any host <i>ip-address</i> Example: Router(config-ext-nacl)# permit tcp any host 192.168.104.136	Sets the permission for an access list using TCP.
Step 5	end Example: Router(config-ext-nacl)# end	Exits extended named access list configuration mode.

Configuring the Identity Policy for Tag and Template

To configure the identity policy for Tag and Template, perform the steps in this section. Usergroup support is achieved by configuring the usergroup that is to be associated with the IP address on the NAD itself using a locally defined identity policy. A tag is received from the ACS that matches a template (identity policy) on the NAD. The user-group associated with the IP address is obtained from the NAD.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **identity policy** *policy-name*
4. **user-group** *group-name*
5. **access-group** *group-name*
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	identity policy <i>policy-name</i> Example: Router(config)# identity policy auth_proxy_ip	Creates an identity policy and enters identity policy configuration mode.
Step 4	user-group <i>group-name</i> Example: Router(config-identity-policy)# user-group auth_proxy_ug	Establishes a user-group.
Step 5	access-group <i>group-name</i> Example: Router(config-identity-policy)# access-group auth_proxy_acl	Specifies the access-group to be applied to the identity policy.
Step 6	end Example: Router(config-identity-policy)# end	Exits identity policy configuration mode.

Configuring Control Type Tag Class-Maps or Policy-Maps for Tag and Template

To configure control type tag class-maps or policy-maps for Tag and Template, perform the steps in this section. Tag names are received from the AAA server as authorization data and are matched with their respective class-maps. The security policies that are associated with the identity policies are applied to the host. In this way host IP addresses gain membership of user-groups.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **policy-map type control tag** *policy-map-name*
4. **class type control tag** *control-class-name*
5. **identity policy** *policy-name*
6. **exit**

7. **configure terminal**
8. **class-map type control tag match-all** *class-map-name*
9. **match tag** *tag-name*
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	policy-map type control tag <i>policy-map-name</i> Example: Router(config)# policy-map type control tag all_tag_cm_pm	Creates a control policy map and enters policy-map configuration mode.
Step 4	class type control tag <i>control-class-name</i> Example: Router(config-pmap)# class type control tag auth_proxy_tag_cm	Creates a control class and enters policy-map-class configuration mode.
Step 5	identity policy <i>policy-name</i> Example: Router(config-pmap-c)# identity policy auth_proxy_ip	Creates an identity policy.
Step 6	exit Example: Router(config-pmap-c)# exit	Exits policy-map-class configuration mode.
Step 7	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 8	class-map type control tag match-all <i>class-map-name</i> Example: Router(config)# class-map type control tag match-all auth_proxy_tag_cm	Creates a control class map and enters class-map configuration mode.

	Command or Action	Purpose
Step 9	match tag <i>tag-name</i> Example: Router(config-cmap)# match tag <i>auth_proxy_tag</i>	Specifies the tag to be matched for a tag type of class map.
Step 10	end Example: Router(config-cmap)# end	Exits class-map configuration mode.

Configuring Supplicant-Group Attribute on the ACS

The supplicant group attribute needs to be configured as a Cisco attribute value (AV) Pair on the ACS for user based firewall support. To configure the supplicant-group attribute on the ACS, perform the steps in this section. The supplicant-group attribute is defined in the RADIUS authorization group attributes from where all authorization data pertaining to the client resides. The user-group information is obtained from the ACS and no further user-group specific configuration is required on the NAD.

SUMMARY STEPS

1. Cisco:Avpair=supplicant-group=*group-name*

DETAILED STEPS

- Step 1** Cisco:Avpair=supplicant-group=eng
Defines the supplicant-group attribute.

Configuring Firewall Class-Maps and Policy-Maps

To configure firewall class-maps and policy-maps, perform the steps in this section. User-groups are configured and attached to policy-maps by using the **inspect** command with each class-map.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **class-map type inspect match-all** *class-map-name*
4. **match protocol** *protocol-name*
5. **match user-group** *group-name*
6. **exit**
7. **configure terminal**
8. **policy-map type inspect** *policy-map-name*
9. **class type inspect** *class-map-name*

10. **inspect**

11. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	class-map type inspect match-all <i>class-map-name</i> Example: Router(config)# class-map type inspect match-all auth_proxy_ins_cm	Creates an inspect type class map and enters class-map configuration mode.
Step 4	match protocol <i>protocol-name</i> Example: Router(config-cmap)# match protocol telnet	Configures the match criterion for the class map on the basis of the specified protocol.
Step 5	match user-group <i>group-name</i> Example: Router(config-cmap)# match user-group auth_proxy_ug	Configures the match criterion for the class map on the basis of the specified user-group.
Step 6	exit Example: Router(config-cmap)# exit	Exits class-map configuration mode.
Step 7	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 8	policy-map type inspect <i>policy-map-name</i> Example: Router(config)# policy-map type inspect all_ins_cm_pm	Creates an inspect type policy map and enters policy-map configuration mode.
Step 9	class type inspect <i>class-map-name</i> Example: Router(config-pmap)# class type inspect auth_proxy_ins_cm	Specifies the traffic (class) on which an action is to be performed.

	Command or Action	Purpose
Step 10	inspect Example: Router(config-pmap)# inspect	Enables Cisco IOS stateful packet inspection.
Step 11	end Example: Router(config-pmap)# end	Exits policy-map configuration mode.

Configuring Firewall Zone Security and Zone-Pair

To configure firewall zone security and zone -pair, perform the steps in this section. Security zones are configured for untrustworthy (outside) and trustworthy (inside) networks or interfaces. Zone-pairs are configured where the source zone is untrustworthy and the destination zone is trustworthy.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **zone security** *zone-name*
4. **end**
5. **configure terminal**
6. **zone-pair security** *zone-pair-name* **source** *source-zone-name* **destination** *destination-zone-name*
7. **service-policy type inspect** *policy-map-name*
8. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	zone security <i>zone-name</i> Example: Router(config)# zone security out_sec_zone	Creates a security zone, and enters security zone configuration mode.

	Command or Action	Purpose
Step 4	end Example: Router(config-sec-zone)# end	Exits security zone configuration mode.
Step 5	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 6	zone-pair security zone-pair-name source source-zone-name destination destination-zone-name Example: Router(config)# zone-pair security out_in source out_sec_zone destination in_sec_zone	Creates a zone-pair and enters security zone-pair configuration mode.
Step 7	service-policy type inspect policy-map-name Example: Router(config-sec-zone-pair)# service-policy type inspect all_ins_cm_pm	Attaches a firewall policy map to the zone-pair.
Step 8	end Example: Router(config-sec-zone-pair)# end	Exits security zone-pair configuration mode.

Configuring ACLs for Authentication Proxy

To configure ACLs for authentication proxy, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended access-list-name**
4. **permit protocol any source-ip-address destination-ip-address**
5. **permit protocol any host destination-ip-address**
6. **permit protocol any any eq bootps**
7. **permit protocol any any eq domain**
8. **end**
9. **configure terminal**
10. **ip access-list extended access-list-name**
11. **permit protocol any host destination-ip-address**
12. **permit protocol any host destination-ip-address eq domain**

13. **permit** *protocol any host destination-ip-address eq www*
14. **permit** *protocol any host destination-ip-address eq port*
15. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended 102	Defines an IP access list and enters extended named access list configuration mode.
Step 4	permit <i>protocol any source-ip-address destination-ip-address</i> Example: Router(config-ext-nacl)# permit ip any 192.168.100.0 10.0.0.255	Sets the permission for an access list using IP.
Step 5	permit <i>protocol any host destination-ip-address</i> Example: Router(config-ext-nacl)# permit ip any host 192.168.104.136	Sets the permission for an access list using IP.
Step 6	permit <i>protocol any any eq bootps</i> Example: Router(config-ext-nacl)# permit ip any any eq bootps	Sets the permission for an access list using IP.
Step 7	permit <i>protocol any any eq domain</i> Example: Router(config-ext-nacl)# permit ip any any eq domain	Sets the permission for an access list using IP.
Step 8	end Example: Router(config-ext-nacl)# end	Exits extended named access list configuration mode.

	Command or Action	Purpose
Step 9	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 10	ip access-list extended access-list-name Example: Router(config)# ip access-list extended 103	Defines an IP access list and enters extended named access list configuration mode.
Step 11	permit protocol any host destination-ip-address Example: Router(config-ext-nacl)# permit ip any host 192.168.104.136	Sets the permission for an access list using IP.
Step 12	permit protocol any host destination-ip-address eq domain Example: Router(config-ext-nacl)# permit udp any host 192.168.104.136 eq domain	Sets the permission for an access list using user datagram protocol (UDP).
Step 13	permit protocol any host destination-ip-address eq www Example: Router(config-ext-nacl)# permit tcp any host 192.168.104.136 eq www	Sets the permission for an access list using TCP.
Step 14	permit protocol any host destination-ip-address eq port Example: Router(config-ext-nacl)# permit udp any host 192.168.104.136 eq 443	Sets the permission for an access list using UDP.
Step 15	end Example: Router(config-ext-nacl)# end	Exits extended named access list configuration mode.

Configuring Authentication Proxy

To configure authentication proxy default IP admissions, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip admission auth-proxy-banner http c Auth-Proxy-Banner-Text c**
4. **ip admission watch-list expiry-time expiry-minutes**

5. **ip admission max-login-attempts** *attempt-number*
6. **ip admission inactivity-timer** *timeout-minutes*
7. **ip admission absolute-timer** *timeout-minutes*
8. **ip admission init-state-timer** *timeout-minutes*
9. **ip admission auth-proxy-audit**
10. **ip admission watch-list enable**
11. **ip admission ratelimit** *limit*
12. **ip admission name** *admission-name* **proxy http list** *acl*
13. **ip admission name** *admission-name* **proxy telnet list** *acl*
14. **ip admission name** *admission-name* **proxy http list** *acl* **service-policy type tag** *service-policy-name*
15. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip admission auth-proxy-banner http c <i>Auth-Proxy-Banner-Text c</i> Example: Router(config)# ip admission auth-proxy-banner http c Auth-Proxy-Banner-Text c	Creates a network admission control rule with an authentication proxy banner to be applied to the interface.
Step 4	ip admission watch-list expiry-time <i>expiry-minutes</i> Example: Router(config)# ip admission watch-list expiry-time 50	Creates a network admission control rule with a watch-list to be applied to the interface.
Step 5	ip admission max-login-attempts <i>attempt-number</i> Example: Router(config)# ip admission max-login-attempts 10	Creates a network admission control rule with a specified maximum login attempts per user number to be applied to the interface.

	Command or Action	Purpose
Step 6	ip admission inactivity-timer <i>timeout-minutes</i> Example: Router(config)# ip admission inactivity-timer 205	Creates a network admission control rule with a specified inactivity timeout to be applied to the interface.
Step 7	ip admission absolute-timer <i>timeout-minutes</i> Example: Router(config)# ip admission absolute-timer 305	Creates a network admission control rule with a specified absolute timeout to be applied to the interface.
Step 8	ip admission init-state-timer <i>timeout-minutes</i> Example: Router(config)# ip admission init-state-timer 15	Creates a network admission control rule with a specified init-state timeout to be applied to the interface.
Step 9	ip admission auth-proxy-audit Example: Router(config)# ip admission auth-proxy-audit	Creates a network admission control rule with authentication proxy auditing to be applied to the interface.
Step 10	ip admission watch-list enable Example: Router(config)# ip admission watch-list enable	Creates a network admission control rule with a watch-list to be applied to the interface.
Step 11	ip admission ratelimit <i>limit</i> Example: Router(config)# ip admission ratelimit 100	Creates a network admission control rule with a specified session rate limit to be applied to the interface.
Step 12	ip admission name <i>admission-name</i> proxy http list <i>acl</i> Example: Router(config)# ip admission name auth_rule proxy http list 103	Creates an IP network admission control rule. <ul style="list-style-type: none"> Telnet, HTTP, or both can be configured.
Step 13	ip admission name <i>admission-name</i> proxy telnet list <i>acl</i> Example: Router(config)# ip admission name auth_rule proxy telnet list 103	Creates an IP network admission control rule. <ul style="list-style-type: none"> Telnet, HTTP, or both can be configured.

	Command or Action	Purpose
Step 14	<p>ip admission name <i>admission-name</i> proxy http list acl service-policy type tag <i>service-policy-name</i></p> <p>Example: Router(config)# ip admission name auth_rule proxy http list 103 service-policy type tag all_tag_cm_pm</p>	<p>(Optional) Creates an IP network admission control rule.</p> <ul style="list-style-type: none"> Configures a control plane service policy when the Tag & Template method of user-group association is used. Control plane tag service policy that is configured using the policy-map type control tag <i>{policy name}</i> command, keyword, and argument. This policy map is used to apply the actions on the host when a tag is received.
Step 15	<p>exit</p> <p>Example: Router(config)# exit</p>	Exits global configuration mode.

Configuring AAA and RADIUS

To configure AAA and RADIUS servers, perform the steps in this section.

SUMMARY STEPSs

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa authentication login default group radius**
5. **aaa authentication login** *list-name* **none**
6. **aaa authentication eou default enable group radius**
7. **aaa authorization network default group radius local**
8. **aaa authorization** *list-name* **default group radius**
9. **aaa accounting auth-proxy default start-stop group** *group-name*
10. **aaa accounting system default start-stop group** *group-name*
11. **aaa session-id common**
12. **radius-server attribute 6 on-for-login-auth**
13. **radius-server attribute 8 include-in-access-req**
14. **radius-server attribute 25 access-request include**
15. **radius-server configure-nas**
16. **radius-server host** *ip-address* **auth-port** *port-number* **acct-port** *port-number* **key** *string*
17. **radius-server host** *ip-address* **auth-port** *port-number* **acct-port** *port-number* **key** *string*
18. **radius-server source-ports extended**
19. **radius-server vsa send authentication**
20. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Router(config)# aaa new-model	Enables the AAA access control model.
Step 4	aaa authentication login default group radius Example: Router(config)# aaa authentication login default group radius	Sets AAA authentication at login using the group radius method.
Step 5	aaa authentication login list-name none Example: Router(config)# aaa authentication login noAAA none	Sets AAA authentication at login and ensures that the authentication succeeds even if all methods of authentication return an error.
Step 6	aaa authentication eou default enable group radius Example: Router(config)# aaa authentication eou default enable group radius	Sets authentication lists for Extensible Authentication Protocol over User Datagram Protocol (EAPoUDP).
Step 7	aaa authorization network default group radius local Example: Router(config)# aaa authorization network default group radius local	Sets parameters that restrict user access to a network using the group radius and local methods. <ul style="list-style-type: none"> The group radius method uses the list of all RADIUS servers for authentication. The local method uses the local database for authorization.
Step 8	aaa authorization list-name default group radius Example: Router(config)# aaa authorization auth-proxy default group radius	Sets parameters that restrict user access to a network using the group radius method.

	Command or Action	Purpose
Step 9	aaa accounting auth-proxy default start-stop group group-name Example: Router(config)# aaa accounting auth-proxy default start-stop group radius	Creates a method list to provide information about all authenticated-proxy user events. <ul style="list-style-type: none"> Sends a “start” accounting notice at the beginning of a process and a “stop” accounting notice at the end of a process.
Step 10	aaa accounting system default start-stop group group-name Example: Router(config)# aaa accounting system default start-stop group radius	Creates a method list to provide accounting for all system-level events not associated with users. <ul style="list-style-type: none"> Sends a “start” accounting notice at the beginning of a process and a “stop” accounting notice at the end of a process.
Step 11	aaa session-id common Example: Router(config)# aaa session-id common	Specifies that the same ID will be assigned for each AAA accounting service type within a call.
Step 12	radius-server attribute 6 on-for-login-auth Example: Router(config)# radius-server attribute 6 on-for-login-auth	Sends the Service-Type attribute in the authentication packets.
Step 13	radius-server attribute 8 include-in-access-req Example: Router(config)# radius-server attribute 8 include-in-access-req	Sends the IP address of a user to the RADIUS server in the access request.
Step 14	radius-server attribute 25 access-request include Example: Router(config)# radius-server attribute 25 access-request include	Sends an arbitrary value that the network access server includes in all accounting packets for the user if supplied by the RADIUS server.
Step 15	radius-server configure-nas Example: Router(config)# radius-server configure-nas	Configures the Cisco router or access server to query the vendor-proprietary RADIUS server for the static routes and IP pool definitions used throughout its domain when the device starts up.
Step 16	radius-server host ip-address auth-port port-number acct-port port-number key string Example: Router(config)# radius-server host 192.168.104.131 auth-port 1645 acct-port 1646 key string1	Specifies a RADIUS server host. <ul style="list-style-type: none"> Specifies the UDP destination port for authentication requests. Specifies the UDP destination port for accounting requests.

	Command or Action	Purpose
Step 17	radius-server host <i>ip-address</i> auth-port <i>port-number</i> acct-port <i>port-number</i> key <i>string</i> Example: Router(config)# radius-server host 192.168.104.132 auth-port 1645 acct-port 1646 key string2	Specifies a RADIUS server host. <ul style="list-style-type: none"> Specifies the UDP destination port for authentication requests. Specifies the UDP destination port for accounting requests.
Step 18	radius-server source-ports extended Example: Router(config)# radius-server source-ports extended	Enables 200 ports in the range from 21645 to 21844 to be used as the source ports for sending out RADIUS requests. <ul style="list-style-type: none"> Ports 1645 and 1646 are used as the source ports for RADIUS requests.
Step 19	radius-server vsa send authentication Example: Router(config)# radius-server vsa send authentication	Configures the network access server (NAS) to recognize and use vendor-specific attributes (VSAs).
Step 20	exit Example: Router(config)# exit	Exits global configuration mode.

Troubleshooting Tips

The following commands can be used to troubleshoot User-Based Firewall Support:

- **clear ip admission cache**
- **debug user-group**
- **show debugging**
- **show epm session ip**
- **show ip access-lists**
- **show ip admission**
- **show logging**
- **show policy-map type inspect zone-pair**
- **show user-group**

Examples

show epm session ip

The following example shows sample output of the **show epm session** command when the **summary** keyword is used.

```
Router# show epm session ip summary
EPM Session Information
-----
Total sessions seen so far: 8
Total Active sessions: 1
```

```

Session IP Address:
-----
192.168.101.131

```

The following example shows sample output of the **show epm session** command when the *ip-address* argument is specified. The output below is displayed if a locally defined user-group association (Tag and Template method) is used.

```

Router# show epm session ip 192.168.101.131
Admission feature: Authproxy
Tag Received: eng_group_tag
Policy map used: all_tag_cm_pm
Class map matched: eng_tag_cm

```

The following example shows sample output of the **show epm session** command when the *ip-address* argument is specified. The output below is displayed if ACS defined (supplicant-group attribute configured on the ACS) user-group association is used.

```

Router# show epm session ip 192.168.101.131
Admission feature: Authproxy
AAA policies:
ACS ACL: xACSAClX-IP-TEST_ACL-47dfc392
Supplicant-Group: eng
Supplicant-Group: mgr
Proxy ACL: permit udp any any
Router#

```

show ip access-lists

The following example shows sample output of the **show ip access-lists** command.

```

Router# show ip access-lists
Extended IP access list 102
    permit icmp host 192.168.101.131 host 192.168.104.136Auth-Proxy ACE downloaded from
AAA
    permit udp host 192.168.101.131 host 192.168.104.136Auth-Proxy ACE downloaded from AAA
    permit tcp host 192.168.101.131 host 192.168.104.136Auth-Proxy ACE downloaded from AAA
10 permit ip any 192.168.100.0 10.0.0.255 (956 matches)
    20 permit ip any 192.168.101.0 10.0.0.255 (9 matches)
    30 permit ip any host 192.168.104.136 (20 matches)
    40 permit udp any any eq bootps
    50 permit udp any any eq domain
Extended IP access list 103
    10 permit ip any host 192.168.104.136 (3 matches)
    20 permit udp any host 192.168.104.136 eq domain
    30 permit tcp any host 192.168.104.136 eq www
    40 permit udp any host 192.168.104.136 eq 443
    50 permit tcp any host 192.168.104.136 eq 443
Extended IP access list vendor_group_acl
    10 permit ip any host 192.168.104.136
Extended IP access list auth_proxy_acl
    10 permit tcp any host 192.168.104.136
    20 permit udp any host 192.168.104.136
    30 permit icmp any host 192.168.104.136
Extended IP access list sales_group_acl
    10 permit ip any host 192.168.104.131
Extended IP access list eng_group_acl
    10 permit ip any host 192.168.100.132
Extended IP access list manager_group_acl
    10 permit ip any host 192.168.104.128
Router#

```

show ip admission

The following example shows sample output of the **show ip admission** command when the **configuration** keyword is used.

```
Router# show ip admission configuration

Authentication Proxy Banner
  HTTP Protocol Banner: Auth-Proxy-Banner-Text
Authentication global cache time is 205 minutes
Authentication global absolute time is 305 minutes
Authentication global init state time is 15 minutes
Authentication Proxy Session ratelimit is 100
Authentication Proxy Session Watch-list is enabled
Watch-list expiry timeout is 50 minutes
Authentication Proxy Auditing is enabled
Max Login attempts per user is 10

Authentication Proxy Rule Configuration
Auth-proxy name auth_rule
  http list 103 inactivity-timer 205 minutes
Router#
```

The following example shows sample output of the **show ip admission** command when the **cache** keyword is used. After a successful Telnet/HTTP-proxy session, from a Cisco Trust Agent (CTA) client to an Audit Server, is established, logs are displayed.

```
Router# show ip admission cache
Authentication Proxy Cache
Client Name aaatestuser, Client IP 192.168.101.131, Port 1870, timeout 205, Time Remaining
205, state ESTAB
```

show logging

The following example shows sample output of the **show logging** command.

```
Router# show logging
Log Buffer (65000 bytes):
*Jul 3 05:33:13.935: %SYS-5-CONFIG_I: Configured from console by console

Configuration Examples for User-Based Firewall Support

This section contains the following example:

- [Cisco IOS Authentication Proxy Mapping: Example, page 24](#)

Cisco IOS Authentication Proxy Mapping: Example

The following example shows how to configure User-Based Firewall Support. The Cisco IOS Authentication Proxy maps two users to different user-groups. Zone Policy Firewall policies are configured on a per user-group basis.

```

!IP Admission configuration
Configure the rule for HTTP based proxy authentication and associate the control plane tag
service policy.
!
configure terminal

ip admission name auth-http proxy http service-policy type tag global-policy
ip http server
ip http secure-server

!AAA configuration
!
aaa new-model
!

```

```
aaa authentication login default group radius
aaa authentication login noAAA none
aaa authentication eou default group radius
aaa authorization network default group radius local
aaa authorization auth-proxy default group radius
aaa accounting auth-proxy default start-stop group radius
aaa accounting system default start-stop group radius
aaa session-id common
!
radius-server attribute 6 on-for-login-auth
radius-server attribute 8 include-in-access-req
radius-server attribute 25 access-request include
radius-server configure-nas
radius-server host 192.168.104.131 auth-port 1645 acct-port 1646 key cisco
radius-server host 192.168.104.132 auth-port 1645 acct-port 1646 key cisco
radius-server source-ports extended
radius-server vsa send authentication
!
!Tag and Template configuration.
Configuration policy attributes for the engineer.
!
identity policy engineer-policy
    access-group engineer-acl
    user-group group-engineer

identity policy manager-policy
    access-group manager-acl
    user-group group-manager

!Define type control tag class-maps
!
class-map type control tag match-all auth_proxy_tag_cm
match tag auth_proxy_tag
class-map type control tag match-all eng_tag_cm
match tag eng_group_tag
class-map type control tag match-all manager_tag_cm
match tag manager_group_tag
!

!Define the control plane tag policy map.
!
policy-map type tag control tag global-policy
    class engineer-class
        identity policy engineer-policy

    class manager-class
        identity policy manager-policy

!Define per-user group traffic classification based on membership of the source IP address
in the specified user-group.
!
class-map type inspect match-all engineer-insp-cmap
    match user-group group-engineer
    match protocol tcp
    match protocol udp

class-map type inspect match-all manager-insp-cmap
    match user-group group-manager
    match protocol http

!Zone Policy Firewall configuration.
Configure zones z1 and z2.
!
zone security z1
```

```

zone security z2

!Configure the policy map to inspect traffic between z1 and z2.
!
policy-map type inspect z1-z2-policy
  class type inspect engineer-insp-cmap
    inspect
  class type inspect manager-insp-cmap
    inspect

!Configure interfaces to their respective zones and apply the ip admission rule on the
source zone member(s).
!
interface e0
  ip admission auth-http
  zone-member security z1

interface e1
  zone-member security z2

!Configure the zone-pair and apply the appropriate policy-map.
!
zone-pair security z1-z2 source z1 destination z2
  service-policy type inspect z1-z2-policy

```

Feature Information for User-Based Firewall Support

Table 1 lists the release history for this feature.

Not all commands may be available in your Cisco IOS software release. For release information about a specific command, see the command reference documentation.

Use Cisco Feature Navigator to find information about platform support and software image support. Cisco Feature Navigator enables you to determine which Cisco IOS and Catalyst OS software images support a specific software release, feature set, or platform. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Note

Table 1 lists only the Cisco IOS software release that introduced support for a given feature in a given Cisco IOS software release train. Unless noted otherwise, subsequent releases of that Cisco IOS software release train also support that feature.

Table 1 Feature Information for User-Based Firewall Support

Feature Name	Releases	Feature Information
User-Based Firewall Support	12.4(20)T	<p>This feature provides the option for configuring a security solution to dynamically authenticate and enforce policies on a per user basis in Cisco IOS software for Release 12.4(20)T and later releases.</p> <p>In Release 12.4(20)T, this feature was introduced on the Cisco 7200, Cisco 1800, Cisco 2800, and Cisco 3800 routers.</p> <p>The following commands were introduced or modified: debug user-group, match user-group, show debugging, show user-group, user-group, user-group logging.</p>

Virtual Fragmentation Reassembly

Currently, the Cisco IOS Firewall—specifically context-based access control (CBAC) and the intrusion detection system (IDS)—cannot identify the contents of the IP fragments nor can it gather port information from the fragment. These inabilities allow the fragments to pass through the network without being examined or without dynamic access control list (ACL) creation.

Virtual fragmentation reassembly (VFR) enables the Cisco IOS Firewall to create the appropriate dynamic ACLs, thereby, protecting the network from various fragmentation attacks.

Restrictions for Virtual Fragmentation Reassembly

Performance Impact

VFR will cause a performance impact on the basis of functions such as packet copying, fragment validation, and fragment reorder. This performance impact will vary depending on the number of concurrent IP datagram that are being reassembled.

VFR Configuration Restriction

VFR should not be enabled on a router that is placed on an asymmetric path. The reassembly process requires all of the fragments within an IP datagram. Routers placed in the asymmetric path may not receive all of the fragments, so the fragment reassembly will fail.

SIP and RTSP Limitation

The Session Initiation Protocol (SIP) and the Real-Time Streaming Protocol (RTSP) do not have the ability to parse port information across noncontiguous buffers. Thus, virtual fragmentation reassembly may fail. (If the application fails, the session will be blocked.)

Information About Virtual Fragmentation Reassembly

To use fragmentation support for Cisco IOS Firewall, you should understand the following concept:

- [Detected Fragment Attacks, page 2](#)
- [Automatically Enabling or Disabling VFR, page 3](#)

Detected Fragment Attacks

VFR is responsible for detecting and preventing the following types of fragment attacks:

- **Tiny Fragment Attack**—In this type of attack, the attacker makes the fragment size small enough to force Layer 4 (TCP and User Datagram Protocol (UDP)) header fields into the second fragment. Thus, the ACL rules that have been configured for those fields will not match.

VFR drops all tiny fragments, and an alert message such as follows is logged to the syslog server: “VFR-3-TINY_FRAGMENTS.”

- **Overlapping Fragment Attack**—In this type of attack, the attacker can overwrite the fragment offset in the noninitial IP fragment packets. When the firewall reassembles the IP fragments, it might create wrong IP packets, causing the memory to overflow or your system to crash.

VFR drops all fragments within a fragment chain if an overlap fragment is detected, and an alert message such as follows is logged to the syslog server: “VFR-3-OVERLAP_FRAGMENT.”

- **Buffer Overflow Attack**—In this type of denial-of-service (DoS) attack, the attacker can continuously send a large number of incomplete IP fragments, causing the firewall to lose time and memory while trying to reassemble the fake packets.

To avoid buffer overflow and control memory usage, configure a maximum threshold for the number of IP datagrams that are being reassembled and the number of fragments per datagram. (Both of these parameters can be specified via the **ip virtual-reassembly** command.)

When the maximum number of datagrams that can be reassembled at any given time is reached, all subsequent fragments are dropped, and an alert message such as the following is logged to the syslog server: “VFR-4_FRAG_TABLE_OVERFLOW.”

When the maximum number of fragments per datagram is reached, subsequent fragments will be dropped, and an alert message such as the following is logged to the syslog server: “VFR-4_TOO_MANY_FRAGMENTS.”

In addition to configuring the maximum threshold values, each IP datagram is associated with a managed timer. If the IP datagram does not receive all of the fragments within the specified time, the timer will expire and the IP datagram (and all of its fragments) will be dropped.

Automatically Enabling or Disabling VFR

VFR is designed to work with any feature that requires fragment reassembly (such as Cisco IOS Firewall and NAT). Currently, NAT enables and disables VFR internally; that is, when NAT is enabled on an interface, VFR is automatically enabled on that interface.

If more than one feature attempts to automatically enable VFR on an interface, VFR will maintain a reference count to keep track of the number of features that have enabled VFR. When the reference count is reduced to zero, VFR is automatically disabled.

How to Use Virtual Fragmentation Reassembly

This section contains the following procedures:

- [Configuring VFR, page 3](#)

Configuring VFR

Use this task to enable VFR on an interface, specify maximum threshold values to combat buffer overflow and control memory usage, and verify any VFR configurations.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface type** *type number*
4. **ip virtual-reassembly** [**max-reassemblies** *number*] [**max-fragments** *number*] [**timeout** *seconds*] [**drop-fragments**]
5. **exit**
6. **exit**
7. **show ip virtual-reassembly** [**interface type**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: Router(config)# interface ethernet1/1	Configures an interface type and enters interface configuration mode.
Step 4	ip virtual-reassembly [max-reassemblies <i>number</i>] [max-fragments <i>number</i>] [timeout <i>seconds</i>] [drop-fragments] Example: Router(config-if)# ip virtual-reassembly max-reassemblies 64 max-fragments 16 timeout 5	Enables VFR on an interface.
Step 5	exit Example: Router(config-if)# exit	Exits interface configuration mode.
Step 6	exit Example: Router(config)# exit	Exits global configuration mode.
Step 7	show ip virtual-reassembly [interface <i>type</i>] Example: Router# show ip virtual-reassembly ethernet1/1	Displays the configuration and statistical information of the VFR. If an interface is not specified, VFR information is shown for all configured interfaces.

Troubleshooting Tips

To view debugging messages related to the VFR subsystem, use the **debug ip virtual-reassembly** command.

Configuration Examples for Fragmentation Reassembly

This section contains the following configuration example:

- [Configuring VFR and a Cisco IOS Firewall: Example, page 5](#)

Configuring VFR and a Cisco IOS Firewall: Example

The following example shows a typical scenario where the Virtual Fragment Reassembly module is enabled on interfaces ethernet2/1, ethernet2/2, and serial3/0 to facilitate the firewall that is enabled in the outbound direction on interface serial3/0. In this example, the firewall rules that specify the list of LAN1 and LAN2 originating protocols (FTP, HTTP and SMTP) are to be inspected.

Glossary

fragment—Part of an IP datagram that is fragmented into multiple pieces. Each piece is called a fragment or an IP fragment.

fragmentation—Process of breaking down an IP datagram into smaller packets (fragments) that are transmitted over different types of network media.

initial fragment— First fragment within a fragment set. This fragment should have a Layer 4 header and should have an offset of zero.

noninitial fragment—All fragments within a fragment set, except the initial fragment.

Any Internet Protocol (IP) addresses used in this document are not intended to be actual addresses. Any examples, command display output, and figures included in the document are shown for illustrative purposes only. VRF Aware Cisco IOS Firewall

VRF Aware Cisco IOS Firewall applies Cisco IOS Firewall functionality to VRF (Virtual Routing and Forwarding) interfaces when the firewall is configured on a service provider (SP) or large enterprise edge router. SPs can provide managed services to small and medium business markets.

The VRF Aware Cisco IOS Firewall supports VRF-aware URL filtering and VRF-lite (also known as Multi-VRF CE).

Prerequisites for VRF Aware Cisco IOS Firewall

- Understand Cisco IOS firewalls.
- Configure VRFs.
- Verify that the VRFs are operational.

Restrictions for VRF Aware Cisco IOS Firewall

- VRF Aware Cisco IOS Firewall is not supported on Multiprotocol Label Switching (MPLS) interfaces.
- If two VPN networks have overlapping addresses, VRF-aware network address translation (NAT) is required for them to support VRF-aware Firewalls.
- When crypto tunnels belonging to multiple VPNs terminate on a single interface, you cannot apply per-VRF firewall policies.

Information About VRF Aware Cisco IOS Firewall

To configure VRF Aware Cisco IOS Firewall, you need to understand the following concepts:

- [Cisco IOS Firewall, page 2](#)
- [VRF, page 3](#)
- [VRF-lite, page 4](#)
- [Per-VRF URL Filtering, page 5](#)
- [Alerts and Audit Trails, page 5](#)
- [MPLS VPN, page 5](#)
- [VRF-aware NAT, page 5](#)
- [VRF-aware IPSec, page 6](#)
- [VRF Aware Cisco IOS Firewall Deployment, page 7](#)

Cisco IOS Firewall

The Cisco IOS Firewall provides robust, integrated firewall and intrusion detection functionality for every perimeter of the network. Available for a wide range of Cisco IOS software-based routers, the Cisco IOS Firewall offers sophisticated security and policy enforcement for connections within an organization (intranet) and between partner networks (extranets), as well as for securing Internet connectivity for remote and branch offices.

The Cisco IOS Firewall enhances existing Cisco IOS security capabilities such as authentication, encryption, and failover, with state-of-the-art security features such as stateful, application-based filtering (context-based access control), defense against network attacks, per-user authentication and authorization, and real-time alerts.

The Cisco IOS Firewall is configurable via Cisco ConfigMaker software, an easy-to-use Microsoft Windows 95, Windows 98, NT 4.0 based software tool.

The Cisco IOS Firewall provides great value in addition to these benefits:

- Flexibility—Provides multiprotocol routing, perimeter security, intrusion detection, VPN functionality, and dynamic per-user authentication and authorization.
- Scalable deployment—Scales to meet any network's bandwidth and performance requirements.
- Investment protection—Leverages existing multiprotocol router investment.
- VPN support—Provides a complete VPN solution based on Cisco IOS IPSec and other CISCOS IOS software-based technologies, including L2TP tunneling and quality of service (QoS).

The VRF Aware Cisco IOS Firewall is different from the non-VRF Aware Firewall because it does the following:

- Allows users to configure a per-VRF Firewall. The firewall inspects IP packets that are sent and received within a VRF.
- Allows SPs to deploy the firewall on the provider edge (PE) router.
- Supports overlapping IP address space, thereby allowing traffic from nonintersecting VRFs to have the same IP address.
- Supports per-VRF (not global) firewall command parameters and Denial-of-Service (DoS) parameters so that the VRF-aware Firewall can run as multiple instances (with VRF instances) allocated to various Virtual Private Network (VPN) customers.
- Performs per-VRF URL filtering.
- Generates VRF-specific syslog messages that can be seen only by a particular VPN. These alert and audit-trail messages allow network administrators to manage the firewall; that is, they can adjust firewall parameters, detect malicious sources and attacks, add security policies, and so forth. The vrf name is tagged to syslog messages being logged to the syslog server.

Both VFR Aware and non-VFR Aware Firewalls now allow you to limit the number of firewall sessions. Otherwise, it would be difficult for VRFs to share router resources because one VRF may consume a maximum amount of resources, leaving few resources for other VRFs. That would cause the denial of service to other VRFs. To limit the number of sessions, enter the **ip inspect name** command.

VRF

VPN Routing and Forwarding (VRF) is an IOS route table instance for connecting a set of sites to a VPN service. A VRF contains a template of a VPN Routing/Forwarding table in a PE router.

The overlapping addresses, usually resulting from the use of private IP addresses in customer networks, are one of the major obstacles to successful deployment of peer-to-peer VPN implementation. The MPLS VPN technology provides a solution to this dilemma.

Each VPN has its own routing and forwarding table in the router, so any customer or site that belongs to a VPN is provided access only to the set of routes contained within that table. Any PE router in the MPLS VPN network therefore contains a number of per-VPN routing tables and a global routing table that is used to reach other routers in the service provider network. Effectively, a number of virtual routers are created in a single physical router.

VRF-lite

VRF-lite is a feature that enables a service provider to support two or more VPNs, where IP addresses can be overlapped among the VPNs. VRF-lite uses input interfaces to distinguish routes for different VPNs and forms virtual packet-forwarding tables by associating one or more Layer 3 interfaces with each VRF. Interfaces in a VRF can be physical, such as Ethernet ports, or logical, such as VLAN switched virtual interfaces (SVIs). However, a Layer 3 interface cannot belong to more than one VRF at a time.

Note

VRF-lite interfaces must be Layer 3 interfaces.

VRF-lite includes these devices:

- Customer edge (CE) devices provide customer access to the service provider network over a data link to one or more provider edge (PE) routers. The CE device advertises the site's local routes to the PE router and learns the remote VPN routes from it. A Catalyst 4500 switch can be a CE.
- Provider edge (PE) routers exchange routing information with CE devices by using static routing or a routing protocol such as BGP, RIPv1, or RIPv2.
- Provider routers (or core routers) are any routers in the service provider network that do not attach to CE devices.
- The PE is only required to maintain VPN routes for those VPNs to which it is directly attached, eliminating the need for the PE to maintain all of the service provider VPN routes. Each PE router maintains a VRF for each of its directly connected sites. Multiple interfaces on a PE router can be associated with a single VRF if all of these sites participate in the same VPN. Each VPN is mapped to a specified VRF. After learning local VPN routes from CEs, a PE router exchanges VPN routing information with other PE routers by using internal BGP (IBPG).

With VRF-lite, multiple customers can share one CE, and only one physical link is used between the CE and the PE. The shared CE maintains separate VRF tables for each customer, and switches or routes packets for each customer based on its own routing table. VRF-lite extends limited PE functionality to a CE device, giving it the ability to maintain separate VRF tables to extend the privacy and security of a VPN to the branch office.

In a VRF-to-VRF situation, if firewall policies are applied on both inbound and outbound interfaces as shown in [Figure 35](#), the firewall on the inbound interface takes precedence over the firewall on the outbound interface. If the incoming packets do not match against the firewall rules (that is, the inspection protocols) configured on the inbound interface, the firewall rule on the outbound interface is applied to the packet.

Figure 35 Firewall in a VRF-to-VRF Scenario

Per-VRF URL Filtering

The VRF Aware firewall supports per-VRF URL filtering. Each VPN can have its own URL filter server. The URL filter server typically is placed in the Shared Service segment of the corresponding VPN. (Each VPN has a VLAN segment in the Shared Service network.) It can also be placed at the customer's site.

Alerts and Audit Trails

CBAC generates real-time alerts and audit trails based on events tracked by the firewall. Enhanced audit trail features use SYSLOG to track all network transactions; recording time stamps, the source host, the destination host, ports used, and the total number of transmitted bytes, for advanced, session-based reporting. Real-time alerts send SYSLOG error messages to central management consoles upon detecting suspicious activity. Using CBAC inspection rules, you can configure alerts and audit trail information on a per-application protocol basis. For example, if you want to generate audit trail information for HTTP traffic, you can specify that in the CBAC rule covering HTTP inspection.

MPLS VPN

When used with MPLS, the VPN feature allows several sites to interconnect transparently through a service provider's network. One service provider network can support several IP VPNs. Each VPN appears to its users as a private network, separate from all other networks. Within a VPN, each site can send IP packets to any other site in the same VPN.

Each VPN is associated with one or more VPN VRF instances. A VRF consists of an IP routing table, a derived Cisco express forwarding (CEF) table, and a set of interfaces that use the forwarding table.

The router maintains a separate routing and CEF table for each VRF. This prevents information from being sent outside the VPN and allows the same subnet to be used in several VPNs without causing duplicate IP address problems.

The router using Multiprotocol BGP (MP-BGP) distributes the VPN routing information using the MP-BGP extended communities.

VRF-aware NAT

Network Address Translation (NAT) allows a single device, such as a router, to act as an agent between the Internet (or public network) and a local (or private) network. Although NAT systems can provide broad levels of security advantages, their main objective is to economize on address space.

NAT allows organizations to resolve the problem of IP address depletion when they have existing networks and need to access the Internet. Sites that do not yet possess NIC-registered IP addresses must acquire them. Cisco IOS NAT eliminates concern and bureaucratic delay by dynamically mapping thousands of hidden internal addresses to a range of easy-to-get addresses.

In general, a NAT system makes it more difficult for an attacker to determine the following:

- Number of systems running on a network
- Type of machines and operating systems they are running
- Network topology and arrangement

NAT integration with MPLS VPNs allows multiple MPLS VPNs to be configured on a single device to work together. NAT can differentiate which MPLS VPN it receives IP traffic from even if the MPLS VPNs are all using the same IP addressing scheme. This enables multiple MPLS VPN customers to share services while ensuring that each MPLS VPN is completely separate from the other.

MPLS service providers would like to provide value-added services such as Internet connectivity, domain name servers (DNS), and VoIP service to their customers. This requires that their customers IP addresses be different when reaching the services. Because MPLS VPN allows customers to use overlapped IP addresses in their networks, NAT must be implemented to make the services possible.

There are two approaches to implementing NAT in the MPLS VPN network. NAT can be implemented on the CE router, which is already supported by NAT, or it can be implemented on a PE router. The NAT Integration with MPLS VPNs feature enables the implementation of NAT on a PE router in an MPLS cloud.

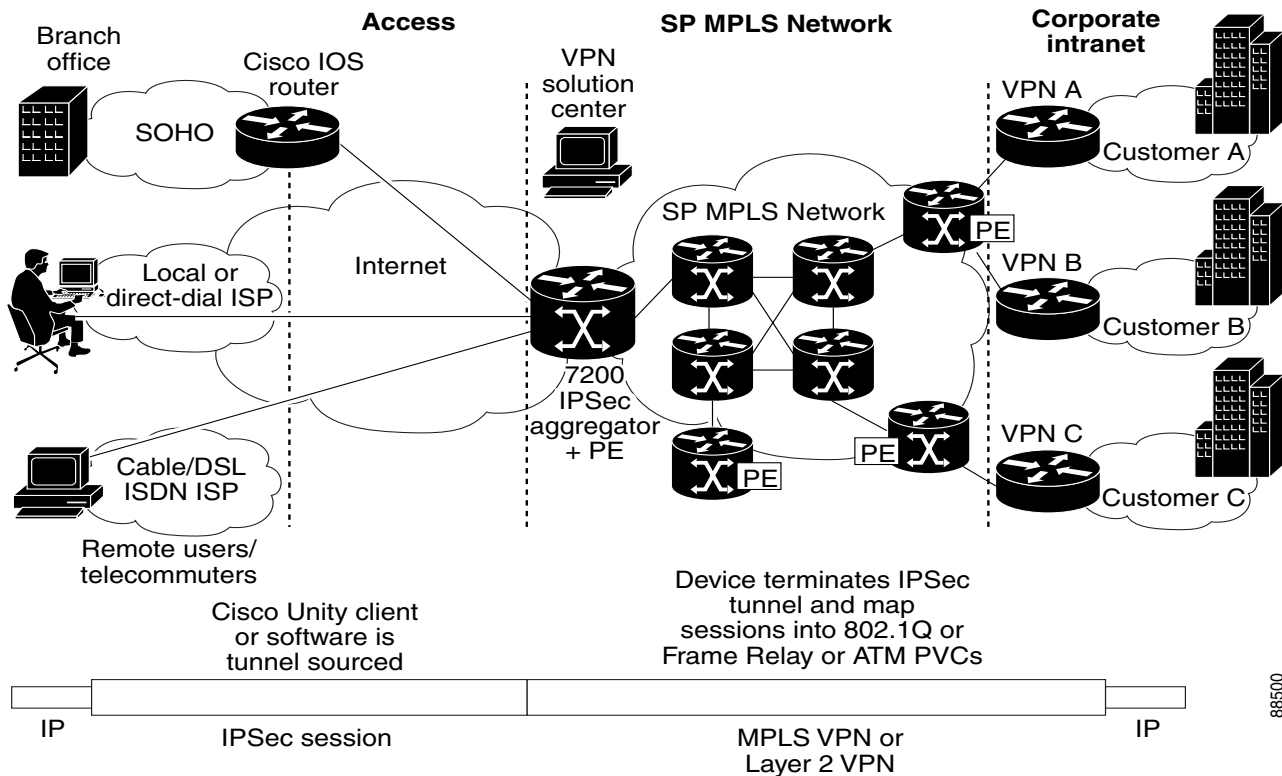

VRF-aware IPSec

The VRF-aware IPSec feature maps an IP Security (IPSec) tunnel to an MPLS VPN. Using the VRF-aware IPSec feature, you can map IPSec tunnels to VRF instances using a single public-facing address.

Each IPSec tunnel is associated with two VRF domains. The outer encapsulated packet belongs to a VRF domain called the Front Door VRF (FVRF). The inner, protected IP packet belongs to a domain called the Inside VRF (IVRF). In other words, the local endpoint of the IPSec tunnel belongs to the FVRF, whereas the source and destination addresses of the inside packet belong to the IVRF.

One or more IPSec tunnels can terminate on a single interface. The FVRF of all these tunnels is the same and is set to the VRF that is configured on that interface. The IVRF of these tunnels can be different and depends on the VRF that is defined in the Internet Security Association and Key Management Protocol (ISAKMP) profile that is attached to a crypto map entry.

[Figure 36](#) illustrates a scenario showing IPSec to MPLS and Layer 2 VPNs.

Figure 36 *IPSec-to-MPLS and Layer 2 VPNs*

VRF Aware Cisco IOS Firewall Deployment

A firewall can be deployed at many points within the network to protect VPN sites from Shared Service (or the Internet) and vice versa. The following firewall deployments are described:

- [Distributed Network Inclusion of VRF Aware Cisco IOS Firewall, page 7](#)
- [Hub-and-Spoke Network Inclusion of VRF Aware Cisco IOS Firewall, page 9](#)

Distributed Network Inclusion of VRF Aware Cisco IOS Firewall

A VRF Aware Cisco IOS Firewall in a distributed network has the following advantages:

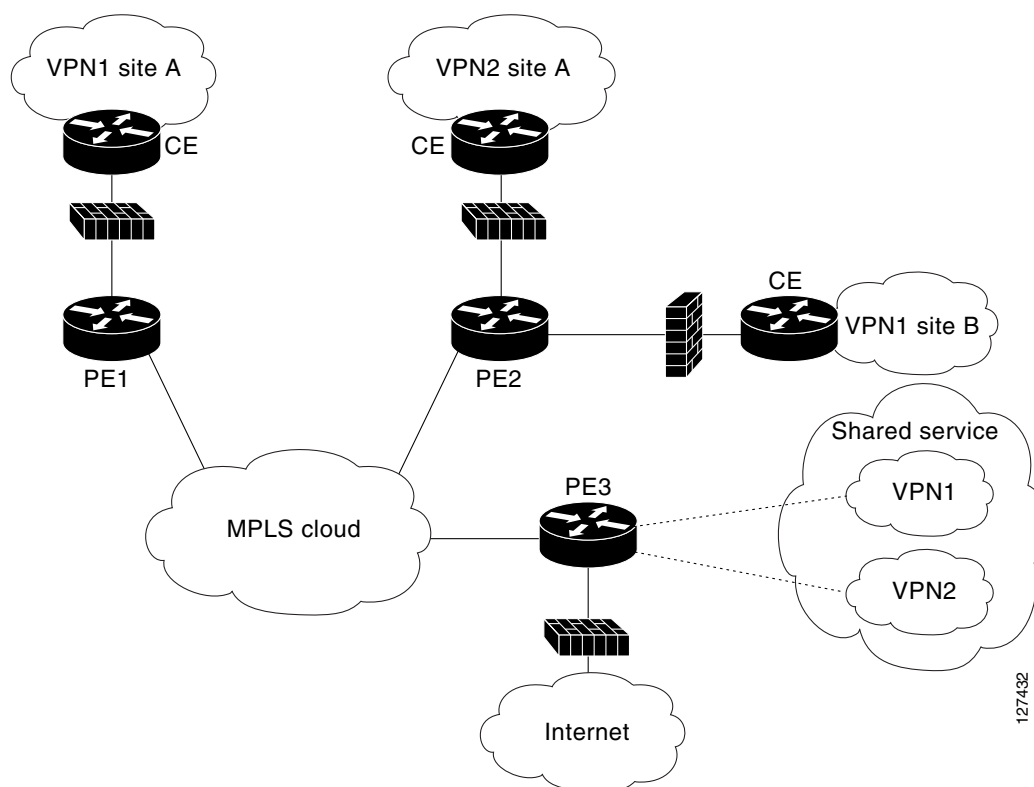

- The firewall is distributed across the MPLS core, so the firewall processing load is distributed to all ingress PE routers.
- VPN Firewall features can be deployed in the inbound direction.
- Shared Service is protected from the VPN site at the ingress PE router; therefore, malicious packets from VPN sites are filtered at the ingress PE router before they enter the MPLS core.

However, the following disadvantages exist:

- There is no centralized firewall deployment, which complicates the deployment and management of the firewall.
- Shared Service firewall features cannot be deployed in the inbound direction.
- The MPLS core is open to the Shared Service. Therefore, malicious packets from Shared Service are filtered only at the ingress PE router after traveling through all core routers.

Figure 37 illustrates a typical situation in which an SP offers firewall services to VPN customers VPN1 and VPN2, thereby protecting VPN sites from the external network (for example, Shared Services and the Internet) and vice versa.

Figure 37 *Distributed Network*

In this example, VPN1 has two sites, Site A and Site B, that span across the MPLS core. Site A is connected to PE1, and Site B is connected to PE2. VPN2 has only one site that is connected to PE2.

Each VPN (VPN1 and VPN2) has the following:

- A VLAN segment in the Shared Service that is connected to the corresponding VLAN subinterface on PE3.
- Internet access through the PE3 router that is connected to the Internet

A distributed network requires the following firewall policies:

- **VPN Firewall (VPN1-FW and VPN2-FW)**—Inspects VPN-generated traffic that is destined to Shared Service or the Internet and blocks all non-firewall traffic that is coming from outside (Shared Service or the Internet), thereby protecting the VPN sites from outside traffic. This firewall typically is deployed on the VRF interface of the ingress PE router that is connected to the VPN site being protected. It is deployed in the inbound direction because the VRF interface is inbound to the VPN site being protected.
- **Shared Service Firewall (SS-FW)**—Inspects Shared Service-originated traffic that is destined to VPN sites and blocks all non-firewall traffic that is coming from outside (the VPN site), thereby protecting the Shared Service network from VPN sites. This firewall typically is deployed on the VRF interface of the ingress PE router that is connected to the VPN site from where the Shared Service is being protected. It is deployed in the outbound direction because the VRF interface is outbound to the Shared Service that is being protected.
- **Generic-VPN Firewall (GEN-VPN-FW)**—Inspects VPN-generated traffic that is destined to the Internet and blocks all non-firewall traffic that is coming from the Internet, thereby protecting all VPNs from the Internet. This firewall typically is deployed on the Internet-facing interface of the PE router that is connected to the Internet. It is deployed in the outbound direction because the Internet-facing interface is outbound to VPNs being protected.
- **Internet Firewall (INET-FW)**—Inspects Internet-generated traffic that is destined to Shared Service and blocks all non-firewall traffic that is coming from VPNs or Shared Service, thereby protecting the Internet from VPNs. This firewall typically is deployed on the Internet-facing interface of the PE router that is connected to the Internet. It is deployed in the inbound direction because the Internet-facing interface is inbound to the Internet being protected.

Hub-and-Spoke Network Inclusion of VRF Aware Cisco IOS Firewall

[Figure 38](#) illustrates a hub-and-spoke network where the firewalls for all VPN sites are applied on the ingress PE router PE3 that is connected to the Shared Service.

Figure 38 *Hub-and-Spoke Network*

Typically each VPN has a VLAN and/or VRF subinterface connected to the Shared Service. When a packet arrives from an MPLS interface, the inner tag represents the VPN-ID. MPLS routes the packet to the corresponding subinterface that is connected to Shared Service.

A Hub-and-Spoke network requires the following firewall policies:

- **VPN Firewall (VPN1-FW and VPN2-FW)**—Inspects VPN-generated traffic that is destined to Shared Service and blocks all non-firewall traffic that is coming from Shared Service, thereby protecting the VPN sites from Shared Service traffic. This firewall typically is deployed on the VLAN subinterface of the egress PE router that is connected to the Shared Service network. It is deployed in the outbound direction because the VLAN interface is outbound to the VPN site being protected.
- **Shared Service Firewall (SS-FW)**—Inspects Shared Service originated traffic that is destined to the VPN/Internet and blocks all non-firewall traffics that is coming from outside, thereby protecting the Shared Service network from VPN/Internet traffic. This firewall typically is deployed on the VLAN interface of the egress PE router that is connected to the Shared Service being protected. It is deployed in the inbound direction because the VLAN interface is inbound to the Shared Service being protected.

- Generic-VPN firewall (GEN-VPN-FW)—Inspects VPN-generated traffic that is destined to the Internet and blocks all non-firewall traffic that is coming from the Internet, thereby protecting all VPNs from the Internet. This firewall typically is deployed on the Internet-facing interface of the PE router that is connected to the Internet. It is deployed in the outbound direction because the Internet-facing interface is outbound to the VPNs being protected.
- Internet firewall (INET-FW)—Inspects Internet-generated traffic that is destined to Shared Service and blocks all non-firewall traffic that is coming from VPNs or Shared Service, thereby protecting the Internet from VPNs. This firewall typically is deployed on the Internet-facing interface of the PE router that is connected to the Internet. It is deployed in the inbound direction because the Internet-facing interface is inbound to the Internet being protected.

How to Configure VRF Aware Cisco IOS Firewall

This section contains the following procedures:

- [Configuring and Checking ACLs to Ensure that Only Inspected Traffic Can Pass Through the Firewall and that Non-Firewall Traffic is Blocked, page 11](#) (required)
- [Creating and Naming Firewall Rules and Applying the Rules to the Interface, page 12](#) (required)
- [Identifying and Setting Firewall Attributes, page 13](#) (optional)

Configuring and Checking ACLs to Ensure that Only Inspected Traffic Can Pass Through the Firewall and that Non-Firewall Traffic is Blocked

To configure ACLs and verify that only inspected traffic can pass through the firewall, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip access-list extended** *access-list-name*
4. **interface** *interface-type*
5. **ip access-group** {*access-list-number* | *access-list-name*} {**in** | **out**}
6. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip access-list extended <i>access-list-name</i> Example: Router(config)# ip access-list extended vpn-acl	Defines an extended IP ACL to block non-firewall traffic in both inbound and outbound directions.
Step 4	interface <i>interface-type</i> Example: Router(config)# interface ethernet0/1.10	Enters interface configuration mode and specifies an interface that is associated with a VRF.
Step 5	ip access-group { <i>access-list-number</i> <i>access-list-name</i> } { in out } Example: Router(config-if)# ip access-group vpn-acl in	Controls access to an interface. Applies the previously defined IP access list to a VRF interface whose non-firewall traffic is blocked.
Step 6	exit Example: Router(config-if)# exit	Exits interface configuration mode. Returns to global configuration mode.

Creating and Naming Firewall Rules and Applying the Rules to the Interface

To create and name firewall rules and apply the rules to the interface, perform the following steps.

SUMMARY STEPS

- enable**
- configure terminal**
- ip inspect name** *inspection-name* [**parameter** *max-sessions* *number*] *protocol* [**alert** {**on** | **off**}] [**audit-trail** {**on** | **off**}] [**timeout** *seconds*]
- interface** *interface-id*
- ip inspect** *rule-name* {**in** | **out**}
- exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect name inspection-name [parameter max-sessions number] protocol [alert {on off}] [audit-trail {on off}] [timeout seconds] Example: Router(config)# ip inspect name vpn_fw ftp	Defines a set of inspection rules.
Step 4	interface interface-id Example: Router(config)# interface ethernet0/1.10	Enters interface configuration mode and specifies an interface that is associated with a VRF.
Step 5	ip inspect rule-name {in out} Example: Router(config-if)# ip inspect vpn_fw in	Applies the previously defined inspection role to a VRF interface whose traffic needs to be inspected.
Step 6	exit Example: Router(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.

Identifying and Setting Firewall Attributes

To identify and set firewall attributes, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. ip inspect tcp max-incomplete host number block-time minutes [vrf vrf-name]
4. exit

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip inspect tcp max-incomplete host <i>number</i> block-time <i>minutes</i> [vrf <i>vrf-name</i>] Example: Router(config)# ip inspect tcp max-incomplete host 256 vrf bank-vrf	Specifies threshold and blocking time values for TCP host-specific denial-of-service detection and prevention.
Step 4	exit Example: Router(config)# exit	Exits global configuration mode.

Verifying the VRF Aware Cisco IOS Firewall Configuration and Functioning

Verify the configuration and functioning of the firewall by entering the commands shown below. For detailed descriptions of these commands and other verification commands, see the [“Command Reference” section on page 26](#).

SUMMARY STEPS

1. **show ip inspect** {name *inspection-name* | config | interfaces | session [detail] | statistics | all}[vrf *vrf-name*]
2. **show ip urlfilter** {config | cache | statistics} [vrf *vrf-name*]

DETAILED STEPS

Step 1 **show ip inspect** {name *inspection-name* | config | interfaces | session [detail] | statistics | all}[vrf *vrf-name*]

Use this command to view the firewall configurations, sessions, statistics, and so forth, pertaining to a specified VRF. For example, to view the firewall sessions pertaining to the VRF bank, enter the following command:

```
Router# show ip inspect interfaces vrf bank
```

Step 2 **show ip urlfilter** {config | cache | statistics} [vrf *vrf-name*]

Use this command to view the configurations, cache entries, statistics, and so forth, pertaining to a specified VRF. For example, to view the URL filtering statistics pertaining to the VRF bank, enter the following command:

```
Router# show ip urlfilter statistics vrf bank
```

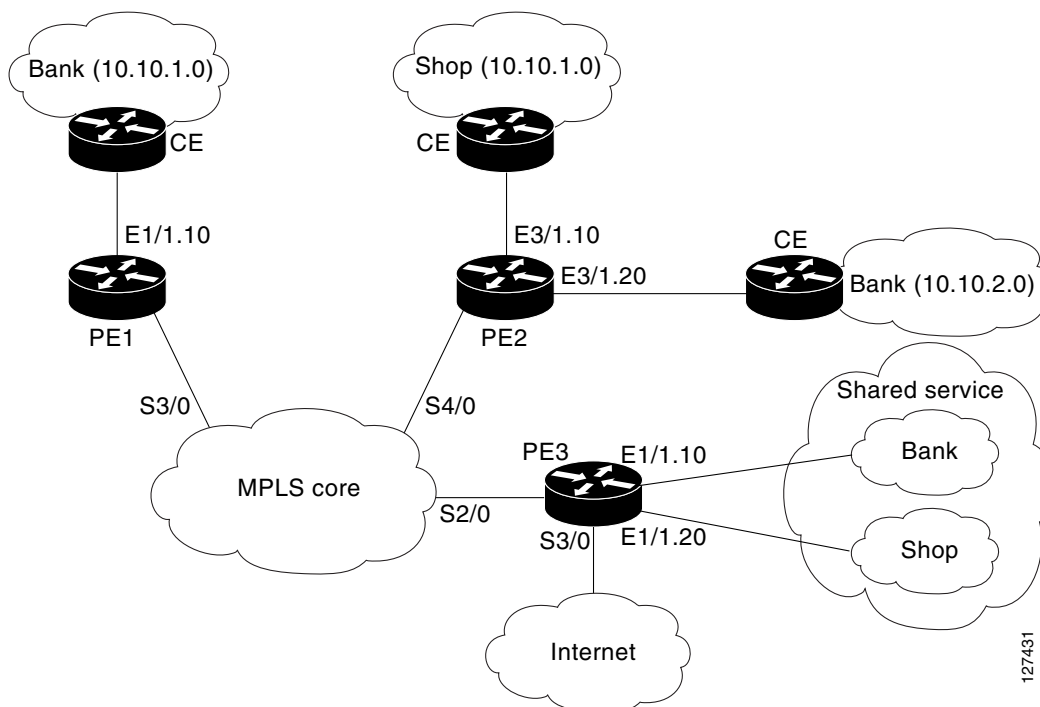

Configuration Examples for VRF Aware Cisco IOS Firewall

In the example illustrated in [Figure 39](#), a service provider offers firewall service to VPN customers **Bank** and **Shop**. The Bank VPN has the following two sites in an MPLS network:

- Site connected to PE1, whose network address is 10.10.1.0/24
- Site connected to PE2, whose network address is 10.10.2.0/24

The Bank VPN also has a VLAN network segment in Shared Service that is connected to PE3.

The Shop VPN has only one site, which is connected to PE4. The network address 10.10.1.0/24 is the same network address to which the Bank VPN site is connected.

Figure 39 *VPN with Two Sites Across MPLS Network*

Each VPN needs the following two firewalls:

- VPN firewall to protect the VPN site from Shared Services
- Shared Service (SS) firewall to protect SS from the VPN site

In addition, the following two firewalls are required:

- Internet firewall to protect VPNs from the Internet
- Generic VPN firewall to protect the Internet from VPNs

In this example, the security policies for Bank and Shop VPNs are as follows:

- Bank VPN Firewall—bank_vpn_fw (Inspects FTP, HTTP, and ESMTP protocols)
- Bank SS Firewall—bank_ss_fw (Inspects ESMTP protocol)
- Shop VPN Firewall—shop_vpn_fw (Inspects HTTP and RTSP protocols)
- Shop SS Firewall—shop_ss_fw (Inspects H323 protocol)

The security policies for the Internet firewall and generic VPN firewall are as follows:

- Internet firewall—innet_fw (Inspects HTTP and ESMTP protocols)
- Generic VPN firewall—gen_vpn_fw (Inspects FTP, HTTP, ESMTP, and RTSP protocols)

In the example illustrated in [Figure 40](#), the Cisco IOS Firewall is configured on PE1 on the VRF interface E3/1. The host on NET1 wants to reach the server on NET2.

Figure 40 Sample VRF Aware Cisco IOS Firewall Network

The configuration steps are followed by a sample configuration and log messages.

1. Configure VRF on PE routers.
2. Ensure that your network supports MPLS traffic engineering.
3. Confirm that the VRF interface can reach NET1 and NET2.
4. Configure the VRF Aware Cisco IOS Firewall.
 - a. Configure and apply ACLs.
 - b. Create Firewall rules and apply them to the VRF interface.
5. Check for VRF firewall sessions.

VRF Configuration on PE1

```

! configure VRF for host1
ip cef
ip vrf vrf1
rd 100:1
route-target export 100:1

Glossary

CE router—customer edge router. A router that is part of a customer network and that interfaces to a provider edge (PE) router.

CBAC—Context-Based Access Control. A protocol that provides internal users with secure access control for each application and for all traffic across network perimeters. CBAC enhances security by scrutinizing both source and destination addresses and by tracking each application's connection status.

data authentication—Refers to one or both of the following: data integrity, which verifies that data has not been altered, or data origin authentication, which verifies that the data was actually sent by the claimed sender.

data confidentiality—A security service where the protected data cannot be observed.

edge router—A router that turns unlabeled packets into labeled packets, and vice versa.

firewall—A router or access server, or several routers or access servers, designated as a buffer between any connected public networks and a private network. A firewall router uses access lists and other methods to ensure the security of the private network.

inspection rule—A rule that specifies what IP traffic (which application-layer protocols) will be inspected by CBAC at an interface.

intrusion detection—The Cisco IOS Firewall's Intrusion Detection System (Cisco IOS IDS) identifies the most common attacks, using signatures to detect patterns of misuse in network traffic.

IPSec—IP Security Protocol. A framework of open standards developed by the Internet Engineering Task Force (IETF). IPSec provides security for transmission of sensitive data over unprotected networks such as the Internet.

managed security services—A comprehensive set of programs that enhance service providers' abilities to meet the growing demands of their enterprise customers. Services based on Cisco solutions include managed firewall, managed VPN (network based and premises based), and managed intrusion detection.

NAT—Network Address Translation. Translates a private IP address used inside the corporation to a public, routable address for use outside of the corporation, such as the Internet. NAT is considered a one-to-one mapping of addresses from private to public.

PE router—provider edge router. A router that is part of a service provider's network and is connected to a customer edge (CE) router.

skinny—Skinny Client Control Protocol (SCCP). A protocol that enables CBAC to inspect Skinny control packets that are exchanged between a Skinny client and the Call Manager (CM); CBAC then configures the router (also known as the Cisco IOS Firewall) to enable the Skinny data channels to traverse through the router.

traffic filtering—A capability that allows you to configure CBAC to permit specified TCP and UDP traffic through a firewall only when the connection is initiated from within the network you want to protect. CBAC can inspect traffic for sessions that originate from either side of the firewall.

traffic inspection—CBAC inspection of traffic that travels through the firewall to discover and manage state information for TCP and UDP sessions. This state information is used to create temporary openings in the firewall's access lists to allow return traffic and additional data connections for permissible sessions (sessions that originated from within the protected internal network).

UDP—User Datagram Protocol. Connectionless transport layer protocol in the TCP/IP protocol stack. UDP is a simple protocol that exchanges datagrams without acknowledgments or guaranteed delivery, requiring that error processing and retransmission be handled by other protocols.

VPN—Virtual Private Network. Enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic from one network to another. A VPN uses “tunneling” to encrypt all information at the IP level.

vrf—A VPN routing/forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a provider edge (PE) router.

VRF table—A table that stores routing data for each VPN. The VRF table defines the VPN membership of a customer site attached to the network access server (NAS). Each VRF table comprises an IP routing table, a derived Cisco Express Forwarding (CEF) table, and guidelines and routing protocol parameters that control the information that is included in the routing table.

Zone-Based Policy Firewall

First Published: February 22, 2006

Last Updated: July 11, 2008

This module describes the Cisco IOS unidirectional firewall policy between groups of interfaces known as zones. Previously, Cisco IOS firewalls were configured as an inspect rule only on interfaces. Traffic entering or leaving the configured interface was inspected based on the direction that the “inspect” rule was applied.

Finding Feature Information in This Module

Your Cisco IOS software release may not support all of the features documented in this module. For the latest feature information and caveats, see the release notes for your platform and software release. To reach links to specific feature documentation in this module and to see a list of the releases in which each feature is supported, use the [“Feature Information for Zone-Based Policy Firewall”](#) section on page 46.

Finding Support Information for Platforms and Cisco IOS and Catalyst OS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS and Catalyst OS software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Prerequisites for Zone-Based Policy Firewall

Before you create zones, think about what should constitute the zones. The general guideline is that you should group together interfaces that are similar when they are viewed from a security perspective.

Restrictions for Zone-Based Policy Firewall

If a configuration includes both security zones and inspect rules on interfaces (the old methodology), the configuration may work, but that type of configuration is not recommend.

Information About Zone-Based Policy Firewall

To configure a zone-based policy firewall, you should understand the following concepts:

- [Top-level Class Maps and Policy Maps, page 2](#)
- [Application-specific Class Maps and Policy Maps, page 3](#)
- [Zones, page 3](#)
- [Security Zones, page 3](#)
- [Zone-Pairs, page 4](#)
- [Zones and Inspection, page 6](#)
- [Zones and ACLs, page 6](#)
- [Zones and VRF Aware Firewall, page 6](#)
- [Zones and Transparent Firewall, page 7](#)
- [Overview of Security Zone Firewall Policies, page 7](#)
- [Class Maps and Policy Maps for Zone-Based Policy Firewalls, page 8](#)
- [Parameter Maps, page 11](#)

Top-level Class Maps and Policy Maps

Top-level class maps allow you to identify the traffic stream at a high level. This is accomplished by using **match access-group** and **match protocol** commands. These class maps cannot be used to classify traffic at the application level (the Layer 7 level). Top-level class maps are also referred to as Layer 3 and Layer 4 class-maps.

Top-level policy maps allow you to define high-level actions such as **inspect**, **drop**, **pass**, and **urlfilter**. You can attach the maps to a target (zone-pair). The maps can contain “child” policies that are also known as application-specific Layer 7 policies.

**Note**

Only inspect class maps can be used in inspect policy maps.

Application-specific Class Maps and Policy Maps

Application-specific class maps allow you to identify traffic based on the attributes of a given protocol. All the match conditions in these class maps are specific to an application (for example, HTTP or SMTP). Application-specific class maps are identified by an additional subtype that generally is the protocol name (HTTP or SMTP) in addition to the type **inspect**.

Application-specific policy maps are used to specify a policy for an application protocol. For example, if you want to drop HTTP traffic with URI lengths exceeding 256 bytes, you must configure an HTTP policy map to do that. Application-specific policy maps cannot be attached directly to a target (zone-pair). They must be configured as “child” policies in a top-level Layer 3 or Layer 4 policy map.

Zones

A zone is a group of interfaces that have similar functions or features. They provide a way for you to specify *where* a Cisco IOS firewall is applied.

For example, on a router, interfaces Ethernet 0/0 and Ethernet 0/1 may be connected to the local LAN. These two interfaces are similar because they represent the internal network, so they can be grouped into a zone for firewall configurations.

Traffic between interfaces in the same zone is not be subjected to any policy. The traffic passes freely.

Firewall zones are used for security features.

Security Zones

A security zone is a group of interfaces to which a policy can be applied.

Grouping interfaces into zones involves two procedures:

- Creating a zone so that interfaces can be attached to it
- Configuring an interface to be a member of a given zone

By default, traffic flows among interfaces that are members of the same zone.

When an interface is a member of a security zone, all traffic to and from that interface (except traffic going to the router or initiated by the router) is dropped. To permit traffic to and from a zone-member interface, you must make that zone part of a zone-pair and then apply a policy to that zone-pair. If the policy permits traffic (via **inspect** or **pass** actions), traffic can flow through the interface.

For traffic to flow among all the interfaces in a router, all the interfaces must be a member of one security zone or another.

It is not necessary for all router interfaces to be members of security zones.

Figure 1 illustrates the following:

- Interfaces E0 and E1 are members of security zone Z1.
- Interface E2 is a member of security zone Z2.
- Interface E3 is not a member of any security zone.

Figure 1 **Security Zone Restrictions**

The following situations exist:

- Traffic flows freely between interfaces E0 and E1 because they are members of the same security zone (Z1).
- If no policies are configured, traffic will not flow between any other interfaces (for example, E0 and E2, E1 and E2, E3 and E1, and E3 and E2).
- Traffic can flow between E0 or E1 and E2 only when an explicit policy permitting traffic is configured between zone Z1 and zone Z2.
- Traffic can never flow between E3 and E0/E1/E2 because E3 is not part of any security zone.

Virtual Interfaces As Members of Security Zones

A virtual template interface is a logical interface configured with generic configuration information for a specific purpose or for configuration common to specific users, plus router-dependent information. The template contains Cisco IOS interface commands that are applied to virtual access interfaces, as needed. To configure a virtual template interface, use the **interface virtual-template** command.

Virtual interfaces can be members of a security zone. The virtual template interface is a member of a zone and all virtual access interfaces created from the template are members of that zone.

Zone member information is acquired from a RADIUS server and then the dynamically created interface is made a member of that zone.

The **zone-member security** command puts the dynamic interface into the corresponding zone.

Zone-Pairs

A zone-pair allows you to specify a unidirectional firewall policy between two security zones.

To define a zone-pair, use the **zone-pair security** command. The direction of the traffic is specified by specifying a source and destination zone. The source and destination zones of a zone-pair must be security zones. The same zone cannot be defined as both the source and the destination.

If desired, you can select the default self zone as either the source or the destination zone. The self zone is a system-defined zone. It does not have any interfaces as members. A zone-pair that includes the self zone, along with the associated policy, applies to traffic directed to the router or traffic generated by the router. It does not apply to traffic through the router.

The most common usage of firewalls is to apply them to traffic through a router, so you usually need at least two zones (that is, you cannot use the self zone).

**Note**

Inspect policing is not allowed in policies that are attached to zone-pairs involving a self-zone.

To permit traffic between zone-member interfaces, you must configure a policy permitting (or inspecting) traffic between that zone and another zone. To attach a firewall policy map to the target zone-pair, use the **service-policy type inspect** command.

Figure 2 shows the application of a firewall policy to traffic flowing from zone z1 to zone z2, which means that the ingress interface for the traffic is a member of zone z1 and the egress interface is a member of zone z2.

Figure 2 **Zone Pairs**

If there are two zones and you require policies for traffic going in both directions (from z1 to z2 and z2 to z1), you must configure two zone-pairs (one for each direction).

If a policy is not configured between a pair of zones, traffic is dropped. However, it is not necessary to configure a zone-pair and a service policy solely for return traffic. Return traffic is allowed, by default, if a service policy permits the traffic in the forward direction. In the above example, it is not mandatory that you configure a zone-pair source Z2 destination Z1 solely for allowing return traffic from Z2 to Z1. The service policy on the Z1-Z2 zone-pair takes care of it.

Zones and Inspection

Zone-based policy firewalls examine the source and destination zones from the ingress and egress interfaces for a firewall policy. It is not necessary that all traffic flowing to or from an interface be inspected; you can designate that individual flows in a zone-pair be inspected through your policy map that you apply across the zone-pair. The policy map will contain class-maps that specify the individual flows.

For example, you can specify a policy map that performs HTTP URL filtering for hosts on 192.168.1.0/24 (engineers), but only does plain HTTP inspection for 192.168.2.0/24 (managers) for my inside_to_outside traffic.

This results in two flows (192.168.1.0/24 to any, 192.168.2.0/24 to any), and you can apply different inspect parameters to the flows to configure the desired different behaviors. Zone-based policy firewalls allow inside-to-internet traffic (source zone inside and destination zone outside).

You can also configure **inspect** parameters like TCP thresholds and timeouts on a per-flow basis.

Zones and ACLs

- Pinholes are not punched for return traffic in interface ACLs.
- ACLs applied to interfaces that are members of zones are processed before the policy is applied on the zone-pair. So, you must relax interface ACLs when there are policies between zones so that they cannot interfere with the policy firewall traffic.

Zones and VRF Aware Firewall

Cisco IOS firewall is VRF aware. It handles IP address overlap across different VRFs, separate thresholds and timeouts for VRFs, and so forth. All interfaces in a zone must belong to the same VRF.

However, you should not group interfaces from different VRFs in the same zone because VRFs belong to different entities that typically have their own policies.

You can configure a zone-pair between two zones that contain different VRFs, as shown in [Figure 3](#).

When multiple VRFs are configured on a router and an interface provides common services to all the VRFs (for example, internet service), you should place that interface in a separate zone. You can then define policies between the common zone and other zones. (There can be one or more zones per VRF.)

Figure 3 **Zones and VRF**

In [Figure 3](#), the interface providing common services is a member of the zone “common.” All of VRF A is in a single zone, vrf_A. VRF B, which has multiple interfaces, is partitioned into multiple zones vrf_B_1 and vrf_B_2. Zone Z1 does not have VRF interfaces. You can specify policies between each of these zones and the common zone. Additionally, you can specify policies between each of the zones vrf_A, vrf_B_n and Z1 if VRF route export is configured and the traffic patterns make sense. You can configure a policy between zones vrf_A and vrf_B_1, but be sure that traffic can flow between them.

There is no need to specify the global thresholds and timers on a per-VRF basis. Instead, parameters are supplied to the **inspect** action through a parameter map.

146618

Zones and Transparent Firewall

The Cisco IOS firewall supports transparent firewalls where the interfaces are placed in bridging mode and IP firewalling is performed on the bridged traffic.

To configure a transparent firewall, use the **bridge** command to enable the bridging of a specified protocol in a specified bridge and the **zone-member security** command to attach an interface to a zone. The **bridge** command on the interface indicates that the interface is in bridging mode.

A bridged interface can be a member of a zone. In a typical case, the Layer 2 domain is partitioned into zones and a policy is applied the same way as for Layer 3 interfaces.

Transparent Firewall Restriction for P2P Inspection

A Cisco IOS Firewall uses Network Based Application Recognition (NBAR) for peer-to-peer (P2P) protocol classification and policy enforcement. NBAR is not available for bridged packets; thus, all P2P packet inspection is not supported for firewalls with transparent bridging.

Overview of Security Zone Firewall Policies

A class is a way of identifying a set of packets based on its contents. Normally you define a class so that you can apply an action on the identified traffic that reflects a policy. A class is designated via class maps.

An action is a specific functionality. It typically is associated with a traffic class. For example, **inspect**, **drop**, **pass**, and **police** are actions.

To create firewall policies, you should complete the following tasks:

- Define a match criteria (**class map**)
- Associate actions to the match criteria (**policy map**)
- Attach the policy map to a zone pair (**service policy**)

The **class-map** command creates a class map to be used for matching packets to a specified class. Packets arriving at the targets (such as the input interface, output interface, or zone-pair), determined by how the **service-policy** command is configured, are checked against the match criteria configured for a class map to determine if the packet belongs to that class.

The **policy-map** command creates or modifies a policy map that can be attached to one or more targets to specify a service policy. Use the **policy-map** command to specify the name of the policy map to be created, added to, or modified before you can configure policies for classes whose match criteria are defined in a class map.

Class Maps and Policy Maps for Zone-Based Policy Firewalls

Quality of Service (QoS) class maps have numerous match criteria; firewalls have fewer match criteria. Firewall class maps have type **inspect**; this information controls what shows up under firewall class maps.

A policy is an association of traffic classes and actions. It specifies what actions should be performed on the defined traffic classes. An action is a specific function, and it is typically associated with a traffic class. For example, **inspect**, **police**, and **drop** are actions.

Layer 3 and Layer 4 Class Maps and Policy Maps

Layer 3 and Layer 4 class maps are used to identify traffic streams on which different actions should be performed.

A Layer 3 or Layer 4 policy map is sufficient for the basic inspection of traffic.

The following example shows how to configure class map c1 with match criterias of ACL 101 and the HTTP protocol, and create an inspect policy map named p1 to specify that packets will be dropped on the traffic at c1:

```
Router(config)# class-map type inspect match-all c1
Router(config-cmap)# match access-group 101
Router(config-cmap)# match protocol http

Router(config)# policy-map type inspect p1
Router(config-pmap)# class type inspect c1
Router(config-pmap-c)# drop
```

To create a Layer 3 or Layer 4 policy, see the section “[Configuring Layer 7 Firewall Policies](#).”

Class-Map Configuration Restriction

If traffic meets multiple match criteria, the match criteria must be applied in the order of specific to less specific. For example, consider the following class map example:

```
class-map type inspect match-any my-test-cmap
  match protocol http
  match protocol tcp
```

In this example, HTTP traffic must first encounter the **match protocol http** command to ensure that the traffic will be handled by the service-specific capabilities of HTTP inspection. If the “match” lines were reversed so traffic encountered the **match protocol tcp** command before it was compared to the **match**

protocol http command, the traffic would simply be classified as TCP traffic and inspected according to the capabilities of the Firewall's TCP Inspection component. This configuration would be a problem for services such as FTP, TFTP, and for several multimedia and voice signaling services such as H.323, SIP, Skinny, and RTSP. These services require additional inspection capabilities to recognize their more complex activities.

Rate Limiting (Policing) Traffic Within a Layer 3 and Layer 4 Policy Map

Starting with Cisco IOS Release 12.4(9)T, you can issue the **police** command within an inspect policy to limit the number of concurrent connections allowed for applications such as Instant Messenger and P2P.

To effectively use the **police** command, you must also enable Cisco IOS stateful packet inspection within the inspect policy map. If you configure the **police** command without configuring the inspect action (via the **inspect** command), you will receive an error message and the **police** command will be rejected.

Compatibility with Existing Police Actions

Police actions provisioned in a Modular Quality of Service (QoS) Command-Line Interface (CLI) (MQC) policy map are applied as input and output policies on an interface. An inspect policy map can only be applied to a zone-pair, not an interface. The police action will be enforced on traffic that traverses the zone-pair. (The direction is inherent to the specification of the zone-pair.) Thus, a QoS policy containing a police action can be present on interfaces that make up a zone-pair and a police action can also be present in an inspect policy map applied across the zone-pair. If both police actions are configured, the zone-pair policer is executed after the input, interface policer, but before the output, interface policer. There is no interaction between the QoS and the inspect policers.

Police Restrictions

- The police action is not allowed in policies that are attached to zone pairs involving a “self” zone. If you want to perform this task, you should use control plane policing.
- Policing can only be specified in Layer 3 and Layer 4 policy maps; it cannot be specified in Layer 7 policy maps.

Layer 7 Class Maps and Policy Maps

Layer 7 class maps can be used in inspect policy maps only for deep packet inspection (DPI).

To create a Layer 7 class map, use the **class-map type inspect** command for the desired protocol. For example, for the HTTP protocol you would enter the **class-map type inspect http** command.

The type of class map (for example, HTTP) determines the match criteria that you can use. For example, if you want to specify HTTP traffic that contains Java applets, you must specify a “match response body java” statement in the context of an “inspect HTTP” class map.

A Layer 7 policy map provides application-level inspection of traffic. The policy map can include class maps only of the same type.

The DPI functionality is delivered through Layer 7 class maps and policy maps.

To create a Layer 7 policy map, specify the protocol in the applicable **policy-map type inspect** command. For example, to create a Layer 7 HTTP policy map, use the **policy-map type inspect http** command. In that command there is an argument where you enter the HTTP policy-map name.

If you do not specify a protocol name (for example, you use the **policy-map type inspect** command), you will be creating a Layer 3 or Layer 4 policy map, which can only be an inspect type policy map.

A Layer 7 policy map must be contained in a Layer 3 or Layer 4 policy map; it cannot be attached directly to a target. To attach a Layer 7 policy map to a top-level policy map, use the **service-policy (policy-map)** command and specify the application name (that is, HTTP, IMAP, POP3, SMTP, or SUNRPC). The parent class for a Layer 7 policy should have an explicit match criterion that matched only one Layer 7 protocol before the policy is attached.

If the Layer 7 policy map is in a lower level, you must specify the **inspect** action at the parent level for a Layer 7 policy map.

Layer 7 Supported Protocols

You can create Layer 7 class maps and policy maps for the following protocols:

- America Online (AOL) Instant Messenger (IM) protocol
- eDonkey P2P protocol
- FastTrack traffic P2P protocol
- Gnutella Version 2 traffic P2P protocol
- H.323 VoIP Protocol Version 4
- HTTP—The protocol used by web browsers and web servers to transfer files, such as text and graphic files.
- Internet Message Access Protocol (IMAP)—Method of accessing e-mail or bulletin board messages kept on a mail server that can be shared.
- I Seek You (ICQ) IM Protocol
- Kazaa Version 2 P2P protocol
- MSN Messenger IM protocol
- Post Office Protocol, Version 3 (POP3)—Protocol that client e-mail applications use to retrieve mail from a mail server.
- SIP—Session Initiation Protocol (SIP)
- SMTP—Simple Network Management Protocol
- SUNRPC—Sun RPC (Remote Procedure Call)
- Windows Messenger IM Protocol
- Yahoo IM protocol

For information on configuring a Layer 7 class map and policy map (policies), see the section [“Configuring Layer 7 Firewall Policies.”](#)

Class-Default Class Map

In addition to user-defined classes, there is a system-defined class map named class-default that represents all packets that do not match any of the user-defined classes in a policy. It always is the last class in a policy map.

You can define explicit actions for this group of packets. If you do not configure any actions for class-default in an inspect policy, the default action is **drop**.

The following example shows how to use class-default in a policy map. In this example, HTTP traffic is dropped and the remaining traffic is inspected. Class map c1 is defined for HTTP traffic, and class-default is used for a policy map p1.

```
Router(config)# class-map type inspect match-all c1
```

```
Router(config-cmap)# match protocol http

Router(config)# policy-map type inspect p1
Router(config-pmap)# class type inspect c1
Router(config-pmap-c)# drop
Router(config-pmap)# class class-default
Router(config-pmap-c)# inspect
```

Hierarchical Policy Maps

A policy can be nested within a policy. A policy that contains a nested policy is called a hierarchical policy.

To create a hierarchical policy, attach a policy directly to a class of traffic. A hierarchical policy contains a child and a parent policy. The child policy is the previously-defined policy that is associated with the new policy through the use of the **service-policy** command. The new policy using the pre-existing policy is the parent policy.

Note

There can be a maximum of two levels in a hierarchical inspect service-policy.

Parameter Maps

A parameter map allows you to specify parameters that control the behavior of actions and match criteria specified under a policy map and a class map, respectively.

There are currently three types of parameter maps:

- Inspect parameter map

An inspect parameter map is optional. If you do not configure a parameter map, the software uses default parameters. Parameters associated with the inspect action apply to all nested actions (if any). If parameters are specified in both the top and lower levels, those in the lower levels override those in the top levels.

- URL Filter parameter map

A parameter map is required for URL filtering (via the urlfilter action in a Layer 3 or Layer 4 policy map and the urlfilter parameter map).

- Protocol-specific parameter map

A parameter map is required for an Instant Messenger application (Layer 7) policy map.

How to Configure Zone-Based Policy Firewall

This section contains the following configuration tasks:

- [Configuring Layer 3 and Layer 4 Firewall Policies, page 12](#) (required)
- [Configuring a Parameter Map, page 15](#) (required)
- [Configuring Layer 7 Firewall Policies, page 21](#) (optional)
- [Creating Security Zones, Zone-Pairs, and Attaching a Policy Map to a Zone-Pair, page 38](#) (required)

Configuring Layer 3 and Layer 4 Firewall Policies

Layer 3 and Layer 4 policies are “top level” policies that are attached to the target (zone-pair). Use the following tasks to configure Layer 3 and Layer 4 firewall policies:

- [Configuring a Class Map for a Layer 3 and Layer 4 Firewall Policy](#), page 12
- [Creating a Policy Map for a Layer 3 and Layer 4 Firewall Policy](#), page 13

Configuring a Class Map for a Layer 3 and Layer 4 Firewall Policy

Use this task to configure a class map for classifying network traffic.

Note

You must perform at least one step from Step 4, 5, or 6.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **class-map type inspect** [**match any** | **match all**] *class-map-name*
4. **match access-group** {*access-group* | **name** *access-group-name*}
5. **match protocol** *protocol_name* [**signature**]
6. **match class-map** *class-map-name*
7. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	class-map type inspect [match-any match-all] <i>class-map-name</i> Example: Router(config)# class-map type inspect match-all c1	Creates a Layer 3 or Layer 4 inspect type class map. Enters class-map configuration mode.
Step 4	match access-group { <i>access-group</i> name <i>access-group-name</i> } Example: Router(config-cmap)# match access-group 101	Configures the match criteria for a class map based on the ACL name or number.

	Command or Action	Purpose
Step 5	match protocol <i>protocol-name</i> [signature] Example: Router(config-cmap)# match protocol http	Configures the match criteria for a class map on the basis of a specified protocol. Only Cisco IOS stateful packet inspection supported protocols can be used as match criteria in inspect type class maps. <ul style="list-style-type: none"> signature—Signature-based classification for peer-to-peer (P2P) packets is enabled.
Step 6	match class-map <i>class-map-name</i> Example: Router(config-cmap)# match class-map c1	Specifies a previously defined class as the match criteria for a class map.
Step 7	exit Example: Router(config-cmap)# exit	Returns to global configuration mode.

Creating a Policy Map for a Layer 3 and Layer 4 Firewall Policy

Use this task to create a policy map for a Layer 3 and Layer 4 firewall policy that will be attached to zone-pairs.

Note

If you are creating an inspect type policy map, note that only the following actions are allowed: drop, inspect, police, pass, service-policy, and urlfilter.

Note

You must perform at least one step from Step 5, 8, 9, or 10.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **policy-map type inspect** *policy-map-name*
4. **class type inspect** *class-name*
5. **inspect** [*parameter-map-name*]
6. **police rate** *bps* **burst** *size*
7. **drop** [log]
8. **pass**
9. **service-policy type inspect** *policy-map-name*
10. **urlfilter** *parameter-map-name*
11. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	policy-map type inspect <i>policy-map-name</i> Example: Router(config)# policy-map type inspect p1	Creates a Layer 3 and Layer 4 inspect type policy map. Enters policy-map configuration mode.
Step 4	class type inspect <i>class-name</i> Example: Router(config-pmap)# class type inspect c1	Specifies the traffic (class) on which an action is to be performed.
Step 5	inspect [<i>parameter-map-name</i>] Example: Router(config-pmap-c)# inspect inspect-params	Enables Cisco IOS stateful packet inspection.
Step 6	police rate <i>bps</i> <i>burst</i> <i>size</i> Example: Router(config-pmap-c)# police rate 2000 burst 3000	(Optional) Limits traffic matching within a firewall (inspect) policy.
Step 7	drop [log] Example: Router(config-pmap-c)# drop	(Optional) Drops packets that are matched with the defined class. Note The actions drop and pass are exclusive, and the actions inspect and drop are exclusive; that is, you cannot specify both of them.
Step 8	pass Example: Router(config-pmap-c)# pass	(Optional) Allows packets that are matched with the defined class.
Step 9	service-policy type inspect <i>policy-map-name</i> Example: Router(config-pmap-c)# service-policy type inspect p1	Attaches a firewall policy map to a zone-pair.

	Command or Action	Purpose
Step 10	urlfilter <i>parameter-map-name</i> Example: Router(config-pmap-c)# urlfilter param1	(Optional) Enables Cisco IOS firewall URL filtering.
Step 11	exit Example: Router(config-pmap-c)# exit	Returns to policy-map configuration mode.

Configuring a Parameter Map

Depending on your policy, you can configure either an inspect, URL filter, or protocol-specific type parameter map. If you are configuring a URL filter type or protocol-specific type policy, you must configure a parameter map, as appropriate. However, a parameter map is optional if you are using an inspect type policy.

Use one of the following tasks to configure a parameter map:

- [Creating an Inspect Parameter Map, page 15](#)
- [Creating a URLFILTER Parameter Map, page 17](#)
- [Configuring a Protocol-Specific Parameter Map, page 19](#)

Creating an Inspect Parameter Map

Use this task to create an inspect type parameter map.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **parameter-map type inspect** *parameter-map-name*
4. **alert** {on | off}
5. **audit-trail** {on | off}
6. **dns-timeout** *seconds*
7. **icmp idle-timeout** *seconds*
8. **max-incomplete** {**low** *number-of-connections* | **high** *number-of-connections*}
9. **one-minute** {**low** *number-of-connections* | **high** *number-of-connections*}
10. **sessions maximum** *sessions*
11. **tcp finwait-time** *seconds*
12. **tcp idle-time** *seconds*
13. **tcp max-incomplete host** *threshold* [**block-time** *minutes*]
14. **tcp synwait-time** *seconds*
15. **udp idle-time** *seconds*

16. exit

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	parameter-map type inspect <i>parameter-map-name</i> Example: Router(config)# parameter-map type inspect eng-network-profile	Configures an inspect parameter map for connecting thresholds, timeouts, and other parameters pertaining to the inspect action. Enters parameter-map type inspect configuration mode.
Step 4	alert {on off} Example: Router(config-profile)# alert on	(Optional) Turns on and off Cisco IOS stateful packet inspection alert messages that are displayed on the console.
Step 5	audit-trail {on off} Example: Router(config-profile)# audit-trail on	(Optional) Turns audit trail messages on or off.
Step 6	dns-timeout <i>seconds</i> Example: Router(config-profile)# dns-timeout 60	(Optional) Specifies the domain name system (DNS) idle timeout (the length of time for which a DNS lookup session will continue to be managed while there is no activity).
Step 7	icmp idle-timeout <i>seconds</i> Example: Router(config-profile)# icmp idle-timeout 90	(Optional) Configures the timeout for Internet Control Message Protocol (ICMP) sessions.
Step 8	max-incomplete {low number-of-connections high number-of-connections} Example: Router(config-profile)# max-incomplete low 800 Router(config-profile)# max-incomplete high 10000	(Optional) Defines the number of existing half-open sessions that will cause the Cisco IOS firewall to start and stop deleting half-open sessions.
Step 9	one-minute {low number-of-connections high number-of-connections} Example: Router(config-profile)# one-minute low 300 Router(config-profile)# one-minute high 400	(Optional) Defines the number of new unestablished sessions that will cause the system to start deleting half-open sessions and stop deleting half-open sessions.

	Command or Action	Purpose
Step 10	sessions maximum <i>sessions</i> Example: Router(config-profile)# sessions maximum 200	(Optional) Sets the maximum number of allowed sessions that can exist on a zone-pair. You may want to use this command to limit the bandwidth used by the sessions. <ul style="list-style-type: none"> <i>sessions</i>—Maximum number of allowed sessions. Range: 1 to 2147483647.
Step 11	tcp finwait-time <i>seconds</i> Example: Router(config-profile)# tcp finwait-time 5	(Optional) Specifies how long a TCP session will be managed after the Cisco IOS firewall detects a FIN-exchange.
Step 12	tcp idle-time <i>seconds</i> Example: Router(config-profile)# tcp idle-time 90	(Optional) Configures the timeout for TCP sessions.
Step 13	tcp max-incomplete host <i>threshold</i> [<i>block-time minutes</i>] Example: Router(config-profile)# tcp max-incomplete host 500 block-time 10	(Optional) Specifies threshold and blocking time values for TCP host-specific DoS detection and prevention.
Step 14	tcp synwait-time <i>seconds</i> Example: Router(config-profile)# tcp synwait-time 3	(Optional) Specifies how long the software will wait for a TCP session to reach the established state before dropping the session.
Step 15	udp idle-time <i>seconds</i> Example: Router(config-profile)# udp idle-time 75	(Optional) Configures the idle timeout of User Datagram Protocol (UDP) sessions going through the firewall.
Step 16	exit Example: Router(config-profile)# exit	Returns to global configuration mode.

Creating a URLFILTER Parameter Map

To create a URLFILTER parameter map, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **parameter-map type urlfilter *parameter-map-name***
4. **alert {on | off}**
5. **allow-mode {on | off}**
6. **audit-trail {on | off}**

7. **cache** *number*
8. **exclusive-domain** {**deny** | **permit**} *domain-name*
9. **max-request** *number-of-requests*
10. **max-resp-pak** *number-of-requests*
11. **server vendor** {**n2h2** | **websense**} {*ip-address* | *hostname* [**port** *port-number*]} [**outside**] [**log**] [**retrans** *retransmission-count*] [**timeout** *seconds*]
12. **source-interface** *interface-name*
13. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	parameter-map type urlfilter <i>parameter-map-name</i> Example: Router(config)# parameter-map type urlfilter eng-network-profile	Creates or modifies a parameter map for URL filtering parameters. Enters URL parameter-map configuration mode.
Step 4	alert { on off } Example: Router(config-profile)# alert on	(Optional) Turns on and off Cisco IOS stateful packet inspection alert messages that are displayed on the console.
Step 5	allow-mode { on off } Example: Router(config-profile)# allow-mode on	(Optional) Turns on or off the default mode of the filtering algorithm.
Step 6	audit-trail { on off } Example: Router(config-profile)# audit-trail on	(Optional) Turns audit trail messages on or off.
Step 7	cache <i>number</i> Example: Router(config-profile)# cache 5	(Optional) Controls how the URL filter handles the cache it maintains of HTTP servers.

	Command or Action	Purpose
Step 8	exclusive-domain {deny permit} domain-name Example: Router(config-profile)# exclusive-domain permit cisco.com	(Optional) Adds or removes a domain name to or from the exclusive domain list so that the Cisco IOS firewall does not have to send look up requests to the vendor server.
Step 9	max-request number-of-requests Example: Router(config-profile)# max-request 80	(Optional) Specifies the maximum number of outstanding requests that can exist at a time.
Step 10	max-resp-pak number-of-requests Example: Router(config-profile)# max-resp-pak 200	(Optional) Specifies the maximum number of HTTP responses that the Cisco IOS firewall can keep in its packet buffer.
Step 11	server vendor {n2h2 websense} {ip-address hostname [port port-number]} [outside] [log] [retrans retransmission-count] [timeout seconds] Example: Router(config-profile)# server vendor n2h2 10.193.64.22 port 3128 outside retrans 9 timeout 8	Specifies the URL filtering server. Note This command is mandatory if you want anything from the urlfilter configuration.
Step 12	source-interface interface-name Example: Router(config-profile)# source-interface ethernet0	(Optional) Specifies the interface whose IP address will be used as the source IP address while making a TCP connection to the URL filter server (Websense or N2H2).
Step 13	exit Example: Router(config-profile)# exit	Returns to global configuration mode.

Configuring a Protocol-Specific Parameter Map

Use this task to configure a Layer 7, protocol-specific parameter map.

Note

Protocol-specific parameter maps can be created only for Instant Messenger applications (AOL, ICQ, MSN Messenger, Yahoo Messenger, and Windows Messenger).

Prerequisites

To enable name resolution to occur, you must also enable the **ip domain name** command and the **ip name-server** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **parameter-map type protocol-info** *parameter-map-name*
4. **server** {name *string* [snoop] | ip {*ip-address* | range *ip-address-start ip-address-end*}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	parameter-map type protocol-info <i>parameter-map-name</i> Example: Router(config)# parameter-map type protocol-info ymsg	Defines an application-specific parameter map. Enters parameter-map type configuration mode. Note Protocol-specific parameter maps can be created only for Instant Messenger applications (AOL, ICQ, MSN Messenger, Yahoo Messenger, and Windows Messenger).
Step 4	server {name <i>string</i> [snoop] ip { <i>ip-address</i> range <i>ip-address-start ip-address-end</i> } Example: Router(config-profile)# server name sdsc.msg.yahoo.com Router(config-profile)# server ip 10.1.1.1	Configures a set of Domain Name System (DNS) servers for which a given instant messenger application will be interacting. Note If at least one server instance is not configured, the parameter map will not have any definitions to enforce; that is, the configured instant messenger policy cannot be enforced. Note To configure more than one set of servers, you can issue the server command multiple times within an instant messenger's parameter map. Multiple entries are treated cumulatively.

Troubleshooting Tips

To display details of an IM protocol-specific parameter map, use the **show parameter-map type protocol-info** command.

Configuring Layer 7 Firewall Policies

Configure Layer 7 policy maps if you are interested in extra provisioning for Layer 7 inspection modules. It is not necessary that you configure all of the Layer 7 policy maps.

Use one of the following tasks to configure a Layer 7, protocol-specific firewall policy:

- [Configuring an HTTP Firewall Policy, page 21](#)
- [Configuring an IMAP Firewall Policy, page 26](#)
- [Configuring an Instant Messenger \(IM\) Policy, page 28](#)
- [Configuring a Peer-to-Peer \(P2P\) Policy, page 30](#)
- [Configuring a POP3 Firewall Policy, page 33](#)
- [Configuring an SMTP Firewall Policy, page 34](#)
- [Configuring a SUNRPC Firewall Policy, page 36](#)

Layer 7 Class Map and Policy Map Restrictions

- Deep packet inspection (DPI) class maps for Layer 7 can only be used in inspect policy maps of the respective type. For example, **class-map type inspect http** can only be used in **policy-map type inspect http**.
- DPI policies require an **inspect** action at the parent level.
- A Layer 7 (DPI) policy map must be nested at the second level in a Layer 3 or Layer 4 inspect policy map, whereas a Layer 3 or Layer 4 inspect policy can be attached at the first level. Therefore, a Layer 7 policy map cannot be attached directly to a zone-pair.
- If no action is specified in the hierarchical path of an inspect service-policy, the packet is dropped. Traffic matching class-default in the top-level policy is dropped if there are no explicit actions configured in class-default. If the traffic does not match any class in a Layer 7 policy, the traffic is not dropped; control returns to the parent policy and subsequent actions (if any) in the parent policy are executed on the packet.
- Layer 7 policy maps include class maps only of the same type.
- You can specify the **reset** action only for TCP traffic; it resets the TCP connection.

Configuring an HTTP Firewall Policy

Use these tasks to configure an HTTP firewall policy—a class map and a policy map, respectively.

If you want to configure match criteria on the basis of an element within a parameter map, you must configure a parameter map as shown in the task “[Creating an Inspect Parameter Map](#).”

You must specify at least one match criterion; otherwise, the firewall policy will not be effective.

Configuring an HTTP Class Map

Use this task to configure an HTTP firewall class map.

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **class-map type inspect http** [match-any | match-all] *class-map-name*
4. **match response body java-applet**
5. **match req-resp protocol violation**
6. **match req-resp body length** {lt *bytes* | gt *bytes*}
7. **match req-resp header content-type** {violation | mismatch | unknown}
8. **match {request | response | req-resp} header** [*header-name*] **count gt** *number*
9. **match {request | response | req-resp} header** [*header-name*] **length gt** *bytes*
10. **match request {uri | arg} length gt** *bytes*
11. **match request method** {connect | copy | delete | edit | get | getattribute | getattributenames | getproperties | head | index | lock | mkdir | move | options | post | put | revadd | revlabel | revlog | revnum | save | setattribute | startrev | stoprev | trace | unedit | unlock}
12. **match request port-misuse** {im | p2p | tunneling | any}
13. **match req-resp header transfer-encoding** {chunked | compress | deflate | gzip | identity | all}
14. **match {request | response | req-resp} header** [*header-name*] **regex** *parameter-map-name*
15. **match request {uri | arg} regex** *parameter-map-name*
16. **match {request | response | req-resp} body regex** *parameter-map-name*
17. **match response status-line regex** *parameter-map-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	class-map type inspect http [match-any match-all] <i>class-map-name</i> Example: Router(config)# class-map type inspect http http-class	Creates a class map for the HTTP protocol so that you can enter match criteria. Enters class-map configuration mode.
Step 4	match response body java-applet Example: Router(config-cmap)# match response body java-applet	(Optional) Identifies Java applets in an HTTP connection.

	Command or Action	Purpose
Step 5	match req-resp protocol violation Example: Router(config-cmap)# match req-resp protocol violation	(Optional) Configures an HTTP class map to allow HTTP messages to pass through the firewall or to reset the TCP connection when HTTP noncompliant traffic is detected.
Step 6	match req-resp body length {lt bytes gt bytes} Example: Router(config-cmap)# match req-resp body length gt 35000	(Optional) Configures an HTTP class map to use the minimum or maximum message size, in bytes, as a match criterion for permitting or denying HTTP traffic through the firewall. The number of bytes can be from 0 to 65535.
Step 7	match req-resp header content-type {violation mismatch unknown} Example: Router(config-cmap)# match req-resp header content-type mismatch	(Optional) Configures an HTTP class map based on the content type of HTTP traffic.
Step 8	match {request response req-resp} header [header-name] count gt number Example: Router(config-cmap)# match req-resp header count gt 16	(Optional) Configure an HTTP firewall policy to permit or deny HTTP traffic on the basis of request, response, or both request and response messages whose header count does not exceed a maximum number of fields.
Step 9	match {request response req-resp} header [header-name] length gt bytes Example: Router(config-cmap)# match response header length gt 50000	(Optional) Permits or denies HTTP traffic based on the length of the HTTP request header. <ul style="list-style-type: none"> <i>header-name</i>—Specific line in the header field. If a specific line is defined, only that specific field length will be used as match criteria. gt bytes—Maximum number of bytes that can be in the header of the HTTP request. Number of bytes range: 0 to 65535.
Step 10	match request {uri arg} length gt bytes Example: Router(config-cmap)# match request uri length gt 500	(Optional) Configures an HTTP firewall policy to use the uniform resource identifier (URI) or argument length in the request message as a match criterion for permitting or denying HTTP traffic.
Step 11	match request method {connect copy delete edit get getattribute getattributenames getproperties head index lock mkdir move options post put revadd revlabel revlog revnum save setattribute startrev stoprev trace unedit unlock} Example: Router(config-cmap)# match request method connect	(Optional) Configures an HTTP firewall policy to use the request methods or the extension methods as a match criterion for permitting or denying HTTP traffic.

	Command or Action	Purpose
Step 12	<pre>match request port-misuse {im p2p tunneling any}</pre> <p>Example: Router(config-cmap)# match request port-misuse any</p>	(Optional) Identifies applications misusing the HTTP port.
Step 13	<pre>match req-resp header transfer-encoding {chunked compress deflate gzip identity all}</pre> <p>Example: Router(config-cmap)# match req-resp header transfer-encoding compress</p>	(Optional) Permits or denies HTTP traffic according to the specified transfer encoding of the message. <ul style="list-style-type: none"> • chunked—Encoding format (specified in RFC 2616, Hypertext Transfer Protocol—HTTP/1) in which the body of the message is transferred in a series of chunks; each chunk contains its own size indicator. • compress—Encoding format produced by the UNIX compress utility. • deflate—ZLIB format defined in RFC 1950, ZLIB Compressed Data Format Specification Version 3.3, combined with the deflate compression mechanism described in RFC 1951, DEFLATE Compressed Data Format Specification Version 1.3. • gzip—Encoding format produced by the gzip (GNU zip) program. • identity—Default encoding, which indicates that no encoding has been performed. • all—All of the transfer encoding types.
Step 14	<pre>match {request response req-resp} header [header-name] regex parameter-map-name</pre> <p>Example: Router(config-cmap)# match req-resp header regex non_ascii_regex</p>	(Optional) Configures HTTP firewall policy match criteria on the basis of headers that match the regular expression defined in a parameter map.
Step 15	<pre>match request {uri arg} regex parameter-map-name</pre> <p>Example: Router(config-cmap)# match request uri regex uri_regex_cm</p>	(Optional) Configure an HTTP firewall policy to permit or deny HTTP traffic on the basis of request messages whose URI or arguments (parameters) match a defined regular expression.

	Command or Action	Purpose
Step 16	match {request response req-resp} body regex <i>parameter-map-name</i> Example: Router(config-cmap)# match response body regex body_regex	(Optional) Configures a list of regular expressions that are to be matched against the body of the request, response or both the request and response message.
Step 17	match response status-line regex <i>parameter-map-name</i> Example: Router(config-cmap)# match response status-line regex status_line_regex	(Optional) Specifies a list of regular expressions that are to be matched against the status-line of a response message.

Configuring an HTTP Policy Map

Use this task to configure an HTTP firewall policy map.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **policy-map type inspect http** *policy-map-name*
4. **class-type inspect http** *http-class-name*
5. **allow**
6. **log**
7. **reset**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	policy-map type inspect http <i>policy-map-name</i> Example: Router(config)# policy-map type inspect http myhttp-policy	Creates a Layer 7 HTTP policy map. Enters policy-map configuration mode.
Step 4	class-type inspect http <i>http-class-name</i> Example: Router(config-pmap)# class-type inspect http http-class	Creates a class map for the HTTP protocol.
Step 5	allow Example: Router(config-pmap)# allow	(Optional) Allows traffic class matching the class.
Step 6	log Example: Router(config-pmap)# log	Generates a log (messages).
Step 7	reset Example: Router(config-pmap)# reset	(Optional) Resets a TCP connection if the data length of the SMTP body exceeds the value that you configured in the class-map type inspect smtp command.

Configuring an IMAP Firewall Policy

Use these tasks to configure an IMAP firewall policy—a class map and a policy map, respectively.

Configuring an IMAP Class Map

Use this task to configure an IMAP class map.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **class-map type inspect imap** [*match-any*] *class-map-name*

4. **log**
5. **match invalid-command**
6. **match login clear-text**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	class-map type inspect imap [match-any] class-map-name Example: Router(config)# class-map type inspect imap imap-class	Creates a class map for the IMAP protocol so that you can enter match criteria. Enters class-map configuration mode.
Step 4	log Example: Router(config-cmap)# log	Generates a log of messages.
Step 5	match invalid-command Example: Router(config-cmap)# match invalid-command	(Optional) Locates invalid commands on an IMAP connection.
Step 6	match login clear-text Example: Router(config-cmap)# match login clear-text	(Optional) Finds a nonsecure login when using an IMAP server.

Configuring an IMAP Policy Map

Use this task to configure an IMAP firewall policy map.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **policy-map type inspect imap policy-map-name**
4. **class-type inspect imap imap-class-name**
5. **log**
6. **reset**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	policy-map type inspect imap <i>policy-map-name</i> Example: Router(config)# policy-map type inspect imap myimap-policy	Creates a Layer 3 IMAP policy map. Enters policy-map configuration mode.
Step 4	class-type inspect imap <i>imap-class-name</i> Example: Router(config-pmap)# class-type inspect imap pimap	Creates a class map for the IMAP protocol.
Step 5	log Example: Router(config-pmap)# log	Generates a log (messages).
Step 6	reset Example: Router(config-pmap)# reset	(Optional) Resets a TCP connection if the data length of the SMTP body exceeds the value that you configured in the class-map type inspect smtp command.

Configuring an Instant Messenger (IM) Policy

Use this task to configure an IM policy—a class map and a policy map.

You can create an IM policy for the following IM applications: America Online (AOL), ICQ, MSN Messenger, Yahoo Messenger, and Windows Messenger.

Configuring an IM Class Map

Use this task to configure a class map for any supported IM application.

SUMMARY STEPS

- enable**
- configure terminal**
- class map type inspect { aol | msnmsgr | ymsgr | icq | winmsgr } [match-any] class-map-name**
- match service { any | text-chat }**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	class map type inspect {aol msnmsgr ymsgr icq winmsgr} [match-any] class-map-name Example: Router(config)# class map type inspect aol myaolclassmap	Creates a IM type class map so you can begin adding match criteria. This command puts the router in class-map configuration mode.
Step 4	match service {any text-chat} Example: Router(config-cmap)# match service text-chat	(Optional) Creates a match criterion on the basis of text chat messages (text-chat) or for any available service within a given IM protocol (any).

Configuring an IM Policy Map

Use this task to configure a policy map for any supported IM application.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **policy map type inspect** *protocol-name policy-map-name*
4. **class type inspect {aol | msnmsgr | ymsgr | icq | winmsgr}** *class-map-name*
5. **reset**
6. **log**
7. **allow**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	policy map type inspect <i>protocol-name</i> <i>policy-map-name</i> Example: Router(config)# policy map type inspect aol myaolpolicymap	Creates an IM policy map. This command puts the router in policy-map configuration mode.
Step 4	class type inspect { <i>aol</i> <i>msnmsgr</i> <i>ymsgr</i> <i>icq</i> <i>winmsgr</i> } <i>class-map-name</i> Example: Router(config-pmap)# class type inspect aol myaolclassmap	Specifies a traffic class on which an action is to be performed. <ul style="list-style-type: none"> <i>class-map-name</i>—This class map name should match the class map specified via the class-map type inspect command.
Step 5	reset Example: Router(config-pmap)# reset	(Optional) Resets the connection.
Step 6	log Example: Router(config-pmap)# log	(Optional) Generates a log message for the matched parameters.
Step 7	allow Example: Router(config-pmap)# allow	(Optional) Allows the connection.

What to Do Next

If you have not done so already, you must configure an IM-specific parameter map as shown in the task [“Configuring a Protocol-Specific Parameter Map.”](#)

Configuring a Peer-to-Peer (P2P) Policy

Use this task to configure a P2P firewall policy—a class map and a policy map, respectively.

You can create a P2P policy for the following P2P applications: eDonkey, FastTrack, Gnutella, and Kazaa Version 2.

Configuring a P2P Class Map

Use this task to configure a class map for any supported P2P application.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **class map type inspect** {edonkey | fasttrack | gnutella | kazaa2} [match-any] *class-map-name*
4. **match file-transfer** [regular-expression]
5. **match search-file-name** [regular-expression]
6. **match text-chat** [regular-expression]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	class map type inspect {edonkey fasttrack gnutella kazaa2} [match-any] <i>class-map-name</i> Example: Router(config)# class map type inspect edonkey myclassmap	Creates a P2P type class map so you can begin adding match criteria. This command puts the router in class-map configuration mode.
Step 4	match file-transfer [regular-expression] Example: Router(config-cmap)# match file-transfer *	(Optional) Matches file transfer connections within any supported P2P protocol. Note To specify that all file transfer connections be identified by the traffic class, use "*" as the regular expression.
Step 5	match search-file name [regular-expression] Example: Router(config-cmap)# match search-file-name	(Optional) Blocks filenames within a search request for clients using the eDonkey P2P application. Note This command is available only for the eDonkey P2P application.
Step 6	match text-chat [regular-expression] Example: Router(config-cmap)# match text-chat	(Optional) Blocks text chat messages between clients using the eDonkey P2P application. Note This command is available only for the eDonkey P2P application.

Configuring a P2P Policy Map

Use this task to configure a policy map for any supported P2P application.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **policy map type inspect p2p** *policy-map-name*
4. **class type inspect {edonkey | fasttrack | gnutella | kazaa2}** *class-map-name*
5. **reset**
6. **log**
7. **allow**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	policy map type inspect p2p <i>policy-map-name</i> Example: Router(config)# policy map type inspect p2p mypolicymap	Creates a P2P policy map. This command puts the router in policy-map configuration mode.
Step 4	class type inspect {edonkey fasttrack gnutella kazaa2} <i>class-map-name</i> Example: Router(config-pmap)# class type inspect edonkey myclassmap	Specifies a traffic class on which an action is to be performed. Enters the policy map configuration mode. <ul style="list-style-type: none"> <i>class-map-name</i>—This class map name should match the class map specified via the class-map type inspect command.
Step 5	reset Example: Router(config-pmap)# reset	(Optional) Resets the connection.
Step 6	log Example: Router(config-pmap)# log	(Optional) Generates a log message for the matched parameters.
Step 7	allow Example: Router(config-pmap)# allow	(Optional) Allows the connection.

Configuring a POP3 Firewall Policy

Use these tasks to configure a POP3 firewall policy—a class map and a policy map, respectively.

Configuring a POP3 Class Map

Use this task to configure a POP3 firewall class map.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **class-map type inspect pop3 [match-any] *class-map-name***
4. **match invalid-command**
5. **match login clear-text**
