Searches this list or its range for an element for which the given [comparison] function returns zero using the binary search algorithm. The list is expected to be sorted so that the signs of the [comparison] function's return values ascend on the list elements, i.e. negative values come before zero and zeroes come before positive values. Otherwise, the result is undefined. If the list contains multiple elements for which [comparison] returns zero, there is no guarantee which one will be found. @param comparison function that returns zero when called on the list element being searched. On the elements coming before the target element, the function must return negative values; on the elements coming after the target element, the function must return positive values. @return the index of the found element, if it is contained in the list within the specified range; otherwise, the inverted insertion point (-insertion point - 1). The insertion point is defined as the index at which the element should be inserted, so that the list (or the specified subrange of list) still remains sorted. @sample

applied to each element of the original sequence by the key returned by the given [keySelector] function applied to the element and puts to the [destination] map each group key associated with a list of corresponding values.

`@return` The [destination] map.

The operation is `_terminal_`.

`@sample`

```

Returns a sequence that wraps each element of the original sequence into an `[IndexedValue]` containing the index of that element and the element itself.

The operation is `_intermediate_` and `_stateless_`.

`public fun <T> Sequence<T>.withIndex(): Sequence<IndexedValue<T>>` {
return IndexingSequence(this)
}

Returns a sequence containing only distinct elements from the given sequence.

Among equal elements of the given sequence, only the first one will be present in the resulting sequence.

The elements in the resulting sequence are in the same order as they were in the source sequence.

The operation is `_intermediate_` and `_stateful_`.

`@sample samples.collections.Collections.Transformations.distinctAndDistinctBy`

`public fun <T> Sequence<T>.distinct(): Sequence<T>` {

Returns a sequence containing only elements from the given sequence having distinct keys returned by the given `[selector]` function.

Among elements of the given sequence with equal keys, only the first one will be present in the resulting sequence.

The elements in the resulting sequence are in the same order as they were in the source sequence.

The operation is `_intermediate_` and `_stateful_`.

`@sample samples.collections.Collections.Transformations.distinctAndDistinctBy`

`public fun <T, K> Sequence<T>.distinctBy(selector: (T) -> K): Sequence<T>` {

Accumulates value starting with `[initial]` value and applying `[operation]` from left to right to current accumulator value and each element.

Returns the specified `[initial]` value if the sequence is empty.

`@param [operation]` function that takes current accumulator value and an element, and calculates the next accumulator value.

The operation is `_terminal_`.

`public inline fun <T, R> Sequence<T>.fold(initial: R, operation: (acc: R, T) -> R): R` {

for (element in this) accumulator = operation(accumulator, element)
return accumulator
}

Accumulates value starting with `[initial]` value and applying `[operation]` from left to right to current accumulator value and each element with its index in the original sequence.

Returns the specified `[initial]` value if the sequence is empty.

`@param [operation]` function that takes the index of an element, current accumulator value and the element itself, and calculates the next accumulator value.

The operation is `_terminal_`.

The compiler produces mangled names for functions with parameters, which is unnatural for usual JavaScript developer. You can put `@JsName(...)` on functions you want to be available from JavaScript.\n * * For some reason you want to rename declaration, e.g. there's common term in JavaScript for a concept provided by the declaration, which is uncommon in Kotlin.\n * Example:\n * ``` kotlin\n * class Person(val name: String) {\n * fun hello() {\n * println("Hello \$name!")\n * }\n * @JsName("helloWithGreeting")\n * fun hello(greeting: String) {\n * println("\$greeting \$name!")\n * }\n * }\n * ```\n * @property name the name which compiler uses both for declaration itself and for all references to the declaration. It's required to denote a valid JavaScript identifier.\n * \n\n@Retention(AnnotationRetention.BINARY)\n@Target(CLASS, FUNCTION, PROPERTY, CONSTRUCTOR, PROPERTY_GETTER, PROPERTY_SETTER)\n\npublic actual annotation class JsName(actual val name: String)\n\n/**\n * Denotes an `external` declaration that must be imported from native JavaScript library.\n * The compiler produces the code relevant for the target module system, for example, in case of CommonJS, it will import the declaration via the `require(...)` function. The annotation can be used on top-level external declarations (classes, properties, functions) and files. In case of file (which can't be `external`) the following rule applies: all the declarations in the file must be `external`. By applying `@JsModule(...)` on a file you tell the compiler to import a JavaScript object that contain all the declarations from the file.\n * Example:\n * ``` kotlin\n * @JsModule("jquery")\n * external abstract class JQuery() {\n * // some declarations here\n * }\n * @JsModule("jquery")\n * external fun JQuery(element: Element): JQuery\n * ```\n * @property import name of a module to import declaration from. It is not interpreted by the Kotlin compiler, it's passed as is directly to the target module system.\n * @see JsNonModule\n * \n\n@Retention(AnnotationRetention.BINARY)\n@Target(CLASS, PROPERTY, FUNCTION, FILE)\n\npublic annotation class JsModule(val import: String)\n\n/**\n * Denotes an `external` declaration that can be used without module system. By default, an `external` declaration is available regardless your target module system. However, by applying [JsModule] annotation you can make a declaration unavailable to *plain* module system. Some JavaScript libraries are distributed both as a standalone downloadable piece of JavaScript and as a module available as an npm package. To tell the Kotlin compiler to accept both cases, you can augment [JsModule] with the `@JsNonModule` annotation. For example:\n * ``` kotlin\n * @JsModule("jquery")\n * @JsNonModule\n * @JsName("\$")\n * external abstract class JQuery() {\n * // some declarations here\n * }\n * @JsModule("jquery")\n * @JsNonModule\n * @JsName("\$")\n * external fun JQuery(element: Element): JQuery\n * ```\n * @see JsModule\n * \n\n@Retention(AnnotationRetention.BINARY)\n@Target(CLASS, PROPERTY, FUNCTION, FILE)\n\npublic annotation class JsNonModule\n\n/**\n * Adds prefix to `external` declarations in a source file. JavaScript does not have concept of packages (namespaces). They are usually emulated by nested objects. The compiler turns references to `external` declarations either to plain unprefix names (in case of *plain* modules) or to plain imports. However, if a JavaScript library provides its declarations in packages, you won't be satisfied with this. You can tell the compiler to generate additional prefix before references to `external` declarations using the `@JsQualifier(...)` annotation. Note that a file marked with the `@JsQualifier(...)` annotation can't contain non-`external` declarations. Example:\n * ```\n * @file:JsQualifier("my.jsPackageName")\n * package some.kotlinPackage\n * external fun foo(x: Int)\n * external fun bar(): String\n * ```\n * @property value the qualifier to add to the declarations in the generated code. It must be a sequence of valid JavaScript identifiers separated by the `.` character.

Examples of valid qualifiers are: `foo`, `bar.Baz`, `_\$0.f`.
