Example Configuration	3-7
Configuring the Switch	3-8
Using Configuration Mode to Configure Your Switch	3-9
Verifying the Running Configuration Settings	3-9
Saving the Running Configuration Settings to Your Start-Up File	3-10
Reviewing the Configuration in NVRAM	3-10
Configuring a Default Gateway	3-11
Configuring a Static Route	3-11
Controlling Access to Privileged EXEC Commands	3-13
Setting or Changing a Static enable Password	3-13
Using the enable password and enable secret Commands	3-14
Setting or Changing a Privileged Password	3-14
Controlling Switch Access with TACACS+	3-15
Encrypting Passwords	3-22
Configuring Multiple Privilege Levels	3-23
Recovering a Lost Enable Password	3-25
Modifying the Supervisor Engine Startup Configuration	3-25
Understanding the Supervisor Engine Boot Configuration	3-25
Configuring the Software Configuration Register	3-26
Specifying the Startup System Image	3-31
Controlling Environment Variables	3-32

Replacing and Rolling-Back Configuration	3-33
Resetting a Switch to Factory Default Settings	3-34
Managing the System Time and Date	4-1
System Clock	4-2
Understanding Network Time Protocol	4-2
Configuring NTP	4-3
Configuring Time and Date Manually	4-11
Managing Software Licenses Using Right-To-Use Licenses	4-15
RTU License Levels	4-15
RTU License Types	4-16
Ordering with Smart Accounts	4-16
Benefits of an RTU License	4-16
Guidelines for the RTU Licensing Model	4-17
Applying an RTU License	4-17
Activating an RTU License	4-18
Deactivating an RTU License	4-19
Displaying Software License Information	4-19
Configuring a System Name and Prompt	4-25
Understanding the Domain Name System	4-25
Default DNS Configuration	4-26
Setting Up DNS	4-26
Displaying the DNS Configuration	4-27
DNS for IPv6	4-27
IPv6 Router Advertisement Options for DNS Configuration	4-28
Configuring DNS Server Using IPv6 Router Advertisement Options	4-29
Configuring DNS Search List Using IPv6 Router Advertisement Options	4-30
Troubleshooting DNS Servers and DNS Search Lists	4-31
Creating a Banner	4-32
Default Banner Configuration	4-33
Configuring a Message-of-the-Day Login Banner	4-33
Configuring a Login Banner	4-35
Managing the MAC Address Table	4-36
Building the Address Table	4-36
MAC Addresses and VLANs	4-37
Default MAC Address Table Configuration	4-38
Changing the Address Aging Time	4-38
Removing Dynamic Address Entries	4-39
Configuring MAC Change Notification Traps	4-39
Configuring MAC Move Notification Traps	4-41

Configuring MAC Threshold Notification Traps	4-43
Adding and Removing Static Address Entries	4-44
Configuring Unicast MAC Address Filtering	4-45
Disabling MAC Address Learning on a VLAN	4-47
Displaying Address Table Entries	4-52
Managing the ARP Table	4-52
Configuring Embedded CiscoView Support	4-52
Understanding Embedded CiscoView	4-53
Installing and Configuring Embedded CiscoView	4-53
Displaying Embedded CiscoView Information	4-56

Cisco High Availability Features in Cisco IOS XE 3.1.0SG	8-41
Restrictions for Configuring Interfaces	9-2
About Interface Configuration	9-2
Using the interface Command	9-2
Configuring a Range of Interfaces	9-5
Using the Ethernet Management Port	9-7
Understanding the Ethernet Management Port	9-7
Supported Features on the Ethernet Management Port	9-12
Configuring the Ethernet Management Port	9-13
Defining and Using Interface-Range Macros	9-13
Deploying SFP+ in X2 Ports	9-14
Deploying 10-Gigabit Ethernet and Gigabit Ethernet SFP Ports on Supervisor Engine V-10GE	9-14
Deploying 10-Gigabit Ethernet or Gigabit Ethernet Ports	9-15
Port Numbering TwinGig Convertors	9-15
Limitations on Using a TwinGig Convertor	9-16
Selecting X2/TwinGig Convertor Model	9-16
Configuring MultiGigabit Ports on WS-X4748-12X48U+E	9-18
Module Modes on WS-X4748-12X48U+E Overview	9-18
Configuring Module Modes on WS-X4748-12X48U+E	9-21
Upgrading the Line Card FPGA Image on WS-X4748-12X48U+E	9-21
Invoking Shared-Backplane Uplink Mode on Supervisor Engine 6-E and Supervisor Engine 6L-E	9-22
Selecting Uplink Mode on a Supervisor Engine 6-E	9-23
Support for WS-X46490-CSFP-E on a 10-slot Chassis	9-23
Limitation and Restrictions on Supervisor Engine 7-E and Supervisor Engine 7L-E	9-24
Selecting the Uplink Port on a Supervisor Engine 7L-E	9-24
Single Supervisor Mode	9-25
Redundant Supervisor Mode	9-25
Limitations and Restrictions on Supervisor Engine 8-E	9-25
Configuring Supervisor Engine 7-E Uplink Mode on Supervisor Engine 8-E	9-26
Supervisor Engine 7-E Mode on Supervisor Engine 8-E	9-26
Supervisor Engine 8-E with Daughter Card Enabled	9-26
Supervisor Engine 8-E Uplink Configurations	9-27

Restrictions for Configuring Sup 7-E Uplink Mode on Supervisor Engine 8-E	9-28
Configuring Supervisor Engine 7-E Mode on Supervisor Engine 8-E	9-28
Supervisor Engine 9-E Uplink Configurations	9-29
Limitations and Restrictions on Supervisor Engine 9-E	9-30
Selecting the Uplink Mode on Supervisor Engine 9-E	9-31
Digital Optical Monitoring Transceiver Support	9-32
Configuring Optional Interface Features	9-32
Configuring Ethernet Interface Speed and Duplex Mode	9-32
Configuring Flow Control	9-38
Configuring Jumbo Frame Support	9-40
Interacting with Baby Giants	9-44
Configuring the Port Debounce Timer	9-44
Configuring Auto-MDIX on a Port	9-45
Understanding Online Insertion and Removal	9-47
Online Insertion and Removal on a WS-4500X-32	9-48
Shutting down a Module	9-48
Booting a Module After if it has been Stopped	9-49
Common Scenarios	9-50
Monitoring and Maintaining the Interface	9-50
Monitoring Interface and Controller Status	9-50
Clearing and Resetting the Interface	9-51
Shutting Down and Restarting an Interface	9-51
Configuring Interface Link Status and Trunk Status Events	9-52
Resetting the Interface to the Default Configuration	9-55
Checking Module Status	10-1
Checking Interfaces Status	10-2
Displaying MAC Addresses	10-3
Checking Cable Status Using Time Domain Reflectometer	10-3

Preface

This preface describes who should read this document, how it is organized, and its conventions. The preface also tells you how to obtain Cisco documents, as well as how to obtain technical assistance.

Audience

This guide is for experienced network administrators who are responsible for configuring and maintaining Catalyst 4500 series switches.

Conventions

This document uses the following typographical conventions:

Convention	Description
boldface font	Commands, command options, and keywords are in boldface .
<i>italic font</i>	Command arguments for which you supply values are in <i>italics</i> .
[]	Command elements in square brackets are optional.
{ x y z }	Alternative keywords in command lines are grouped in braces and separated by vertical bars.
[x y z]	Optional alternative keywords are grouped in brackets and separated by vertical bars.
string	A unquoted set of characters. Do not use quotation marks around the string because the string will include the quotation marks.
screen font	System displays are in <code>screen font</code> .
boldface screen font	Information you must enter verbatim is in boldface screen font .
<i>italic screen font</i>	Arguments for which you supply values are in <i>italic screen font</i> .
→	This pointer highlights an important line of text in an example.
^	Represents the key labeled Control—for example, the key combination ^D in a screen display means hold down the Control key while you press the D key.
< >	Nonprinting characters such as passwords are in angle brackets.

Notes use the following conventions:

Note

Means *reader take note*. Notes contain helpful suggestions or references to material not covered in the publication.

Cautions use the following conventions:

Caution

Means *reader be careful*. In this situation, you might do something that could result in equipment damage or loss of data.

The license and distribution terms for any publicly available version or derivative of this code cannot be changed, that is, this code cannot be copied and put under another distribution license [including the GNU Public License].

Obtaining Documentation and Submitting a Service Request

For information on obtaining documentation, submitting a service request, and gathering additional information, see the monthly *What's New in Cisco Product Documentation*, which also lists all new and revised Cisco technical documentation, at:

<http://www.cisco.com/en/US/docs/general/whatsnew/whatsnew.html>

Subscribe to the *What's New in Cisco Product Documentation* as a Really Simple Syndication (RSS) feed and set content to be delivered directly to your desktop using a reader application. The RSS feeds are a free service and Cisco currently supports RSS Version 2.0.

Product Overview

This chapter provides an overview of Catalyst 4500 series switches and includes the following major sections:

- [Layer 2 Software Features, page 1-1](#)
- [Layer 3 Software Features, page 1-13](#)
- [Management Features, page 1-23](#)
- [Security Features, page 1-34](#)

Layer 2 Software Features

The following subsections describe the key Layer 2 switching software features on the switch:

- [802.1Q Tunneling, VLAN Mapping, and Layer 2 Protocol Tunneling, page 1-2](#)
- [Cisco IOS Auto Smartport Macros, page 1-2](#)
- [Cisco Discovery Protocol, page 1-3](#)
- [Cisco Group Management Protocol \(CGMP\) server, page 1-3](#)
- [EtherChannel Bundles, page 1-3](#)
- [Ethernet CFM, page 1-3](#)
- [Ethernet OAM Protocol, page 1-3](#)
- [Flex Links and MAC Address-Table Move Update, page 1-4](#)
- [Flexible NetFlow \(Supervisor Engine 9-E, 8-E, 8L-E, 7-E, and 7L-E only\), page 1-4](#)
- [Internet Group Management Protocol \(IGMP\) Snooping, page 1-4](#)
- [IPv6 Multicast BSR and BSR Scoped Zone Support, page 1-5](#)
- [IPv6 Multicast Listen Discovery \(MLD\) and Multicast Listen Discovery Snooping, page 1-6](#)
- [Jumbo Frames, page 1-6](#)
- [Link Aggregation Control Protocol, page 1-7](#)
- [Link Layer Discovery Protocol, page 1-7](#)
- [Link State Tracking, page 1-8](#)
- [Location Service, page 1-8](#)
- [Multiple Spanning Tree, page 1-8](#)

- [Per-VLAN Rapid Spanning Tree, page 1-8](#)
- [Quality of Service, page 1-9](#)
- [Resilient Ethernet Protocol, page 1-10](#)
- [SmartPort Macros, page 1-10](#)
- [Spanning Tree Protocol, page 1-10](#)
- [Stateful Switchover, page 1-10](#)
- [SVI Autostate, page 1-11](#)
- [Unidirectional Link Detection, page 1-11](#)
- [VLANs, page 1-11](#)
- [Virtual Switching Systems \(Catalyst 4500-X and Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E\), page 1-12](#)
- [Virtual Switch System Client, page 1-12](#)
- [Y.1731 \(AIS and RDI\), page 1-13](#)

802.1Q Tunneling, VLAN Mapping, and Layer 2 Protocol Tunneling

802.1Q tunneling is a Q-in-Q technique that expands the VLAN space by retagging the tagged packets that enter the service provider infrastructure. 802.1Q tunneling allows service providers to assign a VLAN to each customer without losing the original customer VLAN IDs inside the tunnel. All data traffic that enters the tunnel is encapsulated with the tunnel VLAN ID. Layer 2 Protocol Tunneling is a similar technique for all Layer 2 control traffic.

To map customer VLANs to service-provider VLANs, you can configure VLAN mapping (or VLAN ID translation) on trunk ports connected to a customer network. Packets entering the port are mapped to a service provider VLAN (S-VLAN) based on the port number and the original customer VLAN-ID (C-VLAN) of the packet.

For information on configuring 802.1Q tunneling and VLAN Mapping, see [Chapter 31, “Configuring 802.1Q Tunneling, VLAN Mapping, and Layer 2 Protocol Tunneling.”](#)

Cisco IOS Auto Smartport Macros

Cisco IOS Auto SmartPort macros dynamically configure ports based on the device type detected on the port. When the switch detects a new device on a port it applies the appropriate Cisco IOS Auto Smartports macro. When a link-down event occurs on the port, the switch removes the macro. For example, when you connect a Cisco IP phone to a port, Cisco IOS Auto SmartPorts automatically applies the IP phone macro. The IP phone macro enables quality of service (QoS), security features, and a dedicated voice VLAN to ensure proper treatment of delay-sensitive voice traffic.

For information on configuring SmartPort macros, see [Chapter 22, “Configuring Cisco IOS Auto Smartport Macros.”](#)

Cisco Discovery Protocol

The Cisco Discovery Protocol (CDP) is a device-discovery protocol that is both media- and protocol-independent. CDP is available on all Cisco products, including routers, switches, bridges, and access servers. Using CDP, a device can advertise its existence to other devices and receive information about other devices on the same LAN. CDP enables Cisco switches and routers to exchange information, such as their MAC addresses, IP addresses, and outgoing interfaces. CDP runs over the data-link layer only, allowing two systems that support different network-layer protocols to learn about each other. Each device configured for CDP sends periodic messages to a multicast address. Each device advertises at least one address at which it can receive Simple Network Management Protocol (SNMP) messages.

For information on configuring CDP, see [Chapter 32, “Configuring Cisco Discovery Protocol.”](#)

Cisco Group Management Protocol (CGMP) server

CGMP server manages multicast traffic. Multicast traffic is forwarded only to ports with attached hosts that request the multicast traffic.

EtherChannel Bundles

EtherChannel port bundles allow you to create high-bandwidth connections between two switches by grouping multiple ports into a single logical transmission path.

For information on configuring EtherChannel, see [Chapter 27, “Configuring EtherChannel and Link State Tracking.”](#)

Ethernet CFM

Ethernet CFM is an end-to-end per-service-instance (per-VLAN) Ethernet layer OAM protocol that includes proactive connectivity monitoring, fault verification, and fault isolation. End-to-end can be provider-edge-to-provider-edge (PE-to-PE) device or customer-edge-to-customer-edge (CE-to-CE) device. Ethernet CFM, as specified by IEEE 802.1ag, is the standard for Layer 2 ping, Layer 2 traceroute, and end-to-end connectivity check of the Ethernet network.

For information about CFM, see [Chapter 77, “Configuring Ethernet OAM and CFM.”](#)

Ethernet OAM Protocol

Ethernet Operations, Administration, and Maintenance (OAM) is a protocol for installing, monitoring, and troubleshooting Ethernet networks to increase management capability within the context of the overall Ethernet infrastructure. You can implement Ethernet OAM on any full-duplex, point-to-point, or emulated point-to-point Ethernet link for a network or part of a network (specified interfaces).

For information about OAM, see [Chapter 77, “Configuring Ethernet OAM and CFM.”](#)

Flex Links and MAC Address-Table Move Update

Flex Links are a pair of Layer 2 interfaces (switch ports or port channels) where one interface is configured to act as a backup to the other. The feature provides an alternative solution to the Spanning Tree Protocol (STP). Flex Links are typically configured in service provider or enterprise networks where customers do not want to run STP on the switch.

MAC Address-Table Move Update allows a switch to provide rapid bidirectional convergence when a primary (forwarding) link goes down and the standby link begins forwarding traffic.

For information about Flex Links and MAC Address-Table Move Update, see [Chapter 24, “Configuring Flex Links and MAC Address-Table Move Update.”](#)

Flexible NetFlow (Supervisor Engine 9-E, 8-E, 8L-E, 7-E, and 7L-E only)

Flow is defined as unique set of key fields attributes, which might include fields of packet, packet routing attributes, and input and output interface information. A NetFlow feature defines a flow as a sequence of packets that have the same values for the feature key fields. Flexible NetFlow (FNF) allows a flow record that specifies various flow attributes to be collected and optionally exported. NetFlow collection supports IP, IPv6 and Layer 2 traffic.

For information on configuring Flexible NetFlow, see [Chapter 76, “Configuring Flexible NetFlow.”](#)

Internet Group Management Protocol (IGMP) Snooping

IGMP snooping manages multicast traffic. The switch software examines IP multicast packets and forwards packets based on their content. Multicast traffic is forwarded only to ports with attached hosts that request multicast traffic.

Support for IGMPv3 provides constrained flooding of multicast traffic in the presence of IGMPv3 hosts or routers. IGMPv3 snooping listens to IGMPv3 query and membership report messages to maintain host-to-multicast group associations. It enables a switch to propagate multicast data only to ports that need it. IGMPv3 snooping is fully interoperable with IGMPv1 and IGMPv2.

Explicit Host Tracking (EHT) is an extension to IGMPv3 snooping. EHT enables immediate leave operations on a per-port basis. EHT can be used to track per host membership information or to gather statistics about all IGMPv3 group members.

The IGMP Snooping Querier is a Layer 2 feature required to support IGMP snooping in a VLAN where PIM and IGMP are not configured because the multicast traffic does not require routing.

With SSO support, Stateful IGMP Snooping propagates the IGMP data learned by the active supervisor engine to the redundant supervisor engine so that when a switchover occurs, the newly active supervisor engine is aware of the multicast group membership, which alleviates a disruption to multicast traffic during a switchover.

Beginning with Release IOS XE 3.5.0E and IOS 15.2(1)E, the Catalyst 4500 series switch supports an application of local IGMP snooping, Multicast VLAN Registration (MVR). MVR is designed for applications using wide-scale deployment of multicast traffic across an Ethernet ring-based service provider network (for example, the broadcast of multiple television channels over a service-provider network). MVR allows a subscriber on a port to subscribe and unsubscribe to a multicast stream on the network-wide multicast VLAN. It allows the single multicast VLAN to be shared in the network while subscribers remain in separate VLANs.

For information on configuring IGMP snooping and MVR, see [Chapter 28, “Configuring IGMP Snooping and Filtering, and MVR.”](#)

IPv6 Multicast BSR and BSR Scoped Zone Support

The bootstrap router (BSR) protocol for PIM-SM provides a dynamic, adaptive mechanism to distribute group-to-RP mapping information rapidly throughout a domain. With the IPv6 BSR feature, if an RP becomes unreachable, it will be detected and the mapping tables will be modified so that the unreachable RP is no longer used, and the new tables will be rapidly distributed throughout the domain.

BSR provides scoped zone support by distributing group-to-RP mappings in networks using administratively scoped multicast. The user can configure candidate BSRs and a set of candidate RPs for each administratively scoped region in the user's domain.

For information on BSR and BSR Scoped Zone Support, see this URL with the following caveats related to support on a Catalyst 4500 series switch:

http://www.cisco.com/en/US/docs/ios-xml/ios/ipmulti_pim/configuration/xr-3s/ip6-mcast-bsr.html

- In the section “IPv6 BSR: Scoped Zone Support,” a paragraph starts as follows:

Unless the C-RP is configured with a scope, it discovers the existence of the administratively scoped zone and its group range through reception of a BSM from the scope zone's elected BSR containing the scope zone's group range.

A C-RP can no longer be configured with a scope. So, the sentence should read:

A C-RP discovers the existence of the administratively scoped zone and its group range through reception of a BSM from the scope zone's elected BSR containing the scope zone's group range.

- In the section “Configuring a BSR and Verifying BSR Information” in Step 3 under Summary Steps and Detailed Steps, the command for configuring a C-BSR is listed as:

ipv6 pim [vrf vrf-name] bsr candidate bsr ipv6-address [hash-mask-length] [priority priority-value]

Because the original syntax mistakenly excludes **scope scope-value** and the “new” option (**accept-rp-candidate access-list-name**) is supported with this release.

ipv6 pim [vrf vrf-name] bsr candidate bsr ipv6-address [hash-mask-length] [priority priority-value] [scope scope-value] [accept-rp-candidate access-list-name]

- In the section “Sending PIM RP Advertisements to the BSR” in Step 3 under Summary and Detailed Steps, the keyword **scope scope-value** should be removed. The **scope** keyword no longer exists for C-RPs.

- In the section “Configuring BSR for Use Within Scoped Zones,” several changes apply.

The following paragraph:

If scope is specified on the candidate RP, then this device will advertise itself as C-RP only to the BSR for the specified scope. If the group list is specified along with the scope, then only prefixes in the access list with the same scope as that configured will be advertised.

Should read:

The candidate RP will advertise the different ranges it serves to the respective elected BSRs. If a group list is specified, for each of the prefixes in the group list, it will verify that there is an elected scoped BSR for the scope of the prefix. If none exists, the prefix will be announced to the elected non-scoped BSR, provided one is present.

Note: If a prefix is not scope specific (for example, FF00::/8), it will only be announced to a non-scoped BSR. If the candidate RP is not configured with a group list, it will behave as if a group list with only the prefix FF00::/8 is configured.

Under the Summary Steps, steps 3 and 4 should read as follows:

```
ipv6 pim [vrf vrf-name] bsr candidate bsr ipv6-address [hash-mask-length] [priority  
priority-value] [scope scope-value] [accept-rp-candidate access-list-name]
```

```
ipv6 pim [vrf vrf-name] bsr candidate rp ipv6-address [group-list access-list-name] [priority  
priority-value] [interval seconds] [bidir]
```

Under the Details Steps, Step 3 should read:

```
ipv6 pim [vrf vrf-name] bsr candidate bsr ipv6-address [hash-mask-length] [priority  
priority-value] [scope scope-value] [accept-rp-candidate access-list-name]
```

Example:

```
Device(config)# ipv6 pim bsr candidate bsr 2001:DB8:1:1:4 scope 6
```

Under the Details Steps, Step 4 should read:

```
ipv6 pim [vrf vrf-name] bsr candidate rp ipv6-address [group-list access-list-name] [priority  
priority-value] [interval seconds] [bidir]
```

Example:

```
Device(config)# ipv6 pim bsr candidate rp 2001:DB8:1:1:1 group-list list
```

- In the section "Configuring BSR Devices to Announce Scope-to-RP Mappings," the keyword **scope scope-value** should be removed from Step 3, both under Summary and Detail Steps.
- In the section "Additional References section," it would be helpful to reference RFC 5059.

IPv6 Multicast Listen Discovery (MLD) and Multicast Listen Discovery Snooping

MLD is a protocol used by IPv6 multicast devices to discover the presence of multicast listeners (nodes that want to receive IPv6 multicast packets) on its directly attached links and to discover which multicast packets are of interest to neighboring nodes. MLD snooping is supported in two different versions: MLD v1 and MLD v2. Network switches use MLD snooping to limit the flood of multicast traffic, causing IPv6 multicast data to be selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This lessens the load on devices in the network, minimizing unnecessary bandwidth on links, enabling efficient distribution of IPv6 multicast data.

For information on configuring multicast services, see [Chapter 39, "Configuring IP Multicast."](#)

Jumbo Frames

The jumbo frames feature allows the switch to forward packets as large as 9216 bytes (larger than the IEEE Ethernet MTU), rather than declare those frames "oversize" and discard them. This feature is typically used for large data transfers. The jumbo frames feature can be configured on a per-port basis on Layer 2 and Layer 3 interfaces. The feature is supported only on the following hardware:

- WS-X4306-GB: all ports
- WS-X4232-GB-RJ: ports 1-2

- WS-X4418-GB: ports 1-2
- WS-X4412-2GB-TX: ports 13-14
- WS-4648-RJ45V-E
- WS-X4648+RJ45V+E
- WS-C4500X-16
- WS-C4500X-32
- WS-X4706-10GE linecards
- supervisor engine uplink ports

For information on Jumbo Frames, see [Chapter 9, “Configuring Interfaces.”](#)

Link Aggregation Control Protocol

LACP supports the automatic creation of EtherChannels by exchanging LACP packets between LAN ports. LACP packets are exchanged only between ports in passive and active modes. The protocol "learns" the capabilities of LAN port groups dynamically and informs the other LAN ports. After LACP identifies correctly matched Ethernet links, it facilitates grouping the links into an EtherChannel. Then the EtherChannel is added to the spanning tree as a single bridge port.

Cisco IOS XE IP Application Services Features in Cisco IOS XE 3.1.0SG

This section lists the IP Application Services software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

IEEE 802.3ad Link Aggregation (LACP)

http://www.cisco.com/en/US/docs/ios/cether/configuration/guide/ce_lnkbnld.html

Link Aggregation Control Protocol (LACP) (802.3ad) for Gigabit Interfaces

http://www.cisco.com/en/US/docs/ios/ios_xe/cether/configuration/guide/ce_lnkbnld_xe.html

Link Layer Discovery Protocol

To support non-Cisco devices and to allow for interoperability between other devices, the switch supports the IEEE 802.1AB LLDP. Link Layer Discovery Protocol (LLDP) is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol runs over the data-link layer, which allows two systems running different network layer protocols to learn about each other.

LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type, length, and value descriptions and are referred to as *TLVs*. LLDP supported devices can use TLVs to receive and send information to their neighbors. Details such as configuration information, device capabilities, and device identity can be advertised using this protocol.

For information on configuring LLDP, see [Chapter 33, “Configuring LLDP, LLDP-MED, and Location Service.”](#)

Link State Tracking

Link-state tracking, also known as trunk failover, is a feature that binds the link state of multiple interfaces. For example, link-state tracking provides redundancy in the network when used with server NIC adapter teaming. When server network adapters are configured in a primary or secondary relationship known as teaming, if the link is lost on the primary interface, connectivity is transparently changed to the secondary interface.

For information on configuring Link State Tracking, see [Chapter 27, “Configuring EtherChannel and Link State Tracking.”](#)

Location Service

The location service feature allows the switch to provide location and attachment tracking information for its connected devices to a Cisco Mobility Services Engine (MSE). The tracked device can be a wireless endpoint, a wired endpoint, or a wired switch or controller. The switch informs device link up and link down events through encrypted Network Mobility Services Protocol (NMSP) location and attachment notifications to the MSE.

For information on configuring LLDP, see [Chapter 33, “Configuring LLDP, LLDP-MED, and Location Service.”](#)

Multiple Spanning Tree

IEEE 802.1s Multiple Spanning Tree (MST) allows for multiple spanning tree instances within a single 802.1Q or Inter-Switch Link (ISL) VLAN trunk. MST extends the IEEE 802.1w Rapid Spanning Tree (RST) algorithm to multiple spanning trees. This extension provides both rapid convergence and load balancing within a VLAN environment.

MST allows you to build multiple spanning trees over trunks. You can group and associate VLANs to spanning tree instances. Each instance can have a topology independent of other spanning tree instances. This new architecture provides multiple forwarding paths for data traffic and enables load balancing. Network fault tolerance is improved because a failure in one instance (forwarding path) does not affect other instances (forwarding paths).

For information on configuring MST, see [Chapter 23, “Configuring STP and MST.”](#)

Per-VLAN Rapid Spanning Tree

Per-VLAN Rapid Spanning Tree (PVRST+) is the implementation of 802.1w on a per-VLAN basis. It is the same as PVST+ with respect to STP mode and runs RSTP protocol based on 802.1w.

For information on configuring PVRST+, see [Chapter 23, “Configuring STP and MST.”](#)

Quality of Service

**Note**

QoS functionality on Supervisor Engine 6-E and Supervisor Engine 6L-E are equivalent.

The quality of service (QoS) feature prevents congestion by selecting network traffic and prioritizing it according to its relative importance. Implementing QoS in your network makes network performance more predictable and bandwidth use more effective.

The switch supports the following QoS features:

- Classification and marking
- Ingress and egress policing, including per-port per-VLAN policing
- Sharing and shaping

The Catalyst 4500 series switch supports trusted boundary, which uses the Cisco Discovery Protocol (CDP) to detect the presence of a Cisco IP phone (such as the Cisco IP Phone 7910, 7935, 7940, and 7960) on a switch port. If the telephone is not detected, the trusted boundary feature disables the trusted setting on the switch port and prevents misuse of a high-priority queue.

The Catalyst 4500 series switch also supports QoS Automation (Auto QoS), which simplifies the deployment of existing QoS features through automatic configuration.

Cisco Modular QoS Command-Line-Interface

Cisco Modular QoS CLI (MQC) is the framework that implements Cisco IOS software QoS. MQC allows the user to define a traffic class, create a traffic policy (containing the QoS feature to be applied to the traffic class), and attach the traffic policy to an interface. MQC is a cross-Cisco baseline that provides a consistent syntax and behavior of QoS features across multiple product families. Cisco IOS Software Release 12.2(40)SG complies to MQC for configuration of QoS features on the Supervisor Engine 6-E. MQC enables rapid deployment of new features and technology innovations and facilitates the management of network performance with respect to bandwidth, delay, jitter, and packet loss, enhancing the performance of mission-critical business applications. The rich and advanced QoS features are enabled using Cisco MQC.

Two-Rate Three-Color Policing

The Two-Rate Three-Color Policing feature (also termed *Hierarchical QoS*) limits the input or output transmission rate of a class of traffic based on user-defined criteria and marks or colors packets by setting the applicable differentiated services code point (DSCP) values. This feature is often configured on the interfaces at the edge of a network to limit the rate of traffic entering or leaving the network. Using this feature, traffic that conforms to user-defined criteria can be sent through the interfaces, while traffic that exceeds or violates these criteria is sent out with a decreased priority setting or even dropped.

For information on QoS and Auto QoS, see [Chapter 44, “Configuring Quality of Service.”](#)

Resilient Ethernet Protocol

Resilient Ethernet Protocol (REP) is a Cisco proprietary protocol that provides an alternative to Spanning Tree Protocol (STP) to control network loops, handle link failures, and improve convergence time. REP controls a group of ports connected in a segment, ensures that the segment does not create any bridging loops, and responds to link failures within the segment. REP provides a basis for constructing more complex networks and supports VLAN load balancing.

For information on REP, see [Chapter 25, “Configuring Resilient Ethernet Protocol.”](#)

SmartPort Macros

SmartPort macros provide a convenient way to save and share common configurations. You can use SmartPort macros to enable features and settings based on the location of a switch in the network and for mass configuration deployments across the network.

For information on configuring SmartPort macros, see [Chapter 21, “Configuring SmartPort Macros.”](#)

Spanning Tree Protocol

The Spanning Tree Protocol (STP) allows you to create fault-tolerant internetworks that ensure an active, loop-free data path between all nodes in the network. STP uses an algorithm to calculate the best loop-free path throughout a switched network.

For information on configuring STP, see [Chapter 23, “Configuring STP and MST.”](#)

The Catalyst 4500 series switch supports the following STP enhancements:

- Spanning tree PortFast—PortFast allows a port with a directly attached host to transition to the forwarding state directly, bypassing the listening and learning states.
- Spanning tree UplinkFast—UplinkFast provides fast convergence after a spanning-tree topology change and achieves load balancing between redundant links using uplink groups. Uplink groups provide an alternate path in case the currently forwarding link fails. UplinkFast is designed to decrease spanning-tree convergence time for switches that experience a direct link failure.
- Spanning tree BackboneFast—BackboneFast reduces the time needed for the spanning tree to converge after a topology change caused by an indirect link failure. BackboneFast decreases spanning-tree convergence time for any switch that experiences an indirect link failure.
- Spanning tree root guard—Root guard forces a port to become a designated port so that no switch on the other end of the link can become a root switch.

For information on the STP enhancements, see [Chapter 26, “Configuring Optional STP Features.”](#)

Stateful Switchover

Stateful switchover (SSO) enables you to propagate configuration and state information from the active to the redundant supervisor engine so that sub-second interruptions in Layer 2 traffic occur when the active supervisor engine switches over to the redundant supervisor engine.

- Stateful IGMP Snooping

This feature propagates the IGMP data learned by the active supervisor engine to the redundant supervisor engine so that when a switchover occurs, the newly active supervisor engine is aware of the multicast group membership, which alleviates a disruption to multicast traffic during a switchover.

- Stateful DHCP Snooping

This feature propagates the DHCP-snooped data from the active supervisor engine to the redundant supervisor engine so that when a switchover occurs, the newly active supervisor engine is aware of the DHCP data that was already snooped, and the security benefits continue uninterrupted.

For information about SSO, see [Chapter 13, “Configuring Cisco NSF with SSO Supervisor Engine Redundancy.”](#)

SVI Autostate

When an SVI has multiple ports on a VLAN, normally the SVI will go down when all the ports in the VLAN go down. You can design your network so that some ports are not counted in the calculation of SVI “going up or down.” SVI Autostate provides a knob to mark a port so that it is not counted in the SVI “going up and down” calculation and applies to all VLANs that are enabled on that port.

Unidirectional Link Detection

The Unidirectional Link Detection (UDLD) protocol allows devices connected through fiber-optic or copper Ethernet cables to monitor the physical configuration of the cables and detect a unidirectional link.

With standard UDLD, the time to detect a unidirectional link can vary from a few seconds to several minutes depending on how the timers are configured. Link status messages are exchanged every couple of seconds. With Fast UDLD, you can detect unidirectional links in under one second (this also depends on how the timers are configured). Link status messages are exchanged every couple of hundred milliseconds.

For information about UDLD and Fast UDLD, see [Chapter 34, “Configuring UDLD.”](#)

VLANs

A VLAN configures switches and routers according to logical, rather than physical, topologies. Using VLANs, you can combine any collection of LAN segments within an internetwork into an autonomous user group, such that the segments appear as a single LAN in the network. VLANs logically segment the network into different broadcast domains so that packets are switched only between ports within the VLAN. Typically, a VLAN corresponds to a particular subnet, although not necessarily.

For more information about VLANs, VTP, and Dynamic VLAN Membership, see [Chapter 17, “Configuring VLANs, VTP, and VMPS.”](#)

The following VLAN-related features also are supported:

- VLAN Trunking Protocol (VTP)—VTP maintains VLAN naming consistency and connectivity between all devices in the VTP management domain. You can have redundancy in a domain by using multiple VTP servers, through which you can maintain and modify the global VLAN information. Only a few VTP servers are required in a large network.

- **Private VLANs**—Private VLANs are sets of ports that have the features of normal VLANs and also provide some Layer 2 isolation from other ports on the switch.
For information about private VLANs, see [Chapter 47, “Configuring Private VLANs.”](#)
- **Private VLAN Trunk Ports**—Private VLAN trunk ports allow a secondary port on a private VLAN to carry multiple secondary VLANs.
- **Private VLAN Promiscuous Trunk Ports**—Private VLAN promiscuous trunk extends the promiscuous port to a 802.1Q trunk port, carrying multiple primary VLANs (hence multiple subnets). Private VLAN promiscuous trunk is typically used to offer different services or content on different primary VLANs to isolated subscribers. Secondary VLANs can not be carried over the private VLAN promiscuous trunk.
- **Dynamic VLAN Membership**—Dynamic VLAN Membership allows you to assign switch ports to VLANs dynamically, based on the source Media Access Control (MAC) address of the device connected to the port. When you move a host from a port on one switch in the network to a port on another switch in the network, that switch dynamically assigns the new port to the proper VLAN for that host. With the VMPS Client feature, you can convert a dynamic access port to a VMPS client. VMPS clients can use VQP queries to communicate with the VMPS server to obtain a VLAN assignment for the port based on the MAC address of the host attached to that port.

Virtual Switching Systems (Catalyst 4500-X and Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E)

Network operators increase network reliability by configuring switches and by provisioning links to the redundant pairs. Redundant network elements and redundant links can add complexity to network design and operation. Virtual switching simplifies the network by reducing the number of network elements and hiding the complexity of managing redundant switches and links.

A VSS combines a pair of Catalyst 4500 or 4500-X series switches into a single network element. The VSS manages the redundant links, which externally act as a single port channel. Starting with Cisco Release IOS XE 3.4.0SG, the Catalyst 4500 or 4500-X series switches support VSS.

**Note**

Smart Install Director is not supported with VSS.

For information on VSS, see [Chapter 5, “Configuring Virtual Switching Systems.”](#)

Virtual Switch System Client

Catalyst 4500 series switches support enhanced PAgP. If a Catalyst 4500 series switch is connected to a Catalyst 6500 series Virtual Switch System (VSS) with a PAgP EtherChannel, the Catalyst 4500 series switch will automatically serve as a VSS client, using enhanced PAgP on this EtherChannel for dual-active detection. This VSS client feature has no impact on the performance of Catalyst 4500 series switches and does not require any user configuration.

For more details, see [Chapter 27, “Configuring EtherChannel and Link State Tracking.”](#)

Y.1731 (AIS and RDI)

Y.1731 ETH-AIS (Ethernet Alarm Indication Signal function) and ETH-RDI (Ethernet Remote Defect Indication function) provides fault and performance management for service providers in large networks.

ETH-AIS suppresses alarms following detection of defect conditions at the server (sub) layer. Due to independent restoration capabilities provided within the Spanning Tree Protocol (STP) environments, ETH-AIS is not expected to be applied in the STP environments. In this case, AIS is configurable, and the administrator describes how to enable and disable AIS in STP environment or not.

ETH-RDI can be used by a MEP to communicate to its peer MEPs that a defect condition has been encountered. ETH-RDI is used only when ETH-CC transmission is enabled.

For information about Y.1731, see [Chapter 78, “Configuring Y.1731 \(AIS and RDI\).”](#)

Layer 3 Software Features

A Layer 3 switch is a high-performance switch that has been optimized for a campus LAN or an intranet, and it provides both wire-speed Ethernet routing and switching services. Layer 3 switching improves network performance with two software functions: route processing and intelligent network services.

Compared to conventional software-based switches, Layer 3 switches process more packets faster by using application-specific integrated circuit (ASIC) hardware instead of microprocessor-based engines.

The following sections describe the key Layer 3 switching software features on the switch:

- [Bidirectional Forwarding Detection, page 1-14](#)
- [Cisco Express Forwarding, page 1-14](#)
- [Device Sensor, page 1-14](#)

- [Virtual Router Redundancy Protocol, page 1-23](#)

Bidirectional Forwarding Detection

**Note**

Starting with Cisco IOS XE 3.5.0E and IOS 15.2(1)E, Bidirectional Forwarding Detection (BFD) support was supported on Supervisor Engine 7-E, and Supervisor Engine 7L-E. With Cisco IOS XE 3.6.0E and IOS 15.2(2)E, support was extended to Supervisor Engine 8-E. Starting with Cisco IOS XE Release 3.10.0E, the feature is supported on Supervisor Engine 9-E.

Bidirectional Forwarding Detection (BFD) protocol. BFD is a detection protocol designed to provide fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols. It includes a description of how to configure multihop BFD sessions. BFD provides a consistent failure detection method for network administrators in addition to fast forwarding path failure detection.

For information on configuring BFD, see [Chapter 41, “Configuring Bidirectional Forwarding Detection.”](#)

Cisco Express Forwarding

Cisco Express Forwarding (CEF) is an advanced Layer 3 IP-switching technology. CEF optimizes network performance and scalability in networks with large and dynamic traffic patterns, such as the Internet, and on networks that use intensive web-based applications or interactive sessions. Although you can use CEF in any part of a network, it is designed for high-performance, highly resilient Layer 3 IP-backbone switching.

For information on configuring CEF, see [Chapter 37, “Configuring Cisco Express Forwarding.”](#)

Device Sensor

Device Sensor uses protocols such as Cisco Discovery Protocol (CDP), Link Layer Discovery Protocol (LLDP), and DHCP to obtain endpoint information from network devices and make this information available to its clients. Device Sensor has internal clients, such as the embedded Device Classifier (local analyzer), Auto Smartports (ASP), MediaNet Service Interface (MSI)-Proxy, and EnergyWise. Device Sensor also has an external client, Identity Services Engine (ISE), which uses RADIUS accounting to receive and analyze endpoint data. When integrated with ISE, Device Sensor provides central policy management and device-profiling capabilities.

For more information on Device Sensor, see [Chapter 49, “Configuring 802.1X Port-Based Authentication.”](#)

EIGRP Stub Routing

The EIGRP stub routing feature, available in all images, reduces resource utilization by moving routed traffic closer to the end user.

The IP base image contains only EIGRP stub routing. The IP services image contains complete EIGRP routing.

In a network using EIGRP stub routing, the only route for IP traffic to follow to the user is through a switch that is configured with EIGRP stub routing. The switch sends the routed traffic to interfaces that are configured as user interfaces or are connected to other devices.

For information on configuring EIGRP Stub Routing, see [Chapter 36, “About Layer 3 Interfaces.”](#)

Enhanced Object Tracking

Before the introduction of the Enhanced Object Tracking feature, the Hot Standby Router Protocol (HSRP) had a simple tracking mechanism that allowed you to track the interface line-protocol state only. If the line-protocol state of the interface went down, the HSRP priority of the router was reduced, allowing another HSRP router with a higher priority to become active.

The Enhanced Object Tracking (EOT) feature separates the tracking mechanism from HSRP and creates a separate standalone tracking process that can be used by other Cisco IOS processes as well as HSRP. This feature allows tracking of other objects in addition to the interface line-protocol state.

A client process, such as HSRP, Virtual Router Redundancy Protocol (VRRP), or Gateway Load Balancing Protocol (GLBP), can now register its interest in tracking objects and then be notified when the tracked object changes state.

For details on EOT, refer to this URL:

For platform specific information on Enhanced Object Tracking, see [Chapter 72, “Configuring Enhanced Object Tracking.”](#)

For more detailed information on Enhanced Object Tracking, see the URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/ipapp/configuration/12-4t/iap-eot.html>

GLBP

The Gateway Load Balancing Protocol (GLBP) feature provides automatic router backup for IP hosts configured with a single default gateway on a LAN. Multiple first hop routers on the LAN combine to offer a single virtual first hop IP router while sharing the IP packet forwarding load. GLBP devices share packet-forwarding responsibilities, optimizing resource usage, thereby reducing costs. Other routers on the LAN may act as redundant GLBP routers that will become active if any of the existing forwarding routers fail. This improves the resiliency of the network and reduces administrative burden.

For details on GLBP, refer to this URL:

http://www.cisco.com/en/US/docs/ios/12_2t/12_2t15/feature/guide/ft_glb.html

Cisco IOS XE IP Application Services Features in Cisco IOS XE 3.1.0SG

This section lists the IP Application Services software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. An account on Cisco.com is not required.

Gateway Load Balancing Protocol (GLBP), GLBP MD5 Authentication

http://www.cisco.com/en/US/docs/ios/12_2sx/12_2sxh/feature/guide/sxglbpm.html

HSRP

The Hot Standby Router Protocol (HSRP) provides high network availability by routing IP traffic from hosts on Ethernet networks without relying on the availability of any single Layer 3 switch. This feature is particularly useful for hosts that do not support a router discovery protocol and do not have the functionality to switch to a new router when their selected router reloads or loses power.

For information on configuring HSRP, refer to the following URL:

http://www.cisco.com/en/US/tech/tk648/tk362/tk321/tsd_technology_support_sub-protocol_home.html

Cisco IOS XE IP Application Services: HSRP Features in Cisco IOS XE 3.1.0SG

This section lists the IP Application Services:HSRP software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. SSO—HSRP

http://www.cisco.com/en/US/docs/ios/ipapp/configuration/guide/ipapp_hsrp.html

SSO Aware HSRP

SSO Aware HSRP offers continuous data packet forwarding during a supervisor engine switchover without a path change to the standby HSRP router. During supervisor engine switchover, NSF with SSO continues forwarding data packets along known routes using the HSRP virtual IP address. When both supervisor engines fail on the active HSRP router, the standby HSRP router takes over as the active HSRP router. It further extends reliability and availability offered by the NSF with SSO to Layer 3. SSO aware HSRP is available for Supervisor Engine IV, V, and V-10GE on Catalyst 4507R and 4510R chassis with supervisor redundancy.

NHRP

Beginning in Cisco IOS XE Release 3.7.1E, NHRP is supported on Catalyst 4500 series switches.

The Next Hop Resolution Protocol (NHRP) is an ARP-like protocol that dynamically maps a Non-Broadcast Multi-Access (NBMA) network. With NHRP, systems attached to an NBMA network can dynamically learn the NBMA (physical) address of the other systems that are part of that network, allowing these systems to directly communicate.

NHRP is a client and server protocol where the hub is the Next Hop Server (NHS) and the spokes are the Next Hop Clients (NHCs). Catalyst 4500 series switches act as NHRP clients that communicate with the NHRP hub for registration, and to request the resolution of other spoke addresses.

**Note**

Catalyst 4500 series switches cannot be used as NHRP hubs.

For information on configuring NHRP, see

http://www.cisco.com/c/en/us/td/docs/ios-xml/ios/ipaddr_nhrp/configuration/xe-3s/asr1000/nhrp-xe-3s-asr1000-book/config-nhrp.html

IP Routing Protocols

The following routing protocols are supported on the Catalyst 4500 series switch:

- [BGP, page 1-17](#)
- [EIGRP, page 1-18](#)
- [IS-IS, page 1-18](#)
- [OSPF, page 1-19](#)
- [RIP, page 1-19](#)

BGP

The Border Gateway Protocol (BGP) is an exterior gateway protocol that allows you to set up an interdomain routing system to automatically guarantee the loop-free exchange of routing information between autonomous systems. In BGP, each route consists of a network number, a list of autonomous systems that information has passed through (called the autonomous system path), and a list of other path attributes.

The Catalyst 4500 series switch supports BGP version 4, including classless interdomain routing (CIDR). CIDR lets you reduce the size of your routing tables by creating aggregate routes, resulting in supernets. CIDR eliminates the concept of network classes within BGP and supports the advertising of IP prefixes. CIDR routes can be carried by OSPF, EIGRP, and RIP.

BGP Route-Map Continue

The BGP Route-Map Continue feature introduces the continue clause to the BGP route-map configuration. The continue clause provides more programmable policy configuration and route filtering. It introduces the capability to execute additional entries in a route map after an entry is executed with successful match and set clauses. Continue clauses allow configuring and organizing more modular policy definitions to reduce the number of policy configurations that are repeated within the same route map.

For details on BGP, refer to this URL:

http://www.cisco.com/en/US/docs/ios/12_4t/ip_route/configuration/guide/t_brbbas.html

EIGRP

The Enhanced Interior Gateway Routing Protocol (EIGRP) is a version of IGRP that combines the advantages of link-state protocols with distance-vector protocols. EIGRP incorporates the Diffusing Update Algorithm (DUAL). EIGRP includes fast convergence, variable-length subnet masks, partially bounded updates, and multiple network-layer support. When a network topology change occurs, EIGRP checks its topology table for a suitable new route to the destination. If such a route exists in the table, EIGRP updates the routing table instantly. You can use the fast convergence and partial updates that EIGRP provides to route Internetwork Packet Exchange (IPX) packets.

EIGRP saves bandwidth by sending routing updates only when routing information changes. The updates contain information only about the link that changed, not the entire routing table. EIGRP also takes into consideration the available bandwidth when determining the rate at which it transmits updates.

Note

Layer 3 switching does not support the Next Hop Resolution Protocol (NHRP).

Note

Customers can configure Enhanced Interior Gateway Routing Protocol (EIGRP) to route IPv6 prefixes. EIGRP configuration and protocol behavior for both IPv4 and IPv6 prefixes are similar, providing operational familiarity and continuity. EIGRP support for IPv6 will enable customers to use their existing EIGRP knowledge and processes, allowing them to deploy an IPv6 network at a low cost.

For details on EIGRP, refer to this URL:

http://www.cisco.com/en/US/products/ps6630/products_ios_protocol_option_home.html

IS-IS

The Intermediate System-to-Intermediate System Protocol (IS-IS Protocol) uses a link-state routing algorithm. It closely follows the Open Shortest Path First (OSPF) routing protocol used within the TCP/IP environment. The operation of ISO IS-IS Protocol requires each router to maintain a full topology map of the network (that is, which intermediate systems and end systems are connected to which other intermediate systems and end systems). Periodically, the router runs an algorithm over its map to calculate the shortest path to all possible destinations.

The IS-IS Protocol uses a two-level hierarchy. Intermediate Systems (or routers) are classified as Level 1 and Level 2. Level 1 intermediate systems deal with a single routing area. Traffic is relayed only within that area. Any other internetwork traffic is sent to the nearest Level 2 intermediate systems, which also acts as a Level 1 intermediate systems. Level 2 intermediate systems move traffic between different routing areas within the same domain.

An IS-IS with multi-area support allows multiple Level 1 areas within in a single intermediate system, thus allowing an intermediate system to be in multiple areas. A single Level 2 area is used as backbone for inter-area traffic.

For details on IS-IS, refer to this URL:

http://www.cisco.com/en/US/products/ps6632/products_ios_protocol_option_home.html

OSPF

The Open Shortest Path First (OSPF) protocol is a standards-based IP routing protocol designed to overcome the limitations of RIP. Because OSPF is a link-state routing protocol, it sends link-state advertisements (LSAs) to all other routers within the same hierarchical area. Information on the attached interfaces and their metrics is used in OSPF LSAs. As routers accumulate link-state information, they use the shortest path first (SPF) algorithm to calculate the shortest path to each node. Additional OSPF features include equal-cost multipath routing and routing based on the upper-layer type of service (ToS) requests.

OSPF uses the concept of an *area*, which is a group of contiguous OSPF networks and hosts. OSPF areas are logical subdivisions of OSPF autonomous systems in which the internal topology is hidden from routers outside the area. Areas allow an additional level of hierarchy different from that provided by IP network classes, and they can be used to aggregate routing information and mask the details of a network. These features make OSPF particularly scalable for large networks.

Note

For Catalyst 4500 series switch, usage of OSPF aggressive timers may lead to session transition and packet loss during CPU-intensive operation. It is recommended to use either default OSPF timers or BFD with hardware offload functionality.

For details on OSPF, refer to this URL:

http://www.cisco.com/en/US/tech/tk365/tk480/tsd_technology_support_sub-protocol_home.html

RIP

The Routing Information Protocol (RIP) is a distance-vector, intradomain routing protocol. RIP works well in small, homogeneous networks. In large, complex internetworks it has many limitations, such as a maximum hop count of 15, lack of support for variable-length subnet masks (VLSMs), inefficient use of bandwidth, and slow convergence. RIP II does support VLSMs.

For details on RIP, refer to this URL:

http://www.cisco.com/en/US/tech/tk365/tk554/tsd_technology_support_sub-protocol_home.html

In Service Software Upgrade

SSO requires the same version of Cisco IOS on both the active and standby supervisor engines. Because of version mismatch during an upgrade or downgrade of the Cisco IOS software, a Catalyst 4500 series switch is forced into operating in RPR mode. In this mode, after the switchover you can observe link-flaps and a disruption in service. This issue is solved by the In-Service Software Upgrade (ISSU) feature that enables you to operate in SSO/NSF mode while performing software upgrade or downgrade.

ISSU allows an upgrade or downgrade of the Catalyst IOS or IOS XE images at different release levels on the both the active and standby supervisor engines by utilizing the Version Transformation Framework between the stateful components running on each supervisor engine.

For details on Cisco IOS ISSU, refer to [Chapter 7, “Configuring the Cisco IOS In-Service Software Upgrade Process.”](#)

For details on Cisco IOS XE ISSU, refer to [Chapter 8, “Configuring the Cisco IOS XE In Service Software Upgrade Process.”](#)

IPv6

IPv6 provides services such as end-to-end security, quality of service (QoS), and globally unique addresses. The IPv6 address space reduces the need for private addresses and Network Address Translation (NAT) processing by border routers at network edges.

For more information about IPv6 services supported on a Catalyst 4500 series switch, see [Chapter 64, “Support for IPv6.”](#)

Multicast Services

Multicast services save bandwidth by forcing the network to replicate packets only when necessary and by allowing hosts to join and leave groups dynamically. The following multicast services are supported:

- ANCP Client —ANCP Multicast enables you to control multicast traffic on a Catalyst 4500 switch using either ANCP (rather than IGMP) or direct static configuration on the CLI.
- Cisco Group Management Protocol (CGMP) server—CGMP server manages multicast traffic. Multicast traffic is forwarded only to ports with attached hosts that request the multicast traffic.
- Internet Group Management Protocol (IGMP) snooping—IGMP snooping manages multicast traffic. The switch software examines IP multicast packets and forwards packets based on their content. Multicast traffic is forwarded only to ports with attached hosts that request multicast traffic.

Support for IGMPv3 provides constrained flooding of multicast traffic in the presence of IGMPv3 hosts or routers. IGMPv3 snooping listens to IGMPv3 query and membership report messages to maintain host-to-multicast group associations. It enables a switch to propagate multicast data only to ports that need it. IGMPv3 snooping is fully interoperable with IGMPv1 and IGMPv2.

Explicit Host Tracking (EHT) is an extension to IGMPv3 snooping. EHT enables immediate leave operations on a per-port basis. EHT can be used to track per host membership information or to gather statistics about all IGMPv3 group members.

The IGMP Snooping Querier is a Layer 2 feature required to support IGMP snooping in a VLAN where PIM and IGMP are not configured because the multicast traffic does not require routing.

For information on configuring IGMP snooping, see [Chapter 28, “Configuring IGMP Snooping and Filtering, and MVR.”](#)

- IPv6 Multicast Listen Discovery (MLD) and Multicast Listen Discovery snooping—MLD is a protocol used by IPv6 multicast devices to discover the presence of multicast listeners (nodes that want to receive IPv6 multicast packets) on its directly attached links and to discover which multicast packets are of interest to neighboring nodes. MLD snooping is supported in two different versions: MLD v1 and MLD v2. Network switches use MLD snooping to limit the flood of multicast traffic, causing IPv6 multicast data to be selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This lessens the load on devices in the network, minimizing unnecessary bandwidth on links, enabling efficient distribution of IPv6 multicast data.

For information on configuring multicast services, see [Chapter 30, “Configuring IPv6 Multicast Listener Discovery Snooping.”](#)

- Protocol Independent Multicast (PIM)—PIM is protocol-independent because it can leverage whichever unicast routing protocol is used to populate the unicast routing table, including EIGRP, OSPF, BGP, or static route. PIM also uses a unicast routing table to perform the Reverse Path Forwarding (RPF) check function instead of building a completely independent multicast routing table.

For information on PIM-SSM mapping, see the URL:

http://www.cisco.com/en/US/docs/switches/lan/catalyst6500/ios/15.1SY/config_guide/sup720/ude_udlr.html

- IP Multicast Load Splitting (Equal Cost Multipath (ECMP) Using S, G and Next Hop)—IP Multicast Load Splitting introduces more flexible support for ECMP multicast load splitting by adding support for load splitting based on source and group address and on source, group, and next-hop address. This feature allows multicast traffic from devices that send many streams to groups or that broadcast many channels, such as IPTV servers or MPEG video servers, to be more effectively load shared across equal-cost paths.

For information on configuring multicast services, see [Chapter 39, “Configuring IP Multicast.”](#)

NSF with SSO

Non-Stop Forwarding with Stateful Switchover (NSF/SSO) offers continuous data packet forwarding in a Layer 3 routing environment during supervisor engine switchover. During supervisor engine switchover, NSF/SSO continues forwarding data packets along known routes while the routing protocol information is recovered and validated, avoiding unnecessary route flaps and network instability. With NSF/SSO, IP phone calls do not drop. NSF/SSO is supported for OSPF, BGP, EIGRP, IS-IS, and Cisco Express Forwarding (CEF). NSF/SSO is typically deployed in the most critical parts of an enterprise or service provider network, such as Layer 3 aggregation/core or a resilient Layer 3 wiring closet design. It is an essential component of single chassis deployment for critical applications. NSF/SSO is available for all shipping supervisor engines on Catalyst 4507R and 4510R chassis with supervisor redundancy.

Note

With the IP Base image, NSF is supported with EIGRP-stub routing and OSPF.

Note

With the Enterprise Services image, NSF is supported on all routing protocols except for RIP.

Note

The LAN Base image does not support NSF.

For information on NSF with SSO, see [Chapter 13, “Configuring Cisco NSF with SSO Supervisor Engine Redundancy.”](#)

OSPF for Routed Access

OSPF for Routed Access is designed specifically to enable customers to extend Layer 3 routing capabilities to the access or wiring closet.

**Note**

OSPF for Routed Access supports only one OSPFv2 and one OSPFv3 instance with a maximum number of 1000 dynamically learned routes.

With the typical topology (hub and spoke) in a campus environment, where the wiring closets (spokes) are connected to the distribution switch (hub) forwarding all nonlocal traffic to the distribution layer, the wiring closet switch does not need to hold a complete routing table. Ideally, the distribution switch sends a default route to the wiring closet switch to reach inter-area and external routes (OSPF stub or totally stub area configuration).

Refer to the following link for more details:

<http://www.cisco.com/en/US/docs/solutions/Enterprise/Campus/routed-ex.html>

With Cisco IOS Release 12.2(53)SG, the IP Base image supports OSPF for routed access. The Enterprise Services image is required if you need multiple OSPFv2 and OSPFv3 instances without route restrictions. Enterprise Services also is required to enable the VRF-lite feature.

Policy-Based Routing

Traditional IP forwarding decisions are based purely on the destination IP address of the packet being forwarded. Policy-Based Routing (PBR) enables forwarding based upon other information associated with a packet, such as the source interface, IP source address, Layer 4 ports, and so on. This feature allows network managers more flexibility in how they configure and design their networks.

Starting with Release IOS XE 3.4.0SG and IOS 15.1(2)SG, the PBR Recursive Next Hop feature enhances route maps to enable configuration of a recursive next-hop IP address. The recursive next-hop IP address can be a subnet that is not directly connected. The routing table will be looked up to find the directly connected next-hop to which to send the packet so that it is routed via the recursive next-hop that has been configured.

For more information on policy-based routing, see [Chapter 42, “Configuring Policy-Based Routing.”](#)

Unicast Reverse Path Forwarding

The Unicast Reverse Path Forwarding (Unicast RPF) feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address.

For information on URPF, see [Chapter 38, “Configuring Unicast Reverse Path Forwarding.”](#)

REVIEW DRAFT—CISCO CONFIDENTIAL

Unidirectional Link Routing

Unidirectional link routing (UDLR) provides a way to forward multicast packets over a physical unidirectional interface (such as a satellite link of high bandwidth) to stub networks that have a back channel.

For information on configuring unidirectional link routing, refer to the URL

http://www.cisco.com/en/US/docs/switches/lan/catalyst6500/ios/15.1SY/config_guide/sup720/ude_udlr.html

VRF-lite

VPN routing and forwarding (VRF-lite) is an extension of IP routing that provides multiple routing instances. Along with BGP, it enables the creation of a Layer 3 VPN service by keeping separate IP routing and forwarding tables for each VPN customer. VRF-lite uses input interfaces to distinguish routes for different VPNs. It forms virtual packet-forwarding tables by associating one or more Layer 3 interfaces with each VRF, allowing the creation of multiple Layer 3 VPNs on a single switch. Interfaces in a VRF could be either physical, such as an Ethernet port, or logical, such as a VLAN switch virtual interface (SVI). However, interfaces cannot belong to more than one VRF at any time.

Prior to Release IOS XE 3.5.0E and IOS 15.2(1)E, only IPv4 was available. With Release IOS XE 3.5.0E and IOS 15.2(1)E, VRF-lite support has been extended to IPv6.

For information on VRF-lite, see [Chapter 43, “Configuring VRF-lite.”](#)

Virtual Router Redundancy Protocol

Virtual Router Redundancy Protocol (VRRP) is a standard based first-hop redundancy protocol. With VRRP, a group of routers function as one virtual router by sharing one virtual IP address and one virtual MAC address. The master router performs packet forwarding, while the backup routers stay idle. VRRP is typically used in the multi-vendor first-hop gateway redundancy deployment.

For details on VRRP, refer to this URL:

http://www.cisco.com/en/US/docs/ios/ipapp/configuration/guide/ipapp_vrrp_ps6441_TSD_Products_Configuration_Guide_Chapter.html

Management Features

The Catalyst 4500 series switch offers network management and control using the CLI or through alternative access methods, such as SNMP. The switch software supports these network management features:

- [Cisco Call Home, page 1-24](#)
- [Cisco Energy Wise, page 1-25](#)
- [Cisco IOS IP Service Level Agreements, page 1-25](#)

Cisco Call Home

Call Home provides e-mail-based and web-based notification of critical system events. A versatile range of message formats are available for optimal compatibility with pager services, standard e-mail, or XML-based automated parsing applications. Common uses of this feature may include direct paging of a network support engineer, e-mail notification to a Network Operations Center, XML delivery to a support website, and utilization of Cisco Smart Call Home services for direct case generation with the Cisco Systems Technical Assistance Center (TAC).

The Call Home feature can deliver alert messages containing information on configuration, diagnostics, environmental conditions, inventory, and syslog events.

For more information on Call Home, see [Chapter 79, “Configuring Call Home.”](#)

Cisco Energy Wise

Cisco EnergyWise is an energy-management technology added onto Cisco switching solutions to help you measure, report, and reduce energy consumption across your entire infrastructure. With EnergyWise's management interface, network management applications can communicate with endpoints and each other, using the network as the unifying fabric.

For details refer to the URLs:

http://www.cisco.com/en/US/docs/switches/lan/energywise/phase2/ios/configuration/guide/ew_v2.html

http://www.cisco.com/en/US/docs/switches/lan/energywise/phase2_5/ios/release/notes/ol23554.html#wp604941

Cisco IOS IP Service Level Agreements

Cisco IOS IP Service Level Agreements (SLAs) allows Cisco customers to analyze IP service levels for IP applications and services by using active traffic monitoring—the generation of traffic in a continuous, reliable, and predictable manner—for measuring network performance. With Cisco IOS IP SLA, service provider customers can measure and provide service level agreements, and enterprise customers can verify service levels, verify outsourced service level agreements, and understand network performance. Cisco IOS IP SLAs can perform network assessments, verify quality of service (QoS), ease the deployment of new services, and assist with network troubleshooting.

For platform-specific information on Cisco IOS IP SLA, see [Chapter 80, “Configuring Cisco IOS IP SLA Operations.”](#)

For more detail on Cisco IOS IP SLAs, see the *Cisco IOS IP SLAs Configuration Guide, Release 12.4T*: http://www.cisco.com/en/US/docs/ios/ipsla/configuration/guide/12_4t/sla_12_4t_book.html

A Catalyst 4500 series switch also supports a Built-in Traffic Simulator using Cisco IOS IP SLAs video operations to generate synthetic traffic for a variety of video applications, such as Telepresence, IPTV and IP video surveillance camera. You can use the simulator tool:

- for network assessment before deploying applications that have stringent network performance requirements.
- along with the Cisco IOS Mediatrace for post-deployment troubleshooting for any network related performance issues.

The traffic simulator includes a sophisticated scheduler that allows the user to run several tests simultaneously or periodically and over extended time periods. (Supported only on switches running the Enterprise Services feature set.)

For information on configuring this feature, see the *Configuring Cisco IOS IP SLAs Video Operations* document at:

http://www.cisco.com/en/US/docs/ios-xml/ios/ipsla/configuration/12-2se/sla_video.html

Cisco Media Services Proxy

The Media Services Proxy (MSP) feature identifies various media end points in the network automatically and renders appropriate media services. It acts as a layer that connects appropriate devices with their respective network services automatically.

MSP follows a network-centric model, where the access switches and routers learn information about devices and flow by using mechanisms such as Cisco Discovery Protocol (formerly known as CDP) and DHCP, or by snooping on key protocol packets such as the Session Initiation Protocol (SIP) and H.323. Modifications to the endpoints are not required to achieve the information learning. After the information is gleaned, MSP provides appropriate services to the network devices.

Following are the benefits of MSP:

- Automatic identification of devices and flow in the network.
- Application of appropriate services to the endpoints.
- Configuration control for the administrator, thereby reducing the manual configuration and management of services. For example, configuring the Resource Reservation Protocol (RSVP) in the network for video applications requiring guaranteed bandwidth.

Note The system cannot scale to greater than 512 SIP flows with MSP and Flow Metadata enabled.

For information on configuring this feature, refer to the following documents:

<http://www.cisco.com/en/US/docs/ios-xml/ios/msp/configuration/15-1sg/med-ser-prxy.html>

<http://www.cisco.com/en/US/docs/ios-xml/ios/msp/configuration/xe-3sg/med-ser-prxy-xe.html>

Cisco Medianet AutoQoS

Cisco Medianet AutoQoS provides a default configuration to ease the process of enabling QoS on switches. This process can be difficult given the functional/behavioral differences in QoS across different platforms. This functionality extend AutoQoS functionality for the Catalyst 4500 to support video traffic as well as other kinds of traffic.

The goal of AutoQoS is to simplify the work customers have to undertake while configuring their networks to support QoS. This is done by automating QoS configurations to handle various classes of traffic. AutoQoS for Medianet provides commands, which act as macros that call existing CLI commands to implement desired configurations. You are required to specify the type of device (PC, another switch, ip camera, etc.) connected to a given interface. AutoQoS for Medianet applies a default QoS configuration to that interface, which you can later fine-tune as needed.

For details, refer to [Chapter 44, “Configuring Quality of Service.”](#)

Cisco Medianet Flow Metadata

Flow Metadata is the data that qualifies other data. Flow Metadata aids in supporting an intelligent network by making the network aware about the type, nature, and characteristics of the media stream that flows in the network. Flow Metadata also allows for the network to apply policies on the media streams. Across the Medianet system, Flow Metadata is produced, transported, stored, retrieved, and acted on consistently by a wide variety of Medianet services.

The Flow Metadata infrastructure provides a framework that allows data from one component be available to another component on the same network element as well as across network elements.

Flow Metadata is supported on releases prior to Cisco IOS Release 15.1(1)SG. Flow metadata is the data that describes a flow in the network. This Flow Metadata describes the five tuple flow along with the attributes. Network elements can take action based on the Flow Metadata generated by the endpoints.

The Flow Metadata infrastructure consists of two major components: producers and consumers.

- Flow Metadata producer is any source of Flow Metadata. The producer propagates all the attributes of a given flow. Producers can be anywhere in the network: endpoint, proxy agents, or intermediate nodes. Currently, Flow Metadata generated by the endpoints is supported. Producers use a specific transport protocol, such as RSVP for signalling the Flow Metadata attributes and store the information in a database, referred to as the control plane database, which can then be used by the consumers.
- Flow Metadata consumer is any network element that uses the flow tuple and Flow Metadata provided by the producers. The flow tuple and Flow Metadata can also be propagated along the media path to consumers in different network elements via a transport infrastructure.

For configuration details, refer to the following URLs:

<http://www.cisco.com/en/US/docs/ios-xml/ios/mdata/configuration/xe-3sg/metadata-framework.html>

<http://www.cisco.com/en/US/docs/ios-xml/ios/mdata/configuration/15-1sg/metadata-framework.html>

For details on the Flow Metadata commands, refer to the following URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/qos/command/qos-cr-book.html>

Cisco IOS Mediatrace and Performance Monitor

Cisco IOS Mediatrace helps to isolate and troubleshoot network degradation problems by enabling a network administrator to discover an IP flow's path, dynamically enable monitoring capabilities on the nodes along the path, and collect information on a hop-by-hop basis. This information includes, among other things, flow statistics; utilization information for incoming and outgoing interfaces, CPUs, and memory; as well as any changes to IP routes or the Cisco IOS Mediatrace monitoring state.

For details, see the following URLs:

http://www.cisco.com/en/US/docs/ios-xml/ios/media_monitoring/configuration/15-1sg/mm-pasv-mon.html

http://www.cisco.com/en/US/docs/ios-xml/ios/media_monitoring/configuration/xe-3sg/mm-pasv-mon.html

http://www.cisco.com/en/US/docs/ios/media_monitoring/command/reference/mm_book.html

http://www.cisco.com/en/US/docs/ios-xml/ios/media_monitoring/configuration/15-1sg/mm-mediatriace.html

http://www.cisco.com/en/US/docs/ios-xml/ios/media_monitoring/configuration/xe-3sg/mm-mediatriace.html

Configuration guidelines for Cisco IOS Mediatrace and Performance Monitor include the following:

- Video monitoring is supported only on physical ports.

Limitations for Cisco IOS Mediatrace and Performance Monitor on a Catalyst 4500 series switch include the following:

- Both features can only be configured to monitor ingress traffic.
- Packets cannot be monitored by both CEure and the rxSPAN session with encapsulation. The first-applied configuration takes precedence.
- Not all packets received by an interface can be monitored. After a packet is received by an ingress interface, it might be either unable to make a forwarding decision or dropped at various stages because of configured security features (like IP Source Guard). The switch attempts to monitor packets close to the switch, but only those that are not dropped before the input classification stage can be monitored.

REVIEW DRAFT—CISCO CONFIDENTIAL

- CPU utilization is impacted when you monitor a high traffic rate. After the internally-determined threshold is crossed, monitored packets are dropped although the original packet is forwarded in hardware intact. Starting with Release IOS XE 3.3.0SG and IOS 15.1(1)SG, monitored packets might be dropped if any of the following apply:
 - The packet rate exceeds 512 PPS per flow.
 - The aggregated bandwidth of the monitor traffic exceeds 10Mbps.
 - Resources are insufficient to enqueue a new monitored packet.

When monitored packets are dropped, the *monitor event* will be set to TRUE if the flow record contains *collect monitor event*. If one minute passes with no new drops, the *monitor event* is set to FALSE but is not reflected in the output of the **show performance monitor status** until the new monitor interval starts.

monitor event is a global flag. This means that any packet drops that would trigger "monitor event" be set to TRUE for all monitored flows at that monitor interval. If a metric depends on the collection of continuous packets, the accuracy of that metric might be impacted when a *monitor event* is TRUE.

Cisco Network Assistant

Cisco Network Assistant manages standalone devices, clusters of devices, or federations of devices from anywhere in your intranet. Using its graphical user interface, you can perform multiple configuration tasks without having to remember command-line interface commands. Embedded CiscoView is a device management application that can be embedded on the switch flash and provides dynamic status, monitoring, and configuration information for your switch.

For more information on Cisco Network Assistant, see [Chapter 16, “Configuring Catalyst 4500 Series Switches with Cisco Network Assistant.”](#)

Dynamic Host Control Protocol

The Catalyst 4500 series switch uses DHCP in the following ways:

- Dynamic Host Control Protocol server—The Cisco IOS DHCP server feature is a full DHCP server implementation that assigns and manages IP addresses from specified address pools within the router to DHCP clients. If the Cisco IOS DHCP server cannot satisfy a DHCP request from its own database, it can forward the request to one or more secondary DHCP servers defined by the network administrator.
- Dynamic Host Control Protocol autoconfiguration—With this feature your switch (the DHCP client) is automatically configured at startup with IP address information and a configuration file.

For DHCP server configuration information, refer to the chapter, “Configuring DHCP,” in the *Cisco IOS IP and IP Routing Configuration Guide* at the following URL:

http://www.cisco.com/en/US/docs/ios/ipaddr/configuration/guide/iad_dhcp_rdmf_ps6350_TSD_Products_Configuration_Guide_Chapter.html

Easy Virtual Network

Easy Virtual Network (EVN) is an IP-based virtualization technology that provides end-to-end virtualization of the network. You can use a single IP infrastructure to provide separate virtual networks whose traffic paths remain isolated from each other. Configure Easy Virtual Network to configure two or more virtual IP networks.

For details on EVN, refer to the following URLs:

<http://www.cisco.com/en/US/docs/ios-xml/ios/evn/configuration/xe-3s/evn-xe-3s-book.html>

The following restrictions/feature interactions apply:

- Multicast

When multicast traffic traverses VRFs, where source and receivers are in different VRFs, multicast counters will not increment on receivers' VRFs.

- NetFlow

When configured on an EVN trunk interface, NetFlow captures traffic information for all VRFs but does not preserve the VRF information.

- SPAN

- When an EVN trunk interface is configured as a SPAN source, traffic belonging to all VRFs carried by the EVN trunk is spanned. By default, the VNET tag is not preserved. To preserve it, configure SPAN destination with the **encapsulation dot1q** option.
- To span traffic belonging to specific VRFs on an EVN trunk, configure **filter vlan** on the SPAN session with the corresponding VNET tags as `vlan_ids` and configure VLANs specified in **filter vlan**.
- To span traffic in specific VRFs on all interfaces, configure **vlan** as the SPAN source with VNET tags as `vlan_ids` and configure VLANs specified as sources.
- If `cpu` is configured as a SPAN source, then transmit packets that will be spanned are tagged by default. If the **encapsulation dot1q** option is set on the SPAN session, then the `cpu` transmitted packets, which are spanned, are double tagged.

Refer to [Chapter 69, “Configuring SPAN and RSPAN,”](#) for information on configuring SPAN sessions.

Embedded CiscoView

A web-based tool to configure the Catalyst 4500 series switch. Embedded CiscoView is a device management application that can be embedded on the switch flash and provides dynamic status, monitoring, and configuration information for your switch.

For more information on Embedded CiscoView, see [Chapter 4, “Administering the Switch.”](#)

Embedded Event Manager

Embedded Event Manager (EEM) is a distributed and customized approach to event detection and recovery offered directly in a Cisco IOS device. EEM offers the ability to monitor events and take informational, corrective, or any desired EEM action when the monitored events occur or when a threshold is reached. An EEM policy is an entity that defines an event and the actions to be taken when that event occurs.

For information on EEM, see the URL:

http://www.cisco.com/en/US/products/ps6815/products_ios_protocol_group_home.html

Ethernet Management Port

The Ethernet management port, also referred to as the *Fal or fastethernet1 port*, is a Layer 3 host port to which you can connect a PC. You can use the Ethernet management port instead of the switch console port for network management. When managing a switch stack, connect the PC to the Ethernet management port on a Catalyst 4500 series switch.

For more information on Ethernet management port, see the “Using the Ethernet Management Port” section in [Chapter 9, “Configuring Interfaces.”](#)

File System Management (Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E)

The format command for IOS XE 3.1.0SG changed slightly compared to the classic IOS format because the later does not support ext2 format.

For USB flash under IOS XE 3.1.0SG, there are 3 optional formats, i.e. FAT16, FAT32 and EXT2:

```
Switch# format usb0: ?  
FAT16  FAT16 filesystem type  
FAT32  FAT32 filesystem type  
ext2   ext2 filesystem type
```

For SD card under IOS XE 3.1.0SG, the default format is FAT16:

```
Switch# format slaveusb0: ?  
FAT16  FAT16 filesystem type  
FAT32  FAT32 filesystem type  
ext2   ext2 filesystem type
```

FAT File Management System on Supervisor Engine 6-E, Supervisor Engine 6L-E

The FAT file system is widely used to manage files on devices disks and flash. The support of the FAT file system allows you to easily remove, add, and/or transfer images to and from the flash.

Forced 10/100 Autonegotiation

This feature allows you to configure a port to limit the speed at which it will autonegotiate to a speed lower than the physically maximum speed. This method of reducing the throughput incurs much less overhead than using an ACL.

Intelligent Power Management

Working with powered devices (PDs) from Cisco, this feature uses power negotiation to refine the power consumption of an 802.3af-compliant PD beyond the granularity of power consumption provided by the 802.3af class. Power negotiation also enables the backward compatibility of newer PDs with older modules that do not support either 802.3af or high-power levels as required by IEEE standard.

For more information on Intelligent Power Management, see the “Intelligent Power Management” section in [Chapter 15, “Configuring Power over Ethernet.”](#)

MAC Address Notification

MAC address notification monitors the MAC addresses that are learned by, aged out, or removed from the Catalyst 4500 series switch. Notifications are sent out or retrieved by using the CISCO-MAC-NOTIFICATION MIB. It is typically used by a central network management application to collect such MAC address notification events for host moves. User-configurable MAC table utilization thresholds can be defined to notify any potential DoS or man-in-the-middle attack.

For information on MAC Address Notification, see [Chapter 4, “Administering the Switch.”](#)

MAC Notify MIB

The MAC Notify MIB feature monitors network performance, utilization, and security conditions enabling a network administrator to track the MAC addresses that are learned or removed on the switch forwarding the Ethernet frames.

Power over Ethernet

Power over Ethernet (PoE) allows the LAN switching infrastructure to provide power to an endpoint ("powered device") over a copper Ethernet cable. This capability, once referred to as "inline power," was originally developed by Cisco in 2000 to support emerging IP telephony deployments.

IP telephones need power for operation, and Power over Ethernet supports scalable, manageable power delivery and simplifies IP telephony deployments. As wireless networking emerged, Power over Ethernet began powering wireless devices in locations where local power access did not exist.

For more information on Power over Ethernet, see [Chapter 15, “Configuring Power over Ethernet.”](#)

Secure Shell

Secure Shell (SSH) is a program that enables you to log into another computer over a network, to execute commands remotely, and to move files from one machine to another. The switch may not initiate SSH connections: SSH will be limited to providing a remote login session to the switch and will only function as a server.

Simple Network Management Protocol

Simple Network Management Protocol (SNMP) facilitates the exchange of management information between network devices. The Catalyst 4500 series switch supports these SNMP types and enhancements:

- SNMP—A full Internet standard
- SNMP v2—Community-based administrative framework for version 2 of SNMP
- SNMP v3—Security framework with three levels: noAuthNoPriv, authNoPriv, and authPriv (available only on a crypto image, such as cat4000-i5k91s-mz)

- SNMP trap message enhancements—Additional information with certain SNMP trap messages, including spanning-tree topology change notifications and configuration change notifications

For more information on SNMP, see [Chapter 75, “Configuring SNMP.”](#)

Smart Install

Note

The Smart Install feature is deprecated starting with the following Cisco IOS and IOS XE releases:

- Cisco IOS Release 15.2(2)E9 and later, Cisco IOS XE Release 3.6.9E and later
- Cisco IOS Release 15.2(4)E5 and later, Cisco IOS XE Release 3.8.5E and later
- Cisco IOS Release 15.2(6)E2 and later, Cisco IOS XE Release 3.10.2E and later

For more information, see the Cisco Security Advisory:

<https://tools.cisco.com/security/center/content/CiscoSecurityAdvisory/cisco-sa-20170214-smi>.

Beginning with Cisco IOS XE 3.4.0SG and 15.1(2)SG, Catalyst 4500 series switches supported Smart Install, which is a plug-and-play configuration and image-management feature that provides zero-touch deployment for new switches. You can ship a switch to a location, place it in the network and power it on with no configuration required on the device.

For details on Smart Install, see the URL:

http://www.cisco.com/en/US/docs/switches/lan/smart_install/configuration/guide/smart_install.html

SPAN and RSPAN

Switched Port Analyzer (SPAN) allows you to monitor traffic on any port for analysis by a network analyzer or Remote Monitoring (RMON) probe. You also can do the following:

- Configure ACLs on SPAN sessions.
- Allow incoming traffic on SPAN destination ports to be switched normally.
- Explicitly configure the encapsulation type of packets that are spanned out of a destination port.
- Restrict ingress sniffing depending on whether the packet is unicast, multicast, or broadcast, and depending on whether the packet is valid.
- Mirror packets sent to or from the CPU out of a SPAN destination port for troubleshooting purposes.

For information on SPAN, see [Chapter 69, “Configuring SPAN and RSPAN.”](#)

Remote SPAN (RSPAN) is an extension of SPAN, where source ports and destination ports are distributed across multiple switches, allowing remote monitoring of multiple switches across the network. The traffic for each RSPAN session is carried over a user-specified RSPAN VLAN that is dedicated for that RSPAN session on all participating switches.

For information on RSPAN, see [Chapter 69, “Configuring SPAN and RSPAN.”](#)

Universal Power over Ethernet

The IEEE 802.3 Power over Ethernet (PoE) standard sets the maximum power that can be sourced by data terminal equipment (DTE) at 30W. This power is sourced over two pairs out of the four twisted pairs of conductors in a Class D, or better, cabling as specified in ISO/IEC 11801:1995.

Cisco® Universal Power over Ethernet (UPOE) is a Cisco proprietary technology that extends the IEEE 802.3 PoE standard to provide the capability to source up to 60W of power over standard Ethernet cabling infrastructure (Class D or better).

For more information on UPOE, see the “Configuring Universal PoE” section in [Chapter 15](#), “Configuring Power over Ethernet.”

Web Content Coordination Protocol

**Note**

WCCP version 1 is *not* supported.

Web Content Communication Protocol (WCCP) Version 2 Layer 2 redirection enables Catalyst 4500 series switches to transparently redirect content requests to the directly connected content engines by using a Layer 2 and MAC address rewrite. The WCCPv2 Layer 2 redirection is accelerated in the switching hardware, and is more efficient than Layer 3 redirection using Generic Routing Encapsulation (GRE). The content engines in a cache cluster transparently store frequently accessed content, and then fulfill successive requests for the same content, eliminating repetitive transmissions of identical content from the original content servers. It supports the transparent redirection of HTTP and non-HTTP traffic with ports or dynamic services, such as Web caching, HTTPS caching, File Transfer Protocol (FTP) caching, proxy caching, media caching, and streaming services. WCCPv2 Layer 2 redirection is typically deployed for transparent caching at network edge, such as regional or branch sites. WCCPv2 Layer 2 redirection cannot be enabled on the same input interface with PBR or VRF-lite. ACL-based classification for Layer 2 redirection is not supported.

For information on WCCP, see [Chapter 83](#), “Configuring WCCP Version 2 Services.”

Wireshark

**Note**

Wireshark is supported only on Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, and Catalyst 4500X.

Starting with Cisco IOS Release XE 3.3.0SG and the IP Base and Enterprise Services feature sets, the Catalyst 4500 series switch supports Wireshark. This is a packet analyzer program, formerly known as Ethereal that supports multiple protocols and presents information in a graphical and text-based user interface. Wireshark is applied or enabled on an individual interface; global packet capture is not supported.

For information on Wireshark, see [Chapter 71](#), “Configuring Wireshark.”

XML-PI

eXtensible Markup Language Programmatic Interface (XML-PI) Release 1.0 leverages the Network Configuration Protocol (NETCONF). It provides new data models that collect running configurations and **show** command output down to the keyword level without requiring the technologies or external XML-to-command line interface (CLI) gateways. XML-PI allows you to develop XML-based network management applications to control any number of network devices simultaneously.

Refer to the following link for more details:

http://www.cisco.com/en/US/docs/ios/netmgmt/configuration/guide/nm_xmlpi_v1.html

Security Features

The Catalyst 4500 series switch offers network management and control through the CLI or through alternative access methods, such as SNMP. The switch software supports these security features:

- [802.1X Identity-Based Network Security, page 1-35](#)
- [Dynamic ARP Inspection, page 1-37](#)
- [Cisco TrustSec Security Architecture, page 1-36](#)
- [Cisco TrustSec Security Groups, SGTs and SGACLs, page 1-37](#)
- [Dynamic ARP Inspection, page 1-37](#)
- [Dynamic Host Configuration Protocol Snooping, page 1-37](#)
- [Flood Blocking, page 1-38](#)
- [Hardware-Based Control Plane Policing, page 1-38](#)
- [IP Source Guard, page 1-38](#)
- [IP Source Guard for Static Hosts, page 1-38](#)
- [IPsec VPN, page 1-40](#)
- [IPv6 First Hop Security, page 1-39](#)
- [Local Authentication, RADIUS, and TACACS+ Authentication, page 1-40](#)
- [Network Admission Control, page 1-40](#)
- [Network Security with ACLs, page 1-41](#)
- [Port Security, page 1-41](#)
- [PPPoE Intermediate Agent, page 1-42](#)
- [Session Aware Networking, page 1-42](#)
- [Storm Control, page 1-42](#)
- [uRPF Strict Mode, page 1-43](#)
- [Utilities, page 1-43](#)
- [Web-based Authentication, page 1-44](#)

802.1X Identity-Based Network Security

This security feature consists of the following:

- 802.1X Authentication for Guest VLANs—Allows you to use VLAN assignment to limit network access for certain users.
- 802.1X Authentication Failed Open Assignment—Allows you to configure a switch to handle the case when a device fails to authenticate itself correctly through 802.1X (for example, not providing the correct password).
- 802.1X Authentication with ACL Assignment—Downloads per-host policies such as ACLs and redirect URLs to the switch from the RADIUS server during 802.1X or MAB authentication of the host.
- 802.1X Authentication with Per-User ACL and Filter-ID ACL—Allows ACL policy enforcement using a third-party AAA server.
- 802.1X Convergence—Provides consistency between the switching business units in 802.1X configuration and implementation.
- 802.1X Protocol—Provides a means for a host that is connected to a switch port to be authenticated before it is given access to the switch services.
- 802.1X RADIUS accounting—Allows you to track the use of network devices.
- 802.1X Supplicant and Authenticator Switches with Network Edge Access Topology (NEAT)—Extends identity to areas outside the wiring closet (such as conference rooms). NEAT is designed for deployment scenarios where a switch acting as 802.1X authenticator to end-hosts (PC or Cisco IP-phones) is placed in an unsecured location (outside wiring closet); the authenticator switch cannot always be trusted.
- 802.1X with Authentication Failed VLAN Assignment—Allows you to provide access for authentication failed users on a per-port basis. Authentication failed users are end hosts that are 802.1X-capable but do not have valid credentials in an authentication server or end hosts that do not give any username and password combination in the authentication pop-up window on the user side.
- 802.1X with Inaccessible Authentication Bypass—Applies when the AAA servers are unreachable or nonresponsive. In this situation, 802.1X user authentication typically fails with the port closed, and the user is denied access. Inaccessible Authentication Bypass provides a configurable alternative on the Catalyst 4500 series switch to grant a critical port network access in a locally specified VLAN.
- 802.1X with Port Security—Allows port security on an 802.1X port in either single- or multiple-host mode. When you enable port security and 802.1X on a port, 802.1X authenticates the port, and port security manages the number of MAC addresses allowed on that port, including that of the client.
- 802.1X with MAC Authentication Bypass—Provides network access to agentless devices without 802.1X supplicant capabilities, such as printers. Upon detecting a new MAC address on a switch port, the Catalyst 4500 series switch will proxy an 802.1X authentication request based on the device's MAC address.
- 802.1X with RADIUS-Provided Session Timeouts—Allows you to 802.1X with Unidirectional Controlled Port—Allows the Wake-on-LAN (WoL) magic packets to reach a workstation attached to an unauthorized 802.1X switch port. Unidirectional Controlled Port is typically used to send operating systems or software updates from a central server to workstations at night.
- 802.1X with Violation Mode—This feature allows you to configure 802.1X security violation behavior as either shutdown, restrict, or replace mode, based on the response to the violation.

- 802.1X with VLAN assignment—This feature allows you to enable non-802.1X-capable hosts to access networks that use 802.1X authentication.
- 802.1X with VLAN user distribution—An alternative to dynamically assigning a VLAN ID or a VLAN name, this feature assign a VLAN Group name. It enables you to distribute users belonging to the same group (and characterized by a common VLAN Group name) across multiple VLANs. Ordinarily, you do this to avoid creating an overly large broadcast domain.
- 802.1X with Voice VLAN—This feature allows you to use 802.1X security on a port while enabling it to be used by both Cisco IP phones and devices with 802.1X supplicant support.
- Multi-Domain Authentication—This feature allows both a data device and a voice device, such as an IP phone (Cisco or non-Cisco), to authenticate on the same switch port, which is divided into a data domain and a voice domain.
- RADIUS Change of Authorization—This feature employs Change of Authorization (CoA) extensions defined in RFC 5176 in a push model to allow for the dynamic reconfiguring of sessions from external authentication, authorization, and accounting (AAA) or policy servers.

For more information on 802.1X identity-based network security, see [Chapter 49, “Configuring 802.1X Port-Based Authentication.”](#)

Cisco TrustSec MACsec Encryption

MACsec (Media Access Control Security) is the IEEE 802.1AE standard for authenticating and encrypting packets between two MACsec-capable devices. The Catalyst 4500 series switch supports 802.1AE encryption with MACsec Key Agreement (MKA) on downlink ports for encryption between the switch and host devices. The switch also supports MACsec link layer switch-to-switch security by using Cisco TrustSec Network Device Admission Control (NDAC) and the Security Association Protocol (SAP) key exchange. Link layer security can include both packet authentication between switches and MACsec encryption between switches (encryption is optional).

For more information on TrustSec MACsec encryption, see [Chapter 48, “Configuring MACsec Encryption.”](#)

Cisco TrustSec Security Architecture

The Cisco TrustSec security architecture builds secure networks by establishing domains of trusted network devices. Each device in the domain is authenticated by its peers. Communication on the links between devices in the domain is secured with a combination of encryption, message integrity check, and data-path replay protection mechanisms. Cisco TrustSec uses the device and user credentials acquired during authentication for classifying the packets by security groups (SGs) as they enter the network. This packet classification is maintained by tagging packets on ingress to the Cisco TrustSec network so that they can be properly identified for the purpose of applying security and other policy criteria along the data path. The tag, called the security group tag (SGT), allows the network to enforce the access control policy by enabling the endpoint device to act upon the SGT to filter traffic.

For more information, refer to the following URL:

<http://www.cisco.com/en/US/docs/switches/lan/trustsec/configuration/guide/trustsec.html>

Cisco TrustSec Security Groups, SGTs and SGACLs

**Note**

This support is provided only on Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E, and Catalyst 4500X.

A security group is a grouping of users, endpoint devices, and resources that share access control policies. Security groups are defined by the administrator in the Cisco ISE or Cisco Secure ACS. As new users and devices are added to the Cisco TrustSec domain, the authentication server assigns these new entities to appropriate security groups. Once a device is authenticated, Cisco TrustSec tags any packet that originates from that device with a security group tag (SGT) that contains the security group number of the device. The packet carries this SGT throughout the network.

Using security group access control lists (SGACLs), you can control the operations that users can perform based on the security group assignments of users and destination resources.

For more information, refer to the following URL:

<http://www.cisco.com/en/US/docs/switches/lan/trustsec/configuration/guide/trustsec.html>

For Cisco TrustSec SGFT and SGACL guidelines and restrictions that apply on the Catalyst 4500 series switch, refer to "Appendix B. Notes for the Catalyst 4500 Series Switches" in the *Cisco TrustSec Switch Configuration Guide*.

Dynamic ARP Inspection

Dynamic ARP Inspection (DAI) intercepts all ARP requests, replies on untrusted ports, and verifies each intercepted packet for valid IP to MAC bindings. Dynamic ARP Inspection helps to prevent attacks on a network by not relaying invalid ARP replies out to other ports in the same VLAN. Denied ARP packets are logged by the switch for auditing.

For more information on dynamic ARP inspection, see [Chapter 58, "Configuring Dynamic ARP Inspection."](#)

Dynamic Host Configuration Protocol Snooping

Dynamic Host Configuration Protocol (DHCP) Snooping is a security feature that is a component of a DHCP server. DHCP snooping provides security by intercepting untrusted DHCP messages and by building and maintaining a DHCP snooping binding table. An untrusted message is a message that is received from outside the network or firewall that can cause traffic attacks within your network.

DHCP snooping acts like a firewall between untrusted hosts and DHCP servers. It also provides a way to differentiate between untrusted interfaces connected to the end-user and trusted interfaces connected to the DHCP server or another switch.

With SSO support, DHCP Snooping propagates the DHCP-snooped data from the active supervisor engine to the redundant supervisor engine so that when a switchover occurs, the newly active supervisor engine is aware of the DHCP data that was already snooped, and the security benefits continue uninterrupted.

For DHCP server configuration information, refer to the chapter, "Configuring DHCP," in the *Cisco IOS IP and IP Routing Configuration Guide* at the following URL:

http://www.cisco.com/en/US/docs/ios/ipaddr/configuration/guide/iad_dhcp_rdmf_ps6350_TSD_Products_Configuration_Guide_Chapter.html

For information on configuring DHCP snooping, see [Chapter 60, “Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts.”](#)

Flood Blocking

Flood blocking enables users to disable the flooding of unicast and multicast packets on a per-port basis. Occasionally, unknown unicast or multicast traffic from an unprotected port is flooded to a protected port because a MAC address has timed out or has not been learned by the switch.

For information on flood blocking, see [Chapter 67, “Port Unicast and Multicast Flood Blocking.”](#)

Hardware-Based Control Plane Policing

Control Plane Policing provides a unified solution to limit the rate of CPU bound control plane traffic in hardware. It enables users to install system wide control plane ACLs to protect the CPU by limiting rates or filtering out malicious DoS attacks. Control plane policing ensures the network stability, availability and packet forwarding, and prevents network outages such as loss of protocol updates despite an attack or heavy load on the switch. Hardware-based control plane policing is available for all Catalyst 4500 supervisor engines. It supports various Layer 2 and Layer 3 control protocols, such as CDP, EAPOL, STP, DTP, VTP, ICMP, CGMP, IGMP, DHCP, RIPv2, OSPF, PIM, TELNET, SNMP, HTTP, and packets destined to 224.0.0.* multicast link local addresses. Predefined system policies or user-configurable policies can be applied to those control protocols.

Through Layer 2 Control Packet QoS, you can police control packets arriving on a physical port or VLAN; it enables you to apply QoS on Layer 2 control packets

For information on control plane policing and Layer 2 control packet QoS, see [Chapter 57, “Configuring Control Plane Policing and Layer 2 Control Packet QoS.”](#)

IP Source Guard

Similar to DHCP snooping, this feature is enabled on an untrusted Layer 2 port that is configured for DHCP snooping. Initially all IP traffic on the port is blocked except for the DHCP packets, which are captured by the DHCP snooping process. When a client receives a valid IP address from the DHCP server, a PVACL is installed on the port, which restricts the client IP traffic only to clients with assigned IP addresses, so any IP traffic with source IP addresses other than those assigned by the DHCP server will be filtered out. This filtering prevents a malicious host from attacking a network by hijacking neighbor host's IP address.

For information on configuring IP Source Guard, see [Chapter 60, “Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts.”](#)

IP Source Guard for Static Hosts

This feature allows you to secure the IP address learned from static hosts by using ARP packets and then bind that IP address to a given MAC address using the device tracking database, allowing entries to survive through link down events.

IP Source Guard (IPSG) for static hosts allows multiple bindings per-port per-MAC address for both DHCP and static hosts, in both device tracking database and DHCP snooping binding database. The feature allows you to take action when a limit is exceeded.

For information on configuring IPSG for static hosts, see [Chapter 60, “Configuring DHCP Snooping, IP Source Guard, and IPSG for Static Hosts.”](#)

IPv6 First Hop Security

**Note**

IPv6 First Hop Security is supported only on Catalyst 4500-X, Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, 6L-E, and 6-E.

IPv6 FHS is a suite of features designed to secure link operations in an IPv6 enabled network as well as address certain scalability issues seen in large L2 domains. IPv6 FHS provides effective counter measures for the following types of attacks or misconfiguration errors that could result in DoS or information theft:

- Router impersonation (MiM attacks)
- Address theft
- Address spoofing
- Remote address resolution cache exhaustion (DoS attacks)

These attacks can come from malicious or mis-configured users and could result in severe disruption to users of the Layer 2 domain and to the network in general.

The following features are supported:

- DAD Proxy
- Data Glean
- Destination Guard
- IPv6 Snooping (DHCP Data Gleaning, per-limit Address Limit)
- IPv6 Address Glean
- IPv6 Device Tracking
- Lightweight DHCPv6 Relay Agent (LDRA)
- NDP Inspection
- Per ND Cache Limit
- Per Port Address Limit
- Source and Prefix Guard

**Note**

IPv6 LDRA is the only FHS feature supported on EtherChannels.

**Note**

Configuring IPv6 FHS on secondary VLANs is not allowed; they inherit the policy from the primary VLAN configuration. Whatever policy is applied on the primary VLANs is programmed automatically on the associated secondary VLANs. The applied policy, however, always overrides the VLAN level configuration.

The following caveats are specific for Data Glean, Prefix Guard, and Source Guard enabled on a Catalyst 4500 series switch:

- First Hop Security (FHS) cannot be configured on the same port or VLAN as dot1X, because the latter asserts control over the MAC table and FHS requires similar control to allow only valid NDP or DHCPv6 hosts.
- If unicast Rpf (unicast reverse path forwarding; uRPF) is configured on box and FHS is enabled, Forward Lookup CAM is populated with routes from FHS and uRPF. Packets that normally fail the uRPF check are admitted provided it passes the Source Guard or Prefix Guard check.
- If Data Glean policy and Source Guard (or Prefix Guard) are applied such that VLAN policies and port policies differ, neither VLAN nor port policy are effective.
- All ICMP and DHCP version 6 control packets are permitted even when Source Guard or Prefix Guard is enabled.

For a brief overview of FHS, see the URL:

http://www.cisco.com/en/US/prod/collateral/iosswrel/ps6537/ps6553/aag_c45-707354.pdf

For detailed information on how to implement FHS, see the URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/ipv6/configuration/12-4t/ip6-first-hop-security.html>

IPsec VPN

When a growing organization expands to multiple locations, one of the challenges it faces is how to interconnect remote sites to the corporate network. As network security risks increase and regulatory compliance becomes essential, it is important to address these critical needs.

You can dramatically increase the reach of your network without significantly expanding your infrastructure by using Cisco IOS IPsec VPNs. IPsec is a standards-based encryption technology that enables you to securely connect branch offices and remote users and provides significant cost savings compared to traditional WAN access such as Frame Relay or ATM. IPsec VPNs provide high levels of security through encryption and authentication, protecting data from unauthorized access.

For additional information, refer to the following URL:

http://www.cisco.com/en/US/products/ps6635/products_ios_protocol_group_home.html

Local Authentication, RADIUS, and TACACS+ Authentication

Local Authentication, Remote Authentication Dial-In User Service (RADIUS), and Terminal Access Controller Access Control System Plus (TACACS+) authentication methods control access to the switch. For additional information, refer to the following URL:

http://www.cisco.com/en/US/docs/ios/sec_user_services/configuration/guide/sec_cfg_authntifcn_ps6350_TSD_Products_Configuration_Guide_Chapter.html

Network Admission Control

Network Admission Control consists of two features:

- NAC Layer 2 IP validation

NAC Layer 2 IP is an integral part of Cisco Network Admission Control. It offers the first line of defense for infected hosts (PCs and other devices attached to a LAN port) attempting to connect to the corporate network. NAC Layer 2 IP on the Catalyst 4500 series switch performs posture validation at the Layer 2 edge of the network for non-802.1x-enabled host devices. Host device

posture validation includes antivirus state and OS patch levels. Depending on the corporate access policy and host device posture, a host may be unconditionally admitted, admitted with restricted access, or quarantined to prevent the spread of viruses across the network.

For more information on Layer 2 IP validation, see the URL:

http://www.cisco.com/en/US/docs/net_mgmt/cisco_secure_access_control_server_for_windows/4.1/configuration/guide/nac_conf.html

- NAC Layer 2 802.1X authentication

The Catalyst 4500 series switch extends NAC support to 802.1x-enabled devices. Like NAC Layer 2 IP, the NAC Layer 2 802.1x feature determines the level of network access based on endpoint information.

For more information on 802.1X identity-based network security, see [Chapter 49, “Configuring 802.1X Port-Based Authentication.”](#)

Network Security with ACLs

An access control list (ACL) filters network traffic by controlling whether routed packets are forwarded or blocked at the router interfaces. The Catalyst 4500 series switch examines each packet to determine whether to forward or drop the packet based on the criteria you specified within the access lists.

MAC access control lists (MACLs) and VLAN access control lists (VACLs) are supported. VACLs are also known as VLAN maps in Cisco IOS.

The Catalyst 4500 series switch supports three types of ACLs:

- IP ACLs, which filter IP traffic, including TCP, the User Datagram Protocol (UDP), Internet Group Management Protocol (IGMP), and Internet Control Message Protocol (ICMP)
- IPv6 ACLs
- MAC ACLs which match based on Ethernet addresses and Ether Type

The switch supports the following applications of ACLs to filter traffic:

- MAC address filtering, which enables you to block unicast traffic for a MAC address on a VLAN interface.
- Port ACLs, which enable you to apply ACLs to Layer 2 interfaces on a switch for inbound traffic.
- Router ACLs, which are applied to Layer 3 interfaces to control the access of routed traffic between VLANs.
- VLAN ACLs or VLAN maps to control the access of all packets (bridged and routed).

For information on ACLs, MACLs, VLAN maps, MAC address filtering, and Port ACLs, see [Chapter 62, “Configuring Network Security with ACLs.”](#)

Port Security

Port security restricts traffic on a port based upon the MAC address of the workstation that accesses the port. Trunk port security extends this feature to trunks, including private VLAN isolated trunks, on a per-VLAN basis.

Sticky port security extends port security by saving the dynamically learned MAC addresses in the running configuration to survive port link down and switch reset. It enables a network administrator to restrict the MAC addresses allowed or the maximum number of MAC addresses on each port.

Voice VLAN sticky port security further extends the sticky port security to the voice-over-IP deployment. Voice VLAN sticky port security locks a port and blocks access from a station with a MAC address different from the IP phone and the workstation behind the IP phone.

For information on port security, see [Chapter 55, “Configuring Port Security.”](#)

PPPoE Intermediate Agent

PPPoE Intermediate Agent (PPPoE IA) is placed between a subscriber and BRAS to help the service provider BRAS distinguish between end hosts connected over Ethernet to an access switch. On the access switch, PPPoE IA enables Subscriber Line Identification by appropriately tagging Ethernet frames of different users. (The tag contains specific information such as which subscriber is connected to the switch and VLAN.) PPPoE IA acts as mini-security firewall between host and BRAS by intercepting all PPPoE Active Discovery (PAD) messages on a per-port per-VLAN basis. It provides specific security feature such as verifying the intercepted PAD message from untrusted port, performing per-port PAD message rate limiting, inserting and removing VSA tags into and from PAD messages, respectively.

For information on PPPoE IA, see [Chapter 52, “Configuring the PPPoE Intermediate Agent.”](#)

Session Aware Networking

Session Aware Networking provides an identity-based approach to access management and subscriber management. It offers a consistent way to configure features across technologies, a command interface that allows easy deployment and customization of features, and a robust policy control engine with the ability to apply policies defined locally or received from an external server to enforce policy in the network.

Session Aware Networking allows a single session identifier to be used for web authentication sessions in addition to all 802.1X and MAB authenticated sessions for a client. This session ID is used for all reporting purposes such as show commands, MIBs, and RADIUS messages and allows users to distinguish messages for one session from messages for other sessions. This common session ID is used consistently across all authentication methods and features applied to a session.

**Note**

IPv6 is not supported for web authentication, dot.1X, or MAB.

For additional information, refer to the following URL:

<http://www.cisco.com/en/US/docs/ios-xml/ios/san/configuration/x3e/3850/san-overview.html>

Storm Control

Broadcast suppression is used to prevent LANs from being disrupted by a broadcast storm on one or more switch ports. A LAN broadcast storm occurs when broadcast packets flood the LAN, creating excessive traffic and degrading network performance. Errors in the protocol-stack implementation or in the network configuration can cause a broadcast storm. Multicast and broadcast suppression measures how much broadcast traffic is passing through a port and compares the broadcast traffic with some configurable threshold value within a specific time interval. If the amount of broadcast traffic reaches the threshold during this interval, broadcast frames are dropped, and optionally the port is shut down

Starting with Cisco IOS Release 12.2(40)SG, the Catalyst 4500 series switch allows suppression of broadcast and multicast traffic on a per-port basis.

For information on configuring broadcast suppression, see [Chapter 68, “Configuring Storm Control.”](#)

uRPF Strict Mode

The uRPF feature mitigates problems caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. uRPF deflects denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This helps to protect the network of the customer, the ISP, and the rest of the Internet. When using uRPF in strict mode, the packet must be received on the interface that the router uses to forward the return packet. uRPF strict mode is supported for both IPv4 and IPv6 prefixes.

For information on configuring broadcast suppression, see [Chapter 38, “Configuring Unicast Reverse Path Forwarding.”](#)

Utilities

Supported utilities include the following:

Layer 2 Traceroute

Layer 2 traceroute allows the switch to identify the physical path that a packet takes from a source device to a destination device. Layer 2 traceroute supports only unicast source and destination MAC addresses.

For information about Layer 2 Traceroute, see [Chapter 10, “Checking Port Status and Connectivity.”](#)

Time Domain Reflectometry

Time Domain Reflectometry (TDR) is a technology used for diagnosing the state and reliability of cables. TDR can detect open, shorted, or terminated cable states. The calculation of the distance to the failure point is also supported.

For information about TDR, see [Chapter 10, “Checking Port Status and Connectivity.”](#)

Debugging Features

The switch has several commands to help you debug your initial setup. These commands are included in the following command groups:

- **platform**
- **debug platform**

For more information, refer to the command reference guide.

Web-based Authentication

The web-based authentication feature, known as Web Authentication Proxy, enables you to authenticate end users on host systems that do not run the IEEE 802.1X supplicant. When you initiate an HTTP session, this feature intercepts ingress HTTP packets from the host and sends an HTML login page to your. You key in the credentials, which the web-based authentication feature sends to the AAA server for authentication. If authentication succeeds, web-based authentication sends a Login-Successful HTML page to the host and applies the access policies returned by the AAA server.

For information on configuring web-based authentication, see [Chapter 53, “Configuring Web-Based Authentication.”](#)

Command-Line Interfaces

This chapter describes the CLIs you use to configure the Catalyst 4500 series switch. This chapter includes the following major sections:

Comment - to be deleted.

- [Accessing the Switch CLI, page 2-2](#)
- [Performing Command-Line Processing, page 2-3](#)
- [Performing History Substitution, page 2-4](#)
- [About Cisco IOS Command Modes, page 2-4](#)
- [Getting a List of Commands and Syntax, page 2-5](#)
- [ROMMON Command-Line Interface, page 2-7](#)
- [Archiving Crashfiles Information, page 2-8](#)
- [Displaying a Crash Dump for Supervisor Engine 6-E and 6L-E, page 2-8](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the *Cisco Catalyst 4500 Series Switch Command Reference* and related publications at this location:

<http://www.cisco.com/en/US/products/hw/switches/ps4324/index.html>

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the Cisco IOS library. See related publications at this location:

<http://www.cisco.com/en/US/products/ps6350/index.html>

The following command changes apply only to Supervisor Engines 6-E and 6L-E:

- The **rename** command is supported in the FAT file system for bootflash and slot0.
- The **fsck** command is supported for the slot0 device. It is not supported in the file systems on supervisor engines other than Supervisor Engine 6-E and 6L-E.

The following additional file management commands are supported on Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E:

- **verify** <filename>
- **delete** <filename>
- **copy** <source_filename>, target_filename>

Accessing the Switch CLI

The following sections describe how to access the switch CLI:

- [Accessing the CLI Using the EIA/TIA-232 Console Interface, page 2-2](#)
- [Accessing the CLI Through Telnet, page 2-2](#)

Accessing the CLI Using the EIA/TIA-232 Console Interface

Note

EIA/TIA-232 was known as recommended standard 232 (RS-232) before its acceptance as a standard by the Electronic Industries Alliance (EIA) and Telecommunications Industry Association (TIA).

Perform the initial switch configuration over a connection to the EIA/TIA-232 console interface. Refer to the *Catalyst 4500 Series Switch Module Installation Guide* for console interface cable connection procedures.

To access the switch through the console interface, perform this task:

	Command	Purpose
Step 1	Switch> enable	From the user EXEC prompt (>), enter enable to change to enable mode (also known as privileged mode or privileged EXEC mode).
Step 2	Password: <i>password</i> Switch#	At the password prompt, enter the system password. The prompt (#) appears, indicating that you have accessed the CLI in enabled mode.
Step 3	Switch# quit	When you are finished executing the task command, exit the session.

After accessing the switch through the EIA/TIA-232 interface, you see this display:

```
Press Return for Console prompt

Switch> enable
Password:< >
Switch#
```

Accessing the CLI Through Telnet

Note

Before you make a Telnet connection to the switch, you must set the IP address for the switch. See the [“Configuring Physical Layer 3 Interfaces”](#) section on page 36-13.

The switch supports up to eight simultaneous Telnet sessions. Telnet sessions disconnect automatically after remaining idle for the period specified by the **exec-timeout** command.

To make a Telnet connection to the switch, perform this task:

	Command	Purpose
Step 1	<code>telnet {hostname ip_addr}</code>	From the remote host, enter the telnet command and the name or IP address of the switch you want to access.
Step 2	Password: <code>password</code> Switch#	At the prompt, enter the password for the CLI. If no password has been configured, press Return .
Step 3		Enter the necessary commands to complete your desired tasks.
Step 4	Switch# <code>quit</code>	When finished, exit the Telnet session.

This example shows how to open a Telnet session to the switch:

```

unix_host% telnet Switch_1
Trying 172.20.52.40...
Connected to 172.20.52.40.
Escape character is '^]'.
User Access Verification
Password:< >
Switch_1> enable
Password:
Switch_1#

```

Performing Command-Line Processing

Switch commands are not case sensitive. You can abbreviate commands and parameters if the abbreviations contain enough letters to be different from any other currently available commands or parameters.

You can scroll through the last 20 commands stored in the history buffer and enter or edit a command at the prompt. [Table 2-1](#) lists the keyboard shortcuts for entering and editing switch commands.

Table 2-1 Keyboard Shortcuts

Keystrokes	Result
Press Ctrl-B or press the Left Arrow key ¹	Moves the cursor back one character.
Press Ctrl-F or press the Right Arrow key ¹	Moves the cursor forward one character.
Press Ctrl-A	Moves the cursor to the beginning of the command line.
Press Ctrl-E	Moves the cursor to the end of the command line.
Press Esc-B	Moves the cursor back one word.
Press Esc-F	Moves the cursor forward one word.

1. The Arrow keys function only on ANSI-compatible terminals, such as VT100s.

Performing History Substitution

The history buffer stores the last 20 command lines you entered. History substitution enables you to access these command lines without retyping them. Table 2-2 lists the history substitution commands.

Table 2-2 History Substitution Commands

Command	Purpose
Ctrl-P or the Up Arrow key ¹	Recalls commands in the history buffer, beginning with the most recent command. Repeat the key sequence to recall older commands successively.
Ctrl-N or the Down Arrow key ¹	Returns to more recent commands in the history buffer after commands have been recalled with Ctrl-P or the Up Arrow key. Repeat the key sequence to recall more recent commands.
Switch# show history	Lists the last several commands you have entered in EXEC mode.

1. The Arrow keys function only on ANSI-compatible terminals such as VT100s.

About Cisco IOS Command Modes

Note

For complete information about Cisco IOS command modes, refer to the *Cisco IOS Configuration Fundamentals Configuration Guide* and the *Cisco IOS Configuration Fundamentals Command Reference* at the following URLs:

http://www.cisco.com/en/US/docs/ios/12_2/configfun/configuration/guide/ffun_c.html

http://www.cisco.com/en/US/docs/ios/fundamentals/command/reference/cf_book.html

The Cisco IOS user interface has many different modes: user EXEC, privileged EXEC (enable), global configuration, interface, subinterface, and protocol-specific. The commands available to you depend on which mode you are in. To get a list of the commands in a given mode, enter a question mark (?) at the system prompt. See the “Getting a List of Commands and Syntax” section on page 2-5 for more information.

When you start a session on the switch, you begin in user mode, also called user EXEC mode. Only a small subset of commands are available in EXEC mode. To have access to all commands, you must enter privileged EXEC mode, also called enable mode. To access the privileged EXEC mode, you must enter a password. When you are in the privileged EXEC mode, you can enter any EXEC command or access global configuration mode. Most EXEC commands are one-time commands, such as **show** commands, which display the current configuration status, and **clear** commands, which reset counters or interfaces. The EXEC commands are not saved when the switch is rebooted.

The configuration modes allow you to make changes to the running configuration. If you save the configuration, these commands are stored when you reboot the switch. You must start in global configuration mode. From global configuration mode, you can enter interface configuration mode, subinterface configuration mode, and a variety of protocol-specific modes.

You use a separate mode called ROMMON when the switch cannot boot up properly. For example, the switch might enter ROMMON mode if it does not find a valid system image when it is booting, or if its configuration file is corrupted. For more information, see the [“ROMMON Command-Line Interface” section on page 2-7](#).

Table 2-3 lists and describes frequently used Cisco IOS modes.

Table 2-3 Frequently Used Cisco IOS Command Modes

Mode	What You Use It For	How to Access	Prompt
User EXEC	To connect to remote devices, change terminal settings on a temporary basis, perform basic tests, and display system information.	Log in.	Switch>
Privileged EXEC (enable)	To set operating parameters. The privileged command set includes the commands in user EXEC mode, as well as the configure command. Use the configure command to access the other command modes.	From user EXEC mode, enter the enable command and the enable password (if a password has been configured).	Switch#
Global configuration	To configure features that affect the system as a whole, such as the system time or switch name.	From privileged EXEC mode, enter the configure terminal command.	Switch(config)#
Interface configuration	To enable or modify the operation of a 10-Gigabit Ethernet, Gigabit Ethernet, or Fast Ethernet interface with interface commands.	From global configuration mode, enter the interface <i>type location</i> command.	Switch(config-if)#
Console configuration	To configure the console interface; from the directly connected console or the virtual terminal; used with Telnet.	From global configuration mode, enter the line console 0 command.	Switch(config-line)#

The Cisco IOS command interpreter, called the EXEC, interprets and runs the commands you enter. You can abbreviate commands and keywords by entering just enough characters to make the command unique from other commands. For example, you can abbreviate the **show** command to **sh** and the **configure terminal** command to **confi t**.

When you type **exit**, the switch backs out one level. To exit configuration mode completely and return to privileged EXEC mode, press **Ctrl-Z**.

Getting a List of Commands and Syntax

In any command mode, you can get a list of available commands by entering a question mark (?).

```
Switch> ?
```

To obtain a list of commands that begin with a particular character sequence, enter those characters followed by the question mark (?). Do not include a space before the question mark. This form of help is called word help, because it completes a word for you.

To list keywords or arguments, enter a question mark in place of a keyword or argument. Include a space before the question mark. This form of help is called command syntax help, because it reminds you which keywords or arguments are applicable based on the command, keywords, and arguments you have already entered.

```
Switch# configure ?
memory          Configure from NV memory
network         Configure from a TFTP network host
overwrite-network Overwrite NV memory from TFTP network host
terminal        Configure from the terminal
<cr>
```

To redisplay a command you previously entered, press the **Up Arrow** key or **Ctrl-P**. You can continue to press the **Up Arrow** key to see the last 20 commands you entered.

**Tip**

If you are having trouble entering a command, check the system prompt and enter the question mark (?) for a list of available commands. You might be in the wrong command mode or using incorrect syntax.

Type **exit** to return to the previous mode. Press **Ctrl-Z** or enter the **end** command in any mode to immediately return to privileged EXEC mode.

Virtual Console for Standby Supervisor Engine

Catalyst 4500 series switches can be configured with 2 supervisor engines to provide redundancy. When the switch is powered, one of the supervisor engines becomes active and remains active until a switchover occurs. The other supervisor engine remains in standby mode.

Each supervisor engine has its own console port. Access to the standby supervisor engine is possible only through the console port of the standby supervisor engine. You must connect to the standby console to access, monitor or debug the standby supervisor.

Virtual Console for Standby Supervisor Engine enables you to access the standby console from the active supervisor engine without requiring a physical connection to the standby console. It uses IPC over EOBC to communicate with the standby supervisor engine and thus emulate the standby console on the active supervisor engine. Only one active standby console session is active at any time.

The virtual console for standby supervisor engine enables users who are logged onto the active supervisor engine to remotely execute **show** commands on the standby supervisor engine and view the results on the active supervisor engine. Virtual console is available only from the active supervisor engine.

You can access the standby virtual console from the active supervisor engine with the **attach module**, **session module**, or **remote login** commands on the active supervisor engine. You must be in privilege EXEC mode (level 15) to run these commands to access the standby console.

Once you enter the standby virtual console, the terminal prompt automatically changes to *hostname-standby-console#*, where *hostname* is the configured name of the switch. The prompt is restored back to the original prompt when you exit the virtual console.

You exit the virtual console with the **exit** or **quit** commands. When the inactivity period of the terminal on the active supervisor engine where you logged in exceeds the configured idle time, you are automatically logged out of the terminal on the active supervisor engine. In this case, the virtual console session is also terminated. Virtual console session is also automatically terminated when the standby is rebooted. After the standby boots up, you need to create another virtual console session.

To log in to the standby supervisor engine using a virtual console, enter the following command:

```
Switch# session module 2
Connecting to standby virtual console
Type "exit" or "quit" to end this session
Switch-standby-console# exit
```

If the standby console is not enabled, the following message appears:

```
Switch-standby-console#
Standby console disabled.
Valid commands are: exit, logout
```

Virtual session into the standby console is N/A with RPR:

```
Switch# session module 2
IPC server port name IFConsoleServer:2 not registered on standby.
Secondary cannot be accessed by virtual console
```

**Note**

The standby virtual console provides the standard features that are available from the supervisor console such as command history, command completion, command help and partial command keywords.

The following limitations apply to the standby virtual console:

- All commands on the virtual console run to completion. It does not provide the auto-more feature; it behaves as if the **terminal length 0** command has been executed. It is also noninteractive. A executing command cannot be interrupted or aborted by any key sequence on the active supervisor engine. If a command produces considerable output, the virtual console displays it on the supervisor screen.
- The virtual console is noninteractive. Because the virtual console does not detect the interactive nature of a command, any command that requires user interaction causes the virtual console to wait until the RPC timer aborts the command.
- The virtual console timer is set to 60 seconds. The virtual console returns to its prompt after 60 seconds. During this time, you cannot abort the command from the keyboard. You must wait for the timer to expire before you continue.
- You cannot use virtual console to view debug and syslog messages that are being displayed on the standby supervisor engine. The virtual console only displays the output of commands that are executed from the virtual console. Other information that is displayed on the real standby console does not appear on the virtual console.

ROMMON Command-Line Interface

ROMMON is a ROM-based program that is involved at power-up or reset, or when a fatal exception error occurs. The switch enters ROMMON mode if the switch does not find a valid software image, if the NVRAM configuration is corrupted, or if the configuration register is set to enter ROMMON mode. From the ROMMON mode, you can load a software image manually from flash memory, from a network server file, or from bootflash.

You can also enter ROMMON mode by restarting the switch and pressing **Ctrl-C** during the first five seconds of startup.

**Note**

Ctrl-C is always enabled for 60 seconds after you reboot the switch, even if **Ctrl-C** is configured to be off in the configuration register settings.

When you enter ROMMON mode, the prompt changes to **rommon 1>**. Use the **?** command to see the available ROMMON commands.

For more information about the ROMMON commands, refer to the command reference guide.

Archiving Crashfiles Information

This feature allows you to archive crashinfo files (otherwise overwritten if another system reset were to happen first to the bootflash). Having access to archived crashinfo data greatly assists in troubleshooting.

To archive crashinfo files, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# exception crashinfo file bootflash: name	Enables archiving crashinfo files to bootflash. The files are stored in bootflash with the <i>name</i> specified concatenated with the date.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config	Verifies your entries.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Displaying a Crash Dump for Supervisor Engine 6-E and 6L-E

A crash dump provides the following information:

- Malloc or free traces
- Chuck alloc/free traces
- Process block dump
- Register memory dump
- Current proc stack partial decode
- Interrupt level stack
- Last 128 memory block dump

To display a crash dump, do the following:

```
Switch# show platform crashdump
```

```
Current Time: 9/6/2010 15:47:21
```

```
Last Power Failure: 09/06/2010 15:03:28
```

```
Last Reload Status: 00002000
```

```
Last Software Reset State: 00000000
```

```
Crashdump version: 1
```

```
Last crash: 09/06/2010 06:21:58
```

```
Build: 12.2(20100723:074204) ENT SERVICES
```

```
buildversion addr: 14847D24
```

```

Switch#

Configuring the Switch for the First Time

This chapter describes how to initially configure the switch.

The information presented here supplements the administration information and procedures in the [Configuration Fundamentals Configuration Guide](#) and the [Cisco IOS Configuration Fundamentals Command Reference](#).

This chapter includes the following major sections:

- [Default Switch Configuration, page 3-1](#)
- [Configuring DHCP-Based Autoconfiguration, page 3-2](#)
- [Configuring the Switch, page 3-8](#)
- [Controlling Access to Privileged EXEC Commands, page 3-13](#)
- [Recovering a Lost Enable Password, page 3-25](#)
- [Modifying the Supervisor Engine Startup Configuration, page 3-25](#)
- [Replacing and Rolling-Back Configuration, page 3-33](#)
- [Resetting a Switch to Factory Default Settings, page 3-34](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Default Switch Configuration

This section describes the default configurations for the switch. [Table 3-1](#) shows the default configuration settings for each feature.

Table 3-1 **Default Switch Configuration**

Feature	Default Settings
Administrative connection	Normal mode
Global switch information	No default value for system name, system contact, and location
System clock	No value for system clock time

Table 3-1 **Default Switch Configuration (continued)**

Feature	Default Settings
Passwords	No passwords are configured for normal mode or enable mode (press the Return key)
Switch prompt	Switch>
Interfaces	Enabled, with speed and flow control autonegotiated, and without IP addresses

Configuring DHCP-Based Autoconfiguration

These sections describe how to configure DHCP-based autoconfiguration:

- [About DHCP-Based Autoconfiguration, page 3-2](#)
- [DHCP Client Request Process, page 3-3](#)
- [Configuring the DHCP Server, page 3-4](#)
- [Configuring the TFTP Server, page 3-4](#)
- [Configuring the DNS Server, page 3-5](#)
- [Configuring the Relay Device, page 3-5](#)
- [Obtaining Configuration Files, page 3-6](#)
- [Example Configuration, page 3-7](#)

If your DHCP server is a Cisco device, or if you are configuring the switch as a DHCP server, refer to the “IP Addressing and Services” section in the *Cisco IOS IP and IP Routing Configuration Guide for Cisco IOS Release 12.1* for additional information about configuring DHCP.

About DHCP-Based Autoconfiguration

**Note**

Beginning with Release 12.2(20)EW, you can enable DHCP AutoConfiguration by entering the **write erase** command. This command clears the startup-config in NVRAM. In images prior to Release 12.2(20)EW, this command does not enable autoconfiguration.

DHCP provides configuration information to Internet hosts and internetworking devices. This protocol consists of two components: one component for delivering configuration parameters from a DHCP server to a device and another component that is a mechanism for allocating network addresses to devices. DHCP is built on a client-server model, in which designated DHCP servers allocate network addresses and deliver configuration parameters to dynamically configured devices. The switch can act as both a DHCP client and a DHCP server.

With DHCP-based autoconfiguration, no DHCP client-side configuration is needed on your switch because your switch (the DHCP client) is automatically configured at startup with IP address information and a configuration file. However, you need to configure the DHCP server or the DHCP server feature on your switch for various lease options associated with IP addresses. If you are using DHCP to relay the configuration file location on the network, you might also need to configure a Trivial File Transfer Protocol (TFTP) server and a Domain Name System (DNS) server.

DHCP-based autoconfiguration replaces the BOOTP client functionality on your switch.

DHCP Client Request Process

At startup the switch automatically requests configuration information from a DHCP server if a configuration file is not present on the switch.

Figure 3-1 shows the sequence of messages that are exchanged between the DHCP client and the DHCP server.

Figure 3-1 DHCP Client and Server Message Exchange

The client, Switch A, broadcasts a DHCPDISCOVER message to locate a DHCP server. The DHCP server offers configuration parameters (such as an IP address, subnet mask, gateway IP address, DNS IP address, lease for the IP address, and so forth) to the client in a DHCPOFFER unicast message.

In a DHCPREQUEST broadcast message, the client returns a formal request for the offered configuration information to the DHCP server. The formal request is broadcast so that all other DHCP servers that received the DHCPDISCOVER broadcast message from the client can reclaim the IP addresses that they offered to the client.

The DHCP server confirms that the IP address has been allocated to the client by returning a DHCPACK unicast message to the client. With this message, the client and server are bound, and the client uses the configuration information that it received from the server. The amount of information the switch receives depends on how you configure the DHCP server. For more information, see the [“Configuring the DHCP Server”](#) section on page 3-4.

If the configuration parameters sent to the client in the DHCPOFFER unicast message are invalid (if configuration error exists), the client returns a DHCPDECLINE broadcast message to the DHCP server.

The DHCP server sends the client a DHCPNAK denial broadcast message, which means that the offered configuration parameters have not been assigned, that an error has occurred during the negotiation of the parameters, or that the client has been slow in responding to the DHCPOFFER message. (The DHCP server might have assigned the parameters to another client.)

A DHCP client might receive offers from multiple DHCP servers and can accept any of them; however, the client usually accepts the first offer it receives. The offer from the DHCP server is not a guarantee that the IP address will be allocated to the client; however, the server usually reserves the address until the client has had a chance to formally request the address.

Troubleshooting Tips

Sometimes due to firmware upgrades or client VLAN configuration changes on the device, the DHCP client may send a DHCPREQUEST message with a cached IP address. If the DHCP server does not accept the request, the client may continue to send DHCPREQUEST messages instead of a DHCPDISCOVER message, and fail to get an IP address from the DHCP server.

To remedy this situation, use the **renew deny unknown** command in DHCP pool configuration mode. This command forces the DHCP server to reject renewal requests from clients and the DHCP server sends a DHCPNAK denial message to the client, forcing the client back to its initial state.

Configuring the DHCP Server

A switch can act as both the DHCP client and the DHCP server. By default, the Cisco IOS DHCP server and relay agent features are enabled on your switch.

You should configure the DHCP server, or the DHCP server feature running on your switch, with reserved leases that are bound to each switch by the switch hardware address.

If you want the switch to receive IP address information, you must configure the DHCP server with these lease options:

- IP address of the client (required)
- Subnet mask of the client (required)
- DNS server IP address (optional)
- Router IP address (required)

**Note**

The router IP address is the default gateway address for the switch.

If you want the switch to receive the configuration file from a TFTP server, you must configure the DHCP server with these lease options:

- TFTP server name or IP address (required)
- Boot filename (the name of the configuration file that the client needs) (recommended)
- Host name (optional)

Depending on the settings of the DHCP server or the DHCP server feature running on your switch, the switch can receive IP address information, the configuration file, or both.

If you do not configure the DHCP server, or the DHCP server feature running on your switch, with the lease options described earlier, the switch replies to client requests with only those parameters that are configured. If the IP address and subnet mask are not in the reply, the switch is not configured. If the router IP address or TFTP server name (or IP address) are not found, the switch might send broadcast, instead of unicast, TFTP requests. Unavailability of other lease options does not impact autoconfiguration.

The DHCP server, or the DHCP server feature running on your switch, can be on the same LAN or on a different LAN than the switch. If the DHCP server is running on a different LAN, you should configure a DHCP relay, which forwards broadcast traffic between two directly connected LANs. A router does not forward broadcast packets, but it forwards packets based on the destination IP address in the received packet. For more information on relay devices, see the [“Configuring the Relay Device” section on page 3-5](#).

Configuring the TFTP Server

Based on the DHCP server configuration, the switch attempts to download one or more configuration files from the TFTP server. If you configured the DHCP server to respond to the switch with all the options required for IP connectivity to the TFTP server, and if you configured the DHCP server with a TFTP server name, address, and configuration filename, the switch attempts to download the specified configuration file from the specified TFTP server.

If you did not specify the configuration filename or the TFTP server name, or if the configuration file could not be downloaded, the switch attempts to download a configuration file using various combinations of filenames and TFTP server addresses. The files include the specified configuration

filename (if any) and the following files: `network-config`, `cisconet.cfg`, `hostname.config`, or `hostname.cfg`, where *hostname* is the current hostname of the switch and `router-config` and `ciscotr.cfg`. The TFTP server addresses used include the specified TFTP server address (if any) and the broadcast address (255.255.255.255).

For the switch to successfully download a configuration file, the TFTP server must contain one or more configuration files in its base directory. The files can include the following:

- The configuration file named in the DHCP reply (the actual switch configuration file).
- The `network-config` or the `cisconet.cfg` file (known as the default configuration files).
- The `router-config` or the `ciscotr.cfg` file. (These files contain commands common to all switches. Normally, if the DHCP and TFTP servers are properly configured, these files are not accessed.)

If you specify the TFTP server name in the DHCP server-lease database, you must also configure the TFTP server name-to-IP-address mapping in the DNS-server database.

If the TFTP server you plan to use is on a different LAN from the switch, or if you plan to access it with the switch through the broadcast address (which occurs if the DHCP server response does not contain all the required information described earlier), you must configure a relay to forward the TFTP packets to the TFTP server. For more information, see the [“Configuring the Relay Device” section on page 3-5](#). The preferred solution is to configure either the DHCP server or the DHCP server feature running on your switch with all the required information.

Configuring the DNS Server

The DHCP server, or the DHCP server feature running on your switch, uses the DNS server to resolve the TFTP server name to an IP address. You must configure the TFTP server name-to-IP address map on the DNS server. The TFTP server contains the configuration files for the switch.

You can configure the IP addresses of the DNS servers in the lease database of the DHCP server where the DHCP replies retrieve them. You can enter up to two DNS server IP addresses in the lease database.

The DNS server can be on the same or on a different LAN as the switch. If it is on a different LAN, the switch must be able to access it through a router.

Configuring the Relay Device

You must configure a relay device to forward received broadcast packets to the destination host whenever a switch sends broadcast packets to which a host on a different LAN must respond. Examples of such broadcast packets are DHCP, DNS, and in some cases, TFTP packets.

If the relay device is a Cisco router, enable IP routing (**ip routing** global configuration command) and configure helper addresses (**ip helper-address** interface configuration command). For example, in [Figure 3-2](#), configure the router interfaces as follows:

On interface 10.0.0.2:

```
router(config-if)# ip helper-address 20.0.0.2
router(config-if)# ip helper-address 20.0.0.3
router(config-if)# ip helper-address 20.0.0.4
```

On interface 20.0.0.1:

```
router(config-if)# ip helper-address 10.0.0.1
```

Figure 3-2 Relay Device Used in Autoconfiguration

49068

Obtaining Configuration Files

Depending on the availability of the IP address and the configuration filename in the DHCP reserved lease, the switch obtains its configuration information in these ways:

- The IP address and the configuration filename are reserved for the switch and provided in the DHCP reply (one-file read method).

The switch receives its IP address, subnet mask, TFTP server address, and the configuration filename from either the DHCP server or the DHCP server feature running on your switch. The switch sends a unicast message to the TFTP server to retrieve the named configuration file from the base directory of the server, and upon receipt, completes its boot-up process.

- The IP address and the configuration filename is reserved for the switch, but the TFTP server address is not provided in the DHCP reply (one-file read method).

The switch receives its IP address, subnet mask, and the configuration filename from either the DHCP server or the DHCP server feature running on your switch. The switch sends a broadcast message to a TFTP server to retrieve the named configuration file from the base directory of the server, and upon receipt, completes its boot-up process.

- Only the IP address is reserved for the switch and provided in the DHCP reply. The configuration filename is not provided (two-file read method).

The switch receives its IP address, subnet mask, and the TFTP server address from either the DHCP server or the DHCP server feature running on your switch. The switch sends a unicast message to the TFTP server to retrieve the `network-config` or `cisconet.cfg` default configuration file. (If the `network-config` file cannot be read, the switch reads the `cisconet.cfg` file.)

The default configuration file contains the host names-to-IP-address mapping for the switch. The switch fills its host table with the information in the file and obtains its host name. If the host name is not found in the file, the switch uses the host name in the DHCP reply. If the host name is not specified in the DHCP reply, the switch uses the default *Switch* as its host name.

After obtaining its host name from the default configuration file or the DHCP reply, the switch reads the configuration file that has the same name as its host name (`hostname-config` or `hostname.cfg`, depending on whether or not the `network-config` file or the `cisconet.cfg` file was read earlier) from the TFTP server. If the `cisconet.cfg` file is read, the filename of the host is truncated to eight characters.

If the switch cannot read the network-config, cisco.net.cfg, or the hostname file, it reads the router-config file. If the switch cannot read the router-config file, it reads the ciscotr.cfg file.

**Note**

The switch broadcasts TFTP server requests provided that one of these conditions is met: the TFTP server is not obtained from the DHCP replies; all attempts to read the configuration file through unicast transmissions fail; or the TFTP server name cannot be resolved to an IP address.

Example Configuration

Figure 3-3 shows a network example for retrieving IP information using DHCP-based autoconfiguration.

Figure 3-3 DHCP-Based Autoconfiguration Network Example

Table 3-2 shows the configuration of the reserved leases on either the DHCP server or the DHCP server feature running on your switch.

Table 3-2 DHCP Server Configuration

	Switch 1	Switch 2	Switch 3	Switch 4
Binding key (hardware address)	00e0.9f1e.2001	00e0.9f1e.2002	00e0.9f1e.2003	00e0.9f1e.2004
IP address	10.0.0.21	10.0.0.22	10.0.0.23	10.0.0.24
Subnet mask	255.255.255.0	255.255.255.0	255.255.255.0	255.255.255.0
Router address	10.0.0.10	10.0.0.10	10.0.0.10	10.0.0.10
DNS server address	10.0.0.2	10.0.0.2	10.0.0.2	10.0.0.2
TFTP server name	maritsu or 10.0.0.3	maritsu or 10.0.0.3	maritsu or 10.0.0.3	maritsu or 10.0.0.3
Boot filename (configuration file) (optional)	switch1-confg	switch2-confg	switch3-confg	switch4-confg
Host name (optional)	switch1	switch2	switch3	switch4

DNS Server Configuration

The DNS server maps the TFTP server name *maritsu* to IP address 10.0.0.3.

TFTP Server Configuration (on UNIX)

The TFTP server base directory is set to `/tftpserver/work/`. This directory contains the `network-config` file used in the two-file read method. This file contains the host name that you plan to assign to the switch based on its IP address. The base directory also contains a configuration file for each switch (*switch1-config*, *switch2-config*, and so forth) as shown in the following display:

```
prompt> cd /tftpserver/work/
prompt> ls
network-config
switch1-config
switch2-config
switch3-config
switch4-config
prompt> cat network-config
ip host switch1 10.0.0.21
ip host switch2 10.0.0.22
ip host switch3 10.0.0.23
ip host switch4 10.0.0.24
```

DHCP Client Configuration

No configuration file is present on Switch 1 through Switch 4.

Configuration Explanation

In [Figure 3-3](#), Switch 1 reads its configuration file as follows:

- Switch 1 obtains its IP address 10.0.0.21 from the DHCP server.
- If no configuration filename is given in the DHCP server reply, Switch 1 reads the `network-config` file from the base directory of the TFTP server.
- Switch 1 adds the contents of the `network-config` file to its host table.
- Switch 1 reads its host table by indexing its IP address 10.0.0.21 to its host name (switch1).
- Switch 1 reads the configuration file that corresponds to its host name; for example, it reads *switch1-config* from the TFTP server.

Switches 2 through 4 retrieve their configuration files and IP addresses in the same way.

Configuring the Switch

The following sections describe how to configure your switch:

- [Using Configuration Mode to Configure Your Switch, page 3-9](#)
- [Verifying the Running Configuration Settings, page 3-9](#)
- [Saving the Running Configuration Settings to Your Start-Up File, page 3-10](#)
- [Reviewing the Configuration in NVRAM, page 3-10](#)
- [Configuring a Default Gateway, page 3-11](#)
- [Configuring a Static Route, page 3-11](#)

Using Configuration Mode to Configure Your Switch

To configure your switch from configuration mode, follow these steps:

- Step 1** Connect a console terminal to the console interface of your supervisor engine.
- Step 2** After a few seconds, you see the user EXEC prompt (**Switch>**). Now, you may want to enter privileged EXEC mode, also known as enable mode. Type **enable** to enter enable mode:

```
Switch> enable
```

Note You must be in enable mode to make configuration changes.

The prompt changes to the enable prompt (**#**):

```
Switch#
```

- Step 3** At the enable prompt (**#**), enter the **configure terminal** command to enter global configuration mode:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#
```

- Step 4** At the global configuration mode prompt, enter the **interface type slot/interface** command to enter interface configuration mode:

```
Switch(config)# interface fastethernet 5/1
Switch(config-if)#
```

- Step 5** In either of these configuration modes, enter changes to the switch configuration.
- Step 6** Enter the **end** command to exit configuration mode.
- Step 7** Save your settings. See the [“Saving the Running Configuration Settings to Your Start-Up File”](#) section on page 3-10.

Your switch is now minimally configured and can boot with the configuration you entered. To see a list of the configuration commands, enter **?** at the prompt or press the **help** key in configuration mode.

Verifying the Running Configuration Settings

To verify the configuration settings you entered or the changes you made, enter the **show running-config** command at the enable prompt (**#**), as shown in this example:

```
Switch# show running-config
Building configuration...

Current configuration:
!
version 12.0
service timestamps debug uptime
service timestamps log uptime
no service password-encryption
!
hostname Switch
```

```
<...output truncated...>

!
line con 0
  transport input none
line vty 0 4
  exec-timeout 0 0
  password lab
  login
  transport input lat pad dsipcon mop telnet rlogin udptn nasi
!
end
Switch#
```

Saving the Running Configuration Settings to Your Start-Up File

Caution

This command saves the configuration settings that you created in configuration mode. If you fail to do this step, your configuration is lost the next time you reload the system.

To store the configuration, changes to the configuration, or changes to the startup configuration in NVRAM, enter the **copy running-config startup-config** command at the enable prompt (#), as follows:

```
Switch# copy running-config startup-config
```

Reviewing the Configuration in NVRAM

To display information stored in NVRAM, enter the **show startup-config EXEC** command.

The following example shows a typical system configuration:

```
Switch# show startup-config
Using 1579 out of 491500 bytes, uncompressed size = 7372 bytes
Uncompressed configuration from 1579 bytes to 7372 bytes
!
version 12.1
no service pad
service timestamps debug uptime
service timestamps log uptime
no service password-encryption
service compress-config
!
hostname Switch
!
!
ip subnet-zero
!
!
!
interface GigabitEthernet1/1
  no snmp trap link-status
!
interface GigabitEthernet1/2
  no snmp trap link-status
!--More--

<...output truncated...>
```

```

!
line con 0
  exec-timeout 0 0
  transport input none
line vty 0 4
  exec-timeout 0 0
  password lab
  login
  transport input lat pad dsipcon mop telnet rlogin udptn nasi
!
end

Switch#

```

Configuring a Default Gateway

Note

The switch uses the default gateway only when it is not configured with a routing protocol.

Configure a default gateway to send data to subnets other than its own when the switch is not configured with a routing protocol. The default gateway must be the IP address of an interface on a router that is directly connected to the switch.

To configure a default gateway, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip default-gateway <i>IP-address</i>	Configures a default gateway.
Step 2	Switch# show ip route	Verifies that the default gateway is correctly displayed in the IP routing table.

This example shows how to configure a default gateway and how to verify the configuration:

```

Switch# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# ip default-gateway 172.20.52.35
Switch(config)# end
3d17h: %SYS-5-CONFIG_I: Configured from console by console
Switch# show ip route
Default gateway is 172.20.52.35

Host                Gateway                Last Use    Total Uses  Interface
ICMP redirect cache is empty
Switch#

```

Configuring a Static Route

If your Telnet station or SNMP network management workstation is on a different network from your switch and a routing protocol has not been configured, you might need to add a static routing table entry for the network where your end station is located.

To configure a static route, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip route <i>dest_IP_address mask {forwarding_IP vlan vlan_ID}</i>	Configures a static route to the remote network.
Step 2	Switch# show running-config	Verifies that the static route is displayed correctly.

This example shows how to use the **ip route** command to configure a static route to a workstation at IP address 171.10.5.10 on the switch with a subnet mask and IP address 172.20.3.35 of the forwarding router:

```
Switch# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# ip route 171.10.5.10 255.255.255.255 172.20.3.35
Switch(config)# end
Switch#
```

This example shows how to use the **show running-config** command to confirm the configuration of the static route:

```
Switch# show running-config
Building configuration...
.
<...output truncated...>
.
ip default-gateway 172.20.52.35
ip classless
ip route 171.10.5.10 255.255.255.255 172.20.3.35
no ip http server
!
line con 0
  transport input none
line vty 0 4
  exec-timeout 0 0
  password lab
  login
  transport input lat pad dsipcon mop telnet rlogin udptn nasi
!
end

Switch#
```

This example shows how to use the **ip route** command to configure the static route IP address 171.20.5.3 with subnet mask and connected over VLAN 1 to a workstation on the switch:

```
Switch# configure terminal
Switch(config)# ip route 171.20.5.3 255.255.255.255 vlan 1
Switch(config)# end
Switch#
```

This example shows how to use the **show running-config** command to confirm the configuration of the static route:

```
Switch# show running-config
Building configuration...
.
<...output truncated...>
```

```
.
ip default-gateway 172.20.52.35
ip classless
ip route 171.20.5.3 255.255.255.255 Vlan1
no ip http server
!
!
x25 host z
!
line con 0
  transport input none
line vty 0 4
  exec-timeout 0 0
  password lab
  login
  transport input lat pad dsipcon mop telnet rlogin udptn nasi
!
end

Switch#
```

Controlling Access to Privileged EXEC Commands

The procedures in these sections let you control access to the system configuration file and privileged EXEC commands:

- [Setting or Changing a Static enable Password, page 3-13](#)
- [Using the enable password and enable secret Commands, page 3-14](#)
- [Setting or Changing a Privileged Password, page 3-14](#)
- [Controlling Switch Access with TACACS+, page 3-15](#)
- [Encrypting Passwords, page 3-22](#)
- [Configuring Multiple Privilege Levels, page 3-23](#)

Setting or Changing a Static enable Password

To set or change a static password that controls access to the enable mode, enter this command:

Command	Purpose
Switch(config)# enable password <i>password</i>	Sets a new password or changes an existing password for the privileged EXEC mode.

This example shows how to configure an enable password as lab:

```
Switch# configure terminal
Switch(config)# enable password lab
Switch(config)#
```

For instructions on how to display the password or access level configuration, see the [“Displaying the Password, Access Level, and Privilege Level Configuration”](#) section on page 3-24.

Using the enable password and enable secret Commands

To provide an additional layer of security, particularly for passwords that cross the network or that are stored on a TFTP server, use either the **enable password** or **enable secret** command. Both commands configure an encrypted password that you must enter to access the enable mode (the default) or any other privilege level that you specify.

We recommend that you use the **enable secret** command.

If you configure the **enable secret** command, it takes precedence over the **enable password** command; the two commands cannot be in effect simultaneously.

To configure the switch to require an enable password, enter one of these commands:

Command	Purpose
Switch(config)# enable password [level <i>level</i>] { <i>password</i> <i>encryption-type</i> <i>encrypted-password</i> }	Establishes a password for the privileged EXEC mode.
Switch(config)# enable secret [level <i>level</i>] { <i>password</i> <i>encryption-type</i> <i>encrypted-password</i> }	Specifies a secret password that is saved using a nonreversible encryption method. (If enable password and enable secret commands are both set, users must enter the enable secret password.)

When you enter either of these password commands with the **level** option, you define a password for a specific privilege level. After you specify the level and set a password, give the password only to users who need to have access at this level. Use the **privilege level** configuration command to specify commands accessible at various levels.

If you enable the **service password-encryption** command, the password you enter is encrypted. When you display the password with the **more system:running-config** command, the password displays the password in encrypted form.

If you specify an encryption type, you must provide an encrypted password—an encrypted password you copy from another switch configuration.

Note

You cannot recover a lost encrypted password. You must clear NVRAM and set a new password. See the [“Recovering a Lost Enable Password”](#) section on page 3-25 for more information.

For information on how to display the password or access level configuration, see the [“Displaying the Password, Access Level, and Privilege Level Configuration”](#) section on page 3-24.

Setting or Changing a Privileged Password

To set or change a privileged password, enter this command:

Command	Purpose
Switch(config-line)# password <i>password</i>	Sets a new password or changes an existing password for the privileged level.

For information on how to display the password or access level configuration, see the [“Displaying the Password, Access Level, and Privilege Level Configuration”](#) section on page 3-24.

Controlling Switch Access with TACACS+

This section describes how to enable and configure TACACS+, which provides detailed accounting information and flexible administrative control over authentication and authorization processes. TACACS+ is facilitated through authentication, authorization, accounting (AAA) and can be enabled only through AAA commands.

Note

For complete syntax and usage information for the commands used in this section, see the *Cisco IOS Security Command Reference, Release 12.2*.

This section contains the following configuration information:

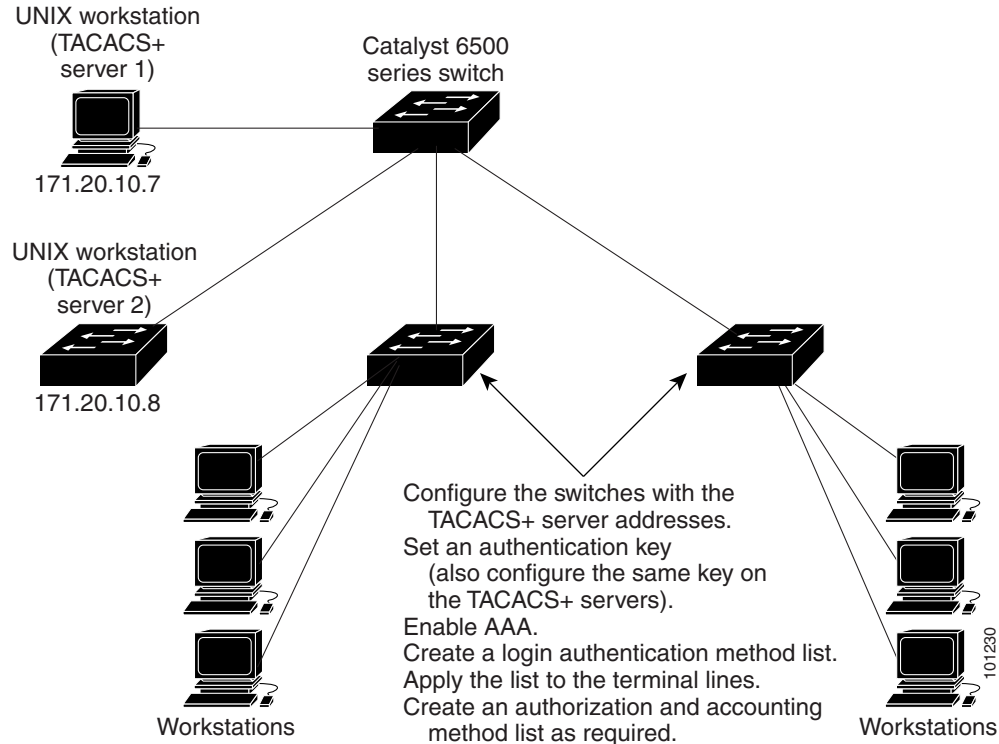

- [Understanding TACACS+, page 3-15](#)
- [TACACS+ Operation, page 3-17](#)
- [Configuring TACACS+, page 3-17](#)
- [Displaying the TACACS+ Configuration, page 3-22](#)

Understanding TACACS+

TACACS+ is a security application that provides centralized validation of users attempting to gain access to your switch. TACACS+ services are maintained in a database on a TACACS+ daemon typically running on a UNIX or Windows NT workstation. You should have access to and should configure a TACACS+ server before configuring TACACS+ features on your switch.

TACACS+ provides for separate and modular AAA facilities. TACACS+ allows for a single access control server (the TACACS+ daemon) to provide each service—authentication, authorization, and accounting—independently. Each service can be locked into its own database to take advantage of other services available on that server or on the network, depending on the capabilities of the daemon.

The goal of TACACS+ is to provide a method for managing multiple network access points from a single management service. Your switch can be a network access server along with other Cisco routers and access servers. A network access server provides connections to a single user, to a network or subnetwork, and to interconnected networks as shown in [Figure 3-4](#).

Figure 3-4 Typical TACACS+ Network Configuration

TACACS+ administered through the AAA security services can provide these services:

- **Authentication**—Provides complete control of authentication through login and password dialog, challenge and response, and messaging support.
The authentication facility can conduct a dialog with the user (such as, after a username and password are provided, to challenge a user with several questions such as home address, mother's maiden name, service type, and social security number). The TACACS+ authentication service can also send messages to user screens. For example, a message could notify users that their passwords must be changed because of the company's password aging policy.
- **Authorization**—Provides strict control over user capabilities for the duration of the user's session, including but not limited to setting autocommands, access control, session duration, or protocol support. You can also enforce restrictions on the commands a user can execute with the TACACS+ authorization feature.
- **Accounting**—Collects and sends information used for billing, auditing, and reporting to the TACACS+ daemon. Network managers can use the accounting facility to track user activity for a security audit or to provide information for user billing. Accounting records include user identities, start and stop times, executed commands (such as PPP), number of packets, and number of bytes.

The TACACS+ protocol provides authentication between the switch and the TACACS+ daemon, and it ensures confidentiality because all protocol exchanges between the switch and the TACACS+ daemon are encrypted.

You need a system running the TACACS+ daemon software to use TACACS+ on your switch.

TACACS+ Operation

When a user attempts a simple ASCII login by authenticating to a switch using TACACS+, this process occurs:

1. When the connection is established, the switch contacts the TACACS+ daemon to obtain a username prompt, which is then displayed to the user. The user enters a username, and the switch then contacts the TACACS+ daemon to obtain a password prompt. The switch displays the password prompt to the user, the user enters a password, and the password is then sent to the TACACS+ daemon.

TACACS+ allows a conversation between the daemon and the user until the daemon receives enough information to authenticate the user. The daemon prompts for a username and password combination, but can include other items such as the user's mother's maiden name.

2. The switch eventually receives one of these responses from the TACACS+ daemon:
 - **ACCEPT**—The user is authenticated and service can begin. If the switch is configured to require authorization, authorization begins at this time.
 - **REJECT**—The user is not authenticated. The user can be denied access or is prompted to retry the login sequence, depending on the TACACS+ daemon.
 - **ERROR**—An error occurred at some time during authentication with the daemon or in the network connection between the daemon and the switch. If an **ERROR** response is received, the switch typically tries to use an alternative method for authenticating the user.
 - **CONTINUE**—The user is prompted for additional authentication information.

After authentication, the user undergoes an additional authorization phase if authorization has been enabled on the switch. Users must first successfully complete TACACS+ authentication before proceeding to TACACS+ authorization.

3. If TACACS+ authorization is required, the TACACS+ daemon is again contacted, and it returns an **ACCEPT** or **REJECT** authorization response. If an **ACCEPT** response is returned, the response contains data in the form of attributes that direct the **EXEC** or **NETWORK** session for that user and the services that the user can access:
 - Telnet, Secure Shell (SSH), rlogin, or privileged **EXEC** services
 - Connection parameters, including the host or client IP address, access list, and user timeouts

Configuring TACACS+

This section describes how to configure your switch to support TACACS+. At a minimum, you must identify the host or hosts maintaining the TACACS+ daemon and define the method lists for TACACS+ authentication. You can optionally define method lists for TACACS+ authorization and accounting. A method list defines the sequence and methods used to authenticate, to authorize, or to keep accounts on a user. Use method lists to designate one or more security protocols, ensuring a backup system if the initial method fails. The software uses the first method listed to authenticate, to authorize, or to keep accounts on users; if that method does not respond, the software selects the next method in the list. This process continues until there is successful communication with a listed method or the method list is exhausted.

Note

Beginning with Cisco IOS XE Release 3.11.3aE, the legacy command **tacacs-server** is deprecated. Use the **tacacs server** command if the software running on your device is Cisco IOS XE Release 3.11.3aE or later releases.

This section contains the following configuration information:

- [Default TACACS+ Configuration, page 3-18](#)
- [Identifying the TACACS+ Server Host and Setting the Authentication Key, page 3-18](#)
- [Configuring TACACS+ Login Authentication, page 3-19](#)
- [Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services, page 3-21](#)
- [Starting TACACS+ Accounting, page 3-21](#)

Default TACACS+ Configuration

TACACS+ and AAA are disabled by default.

To prevent a lapse in security, you cannot configure TACACS+ through a network management application. When enabled, TACACS+ can authenticate users accessing the switch through the CLI.

Note

Although TACACS+ configuration is performed through the CLI, the TACACS+ server authenticates HTTP connections that have been configured with a privilege level of 15.

Identifying the TACACS+ Server Host and Setting the Authentication Key

You can configure the switch to use a single server or AAA server groups in order to group existing server hosts for authentication. You can group servers to select a subset of the configured server hosts and use them for a particular service. The server group is used with a global server-host list and contains the list of IP addresses of the selected server hosts.

Note

Beginning with Cisco IOS XE Release 3.11.3aE, the legacy command **tacacs-server** is deprecated. Use the **tacacs server** command if the software running on your device is Cisco IOS XE Release 3.11.3aE or later releases.

To identify the IP host or host maintaining TACACS+ server and optionally set the encryption key, perform this task, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	tacacs server <i>servername</i>	Identifies the IP host or hosts maintaining a TACACS+ server. Enter this command multiple times to create a list of preferred hosts. The software searches for hosts in the order in which you specify them. For <i>servername</i> , specify the name of the server.
Step 3	address { <i>ipv4</i> <i>ipv6</i> } <i>ipaaddress</i>	Configures the IP address for the TACACS server.
Step 4	aaa new-model	Enables AAA.
Step 5	aaa group server tacacs+ <i>group-name</i>	(Optional) Defines the AAA server-group with a group name. This command puts the switch in a server group subconfiguration mode.
Step 6	server name <i>servername</i>	(Optional) Associates a particular TACACS+ server with the defined server group. Repeat this step for each TACACS+ server in the AAA server group. Each server in the group must be previously defined in Step 2.

	Command	Purpose
Step 7	<code>end</code>	Returns to privileged EXEC mode.
Step 8	<code>show tacacs</code>	Verifies your entries.
Step 9	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

To remove the specified TACACS+ server name or address, use the **no tacacs server *servername*** global configuration command. To remove a server group from the configuration list, use the **no aaa group server tacacs+ *group-name*** global configuration command. To remove the IP address of a TACACS+ server, use the **no server *ip-address*** server group subconfiguration command.

Configuring TACACS+ Login Authentication

To configure AAA authentication, define a named list of authentication methods and then apply that list to various ports. The method list defines the types of authentication you intend to perform and the sequence in which you intend to perform them; you must apply the list to a specific port before you can perform any of the defined authentication methods. The only exception is the default method list (which, by coincidence, is named *default*). The default method list is automatically applied to all ports except those that have a named method list explicitly defined. A defined method list overrides the default method list.

A method list describes the sequence and authentication methods that must be queried to authenticate a user. You can designate one or more security protocols for authentication, ensuring a backup system for authentication in case the initial method fails. The software uses the first method listed to authenticate users; if that method fails to respond, the software selects the next authentication method in the method list. This process continues until there is successful communication with a listed authentication method or until all defined methods are exhausted. If authentication fails at any point in this cycle—meaning that the security server or local username database responds by denying the user access—the authentication process stops, and no other authentication methods are attempted.

To configure login authentication, perform this task, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>aaa new-model</code>	Enables AAA.

	Command	Purpose
Step 3	<code>aaa authentication login {default list-name} method1 [method2...]</code>	<p>Creates a login authentication method list.</p> <ul style="list-style-type: none"> To create a default list that is used when a named list is <i>not</i> specified in the login authentication command, use the default keyword followed by the methods that you plan to use in default situations. The default method list is automatically applied to all ports. For <i>list-name</i>, specify a character string to name the list you are creating. For <i>method1...</i>, specify the actual method the authentication algorithm tries. The additional methods of authentication are used only if the previous method returns an error, not if it fails. <p>Select one of these methods:</p> <ul style="list-style-type: none"> enable—Use the enable password for authentication. Before you can use this authentication method, you must define an enable password by using the enable password global configuration command. group tacacs+—Uses TACACS+ authentication. Before you can use this authentication method, you must configure the TACACS+ server. For more information, see the “Identifying the TACACS+ Server Host and Setting the Authentication Key” section on page 3-18. line—Use the line password for authentication. Before you can use this authentication method, you must define a line password. Use the password password line configuration command. local—Use the local username database for authentication. You must enter username information in the database. Use the username password global configuration command. local-case—Use a case-sensitive local username database for authentication. You must enter username information in the database by using the username name password global configuration command. none—Do not use any authentication for login.
Step 4	<code>line [console tty vty] line-number [ending-line-number]</code>	Enters line configuration mode, and configures the lines to which you want to apply the authentication list.
Step 5	<code>login authentication {default list-name}</code>	<p>Applies the authentication list to a line or set of lines.</p> <ul style="list-style-type: none"> If you specify default, use the default list created with the aaa authentication login command. For <i>list-name</i>, specify the list created with the aaa authentication login command.
Step 6	<code>end</code>	Returns to privileged EXEC mode.
Step 7	<code>show running-config</code>	Verifies your entries.
Step 8	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

To disable AAA, use the **no aaa new-model** global configuration command. To disable AAA authentication, use the **no aaa authentication login {default | list-name} method1 [method2...]** global configuration command. To either disable TACACS+ authentication for logins or to return to the default value, use the **no login authentication {default | list-name}** line configuration command.

Configuring TACACS+ Authorization for Privileged EXEC Access and Network Services

AAA authorization limits the services available to a user. When AAA authorization is enabled, the switch uses information retrieved from the user's profile, which is located either in the local user database or on the security server, to configure the user's session. The user is granted access to a requested service only if the information in the user profile allows it.

To set parameters that restrict a user's network access to privileged EXEC mode, use the **aaa authorization** global configuration command with the **tacacs+** keyword.

The **aaa authorization exec tacacs+ local** command sets these authorization parameters:

- Use TACACS+ for privileged EXEC access authorization if authentication was performed by using TACACS+.
- Use the local database if authentication was not performed by using TACACS+.

Note

Authorization is bypassed for authenticated users who log in through the CLI even if authorization has been configured.

To specify TACACS+ authorization for privileged EXEC access and network services, perform this task, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>aaa authorization network tacacs+</code>	Configures the switch for user TACACS+ authorization for all network-related service requests.
Step 3	<code>aaa authorization exec tacacs+</code>	Configures the switch for user TACACS+ authorization if the user has privileged EXEC access. The exec keyword might return user profile information (such as autocommand information).
Step 4	<code>end</code>	Returns to privileged EXEC mode.
Step 5	<code>show running-config</code>	Verifies your entries.
Step 6	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

To disable authorization, use the **no aaa authorization {network | exec} method1** global configuration command.

Starting TACACS+ Accounting

The AAA accounting feature tracks the services that users are accessing and the amount of network resources that they are consuming. When AAA accounting is enabled, the switch reports user activity to the TACACS+ security server in the form of accounting records. Each accounting record contains accounting attribute-value (AV) pairs and is stored on the security server. This data can then be analyzed for network management, client billing, or auditing.

To enable TACACS+ accounting for each Cisco IOS privilege level and for network services, perform this task, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>aaa accounting network start-stop tacacs+</code>	Enables TACACS+ accounting for all network-related service requests.
Step 3	<code>aaa accounting exec start-stop tacacs+</code>	Enables TACACS+ accounting to send a start-record accounting notice at the beginning of a privileged EXEC process and a stop-record at the end.
Step 4	<code>end</code>	Returns to privileged EXEC mode.
Step 5	<code>show running-config</code>	Verifies your entries.
Step 6	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

To disable accounting, use the **no aaa accounting {network | exec} {start-stop} method1...** global configuration command.

Displaying the TACACS+ Configuration

To display TACACS+ server statistics, use the **show tacacs** privileged EXEC command.

Encrypting Passwords

Because protocol analyzers can examine packets (and read passwords), you can increase access security by configuring the Cisco IOS software to encrypt passwords. Encryption prevents the password from being readable in the configuration file.

To configure the Cisco IOS software to encrypt passwords, enter this command:

Command	Purpose
Switch(config)# service password-encryption	Encrypts a password.

Encryption occurs when the current configuration is written or when a password is configured. Password encryption is applied to all passwords, including authentication key passwords, the privileged command password, console and virtual terminal line access passwords, and Border Gateway Protocol (BGP) neighbor passwords. The **service password-encryption** command keeps unauthorized individuals from viewing your password in your configuration file.

Caution

The **service password-encryption** command does not provide a high-level of network security. If you use this command, you should also take additional network security measures.

Although you cannot recover a lost encrypted password (that is, you cannot get the original password back), you can regain control of the switch after having lost or forgotten the encrypted password. See the [“Recovering a Lost Enable Password”](#) section on page 3-25 for more information.

For information on how to display the password or access level configuration, see the [“Displaying the Password, Access Level, and Privilege Level Configuration”](#) section on page 3-24.

Configuring Multiple Privilege Levels

By default, Cisco IOS software has two modes of password security: user EXEC mode and privileged EXEC mode. You can configure up to 16 hierarchical levels of commands for each mode. By configuring multiple passwords, you can allow different sets of users to have access to specified commands.

For example, if you want many users to have access to the **clear line** command, you can assign it level 2 security and distribute the level 2 password to more users. If you want more restricted access to the **configure** command, you can assign it level 3 security and distribute that password to fewer users.

The procedures in the following sections describe how to configure additional levels of security:

- [Setting the Privilege Level for a Command, page 3-23](#)
- [Changing the Default Privilege Level for Lines, page 3-23](#)
- [Logging In to a Privilege Level, page 3-24](#)
- [Exiting a Privilege Level, page 3-24](#)
- [Displaying the Password, Access Level, and Privilege Level Configuration, page 3-24](#)

Setting the Privilege Level for a Command

To set the privilege level for a command, perform this task:

	Command	Purpose
Step 1	Switch(config)# privilege mode level level <i>command</i>	Sets the privilege level for a command.
Step 2	Switch(config)# enable password level level <i>[encryption-type] password</i>	Specifies the enable password for a privilege level.

For information on how to display the password or access level configuration, see the [“Displaying the Password, Access Level, and Privilege Level Configuration”](#) section on page 3-24.

Changing the Default Privilege Level for Lines

To change the default privilege level for a given line or a group of lines, perform this task:

Command	Purpose
Switch(config-line)# privilege level level	Changes the default privilege level for the line.

For information on how to display the password or access level configuration, see the [“Displaying the Password, Access Level, and Privilege Level Configuration”](#) section on page 3-24.

Logging In to a Privilege Level

To log in at a specified privilege level, enter this command:

Command	Purpose
Switch# enable <i>level</i>	Logs in to a specified privilege level.

Exiting a Privilege Level

To exit to a specified privilege level, enter this command:

Command	Purpose
Switch# disable <i>level</i>	Exits to a specified privilege level.

Displaying the Password, Access Level, and Privilege Level Configuration

To display detailed password information, perform this task:

	Command	Purpose
Step 1	Switch# show running-config	Displays the password and access level configuration.
Step 2	Switch# show privilege	Shows the privilege level configuration.

This example shows how to display the password and access level configuration:

```
Switch# show running-config
Building configuration...

Current configuration:
!
version 12.0
service timestamps debug datetime localtime
service timestamps log datetime localtime
no service password-encryption
!
hostname Switch
!
boot system flash sup-bootflash
enable password lab
!
<...output truncated...>
```

This example shows how to display the privilege level configuration:

```
Switch# show privilege
Current privilege level is 15
Switch#
```

Recovering a Lost Enable Password

**Note**

For more information on the configuration register which is preconfigured in NVRAM, see [“Configuring the Software Configuration Register”](#) section on page 3-26.

To recover a lost enable password, follow these steps:

-
- | | |
|---------------|--|
| Step 1 | Connect to the console interface. |
| Step 2 | Stop the boot sequence and enter ROM monitor by pressing Ctrl-C during the first 5 seconds of bootup. |
| Step 3 | Configure the switch to boot-up without reading the configuration memory (NVRAM). |
| Step 4 | Reboot the system. |
| Step 5 | Access enable mode (this can be done without a password if a password has not been configured). |
| Step 6 | View or change the password, or erase the configuration. |
| Step 7 | Reconfigure the switch to boot-up and read the NVRAM as it normally does. |
| Step 8 | Reboot the system. |
-

Modifying the Supervisor Engine Startup Configuration

These sections describe how the startup configuration on the supervisor engine works and how to modify the BOOT variable and the configuration register:

- [Understanding the Supervisor Engine Boot Configuration, page 3-25](#)
- [Configuring the Software Configuration Register, page 3-26](#)
- [Specifying the Startup System Image, page 3-31](#)
- [Controlling Environment Variables, page 3-32](#)

Understanding the Supervisor Engine Boot Configuration

The supervisor engine boot process involves two software images: ROM monitor and supervisor engine software. When the switch is booted or reset, the ROMMON code is executed. Depending on the NVRAM configuration, the supervisor engine either stays in ROMMON mode or loads the supervisor engine software.

Two user-configurable parameters determine how the switch boots: the configuration register and the BOOT environment variable. The configuration register is described in the [“Modifying the Boot Field and Using the boot Command”](#) section on page 3-28. The BOOT environment variable is described in the [“Specifying the Startup System Image”](#) section on page 3-31.

Understanding the ROM Monitor

The ROM monitor (ROMMON) is invoked at switch bootup, reset, or when a fatal exception occurs. The switch enters ROMMON mode if the switch does not find a valid software image, if the NVRAM configuration is corrupted, or if the configuration register is set to enter ROMMON mode. From ROMMON mode, you can manually load a software image from bootflash or a flash disk, or you can boot up from the management interface. ROMMON mode loads a primary image from which you can configure a secondary image to boot up from a specified source either locally or through the network using the BOOTLDR environment variable. This variable is described in the “[Switch#](#)” section on [page 3-33](#).

You can also enter ROMMON mode by restarting the switch and then pressing **Ctrl-C** during the first five seconds of startup. If you are connected through a terminal server, you can escape to the Telnet prompt and enter the **send break** command to enter ROMMON mode.

Note

Ctrl-C is always enabled for five seconds after you reboot the switch, regardless of whether the configuration-register setting has **Ctrl-C** disabled.

The ROM monitor has these features:

- Power-on confidence test
- Hardware initialization
- Boot capability (manual bootup and autoboot)
- File system (read-only while in ROMMON)

Configuring the Software Configuration Register

The switch uses a 16-bit software configuration register, which allows you to set specific system parameters. Settings for the software configuration register are preconfigured in NVRAM.

Here are some reasons why you might want to change the software configuration register settings:

- To select a boot source and default boot filename
- To control broadcast addresses
- To set the console terminal baud rate
- To load operating software from flash memory
- To recover a lost password
- To manually boot the system using the **boot** command at the bootstrap program prompt
- To force an automatic bootup from the system bootstrap software (boot image) or from a default system image in onboard flash memory, and read any **boot system** commands that are stored in the configuration file in NVRAM

Caution

To avoid possibly halting the switch, remember that valid configuration register settings might be combinations of settings and not just the individual settings listed in [Table 3-3](#). For example, the factory default value of 0x2101 is a combination of settings.

Table 3-3 lists the meaning of each of the software configuration memory bits. Table 3-4 defines the *boot* field.

Table 3-3 Software Configuration Register Bits

Bit Number ¹	Hexadecimal	Meaning
00 to 03	0x0000 to 0x000F	Boot field (see Table 3-4)
04	0x0010	Unused
05	0x0020	Bit two of console line speed
06	0x0040	Causes system software to ignore NVRAM contents
07	0x0080	OEM ² bit enabled
08	0x0100	Unused
09	0x0200	Unused
10	0x0400	IP broadcast with all zeros
11 to 12	0x0800 to 0x1000	Bits one and zero of Console line speed (default is 9600 baud)
13	0x2000	Loads ROM monitor after netboot fails
14	0x4000	IP broadcasts do not have network numbers

1. The factory default value for the configuration register is 0x2101. This value is a combination of the following: binary bit 13, bit 8 = 0x0100 and binary bits 00 through 03 = 0x0001. See Table 3-4.
2. OEM = original equipment manufacturer.

Table 3-4 Explanation of Boot Field (Configuration Register Bits 00 to 03)

Boot Field	Meaning
00	Stays at the system bootstrap prompt (does not autoboot).
01	Boots the first file in onboard flash memory.
02	Auto boots using image(s) specified by the BOOT environment variable. If more than one image is specified, the switch attempts to boot the first image specified in the BOOT variable. As long as the switch can successfully boot from this image, the same image is used on a reboot. If the switch fails to boot from the image specified in the BOOT variable, the switch tries to boot from the next image listed in the BOOT variable. If the end of the BOOT variable is reached without the switch booting successfully, the switch attempts the boot from the beginning of the BOOT variable. The autoboot continues until the switch successfully boots from one of the images specified in the BOOT variable.
03	Unsupported or unused. If the boot field is set to this value, a warning message is displayed, indicating that you must check and reenter the correct value.
04 ¹	Auto boots the image that is retrieved from a network-based source, that is, a DHCP server. Depending on how you configure the DHCP boot file field, the system then retrieves the files from the specified remote (HTTP or TFTP) server.

Table 3-4 Explanation of Boot Field (Configuration Register Bits 00 to 03) (continued)

Boot Field	Meaning
05 ¹	Auto boots the image that is retrieved from a network-based source, that is, a DHCP server. Depending on how you configure the DHCP boot file field, the system then retrieves the files from the specified remote (HTTP or TFTP) server. If this fails, the system resorts to the method specified in boot field 01.
06 ¹	Auto boots the image that is retrieved from a network-based source, that is, a DHCP server. Depending on how you configure the DHCP boot file field, the system then retrieves the files from the specified remote (HTTP or TFTP) server. If this fails, the system resorts to the method specified in boot field 02.

1. Note: Requires ROMMON version 15.0(1r)SG14 on Catalyst 4500-X Series Switches, and ROMMON version 15.1(1r)SG8 on Catalyst 4500-E Series Switches.

Modifying the Boot Field and Using the boot Command

The configuration register boot field determines whether the switch loads an operating system image and, if so, where it obtains this system image. The following sections describe how to use and set the configuration register boot field and the procedures you must perform to modify the configuration register boot field. In ROMMON, to modify the configuration register and change boot settings, use the **confreg** command.

Bits 0 through 3 of the software configuration register contain the boot field.

Note

The factory default configuration register setting for systems and spares is 0x2101. However, the recommended value is 0x0102.

When the boot field is set to either 00 or 01 (0-0-0-0 or 0-0-0-1), the system ignores any boot instructions in the system configuration file and the following occurs:

- When the boot field is set to 00, you must boot up the operating system manually by entering the **boot** command at the system bootstrap or ROMMON prompt.
- When the boot field is set to 01, the system boots the first image in the bootflash single in-line memory module (SIMM).
- When the entire boot field equals a value between 0-0-1-0 and 1-1-1-1, the switch loads the system image specified by **boot system** commands in the startup configuration file.

Caution

If you set bootfield to a value between 0-0-1-0 and 1-1-1-1, you must specify a value in the **boot system** command, else the switch cannot boot up and remains in ROMMON.

You can enter the **boot** command only or enter the command and include additional boot instructions, such as the name of a file stored in flash memory, or a file that you specify for booting from a network server. If you use the **boot** command without specifying a file or any other boot instructions, the system boots from the default flash image (the first image in onboard flash memory). Otherwise, you can instruct the system to boot up from a specific flash image (using the **boot system flash filename** command).

You can also use the **boot** command to boot up images stored in the compact flash cards located in slot 0 on the supervisor engine.

You must **reload** the switch for any changes to take effect.

Modifying the Boot Field

To modify the boot field from the software configuration register, perform this task:

	Command	Purpose
Step 1	Switch# show version	Determines the current configuration register setting.
Step 2	Switch# configure terminal	Enters configuration mode, and specify the terminal option.
Step 3	Switch(config)# config-register <i>value</i>	Modifies the existing configuration register setting to reflect the way you want the switch to load a system image.
Step 4	Switch(config)# end	Exits configuration mode.
Step 5	Switch# reload	Reboots the switch to make your changes take effect.

To modify the configuration register while the switch is running Cisco IOS software, perform this task:

	Command	Purpose
Step 1	Switch# enable	Enters the privileged EXEC mode. Enter the password if required.
Step 2	Switch# configure terminal	Enters configuration mode, and specifies the terminal option.
Step 3	Switch(config)# config-register 0x102	Sets the contents of the configuration register to the specified <i>value</i> , where <i>value</i> is a hexadecimal number preceded by 0x (see Table 3-3 on page 3-27).
Step 4	Switch(config)# end	Exits configuration mode. The new value settings are saved to memory; however, the new settings do not take effect until the system is rebooted.
Step 5	Switch# show version	Displays the configuration register value currently in effect. The value is displayed on the last line of the screen display, as shown in this sample output: Configuration register is 0x141 (will be 0x102 at next reload)
Step 6	Save your settings.	See the “Saving the Running Configuration Settings to Your Start-Up File” section on page 3-10 . Note that configuration register changes take effect only after the system reloads, such as when you enter a reload command from the console.
Step 7	Switch# reload	The new configuration register value takes effect with the next system boot up.

Modifying the Configuration Register Value for Wireless Mode

On Catalyst 4500E Series Switches with Supervisor Engine 9-E and 8-E, to boot the system in wireless mode, perform this task:

	Command	Purpose
Step 1	Switch# enable	Enters the privileged EXEC mode. Enter the password if required.
Step 2	Switch# configure terminal	Enters configuration mode, and specifies the terminal option.
Step 3	Switch(config)# boot system bootflash:packages.conf	Instructs the system to boot up from the specified flash image.
Step 4	Switch(config)# config-register 0x2102	Sets the contents of the configuration register to the specified value.
Step 5	Switch(config)# end	Exits configuration mode. The new value settings are saved to memory; however, the new settings do not take effect until the system is rebooted.

Verifying the Configuration Register Setting

Enter the **show version** EXEC command to verify the current configuration register setting. In ROMMON mode, enter the **show version** command to verify the configuration register setting.

To verify the configuration register setting for the switch, perform this task:

Command	Purpose
Switch# show version	Displays the configuration register setting.

In this example, the **show version** command indicates that the current configuration register is set so that the switch does not automatically load an operating system image. Instead, it enters ROMMON mode and waits for you to enter ROM monitor commands.

Supervisor Engine 6-E and Supervisor Engine 6L-E

Specifying the Startup System Image

You can enter multiple boot commands in the startup configuration file or in the BOOT environment variable to provide backup methods for loading a system image.

The BOOT environment variable is also described in the “Specify the Startup System Image in the Configuration File” section in the “Loading and Maintaining System Images and Microcode” chapter of the *Cisco IOS Configuration Fundamentals Configuration Guide*.

Use the following sections to configure your switch to boot from flash memory. Flash memory can be either single in-line memory modules (SIMMs) or flash disks. Check the appropriate hardware installation and maintenance guide for information about types of flash memory.

Flash Memory Features

Flash memory allows you to do the following:

- Remotely load multiple system software images through TFTP or RCP transfers (one transfer for each file loaded)
- Boot a switch manually or automatically from a system software image stored in flash memory (you can also boot directly from ROM)
- Copy the system image to flash memory using TFTP

- Boot the system from flash memory either automatically or manually
- Copy the flash memory image to a network server using TFTP or RCP

For more information on flash memory, see this URL:

http://www.cisco.com/en/US/docs/switches/lan/catalyst4500/hardware/configuration/notes/OL_2788.html

Security Precautions

Note the following security precaution when loading from flash memory:

Caution

You can only change the system image stored in flash memory from privileged EXEC level on the console terminal.

Configuring Flash Memory

To configure your switch to boot from flash memory, perform the following procedure. Refer to the appropriate hardware installation and maintenance publication for complete instructions on installing the hardware.

-
- Step 1** Copy a system image to flash memory using TFTP, FTP, or through a VRF interface.
- Refer to section “Copy Configuration Files from a Network Server to the Router” in chapter “Managing Configuration Files”, of the “Managing Configuration Files Configuration Guide” at the following URL:
- <http://www.cisco.com/c/en/us/td/docs/ios-xml/ios/config-mgmt/configuration/xr-3e/config-mgmt-xr-3e-book/cm-config-files.html>.
- Configure the system to boot automatically from the desired file in flash memory.
- You might need to change the configuration register value. See the “[Modifying the Boot Field and Using the boot Command](#)” section on page 3-28, for more information on modifying the configuration register.
- Step 2** Save your configurations.
- Step 3** Power cycle and reboot your system to verify that all is working as expected.
-

Controlling Environment Variables

Although the ROM monitor controls environment variables, you can create, modify, or view them with certain commands. To create or modify the BOOT and BOOTLDR variables, use the **boot system** and **boot bootldr** global configuration commands, respectively. Refer to the “Specify the Startup System Image in the Configuration File” section in the “Loading and Maintaining System Images and Microcode” chapter of the *Configuration Fundamentals Configuration Guide* for details on setting the BOOT environment variable.

**Note**

When you use the **boot system** and **boot bootldr** global configuration commands, you affect only the running configuration. To save the configuration for future use, you must save the environment variable settings to your startup configuration, which places the information under ROM monitor control. Enter the **copy system:running-config nvram:startup-config** command to save the environment variables from your running configuration to your startup configuration.

You can view the contents of the BOOT and BOOTLDR variables using the **show bootvar** command. This command displays the settings for these variables as they exist in the startup configuration and in the running configuration if a running configuration setting differs from a startup configuration setting. This example shows how to check the BOOT and BOOTLDR variables on the switch:

```
Switch# show bootvar
BOOTLDR variable = bootflash:cat4000-is-mz,1;
Configuration register is 0x0
Switch#
```

Replacing and Rolling-Back Configuration

For detailed information about this feature, see the “Configuration Replace and Configuration Rollback” chapter of the [Managing Configuration Files](#) feature guide on cisco.com.

The following restrictions pertain to the use of this feature on Catalyst 4500 Series Switches:

- You cannot use this feature to convert a VSS system to a non-VSS (standalone) system, or the other way around. The configuration that is replaced and the new configuration that is replacing the existing, must both apply to the same kind of system - whether VSS or non-VSS.
- Do not use the **configure replace** command to replace wireless configuration with non-wireless configuration, or the other way around.
- Catalyst 4500 Series Switches in a high availability (HA) configuration cannot accept any configuration changes when the standby supervisor is booting.

This restriction also applies to the **configure replace** command.

- If the hw-module line in the existing configuration is being replaced by configuration with a different hw-module line, you must manually reload the entire system. To locate the hw-module line see the following sample output (truncated output):

```
Switch# show running-config brief
Building configuration...
Current configuration : 8730 bytes
Last configuration change at 19:40:01 UTC Mon Oct 26 2015 by cisco
version 15.2
-----output truncated-----
hw-module module 5 mode 1
```

Resetting a Switch to Factory Default Settings

Manufacturing and repair centers can use the **erase /all non-default** command to do the following:

- Clear the nonvolatile configurations and states of the local supervisor engine (NVRAM and flashes).
- Set the factory default parameters on the Catalyst 4500 Series Switches before it is ready to ship to a customer.

For example, entering this command can generate the following output:

```
Switch# erase /all non-default
Erase and format operation will destroy all data in non-volatile storage. Continue?
[confirm]
Formatting bootflash: ...

Format of bootflash complete
Erasing nvram:
Erasing cat4000_flash:
Clearing crashinfo:data
Clearing the last power failure timestamp
Clearing all ROMMON variables
Setting default ROMMON variables:
    ConfigReg=0x2101
    PS1=rommon ! >
    EnableAutoConfig=1
Setting vtp mode to transparent
%WARNING! Please reboot the system for the changes to take effect
Switch#
00:01:48: %SYS-7-NV_BLOCK_INIT: Initialized the geometry of nvram
Switch#
```

If the switch is accessible to a TFTP server, you can copy an image to the bootflash memory with the TFTP command:

```
Switch# copy tftp://192.20.3.123/tftpboot/abc/cat4500-entservices-mz.bin bootflash:
```

When the copying is completed, you can reboot the just-copied switch image to the image stored in the bootflash memory with the **reload** command:

```
Switch# reload

System configuration has been modified. Save? [yes/no]: no
Proceed with reload? [confirm]

00:06:17: %SYS-5-RELOAD: Reload requested by console. Reload Reason: Reload Command.
```

To see details about the default parameters set by the **erase /all non-default** command, see the usage guidelines for the **erase** command in the *Catalyst 4500 Series Switch Cisco IOS Command Reference*.

Administering the Switch

This chapter describes how to perform one-time operations to administer the Catalyst 4500 series switch.

This chapter also describes how to install and configure the Embedded CiscoView network management system to provide a graphical representation of a Catalyst 4500 series switch and to provide a GUI-based management and configuration interface.

This chapter includes the following major sections:

- [Managing the System Time and Date, page 4-1](#)
- [Managing Software Licenses Using Right-To-Use Licenses, page 4-15](#)
- [Configuring a System Name and Prompt, page 4-26](#)
- [Understanding the Domain Name System, page 4-26](#)
- [Creating a Banner, page 4-33](#)
- [Managing the MAC Address Table, page 4-37](#)
- [Managing the ARP Table, page 4-53](#)
- [Configuring Embedded CiscoView Support, page 4-53](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Managing the System Time and Date

You can configure the system time and date on your switch manually or automatically by using Network Time Protocol (NTP).

These sections contain this configuration information:

- [System Clock, page 4-2](#)
- [Understanding Network Time Protocol, page 4-2](#)
- [Configuring NTP, page 4-3](#)
- [Configuring Time and Date Manually, page 4-11](#)

System Clock

The core of the time service is the system clock, which monitors the date and time. This clock starts when the system starts.

The system clock can provide time to these services:

- User **show** commands
- Logging and debugging messages

The system clock keeps track of time internally based on Universal Time Coordinated (UTC), also known as Greenwich Mean Time (GMT). You can configure information about the local time zone and summer time (daylight saving time) so that the time is correct for the local time zone.

The system clock keeps track of whether the time is *authoritative* or not (whether it was set by a time source considered to be authoritative). If it is not authoritative, the time is available only for display purposes and is not redistributed. For configuration information, see the [“Configuring Time and Date Manually” section on page 4-11](#).

Understanding Network Time Protocol

The NTP is designed to synchronize a network of devices. NTP runs over User Datagram Protocol (UDP), which runs over IP. NTP is documented in RFC 1305.

An NTP network usually gets its time from an authoritative time source, such as a radio clock or an atomic clock attached to a time server. NTP then distributes this time across the network. NTP is extremely efficient; no more than one packet per minute is necessary to synchronize two devices to within a millisecond of one another.

NTP uses the concept of a *stratum* to describe how many NTP hops away a device is from an authoritative time source. A stratum 1 time server has a radio or atomic clock directly attached, a stratum 2 time server receives its time through NTP from a stratum 1 time server, and so on. A device running NTP automatically chooses as its time source the device with the lowest stratum number with which it communicates through NTP. This strategy effectively builds a self-organizing tree of NTP speakers.

NTP avoids synchronizing to a device whose time might not have been synchronized. NTP also compares the time reported by several devices and does not synchronize to a device whose time is significantly different than the others, even if its stratum is lower.

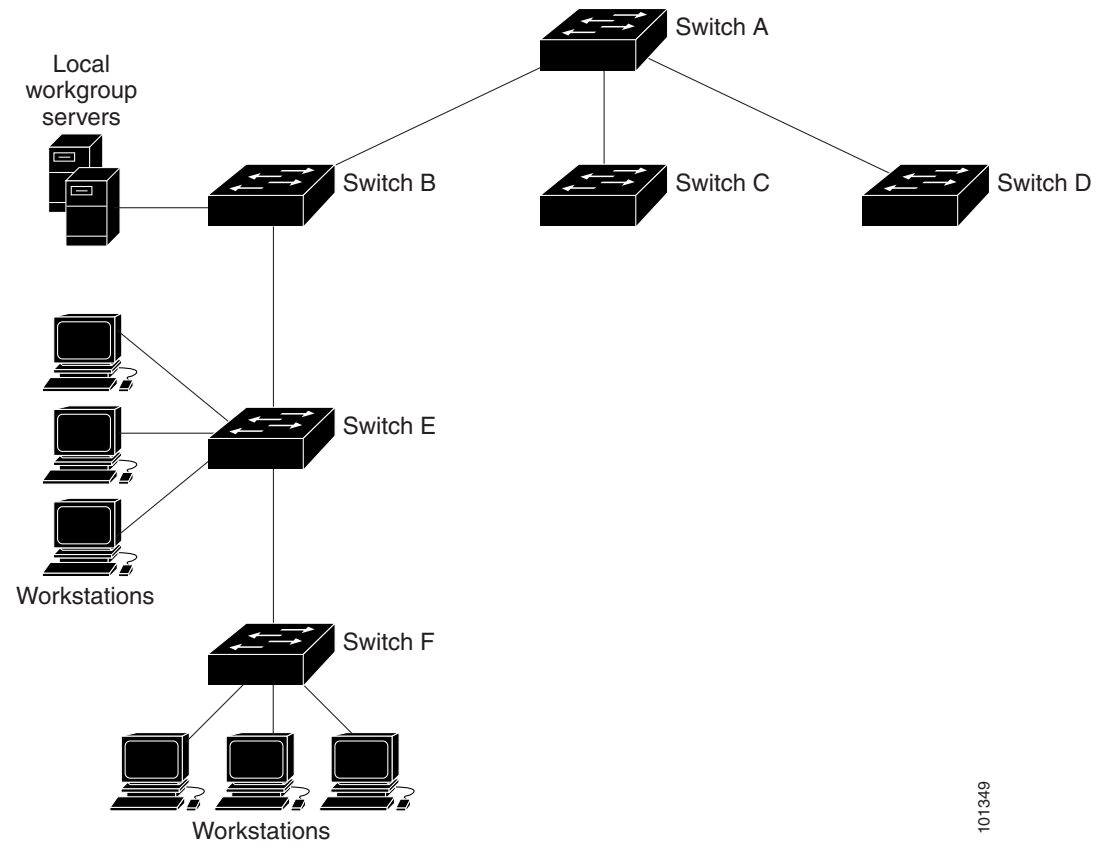

The communications between devices running NTP (known as *associations*) are usually statically configured; each device is given the IP address of all devices with which it should associate. Accurate timekeeping is possible by exchanging NTP messages between each pair of devices with an association. However, in a LAN environment, NTP can be configured to use IP broadcast messages instead. This alternative reduces configuration complexity because each device can be configured to send or receive broadcast messages; however, information flow is one-way only.

The time kept on a device is a critical resource; you should use the security features of NTP to avoid the accidental or malicious setting of an incorrect time. Two mechanisms are available: an access list-based restriction scheme and an encrypted authentication mechanism.

Cisco’s implementation of NTP does not support stratum 1 service; it is not possible to connect to a radio or atomic clock. We recommend that the time service for your network be derived from the public NTP servers available on the IP Internet.

Figure 4-1 shows a typical network example using NTP. Switch A is the NTP master, with Switches B, C, and D configured in NTP server mode, in server association with Switch A. Switch E is configured as an NTP peer to the upstream and downstream switches, Switch B and Switch F, respectively.

Figure 4-1 Typical NTP Network Configuration

If the network is isolated from the Internet, Cisco's implementation of NTP allows a device to act as if it is synchronized through NTP, when it is not. Other devices then synchronize to that device through NTP.

NTP time overrides the time set by any other method.

Several manufacturers include NTP software for their host systems, and a public version for systems running UNIX and its various derivatives is also available. This software allows host systems to be synchronized as well.

Configuring NTP

These sections contain this configuration information:

- [Default NTP Configuration, page 4-4](#)
- [Configuring NTP Authentication, page 4-4](#)
- [Configuring NTP Associations, page 4-6](#)
- [Configuring NTP Broadcast Service, page 4-7](#)
- [Configuring NTP Access Restrictions, page 4-8](#)

- [Configuring the Source IP Address for NTP Packets, page 4-10](#)
- [Displaying the NTP Configuration, page 4-11](#)

Default NTP Configuration

Table 4-1 shows the default NTP configuration.

Table 4-1 Default NTP Configuration

Feature	Default Setting
NTP authentication	Disabled. No authentication key is specified.
NTP peer or server associations	None configured.
NTP broadcast service	Disabled; no interface sends or receives NTP broadcast packets.
NTP access restrictions	No access control is specified.
NTP packet source IP address	The source address is set by the outgoing interface.

NTP is enabled on all interfaces by default. All interfaces receive NTP packets.

Configuring NTP Authentication

This procedure must be coordinated with the administrator of the NTP server; the information you configure in this procedure must be matched by the servers used by the switch to synchronize its time to the NTP server.

To authenticate the associations (communications between devices running NTP that provide for accurate timekeeping) with other devices for security purposes, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ntp authenticate</code>	Enables the NTP authentication feature, which is disabled by default.
Step 3	<code>ntp authentication-key number md5 value</code>	<p>Defines the authentication keys. By default, none are defined.</p> <ul style="list-style-type: none"> • For <i>number</i>, specify a key number. The range is 1 to 4294967295. • md5 specifies that message authentication support is provided by using the message digest algorithm 5 (MD5). • For <i>value</i>, enter an arbitrary string of up to eight characters for the key. <p>The switch does not synchronize to a device unless both have one of these authentication keys, and the key number is specified by the <code>ntp trusted-key key-number</code> command.</p>

	Command	Purpose
Step 4	ntp trusted-key <i>key-number</i>	Specifies one or more key numbers (defined in Step 3) that a peer NTP device must provide in its NTP packets for this switch to synchronize to it. By default, no trusted keys are defined. For <i>key-number</i> , specify the key defined in Step 3. This command provides protection against accidentally synchronizing the switch to a device that is not trusted.
Step 5	end	Returns to privileged EXEC mode.
Step 6	show running-config	Verifies your entries.
Step 7	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable NTP authentication, use the **no ntp authenticate** global configuration command. To remove an authentication key, use the **no ntp authentication-key** *number* global configuration command. To disable authentication of the identity of a device, use the **no ntp trusted-key** *key-number* global configuration command.

This example shows how to configure the switch to synchronize only to devices providing authentication key 42 in the device's NTP packets:

```
Switch# configure terminal
Switch(config)# ntp authenticate
Switch(config)# ntp authentication-key 42 md5 aNiceKey
Switch(config)# ntp trusted-key 42
Switch(config)# end
Switch#
```

Configuring NTP Associations

An NTP association can be a peer association (this switch can either synchronize to the other device or allow the other device to synchronize to it), or it can be a server association (meaning that only this switch synchronizes to the other device, and not the other way around).

To form an NTP association with another device, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ntp peer ip-address [version number]</code> <code>[key keyid] [source interface]</code> <code>[prefer]</code> or <code>ntp server ip-address [version number]</code> <code>[key keyid] [source interface]</code> <code>[prefer]</code>	Configures the switch system clock to synchronize a peer or to be synchronized by a peer (peer association). or Configures the switch system clock to be synchronized by a time server (server association). No peer or server associations are defined by default. <ul style="list-style-type: none"> For <i>ip-address</i> in a peer association, specify either the IP address of the peer providing, or being provided, the clock synchronization. For a server association, specify the IP address of the time server providing the clock synchronization. (Optional) For <i>number</i>, specify the NTP version number. The range is 1 to 3. By default, Version 3 is selected. (Optional) For <i>keyid</i>, enter the authentication key defined by entering the ntp authentication-key global configuration command. (Optional) For <i>interface</i>, specify the interface from which to pick the IP source address. By default, the source IP address is taken from the outgoing interface. (Optional) Enter the prefer keyword to make this peer or server the preferred one that provides synchronization. This keyword reduces switching back and forth between peers and servers.
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	<code>show running-config</code>	Verifies your entries.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

You need to configure only one end of an association; the other device can automatically establish the association. If you are using the default NTP version (Version 3) and NTP synchronization does not occur, try using NTP Version 2. Many NTP servers on the Internet run Version 2.

To remove a peer or server association, use the **no ntp peer ip-address** or the **no ntp server ip-address** global configuration command.

This example shows how to configure the switch to synchronize its system clock with the clock of the peer at IP address 172.16.22.44 using NTP Version 2:

```
Switch# configure terminal
Switch(config)# ntp server 172.16.22.44 version 2
Switch(config)# end
Switch#
```

Configuring NTP Broadcast Service

The communications between devices running NTP (known as *associations*) are usually statically configured; each device is given the IP addresses of all devices with which it should form associations. Accurate timekeeping is possible by exchanging NTP messages between each pair of devices with an association. However, in a LAN environment, NTP can be configured to use IP broadcast messages instead. This alternative reduces configuration complexity because each device can be configured to send or receive broadcast messages. However, the information flow is one-way only.

The switch can send or receive NTP broadcast packets on an interface-by-interface basis if there is an NTP broadcast server, such as a router, broadcasting time information on the network. The switch can send NTP broadcast packets to a peer so that the peer can synchronize to it. The switch can also receive NTP broadcast packets to synchronize its own clock. This section provides procedures for both sending and receiving NTP broadcast packets.

To configure the switch to send NTP broadcast packets to peers so that they can synchronize their clock to the switch, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>interface interface-id</code>	Specifies the interface to send NTP broadcast packets, and enter interface configuration mode.
Step 3	<code>ntp broadcast [version number] [key keyid] [destination-address]</code>	Enables the interface to send NTP broadcast packets to a peer. By default, this feature is disabled on all interfaces. <ul style="list-style-type: none"> • (Optional) For <i>number</i>, specify the NTP version number. The range is 1 to 3. If you do not specify a version, Version 3 is used. • (Optional) For <i>keyid</i>, specify the authentication key to use when sending packets to the peer. • (Optional) For <i>destination-address</i>, specify the IP address of the peer that is synchronizing its clock to this switch.
Step 4	<code>end</code>	Returns to privileged EXEC mode.
Step 5	<code>show running-config</code>	Verifies your entries.
Step 6	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

To disable the interface from sending NTP broadcast packets, use the **no ntp broadcast** interface configuration command.

This example shows how to configure a port to send NTP Version 2 packets:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet0/1
Switch(config-if)# ntp broadcast version 2
Switch(config-if)# end
Switch#
```

To configure the switch to receive NTP broadcast packets from connected peers, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>interface interface-id</code>	Specifies the interface to receive NTP broadcast packets, and enter interface configuration mode.
Step 3	<code>ntp broadcast client</code>	Enables the interface to receive NTP broadcast packets. By default, no interfaces receive NTP broadcast packets.
Step 4	<code>exit</code>	Returns to global configuration mode.
Step 5	<code>ntp broadcastdelay microseconds</code>	(Optional) Changes the estimated round-trip delay between the switch and the NTP broadcast server. The default is 3000 microseconds; the range is 1 to 999999.
Step 6	<code>end</code>	Returns to privileged EXEC mode.
Step 7	<code>show running-config</code>	Verifies your entries.
Step 8	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

To disable an interface from receiving NTP broadcast packets, use the **no ntp broadcast client** interface configuration command. To change the estimated round-trip delay to the default, use the **no ntp broadcastdelay** global configuration command.

This example shows how to configure a port to receive NTP broadcast packets:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet0/1
Switch(config-if)# ntp broadcast client
Switch(config-if)# end
Switch#
```

Configuring NTP Access Restrictions

You can control NTP access on two levels as described in these sections:

- [Creating an Access Group and Assigning a Basic IP Access List, page 4-9](#)
- [Disabling NTP Services on a Specific Interface, page 4-10](#)

Creating an Access Group and Assigning a Basic IP Access List

To control access to NTP services by using access lists, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ntp access-group {query-only serve-only serve peer} access-list-number</code>	Creates an access group, and apply a basic IP access list. The keywords have these meanings: <ul style="list-style-type: none"> • query-only—Allows only NTP control queries. • serve-only—Allows only time requests. • serve—Allows time requests and NTP control queries, but does not allow the switch to synchronize to the remote device. • peer—Allows time requests and NTP control queries and allows the switch to synchronize to the remote device. For <i>access-list-number</i> , enter a standard IP access list number from 1 to 99.
Step 3	<code>access-list access-list-number permit source [source-wildcard]</code>	Creates the access list. <ul style="list-style-type: none"> • For <i>access-list-number</i>, enter the number specified in Step 2. • Enter the permit keyword to permit access if the conditions are matched. • For <i>source</i>, enter the IP address of the device that is permitted access to the switch. • (Optional) For <i>source-wildcard</i>, enter the wildcard bits to be applied to the source. Note When creating an access list, remember that, by default, the end of the access list contains an implicit deny statement for everything if it did not find a match before reaching the end.
Step 4	<code>end</code>	Returns to privileged EXEC mode.
Step 5	<code>show running-config</code>	Verifies your entries.
Step 6	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

The access group keywords are scanned in this order, from least restrictive to most restrictive:

1. **peer**—Allows time requests and NTP control queries and allows the switch to synchronize itself to a device whose address passes the access list criteria.
2. **serve**—Allows time requests and NTP control queries, but does not allow the switch to synchronize itself to a device whose address passes the access list criteria.
3. **serve-only**—Allows only time requests from a device whose address passes the access list criteria.
4. **query-only**—Allows only NTP control queries from a device whose address passes the access list criteria.

If the source IP address matches the access lists for more than one access type, the first type is granted. If no access groups are specified, all access types are granted to all devices. If any access groups are specified, only the specified access types are granted.

To remove access control to the switch NTP services, use the **no ntp access-group {query-only | serve-only | serve | peer}** global configuration command.

This example shows how to configure the switch to allow itself to synchronize to a peer from access list 99. However, the switch restricts access to allow only time requests from access list 42:

```
Switch# configure terminal
Switch(config)# ntp access-group peer 99
Switch(config)# ntp access-group serve-only 42
Switch(config)# access-list 99 permit 172.20.130.5
Switch(config)# access list 42 permit 172.20.130.6
Switch(config)# end
Switch#
```

Disabling NTP Services on a Specific Interface

NTP services are enabled on all interfaces by default.

To disable NTP packets from being received on an interface, perform this task:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	interface <i>interface-id</i>	Enters interface configuration mode, and specify the interface to disable.
Step 3	ntp disable	Disables NTP packets from being received on the interface. By default, all interfaces receive NTP packets. To reenabling receipt of NTP packets on an interface, use the no ntp disable interface configuration command.
Step 4	end	Returns to privileged EXEC mode.
Step 5	show running-config	Verifies your entries.
Step 6	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Configuring the Source IP Address for NTP Packets

When the switch sends an NTP packet, the source IP address is normally set to the address of the interface through which the NTP packet is sent. To use a particular source IP address for all NTP packets, use the **ntp source** global configuration command. The address is taken from the specified interface. This command is useful if the address on an interface cannot be used as the destination for reply packets.

To configure a specific interface from which the IP source address is to be taken, perform this task:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	ntp source <i>type number</i>	Specifies the interface type and number from which the IP source address is taken. By default, the source address is set by the outgoing interface.
Step 3	end	Returns to privileged EXEC mode.
Step 4	show running-config	Verifies your entries.
Step 5	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The specified interface is used for the source address for all packets sent to all destinations. If a source address is to be used for a specific association, use the **source** keyword in the **ntp peer** or **ntp server** global configuration command as described in the [“Configuring NTP Associations”](#) section on page 4-6.

Displaying the NTP Configuration

Use the following privileged EXEC commands to display NTP information:

- **show ntp associations [detail]**
- **show ntp status**

For detailed information about the fields in these displays, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.3*.

Configuring Time and Date Manually

If no other source of time is available, you can manually configure the time and date after the system is restarted. The time remains accurate until the next system restart. We recommend that you use manual configuration only as a last resort. If you have an outside source to which the switch can synchronize, you do not need to manually set the system clock.

These sections contain this configuration information:

- [Setting the System Clock, page 4-11](#)
- [Displaying the Time and Date Configuration, page 4-12](#)
- [Configuring the Time Zone, page 4-12](#)
- [Configuring Summer Time \(Daylight Saving Time\), page 4-13](#)

Setting the System Clock

If you have an outside source on the network that provides time services, such as an NTP server, you do not need to manually set the system clock.

To set the system clock, perform this task:

	Command	Purpose
Step 1	clock set <i>hh:mm:ss day month year</i> or clock set <i>hh:mm:ss month day year</i>	Manually sets the system clock using one of these formats. <ul style="list-style-type: none"> • For <i>hh:mm:ss</i>, specify the time in hours (24-hour format), minutes, and seconds. The time specified is relative to the configured time zone. • For <i>day</i>, specify the day by date in the month. • For <i>month</i>, specify the month by name. • For <i>year</i>, specify the year (no abbreviation).

This example shows how to manually set the system clock to 1:32 p.m. on July 23, 2001:

```
Switch# clock set 13:32:00 23 July 2001
```

Displaying the Time and Date Configuration

To display the time and date configuration, use the **show clock [detail]** privileged EXEC command.

The system clock keeps an *authoritative* flag that shows whether the time is authoritative (believed to be accurate). If the system clock was set by a timing source such as NTP, the flag is set. If the time is not authoritative, it is used only for display purposes. Until the clock is authoritative and the *authoritative* flag is set, the flag prevents peers from synchronizing to the clock when the peers' time is invalid.

The symbol that precedes the **show clock** display has this meaning:

- *—Time is not authoritative.
- (blank)—Time is authoritative.
- .—Time is authoritative, but NTP is not synchronized.

Configuring the Time Zone

To manually configure the time zone, perform this task:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	clock timezone <i>zone</i> <i>hours-offset</i> [<i>minutes-offset</i>]	<p>Sets the time zone.</p> <p>To set the time to UTC, use the no clock timezone global configuration command.</p> <p>The switch keeps internal time in universal time coordinated (UTC), so this command is used only for display purposes and when the time is manually set.</p> <ul style="list-style-type: none"> • For <i>zone</i>, enter the name of the time zone to be displayed when standard time is in effect. The default is UTC. • For <i>hours-offset</i>, enter the hours offset from UTC. • (Optional) For <i>minutes-offset</i>, enter the minutes offset from UTC.
Step 3	end	Returns to privileged EXEC mode.
Step 4	show running-config	Verifies your entries.
Step 5	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The *minutes-offset* variable in the **clock timezone** global configuration command is available for those cases where a local time zone is a percentage of an hour different from UTC. For example, the time zone for some sections of Atlantic Canada (AST) is UTC-3.5, where the 3 means 3 hours and .5 means 50 percent. The necessary command is **clock timezone AST -3 30**.

Configuring Summer Time (Daylight Saving Time)

To configure summer time (daylight saving time) in areas where it starts and ends on a particular day of the week each year, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>clock summer-time zone recurring</code> [<i>week day month hh:mm week day</i> <i>month hh:mm [offset]</i>]	Configures summer time to start and end on the specified days every year. Summer time is disabled by default. If you specify clock summer-time zone recurring without parameters, the summer time rules default to the United States rules. <ul style="list-style-type: none"> For <i>zone</i>, specify the name of the time zone (for example, PDT) to be displayed when summer time is in effect. (Optional) For <i>week</i>, specify the week of the month (1 to 5 or last). (Optional) For <i>day</i>, specify the day of the week (Sunday, Monday...). (Optional) For <i>month</i>, specify the month (January, February...). (Optional) For <i>hh:mm</i>, specify the time (24-hour format) in hours and minutes. (Optional) For <i>offset</i>, specify the number of minutes to add during summer time. The default is 60.
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	<code>show running-config</code>	Verifies your entries.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

The first part of the **clock summer-time** global configuration command specifies when summer time begins, and the second part specifies when it ends. All times are relative to the local time zone. The start time is relative to standard time. The end time is relative to summer time. If the starting month is after the ending month, the system assumes that you are in the southern hemisphere.

This example shows how to specify that summer time starts on the first Sunday in April at 02:00 and ends on the last Sunday in October at 02:00:

```
Switch# configure terminal
Switch(config)# clock summer-time PDT recurring 1 Sunday April 2:00 last Sunday October 2:00
Switch(config)# end
Switch#
```

If summer time in your area does not follow a recurring pattern (configure the exact date and time of the next summer time events), perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>clock summer-time zone date [month date year hh:mm month date year hh:mm [offset]]</code> or <code>clock summer-time zone date [date month year hh:mm date month year hh:mm [offset]]</code>	<p>Configures summer time to start on the first date and end on the second date.</p> <p>To disable summer time, use the no clock summer-time global configuration command.</p> <p>Summer time is disabled by default.</p> <ul style="list-style-type: none"> For <i>zone</i>, specify the name of the time zone (for example, PDT) to be displayed when summer time is in effect. (Optional) For <i>week</i>, specify the week of the month (1 to 5 or last). (Optional) For <i>day</i>, specify the day of the week (Sunday, Monday...). (Optional) For <i>month</i>, specify the month (January, February...). (Optional) For <i>hh:mm</i>, specify the time (24-hour format) in hours and minutes. (Optional) For <i>offset</i>, specify the number of minutes to add during summer time. The default is 60.
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	<code>show running-config</code>	Verifies your entries.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

The first part of the **clock summer-time** global configuration command specifies when summer time begins, and the second part specifies when it ends. All times are relative to the local time zone. The start time is relative to standard time. The end time is relative to summer time. If the starting month is after the ending month, the system assumes that you are in the southern hemisphere.

To disable summer time, use the **no clock summer-time** global configuration command.

This example shows how to set summer time to start on October 12, 2000, at 02:00, and end on April 26, 2001, at 02:00:

```
Switch# configure terminal
Switch(config)# clock summer-time pdt date 12 October 2000 2:00 26 April 2001 2:00
Switch#
```

Managing Software Licenses Using Right-To-Use Licenses

Starting with Cisco IOS XE Release 3.4.2SG, the RTU licensing feature (**license right-to-use** command) enabled you to order and activate a specific license type and level, and then to manage license usage on your switch. You can also use RTU licenses to

- Upgrade from a lower license to a higher license.
- Downgrade from a higher license to a lower license.

You cannot relocate an RTU license to another device because the license is bundled with the image. So, by upgrading the IOS image, you obtain the RTU license.

The Right-to-Use (RTU) license is not installable and it cannot be cleared; it is available by default.

Starting with Cisco IOS XE Release 3.10.0E, on Cisco Catalyst 4500E Series Switches and Cisco Catalyst 4500-X Series Switches, you can configure add-on licenses. This is in addition to the base license you have configured (LAN Base, IP Base, Enterprise Services). The features available with add-on license levels provide Cisco innovations on the switch, as well as on the Cisco Digital Network Architecture Center (Cisco DNA Center).

Node-Locked Licenses

Prior to IOS Release XE 3.4.2SG, when you upgraded from one license level to another (e.g., IP Base to Entservices), you visited <http://www.cisco.com/go/license>, obtained the desired license using your device's PAK, and then applied the license on your device.

If you want to upgrade or downgrade from one license level to another, we recommend that you use the right-to-use (RTU) license instead of the node-locked license.

For details of this older activation process, see the *Configuring the Cisco IOS Software Activation Feature* guide at this URL:

http://www.cisco.com/en/US/docs/ios/csa/configuration/guide/csa_commands.html

RTU License Levels

Options for Base License Levels

- LAN Base (Only on Cisco Catalyst 4500E Series Switches)
- IP Base
- Enterprise Services

Options for Add-On License Levels

Add-On licenses require a base license as a pre-requisite.

- DNA Essentials
- DNA Advantage

When ordering an add-on license with a particular base license, note the combinations that are permitted and those that are not permitted:

Base License + Add-on License	Cisco Catalyst 4500E Series Switches	Cisco Catalyst 4500-X Series Switches
LAN Base + DNA Essentials	Yes Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E	Not applicable
LAN Base + DNA Advantage	No	Not applicable
IP Base + DNA Essentials	Yes Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E	Yes
IP Base + DNA Advantage	Yes Supervisor Engine 9-E and Sup8-E	No
Enterprise Services + DNA Essentials	Yes Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E	Yes
Enterprise Services + DNA Advantage	Yes Supervisor Engine 9-E and Sup8-E	No

RTU License Types

The types of licenses available to order by duration are:

- Permanent—for base license levels only, and without an expiration date.
- Term—for add-on license levels only.
- Evaluation—for a base or add-on license level, preinstalled on the device, and for a 90-day trial period only.

Ordering with Smart Accounts

We recommend that you use Smart Accounts to order devices as well as licenses. Smart Accounts enable you to manage all of your software licenses for switches, routers, firewalls, access-points or tools from one centralized website. To create Smart Accounts, use the Cisco Smart Software Manager (Cisco SSM).

Note

This is especially relevant to the term licenses that you order, because information about the expiry of term licences is available only through the Cisco SSM website.

For more information about Cisco SSM, see:

<http://www.cisco.com/c/en/us/buy/smart-accounts/software-licensing.html>

Benefits of an RTU License

- They are not associated with a specific switch.

With the *node-locked* license model, in a release prior to IOS Cisco XE 3.4.2SG, a license was applicable to a specific switch UID. Therefore, to activate a license on a new switch, you had to obtain a new license for the new UID. With PRTU licenses, logging on the Cisco server is unnecessary to download and install the license. The license is available with the image.

- They can be instantly activated on any supported switch.

With the node-locked license model, you open the Cisco Product License Registration Portal to obtain a license for a new switch that you purchase or an RMA switch that you need to replace. This process is often cumbersome and lengthy, and applying the license on the new switch is an error-prone activity. With RTU licenses, you can apply a license on a switch and activate it immediately.

- They can be applied without requiring an Internet connection.

With the node-locked license model, you need to access an Internet connection to obtain a license for your device's UID. This may be difficult in some deployment scenarios where an Internet connection is unavailable. With RTU licenses, you can apply a supported license on any switch at any time without requiring an Internet connection to interact with the Cisco Product License Registration Portal.

Guidelines for the RTU Licensing Model

- The RTU license model is based on mutual trust between you and Cisco. When you apply a RTU license, it is implied that you have first purchased the license from Cisco. This agreement is explained in detail in the EULA, which is displayed when you activate the license.
- The RTU license model does not replace the node-locked license model. Instead, it simplifies upgrading or moving your switch's license. The node-locked license model is still available.
- Base licenses (LAN Base, IP Base, Enterprise Services) may be ordered only with a permanent license type.
- Add-on licenses (DNA Essentials and DNA Advantage) may be ordered only with a term license type.

You can set up Cisco SSM to receive daily e-mail alerts, to be notified of expiring add-on licenses that you want to renew.

Applying an RTU License

To apply an RTU license on a switch, follow these steps:

-
- | | |
|---------------|---|
| Step 1 | Upgrade from one license level to another by using the Cisco sales ordering tool to purchase the license. You will receive an e-mail or paper confirmation that grants you permission to activate the license on your switch. |
| Step 2 | Apply the license by entering the appropriate commands on your switch. If you are upgrading a license on a switch, enter the activation command to activate the higher license. If you are moving a license from one switch to another, enter the deactivation command on the first switch and the activation command on the second switch. |

**Note**

Prior to IOS Release XE 3.4.2SG, you provided the license file to a Cisco server, then obtained the new license file. With IOS Release XE 3.4.2SG, you do not require those operations. Once the IOS image is upgraded, you receive the license on the switch and activate it with the **license right-to-use activate** *feature name* command.

Step 3 Read and accept the EULA.

Step 4 If you change the license boot level, reboot.

**Note**

Reboot is not necessary when:
 Activating RTU for the same license level as the existing one.
 Activating or deactivating an add-on license level.

Activating an RTU License

To activate a PRTU license on a switch, use either of the following commands in privileged EXEC mode:

	Command	Purpose
Step 1	license right-to-use [activate deactivate] [ipbase entservices lanbase] [acceptEULA] OR license right-to-use [activate deactivate] [addon { dna-essentials dna-advantage }] { subscription evaluation } [acceptEULA]	Activates the specified license level on a switch and enables acceptance of the end-user license agreement (EULA).
	Example Switch# license right-to-use activate ipbase acceptEULA Switch# license right-to-use activate addon dna-essentials subscription acceptEULA	

	Command	Purpose
Step 2	reload Example Switch# reload	Reboots the switch. The reminder to accept the EULA is displayed after reload if it was not accepted earlier. When changing license level, you are not required to save the configuration. But, it is a good practice to ensure all the configuration is stored properly before reload. Changing from a higher license level to a lower license level on reboot will remove CLIs that are not applicable. Ensure that all features in the lower license level that are actively used are not removed.
Step 3	show license right-to-use usage	Displays detailed usage information. If the command output displays the following values for In-Use and EULA parameters, disregard the In-Use status. In-Use: no EULA: yes The license will be in use if it is activated and EULA is accepted.

Deactivating an RTU License

To deactivate a PRTU license on a switch, enter the following command in privileged EXEC mode:

	Command	Purpose
Step 1	license right-to-use deactivate [ipbase entservices lanbase addon {dna-essentials dna-advantage }]	Deactivates a license on a switch.
Step 2	reload Example Switch# reload	Reboots the switch. The reminder to accept the EULA is displayed after reload if it was not accepted earlier. When changing license level, you are not required to save the configuration. But, it is a good practice to ensure all the configuration is stored properly before reload. Changing from a higher license level to a lower license level on reboot will remove CLIs that are not applicable. Ensure that all features in the lower license level that are actively used are not removed.

Displaying Software License Information

To display information about the software licenses on your switch, use one of these methods:

- Use Cisco License Manager to view license and device information. In the GUI, the discovery and polling features collect all the license and device information that appears in the Properties window. For detailed instructions, see the Cisco License Manager online help.

- Use the Cisco IOS privileged EXEC commands in [Table 2](#).

Table 2 **Commands for Displaying Software License Information**

Command	Description
show license agent {counters session}	Displays the information about the software license agent. For information about the show license agent privileged EXEC command, see the <i>Cisco Software Activation Tasks and Commands</i> feature module.
show license [agent all detail evaluation expiring feature file image in-use permanent right-to-use statistics status summary udi]	Displays information about the software license. For information about the show license privileged EXEC command, see the <i>Cisco IOS Software Licensing</i> feature module at this URL: http://www.cisco.com/en/US/docs/ios/12_2/12_2se/feature/guide/se_cisl.html
show license right-to-use [eula default detail mismatch summary usage]	Displays information related to the right-to-use licenses on the device. If the command output displays the following values for In-Use and EULA parameters, disregard the In-Use status. In-Use: no EULA: yes The license will be in use if it is activated and EULA is accepted.
show version	Displays the software licenses installed on the switch.

This is an example of output from the **show license all** command:

```
Switch# show license all
License Store: Primary License Storage

Configuring a System Name and Prompt

You configure the system name on the switch to identify it. By default, the system name and prompt are *Switch*.

If you have not configured a system prompt, the first 20 characters of the system name are used as the system prompt. A greater-than symbol [>] is appended. The prompt is updated whenever the system name changes.

For complete syntax and usage information for the commands used in this section, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.3* and the *Cisco IOS IP Command Reference, Volume 2 of 3: Routing Protocols, Release 12.3*.

To manually configure a system name, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>hostname name</code>	Manually configures a system name. When you set the system name, it is also used as the system prompt. The default setting is <i>switch</i> . The name must follow the rules for ARPANET hostnames. They must start with a letter, end with a letter or digit, and have as interior characters only letters, digits, and hyphens. Names can be up to 63 characters. To return to the default hostname, use the no hostname global configuration command.
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	<code>show running-config</code>	Verifies your entries.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Understanding the Domain Name System

The DNS protocol controls the Domain Name System (DNS), a distributed database with which you can map hostnames to IP addresses. When you configure DNS on your switch, you can substitute the hostname for the IP address with all IP commands, such as **ping**, **telnet**, **connect**, and related Telnet support operations.

IP defines a hierarchical naming scheme that allows a device to be identified by its location or domain. Domain names are pieced together with periods (.) as the delimiting characters. For example, Cisco Systems is a commercial organization that IP identifies by a *com* domain name, so its domain name is *cisco.com*. A specific device in this domain, for example, the File Transfer Protocol (FTP) system is identified as *ftp.cisco.com*.

To keep track of domain names, IP has defined the concept of a domain name server, which holds a cache (or database) of names mapped to IP addresses. To map domain names to IP addresses, you must first identify the hostnames, specify the name server that is present on your network, and enable the DNS.

These sections contain this configuration information:

Default DNS Configuration

Table 4-3 shows the default DNS configuration.

Table 4-3 *Default DNS Configuration*

Feature	Default Setting
DNS enable state	Enabled.
DNS default domain name	None configured.
DNS servers	No name server addresses are configured.

Setting Up DNS

To set up your switch to use the DNS, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>ip domain-name name</code>	<p>Defines a default domain name that the software uses to complete unqualified hostnames (names without a dotted-decimal domain name).</p> <p>To remove a domain name, use the no ip domain-name name global configuration command.</p> <p>Do not include the initial period that separates an unqualified name from the domain name.</p> <p>At boot time, no domain name is configured; however, if the switch configuration comes from a BOOTP or Dynamic Host Configuration Protocol (DHCP) server, then the default domain name might be set by the BOOTP or DHCP server (if the servers were configured with this information).</p>
Step 3	<code>ip name-server server-address1 [server-address2 ... server-address6]</code>	<p>Specifies the address of one or more name servers to use for name and address resolution.</p> <p>To remove a name server address, use the no ip name-server server-address global configuration command.</p> <p>You can specify up to six name servers. Separate each server address with a space. The first server specified is the primary server. The switch sends DNS queries to the primary server first. If that query fails, the backup servers are queried.</p>

	Command	Purpose
Step 4	<code>ip domain-lookup</code>	(Optional) Enables DNS-based hostname-to-address translation on your switch. This feature is enabled by default. To disable DNS on the switch, use the no ip domain-lookup global configuration command. If your network devices require connectivity with devices in networks for which you do not control name assignment, you can dynamically assign device names that uniquely identify your devices by using the global Internet naming scheme (DNS).
Step 5	<code>end</code>	Returns to privileged EXEC mode.
Step 6	<code>show running-config</code>	Verifies your entries.
Step 7	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

If you use the switch IP address as its hostname, the IP address is used and no DNS query occurs. If you configure a hostname that contains no periods (.), a period followed by the default domain name is appended to the hostname before the DNS query is made to map the name to an IP address. The default domain name is the value set by the **ip domain-name** global configuration command. If there is a period (.) in the hostname, the Cisco IOS software looks up the IP address without appending any default domain name to the hostname.

Displaying the DNS Configuration

To display the DNS configuration information, use the **show running-config** privileged EXEC command.

DNS for IPv6

IPv6 supports DNS record types that are supported in the DNS name-to-address and address-to-name lookup processes. The DNS record types support IPv6 addresses. IPv6 also supports the reverse mapping of IPv6 addresses to DNS names.

The table below lists the IPv6 DNS record types.

Table 4-1 IPv6 DNS Record Types

Record Type	Description	Format
AAAA	Maps a hostname to an IPv6 address. (Equivalent to an A record in IPv4.)	www.abc.test AAAA 3FFE:YYYY:C18:1::2
PTR	Maps an IPv6 address to a hostname. (Equivalent to a PTR record in IPv4.)	2.0.0.0.0.0.0.0.0.0.0.0.0.0.0.0.1.0.0.0.8.1 .c.0.y.y.y.e.f.f.3.ip6.int PTR www.abc.test
	 Note Cisco software supports resolution of PTR records for the IP6.INT domain.	

IPv6 Router Advertisement Options for DNS Configuration

Starting with Cisco IOS XE Release 3.10.0E, IPv6 Router Advertisement Options for DNS Configuration feature is supported on the Cisco Catalyst 4500E Series Switches and Cisco Catalyst 4500-X Series Switches, at all available license levels for these platforms.

DNS configuration based on IPv6 Router Advertisement (RA) options ([RFC 6106](#)) is useful in networks where:

- An IPv6 host's address is autoconfigured through IPv6 stateless address autoconfiguration.
- There is either no DHCP IPv6 infrastructure at all or some hosts do not have a DHCPv6 client.

In these scenarios, it is not feasible to manually configure hosts each time they connect to a different network. While a one-time static configuration is possible, it is generally not desirable on general-purpose hosts such as laptops and mobile phones.

Neighbor Discovery (ND) for IPv6 and IPv6 stateless address autoconfiguration provide ways to configure either fixed or mobile nodes with one or more IPv6 addresses, default routers, and some other parameters [RFC4861][RFC4862]. Most Internet services are identified by using a DNS name. The following RA options defined in RFC 6106 provide the DNS information needed for an IPv6 host to reach Internet services:

Recursive DNS Server (RDNSS) Option

RDNSS provides a recursive DNS resolution service for translating domain names into IP addresses as defined in [RFC1034] and [RFC1035]. The RDNSS option contains one or more IPv6 addresses of recursive DNS servers. All addresses share the same Lifetime value, which is the maximum time in seconds over which this RDNSS address may be used for name resolution. If different Lifetime values are required, multiple RDNSS options can be used. There can be up to 5 DNS servers.

DNS Search List (DNSSL) Option

DNSSL is a list of DNS suffix domain names used by IPv6 hosts when they perform DNS query searches for short, unqualified domain names. The DNSSL option contains one or more domain names. All domain names share the same Lifetime value, which is the maximum time in seconds over which this DNSSL may be used. If different Lifetime values are required, multiple DNSSL options can be used. There can be up to 5 DNSSLs.

**Note**

If DNS information is available from multiple RAs and/or from DHCP, the host must maintain an ordered list of this DNS information.

Configuring DNS Server Using IPv6 Router Advertisement Options

RFC 6106 specifies IPv6 Router Advertisement (RA) options to allow IPv6 routers to advertise a list of recursive DNS server (RDNSS) addresses used for the DNS name resolution in IPv6 hosts.

The DNS lifetime range should be between maximum RA interval and twice the maximum RA interval:

```
(max ra interval) <= dns lifetime <= (2*(max ra interval))
```

The maximum RA interval can have a value between 4 and 1800 seconds (default is 240 seconds). Therefore, the following configuration will result in a lifetime out of range:

```
Switch(config-if)# ipv6 nd ra dns server 4::4 3600 <<< Lifetime configured out of range
for the interface having default maximum RA interval
```

The following is a sample configuration of recursive DNS server:

```
Switch# configure terminal
Switch(config)# interface GigabitEthernet 0/2/0/0
Switch(config-if)# ipv6 nd prefix 2002:4898:e8:1011::/64 1111 222
Switch(config-if)# ipv6 nd prefix 2002:4899:e8:1011::/64 1111 222
Switch(config-if)# ipv6 nd ra-lifetime 9000
Switch(config-if)# ipv6 nd ra dns server 4::4 infinite-lifetime
Switch(config-if)# ipv6 nd router-preference high
Switch(config-if)# ipv6 nd ra specific route 3::3/116 Lifetime 1112 preference low
```

Use the **show running-config** command to display the DNS server configuration for a specific interface:

```
Switch# show running-config interface gigabitEthernet 0/2/0/0
interface GigabitEthernet0/2/0/0
ipv6 nd prefix 2002:4898:e8:1011::/64 1111 222
ipv6 nd prefix 2002:4899:e8:1011::/64 1111 222
ipv6 nd ra-lifetime 9000
/* RDNSS configuration */
ipv6 nd ra dns server 4::4 infinite-lifetime
ipv6 nd router-preference high
ipv6 nd ra specific route 3::3/116 Lifetime 1112 preference low !
```

Use the **show ipv6 nd idb interface** command to verify DNS server configuration based on IPv6 RA options:

```
Switch# show ipv6 nd idb interface gigabitEthernet 0/2/0/0 detail location 0/2/CPU0
Mon Jul 4 14:28:53.422 IST
ifname: Gi0/2/0/0, ifh: 0x01000300, iftype: 15, VI-type: 0, Pseudo IDB: FALSE
vrf-id: 0x60000000, table-id: 0xe0800000
Mac Addr: 02d1.1e2b.0baf, size: 6, Vlan tag set: FALSE

Media Name: ether, Media Encap: 0x1 (ARPA)
Mac Length: 6, Media Header Len: 14, Media Proto: 0xdd86
Current Encap: 0x1 (ARPA), Mcast Encap : 0x1 (ARPA)

IPv6 Interface: Enabled, IPV6: Enabled, MPLS: Disabled
Link local address: fe80::d1:1eff:fe2b:baf, Global Addr count: 1
Global Addresses:1::1(0x2),
Default Prefix Address: ::, Prefix Addr Count: 3,
Prefix addresses: 1::(0x401), 2002:4898:e8:1011::(0x4), 2002:4899:e8:1011::(0x4)
```

```

RA Specific Route Count: 1,
RA Specific Route : Address 3:: Prefix Length 116 Lifetime 1112 Preference Low

RA DNS Servers Addr Count: 3,
RA DNS Server adresse: Address 5::6 Lifetime 240
RA DNS Server adresse: Address 5::5 Lifetime 240
RA DNS Server adresse: Address 4::4 Lifetime 4294967295

```

Use the **no ipv6 nd ra dns server ipv6 address** command to delete a single DNS server under an interface. Use the **no ipv6 nd ra dns server** command to delete all DNS servers under an interface.

Configuring DNS Search List Using IPv6 Router Advertisement Options

RFC 6106 specifies IPv6 Router Advertisement (RA) options to allow IPv6 routers to advertise a DNS Search List (DNSSL) to IPv6 hosts for an enhanced DNS configuration.

The DNS lifetime range should be between maximum RA interval and twice the maximum RA interval:

```
(max ra interval) <= dns lifetime <= (2*(max ra interval))
```

The maximum RA interval can have a value between 4 and 1800 seconds (default is 240 seconds).

Therefore, the following configuration will result in a lifetime out of range:

```
Switch(config-if)#ipv6 nd ra dns search list sss.com 3600 <<< Lifetime configured out of
range for the interface having default maximum RA interval
```

The following is a sample configuration of a DNS search list:

```

Switch# configure terminal
Switch(config)# interface GigabitEthernet 0/2/0/0
Switch(config-if)# ipv6 nd prefix 2002:4898:e8:1011::/64 1111 222
Switch(config-if)# ipv6 nd prefix 2002:4899:e8:1011::/64 1111 222
Switch(config-if)# ipv6 nd ra-lifetime 9000
Switch(config-if)# ipv6 nd ra dns search list aaa.cc.com infinite-lifetime
Switch(config-if)# ipv6 address 1::1/64

```

Note The domain name configuration should follow RFC 1035. If not, the configuration will be rejected. For example, the following domain name configuration will result in an error:

```
Switch(config-if)# ipv6 nd ra dns search list .aaa.cc.com infinite-lifetime
```

Use the **no ipv6 nd ra dns search list name** command to delete a single DNS search list under an interface. Use the **no ipv6 nd ra dns search list** command to delete all DNS search lists under an interface.

Use the **show running-config** command to display the configuration for a specific interface:

```

Switch# show running-config interface gigabitEthernet 0/2/0/0
interface GigabitEthernet0/2/0/0
  ipv6 nd prefix 2002:4898:e8:1011::/64 1111 222
  ipv6 nd prefix 2002:4899:e8:1011::/64 1111 222
  ipv6 nd ra-lifetime 9000
  ipv6 nd router-preference high
  ipv6 nd ra specific route 3::3/116 Lifetime 1112 preference low
/* DNSSL configuration */?ipv6 nd ra dns search list aaa.cc.com infinite-lifetime ipv6
address 1::1/64?!

```

Use the **show ipv6 nd idb interface** command to verify DNS search list configuration based on IPv6 RA options:

```
Switch# show ipv6 nd idb interface gigabitEthernet 0/2/0/0 detail location 0/2/CPU0
Mon Jul  4 14:28:53.422 IST

ifname: Gi0/2/0/0, ifh: 0x01000300, iftype: 15, VI-type: 0, Pseudo IDB: FALSE
vrf-id: 0x60000000, table-id: 0xe0800000
Mac Addr: 02d1.1e2b.0baf, size: 6, Vlan tag set: FALSE

Media Name: ether, Media Encap: 0x1 (ARPA)
Mac Length: 6, Media Header Len: 14, Media Proto: 0xdd86
Current Encap: 0x1 (ARPA), Mcast Encap : 0x1 (ARPA)

IPv6 Interface: Enabled, IPv6: Enabled, MPLS: Disabled
Link local address: fe80::d1:1eff:fe2b:baf, Global Addr count: 1
Global Addresses: 1::1(0x2),
Default Prefix Address: ::, Prefix Addr Count: 3,
Prefix addresses: 1::(0x401), 2002:4898:e8:1011::(0x4), 2002:4899:e8:1011::(0x4)

```

Troubleshooting DNS Servers and DNS Search Lists

Recursive DNS servers and DNS search lists are sent as part of RA messages.

The interface for which the DNS servers and DNS search lists are configured, should be IPv6 enabled and the IPv6 protocol should be up. Verify using the following command:

```
Switch# show ipv6 interface gigabitEthernet 0/2/0/0
Wed Jun 29 18:52:31.936 IST
GigabitEthernet0/2/0/0 is Up, ipv6 protocol is Up, Vrfid is default (0x60000000)
IPv6 is enabled, link-local address is fe80::d1:1eff:fe2b:baf
Global unicast address(es):
  1::1, subnet is 1::/64
Joined group address(es): ff02::1:ff00:1 ff02::1:ff2b:baf ff02::2
  ff02::1
```

If the interface has IPv6 protocol up and the RAs are not being sent, then verify whether RA is suppressed:

```
Switch# show running-config interface gigabitEthernet 0/2/0/0
interface GigabitEthernet0/2/0/0
ipv6 nd suppress-ra <<< configuration of RA suppression under interface
ipv6 nd router-preference high
ipv6 nd ra specific route 3::3/116 Lifetime 1112 preference low
ipv6 address 1::1/64
!
```

If the interface has IPv6 protocol up and the RAs are not being sent, then verify whether RA is enabled in Interface Descriptor Block (IDB). The RA flag is 1.

```
Switch# show ipv6 nd idb interface gigabitEthernet 0/2/0/0 detail location 0/2/CPU0
Thu Jun 30 20:02:20.211 IST
ifname: Gi0/2/0/0, ifh: 0x01000300, iftype: 15, VI-type: 0, Pseudo IDB: FALSE
vrf-id: 0x60000000, table-id: 0xe0800000
Mac Addr: 02d1.1e2b.0baf, size: 6, Vlan tag set: FALSE
RA Specific Route Count: 1,
RA Specific Route : Address 3:: Prefix Length 116 Lifetime 1112 Preference Low
RA DNS Servers Addr Count: 1,
```

```

RA DNS Server address: Address 4::4 Lifetime 4294967295 <<< RDNSS for interface
RA DNS Search List Count: 1,
RA DNS Search List : Name aaa.cc.com Lifetime 4294967295 <<< DNSSL for interface
RA flag: 0x1, Unicast RA send: FALSE, Initial RA count: 3, RA pkts sent count: 442 <<<
RA flag should be 1

```

Run the IPv6 ND traces to debug any particular issue related to a DNS servers and DNS search lists:

```

Creating a Banner

You can configure a message-of-the-day (MOTD) and a login banner. The MOTD banner displays on all connected terminals at login and is useful for sending messages that affect all network users (such as impending system shutdowns).

The login banner also displays on all connected terminals. It appears after the MOTD banner and before the login prompts.

Note

For complete syntax and usage information for the commands used in this section, see the *Cisco IOS Configuration Fundamentals Command Reference, Release 12.3*.

The contain this configuration information:

- [Default Banner Configuration, page 4-34](#)
- [Configuring a Message-of-the-Day Login Banner, page 4-34](#)

- [Configuring a Login Banner, page 4-36](#)

Default Banner Configuration

The MOTD and login banners are not configured.

Configuring a Message-of-the-Day Login Banner

You can create a single or multiline message banner that appears on the screen when someone logs in to the switch.

To configure a MOTD login banner, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>banner motd c message c</code>	<p>Specifies the message of the day.</p> <p>To delete the MOTD banner, use the no banner motd global configuration command.</p> <p>For <i>c</i>, enter the delimiting character of your choice, for example, a pound sign (#), and press the Return key. The delimiting character signifies the beginning and end of the banner text. Characters after the ending delimiter are discarded.</p> <p>Note When configuring a banner using the "#" sign as a delimiter on Supervisor Engine 7-E and Supervisor Engine 7L-E, you must first turn off shell processing with the no shell processing command. Else, you can not exit from the banner configuration.</p> <pre>### With shell processing enabled ### Sup7# conf t Enter configuration commands, one per line. End with CNTL/Z. Sup7(config)# ban Sup7(config)# banner lo Sup7(config)# banner login # Enter TEXT message. End with the character '#' test login banner # ## e# Sup7(config)# ### With shell processing disabled ### Sup7(config)# banner login # Enter TEXT message. End with the character '#' test login banner # Sup7(config)#</pre> <p>For <i>message</i>, enter a banner message up to 255 characters. You cannot use the delimiting character in the message.</p>

	Command	Purpose
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	<code>show running-config</code>	Verifies your entries.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

This example shows how to configure a MOTD banner for the switch by using the pound sign (#) symbol as the beginning and ending delimiter:

```
Switch(config)# banner motd #
it is a secure site. Only authorized users are allowed.
For access, contact technical support.
#
Switch(config)#
```

This example shows the banner that appears from the previous configuration:

```
Unix> telnet 172.2.5.4
Trying 172.2.5.4...
Connected to 172.2.5.4.
Escape character is '^]'.

it is a secure site. Only authorized users are allowed.
For access, contact technical support.

User Access Verification

Password:
```

Configuring a Login Banner

You can configure a login banner to be displayed on all connected terminals. This banner appears after the MOTD banner and before the login prompt.

To configure a login banner, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>banner login c message c</code>	<p>Specifies the login message.</p> <p>To delete the login banner, use the no banner login global configuration command.</p> <p>For <i>c</i>, enter the delimiting character of your choice, for example, a pound sign (#), and press the Return key. The delimiting character signifies the beginning and end of the banner text. Characters after the ending delimiter are discarded.</p> <p>Note When configuring a banner using the "#" sign as a delimiter on Supervisor Engine 7-E and Supervisor Engine 7L-E, you must first turn off shell processing with the no shell processing command. Else, you can not exit from the banner configuration.</p> <pre> ### With shell processing enabled ### Sup7# conf t Enter configuration commands, one per line. End with CNTL/Z. Sup7(config)# ban Sup7(config)# banner lo Sup7(config)# banner login # Enter TEXT message. End with the character '#' test login banner # ## e# Sup7(config)# ### With shell processing disabled ### Sup7(config)# banner login # Enter TEXT message. End with the character '#' test login banner # Sup7(config)# </pre> <p>For <i>message</i>, enter a login message up to 255 characters. You cannot use the delimiting character in the message.</p>
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	<code>show running-config</code>	Verifies your entries.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

This example shows how to configure a login banner for the switch by using the dollar sign (\$) symbol as the beginning and ending delimiter:

```
Switch# configuration terminal
Switch(config)# banner login $
Access for authorized users only. Please enter your username and password.
$
Switch(config)# end
Switch#
```

Managing the MAC Address Table

The MAC address table contains address information that the switch uses to forward traffic between ports. All MAC addresses in the address table are associated with one or more ports. The address table includes these types of addresses:

- Dynamic address—A source MAC address that the switch learns and then ages when it is not in use.
- Static address—A manually entered unicast address that does not age and that is not lost when the switch resets.

The address table lists the destination MAC address, the associated VLAN ID, and port number associated with the address and the type (static or dynamic).

Note

For complete syntax and usage information for the commands used in this section, see the command reference for this release.

These sections contain this configuration information:

- [Building the Address Table, page 4-37](#)
- [MAC Addresses and VLANs, page 4-38](#)
- [Default MAC Address Table Configuration, page 4-39](#)
- [Changing the Address Aging Time, page 4-39](#)
- [Removing Dynamic Address Entries, page 4-40](#)
- [Configuring MAC Change Notification Traps, page 4-40](#)
- [Configuring MAC Move Notification Traps, page 4-42](#)
- [Configuring MAC Threshold Notification Traps, page 4-44](#)
- [Adding and Removing Static Address Entries, page 4-45](#)
- [Configuring Unicast MAC Address Filtering, page 4-46](#)
- [Disabling MAC Address Learning on a VLAN, page 4-48](#)
- [Displaying Address Table Entries, page 4-53](#)

Building the Address Table

With multiple MAC addresses supported on all ports, you can connect any port on the switch to individual workstations, repeaters, switches, routers, or other network devices. The switch provides dynamic addressing by learning the source address of packets it receives on each port and adding the

address and its associated port number to the address table. As stations are added or removed from the network, the switch updates the address table, adding new dynamic addresses and aging out those that are not in use.

The aging interval is globally configured. However, the switch maintains an address table for each VLAN, and STP can accelerate the aging interval on a per-VLAN basis.

The switch sends packets between any combination of ports, based on the destination address of the received packet. Using the MAC address table, the switch forwards the packet only to the port associated with the destination address. If the destination address is on the port that sent the packet, the packet is filtered and not forwarded. The switch always uses the store-and-forward method: complete packets are stored and checked for errors before transmission.

MAC Addresses and VLANs

All addresses are associated with a VLAN. An address can exist in more than one VLAN and have different destinations in each. Unicast addresses, for example, could be forwarded to port 1 in VLAN 1 and ports 9, 10, and 1 in VLAN 5.

Each VLAN maintains its own logical address table. A known address in one VLAN is unknown in another until it is learned or statically associated with a port in the other VLAN.

When PVLANs are configured, address learning depends on the type of MAC address:

- Dynamic MAC addresses learned in one VLAN of a PVLAN are replicated in the associated VLANs. For example, a MAC address learned in a private-VLAN secondary VLAN is replicated in the primary VLAN.
- Static MAC addresses configured in a primary or secondary VLAN are not replicated in the associated VLANs. When you configure a static MAC address in a PVLAN primary or secondary VLAN, you should also configure the same static MAC address in all associated VLANs.

For more information about PVLANs, see [Chapter 47, “Configuring Private VLANs.”](#)

Default MAC Address Table Configuration

[Table 4-4](#) shows the default MAC address table configuration.

Table 4-4 Default MAC Address Table Configuration

Feature	Default Setting
Aging time	300 seconds
Dynamic addresses	Automatically learned
Static addresses	None configured

Changing the Address Aging Time

Dynamic addresses are source MAC addresses that the switch learns and then ages when they are not in use. You can change the aging time setting for all VLANs or for a specified VLAN.

Setting too short an aging time can cause addresses to be prematurely removed from the table. When the switch receives a packet for an unknown destination, it floods the packet to all ports in the same VLAN as the receiving port. This unnecessary flooding can impact performance. Setting too long an aging time can cause the address table to be filled with unused addresses, which prevents new addresses from being learned. Flooding results, which can impact switch performance.

To configure the dynamic address table aging time, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>mac address-table aging-time [0 10-1000000] [vlan vlan-id]</code>	<p>Sets the length of time that a dynamic entry remains in the MAC address table after the entry is used or updated.</p> <p>To return to the default value, use the no mac address-table aging-time global configuration command.</p> <p>The range is 10 to 1000000 seconds. The default is 300. You can also enter 0, which disables aging. Static address entries are never aged or removed from the table.</p> <p>For <i>vlan-id</i>, valid IDs are 1 to 4094.</p>
Step 3	<code>end</code>	Returns to privileged EXEC mode.

	Command	Purpose
Step 4	<code>show mac address-table aging-time</code>	Verifies your entries.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

Removing Dynamic Address Entries

To remove all dynamic entries, use the **clear mac address-table dynamic** command in EXEC mode. You can also remove a specific MAC address (**clear mac address-table dynamic address** *mac-address*), remove all addresses on the specified physical port or port channel (**clear mac address-table dynamic interface** *interface-id*), or remove all addresses on a specified VLAN (**clear mac address-table dynamic vlan** *vlan-id*).

To verify that dynamic entries have been removed, use the **show mac address-table dynamic** privileged EXEC command.

Configuring MAC Change Notification Traps

MAC change notification allows you to track users on a network by storing the MAC change activity on the switch. Whenever the switch learns or removes a MAC address, an SNMP notification can be generated and sent to the network management system. If you have many users entering and exiting the network, you can set a trap interval time to bundle the notification traps and reduce network traffic. The MAC notification history table stores the MAC address activity for each hardware port for which the trap is enabled. MAC address notifications are generated for dynamic and static MAC addresses; events are not generated for self addresses or multicast addresses.

To send MAC change notification traps to an NMS host, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>snmp-server host host-addr [traps informs] {version {1/2c/3}} [auth noauth priv] community-string [udp-port port] [notification-type]</code>	Specifies the recipient of the trap message. <ul style="list-style-type: none"> For <i>host-addr</i>, specify the name or address of the NMS. Specify traps (the default) to send SNMP traps to the host. Specify informs to send SNMP informs to the host. Specify the SNMP version to support. Version 1, the default, is not available with informs. For <i>community-string</i>, specify the string to send with the notification operation. Though you can set this string by using the snmp-server host command, we recommend that you define this string by using the snmp-server community command before using the snmp-server host command. For <i>notification-type</i>, use the mac-notification keyword.

	Command	Purpose
Step 3	<code>snmp-server enable traps mac-notification change</code>	Enables the switch to send MAC change traps to the NMS. To disable the switch from sending MAC change notification traps, use the no snmp-server enable traps mac-notification change global configuration command.
Step 4	<code>mac address-table notification change</code>	Enables the MAC address change notification feature.
Step 5	<code>mac address-table notification change [interval value] [history-size value]</code>	Enters the trap interval time and the history table size. <ul style="list-style-type: none"> • (Optional) For interval value, specify the notification trap interval in seconds between each set of traps that are generated to the NMS. The range is 0 to 2147483647 seconds; the default is 1 second. • (Optional) For history-size value, specify the maximum number of entries in the MAC notification history table. The range is 0 to 500; the default is 1. To disable the MAC change notification feature, use the no mac address-table notification change global configuration command.
Step 6	<code>interface interface-id</code>	Enters interface configuration mode, and specifies the interface on which to enable the SNMP MAC change notification trap.
Step 7	<code>snmp trap mac-notification change {added removed}</code>	Enables the MAC change notification trap. <ul style="list-style-type: none"> • Enable the MAC change notification trap whenever a MAC address is added on this interface. • Enable the MAC change notification trap whenever a MAC address is removed from this interface. To disable the MAC change notification traps on a specific interface, use the no snmp trap mac-notification change {added removed} interface configuration command.
Step 8	<code>end</code>	Returns to privileged EXEC mode.
Step 9	<code>show mac address-table notification change interface</code> <code>show running-config</code>	Verifies your entries.
Step 10	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

This example shows how to specify 172.69.59.93 as the network management system, enable the switch to send MAC change notification traps to the network management system, enable the MAC change notification feature, set the interval time to 60 seconds, set the history-size to 100 entries, and enable traps whenever a MAC address is added on the specified port:

```
Switch# configure terminal
Switch(config)# snmp-server host 172.69.59.93 private mac-notification
Switch(config)# snmp-server enable traps mac-notification change
Switch(config)# mac address-table notification change
Switch(config)# mac address-table notification change interval 60
Switch(config)# mac address-table notification change history-size 100
Switch(config)# interface fastethernet0/2
Switch(config-if)# snmp trap mac-notification change added
Switch(config-if)# end
Switch# show mac address-table notification change interface
MAC Notification Feature is Enabled on the switch

Switch#
```

Configuring MAC Move Notification Traps

When you configure MAC move notification, an SNMP notification is generated and sent to the network management system whenever a MAC address moves from one port to another within the same VLAN.

To configure MAC move notification, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>snmp-server host host-addr [traps informs] {version {1/2c/3}} [auth noauth priv] community-string [udp-port port] [notification-type]</code>	Specifies the recipient of the trap message. <ul style="list-style-type: none"> For <i>host-addr</i>, specify the name or address of the NMS. Specify traps (the default) to send SNMP traps to the host. Specify informs to send SNMP informs to the host. Specify the SNMP version to support. Version 1, the default, is not available with informs. For <i>community-string</i>, specify the string to send with the notification operation. Though you can set this string by using the snmp-server host command, we recommend that you define this string by using the snmp-server community command before using the snmp-server host command. For <i>notification-type</i>, use the mac-notification keyword.
Step 3	<code>snmp-server enable traps mac-notification move</code>	Enables the switch to send MAC move notification traps to the NMS. To disable the switch from sending MAC notification traps, use the no snmp-server enable traps mac-notification move global configuration command.
Step 4	<code>mac address-table notification mac-move</code>	Enables the MAC-move notification feature. To disable this feature, use the no mac-address-table notification mac-move global configuration command.
Step 5	<code>end</code>	Returns to privileged EXEC mode.
Step 6	<code>show mac address-table notification mac-move</code> <code>show running-config</code>	Displays the MAC-move notification status.
Step 7	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

This example shows how to specify 172.69.59.93 as the network management system, enable the switch to send MAC move notification traps to the NMS, enable the MAC move notification feature, and enable traps whenever a MAC address moves from one port to another:

```
Switch# configure terminal
Switch(config)# snmp-server host 171.69.59.93 private mac-notification
Switch(config)# snmp-server enable traps mac-notification move
Switch(config)# mac address-table notification mac-move
Switch(config)# end
Switch# show mac address-table notification mac-move
MAC Move Notification: Enabled
```

Configuring MAC Threshold Notification Traps

When you configure MAC threshold notification, an SNMP notification is generated and sent to the network management system when a MAC address table (MAT) threshold limit is reached or exceeded.

To configure MAC address threshold notification, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>snmp-server host host-addr [traps/informs] {version {1/2c/3}} [auth noauth priv] community-string [udp-port port] [notification-type]</code>	Specifies the recipient of the trap message. <ul style="list-style-type: none"> For <i>host-addr</i>, specify the name or address of the NMS. Specify traps (the default) to send SNMP traps to the host. Specify informs to send SNMP informs to the host. Specify the SNMP version to support. Version 1, the default, is not available with informs. For <i>community-string</i>, specify the string to send with the notification operation. Though you can set this string by using the snmp-server host command, we recommend that you define this string by using the snmp-server community command before using the snmp-server host command. For <i>notification-type</i>, use the mac-notification keyword.
Step 3	<code>snmp-server enable traps mac-notification threshold</code>	Enables the switch to send MAC threshold notification traps to the NMS. To disable the switch from sending MAC threshold notification traps, use the no snmp-server enable traps mac-notification threshold global configuration command.
Step 4	<code>mac address-table notification threshold</code>	Enables the MAC address threshold notification feature. To disable this feature, use the no address-table notification threshold global configuration command.
Step 5	<code>mac address-table notification threshold [limit percentage] [interval time]</code>	Enters the threshold value for the MAT usage monitoring. <ul style="list-style-type: none"> (Optional) For limit percentage, specify the percentage of the MAT utilization; valid values are from 1 to 100 percent. Default is 50 percent. (Optional) For interval time, specify the time between notifications; valid values are greater than or equal to 120 seconds. Default is 120 seconds.

	Command	Purpose
Step 6	<code>end</code>	Returns to privileged EXEC mode.
Step 7	<code>show mac address-table notification threshold</code> <code>show running-config</code>	Displays the MAC utilization threshold notification status.
Step 8	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

This example shows how to specify 172.69.59.93 as the network management system, enable the MAC threshold notification feature, enable the switch to send MAC threshold notification traps to the NMS, set the interval to 123 seconds, and set the limit to 78 percent:

```
Switch# configure terminal
Switch(config)# snmp-server host 171.69.59.93 private mac-notification
Switch(config)# snmp-server enable traps mac-notification threshold
Switch(config)# mac address-table notification threshold
Switch(config)# mac address-table notification threshold interval 123
Switch(config)# mac address-table notification threshold limit 78
Switch(config)# end
Switch# show mac-address-table notification threshold
      Status      limit      Interval
-----+-----+-----
      enabled      78          123
Switch#
```

Adding and Removing Static Address Entries

A static address has these characteristics:

- It is manually entered in the address table and must be manually removed.
- It can be a unicast or multicast address.
- It does not age and is retained when the switch restarts.

You can add and remove static addresses and define the forwarding behavior for them. The forwarding behavior defines how a port that receives a packet forwards it to another port for transmission. Because all ports are associated with at least one VLAN, the switch acquires the VLAN ID for the address from the ports that you specify. You can specify a different list of destination ports for each source port.

A packet with a static address that arrives on a VLAN where it has not been statically entered is flooded to all ports and not learned.

You add a static address to the address table by specifying the destination MAC unicast address and the VLAN from which it is received. Packets received with this destination address are forwarded to the interface specified with the *interface-id* option.

When you configure a static MAC address in a private-VLAN primary or secondary VLAN, you should also configure the same static MAC address in all associated VLANs. Static MAC addresses configured in a private-VLAN primary or secondary VLAN are not replicated in the associated VLAN. For more information about PVLANS, see [Chapter 47, “Configuring Private VLANs.”](#)

To add a static address, perform this task:

	Command	Purpose
Step 1	<code>configure terminal</code>	Enters global configuration mode.
Step 2	<code>mac address-table static mac-addr vlan vlan-id interface interface-id</code>	<p>Adds a static address to the MAC address table.</p> <ul style="list-style-type: none"> For <i>mac-addr</i>, specify the destination MAC unicast address to add to the address table. Packets with this destination address received in the specified VLAN are forwarded to the specified interface. For <i>vlan-id</i>, specify the VLAN for which the packet with the specified MAC address is received. Valid VLAN IDs are 1 to 4094. For <i>interface-id</i>, specify the interface to which the received packet is forwarded. Valid interfaces include physical ports or port channels. <p>You can specify static multicast addresses for multiple interface IDs. However, you cannot assign static unicast MAC address to multiple interfaces with the same MAC address and VLAN ID.</p> <p>To remove static entries from the address table, use the no mac address-table static mac-addr vlan vlan-id [interface interface-id] global configuration command.</p>
Step 3	<code>end</code>	Returns to privileged EXEC mode.
Step 4	<code>show mac address-table static</code>	Verifies your entries.
Step 5	<code>copy running-config startup-config</code>	(Optional) Saves your entries in the configuration file.

This example shows how to add the static address c2f3.220a.12f4 to the MAC address table. When a packet is received in VLAN 4 with this MAC address as its destination address, the packet is forwarded to the specified port:

```
Switch# configure terminal
Switch(config)# mac address-table static c2f3.220a.12f4 vlan 4 interface
gigabitethernet0/1
Switch(config)# end
Switch#
```

Configuring Unicast MAC Address Filtering

When unicast MAC address filtering is enabled, the switch drops packets with specific source or destination MAC addresses. This feature is disabled by default and only supports unicast static addresses.

When using unicast address filtering, consider these guidelines:

- Multicast MAC addresses, broadcast MAC addresses, and router MAC addresses are not supported. If you specify one of these addresses when entering the **mac address-table static vlan drop** global configuration command, one of these messages appears:
 - % Only unicast addresses can be configured to be dropped
 - % CPU destined address cannot be configured as drop address
- Packets that are forwarded to the CPU are also not supported.

- If you add a unicast MAC address as a static address and configure unicast MAC address filtering, the switch either adds the MAC address as a static address or drops packets with that MAC address, depending on which command was entered last. The second command that you entered overrides the first command.

For example, if you enter the **mac address-table static vlan interface** global configuration command followed by the **mac address-table static vlan drop** command, the switch drops packets with the specified MAC address as a source or destination.

If you enter the **mac address-table static vlan drop** global configuration command followed by the **mac address-table static vlan interface** command, the switch adds the MAC address as a static address.

You enable unicast MAC address filtering and configure the switch to drop packets with a specific address by specifying the source or destination unicast MAC address and the VLAN from which it is received.

To configure the switch to drop a source or destination unicast static address, perform this task:

	Command	Purpose
Step 1	configure terminal	Enters global configuration mode.
Step 2	mac address-table static <i>mac-addr</i> vlan <i>vlan-id</i> drop	Enables unicast MAC address filtering and configure the switch to drop a packet with the specified source or destination unicast static address. <ul style="list-style-type: none"> • For <i>mac-addr</i>, specify a source or destination unicast MAC address. Packets with this MAC address are dropped. • For <i>vlan-id</i>, specify the VLAN for which the packet with the specified MAC address is received. Valid VLAN IDs are 1 to 4094. To disable unicast MAC address filtering, use the no mac address-table static vlan global configuration command.
Step 3	end	Returns to privileged EXEC mode.
Step 4	show mac address-table static	Verifies your entries.
Step 5	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable unicast MAC address filtering and to configure the switch to drop packets that have a source or destination address of c2f3.220a.12f4. When a packet is received in VLAN 4 with this MAC address as its source or destination, the packet is dropped:

```
Switch# configure terminal
Switch(config)# mac address-table static c2f3.220a.12f4 vlan 4 drop
Switch(config)# end
Switch#
```

Note

To filter MAC addresses on a secondary VLAN, specify the corresponding primary VLAN in the above configuration. If the specified VLAN is a primary VLAN, all matching packets received in this primary VLAN and associated secondary VLANs are dropped.

Disabling MAC Address Learning on a VLAN

By default, MAC address learning is enabled on all VLANs on the switch. By controlling which VLANs can learn MAC addresses, you can manage the available MAC address table space. By disabling learning on a VLAN, you can conserve the MAC address table space because all the MAC addresses seen on this VLAN are not learned.

Before disabling MAC address learning, you should understand the network topology and features deployed. Many Layer 2 features use MAC addresses and may not work properly if learning is disabled. Because disabling learning causes flooding of packets, you need to understand the impact of flooding on the network.

These sections contain this information:

- [Deployment Scenarios, page 4-49](#)
- [Configuring Disable MAC Address Learning, page 4-48](#)
- [Usage Guidelines, page 4-49](#)
- [Deployment Scenarios, page 4-49](#)
- [Feature Compatibility, page 4-51](#)
- [Feature Incompatibility, page 4-52](#)

Configuring Disable MAC Address Learning

To disable MAC address learning on a VLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# no mac address-table learning vlan <i>vlan-id range</i>	Disables MAC address learning on the specified VLAN or VLANs. You can specify a single VLAN ID or a range of VLAN IDs separated by a hyphen or comma. Valid VLAN IDs are 1 to 4094. You can reenable MAC address learning on a VLAN by entering the mac address-table learning vlan global configuration command.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show mac address-table learning [vlan <i>vlan-id range</i>]	Displays the MAC address learning status of all VLANs or a specified VLAN.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to disable learning on any VLAN or range of VLANs:

```
Switch# configure terminal
Switch(config)# no mac address-table learning vlan 9-16
Switch(config)# end
Switch#

Switch# show mac address-table learning
Learning disabled on vlans: 9-11,13-16

Switch# show mac address-table learning vlan 10-15
Learning disabled on vlans: 10-11,13-15
```

Usage Guidelines

**Note**

These guidelines are advisory only. Contact the Cisco solution provider team for specific solution implementations.

When disabling MAC address learning on a VLAN, consider these guidelines:

- If learning is disabled on a VLAN with an SVI interface, it floods every IP packet in the Layer 2 domain. Because this flooding may be undesirable, you should disable MAC address learning on a SVI VLAN carefully.
- If you provide a VLAN range that includes reserved VLAN (such as 1000-1006), the command is accepted and disable learning is enabled for all VLANs except for 1002-005 (that is, 1000-1001,1006). However, if you specify an invalid range (such as 1-5000), the command fails and disable learning is not enabled on any of the VLANs.
- With PVLANS, you need to disable learning on the primary VLAN and all secondary VLANs associated with that primary VLANs. Otherwise, you encounter traffic flooding in one direction and unicast flooding in the other direction.
- To disable MAC address learning on a VLAN, consider the flooding implications.

Deployment Scenarios

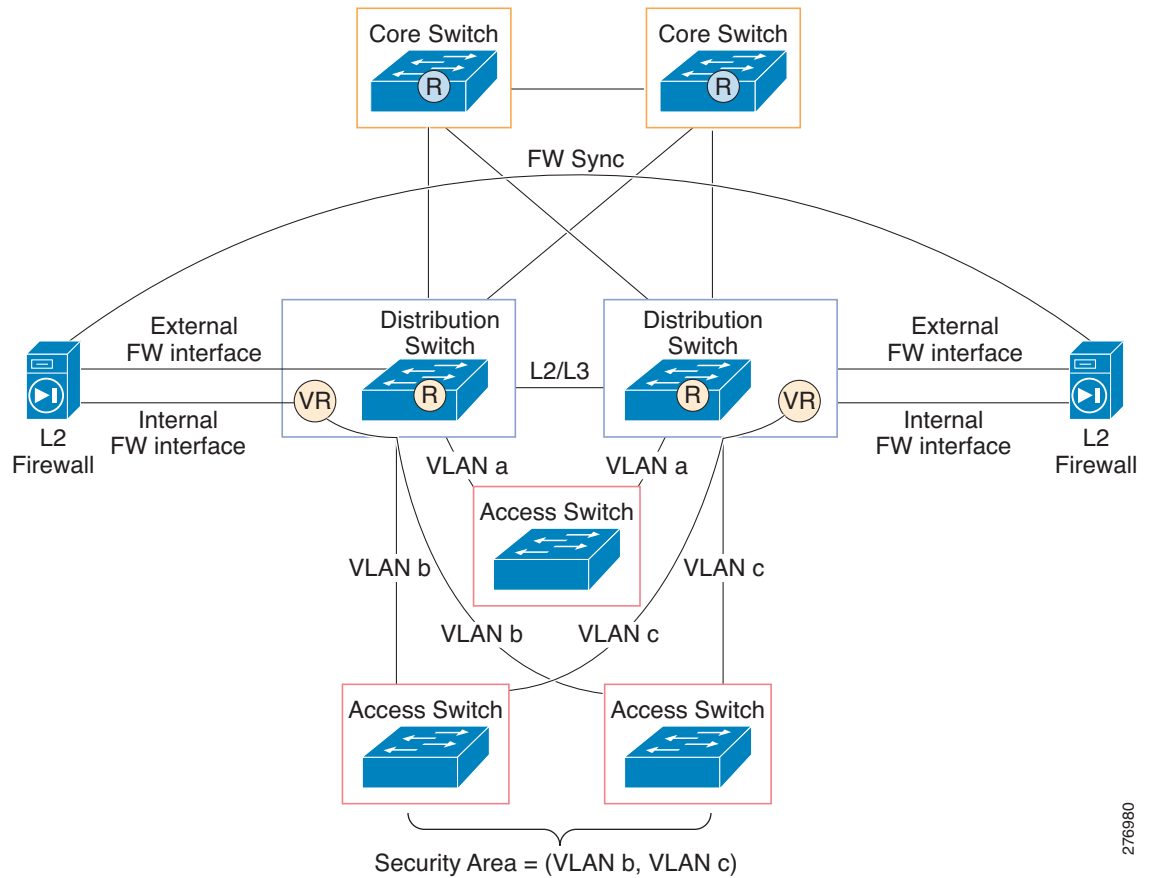

This section includes these deployment scenarios:

- [Metro \(Point to Point Links\), page 4-49](#)
- [Network Load Balancers, page 4-50](#)
- [Layer 2 Firewall or Cache, page 4-51](#)

Metro (Point to Point Links)

In this topology, you have two ports on a VLAN; traffic enters one and must exit the other. On a point-to-point link in metro networks, numerous MAC addresses are on these types of ports by disabling learning on the VLAN to which these two ports belong, many entries in the MAC address table space can be saved. Because there is only one egress port for the traffic, you can flood the packet and avoid having to learn all the MAC addresses seen on this port. This process saves considerable space in the MAC address table.

To obtain source learning, packets are bridged as Layer 2 flood packets. Replicated packets use a distinct dedicated bandwidth. Regardless of the number of ports in a flood set, a flood packet always consumes replication packet bandwidth, which consumes some multicast and broadcast packet-processing bandwidth ([Figure 4-2](#)).

Figure 4-2 Disabling MAC Address Learning: Point-to-Point Links

276980

Network Load Balancers

In this topology, you have two devices, one active and one standby. To perform load balancing, both devices must receive all packets. You could place both devices on the same VLAN. If learning can be disabled on this VLAN, the packet is flooded and both devices receive all traffic destined to any MAC address on the VLAN. You also can assign a multicast MAC address to both load balancers to ensure that all packets reach them. (Figure 4-3).

Figure 4-3 Disabling MAC Address Learning: Network Load Balancers

276981

Layer 2 Firewall or Cache

In this topology, a rewritten Layer 3 packet is routed back to a Layer 2 firewall (or cache) before exiting. When the packet reenters the switch from the firewall, it possesses the switch's MAC address because the packet was previously routed. If the ingress port is a switch port, the switch learns the router's MAC address. For a routed port or SVI, however, the switch does not learn the address. Source misses are generated continuously for all arriving data packets and the switch shows a very high CPU utilization.

By disabling learning on the VLAN that the firewall or cache egress is connected to, you will routinely suppress the source miss and do not observe high CPU utilization (Figure 4-4).

Figure 4-4 Disabling MAC Address Learning: Layer 2 Firewall/Cache

Feature Compatibility

The following features are compatible with disabling MAC address learning on a VLAN:

- **EtherChannel**—The learning disable feature has no impact on EtherChannel provided that the MAC learning state is either disabled or enabled for a VLAN on EtherChannel ports.
- **Switch Virtual Interface (SVI, Layer 3 on a VLAN)**— The learning disable feature has no impact on SVI. Although disabling MAC address learning on a SVI VLAN causes flooding, it does not impact any Layer 3 feature.
- **REP**—The learning disable feature has no impact on REP provided that the MAC learning state is either disabled or enabled for an active VLAN on a port where REP is running.
- **Unicast, Multicast, and Broadcast**—When you enable learning on a VLAN, learning is disabled on all types of traffic.
- **DAI, ESMP, and IGMP snooping**— These features do not interact with the learning disable feature.
- **Control packets**— Control packets arrive at the CPU even if learning is disabled.
- **RSPAN**— Learning on a VLAN and on an RSPAN are compatible.
- **VLAN translation**—To disable learning on a VLAN that is being translated, you must disable learning on the translated VLAN.

Feature Incompatibility

The following features are incompatible with disabling MAC address learning and do not work properly when the feature is enabled:

- 802.1X—The 802.1X class of features does not work when learning is disabled because some of these features require source miss, which is ignored.
- Port security—Port security VLANs requires learning to be enabled. To secure MAC addresses, packets must first arrive at the CPU. However, if you disable learning on a VLAN, SA suppression ensures that packets do not operate this way.
- Unicast flood blocking—When unicast flood blocking is enabled on a port, it is removed from the VLAN flood set. If learning is disabled on the same VLAN, the host connected to that port do not receive traffic.
- DHCP snooping—To send the packet out the correct port once a DHCP request has been resolved, DHCP snooping must learn the MAC address. If you disable learning, the switch do not know on which port to exit the packet; the two features are incompatible.
- Broadcast storm control—This feature does not interact with the learning disable feature.
- Flooding of packets in a VLAN domain in which learning is disabled through PVL.

Partial Feature Incompatibility

Although the following features are partially incompatible with disabling MAC address learning, they still retain a large portion of their functionality:

- FlexLink—FlexLink functions and upstream convergence is not impacted. However, downstream fast convergence uses a MAC table to send dummy multicast packets for each learned MAC address upstream to expedite downstream convergence. This situation does not happen if you enabled learning disable. FlexLink downstream convergence occurs naturally, but it is slower if learning is enabled on that VLAN.
- PVLAN—To observe correct behavior, you must disable learning on the primary VLAN and all secondary VLANs associated with the primary VLAN.

**Note**

To avoid confusion, configure PVLAN similarly on both the primary and secondary VLANs in the PVLAN space.

- Spanning Tree (STP)—Except for the UplinkFast feature, per-VLAN spanning tree functionality is not impacted. To achieve faster downstream convergence, UplinkFast forwards dummy multicast packets using learned MAC addresses. This action is not possible unless MAC learning is enabled.

Displaying Address Table Entries

You can display the MAC address table by using one or more of the privileged EXEC commands described in [Table 4-5](#).

Table 4-5 *Commands for Displaying the MAC Address Table*

Command	Description
<code>show ip igmp snooping groups</code>	Displays the Layer 2 multicast entries for all VLANs or the specified VLAN.
<code>show mac address-table address</code>	Displays MAC address table information for the specified MAC address.
<code>show mac address-table aging-time</code>	Displays the aging time in all VLANs or the specified VLAN.
<code>show mac address-table count</code>	Displays the number of addresses present in all VLANs or the specified VLAN.
<code>show mac address-table dynamic</code>	Displays only dynamic MAC address table entries.
<code>show mac address-table interface</code>	Displays the MAC address table information for the specified interface.
<code>show mac address-table notification</code>	Displays the MAC notification parameters and history table.
<code>show mac address-table static</code>	Displays only static MAC address table entries.
<code>show mac address-table vlan</code>	Displays the MAC address table information for the specified VLAN.

Managing the ARP Table

To communicate with a device (over Ethernet, for example), the software first must learn the 48-bit MAC address or the local data link address of that device. The process of learning the local data link address from an IP address is called *address resolution*.

The Address Resolution Protocol (ARP) associates a host IP address with the corresponding media or MAC addresses and the VLAN ID. Using an IP address, ARP finds the associated MAC address. When a MAC address is found, the IP-MAC address association is stored in an ARP cache for rapid retrieval and the IP datagram is encapsulated in a link-layer frame and sent over the network. Encapsulation of IP datagrams and ARP requests and replies on IEEE 802 networks other than Ethernet is specified by the Subnetwork Access Protocol (SNAP). By default, standard Ethernet-style ARP encapsulation (represented by the **arpa** keyword) is enabled on the IP interface.

ARP entries added manually to the table do not age and must be manually removed.

For CLI procedures, see the Cisco IOS Release 12.3 documentation on Cisco.com.

Configuring Embedded CiscoView Support

The Catalyst 4500 series switch supports CiscoView web-based administration using the Catalyst Web Interface (CWI) tool. CiscoView is a device management application that can be embedded on the switch flash and provides dynamic status, monitoring, and configuration information for your switch.

CiscoView displays a physical view of your switch chassis with color-coded modules and ports and monitoring capabilities that display the switch status, performance, and other statistics. Configuration capabilities allow comprehensive changes to devices, if the required security privileges have been granted. The configuration and monitoring capabilities for the Catalyst 4500 series of switches mirror those available in CiscoView in all server-based CiscoWorks solutions, including CiscoWorks LAN Management Solution (LMS) and CiscoWorks Routed WAN Management Solution (RWAN).

These sections describe the Embedded CiscoView support available with Cisco IOS Release 12.1(20)EW and later releases:

- [Understanding Embedded CiscoView, page 4-54](#)
- [Installing and Configuring Embedded CiscoView, page 4-54](#)
- [Displaying Embedded CiscoView Information, page 4-57](#)

Understanding Embedded CiscoView

The Embedded CiscoView network management system is a web-based interface that uses HTTP and SNMP to provide a graphical representation of the switch and to provide a GUI-based management and configuration interface.

Installing and Configuring Embedded CiscoView

To install and configure Embedded CiscoView, perform this task:

	Command	Purpose
Step 1	Switch# dir <i>device_name</i>	Displays the contents of the device. If you are installing Embedded CiscoView for the first time, or if the CiscoView directory is empty, skip to Step 5 .
Step 2	Switch# delete <i>device_name:cv/*</i>	Removes existing files from the CiscoView directory.
Step 3	Switch# squeeze <i>device_name:</i>	Recovers the space in the file system.
Step 4	Switch# copy tftp bootflash	Copies the tar file to bootflash.
Step 5	Switch# archive tar /xtract tftp:// ip address of tftp server/ciscoview.tar device_name:cv	Extracts the CiscoView files from the tar file on the TFTP server to the CiscoView directory.
Step 6	Switch# dir <i>device_name:</i>	Displays the contents of the device. In a redundant configuration, repeat Step 1 through Step 6 for the file system on the redundant supervisor engine.
Step 7	Switch# configure terminal	Enters global configuration mode.
Step 8	Switch(config)# ip http server	Enables the HTTP web server.
Step 9	Switch(config)# snmp-server community string ro	Configures the SNMP password for read-only operation.
Step 10	Switch(config)# snmp-server community string rw	Configures the SNMP password for read/write operation.

Note

The default password for accessing the switch web page is the enable-level password of the switch.

The following example shows how to install and configure Embedded CiscoView on your switch:

```

Configuring Virtual Switching Systems

This chapter describes how to configure a virtual switching system (VSS) on Catalyst 4500 series switches with Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E, and Catalyst 4500-X). VSS is supported on Cisco Release IOS XE 3.4.0SG and later.

Note

For complete syntax and usage information for virtual switch commands used in this chapter, see the publication at this location:

[Cisco IOS Virtual Switch Command Reference](#)

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

This chapter consists of these sections:

- [Restrictions for Virtual Switching Systems, page 5-1](#)
- [Understanding Virtual Switching Systems, page 5-2](#)
- [VSS Configuration Guidelines and Restrictions, page 5-28](#)
- [Configuring a VSS, page 5-30](#)
- [In-Service Software Upgrade \(ISSU\) on a VSS, page 5-56](#)
- [License Upgrade on a VSS, page 5-85](#)

Restrictions for Virtual Switching Systems

Virtual Switching System (VSS) requires all the supervisors to have the same license level. For the In-chassis Standby supervisors to be capable of Route Processor Redundancy (RPR) their licenses should match those on the In-chassis Active supervisors. For VSS to function, install the same license levels on the In-chassis Standby supervisors as the In-chassis Active supervisors.

Understanding Virtual Switching Systems

These sections describe a VSS:

- [VSS Overview, page 5-2](#)
- [VSS Redundancy, page 5-10](#)
- [Multichassis EtherChannels, page 5-13](#)
- [Packet Handling, page 5-15](#)
- [System Monitoring, page 5-19](#)
- [Dual-Active Detection, page 5-23](#)
- [Configuring a Recovery IP Address, page 5-25](#)
- [VSS Initialization, page 5-26](#)

VSS Overview

Network operators increase network reliability by configuring switches and by provisioning links to the redundant pairs. [Figure 5-1](#) shows a typical switch network configuration. Redundant network elements and redundant links can add complexity to network design and operation. Virtual switching simplifies the network by reducing the number of network elements and hiding the complexity of managing redundant switches and links.

A VSS combines a pair of Catalyst 4500 or 4500-X series switches into a single network element. The VSS manages the redundant links, which externally act as a single port channel.

The VSS simplifies network configuration and operation by reducing the number of Layer 3 routing neighbors and by providing a loop-free Layer 2 topology.

Figure 5-1 Typical Switch Network Design

The following sections present an overview of the VSS. These topics are covered in detail in subsequent chapters:

- [Key Concepts, page 5-3](#)
- [VSS Functionality, page 5-5](#)

- [Hardware Requirements, page 5-8](#)
- [Understanding VSL Topology, page 5-10](#)

Key Concepts

The VSS incorporates the following key concepts:

- [Virtual Switching System, page 5-3](#)
- [VSS Active and VSS Standby Switch, page 5-3](#)
- [Virtual Switch Link, page 5-4](#)
- [Multichassis EtherChannel, page 5-5](#)

Virtual Switching System

A VSS combines a pair of switches into a single network element. For example, a VSS in the distribution layer of the network interacts with the access and core networks as if it were a single switch. See [Figure 5-2](#).

An access switch connects to both switches of the VSS using one logical port channel. The VSS manages redundancy and load balancing on the port channel. This capability enables a loop-free Layer 2 network topology. The VSS also simplifies the Layer 3 network topology by reducing the number of routing peers in the network.

Figure 5-2 VSS in the Distribution Network

VSS Active and VSS Standby Switch

When you create or restart a VSS, the peer switches negotiate their roles. One switch becomes the VSS Active switch, and the other switch becomes the VSS Standby switch.

The VSS Active controls the VSS, running the Layer 2 and Layer 3 control protocols for the switching modules on both switches. The VSS Active switch also provides management functions for the VSS, such as module online insertion and removal (OIR) and the console interface.

The VSS Active and VSS Standby switches perform packet forwarding for ingress data traffic on their locally hosted interfaces. However, the VSS Standby switch sends all control traffic to the VSS Active switch for processing.

Virtual Switch Link

For the two switches of the VSS to act as one network element, they need to share control information and data traffic.

The virtual switch link (VSL) is a special link that carries control and data traffic between the two switches of a VSS, as shown in [Figure 5-3](#). The VSL is implemented as an EtherChannel with up to eight links. The VSL gives control and management traffic higher priority than data traffic so that control and management messages are never discarded. Data traffic is load balanced among the VSL links by the EtherChannel load-balancing algorithm.

Note

EtherChannel load balancing method is a global configuration; VSL observes that method of load balancing.

Figure 5-3 Virtual Switch Link

When you configure VSL, all existing configurations are removed from the interface except for specific allowed commands. When you configure VSL, the system puts the interface into a restricted mode. This means that only specific configuration commands can be configured on the interface.

The following VSL configuration commands are inserted automatically on all VSL member ports:

- **switchport mode trunk**
- **switchport nonegotiate**
- **no lldp transmit**
- **no lldp receive**
- **no cdp enable**
- **service-policy output VSL-Queuing-Policy**

In VSL restricted mode, only these configuration commands are available:

- **channel-group**
- **default**
- **description**
- **exit**
- **load-interval**
- **logging**
- **no**
- **power**

- **service-policy**
- **shutdown**

Multichassis EtherChannel

Note

Beginning with Cisco Release IOS XE 3.5.0E and IOS 15.2(1)SG, Layer 3 MEC is supported on the Catalyst 4500 series switch. Cisco Release IOS XE 3.4.0SG does not support Layer 3 MEC.

An EtherChannel (also known as a port channel) is a collection of two or more physical links that combine to form one logical link. Layer 2 protocols operate on the EtherChannel as a single logical entity. A VSS enables the creation of Multi-Chassis EtherChannel (MEC), which is an Etherchannel whose member ports can be distributed across the member switches in a VSS. Because non-VSS switches connected to a VSS view the MEC as a standard EtherChannel, non-VSS switches can connect in a dual homed manner. [Figure 5-4](#) displays a dual-homed connection for an MEC into the VSS; VSS is seen as a single logical switch. Traffic traversing an MEC can be load balanced locally within a VSS member switch much as in standard EtherChannels. Cisco MEC supports the bundling protocols LACP and PAGP as well as ON mode.

Figure 5-4 VSS with MEC

VSS supports a maximum of 256 EtherChannels. This limit applies to the total number of regular EtherChannels and MECs. Because the VSL requires two EtherChannel numbers (one for each switch in the VSS), there are 254 user-configurable EtherChannels.

For information on how to configure Layer 3 Multichassis EtherChannels, see [For information on how to configure Layer 3 Multichassis EtherChannels, see, page 5-5](#)

VSS Functionality

The following sections describe the main functionality of a VSS:

- [Redundancy and High Availability, page 5-6](#)
- [Packet Handling, page 5-6](#)

- [System Management, page 5-6](#)
- [Quad-Supervisor \(In-chassis Standby Supervisor Engine\) Support, page 5-6](#)
- [Asymmetric chassis support, page 5-7](#)
- [Interface Naming Convention, page 5-7](#)
- [Module Number Convention, page 5-7](#)
- [Key Software Features not Supported on VSS, page 5-8](#)

Redundancy and High Availability

In a VSS, supervisor engine redundancy operates between the VSS Active and VSS Standby switch, using stateful switchover (SSO) and nonstop forwarding (NSF). The peer switch exchange configuration and state information across the VSL and the VSS Standby supervisor engine runs in SSO-HOT mode.

The VSS Standby switch monitors the VSS Active switch using the VSL. If it detects failure, the VSS Standby switch initiates a switchover and takes on the VSS Active role. When the failed switch recovers, it takes on the VSS Standby role.

If either the VSS Active switch fails or all links that belong to the VSL port-channel fail, the VSS Standby switch initiates a switchover and assumes the role of the VSS Active switch. If the previous VSS Active switch has failed, it reloads and boots as the VSS Standby switch. However, if only the VSL port-channel failure caused the switchover, the previous VSS Active switch enters recovery mode (provided dual-active detection is configured). In this scenario, the previous VSS Active chassis (now in recovery mode) carries no traffic and only monitors the VSL link. When one link in the VSL port-channel is up, the recovery mode switch reloads and boots as a VSS Standby chassis. For additional information about dual-active detection, see the [“Dual-Active Detection” section on page 5-23](#).

Packet Handling

The VSS Active supervisor engine runs the Layer 2 and Layer 3 protocols and features for the VSS and manages all ports on both switches.

The VSS uses VSL to communicate protocol and system information between the peer switches and to carry data traffic between the switches when required.

Both switches perform packet forwarding for ingress traffic on their interfaces. If possible, ingress traffic is forwarded to an outgoing interface on the same switch to minimize data traffic that must traverse the VSL.

System Management

The VSS Active supervisor engine acts as a single point of control for the VSS. For example, the VSS Active supervisor engine handles OIR of switching modules on both switches. The VSS Active supervisor engine uses VSL to send messages to and from local ports on the VSS Standby switch.

The command console on the VSS Active supervisor engine is used to control both switches. In virtual switch mode, the command console on the VSS Standby supervisor engine blocks attempts to enter configuration mode.

The VSS Standby switch runs a subset of system management tasks. For example, the VSS Standby switch handles its own power management, linecard bringup, and other local hardware management.

Quad-Supervisor (In-chassis Standby Supervisor Engine) Support

Beginning with IOS XE release 3.8.0E, Cisco Catalyst 4500-E switches configured with Supervisor Engines 7-E, 7-LE, or 8E support Quad-Supervisor VSS Mode.

With Quad-Supervisor VSS mode, each chassis in the VSS supports a redundant supervisor engine, called the in-chassis standby (ICS). The ICS supervisor engines use Route Processor Redundancy (RPR) mode, and remain in RPR Standby Cold redundancy state. If the Active supervisor fails, the ICS supervisor boots fully, and becomes the Active supervisor within the chassis, while the local chassis remains nonoperational till SSO redundancy is established with the VSS Active supervisor.

The following table displays a matrix of the chassis that support Quad-Supervisor VSS mode, and the corresponding number of supervisors required in each case.

Chassis	4507R+E	4507R-E	4510R-E	4510R+E
4503-E	3	3	3	3
4506-E	3	3	3	3
4507R+E	4	4	4	4
457R-E	4	4	4	4
4510R+E	4	4	4	4
4510R+E	4	4	4	4

Asymmetric chassis support

Ensure that both participating switches in the VSS have the same supervisor engine type. The chassis can differ in type (i.e., +E and -E chassis can be in a single VSS) and also can differ in the number of slots in chassis. VSS cannot be formed between different flavors of Catalyst 4500X (e.g., 4500X-16 and 4500X-32).

Interface Naming Convention

In VSS mode, interfaces are specified using the switch number (in addition to slot and port), because the same slot numbers are used on both chassis. For example, the **interface 1/5/4** command specifies port 4 of the switching module in slot 5 of switch 1. The **interface 2/5/4** command specifies port 4 on the switching module in slot 5 of switch 2.

Module Number Convention

IOS treats modules in both chassis as if they belong to one single chassis and the module number space is 1-20.

Switch 1 receives a module number from 1-10 and switch 2 receives a number from 11-20, irrespective the chassis type, supervisor type, or number of slots in a chassis. For example, on a 3-slot chassis VSS, the module numbers on switch 1 would be 1, 2, and 3, and on switch 2, the numbers would be 11, 12, and 13. The module number on switch 2 always starts from 11.

The **show switch virtual slot-map** command provides virtual to physical slot mapping. The following is a sample output:

Virtual Slot No	Remote Switch No	Physical Slot No	Module Uptime
1	1	1	00:24:14
2	1	2	00:23:46
3	1	3	-
4	1	4	-

5	1	5	-
6	1	6	-
7	1	7	-
8	1	8	-
9	1	9	-
10	1	10	-
11	2	1	00:22:03
12	2	2	00:24:43
13	2	3	00:24:43
14	2	4	-
15	2	5	-
16	2	6	-
17	2	7	-
18	2	8	-
19	2	9	-
20	2	10	-

Key Software Features not Supported on VSS

With some exceptions, the VSS maintains feature parity with the standalone Catalyst 4500 or 4500-X series switches. Major exceptions include:

- CFM D8.1
- Energywise
- Mediatrace (Medianet active video monitoring feature)
- Metadata (Medianet feature)
- Per VLAN Learning
- UDE
- UDLR
- VMPS Client

Hardware Requirements

The following sections describe the hardware requirements of a VSS:

- [Chassis and Modules, page 5-8](#)
- [VSL Hardware Requirements, page 5-9](#)
- [Multichassis EtherChannel Requirements, page 5-10](#)

Chassis and Modules

[Table 5-1](#) describes the hardware requirements for the VSS chassis and modules.

Table 5-1 VSS Hardware Requirements

Hardware	Count	Requirements
Chassis	2	VSS is available on a Catalyst 4500-X switch and on chassis that support Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E. Note +E and -E chassis can be mixed; R-E chassis are not supported with Supervisor Engine 9-E
Supervisor Engines	2	VSS is available on Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E, and on the Catalyst 4500-X switch series. All supervisor engines or systems in a VSS must match precisely.
Linecard	0 to as many linecard slots are available in a chassis.	WS-X4748-12X48U+E WS-X4712-SFP-E WS-X4724-SFP-E WS-X4748-SFP-E WS-X4748-RJ45V+E WS-X4712-SFP+E WS-X4640-CSFP-E WS-X4748-UPOE+E WS-X4748-RJ45-E WS-X4606-X2-E WS-X4648-RJ45V-E WS-X4648-RJ45V+E WS-X4648-RJ45-E WS-X4624-SFP-E WS-X4612-SFP-E WS-X4548-RJ45V+ WS-X4448-GB-SFP WS-X4306-GB WS-X4248-RJ45V WS-X4248-FE-SFP WS-X4148-RJ WS-X4148-FX-MT

VSL Hardware Requirements

The VSL EtherChannel supports both 10-Gigabit Ethernet ports and 1- Gigabit Ethernet ports.

We recommend that you use at least two of the 10-Gigabit/1-Gigabit Ethernet ports to create the VSL between the two switches. You cannot combine 10-Gigabit and 1-Gigabit Ethernet ports in a VSL port-channel.

Be aware of the following:

- You can add additional physical links to the VSL EtherChannel with the 10-Gigabit Ethernet ports on any supported supervisor engine or linecard.
- Oversubscribed linecard ports can be used for VSL but total bandwidth requirements of VSL or any traffic drop because of a certain hashing mechanism must be accounted for before using oversubscribed linecard ports for VSL.
- VSL ports can have only 10 Gigabit Ethernet port mode on a WS-X4606-X2-E linecard; non-VSL ports can be configured as 10 or 1 Gigabit Ethernet port mode.
- 1 Gigabit Ethernet ports on line card X4606-X2-E cannot be used as VSL links.

Multichassis EtherChannel Requirements

Physical links from any of the supervisor engines or linecard modules can be used to implement a Multichassis EtherChannel (MEC).

Understanding VSL Topology

A VSS contains two switches that communicate using the VSL, which is a special port group.

We recommend that you configure at least two of the 10-Gigabit/1-Gigabit Ethernet ports as VSL, selecting ports from different modules. [Figure 5-5](#) shows a example topology.

Figure 5-5 VSL Topology Example

VSS Redundancy

The following sections describe how redundancy in a VSS supports network high availability:

- [Overview, page 5-11](#)
- [RPR and SSO Redundancy, page 5-11](#)
- [Switch Roles in a VSS, page 5-12](#)
- [Failed Switch Recovery, page 5-12](#)
- [VSL Failure, page 5-13](#)
- [User Actions, page 5-13](#)

Overview

A VSS operates stateful switchover (SSO) between the VSS Active and VSS Standby supervisor engines. Compared to standalone mode, a VSS has the following important differences in its redundancy model:

- The VSS Active and VSS Standby supervisor engines are hosted in separate switches and use the VSL to exchange information.
- The VSS Active supervisor engine controls both switches of the VSS. The VSS Active supervisor engine runs the Layer 2 and Layer 3 control protocols and manages the switching modules on both switches.
- The VSS Active and VSS Standby switches perform data traffic forwarding.

If the VSS Active supervisor engine fails, the VSS Standby supervisor engine initiates a switchover and assumes the VSS Active role.

RPR and SSO Redundancy

Beginning in IOS XE release 3.8.0E, Quad-Supervisor VSS mode supports intra-chassis redundancy. When the VSS Active fails, the in-chassis standby supervisor operates in RPR mode and becomes the VSS Standby.

A VSS operates with stateful switchover (SSO) redundancy if it meets the following requirements:

- Both supervisor engines must be running the same software version, unless it is in the process of software upgrade.

**Note**

If the supervisors are running different software versions, the system will reach SSO only if the two versions are ISSU-compatible. However, this is not supported in the current release.

- VSL-related configuration in the two switches must match.
- SSO and nonstop forwarding (NSF) must be configured on each switch.

**Note**

See the [“SSO Dependencies” section on page 5-26](#) for additional details about the requirements for SSO redundancy on a VSS. See [Chapter 13, “Configuring Cisco NSF with SSO Supervisor Engine Redundancy”](#) for information about configuring SSO and NSF.

With SSO redundancy, the VSS Standby supervisor engine is always ready to assume control following a fault on the VSS Active supervisor engine. Configuration, forwarding, and state information are synchronized from the VSS Active supervisor engine to the redundant supervisor engine at startup and whenever changes to the VSS Active supervisor engine configuration occur. If a switchover occurs, traffic disruption is minimized.

If a VSS does not meet the requirements for SSO redundancy, it will be incapable of establishing a relationship with the peer switch.

The VSS runs stateful switchover (SSO) between the VSS Active and VSS Standby supervisor engines (see [Figure 5-6](#)). The VSS determines the role of each supervisor engine during initialization.

The supervisor engine in the VSS Standby switch runs in hot standby state. The VSS uses the VSL link to synchronize configuration data from the VSS Active to the VSS Standby supervisor engine. Also, protocols and features that support high availability synchronize their events and state information to the VSS Standby supervisor engine.

Switch Roles in a VSS

Figure 5-6 illustrates the switches' roles in a VSS.

Figure 5-6 Switches' Roles in a VSS

Failed Switch Recovery

If the VSS Active switch or supervisor engine fails, the VSS initiates a stateful switchover (SSO) and the former VSS Standby supervisor engine assumes the VSS Active role. The failed switch performs recovery action by reloading the supervisor engine.

In Quad-Supervisor VSS mode, if the VSS Active switch or supervisor engine fails, the VSS initiates a stateful switchover (SSO) and the former VSS Standby supervisor engine assumes the VSS Active role. The in-chassis standby (ICS) on the failed switch becomes the VSS Standby and the former VSS Active becomes the ICS for the VSS Standby.

If the VSS Standby switch or supervisor engine fails, no switchover is required. The failed switch performs recovery action by reloading the supervisor engine.

The VSL links are unavailable while the failed switch recovers. After the switch reloads, it becomes the new VSS Standby switch and the VSS reinitializes the VSL links between the two switches.

The switching modules on the failed switch are unavailable during recovery, so the VSS operates only with the MEC links that terminate on the VSS Active switch. The bandwidth of the VSS is reduced until the failed switch has completed its recovery and become operational again. Any devices that are connected only to the failed switch experience an outage.

Note

The VSS may experience a brief data path disruption when the switching modules in the VSS Standby switch become operational after the SSO.

After the SSO, much of the processing power of the VSS Active supervisor engine is consumed in bringing up a large number of ports simultaneously in the VSS Standby switch. As a result, some links might be brought up before the supervisor engine has configured forwarding for the links, causing traffic to those links to be lost until the configuration is complete. This condition is especially disruptive if the link is an MEC link and it is running in "ON" mode. This is why it is recommended that MEC ports always have either PAGP or LACP mode of EtherChannel configured.

**Note**

We recommend not configuring LACP independent mode (standalone-mode) for MEC because ports on the VSS Standby switch (while it boots) come up tens of seconds before the control plane is fully functional. This behavior causes a port to start working in independent mode and might cause traffic loss until the port is bundled.

VSL Failure

To ensure fast recovery from VSL failures, fast link failure detection is enabled in virtual switch mode on all VSL port channel members.

**Note**

Fast link notification is based upon internal hardware assisted BFD sessions between the pair of physical VSL links.

If a single VSL physical link goes down, the VSS adjusts the port group so that the failed link is not selected.

If the VSS Standby switch detects complete VSL link failure, it initiates a stateful switchover (SSO). If the VSS Active switch has failed (causing the VSL links to go down), the scenario is switch failure, as described in the previous section.

If only the VSL has failed and the VSS Active switch is still operational, this is a dual-active scenario. The VSS detects that both switches are operating in VSS Active mode and performs recovery action. See the [“Dual-Active Detection” section on page 5-23](#) for additional details about the dual-active scenario.

User Actions

From the VSS Active switch command console, you can initiate a VSS switchover or a reload.

If you enter the **reload** command from the command console, it performs a reload on the switch where reload is issued.

To reload only the VSS Standby switch, use the **redundancy reload peer** command.

To force a switchover from the VSS Active to the VSS Standby supervisor engine, use the **redundancy force-switchover** command.

To reset both the VSS Active and Standby switch, use the **redundancy reload shelf** command.

To reset the in-chassis standby (ICS), use the **hw-module module <supervisor slot number> reset** command.

Multichassis EtherChannels

These sections describe multichassis EtherChannels (MECs):

- [Overview, page 5-14](#)
- [MEC Failure Scenarios, page 5-14](#)

Overview

A multichassis EtherChannel is an EtherChannel with ports that terminate on both switches of the VSS (see [Figure 5-7](#)). A VSS MEC can connect to any network element that supports EtherChannel (such as a host, server, router, or switch).

At the VSS, an MEC is an EtherChannel with additional capability: the VSS balances the load across ports in each switch independently. For example, if traffic enters the VSS Active switch, the VSS will select an MEC link from the VSS Active switch. This MEC capability ensures that data traffic does not unnecessarily traverse the VSL.

Each MEC can optionally be configured to support either PAgP or LACP. These protocols run only on the VSS Active switch. PAgP or LACP control packets destined for an MEC link on the VSS Standby switch are sent across VSL.

An MEC can support up to eight physical links, which can be distributed in any proportion between the VSS Active and VSS Standby switch.

Figure 5-7 MEC Topology

MEC Failure Scenarios

We recommend that you configure the MEC with at least one link to each switch. This configuration conserves VSL bandwidth (traffic egress link is on the same switch as the ingress link), and increases network reliability (if one VSS supervisor engine fails, the MEC is still operational).

The following sections describe possible failures and the resulting impacts:

- [Single MEC Link Failure, page 5-15](#)
- [All MEC Links to the VSS Active Switch Fail, page 5-15](#)
- [All MEC Links to the VSS Standby Switch Fail, page 5-15](#)
- [All MEC Links Fail, page 5-15](#)
- [VSS Standby Switch Failure, page 5-15](#)
- [VSS Active Switch Failure, page 5-15](#)

Single MEC Link Failure

If a link within the MEC fails (and other links in the MEC are still operational), the MEC redistributes the load among the operational links, as in a regular port.

All MEC Links to the VSS Active Switch Fail

If all links to the VSS Active switch fail, the MEC becomes a regular EtherChannel with operational links to the VSS Standby switch.

Data traffic terminating on the VSS Active switch reaches the MEC by crossing the VSL to the VSS Standby switch. Control protocols continue to run in the VSS Active switch. Protocol messages reach the MEC by crossing the VSL.

All MEC Links to the VSS Standby Switch Fail

If all links fail to the VSS Standby switch, the MEC becomes a regular EtherChannel with operational links to the VSS Active switch.

Control protocols continue to run in the VSS Active switch. All control and data traffic from the VSS Standby switch reaches the MEC by crossing the VSL to the VSS Active switch.

All MEC Links Fail

If all links in an MEC fail, the logical interface for the EtherChannel is set to unavailable. Layer 2 control protocols perform the same corrective action as for a link-down event on a regular EtherChannel.

On adjacent switches, routing protocols and Spanning Tree Protocol (STP) perform the same corrective action as for a regular EtherChannel.

VSS Standby Switch Failure

If the VSS Standby switch fails, the MEC becomes a regular EtherChannel with operational links on the VSS Active switch. Connected peer switches detect the link failures, and adjust their load-balancing algorithms to use only the links to the VSS Active switch.

In Quad-Supervisor VSS mode, the in-chassis standby (ICS supervisor in the VSS Standby switch becomes the VSS Standby supervisor and the former VSS Standby supervisor becomes the ICS.

VSS Active Switch Failure

VSS Active switch failure results in a stateful switchover (SSO). See the [“VSS Redundancy” section on page 5-10](#) for details about SSO on a VSS. After the switchover, the MEC is operational on the new VSS Active switch. Connected peer switches detect the link failures (to the failed switch), and adjust their load-balancing algorithms to use only the links to the new VSS Active switch.

Packet Handling

In a VSS, the VSS Active supervisor engine runs the Layer 2 and Layer 3 protocols and features for the VSS and manages the ports on both switches.

The VSS uses the VSL to communicate system and protocol information between the peer switches and to carry data traffic between the two switches.

Both switches perform packet forwarding for ingress traffic on their local interfaces. The VSS minimizes the amount of data traffic that must traverse the VSL.

The following sections describe packet handling in a VSS:

- [Traffic on the VSL, page 5-16](#)
- [Layer 2 Protocols, page 5-16](#)
- [Layer 3 Protocols, page 5-18](#)

Traffic on the VSL

The VSL carries data traffic and in-band control traffic between the two switches. All frames forwarded over the VSL link are encapsulated with a special header (up to ten bytes for data traffic and 18 bytes for control packets), which provides information for the VSS to forward the packet on the peer switch.

The VSL transports control messages between the two switches. Messages include protocol messages that are processed by the VSS Active supervisor engine, but received or transmitted by interfaces on the VSS Standby switch. Control traffic also includes module programming between the VSS Active supervisor engine and switching modules on the VSS Standby switch.

The VSS needs to transmit data traffic over the VSL under the following circumstances:

- Layer 2 traffic flooded over a VLAN (even for dual-homed links).
- Packets processed by software on the VSS Active supervisor engine where the ingress interface is on the VSS Standby switch.
- The packet destination is on the peer switch, such as the following examples:
 - Traffic within a VLAN where the known destination interface is on the peer switch.
 - Traffic that is replicated for a multicast group and the multicast receivers are on the peer switch.
 - The known unicast destination MAC address is on the peer switch.
 - The packet is a MAC notification frame destined for a port on the peer switch.

VSL also transports system data, such as NetFlow export data and SNMP data, from the VSS Standby switch to the VSS Active supervisor engine.

To preserve the VSL bandwidth for critical functions, the VSS uses strategies to minimize user data traffic that must traverse the VSL. For example, if an access switch is dual-homed (attached with an MEC terminating on both VSS switches), the VSS transmits packets to the access switch using a link on the same switch as the ingress link.

Traffic on the VSL is load-balanced with the same global hashing algorithms available for EtherChannels (the default algorithm is source-destination IP).

Layer 2 Protocols

The VSS Active supervisor engine runs the Layer 2 protocols (such as STP and VTP) for the switching modules on both switches. Protocol messages that are transmitted and received on the VSS Standby switch switching modules must traverse the VSL to reach the VSS Active supervisor engine.

All Layer 2 protocols in VSS work similarly in standalone mode. The following sections describe the difference in behavior for some protocols in VSS:

- [Spanning Tree Protocol, page 5-17](#)
- [EtherChannel Control Protocols, page 5-17](#)
- [Jumbo frame size restriction, page 5-17](#)
- [SPAN, page 5-17](#)

- [Private VLANs, page 5-17](#)

Spanning Tree Protocol

The VSS Active switch runs Spanning Tree Protocol (STP). The VSS Standby switch redirects STP BPDUs across the VSL to the VSS Active switch.

The STP bridge ID is commonly derived from the chassis MAC address. To ensure that the bridge ID does not change after a switchover, the VSS continues to use the original chassis MAC address for the STP Bridge ID.

EtherChannel Control Protocols

Link Aggregation Control Protocol (LACP) and Port Aggregation Protocol (PAgP) packets contain a device identifier. The VSS defines a common device identifier for both chassis. You should use PAgP or LACP on MECs instead of mode ON, although all three modes are supported.

A new PAgP enhancement has been defined for assisting with dual-active scenario detection. For additional information, see the [“Dual-Active Detection” section on page 5-23](#).

Jumbo frame size restriction

The maximum jumbo frame size supported on a VSS interface is 9188 bytes (MTU of 9170 bytes). This accommodates the overhead of transporting packets between the two member switches over VSL.

Not all frames traverse VSL. So, packets confined to one of the member switches could have a size of 9216 bytes (MTU of 9198 bytes). Such frames may require diversion over VSL when a failure occurs. This is why the *max configured MTU* on non-VSL front panel ports is 9170.

Note The MTU CLI is unavailable on a VSL interface. It is set internally to 9198 (Max frame size of 9216), addressing the overhead of VSL.

For example, if we send traffic between two ports on the active switch, no overhead exists. However, overhead exists when we send packets between ports of active to ports of standby. Even more overhead exists when we send packets from standby ports to the active CPU. The higher limit accommodates the worst case and guarantees consistent forwarding under all scenarios.

SPAN

VSS supports all SPAN features for non-VSL interfaces.

Note SPAN on VSL ports is not supported; VSL ports can be neither a SPAN source, nor a SPAN destination.

The number of SPAN sessions available on a VSS matches that on a single switch running in standalone mode.

Private VLANs

Private VLANs on VSS work similarly in standalone mode. The only exception is that the native VLAN on isolated trunk ports must be configured explicitly. Refer to [Chapter 47, “Configuring Private VLANs”](#) for details on how to configure the native VLAN on isolated trunk ports.

Layer 3 Protocols

The VSS Active supervisor engine runs the Layer 3 protocols and features for the VSS. All layer 3 protocol packets are sent to and processed by the VSS Active supervisor engine. Both member switches perform hardware forwarding for ingress traffic on their interfaces. If possible, to minimize data traffic that must traverse the VSL, ingress traffic is forwarded to an outgoing interface on the same switch. When software forwarding is required, packets are sent to the VSS Active supervisor engine for processing.

The same router MAC address, assigned by the VSS Active supervisor engine, is used for all Layer 3 interfaces on both VSS member switches. After a switchover, the original router MAC address is still used. The router MAC address is configurable and can be chosen from three options: virtual-mac (derived from domainId), chassis-mac (preserved after switchover), and user-configured MAC address. VSS uses virtual MAC address as the default.

The following sections describe Layer 3 protocols for a VSS:

- [IPv4, page 5-18](#)
- [IPv6, page 5-18](#)
- [IPv4 Multicast, page 5-19](#)
- [Software Features, page 5-19](#)

IPv4

The supervisor engine on the VSS Active switch runs the IPv4 routing protocols and performs any required software forwarding. All routing protocol packets received on the VSS Standby switch are redirected to the VSS Active supervisor engine across the VSL. The VSS Active supervisor engine generates all routing protocol packets to be sent out over ports on either VSS member switch.

Hardware forwarding is distributed across both members on the VSS. The supervisor engine on the VSS Active switch sends Forwarding Information Base (FIB) updates to the VSS Standby supervisor engine, which installs all routes and adjacencies in its hardware.

Packets intended for a local adjacency (reachable by local ports) are forwarded locally on the ingress switch. Packets intended for a remote adjacency (reachable by remote ports) must traverse the VSL.

The supervisor engine on the VSS Active switch performs all software forwarding (for protocols such as IPX) and feature processing (such as fragmentation and TTL exceed). If a switchover occurs, software forwarding is disrupted until the new VSS Active supervisor engine obtains the latest CEF and other forwarding information.

In virtual switch mode, the requirements to support non-stop forwarding (NSF) match those in standalone redundant mode of operation.

From a routing peer perspective, Multi-Chassis EtherChannels (MEC) remain operational during a switchover (only the links to the failed switch are down, but the routing adjacencies remain valid).

The VSS achieves Layer 3 load-balancing over all paths in the FIB entries, be it local or remote.

IPv6

VSS supports IPv6 unicast and multicast as it is there on standalone system.

IPv4 Multicast

The IPv4 multicast protocols run on the VSS Active supervisor engine. Internet Group Management Protocol (IGMP) and Protocol Independent Multicast (PIM) protocol packets received on the VSS Standby supervisor engine are transmitted across VSL to the VSS Active supervisor engine. The VSS Active supervisor engine generates IGMP and PIM protocol packets to be sent over ports on either VSS member.

The VSS Active supervisor engine syncs Multicast Forwarding Information Base (MFIB) state to the VSS Standby supervisor engine. On both member switches, all multicast routes are loaded in hardware with replica expansion table (RET) entries programmed for only local outgoing interfaces. Both member switches are capable of performing hardware forwarding.

Note

To avoid multicast route changes as a result of the switchover, we recommend that all links carrying multicast traffic be configured as MEC rather than Equal Cost Multipath (ECMP).

For packets traversing VSL, all Layer 3 multicast replication occurs on the egress switch. If there are multiple receivers on the egress switch, only one packet is replicated and forwarded over the VSL, and then replicated to all local egress ports.

Software Features

Software features run only on the VSS Active supervisor engine. Incoming packets to the VSS Standby switch that require software processing are sent across the VSL to the VSS Active supervisor engine.

System Monitoring

The following sections describe system monitoring and system management for a VSS:

- [Environmental Monitoring, page 5-19](#)
- [File System Access, page 5-19](#)
- [Diagnostics, page 5-20](#)
- [Network Management, page 5-21](#)

Environmental Monitoring

Environmental monitoring runs on both supervisor engines. The VSS Standby switch reports notifications to the VSS Active supervisor engine. The VSS Active switch gathers log messages for both switches. The VSS Active switch synchronizes the calendar and system clock to the VSS Standby switch.

File System Access

File system access on VSS is the same as it is on dual supervisor standalone system. All files on a standby switch are accessible with slave prefix as following:

```
Switch# dir ?
/all          List all files
/recursive    List files recursively
all-filesystems List files on all filesystems
bootflash:    Directory or file name
```

```

cat4000_flash:      Directory or file name
cns:                Directory or file name
crashinfo:          Directory or file name
kinfo:              Directory or file name
null:               Directory or file name
nvram:              Directory or file name
revrcsf:            Directory or file name
slavebootflash:     Directory or file name
slavecat4000_flash: Directory or file name
slavecrashinfo:     Directory or file name
slavekinfo:          Directory or file name
slavenvram:          Directory or file name
slaveslot0:          Directory or file name
slaveusb0:           Directory or file name
slot0:              Directory or file name
system:              Directory or file name
tar:                 Directory or file name
tmpsys:              Directory or file name
usb0:                Directory or file name
|                    Output modifiers

```

All file or directory name with prefix "slave" show vss standby files.

In Quad-Supervisor VSS mode, the following output is displayed:

```

Switch dir ?
/all List all files
/recursive List files recursively
all-filestems List files on
all filestems
bootflash-ics: Directory or file name
bootflash: Directory or file name
cat4000_flash: Directory or file name
cns: Directory or file name
crashinfo: Directory or file name
kinfo: Directory or file name
lcfpga: Directory or file name
null: Directory or file name
nvram: Directory or file name
revrcsf: Directory or file name
slavebootflash-ics: Directory or file name
slavebootflash: Directory or file name
slavecat4000_flash: Directory or file name
slavecrashinfo: Directory or file name
slavekinfo: Directory or file name
slavenvram: Directory or file nameslaveslot0: Directory or file name
slaveusb0: Directory or file nameslot0: Directory or file name
smi: Directory or file name
system: Directory or file name
tar: Directory or file name
tmpsys: Directory or file nameusb0: Directory or file name| Output modifiers

```

Note

The in-chassis standby (ICS) bootflash is displayed as `bootflash-ics:` and `slavebootflash-ics`. The ICS USB0: and `slot0:` is not accessible from the VSS Active switch, and is not displayed in the output.

Diagnostics

Bootup diagnostics are run independently on both switches. Online diagnostics can be invoked on the basis of virtual slots, which provide accessibility to modules on both switches. Use the **show switch virtual slot-map** command to display the virtual to physical slot mapping.

```
Switch# show switch virtual slot-map
Virtual Slot to Remote Switch/Physical Slot Mapping Table:
```

Virtual Slot No	Remote Switch No	Physical Slot No	Module Uptime
1	1	1	-
2	1	2	-
3	1	3	02:43:51
4	1	4	-
5	1	5	-
6	1	6	02:45:20
7	1	7	-
8	1	8	02:43:50
9	1	9	-
10	1	10	-
11	2	1	02:46:50
12	2	2	02:46:50
13	2	3	-
14	2	4	-
15	2	5	02:42:23
16	2	6	-
17	2	7	-
18	2	8	-
19	2	9	-
20	2	10	-

Network Management

The following sections describe network management for a VSS:

- [Telnet over SSH Sessions and the Web Browser User Interface, page 5-21](#)
- [SNMP, page 5-21](#)
- [Command Console, page 5-22](#)
- [Accessing the Remote Console on VSS, page 5-22](#)
- [Copying Files to Bootflash, page 5-22](#)
- [Transferring a Large File over VSL, page 5-23](#)

Telnet over SSH Sessions and the Web Browser User Interface

A VSS supports remote access using Telnet over SSH sessions and the Cisco web browser user interface. All remote access is directed to the VSS Active supervisor engine, which manages the whole VSS. If the VSS performs a switchover, Telnet over SSH sessions and web browser sessions are disconnected.

SNMP

The SNMP agent runs on the VSS Active supervisor engine.

CISCO-VIRTUAL-SWITCH-MIB is a new MIB for virtual switch mode and contains the following main components:

- cvsGlobalObjects — Domain #, Switch #, Switch Mode
- cvsCoreSwitchConfig — Switch Priority
- cvsChassisTable — Switch Role and Uptime

- cvsModuleTable — Information on the physical modules listed in the ENTITY-MIB entPhysicalTable, whose entPhysicalClass is module(9)
- cvsVSLConnectionTable — VSL Port Count, Operational State
- cvsVSLStatsTable — Total Packets, Total Error Packets
- cvsVSLPortStatsTable — TX/RX Good, Bad, Bi-dir and Uni-dir Packets

Command Console

Because the management plane of the two switches are common (that is, both switches in a VSS can be configured and managed from Active switch itself), you do not require access to the Standby console. However, the consoles of both switches are available by connecting console cables to both supervisor engine console ports. Availability of the Standby console does not imply that you can configure the switch from Standby console as well. Config mode is not available on the Standby and **show** commands are limited in availability. Observe that all **show** commands, even for remote ports, are available on the Active switch.

The console on the VSS Standby switch will indicate that switch is operating in VSS Standby mode by adding the characters “-stdby” to the command line prompt. You cannot enter configuration mode on the VSS Standby switch console.

The following example shows the prompt on the VSS Standby console:

```
Switch-standby> sh clock
*14:04:58.705 UTC Tue Nov 20 2012
```

Accessing the Remote Console on VSS

Note

The **remote login** command is not supported on switches running Quad-Supervisor VSS mode.

Remote console (the Standby's console) can be accessed from the Local (Active) switch. This is available on a standalone system and works similarly on VSS. To access the remote console from the Active, you can use the **remote login** command with a VSS-Standby module number. Observe that the module number is a virtual slot and it would be an In-Chassis-Active supervisor module number on the remote chassis.

```
Switch# remote login module 11
Connecting to standby virtual console
Type "exit" or "quit" to end this session

9 Switch-standby-console>
```

Because the Standby console is not available in config mode and only partially available in EXEC mode, distributed features like Netflow and Wireshark have special exemptions for respective commands (that is, these commands are allowed). Refer to [Chapter 76, “Configuring Flexible NetFlow”](#) and [Chapter 71, “Configuring Wireshark”](#) for details.

Copying Files to Bootflash

When you copy a file to a bootflash on the Active, it is not automatically copied to the Standby bootflash. This means that when you perform an ISSU upgrade or downgrade, both switches must receive the files individually. This behavior matches that on a dual-supervisor standalone system. Similarly, the removal of a file on one switch does not cause the removal of the same file on the other switch.

Transferring a Large File over VSL

Because the management plane of the VSS switches are performed through the Active, you might need to send a large-config/image file from one switch to another (that is, sending a file transfer over VSL). When you do this, the VSL link becomes “busy.” Because data is flowing on a front panel port, it [the data] is significantly slower than what you might see on a dual-supervisor standalone system because in the latter, this action occurs through dedicated EOBC link.

On VSS, copying a large file from one switch to another may take several minutes. Hence, you should do this only when needed. Consider a wait of several minutes before file transfer completes.

Dual-Active Detection

If the VSL fails, the VSS Standby switch cannot determine the state of the VSS Active switch. To ensure that switchover occurs without delay, the VSS Standby switch assumes the VSS Active switch has failed and initiates switchover to take over the VSS Active role.

If the original VSS Active switch is still operational, both switch are now VSS Active. This situation is called a *dual-active scenario*. A dual-active scenario can have adverse effects on network stability, because both switches use the same IP addresses, SSH keys, and STP bridge ID. The VSS must detect a dual-active scenario and take recovery action.

The VSS supports the methods, Enhanced PAgP and Fast-Hello, for detecting a dual-active scenario. PAgP uses messaging over the MEC links to communicate between the two switches through a neighbor switch. Enhanced PAgP requires a neighbor switch that supports the PAgP enhancements.

The dual-active detection and recovery methods are described in the following sections:

- [Dual-Active Detection Using Enhanced PAgP, page 5-23](#)
- [Dual-Active Detection Using Fast-Hello, page 5-24](#)
- [Recovery Actions, page 5-24](#)

Dual-Active Detection Using Enhanced PAgP

Port aggregation protocol (PAgP) is a Cisco-proprietary protocol for managing EtherChannels. If a VSS MEC terminates to a Cisco switch, you can run PAgP protocol on the MEC. If PAgP is running on the MECs between the VSS and an upstream or downstream switch, the VSS can use PAgP to detect a dual-active scenario. The MEC must have at least one port on each switch of the VSS.

In virtual switch mode, PAgP messages include a new type length value (TLV) which contains the ID of the VSS Active switch. Only switches in virtual switch mode send the new TLV.

For dual-active detection to operate successfully, one or more of the connected switches must be able to process the new TLV. Catalyst 4500, Catalyst 4500-X, and Catalyst 49xx series switches have this capability. For a list of other Cisco products that support enhanced PAgP, refer to Release Notes for Cisco IOS Release at this URL:

http://www.cisco.com/en/US/products/ps6350/tsd_products_support_series_home.html

When the VSS Standby switch detects VSL failure, it initiates SSO and becomes VSS Active. Subsequent PAgP messages to the connected switch from the newly VSS Active switch contain the new VSS Active ID. The connected switch sends PAgP messages with the new VSS Active ID to both VSS switches.

If the formerly VSS Active switch is still operational, it detects the dual-active scenario because the VSS Active ID in the PAGP messages changes. This switch initiates recovery actions as described in the [“Recovery Actions” section on page 5-24](#).

Dual-Active Detection Using Fast-Hello

Dual-Active fast-hello employs fast-hello Layer 2 messages over a direct Ethernet connection. When the VSL goes down, the event is communicated to the peer switch. If the switch was operating as the active before the VSL went down, it goes into recovery mode upon receipt of a VSL down indication from the peer switch. This method is faster than IP BFD and ePAGP and does not require a neighboring switch.

Fast-Hello Link

A fast-hello link is configured between two VSS members with the intention of detecting a dual-active condition. Configuring dual-active fast-hello automatically removes all configurations from the specified interfaces, and restricts the interface to dual-active configuration commands. The following commands are allowed only in restricted mode on a fast-hello interface:

- default**—Sets a command to its defaults
- description**—Describes the interface
- dual-active**—Specifies a virtual switch dual-active config
- exit**—Exits from the fast hello interface configuration mode
- load-interval**—Specifies the interval for load calculation on an interface
- logging**—Configures logging for interface
- no**—Negates a command or set its defaults
- shutdown**—Shuts down the selected interface

No data traffic other than fast-hello can be used by fast-hello links.

For details on how to configure fast-hello dual-active detection, see the [“Configuring Fast-Hello Dual-Active Detection” section on page 5-53](#).

Recovery Actions

An VSS Active switch that detects a dual-active condition shuts down (by err-disabling) all of its non-VSL interfaces to remove itself from the network, and waits in recovery mode until the VSL links have recovered. You might need to intervene directly to fix the VSL failure. When the shut down switch detects that VSL is operational again, the switch reloads and returns to service as the VSS Standby switch.

Loopback interfaces are also shut down in recovery mode. The loopback interfaces are operationally down and not err-disabled.

Note

If the running configuration of the switch in recovery mode has been changed without saving, the switch will not automatically reload. In this situation, you must write the configuration to memory and then reload manually using the **reload** command. Only configuration changes applied to VSL ports on the switch can be saved. All other configuration changes are discarded as the node reboots as VSS standby.

When a switch becomes active (either due to dual-active scenario or otherwise), the IP address configured for fa1 management interface is associated with the active switch. By default, the switch in recovery mode will not have any IP address for the fa1 interface on its supervisor engine. To ensure IP connectivity to the switch during recovery, you can configure a recovery IP address. (IP address configuration is mandatory if you want IP connectivity while switch is in recovery.) When a switch enters recovery mode, the IP address for the management interface on its supervisor engine is associated with the recovery IP address.

The recovery IP address for a management interface can be verified in the output of commands such as **show ip interface brief** and **show interfaces**.

Configuring a Recovery IP Address

The recovery IP address is the IP address that is used for the fa1 interface (of a switch) while in recovery mode.

To configure the recovery IP address for the fa1 interface, perform the following task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch (config)# switch virtual domain <i>domain-id</i>	Specifies virtual switch domain.
Step 3	Switch (config-vs-domain)# [no] dual-active recovery [switch n] ip address <i>recovery-ip-address</i> <i>recovery-ip-mask</i>	Configures a recovery IP address. <i>n</i> is the VSS switch ID.

The following example shows how to set a recovery IP address 10.1.1.1:

```
Switch# configure terminal
Switch(config)# switch virtual domain 19
Switch(config-vs-domain)# dual-active recovery ip address 10.1.1.1 255.255.255.0
```

By default, **ip address** is not configured for recovery mode. So, the switch-fa1 interface is not associated with an IP address while the switch is in recovery mode. This ensures that two devices do not respond to the same IP address.

Without the **switch n** option, the (same) *recovery ip address* is used by either switch when it enters recovery mode. By definition, there is only one switch (in a given VSS system) in recovery mode at a time, making one recovery ip address sufficient.

If the two switches must use different IP addresses when the respective switch is in recovery mode, use the **switch n** option.

You can configure recovery IP addresses without the **switch n** option and with the **switch n** option simultaneously (for a total of three IP addresses, one global and one per switch). When done, the per-switch IP address takes precedence. If no per-switch IP address exists, the global IP address is used. Following are two examples:

Scenario 1

The VSS System is configured as follows:

- Global IP address- GIP
- switch 1 IP address - IP1
- switch 2 IP address - IP2

In this scenario, if switch 1 enters recovery mode, it will use IP1 for the fa1 interface on switch 1. Conversely, if switch 2 enters recovery mode, it will use IP2 for the fa1 interface on switch2.

Scenario 2

The VSS system is configured as follows:

- Global IP address - GIP
- switch 1 IP address - IP1
- switch 2 specific IP address

In this scenario, if switch 1 enters recovery mode, it will use IP1 for the fa1 interface on the switch 1. Conversely, if switch 2 enters recovery mode, it will use GIP for the fa1 interface on switch2.

VSS Initialization

A VSS is formed when the two switches and the VSL link between them become operational. The peer switch communicates over the VSL to negotiate the switches' roles.

If only one switch becomes operational, it assumes the VSS Active role. The VSS forms when the second switch becomes operational and both switches bring up their VSL interfaces.

VSS initialization is described in the following sections:

- [Virtual Switch Link Protocol, page 5-26](#)
- [SSO Dependencies, page 5-26](#)
- [Initialization Procedure, page 5-27](#)

Virtual Switch Link Protocol

The Virtual Switch Link Protocol (VSLP) consists of several protocols that contribute to virtual switch initialization. The VSLP includes the following protocols:

- Role Resolution Protocol

The peer switch use Role Resolution Protocol (RRP) to negotiate the role (VSS Active or VSS Standby) for each switch.

- Link Management Protocol

The Link Management Protocol (LMP) runs on all VSL links, and exchanges information required to establish communication between the two switches.

LMP identifies and rejects any unidirectional links. If LMP flags a unidirectional link, the switch that detects the condition brings the link down and up to restart the VSLP negotiation. VSL moves the control traffic to another port if necessary.

SSO Dependencies

For the VSS to operate with SSO redundancy, the VSS must meet the following conditions:

- Identical software versions (except during ISSU with compatible versions)
- VSL configuration consistency

During the startup sequence, the VSS Standby switch sends virtual switch information from the startup-config file to the VSS Active switch.

The VSS Active switch ensures that the following information matches correctly on both switches:

- Switch virtual domain
 - Switch virtual node
 - Switch priority (optional)
 - VSL port channel: switch virtual link identifier
 - VSL ports: channel-group number, shutdown, total number of VSL ports
- If the VSS detects a mismatch, it prints out an error message on the VSS Active switch console and the VSS Standby switch does not bootup. There are various ways to recover from this situation. If the switch is not running live traffic, you can either disconnect the VSL links or shutdown VSL ports on the peer, which would boot in VSS Active mode. You can make the necessary changes afterwards and reboot the switch and ensure VSL links are connected and not put in shutdown mode. Alternatively, you could clear the VSS rommon variable (VS_SWITCH_NUMBER) and allow the switch to boot in standalone mode. This method requires that no traffic flows through this switch. Once the switch is in standalone mode, you can convert it to VSS and then reboot it.
 - SSO and NSF enabled
- SSO and NSF must be configured and enabled on both switches. For detailed information on configuring and verifying SSO and NSF, see [Chapter 13, “Configuring Cisco NSF with SSO Supervisor Engine Redundancy.”](#)

If these conditions are unsatisfied, the VSS stops booting and ensures that the forwarding plane is not performing forwarding. For a description of SSO and RPR, see the [“VSS Redundancy” section on page 5-10](#).

Initialization Procedure

The following sections describe the VSS initialization procedure:

- [VSL Initialization, page 5-27](#)
- [System Initialization, page 5-28](#)
- [VSL Down, page 5-28](#)

VSL Initialization

A VSS is formed when the two switches and the VSL link between them become operational. Because both switches need to be assigned their role (VSS Active or VSS Standby) before completing initialization, VSL is brought online before the rest of the system is initialized. The initialization sequence is as follows:

1. The VSS initializes all cards with VSL ports, and then initializes the VSL ports.
2. The two switch communicate over VSL to negotiate their roles (VSS Active or VSS Standby).
3. The VSS Active switch completes the boot sequence, including the consistency check described in the [“SSO Dependencies” section on page 5-26](#).
4. If the consistency check completed successfully, the VSS Standby switch comes up in SSO VSS Standby mode. If the consistency check failed, the VSS Standby switch comes up in RPR mode.
5. The VSS Active switch synchronizes configuration and application data to the VSS Standby switch. If VSS is either forming for the first time or a mismatch exists between VSL information sent by the Standby switch and what is on the Active switch, the new configuration is absorbed in the

startup-config. This means that if the Active switch was running prior to the Standby switch and unsaved configurations existed, they would be written to the startup-config if the Standby switch sends mismatched VSL information.

System Initialization

If you boot both switches simultaneously, the switch configured as Switch 1 boots as VSS Active and the one with Switch 2 boots as VSS Standby. If priority is configured, the higher priority switch becomes active.

If you boot only one switch, the VSL ports remain inactive, and the switch boots as VSS Active. When you subsequently boot the other switch, the VSL links become active, and the new switch boots as VSS Standby. Because preemption is not supported, if a VSS Active is already running, the peer switch would always receive the VSS Standby role, even if its priority is higher than that of the Active's.

VSL Down

If the VSL is down when both switches try to boot up, the situation is similar to a dual-active scenario.

One of the switch becomes VSS Active and the other switch initiates recovery from the dual-active scenario. For further information, see the [“Configuring Dual-Active Detection”](#) section on page 5-52.

VSS Configuration Guidelines and Restrictions

The following sections describe restrictions and guidelines for VSS configuration:

- [General VSS Restrictions and Guidelines, page 5-28](#)
- [Multichassis EtherChannel Restrictions and Guidelines, page 5-29](#)
- [Dual-Active Detection Restrictions and Guidelines, page 5-30](#)

General VSS Restrictions and Guidelines

When configuring the VSS, note the following guidelines and restrictions:

- Beginning in Cisco IOS XE 3.8.0E, Quad-Supervisor VSS mode is supported on the Catalyst 4500 series switches.
- In Cisco IOS XE 3.4.0E (15.1(2)SG, E, VSS did not support SMI (both Director and Client).
Beginning with Cisco IOS XE 3.5.0E (15.2(1)E, VSS supports SmartInstall Director but not SMI Client.
Beginning with Cisco IOS XE 3.6.0E (15.2(2)E), VSS supports SmartInstall Director and SMI Client.
VSS [mode] is transparent to SMI except for the changes in interface names.
- The SMI Director has only one instance on VSS and runs on the VSS active switch. The standby Catalyst 4500 switch in a VSS is not listed as a director in the output of the **sh vstack status** command.
- The VSS configurations in the startup-config file must match on both switches; that is, the domain must match, the switch ID must be unique, and the VSL ports' information must match the physical connection.

- There is no restriction to configure oversubscribed linecard ports as VSL. The responsibility of bandwidth availability for a given network requirement lies with the network operator.
- VSL portchannel must have more than one port in the channel, preferably distributed on more than one module. If the VSL consists of only one link, its failure causes a Dual-Active operation of the VSS. Also, all VSL links configured on one module may cause a Dual-Active operation, if the module goes down..
- Classification and marking based on 'qos-group' in a QoS policy-map is not supported in VSS.
- The following older generation linecards (WS-X42xy to WS-X45xy) are supported with the VSS feature:
 - WS-X4148-RJ
 - WS-X4148-RJ
 - WS-X4148-FX-MT
 - WS-X4306-GB
 - WS-X4548-RJ45V+
 - WS-X4448-GB-SFP
 - WS-X4248-FE-SFP
 - WS-X4248-RJ45V

Please remove all other linecards from your system when converting from standalone to VSS mode.

- Do not attach a QoS policy with the maximum queue-limit (8184) to a large number of targets in a VSS system. This will cause continuous reloads on the standby supervisor engine.
- When an asymmetric virtual switch (i.e. a VSS comprising of chassis with different slot capacities) boots initially after conversion from standalone mode, the entPhysicalDescr object for the standby chassis does not hold the correct value. The entPhysicalDescr objects for both the active and standby chassis will match and hold the value for the active chassis.

After the running configuration is saved and a shelf reload occurs, this behaviour is not observed - the entPhysicalDescr objects for both chassis accurately reflects the correct chassis types.

Multichassis EtherChannel Restrictions and Guidelines

When configuring MECs, note the following guidelines and restrictions:

- Port Security over EtherChannels is not supported.
- All links in an MEC must terminate locally on the VSS Active or VSS Standby switch of the same virtual domain.
- An MEC can be connected to another MEC on a different VSS domain.
- Policers applied on an MEC are applied on two switches independently; if a policer is applied for 100 Mbps of conforming action, it will apply 100Mbps on both switches, resulting in a total conforming rate of 200 Mbps. To mitigate this, you can reduce the policer rate. In a more restrictive case, a rate of 50 Mbps might be necessary to achieve a maximum of 100Mbps. In a more liberal case, where conforming action of 200 Mbps is not a problem, policing rate could be kept to 100Mbps.

Dual-Active Detection Restrictions and Guidelines

When configuring dual-active detection, note the following guidelines and restrictions:

- For line redundancy, we recommend configuring at least two ports per switch for dual-active detection. For module redundancy, the two ports can be on different modules in each switch, and should be on different modules than the VSL ports, if feasible.
- Only trusted PAgP channels are relied upon to detect dual-active mode of operation.

Configuring a VSS

These sections describe how to configure a VSS:

- [Configuring Easy VSS, page 5-30](#)
- [Converting to a VSS, page 5-32](#)
- [Converting to Quad-Supervisor VSS, page 5-37](#)
- [Displaying VSS Information, page 5-39](#)
- [Converting a VSS to Standalone Switch, page 5-41](#)
- [Configuring VSS Parameters, page 5-42](#)
- [Configuring Multichassis EtherChannels, page 5-48](#)
- [Configuring Dual-Active Detection, page 5-52](#)

Configuring Easy VSS

Beginning with Cisco IOS XE 3.6.0E (IOS 15.2(2)E), the Catalyst 4500 series switch supports Easy VSS, which enables you to configure VSS with a single command on the active switch and no action on the VSS standby switch.

The active switch can gather information from all switches that are Layer 3 *reachable*.

**Note**

Quad-Supervisor VSS mode is not supported with Easy VSS.

**Note**

Both switches are directly connected to each other using Layer 3 physical interfaces and are reachable through these interfaces. These physical interfaces are candidate VSL interfaces and are displayed in a list of "potential" VSL interfaces in the output of the `vs1 ?` command in easy-vss mode. This output also displays a list of indirectly-reachable Layer 3 interfaces.

Cisco IOS XE 3.6.0E (IOS 15.2(2)E) only supports reachability using a default route. Management and user-created VRF are not supported.

**Note**

Switches are reachable to each other through management interfaces. Reachability to neighboring switches using a management interface isn't supported although the management interface appears in the candidate VSL list.

Switches can be Layer 3 reachable indirectly but directly connected. The directly-connected physical interfaces display in the output of the **vsl?** command, which displays all switches that have direct physical connections.

Alternatively, you can make a physical interface Layer 3 “capable” (i.e., make two switches reachable via directly connected Layer 3 links), by performing the following steps on both switches (A and B):

	Command	Purpose
Step 1	Switch(config)# interface <i>interface</i>	Selects interface and switches to interface configuration mode.
Step 2	Switch(config-if)# no switchport	Converts the switch to a Layer 3 interface.
Step 3	Switch(config-if)# ip add <i>a.a.a.a b.b.b.b</i>	Configures an IP address for temporary use.
Step 4	Switch(config-if)# exit	Exits interface configuration mode.

```
On Switch-A
Switch-A(config)# int G2/15
Switch-A(config-if)# no switchport
Switch-A(config-if)# ip address 5.5.5.6 255.255.255.0
```

```
On Switch-B
Switch-B(config)# int G3/15
Switch-B(config-if)# no switchport
Switch-B(config-if)# ip address 5.5.5.5 255.255.255.0
Ping 5.5.5.6 from switch-B
```

Issuing the **switch convert mode easy-virtual-switch** exec command on a VSS active switch displays a list of potential VSS standby switches - those that are directly connected and hardware compatible. From the displayed list, the sub-command **vsl ?** derives input from interfaces that belong to the switch where we are executing the command.

Perform the following task on the VSS active switch that you want to make the master switch, which manages the standby switch after VSS boot-up:

	Command	Purpose
Step 1	Switch# switch convert mode easy-virtual-switch	Switches to easy VSS sub-mode
Step 2	Switch(easy-vss)# VSL ? and Switch(easy-vss)# VSL local-interface	Displays a list of local inter-faces (with their peer interfaces, switch-ip and switch-name). Assigns the local interfaces that we want to convert to VSL. Choose interfaces under the column Local Interfaces under 'VSL?'
Step 3	Switch(easy-vss)# exit	Return to exec command mode.

The following example illustrates use of the **vsl ?** command:

```
SwitchA# switch convert mode easy-virtual-switch
# (easy-vss)# VLS ?
Local Interface      Remote Interface      Hostname      Standby-IP
GigabitEthernet2/15  GigabitEthernet3/15   Switch-B      5.5.5.5
GigabitEthernet2/17  GigabitEthernet3/17   Switch-B      5.5.5.5
GigabitEthernet2/4   GigabitEthernet3/4    Switch-C      4.4.4.4
```

The switch on which we execute the above commands becomes the master switch after VSS boots. Local Interfaces lists interfaces on the switch where we are executing the commands. Remote Interfaces lists the interfaces on the peer switch connected with the local interfaces.

Select a maximum of eight VSL local interfaces (i.e., interfaces under the Local Interface column).

This example forces both the master and standby switches to reboot and come up in VSS. Now, we have two interfaces as VSL members with the local interfaces GigabitEthernet 2/15 and GigabitEthernet 2/17.

```
SwitchA# switch convert mode easy-virtual-switch
SwitchA(easy-vss)# VSL GigabitEthernet2/15 GigabitEthernet2/17
```

Note 10G and 1G interfaces cannot be mixed. Chosen interfaces should belong to the same peer.

The master switch shares the tftp image path with the standby switch. On reboot, if the tftp path is used for loading the image, both switches boot with the same image.

Converting to a VSS

By default, the Catalyst 4500 series switch is configured to operate in standalone mode (the switch works independently). The VSS combines two standalone switches into one virtual switch, operating in virtual switch mode.

Note When you convert two standalone switches into one VSS, all non-VSL configuration settings on the VSS Standby switch will revert to the default configuration.

Note Preferably, conversion to VSS should be done on a maintenance window. If you plan to use the same port channel number for VSL, default the existing port channel configurations that are available on standalone switches. Then, follow the guidelines in section [Configuring VSL Port Channel and Ports, page 5-34](#).

To convert two standalone switches into a VSS, you perform the following major activities:

- Save the standalone configuration files.
- Configure each switch for required VSS configurations.
- Convert to a VSS.

In virtual switch mode, both switches use the same configuration file. When you make configuration changes on the VSS Active switch, these changes are automatically propagated to the VSS Standby switch.

The tasks required to convert the standalone switch to a VSS are detailed in the following sections:

- [Backing Up the Standalone Configuration, page 5-33](#)
- [Configuring SSO and NSF, page 5-34](#)
- [Assigning Virtual Switch Domain and Switch Numbers, page 5-34](#)
- [Configuring VSL Port Channel and Ports, page 5-34](#)
- [Converting the Switch to Virtual Switch Mode, page 5-36](#)
- [\(Optional\) Configuring VSS Standby Switch Modules, page 5-39](#)

In the procedures that follow, the example commands assume the configuration shown in [Figure 5-8](#).

Figure 5-8 Example VSS

Two chassis, A and B, are converted into a VSS with virtual switch domain 100. Interface 10-Gigabit Ethernet 5/1 on Switch 1 is connected to interface 10-Gigabit Ethernet 5/2 on Switch 2 to form the VSL.

Note

The port channels 10 and 20 mentioned in the config steps below are merely exemplary. You can configure any port channel number from 1-64 for VSL port channel.

Backing Up the Standalone Configuration

Save the configuration files for both switches operating in standalone mode. You need these files to revert to standalone mode from virtual switch mode.

Perform this task on both switches:

	Command	Purpose
Step 1	Switch-1# copy running-config startup-config	(Optional) Saves the running configuration to startup configuration.
Step 2	Switch-1# copy startup-config bootflash:old-startup-config Or Switch-1# copy startup-config slot0:old-startup-config	Copies the startup configuration to a backup file.
Step 3	Switch-1# copy startup-config slavebootflash:old-startup-config Or Switch-1# copy startup-config slaveslot0:old-startup-config	Note This step is required for switches in Quad-Supervisor VSS mode only. Copies the startup configuration to the standby supervisors.

Configuring SSO and NSF

SSO and NSF are configured as default on VSS.

Assigning Virtual Switch Domain and Switch Numbers

You must configure the same virtual switch domain number on both switches of the VSS. The virtual switch domain is a number between 1 and 255, and must be unique for each VSS in your network (the domain number is incorporated into various identifiers to ensure that these identifiers are unique across the network).

Within the VSS, you must configure one switch to be switch number 1 and the other switch to be switch number 2.

To configure the virtual switch domain and switch number on both switches, perform this task on Switch 1:

	Command	Purpose
Step 1	Switch-1(config)# switch virtual domain 100	Configures the virtual switch domain on Switch A.
Step 2	Switch-1(config-vs-domain)# switch 1	Configures Switch A as virtual switch number 1.
Step 3	Switch-1(config-vs-domain)# exit	Exits config-vs-domain.

Perform the following task on Switch 2:

	Command	Purpose
Step 1	Switch-2(config)# switch virtual domain 100	Configures the virtual switch domain on Switch B.
Step 2	Switch-2(config-vs-domain)# switch 2	Configures Switch B as virtual switch number 2.
Step 3	Switch-2(config-vs-domain)# exit	Exits config-vs-domain.

Note

The switch number is not stored in the startup or running configuration, because both switches use the same configuration file (but must not have the same switch number).

Configuring VSL Port Channel and Ports

The VSL is configured with a unique port channel on each switch. During the conversion, the VSS configures both port channels on the VSS Active switch. If the VSS Standby switch VSL port channel number has been configured for another use, the VSS comes up in RPR mode. To avoid this situation, check that both port channel numbers are available on both of the switches.

Check the port channel number with the **show running-config interface port-channel** command. The command displays an error message if the port channel is available for VSL. For example, the following command shows that port channel 20 is available on Switch 1:

```
Switch-1 # show running-config interface port-channel 20
% Invalid input detected at '^' marker.
```

To configure the VSL port channels, perform this task on Switch 1:

**Note**

The port channels 10 and 20 mentioned in the configuration steps below are exemplary only. You can configure any port channel number from 1-64 for VSL port channel.

	Command	Purpose
Step 1	Switch-1(config)# interface port-channel 10	Configures port channel 10 on Switch 1.
Step 2	Switch-1(config)# switchport	Convert to a Layer 2 port.
Step 3	Switch-1(config-if)# switch virtual link 1	Associates Switch 1 as owner of port channel 10.
Step 4	Switch-1(config-if)# no shutdown	Activates the port channel.
Step 5	Switch-1(config-if)# exit	Exits interface configuration.

Perform the following task on Switch 2:

	Command	Purpose
Step 1	Switch-2(config)# interface port-channel 20	Configures port channel 20 on Switch 2.
Step 2	Switch-2(config)# switchport	Convert to a Layer 2 port.
Step 3	Switch-2(config-if)# switch virtual link 2	Associates Switch 2 as owner of port channel 20.
Step 4	Switch-2(config-if)# no shutdown	Activates the port channel.
Step 5	Switch-2(config-if)# exit	Exits interface configuration mode.

You must add the VSL physical ports to the port channel. In the following example, interfaces 10-Gigabit Ethernet 3/1 and 3/2 on Switch 1 are connected to interfaces 10-Gigabit Ethernet 5/2 and 5/3 on Switch 2.

**Tip**

For line redundancy, we recommend configuring at least two ports per switch for the VSL. For module redundancy, the two ports can be on different switching modules in each chassis.

To configure the VSL ports, perform this task on Switch 1:

	Command	Purpose
Step 1	Switch-1(config)# interface range tengigabitethernet 3/1-2	Enters configuration mode for interface range tengigabitethernet 3/1-2 on Switch 1.
Step 2	Switch-1(config-if)# channel-group 10 mode on	Adds this interface to channel group 10.

**Note**

1G ports, which are converted from 10G ports using a connector, are not supported for VSL. This impacts Sup7-E and Sup7L-E ports.

On Switch 2, perform this task:

	Command	Purpose
Step 1	Switch-2(config)# interface range tengigabitethernet 5/2-3	Enters configuration mode for interface range tengigabitethernet 5/2-3 on Switch 2.
Step 2	Switch-2(config-if)# channel-group 20 mode on	Adds this interface to channel group 20.

**Note**

1G ports, which are converted from 10G ports using a connector, are not supported for VSL. This impacts Sup7-E and Sup7L-E ports.

Converting the Switch to Virtual Switch Mode

Conversion to virtual switch mode requires a restart for both switches. After the reboot, commands that specify interfaces with module/port now include the switch number. For example, a port on a switching module is specified by switch/module/port.

Prior to the restart, the VSS converts the startup configuration to use the switch/module/port convention. A backup copy of the startup configuration file is saved in bootflash. This file is assigned a default name, but you are also prompted to override the default name if you want to change it.

To convert Switch 1 to virtual switch mode, perform this task:

Command	Purpose
Switch-1# switch convert mode virtual	<p>Converts Switch 1 to virtual switch mode.</p> <p>After you enter the command, you are prompted to confirm the action. Enter yes.</p> <p>The system creates a converted configuration file, and saves the file to the bootflash of the VSS active supervisor. In Quad-Supervisor VSS mode, the configuration files must be copied from the active supervisor to the in-chassis standby supervisor, using the copy bootflash: <image_name> slavebootflash-ics: <image_name> command.</p>

To convert Switch 2 to virtual switch mode, perform this task on Switch 2:

Command	Purpose
Switch-2# switch convert mode virtual	<p>Converts Switch 2 to virtual switch mode.</p> <p>After you enter the command, you are prompted to confirm the action. Enter yes.</p> <p>The system creates a converted configuration file, and saves the file to the bootflash.</p>

**Note**

After you confirm the command (by entering **yes** at the prompt), the running configuration is automatically saved as the startup configuration and the switch reboots. After the reboot, the switch is in virtual switch mode, so you must specify interfaces with three identifiers (switch/module/port).

When switches are being converted to VSS, you should not set them to ignore startup-config. If done, the switch can be enabled to parse the startup-config at the rommon prompt. Ignoring startup-config in VSS mode, causes a switch to boot in a semi-VSS mode, which can only be corrected by a reboot and by enabling the parsing of startup-config.

Converting to Quad-Supervisor VSS

You can convert to Quad-Supervisor VSS mode using one of the following ways:

- [Converting an Existing VSS Switch to Quad-Supervisor VSS Mode](#)
- [Converting a Standalone Switch to Quad-Supervisor VSS, page 5-37](#)

Converting an Existing VSS Switch to Quad-Supervisor VSS Mode

To convert to Quad-Supervisor VSS from an existing VSS setup, perform the following task:

- | | |
|---------------|---|
| Step 1 | Perform an ISSU or a switch reload, to upgrade the chassis active supervisors with the Cisco IOS XE image that supports Quad-Supervisor VSS mode. Ensure that the switch reaches Stateful Switchover (SSO) in the VSS. The BOOT variable must point to the path of the Cisco IOS XE image and must be saved in the startup configuration. For more information about ISSU upgrade, see In-Service Software Upgrade (ISSU) on a VSS, page 5-56 . |
| Step 2 | Insert the redundant supervisors in the appropriate slots. Configure ROM monitor to auto-boot on the standby supervisors of both the VSS Active and the VSS Standby switches, using config register. Load the Cisco IOS XE image on both the standby supervisors and ensure that both supervisors are brought up in RPR mode as in-chassis standby (ICS) supervisors. The in-chassis active supervisor then syncs its startup configuration to the ICS. |
| Step 3 | Copy the Cisco IOS XE image on the standby supervisors of both the switches, from the VSS Active switch console, using the IOS copy command so that the boot variable has a valid path to point to |

Command	Purpose
Switch# copy bootflash: <image_name> bootflash-ics: <image_name>	Copies the image from the VSS Active switch to the ICS bootflash system of the VSS Active.
Switch# copy bootflash: <image_name> slavebootflash-ics: <image_name>	Copies the image from the VSS Active switch to the ICS bootflash system of the in-chassis standby supervisor.

The ICS bootflash filesystem is mounted with the name `bootflash-ics:`. On the VSS Active switch, the ICS bootflash filesystem of the VSS standby switch is available as `slavebootflash-ics:`.

Converting a Standalone Switch to Quad-Supervisor VSS

To convert a standalone switch to Quad-Supervisor VSS mode, perform the following task:

- Step 1** Copy the Cisco IOS XE image that supports Quad-Supervisor VSS mode on the bootflash: on the active and standby supervisors on both switches.
- Step 2** Follow the steps in [Converting to a VSS, page 5-32](#).

Example of Show Module Output for Switches in Quad- Supervisor VSS Mode

The **show module** command should display similar output in Quad-Supervisor VSS mode:

Switch# **show module**

Switch Number: 1 Role: Virtual Switch Active

Chassis Type : WS-C4507R+E

(Optional) Configuring VSS Standby Switch Modules

Note

You cannot configure or provision modules on VSS.

When switches form initial VSS relationships, they send module information to each other and this information is pushed to the configuration and used subsequently for provisioning, provided the switch is booting and the peer is down or not present.

The following example shows the module provisioning information:

```
module provision switch 1
  slot 1 slot-type 148 port-type 60 number 4   virtual-slot 17
  slot 2 slot-type 137 port-type 31 number 16  virtual-slot 18
  slot 3 slot-type 227 port-type 60 number 8   virtual-slot 19
  slot 4 slot-type 225 port-type 61 number 48  virtual-slot 20
  slot 5 slot-type 82  port-type 31 number 2   virtual-slot 21
module provision switch 2
  slot 1 slot-type 148 port-type 60 number 4   virtual-slot 33
  slot 2 slot-type 227 port-type 60 number 8   virtual-slot 34
  slot 3 slot-type 137 port-type 31 number 16  virtual-slot 35
  slot 4 slot-type 225 port-type 61 number 48  virtual-slot 36
  slot 5 slot-type 82  port-type 31 number 2   virtual-slot 37
```

These commands are not available to the user and that various numbers used in these commands are internal to the system and used to identify a module. These commands are written to the startup-config when a switch detects a given module while it is running in VSS mode. When reconverted to standalone mode, these commands are removed from the startup-config.

Displaying VSS Information

To display basic information about the VSS, perform one of these tasks:

Command	Purpose
Switch# show switch virtual	Displays the virtual switch domain number, and the switch number and role for each of the switches.
Switch# show switch virtual role	Displays the role, switch number, and priority for each of the switch in the VSS.
Switch# show switch virtual link	Displays the status of the VSL.

The following example shows the information output from these commands:

```
Switch# show switch virtual
Executing the command on VSS member switch role = VSS Active, id = 1

Switch mode                : Virtual Switch
Virtual switch domain number : 100
Local switch number        : 1
Local switch operational role: Virtual Switch Active
Peer switch number         : 2
Peer switch operational role : Virtual Switch Standby

Executing the command on VSS member switch role = VSS Standby, id = 2

Switch mode                : Virtual Switch
```

```

Virtual switch domain number : 100
Local switch number          : 2
Local switch operational role: Virtual Switch Standby
Peer switch number           : 1
Peer switch operational role : Virtual Switch Active

```

Switch# **show switch virtual role**

Executing the command on VSS member switch role = VSS Active, id = 1

Converting a VSS to Standalone Switch

To convert a VSS into two standalone systems, you perform the following major steps:

- [Copying the VSS Configuration to a Backup File, page 5-41](#)
- [Converting the VSS Active Switch to Standalone, page 5-41](#)
- [Converting the VSS Standby Switch to Standalone, page 5-42](#)

Copying the VSS Configuration to a Backup File

Save the configuration file from the VSS Active switch. You may need this file if you convert to virtual switch mode again. You only need to save the file from the VSS Active switch, because the configuration file on the VSS Standby switch is identical to the file on the VSS Active switch.

	Command	Purpose
Step 1	Switch-1# copy running-config startup-config	(Optional) Saves the running configuration to startup configuration. This step is only required if there are unsaved changes in the running configuration that you want to preserve.
Step 2	Switch-1# copy startup-config bootflash:vs-startup-config	Copies the startup configuration to a backup file.

Converting the VSS Active Switch to Standalone

When you convert the VSS Active switch to standalone mode, the VSS Active switch removes the provisioning and configuration information related to VSL links and the peer chassis modules, saves the configuration file, and performs a reload. The switch comes up in standalone mode with only the configuration data relevant to the standalone system.

The VSS Standby switch of the VSS becomes VSS Active. VSL links on this switch are down because the peer is now unavailable.

To convert the VSS Active switch to standalone mode, perform this task on the VSS Active switch:

Command	Purpose
Switch-1# switch convert mode stand-alone	Converts Switch 1 to standalone mode. After you enter the command, you are prompted to confirm the action. Enter yes .

Conversion from VSS to standalone causes all physical interfaces to be administratively shutdown and written to the startup-config. This is a safeguard against a standalone system arriving in the network alive and conflicting with a bridge or router MAC address, which might still be there if one of the VSS switches is still running in VSS mode.

We do not recommend that you convert a VSS to standalone in a live network.

Converting the VSS Standby Switch to Standalone

When you convert the new VSS Active switch to standalone mode, the switch removes the provisioning and configuration information related to VSL links and the peer switch modules, saves the configuration file and performs a reload. The switch comes up in standalone mode with only its own provisioning and configuration data.

To convert the peer switch to standalone, perform this task on the VSS Standby switch:

Command	Purpose
Switch-2# switch convert mode stand-alone	Converts Switch 2 to standalone mode. After you enter the command, you are prompted to confirm the action. Enter yes .

Configuring VSS Parameters

These sections describe how to configure VSS parameters:

- [Configuring VSL Switch Priority, page 5-43](#)
- [Configuring a VSL, page 5-44](#)
- [Adding and Deleting a VSL Port After the Bootup, page 5-44](#)
- [Displaying VSL Information, page 5-45](#)
- [Configuring VSL QoS, page 5-46](#)
- [Configuring the Router MAC Address, page 5-47](#)

Configuring VSL Switch Priority

To configure the switch priority, perform this task:

	Command	Purpose
Step 1	Switch(config)# switch virtual domain 100	Enters configuration mode for the virtual switch domain.
Step 2	Switch(config-vs-domain)# switch [1 2] priority [priority_num]	<p>Configures the priority for the switch. The switch with the higher priority assumes the VSS Active role. The range is 1 (lowest priority) to 255 (highest priority); the default is 100.</p> <p>Note</p> <ul style="list-style-type: none"> The new priority value only takes effect after you save the configuration and perform a reload of the VSS. If the higher priority switch is currently in VSS Standby state, you can make it the VSS Active switch by initiating a switchover with the redundancy force-switchover command. <p>The show switch virtual role command displays the operating priority and the configured priority for each switch in the VSS.</p> <ul style="list-style-type: none"> The no form of the command resets the priority value to the default value of 100. The new value takes effect after you save the configuration and perform a reload.
Step 3	Switch# show switch virtual role	Displays the current priority.

Note

If you make configuration changes to the switch priority, the changes only take effect after you save the running configuration to the startup configuration file and perform a reload. The **show switch virtual role** command shows the operating and configured priority values. You can manually set the VSS Standby switch to VSS Active using the **redundancy force-switchover** command.

This example shows how to configure virtual switch priority:

```
Switch(config)# switch virtual domain 100
Switch(config-vs-domain)# switch 1 priority 200
Switch(config-vs-domain)# exit
```

This example shows how to display priority information for the VSS:

```
Switch# show switch virtual role
Switch  Switch Status  Preempt   Priority  Role      Session ID
        Number         Oper (Conf) Oper (Conf) Local Remote
-----
LOCAL   1      UP        FALSE(N)  100(200)  ACTIVE    0        0
REMOTE  2      UP        FALSE(N)  100(100)  STANDBY   8158     1991
```

In dual-active recovery mode: No

Configuring a VSL

To configure a port channel to be a VSL, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface port-channel <i>channel_num</i>	Enters configuration mode for the specified port channel.
Step 2	Switch(config-if)# switch virtual link <i>switch_num</i>	Assigns the port channel to the virtual link for the specified switch.

Note

We recommend that you configure the VSL prior to converting the switch into a VSS.

This example shows how to configure the VSL:

```
Switch-1(config)# interface port-channel 10
Switch-1(config-if)# switch virtual link 1
Switch-1(config-if)# no shutdown (If the port is admin shutdown)
Switch-1(config)# interface tenGigabitEthernet 5/1
Switch-1(config-if)# channel-group 10 mode on
Switch-1(config-if)# no shutdown (If the port is admin shutdown)

Switch-2(config)# interface port-channel 25
Switch-2(config-if)# switch virtual link 2
Switch-2(config-if)# no shutdown (If the port is admin shutdown)
Switch-2(config-if)# interface tenGigabitEthernet 5/2
Switch-2(config-if)# channel-group 25 mode on
Switch-2(config-if)# no shutdown (If the port is admin shutdown)
```

Adding and Deleting a VSL Port After the Bootup

At any time, you can add and delete VSL ports from a port-channel to increase the number of links in the VSL, to move the port from one port to another, or to remove it from VSL.

Before adding or deleting VSL ports, do the following:

- Ensure all ports are physically connected to the peer switch. The peer port must also be configured for VSL.
- Shutdown the port before configuring VSL. When both ports on the link are configured for VSL, **unshut** them.
- Spread VSL ports across multiple modules.
- While deleting a port, retain at least one “active” VSL port pair. Else, a dual-active operation could occur.
- To save link flap and high CPU, shutdown the ports before VSL is unconfigured.
- After adding, deleting, or modifying VSL ports, write the config to nvram (that is, startup-config).
- If you need to move ports to another port, account for the bandwidth requirement of VSL. You should add an additional VSL link in the channel, move ports and remove additional links in the channel.

Displaying VSL Information

To display information about the VSL, perform one of these tasks:

Command	Purpose
Switch# show switch virtual link	Displays information about the VSL.
Switch# show switch virtual link port-channel	Displays information about the VSL port channel.
Switch# show switch virtual link port	Displays information about the VSL ports.

This example shows how to display VSL information:

```
Switch# show switch virtual link
VSL Status : UP
VSL Uptime : 1 day, 3 hours, 39 minutes
VSL Control Link : Te 1/5/1

Switch# show switch virtual link port-channel

Flags:  D - down          P - bundled in port-channel
        I - stand-alone  s - suspended
        H - Hot-standby  (LACP only)
        R - Layer3       S - Layer2
        U - in use       N - not in use, no aggregation
        f - failed to allocate aggregator

        M - not in use, no aggregation due to minimum links not met
        m - not in use, port not aggregated due to minimum links not met
        u - unsuitable for bundling
        w - waiting to be aggregated

```

Configuring VSL QoS

When a physical port is configured as a member of a VSL port-channel, a queuing policy is automatically attached to the VSL member ports. This queuing policy provides a dedicated queue for VSS Management, VSLP, BFD, Layer 2 and Layer 3 control protocols, and voice and video data traffic. Each queue is provided with a minimum bandwidth, ensuring that VSS management and control protocol packets are not dropped when congestion occurs on the VSL. The bandwidth assigned to a class of traffic is the minimum bandwidth that is guaranteed to the class during congestion. The VSL link uses Transmit Queue Sharing, where the output link bandwidth is shared among multiple queues of a given VSL port. Any modification or removal of VSL Queuing policy is restricted in a VSS system.

The following command sequence is inserted automatically by software.

```

interface TenGigabitEthernet1/1/1
  switchport mode trunk
  switchport nonegotiate
  no lldp transmit
  no lldp receive
  no cdp enable
  channel-group 10 mode on
  service-policy output VSL-Queuing-Policy
end

Configuring the Router MAC Address

On VSS, all routing protocols are centralized on the active supervisor engine. A common router MAC address is used for Layer 3 interfaces on both active and standby switches. Additionally, to ensure non-stop forwarding, the same router MAC address is used after switchover to Standby, so that all layer 3 peers see a consistent router MAC address.

There are three ways to configure a router MAC address on VSS:

- **HHH**—Manually set a router MAC address. Ensure that this MAC address is reserved for this usage.
- **chassis**—Use the mac-address range reserved for Chassis. This is the Cisco MAC address assigned to the chassis.
- **use-virtual**—Use the mac-address range reserved for the VSS. This is the served Cisco MAC address pool, which is derived from a base MAC address +vvs domain-id.

By default, the virtual domain based router MAC address is used. Any change of router MAC address configuration requires a reboot of both VSS supervisor engines

The follow table shows how to configure the router MAC address.

Command	Purpose
Switch(config)# switch virtual domain <i>domain_id</i>	Enters VSS configuration mode.
Switch(config-vs-domain)# mac-address use-virtual	Assigns the router MAC address from a reserved pool of domain-based addresses. Note This is the default. This is shown in the configuration, even if it the default.
Switch(config-vs-domain)# mac-address <i>mac-address</i>	Assigns the router MAC address in three 2-byte hexadecimal numbers.
Switch(config-vs-domain)# mac-address chassis	Specifies the router MAC address as the last address of chassis MAC address range.

Configuring Multichassis EtherChannels

Configure multichassis EtherChannels (MECs) as you would for a regular EtherChannel. The VSS will recognize that the EtherChannel is an MEC when ports from both switches are added to the EtherChannel. You can verify the MEC configuration by entering the **show etherchannel** command.

One VSS supports a maximum of 256 port channels.

To configure Layer 3 Multichassis EtherChannels, create the port channel logical interface and then put the Ethernet interfaces from both the VSS active and VSS standby into the port channel.

These sections describe Layer 3 EtherChannel configuration:

- [Creating Port Channel Logical Interfaces, page 5-48](#)
- [Configuring Physical Interfaces as Layer 3 EtherChannels, page 5-49](#)

Creating Port Channel Logical Interfaces

Note

To move an IP address from a physical interface to an EtherChannel, you must delete the IP address from the physical interface before configuring it on the port channel interface.

To create a port channel interface for a Layer 3 EtherChannel, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface port-channel <i>port_channel_number</i>	Creates the port channel interface. The value for <i>port_channel_number</i> can range from 1 to 64.
Step 2	Switch(config-if)# ip address <i>ip_address mask</i>	Assigns an IP address and subnet mask to the EtherChannel.
Step 3	Switch(config-if)# end	Exits configuration mode.
Step 4	Switch# show running-config interface port-channel <i>port_channel_number</i>	Verifies the configuration.

This example shows how to create port channel interface 1:

```
Switch# configure terminal
Switch(config)# interface port-channel 1
```

```
Switch(config-if)# ip address 172.32.52.10 255.255.255.0
Switch(config-if)# end
```

This example shows how to verify the configuration of port channel interface 1:

```
Switch# show running-config interface port-channel 1
Building configuration...
```

```
Current configuration:
!
interface Port-channel1
 ip address 172.32.52.10 255.255.255.0
end
```

```
Switch#
```

Configuring Physical Interfaces as Layer 3 EtherChannels

To configure physical interfaces as Layer 3 EtherChannels, perform this task for each interface:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Selects a physical interface to configure.
Step 2	Switch(config-if)# no switchport	Makes this a Layer 3 routed port.
Step 3	Switch(config-if)# no ip address	Ensures that no IP address is assigned to the physical interface.
Step 4	Switch(config-if)# channel-group <i>port_channel_number</i> mode { active on auto passive desirable }	Configures the interface in a port channel and specifies the PAgP or LACP mode. If you use PAgP, enter the keywords auto or desirable . If you use LACP, enter the keywords active or passive .
Step 5	Switch(config-if)# end	Exits configuration mode.
Step 6	Switch# show running-config interface port-channel <i>port_channel_number</i> Switch# show running-config interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> Switch# show interfaces { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> etherchannel Switch# show etherchannel 1 port-channel	Verifies the configuration.

This example shows how to configure Gigabit Ethernet interfaces 1/3/26 and 2/2/26 into port channel 1 with PAgP mode **desirable**:

```
Switch(config)# conf terminal
Switch(config)# int gigabitEthernet 1/3/26
Switch(config-if)# no switchport
Switch(config-if)# no ip address
Switch(config-if)# channel-group 1 mode desirable
Switch(config-if)# exit
Switch(config)# int gigabitEthernet 2/2/6
Switch(config-if)# no switchport
```

```
Switch(config-if)# no ip address
Switch(config-if)# channel-group 1 mode desirable
Switch(config-if)# end
```

**Note**

See the “[Configuring a Range of Interfaces](#)” section on page 9-5 for information about the **range** keyword.

The following two examples show how to verify the configuration of GigabitEthernet interface 1/3/26:

```
Switch# show running-config interface gigabitEthernet 1/3/26
Building configuration...
```

```
Current configuration : 101 bytes
!
interface GigabitEthernet1/3/26
  no switchport
  no ip address
  channel-group 1 mode desirable
end
```

```
Switch# show interfaces gigabitEthernet 1/3/26 etherchannel
```

```
Port state      = Up Mstr In-Bndl
Channel group = 1          Mode = Desirable-Sl      Gcchange = 0
Port-channel   = Po1       GC   = 0x00010001       Pseudo port-channel = Po1
Port index     = 0         Load = 0x00             Protocol =   PAgP

Flags:  S - Device is sending Slow hello.  C - Device is in Consistent state.
        A - Device is in Auto mode.         P - Device learns on physical port.
        d - PAgP is down.

Timers:  H - Hello timer is running.        Q - Quit timer is running.
        S - Switching timer is running.     I - Interface timer is running.
```

Local information:

Port	Flags	State	Timers	Hello Interval	Partner Count	PAgP Priority	Learning Method	Group Ifindex
Gi1/3/26	SC	U6/S7	H	30s	1	128	Any	632

Partner's information:

Port	Partner Name	Partner Device ID	Partner Port	Age	Flags	Partner Group Cap.
Gi1/3/26	3750x	2c54.2dd4.ad80	Gi1/0/25	20s	SAC	50001

```
Age of the port in the current state: 0d:00h:04m:04s
Switch#
```

This example shows how to verify the configuration of port channel interface 1 after the interfaces have been configured:

```
Switch# show etherchannel 1 port-channel
Port-channels in the group:
-----
```

```
Port-channel: Po1
-----
```

```
Age of the Port-channel   = 0d:00h:53m:41s
Logical slot/port         = 21/1           Number of ports = 2
GC                         = 0x00010001
Passive port list         = Gi1/3/26 Gi2/2/26
Port state                 = Port-channel L3-Ag Ag-Inuse
Protocol                   =   PAgP
```

```
Port security          = Disabled
```

```
Ports in the Port-channel:
```

Index	Load	Port	EC state	No of bits
0	00	Gi1/3/26	Desirable-Sl	0
1	00	Gi2/2/26	Desirable-Sl	0

```
Time since last port bundled:    0d:00h:05m:25s    Gi2/2/26
Switch#
```

This example shows how to display a one-line summary per channel group:

```
Switch# show etherchannel summary
Flags:  D - down          P - bundled in port-channel
        I - stand-alone  s - suspended
        H - Hot-standby (LACP only)
        R - Layer3       S - Layer2
        U - in use       f - failed to allocate aggregator

        M - not in use, minimum links not met
        u - unsuitable for bundling
        w - waiting to be aggregated
        d - default port
```

```
Number of channel-groups in use: 3
Number of aggregators:          3
```

Group	Port-channel	Protocol	Ports
1	Po1(RU)	PAgP	Gi1/3/26(P) Gi2/2/26(P)
10	Po10(SU)	-	Te1/1/1(P) Te1/1/4(D)
20	Po20(SU)	-	Te2/1/1(P)

Prior to Cisco Release IOS XE 3.5.0E and IOS 15.2(1)SG, when you tried to add a port to an EtherChannel from different chassis of the VSS system, an error message displayed:

```
Switch(config)# int gi2/3/26
Switch(config-if)# no switchport
Switch(config-if)# channel-group 50 mode on
Switch(config-if)#
Switch(config)# int gi1/1/48
Switch(config-if)# no switchport
Switch(config-if)# channel-group 50 mode on
Layer 3 MEC is not supported: GigabitEthernet1/1/48 on switch 1 cannot be part of
port-channel 50 with members on switch 2.
Command rejected: conflicts with Unsupported Layer 3 MEC
Switch(config-if)#
```

Configuring Dual-Active Detection

The following sections describe how to configure dual-active detection:

- [Configuring Enhanced PAgP Dual-Active Detection, page 5-52](#)
- [Configuring Fast-Hello Dual-Active Detection, page 5-53](#)
- [Displaying Dual-Active Detection, page 5-54](#)

Configuring Enhanced PAgP Dual-Active Detection

If enhanced PAgP is running on the MECs between the VSS and its access switches, the VSS can use enhanced PAgP messaging to detect a dual-active scenario.

By default, PAgP dual-active detection is enabled. However, the enhanced messages are only sent on port channels with trust mode enabled (see the trust mode description in the note).

Note

Before changing PAgP dual-active detection configuration, ensure that all port channels with trust mode enabled are in administrative down state. Use the **shutdown** command in interface configuration mode for the port channel. Remember to use the **no shutdown** command to reactivate the port channel when you are finished configuring dual-active detection.

To enable or disable PAgP dual-active detection, perform this task:

	Command	Purpose
Step 1	Switch(config)# switch virtual domain <i>domain_id</i>	Enters virtual switch submenu.
Step 2	Switch(config-vs-domain)# dual-active detection pagp	Enables sending of the enhanced PAgP messages.

You must configure trust mode on the port channels that will detect PAgP dual-active detection. By default, trust mode is disabled.

Note

If PAgP dual-active detection is enabled, you must place the port channel in administrative down state before changing the trust mode. Use the **shutdown** command in interface configuration mode for the port channel. Remember to use the **no shutdown** command to reactivate the port channels when you are finished configuring trust mode on the port channel.

To configure trust mode on a port channel, perform this task:

	Command	Purpose
Step 1	Switch(config)# switch virtual domain <i>domain_id</i>	Enters virtual switch submenu.
Step 2	Switch(config-vs-domain)# dual-active detection pagp trust channel-group <i>group_number</i>	Enables trust mode for the specified port channel.

This example shows how to enable PAgP dual-active detection:

```
Switch(config)# interface port-channel 20
Switch(config-if)# shutdown
Switch(config-if)# exit
Switch(config)# switch virtual domain 100
```

```
Switch(config-vs-domain)# dual-active detection pagp
Switch(config-vs-domain)# dual-active detection pagp trust channel-group 20
Switch(config-vs-domain)# exit
Switch(config)# interface port-channel 20
Switch(config-if)# no shutdown
Switch(config-if)# exit
```

This example shows the error message if you try to enable PAgP dual-active detection when a trusted port channel is not shut down first:

```
Switch(config)# switch virtual domain 100
Switch(config-vs-domain)# dual-active detection pagp
```

This example shows the error message if you try to configure trust mode for a port channel that is not shut down first:

```
Switch(config)# switch virtual domain 100
Switch(config-vs-domain)# dual-active detection pagp trust channel-group 20
```

Trusted port-channel 20 is not administratively down. To change the pagp dual-active trust configuration, "shutdown" the port-channel first. Remember to "no shutdown" the port-channel afterwards.

Configuring Fast-Hello Dual-Active Detection

To configure an interface as part of a dual-active detection pair, you need to configure dual-active fast-hello on the interface. Although fast hello dual-active detection is enabled by default, you must configure dual-active interface pairs to act as fast hello dual-active messaging links.

To enable or disable fast-hello dual-active detection, perform this task:

	Command	Purpose
Step 1	Switch(config) # switch virtual domain <i>domain_id</i>	Enters virtual switch submenu.
Step 2	Switch(config-vs-domain) # dual-active detection fast-hello	Enables the fast hello dual-active detection method. Note Fast hello dual-active detection is enabled by default.
Step 3	Switch(config-vs-domain) # exit	Exits virtual switch submenu.
Step 4	Switch(config) # interface <i>type switch/slot/port</i>	Selects the interface to configure. Note This interface must be directly connected to the other chassis and must not be a VSL link.
Step 5	Switch(config-if) # dual-active fast-hello	Enables fast hello dual-active detection on the interface, automatically removes all other configuration from the interface, and restricts the interface to dual-active configuration commands.
Step 6	Switch(config-if) # no shutdown	Activates the interface.
Step 7	Switch(config-if) # exit	Exits interface configuration mode.
Step 8	Switch(config) # exit	Exits global configuration mode.
Step 9	Switch) # show run interface <i>type switch/slot/port</i>	Displays status of dual-active fast-hello configuration.

When you configure fast hello dual-active interface pairs, note the following information:

- You can configure a maximum of four interfaces on each chassis to connect with the other chassis in dual-active interface pairs. Attempting to configure more than four interfaces causes an error message to display (and your command is rejected).
- Each interface must be directly connected to the other chassis and must not be a VSL link. We recommend using links from a switching module not used by the VSL.
- Each interface must be a physical port. Logical ports such as an SVI are not supported.
- The fast-hello links are Layer 2 ports.
- Configuring fast hello dual-active mode automatically removes all existing configuration from the interface and restricts the interface to fast hello dual-active configuration commands. It can only be used for “fast-hello” traffic.
- Unidirectional link detection (UDLD) is disabled on fast hello dual-active interface pairs.
- Do not configure fast-hello ports on an oversubscribed line card. Doing so might lead to a loss of fast-hello messages, impacting the functionality of fast-hello based dual-active detection.

This example shows how to configure an interface for fast hello dual-active detection:

```
Switch(config)# switch virtual domain 255
Switch(config-vs-domain)# dual-active detection fast-hello
Switch(config-vs-domain)# exit
Switch(config)# interface fastethernet 1/2/40
Switch(config-if)# dual-active fast-hello
WARNING: Interface FastEthernet1/2/40 placed in restricted config mode. All extraneous
configs removed!
Switch(config-if)# no shutdown
Switch(config-if)# exit
Switch(config)# exit
Switch# show run interface fastethernet 1/2/40
interface FastEthernet1/2/40
 switchport mode access
 switchport nonegotiate
 dual-active fast-hello
 no switchport
 no ip address
 dual-active fast-hello
end
```

Displaying Dual-Active Detection

To display information about dual-active detection, perform this task:

Command	Purpose
Switch# show switch virtual [dual-active {pagp fast-hello summary} link [counters detail port-channel ports] redundancy role slot-map]	Displays information about dual-active detection configuration and status.

This example shows how to display the summary status for dual-active detection:

```
Switch# show switch virtual dual-active summary
Switch(recovery-mode)# show switch virtual dual-act summary
Pagp dual-active detection enabled: Yes
In dual-active recovery mode: Yes
  Triggered by: PagP
  Triggered on Interface: Gi1/3/11
```

```
Received id: e8b7.488e.b7c0
Expected id: e8b7.488e.b700
```

This example shows how to display the summary status for dual-active detection when recovery is triggered by RRP rather than PagP:

```
Switch# show switch virtual dual-active summary
Switch(recovery-mode)# show switch virtual dual-act summary
Pagp dual-active detection enabled: Yes
In dual-active recovery mode: Yes
  Triggered by: RRP
```

This example shows how to display PAGP status and the channel groups with trust mode enabled:

```
Switch# show pagp dual-active
PAGP dual-active detection enabled: Yes
PAGP dual-active version: 1.1

Channel group 25 dual-active detect capability w/nbrs
Dual-Active trusted group: Yes
```

Port	Dual-Active Detect Capable	Partner Name	Partner Port	Partner Version
Gi1/3/11	Yes	g9-68	Gi1/11	1.1
Gi2/2/12	Yes	g9-68	Gi1/12	1.1

This example shows how to display the status of links configured as fast-hello:

```
Switch# show switch virtual dual-active fast-hello

Executing the command on VSS member switch role = VSS Active, id = 2

Fast-hello dual-active detection enabled: Yes

Fast-hello dual-active interfaces:
```

Port	Local State	Peer Port
Gi2/2/11	Dual Active Capable	Gi1/1/5

```

Executing the command on VSS member switch role = VSS Standby, id = 1

Fast-hello dual-active detection enabled: Yes

Fast-hello dual-active interfaces:
```

Port	Local State	Peer Port
Gi1/1/5	Dual Active Capable	Gi2/2/11

This example shows how to display the status of packet exchanges between the individual fast-hello links:

```
Switch# show switch virtual dual-active fast-hello counters

Executing the command on VSS member switch role = VSS Active, id = 2

Dual-active fast-hello link counters:
```

Port	Tx OK	Rx OK
Gi2/2/11	762	759

```

Executing the command on VSS member switch role = VSS Standby, id = 1
```

```

Dual-active fast-hello link counters:
      Tx      Rx
Port      OK      OK
-----
Gi1/1/5    762    759

```

This example shows how to display the status of total packets exchanged between the fast-hello links on the VSS:

```
Switch# show switch virtual dual-active fast-hello packet
```

Executing the command on VSS member switch role = VSS Active, id = 2

```

Dual-active fast-hello packet counters:
SwitchId : 2
Transmitted:
  total      = 465
Received:
  total      = 465

```

Executing the command on VSS member switch role = VSS Standby, id = 1

```

Dual-active fast-hello packet counters:
SwitchId : 1
Transmitted:
  total      = 465
Received:
  total      = 465

```

In-Service Software Upgrade (ISSU) on a VSS

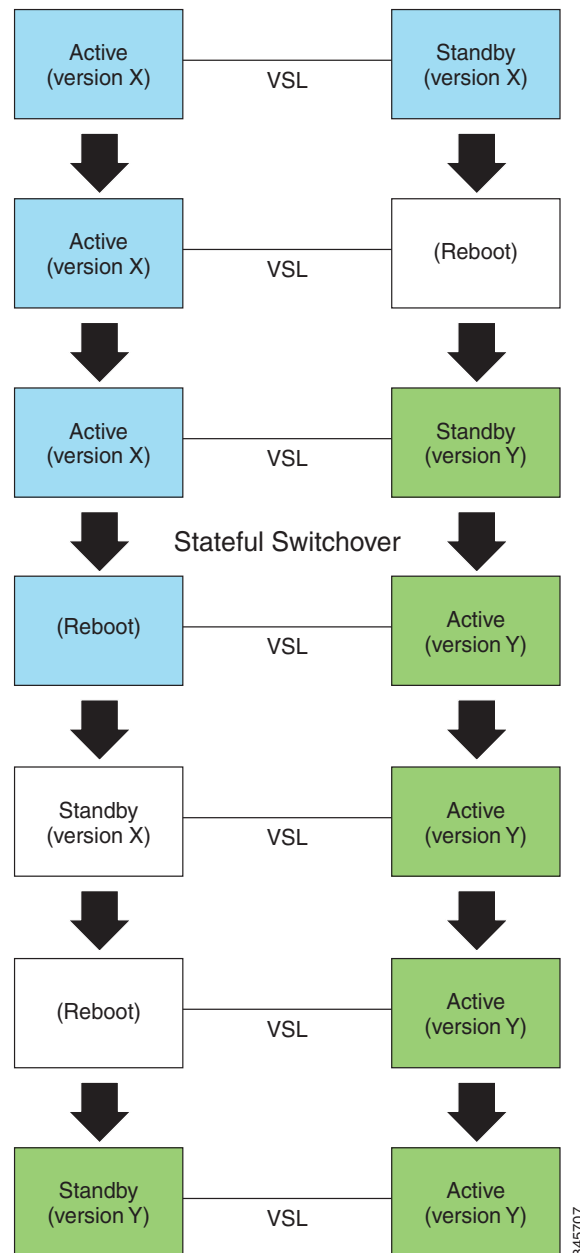

Topics include

- [License installation and subsequent VSS formation are now complete., page 5-86](#)

VSS ISSU Concept

In a VSS, the supervisor engines on the peer switches maintain an SSO (stateful switchover) relationship between themselves. This facilitates the ability to perform a software upgrade (or downgrade) on both the VSS supervisor engines.

[Figure 5-9](#) below depicts (at a conceptual level) the sequence of events that take place when the VSS system is upgraded from software version X to version Y.

Figure 5-9 Upgrading VSS System

Note that at any given instant, at least one of the switches is Active. The Active switch is in operation, i.e. continues to forward traffic and participate in network control protocols throughout the duration of the upgrade operation.

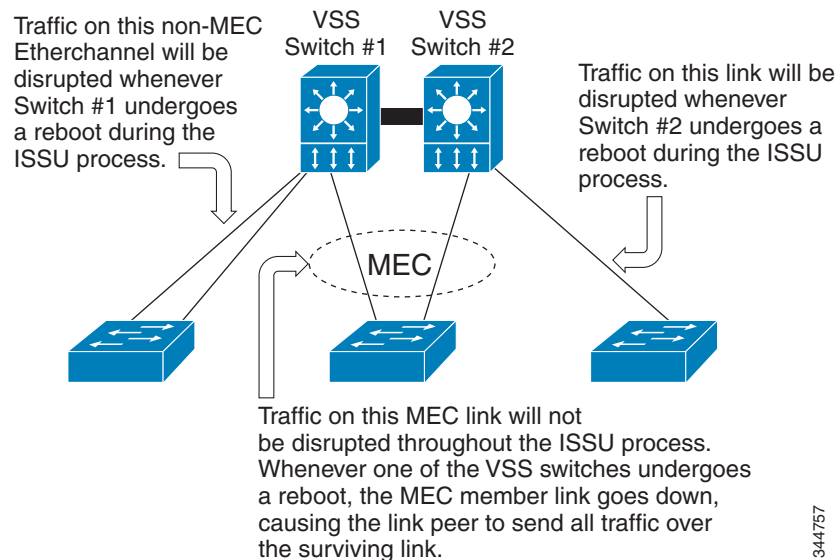

Traffic and Network Protocol Disruption During ISSU in a VSS

Figure 5-9 indicates that both switches in a VSS reboot at some point during the upgrade process.

When a switch reboots, all the network links that terminate on that switch undergo a link-down event. This means that network devices that are connected to the switch that is rebooting will observe a disruption in service, unless the connection is over an MEC that contains at least one link that terminates

on the other switch. If a peer device is connected to the VSS over an MEC that has links terminating in both switches, that device will not experience a disruption of service during the software upgrade process. This is illustrated in Figure 5-10.

Figure 5-10 Connecting a Peer Device to VSS to Avoid Service Disruption

Performing ISSU	<i>Cisco IOS Software: Guide to Performing In Service Software Upgrades</i>

Prerequisites to Performing ISSU

Before performing ISSU, you must meet these prerequisites:

- Ensure that the current Cisco IOS XE version running in the system supports ISSU. Also ensure that the target version supports ISSU.
- In a Quad-Supervisor VSS setup, ensure that you copy the Cisco IOS XE image on the standby supervisors of both the switches, from the VSS Active switch console, using the IOS **copy** command so that the boot variable has a valid path to point to.

You can enter various commands on the switch to determine supervisor engine versioning and Cisco IOS XE software compatibility. Alternatively, you can use the ISSU application on Cisco Feature Navigator to determine this.

- The type of the pre- and post-upgrade images must match precisely. Identical. ISSU is not supported from a Universal_lite to a Universal image, or vice versa. ISSU is also not supported from a k9 image to a non-k9 image, or vice versa.

- VSS must be functionally in SSO mode; that is, both switches must be powered up and operational, with one supervisor engine running as the SSO active, and the other as the SSO standby.
- The pre- and post-upgrade Cisco IOS XE software image files must both be available in the local file systems (bootflash, SD card, or USB) of both the Active and the standby supervisor engines before you begin the ISSU process.

Both supervisor engines should be running the pre-upgrade image, and should have booted from the image location in the local file system. (bootflash, SD card, or USB).

Note Beginning in Cisco IOS XE release 3.8.0E, in VSS mode, `usb0:` and `slot0:` are not available on the in-chassis standby (ICS).

Note The **show version** command can be used to confirm that the supervisor engine has actually booted from the pre-upgrade image location in the local filesystem.

Note Auto-boot must be enabled in the rommon for ISSU to succeed. The config-register value displayed in the output of **show version** can be used to confirm this.

- It is advisable to take measures to mitigate the effects of switch down-time. ISSU in a VSS will result in loss of service on non-MEC links, and peers must be prepared for this. On links connected over MECs, Nonstop Forwarding (NSF) must be configured and working properly. If you do not have NSF enabled, see the *Cisco Nonstop Forwarding* document for further information on how to enable and configure NSF.
- Autoboot is turned on and the current booted image matches the one specified in the BOOT environmental variable. For details on how to configure and verify these, please refer to [“Modifying the Boot Field and Using the boot Command”](#) section on page 3-28.
- The **no ip routing** command is not supported - both before starting the ISSU process, and at any time during the ISSU process.
- Save the image on the same partition in both supervisor engines (e.g. if it is saved at slot0: in the active supervisor engine it should be saved at slaveslot0:). Similarly if it is at bootflash: in the active supervisor engine, it should be at savebootflash: in the standby supervisor engine.

About Performing ISSU

Note Do not make any hardware changes while performing ISSU.

Before you perform ISSU, you should understand the following concepts:

- [Performing an ISSU Upgrade: Two Methods](#), page 5-59
- [Guidelines for Performing ISSU](#), page 5-63

Performing an ISSU Upgrade: Two Methods

There are two ways to perform an ISSU upgrade:

- manually using a sequence of four commands
- automatically; using a single command

ISSU using the four-command sequence

The manual ISSU upgrade process involves issuing four distinct ISSU EXEC commands in sequence

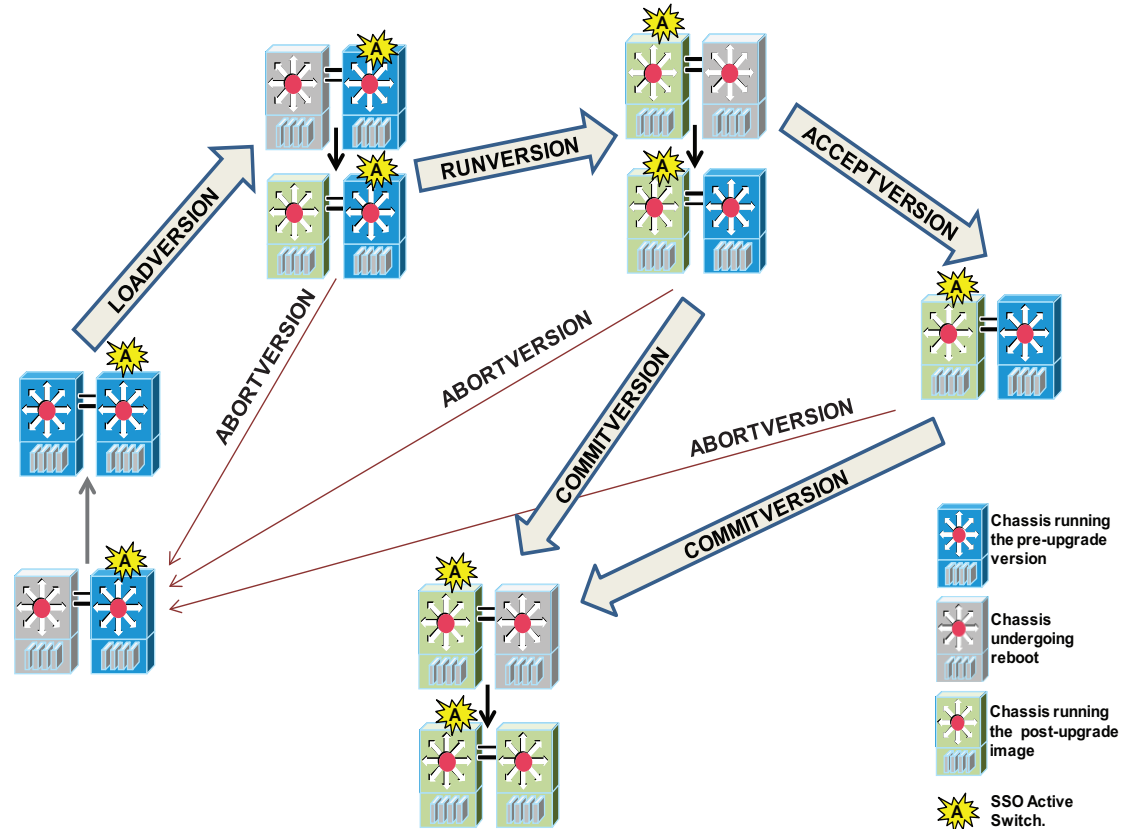

- **issu loadversion**
- **issu runversion**
- **issu acceptversion**
- **issu commitversion**

A fifth command, **issu abortversion**, enables you to abort the ISSU upgrade process at any time, and to revert to the initial system state.

These four commands take the VSS through a series of states that culminate in the Active and standby supervisor engines running the post-upgrade IOS XE image. The VSS continues to operate throughout the entire process; however as explained in [Traffic and Network Protocol Disruption During ISSU in a VSS, page 5-57](#), service is disrupted on network links that terminate on interfaces that reside in the switch that is undergoing a reboot.

[Figure 5-11](#) depicts the states through which the VSS Active and standby supervisor engines progress as the sequence of four commands entered. It also shows the effect of the **issu abortversion** command at any given point during the process.

Figure 5-11 States of VSS Active and Standby during Command Execution

34-4800

During the ISSU process, several **show** commands are available to evaluate the success of each command before proceeding to the next step.

ISSU using the Single Command Sequence (**issu changeversion**)

The use of multiple ISSU commands dictates an additional level of care to ensure no service disruption. However, in some scenarios, this upgrade procedure might be cumbersome and of minimal value. A typical example is during a network upgrade that involves performing an ISSU upgrade on a large number of Catalyst 4500 switches. In these cases, we recommend that you first perform the manual (four command) ISSU upgrade procedure on one VSS (possibly in a lab environment) to verify successful upgrade. Then, use the single **issu changeversion** procedure to perform an automatic ISSU on the rest of the Catalyst 4500 switches in the network.

The **issu changeversion** command launches a single-step complete ISSU upgrade cycle. It performs the logic for all four of the standard commands (**issu loadversion**, **issu runversion**, **issu acceptversion**, and **issu commitversion**) without user intervention, streamlining the upgrade through a single CLI step.

Additionally, **issu changeversion** allows the upgrade process to be scheduled for a future time. This enables you to stage a number of systems to perform upgrades sequentially when a potential disruption would be least harmful.

After the standby supervisor engine initializes and the system reaches a terminal state (SSO), the upgrade process is complete and the BOOT variable is permanently written with the new IOS XE software image. Hence, a reset on any RP will keep the system booting the new software image. Console and syslog messages will be generated to notify anyone monitoring the upgrade that the state transition has occurred.

Similar to the normal ISSU upgrade procedure, the in-progress upgrade procedure initiated by the **issu changeversion** command can be aborted with the **issu abortversion** command. If the system detects any problems or detects an unhealthy system during an upgrade, the upgrade might be automatically aborted.

When the **issu runversion** command is entered during the four step manual upgrade process, if any incompatible ISSU clients exist, the upgrade process reports them and their side effects, and allows the user to abort the upgrade. While performing a single-step upgrade process, when the process reaches the runversion state, it will either automatically continue with the upgrade provided the base clients are compatible, or automatically abort because of client incompatibility.

Changeversion: “quick” option

The **issu changeversion** command provides a “quick” option that can reduce the time required to perform the automatic ISSU upgrade. When the **quick** command option is applied, the ISSU upgrade state transition differs from that illustrated in [Figure 5-9](#). With this option, the state progression up to the loadversion stage remains the same as described in the figure, but the runversion and commitversion stages are combined. This progression skips the step in the upgrade procedure that loads the old software version on the new standby (old active) supervisor, thereby reducing the time required for the automatic ISSU upgrade by about a third.

Scheduled Changeversion: “in” and “at” Options

issu changeversion provides **in** and **at** command options that enable you to schedule a future automatic ISSU upgrade.

The **at** command option schedules an automatic ISSU upgrade to begin at a specific time. This option specifies an exact time (*hh:mm*, 24 hour format) in the next 24 hours at which the upgrade will occur.

The **in** command option schedules an automatic ISSU upgrade to begin after a certain amount of time has elapsed. This option specifies the number of hours and minutes (*hh:mm* format) that must elapse before an upgrade will occur, with a maximum value of 99:59.

Changeversion Deployment Scenario

The typical **issu changeversion** command usage scenario is for experienced users with a large installed base. These users typically validate a new image using a topology and configuration similar to their production network. The validation process should be done using both the existing multi-command process and the new **issu changeversion** command process. Once users certify an IOS XE software image and want to roll it out broadly, they can use the single command process to perform an efficient upgrade of their network.

Aborting an In-Progress Changeversion Procedure

The **issu changeversion** command functionality is designed to perform an ISSU software upgrade without user intervention. However, status messages are displayed to the console as the upgrade transitions through the various states. If any anomalies are noticed during the automatic upgrade, perhaps with peers or other parts of the network, you can use the **issu abortversion** command to manually abort the upgrade at any point in the process prior to the commitversion operation.

Guidelines for Performing ISSU

Be aware of the following guidelines while performing the ISSU process:

- Even with ISSU, it is recommended that upgrades be performed during a maintenance window.
- As explained in [Traffic and Network Protocol Disruption During ISSU in a VSS, page 5-57](#), ISSU on VSS may cause loss of network connectivity to both the VSS switches at some point during the process (although not at the same time). The mitigation steps as explained in that section must be implemented.
- The new features should not be enabled (if they require change of configuration) during the ISSU process.

Note Enabling them will cause the system to enter RPR mode because commands are only supported on the new version.

- In a downgrade scenario, if any feature is not available in the downgrade revision of the Cisco IOS XE software handle, that feature should be disabled prior to initiating the ISSU process.

Note On a Catalyst 4500 switch in VSS or a standalone chassis with redundant supervisors, an ISSU upgrade from any prior release to the Cisco IOS XE Release 3.11.10E specifically will fail. Instead, when upgrading to the Cisco IOS XE Release 3.11.10E, you must perform a reload-based upgrade where both the chassis or both supervisors are reloaded at the same time.

Compatibility Matrix

ISSU requires additional information to determine compatibility between software versions. Therefore, a compatibility matrix is defined that contains information about other IOS XE software image with respect to the one in question.

This compatibility matrix represents the compatibility of two software versions, one running on the active and the other on the standby supervisor engine, and to allow the system to determine the highest operating mode it can achieve. Incompatible versions will not be able to progress to SSO operational mode. Because SSO is a pre-requisite for a VSS, incompatibility will also lead to the loss of VSS relationship between the supervisors engines in the two switches.

The compatibility matrix represents the compatibility relationship a Cisco IOS XE software image has with all of the other Cisco IOS XE software versions within the designated support window (for example, all of those software versions the IOS XE software image “knows” about) and is populated and released with every IOS XE software image. The matrix stores compatibility information between its own release and prior releases. It is always the newest release that contains the latest information about compatibility with existing releases in the field. The compatibility matrix is available within the Cisco IOS XE software image and on Cisco.com so that users can determine in advance whether a successful upgrade can be achieved using the ISSU process.

You can perform the ISSU process when the old and new Cisco IOS XE software are compatible. The compatibility matrix information stores the compatibility among releases as follows:

- **Compatible**—The base-level system infrastructure and all optional HA-aware subsystems are compatible. An in-service upgrade or downgrade between these versions will succeed with minimal service impact. The matrix entry designates the images to be compatible (C).
- **Base-level compatible**—One or more of the optional HA-aware subsystems is not compatible. An in-service upgrade or downgrade between these versions will succeed; however, some subsystems will not be able to maintain state always during the transition from the old to the new version of Cisco IOS XE. The matrix entry designates the images to be base-level compatible (B).
- **Incompatible**—A core set of system infrastructure exists in Cisco IOS XE that must be able to interoperate in a stateful manner for SSO to function correctly. If any of these required features or subsystems is not interoperable, then the two versions of the Cisco IOS XE software image are declared to be incompatible. An in-service upgrade or downgrade between these versions is not

possible. The matrix entry designates the images to be incompatible (I). The system operates in RPR mode during the upgrade process when the versions of Cisco IOS XE at the active and standby supervisor engines are incompatible.

- Cisco IOS XE determines the compatibility between the active and the standby IOS XE software dynamically during Standby boot up. The matrix is represented by “x”.

To display the compatibility matrix data between two software versions on a given system, enter the **show issu comp-matrix stored** command.

**Note**

This command is useful *only for verification purposes* because it is available *only after* the ISSU process has started. You might want to check the compatibility matrix prior to starting ISSU. Use the Feature Navigator to obtain the needed information:

<http://tools.cisco.com/ITDIT/CFN/jsp/index.jsp>

Compatibility Verification Using Cisco Feature Navigator

The ISSU application on Cisco Feature Navigator allows you to:

- Select a specific software bundle.
- Identify which software images are compatible with the selected software image.
- Compare two IOS XE software images and understand the compatibility level of the software images (that is, compatible, base-level compatible, and incompatible), or dynamically determined.
- Compare two software images and see the client compatibility for each ISSU client.
- Provide links to release notes for the software image.

How to Perform the ISSU Process

Unlike SSO, which is a mode of operation for the device and a prerequisite for performing ISSU, the ISSU process is a series of steps performed while the switch is in operation. The steps result in an upgrade to new or modified Cisco IOS XE software, and have a minimal impact to traffic.

**Note**

For an illustration of the process flow for ISSU, refer to [Figure 5-11](#).

This section includes the following topics:

- [Verifying the ISSU Software Installation, page 5-65](#)

- [ISSU using the Four-command Sequence: Step 2 \(runversion\), page 5-70](#)
- [ISSU using the Four Command Sequence: Step 3 \(acceptversion\), page 5-72](#)
- [ISSU using the Four Command Sequence: Step 4 \(commitversion\), page 5-72](#)
- [Using changeversion to Automate an ISSU Upgrade, page 5-73](#)

- [Aborting a Software Upgrade During ISSU, page 5-79](#)
- [Configuring the Rollback Timer to Safeguard Against Upgrade Issues, page 5-81](#)
- [The ISSU Compatibility Matrix, page 5-82](#)

Verifying the ISSU Software Installation

During the ISSU process, there are five valid states: disabled, init, load version, run version, and system reset. Use the **show issu state** command to obtain the current ISSU state:

- Disabled state—The state for the standby supervisor engine while this supervisor engine is resetting.
- Init state—The initial state for two supervisor engines, one active and one standby, before the ISSU process is started. It is also the final state after the ISSU process completes.
- Load version (LV) state—The standby supervisor engine is loaded with the new version of Cisco IOS XE software.
- Run version (RV) state—The **issu runversion** command forces the switchover of the supervisor engines. The newly active supervisor engine runs the new Cisco IOS XE software image.
- While running ISSU, if both supervisor engines are reset (because of a power outage, for example), the ISSU context is lost and the system returns to the Init state. Both supervisor engines return to the old software.

You can verify the ISSU software upgrade by entering **show** commands to provide information on the state of the during the ISSU process:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# show issu state [detail]	Displays the current state of the ISSU process.
Step 3	Switch# show redundancy	Displays current or historical status, mode, and related redundancy information about the device.
Step 4	Switch# show switch virtual	Identifies which switch of the VSS is currently performing the Active role, and which switch the Standby.

This example shows how to display the state and the current status of the supervisor engine during the ISSU process:

```
Switch> enable
Switch# show issu state
Switch# show redundancy
Switch# show switch virtual
```

Verifying Redundancy Mode Before Beginning the ISSU Process

Before you begin the ISSU process, verify that the VSS is operating correctly; one supervisor engine operates as the SSO Active and the peer supervisor engine in the other switch operating as the SSO Hot Standby.

The following example displays verification that the system operating correctly as a VSS. Slot 1/1 (the supervisor engine in slot 1 of Switch 1) is the active supervisor engine, and Slot 2/1 (the supervisor engine in slot 1 of Switch 2) is the standby supervisor engine.

```

Switch# show redundancy states
    my state = 13 -ACTIVE
    peer state = 8 -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 1

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
    Redundancy State = Stateful Switchover
        Manual Swact = enabled

Communications = Up

    client count = 77
    client_notification_TMR = 240000 milliseconds
        keep_alive TMR = 9000 milliseconds
        keep_alive count = 0
    keep_alive threshold = 18
        RF debug mask = 0

Switch# show redundancy
Redundant System Information :

-----
    Available system uptime = 11 minutes
Switchovers system experienced = 0
    Standby failures = 0
    Last switchover reason = none

        Hardware Mode = Duplex
    Configured Redundancy Mode = Stateful Switchover
    Operating Redundancy Mode = Stateful Switchover
        Maintenance Mode = Disabled
        Communications = Up

Current Processor Information :

Local switch number   : 1
Local switch operational role: Virtual Switch Active
Peer switch number    : 2
Peer switch operational role : Virtual Switch Standby
Switch#
```

Verifying the ISSU State Before Beginning the ISSU Process

Ensure that both the supervisor engines are configured to auto-boot, and that they have currently been booted from the pre-upgrade image residing on the local file system. This is verified by the values of the BOOT variable and the configuration register (refer to the sample output of **show redundancy** command in the previous section).

Ensure that the active and standby supervisor engines are up and in ISSU Init state and that both supervisor engines are running the same current image.

The following example displays the ISSU state before the process begins:

```
Switch# show issu state detail
                Slot = 1
                RP State = Active
                ISSU State = Init
                Operating Mode = Stateful Switchover
                Current Image =
bootflash:cat4500e-universal.SSA.03.03.00.SGN1.33.151-2.SGN1.33.bin
                Pre-ISSU (Original) Image = N/A
                Post-ISSU (Targeted) Image = N/A

                Slot = 11
                RP State = Standby
                ISSU State = Init
                Operating Mode = Stateful Switchover
                Current Image =
bootflash:cat4500e-universal.SSA.03.03.00.SGN1.33.151-2.SGN1.33.bin
                Pre-ISSU (Original) Image = N/A
                Post-ISSU (Targeted) Image = N/A
```

Note that the Standby slot number is reported as 11, which is a Virtual Slot number that corresponds to physical slot 1 on Switch 2. The correspondence between the Virtual Slot number and the physical location of the slot can be determined using the **show switch virtual slot-map** command, as shown in the following example:

```
Switch# show switch virtual slot-map
Virtual Slot to Remote Switch/Physical Slot Mapping Table:
```

Virtual Slot No	Remote Switch No	Physical Slot No	Module Uptime
1	1	1	00:33:04
2	1	2	00:32:50
3	1	3	00:32:36
4	1	4	-
5	1	5	-
6	1	6	-

ISSU using the Four-command Sequence: Step 1 (loadversion)

This task describes the first step of the ISSU four-command sequence, loadversion, wherein the standby supervisor engine is loaded with the post-upgrade image.

Please ensure that you have read the [Prerequisites to Performing ISSU, page 5-58](#) section, and implemented the appropriate steps.

Perform the following steps at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu loadversion [<i>active-slot</i>] <i>active-image-new</i> [<i>standby-slot</i>] <i>standby-image-new</i>	Starts the ISSU process and (optionally) overrides the automatic rollback when the new Cisco IOS XE software version is detected to be incompatible. It may take several minutes after entering the issu loadversion command for Cisco IOS XE software to load onto the standby supervisor engine and for the standby supervisor engine to transition to SSO mode. This causes the standby supervisor engine to reload with the new software image. If used, the <i>active-slot</i> and <i>standby-slot</i> numbers should be specified as Virtual Slot numbers. Use the show switch virtual slot-map command to determine the correspondence between Virtual slot numbers and their physical locations.
Step 3	Switch# show issu state [<i>detail</i>]	Displays the state of ISSU during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded and is in SSO mode. It may take several minutes after entering the issu loadversion command for Cisco IOS XE software to load onto the standby supervisor engine and the standby supervisor engine to transition to SSO mode. If you enter the show issu state command too quickly, you may not see the information you need.
Step 4	Switch# show redundancy [<i>states</i>]	Displays redundancy facility state information.

This example shows how to start the ISSU process, boot the standby supervisor engine in the Standby Hot state, and load the standby supervisor engine slot (6) with the new IOS XE software image:

```
Switch> enable
Switch# issu loadversion 1 bootflash:new_image 11 slavebootflash:new_image
%issu loadversion executed successfully, Standby is being reloaded
Switch# show issu state detail
      Slot = 1
      RP State = Active
      ISSU State = Load Version
      Operating Mode = Stateful Switchover
      Current Image = bootflash:old_image
      Pre-ISSU (Original) Image = bootflash:old_image
      Post-ISSU (Targeted) Image = bootflash:new_image

      Slot = 11
      RP State = Standby
      ISSU State = Load Version
      Operating Mode = Stateful Switchover
      Current Image = bootflash:new_image
      Pre-ISSU (Original) Image = bootflash:old_image
      Post-ISSU (Targeted) Image = bootflash:new_image
```

```

Switch# show redundancy states
    my state = 13 -ACTIVE
    peer state = 8 -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 1

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
    Redundancy State = Stateful Switchover
        Manual Swact = enabled

Communications = Up

    client count = 474
    client_notification_TMR = 240000 milliseconds
        keep_alive TMR = 9000 milliseconds
        keep_alive count = 1
    keep_alive threshold = 18
        RF debug mask = 0

```

ISSU using the Four-command Sequence: Step 2 (runversion)

This task describes the second step of the ISSU four-command sequence, runversion, wherein a switchover occurs and the standby supervisor engine, which is now loaded with the post-upgrade image, takes over as the new Active.

At the end of the loadversion step, the following message is logged:

```
*Aug 14 13:07:08.240: %INSTALLER-7-ISSU_OP_SUCC: Peer state is [STANDBY SSO]; Please issue the runversion command
```

Now, you are ready to proceed to the next step.

Perform the following steps at the active supervisor engine.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu runversion [<i>standby-slot</i>] [<i>standby-image-new</i>]	Forces a switchover from the active to the standby supervisor engine and reloads the former active (current standby) supervisor engines with the old IOS XE image. As with any SSO switchover, you are prompted to save the running configuration if you have changed it. Respond as appropriate. When you enter the issu runversion command, an SSO switchover will be performed, and NSF procedures will be invoked if so configured.
Step 3	Switch# show issu state [<i>detail</i>]	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that a switchover occurs to slot 11.
Step 4	Switch# show redundancy [<i>states</i>]	Displays redundancy facility state information.

This example shows how to cause a switchover to the former standby supervisor engine (slot 11), reset the former active supervisor engine and reload it with the old IOS XE software image so it becomes the standby supervisor engine:

```
Switch> enable
Switch# issu runversion 11 slavebootflash:new_image
%issu runversion initiated successfully
```

A switchover happens at this point. At the new active supervisor engine, do the following after old active supervisor engine comes up as standby.

```
Switch# show issu state detail

          Slot = 11
          RP State = Active
          ISSU State = Run Version
          Operating Mode = Stateful Switchover
          Current Image = bootflash:new_image
          Pre-ISSU (Original) Image = bootflash:old_image
          Post-ISSU (Targeted) Image = bootflash:new_image

          Slot = 1
          RP State = Standby
          ISSU State = Run Version
          Operating Mode = Stateful Switchover
          Current Image = bootflash:old_image
          Pre-ISSU (Original) Image = bootflash:old_image
          Post-ISSU (Targeted) Image = bootflash:new_image
```

Note

The new active supervisor engine is now running the new version of software, and the standby supervisor engine is running the old version of software and is in the standby hot state.

```
Switch# show redundancy states

my state = 13 -ACTIVE
peer state = 8 -STANDBY HOT
  Mode = Duplex
  Unit = Primary
  Unit ID = 11

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
  Redundancy State = Stateful Switchover
  Manual Swact = enabled

Communications = Up

  client count = 474
  client_notification_TMR = 240000 milliseconds
  keep_alive TMR = 9000 milliseconds
  keep_alive count = 0
  keep_alive threshold = 18
  RF debug mask = 0
```

Once Runversion has completed, the new active supervisor engine will be running the new version of software and the previously active supervisor engine will now become the standby supervisor engine. The standby supervisor engine will be reset and reloaded, but it will remain on the previous version of software and come back online in Standby hot status.

Use the **show redundancy**, **show redundancy states**, and **show issu state [detailed]** commands described previously to verify that the standby supervisor engine is running the pre-upgrade version and that the Active is running the post-upgrade version.

ISSU using the Four Command Sequence: Step 3 (acceptversion)

This step is optional. It is needed only if you wish to stop the ISSU rollback timer. Otherwise you may proceed to the next step (**commitversion**)

Cisco IOS XE software maintains an ISSU rollback timer to safeguard against an upgrade that may leave the new active supervisor engine in a state in which communication with the standby supervisor engine is severed. By default, this duration is 45 minutes. If the **commitversion** command is not applied before the rollback timer duration expires, the VSS reverts to the pre-upgrade version.

The **acceptversion** command stops the rollback timer. This means that you can maintain the system in the current state (runversion, with the post-upgrade version running on the active supervisor engine, and pre-upgrade image running on the standby supervisor engine) for an extended duration, and proceed to the commitversion state only when you are satisfied with the behavior of the post-upgrade software version.

This optional task describes how to stop the rollback timer.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu acceptversion [<i>active-slot</i>] [<i>active-image-new</i>]	Halts the rollback timer and ensures the new Cisco IOS XE ISSU process is not automatically aborted during the ISSU process. Enter the issu acceptversion command within the time period specified by the rollback timer to acknowledge that the supervisor engine has achieved connectivity to the outside world; otherwise, the ISSU process is terminated, when the rollback timer expires, and the system reverts to the previous version of Cisco IOS XE software by switching to the standby supervisor engine.
Step 3	Switch# show issu rollback-timer	Displays the amount of time left before an automatic rollback will occur.

This example displays the Timer before you stop it. In the following example, the “Automatic Rollback Time” information indicates the amount of time remaining before an automatic rollback will occur.

```
Switch> enable
Switch# show issu rollback-timer
    Rollback Process State = 00:31:09 remaining
    Configured Rollback Time = 00:45:00

Switch# issu acceptversion 611 bootflash:new_image
% Rollback timer stopped. Please issue the commitversion command.
Switch# show issu rollback-timer
    Rollback Process State = Not in progress
    Configured Rollback Time = 00:45:00
```

ISSU using the Four Command Sequence: Step 4 (commitversion)

The commitversion step reloads the standby supervisor engine with the post-upgrade image.

Perform the following steps at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu commitversion [<i>standby-slot</i>] [<i>standby-image-new</i>]	Allows the new Cisco IOS XE software image to be loaded into the standby supervisor engine.
Step 3	Switch# show redundancy [<i>states</i>]	Displays redundancy facility state information.
Step 4	Switch# show issu state [<i>detail</i>]	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded with the new image.

This example shows how to reset and reload the current standby supervisor engine (slot 1) with the new Cisco IOS XE software version. After you enter the **commitversion** command, the standby supervisor engine boots in the Standby Hot state.

```
Switch> enable
Switch# issu commitversion 1 slavebootflash:new_image
%issu commitversion executed successfully
```

As in prior states, the **show redundancy**, **show redundancy states**, **show issu state [detailed]**, and **show switch virtual** commands can be used to verify that the VSS has reached the desired state.

At the end of the commitversion state, the ISSU process has completed. At this stage, any further Cisco IOS XE software version upgrade or downgrade will require that a new ISSU process be invoked anew.

Using changeversion to Automate an ISSU Upgrade

This task describes how to use the **issu changeversion** command to perform a one step ISSU upgrade.

Please ensure that you have read [Prerequisites to Performing ISSU, page 5-58](#), and implemented the appropriate steps.

Perform the following steps at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu changeversion [<i>active-slot</i> <i>active-image-new</i>] [<i>standby-slot</i> <i>standby-image-new</i>] [at <i>hh:mm</i> in <i>hh:mm</i>] [quick]	Initiates a single-step complete upgrade process cycle. Performs the logic of the four standard commands (issu loadversion, issu runversion, issu acceptversion, and issu commitversion) without user intervention. <i>active-slot</i> —Defines the active slot number (the Virtual slot number). Use the show switch virtual slot-map command to determine the virtual slot number from the physical slot number. <i>new-image</i> —Specifies IOS XE image URL to be upgraded to. <i>standby-slot</i> —Defines the standby slot number (the Virtual slot number). <i>standby-image</i> —Specifies the standby IOS XE image URL. at hh:mm —Schedules an ISSU upgrade to begin in the future. Provides an exact time (<i>hh:mm</i> , 24 hour format) in the next 24 hours when the upgrade will occur. in hh:mm —Schedules an ISSU upgrade to begin in the future. Provides the number of hours and minutes (<i>hh:mm</i> format) that will elapse before an upgrade will occur (99:59 max). quick —Upon switchover, boots the standby supervisor engine with the new, rather than old, image for faster upgrade.
Step 3	Switch# show issu state [detail]	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded and is in SSO mode.
Step 4	Switch# show redundancy [states]	Displays redundancy facility state information.

This example shows how to initiate an ISSU upgrade process using the **issu changeversion** command. The outputs of the **show switch virtual**, **show issu state detail**, **show redundancy**, and **show redundancy states** commands are included to show the supervisor state before and after the upgrade procedure.

```
Switch> enable
Switch# show switch virtual
Switch mode           : Virtual Switch
Virtual switch domain number : 16
Local switch number   : 1
Local switch operational role: Virtual Switch Active
Peer switch number    : 2
Peer switch operational role : Virtual Switch Standby
Switch#
Switch#show redundancy states
      my state = 13 -ACTIVE
      peer state = 8 -STANDBY HOT
```

```

The following example shows how to use `issu changeversion` with the "at" command option to schedule an ISSU upgrade procedure to automatically start at the specified time. This example specifies that the ISSU upgrade should be started at 16:30 (24 hour format).

```

Switch> enable
Switch# issu changeversion 1 bootflash:y.bin 11 slavebootflash:y at 16:30
% 'issu changeversion' was executed at [ Aug 12 16:27:43 ].
% The planned ISSU changeversion is to occur in (hh:mm:ss) [ 00:03:00 ] at [ Apr 12
16:30:43 ].
% Current system time: [ Aug 12 16:27:43 ]
% Planned upgrade image: bootflash:y.bin
% To cancel the planned upgrade, please execute 'issu abortversion'

Switch# show issu state detail
      Slot = 1
      RP State = Active
      ISSU State = Init
      Changeversion = TRUE
      Operating Mode = Stateful Switchover
      Current Image = bootflash:x.bin
      Pre-ISSU (Original) Image = N/A
      Post-ISSU (Targeted) Image = N/A

      Slot = 11
      RP State = Standby
      ISSU State = Init
      Changeversion = TRUE
      Operating Mode = Stateful Switchover
      Current Image = bootflash:x.bin
      Pre-ISSU (Original) Image = N/A
      Post-ISSU (Targeted) Image = N/A

```

Aborting a Software Upgrade During ISSU

You can abort the ISSU process at any stage manually (prior to entering the `issu commitversion` command) by entering the `issu abortversion` command. The `issu abortversion` command may also be issued after entering the `issu changeversion` command while the automatic ISSU upgrade is still in progress. The ISSU process also aborts on its own if the software detects a failure.

Note

If you enter the **issu abortversion** command before the standby supervisor engine becomes hot, the traffic might be disrupted.

If you abort the process after you issue the **issu loadversion** command, the standby supervisor engine is reset and reloaded with the original software.

If the process is aborted after you enter either the **issu runversion** or **issu acceptversion** command, then a second switchover is performed to the new standby supervisor engine that is still running the original software version. The supervisor engine that had been running the new software is reset and reloaded with the original software version.

Note

Ensure that the standby supervisor is fully booted *before* issuing the **abortversion** command on an active supervisor engine.

The following task describes how to abort the ISSU process before you complete the ISSU process with the **issu commitversion** command.

Perform the following task on the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu abortversion [<i>active slot</i> [<i>active-image-new</i>]]	Cancels the ISSU upgrade or downgrade process in progress and restores the switch to its state before the process had started.

This example shows how to abort the ISSU process on slot number 11, the slot for the current active supervisor engine. In this example, the ISSU upgrade process is in the Runversion state when the **issu abortversion** command is entered:

```
Switch> enable
Switch# show issu state detail
      Slot = 11
      RP State = Active
      ISSU State = Run Version
      Operating Mode = Stateful Switchover
      Current Image = bootflash:x.bin
      Pre-ISSU (Original) Image = bootflash:y.bin
      Post-ISSU (Targeted) Image = bootflash:x.bin

      Slot = 1
      RP State = Standby
      ISSU State = Run Version
      Operating Mode = Stateful Switchover
      Current Image = bootflash:y.bin
      Pre-ISSU (Original) Image = bootflash:y.bin
      Post-ISSU (Targeted) Image = bootflash:x.bin

Switch# issu abortversion 11
% issu abortversion initiated successfully
Switch# show issu state detail

      Slot = 1
      RP State = Active
```

```

ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:y.bin
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A

Slot = 11
RP State = Standby
ISSU State = Init
Operating Mode = Stateful Switchover
Current Image = bootflash:y.bin
Pre-ISSU (Original) Image = N/A
Post-ISSU (Targeted) Image = N/A

```

Switch#

Configuring the Rollback Timer to Safeguard Against Upgrade Issues

Cisco IOS XE software maintains an ISSU rollback timer, to safeguard against an upgrade that may leave the new active supervisor engine in a state in which communication with the standby supervisor engine is severed.

You may want to configure the rollback timer to fewer than 45 minutes (the default) so that you need not wait in case the new software is not committed or the connection to the switch was lost while it was in runversion mode. Conversely, you may want to configure the rollback timer to more than 45 minutes in order to have enough time to verify the operation of the new Cisco IOS XE software before committing the new software image.

The ISSU rollback timer kicks in immediately after **issu run version** is entered so that the minimum value configured should be more than the time required for a chassis reload. Else, the process fails.

Note

The valid timer value range is from 0 to 7200 seconds (two hours). A value of 0 seconds disables the rollback timer.

Once you are satisfied that the new image at the active supervisor engine has been successful and you want to remain in the current state, you may indicate acceptance by issuing the **issu acceptversion** command, which stops the rollback timer.

Issuing the **issu commitversion** command at this stage is equal to entering both the **issu acceptversion** and the **issu commitversion** commands. Use the **issu commitversion** command if you do not intend to run in the current state for a period of time and are satisfied with the new software version.

Note

The rollback timer can be configured only in the ISSU Init state.

This task explains how to configure the rollback timer:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# issu set rollback-timer value	Configures the rollback timer value, which can range from 0 to 7200.

	Command or Action	Purpose
Step 4	Switch(config)# exit	Returns the user to privileged EXEC mode.
Step 5	Switch# show issu rollback-timer	Displays the current setting of the ISSU rollback timer.

This example shows how to set the rollback timer to 3600 seconds:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# issu set rollback-timer 3600
% Rollback timer value set to [ 3600 ] seconds

Switch(config)# exit

Switch# show issu rollback-timer
Rollback Process State = Not in progress
Configured Rollback Time = 60:00
```

The Rollback Timer cannot be set in loadversion or runversion state, as the following example illustrates:

```
Switch# show issu state detail
Slot = 1
RP State = Active
ISSU State = Load Version
Operating Mode = Stateful Switchover
Current Image = bootflash:old_image
Pre-ISSU (Original) Image = bootflash:old_image
Post-ISSU (Targeted) Image = bootflash:new_image

Slot = 11
RP State = Standby
ISSU State = Load Version
Operating Mode = Stateful Switchover
Current Image = bootflash:new_image
Pre-ISSU (Original) Image = bootflash:old_image
Post-ISSU (Targeted) Image = bootflash:new_image

Switch# show issu rollback-timer
Rollback Process State = Not in progress
Configured Rollback Time = 60:00

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# issu set rollback-timer 20
% ISSU state should be [ init ] to set the rollback timer
```

The ISSU Compatibility Matrix

The ISSU Compatibility Matrix contains information about the compatibility of the IOS XE software version currently running on the system, and other versions. The Compatibility Matrix deals with two kinds of information:

- [Stored Information, page 5-83](#)
- [Negotiated Information, page 5-83](#)

Stored Information

The stored compatibility matrix contains a list of other IOS XE software releases for the Catalyst 4500 platform that are compatible with this release. This information is precomputed and stored inside the IOS XE image.

When an ISSU upgrade is attempted, the software looks up the Stored Compatibility Matrix on the supervisor engine that is running the higher (that is, later) IOS XE version. In this matrix, the software tries to locate the IOS XE version number that is running on the other supervisor engine (that is, the lower or earlier version number). If this information is missing, the ISSU upgrade cannot proceed.

All current IOS XE releases on the Catalyst 4500 platform support Dynamic Image Version Capability (DIVC). This means that the ISSU compatibility for the specified version is dynamically computed, as illustrated with the following example:

```
Switch# show issu comp-matrix stored
```

```
Number of Matrices in Table = 1
```

```
(1) Matrix for cat4500e-UNIVERSAL-M(182) - cat4500e-UNIVERSAL-M(182)
=====
Start Flag (0xDEADBABE)
```

My Image ver:	03.03.01.SG
Peer Version	Compatibility
-----	-----
03.02.00.SG	Dynamic(0)
03.02.01.SG	Dynamic(0)
03.02.00.XO	Dynamic(0)
03.02.02.SG	Dynamic(0)
03.02.03.SG	Dynamic(0)
03.02.04.SG	Dynamic(0)
03.03.00.SG	Dynamic(0)
03.03.01.SG	Comp(3)

The above Stored Compatibility Matrix is for IOS XE version 03.03.01.SG.

The "Comp(3)" entry shows that IOS XE version 03.03.01.SG is compatible with this version, and the end result is guaranteed to succeed.

The "Dynamic(0)" entry against IOS XE version 03.02.04.SG means that an ISSU upgrade from or to IOS XE version 03.02.04.SG is permitted. However, the end result will depend upon the ability of individual software features comprising the two versions to successfully complete the ISSU negotiation.

IOS XE version 03.01.01.SG is not in the list. This means that an ISSU upgrade from that version to this IOS XE version (03.03.01.SG) is not possible.

Negotiated Information

While the Stored compatibility matrix information is used before an ISSU upgrade is attempted, the Negotiated compatibility matrix information pertains to the ISSU state after or during an ISSU upgrade attempt. It contains information about how the different software components comprising the IOS XE images on the two supervisor engines were able to negotiate their states. So, this data is useful for troubleshooting failed ISSU upgrade operations.

To display information about the ISSU compatibility matrix, perform this task:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# show issu comp-matrix { negotiated xml }	Displays the negotiated ISSU compatibility matrix, either in plain text or in XML form. <ul style="list-style-type: none"> • negotiated—Displays negotiated compatibility matrix information in plain text. • xml—Displays negotiated compatibility matrix information in XML form. <p>Note These commands display only the data within IOSd process.</p> <p>Use the show package compatibility command to display the information for the whole system.</p>
Step 3	Switch# show package compatibility	Displays information regarding all client compatibility in the system.

This example shows how to display negotiated information regarding the compatibility matrix:

```
Switch> enable
Switch# show issu comp-matrix negotiated

License Upgrade on a VSS

When a current license is about to expire, or a new license is to be installed, perform the following task to update the license on a VSS:

- Step 1** Ensure that the new license is installed on both VSS active (Switch 1) and VSS standby (Switch 2). If your device supports using Right-to-use (RTU) licensing, use the following command to activate the new license on both switches:
Switch# **license right-to-use activate** [add-on {dna-advantage | dna-essentials } { evaluation | subscription} | entservices | internal_service | ipbase | lanbase] [accepteula]
- Step 2** Run the Switch# **write memory** command to save the configuration.
- Step 3** On Switch 2, the VSS standby, shutdown all the non-VSL ports.

Caution

Shutting down the VSL ports on the VSS active detaches the standby, which might transition to the VSS active. If not, reload the VSS standby and allow it to boot as the VSS active. A VSS standby booting as the active does not pose a network problem because all non-VSL ports are shutdown.

- Step 4** On Switch 1, shut down the VSL ports. The VSS standby (Switch 2) becomes the VSS active switch.
- Step 5** Reload Switch 2.
- Step 6** While Switch 2 boots up with the updated license, run the **no shut** command on the VSL ports on Switch 1 and reload Switch1 immediately. Switch 2 boots as the VSS standby.
- Step 7** When Switch 2 achieves SSO-HOT, run the **no shut** command on all ports.
- Step 8** Failover the chassis to bring the VSS pair license to the correct level.

License installation and subsequent VSS formation are now complete.

Programmability

Programmability is supported only on Cisco Catalyst 4500-X Series Switches and Cisco Catalyst 4500E Series Switches with Supervisor Engine 9-E, 8L-E, and 8-E. The feature is supported on all available license levels for these switches. This chapter describes how to set-up and configure the feature. It includes the following major sections:

- [About Programmability, page 6-1](#)
- [Configuring Programmability Components, page 6-4](#)
- [Using NETCONF and RESTCONF Protocols, page 6-14](#)
- [Using ODM Models, page 6-15](#)
- [Monitoring Programmability, page 6-23](#)
- [Troubleshooting Programmability, page 6-25](#)
- [Sample Configuration and Reference Information, page 6-28](#)

About Programmability

- [Overview, page 6-1](#)
- [Programmability Components, page 6-2](#)
- [Protocols and Data Models for Programmatic Device Configuration, page 6-2](#)
- [Default Configuration, page 6-3](#)

Overview

Programmability is the capability to configure and manage networking devices using protocols that are specifically designed to be consumed by software, that is, machine to machine interfaces.

The traditional way of configuring and managing Cisco networking devices, has been manual configuration, through the command line interface (CLI). As deployments become more complex, programmability of devices has enabled a shift from manual to automatic network provisioning and configuration.

Managing device configuration programmatically enables you to:

- **Configure and control at scale**—You can automate network configuration while also overcoming difficulties posed by multiple platforms, multiple operating systems, and multiple vendor devices in your network.

- Check to make sure that dependencies are satisfied before committing a change; and also easily roll-back changes when they are not consistently compatible across the network.

To address configuration and monitoring issues, the Internet Engineering Task Force (IETF) has defined these standards in network management:

- Yet Another Next Generation (YANG) data modeling—[RFC 6020](#).
- Network Configuration Protocol (NETCONF)—[RFC 6241](#)
- Representational State Transfer Configuration Protocol (RESTCONF)—uses the same data models as defined for NETCONF using YANG (<https://tools.ietf.org/html/draft-ietf-netconf-restconf-04>).

On Catalyst 4500 Series Switches, the Programmability feature provides the use of NETCONF and RESTCONF interfaces. They reside in a container on the switch and provide interfaces that enable remote management. The YANG data models available with these interfaces determine the scope of functions or actions that can be performed. See [Figure 6-1](#).

Programmability Components

This section describes the components involved in the setup of the feature. See the [Configuring Programmability Components, page 6-4](#) for information about how to configure individual components.

- The Virtual Services Container—Also referred to as a virtual machine (VM), virtual service, or container, is a virtual environment on the switch.

You can install an application within a virtual services container. The application then runs in the virtual services container of the operating system of a switch. The application is delivered as an open virtual application (OVA), which is a tar file with a .ova extension. The OVA package is installed and enabled on the switch through the device CLI.

- The Data Model Interface (DMI)—A container solution that provides the NETCONF and RESTCONF programmable interfaces. You must install and activate this container on the switch. After you activate it, the YANG models and APIs are available for use.
- The Network Bootloader—Network boot loaders support booting from a network-based source.

On the Catalyst 4500 series switches, the Preboot Execution Environment (PXE) feature, also called PXE boot, enables the switch to retrieve the software image, configuration files, scripts, and ova files from a remote server, without end-user intervention, that is, Zero-Touch Provisioning. The remote server can be an HTTP or a TFTP server.

PXE boot requires the configuration of a DHCP server, and the boot field set to one of the autoboot options in the ROMMON.

Throughout the document, PXE boot is used to refer to the method of booting from a network-based source.

Protocols and Data Models for Programmatic Device Configuration

This section describes the protocols and modeling languages that enable a programmatic way of writing configurations to a network device.

- NETCONF—An XML-based protocol that you can use to request information from and make configuration changes to the switch. NETCONF Application Programming Interfaces (APIs) use Secure Shell Version 2 (SSHv2).

- RESTCONF— Uses structured data (XML or JSON) and YANG to provide a REST-like APIs, enabling you to programmatically access different network devices. RESTCONF APIs use HTTPs methods.
- YANG—A data modeling language that is used to model configuration and operational features on the switch. YANG determines the scope and the kind of functions that can be performed by NETCONF and RESTCONF APIs. The following data models are supported:
 - The **ned.yang** model—A Cisco-specific configuration data model that enables to you perform write (SET) operations.
 - The Operational Data Manager (ODM)—Enables you to read operational state data (GET operations) using YANG models.

Figure 6-1 shows how the different components of Programmability come together.

Figure 6-1 Programmability Components

Default Configuration

Programmability is not enabled.

Configuring Programmability Components

You can use Zero-Touch Provisioning to configure the programmability components or follow the standard configuration method (by configuring all required tasks individually).

The following applies to both methods of configuration:

- [Prerequisites for Configuring Programmability, page 6-4](#)
- [Restrictions and Limitations for Configuring Programmability, page 6-5](#)

For zero touch provisioning, you must ensure that you have met:

- [Zero-Touch Provisioning Requirements, page 6-5](#)

For the standard configuration method, you must complete the following:

- [Installing and Activating the DMI Container, page 6-9](#)
- [Configuring One Platform Kit \(OnePK\), page 6-10](#)
- [Providing Privilege Access to Use NETCONF and RESTCONF, page 6-11](#)
- [Enabling the NETCONF Interface, page 6-12](#)
- [Enabling Cisco IOS HTTP Services for RESTCONF, page 6-13](#)

Prerequisites for Configuring Programmability

- Prerequisites for NETCONF and RESTCONF:

Your access to the switch is configured with privilege level 15. This is required to start working with NETCONF and RESTCONF interfaces. See [Providing Privilege Access to Use NETCONF and RESTCONF, page 6-11](#).

- To use the programmability feature, you must use the Universal Crypto Image. See section “Orderable Product Numbers” in the corresponding release notes:

- [Release Notes for the Catalyst 4500-X Series Switches](#)
- [Release Notes for the Catalyst 4500-E Series](#)

- Prerequisites for using PXE boot:

- The boot capability is set to autoboot and the bootfield is set to 04, 05, or 06. PXE boot is supported only if you have enabled autoboot.

**Note**

For PXE boot, the boot capability is set to autoboot by default.

- The required ROMMON version is installed:

On Catalyst 4500-X Series Switches, ROMMON version 15.0(1r)SG14 applies.

On Catalyst 4500-E Series Switches, ROMMON version 15.1(1r)SG8 applies.

With the above ROMMON versions, the factory default setting for the configuration register value is 0x2106 (boot field 06). This is also the recommended setting if you are using an existing device and upgrading to these ROMMON versions.

**Note**

If you are not using PXE boot, you do not have to upgrade the ROMMON version.

Restrictions and Limitations for Configuring Programmability

- Data model related restrictions:
 - Only a subset of the IETF, or common data models are supported.
 - Only the Cisco device-specific **ned.yang** model is supported.
 - When using ODM models, you must stop and restart the ODM control process if the crypto keys are regenerated. See [Activating and Deactivating the ODM, page 6-17](#)
- DMI solution related restrictions:
 - IPv6 is not supported.
 - Switches operating in the VSS mode are not supported.
 - It is not ISSU-capable.
- Only up to 4 simultaneous NETCONF sessions are supported. Further, a session that is idle for more than 180 seconds will timeout.
- Requests coming on an EtherChannel that is part of a Layer 3 Switched Virtual Interface (SVI), and is sharing its IP with the DMI container, is not supported
- AAA remote authentication is not supported.

Zero-Touch Provisioning Requirements

Zero-Touch Provisioning is achieved by using the PXE boot feature. Ensure that you have completed the following:

- Set the boot field value. See [Boot Field, page 6-6](#)
- Configured the DHCP server and an HTTP or TFTP server. See [PXE Boot Requirements—Configuring the DHCP Server, page 6-6](#) and [PXE Boot Process Flow, page 6-7](#)
- Entered the following global configuration commands in the start-up configuration file. This refers to the *<filename>.config* file and is downloaded during the PXE boot process. This is required if you want NETCONF and RESTCONF to be available for use from Day 0.
 - The **virtual-service DMI** command (The virtual service name must be DMI if one opts for Zero-Touch Provisioning).
 - The **activate** command
 - The **ip shared host-interface** *interface-id* command
 - The **onep** command
 - The **service set vty** command
 - The **username** *name* **privilege** level **password** *password* command

To use NETCONF

- The **netconf-yang** command

To use RESTCONF

- The **restconf** command
- The **ip http server** or the **ip http secure-server** command
- The **ip http authentication local** command

The following is a sample output of the **show running-config** command. It displays the commands that are configured as part of start-up configuration

```
Switch #show running-config

Building configuration...

Boot Field

To use PXE boot, you must enable autoboot, and set the boot field 04, 05, or 06. This automatically sets the corresponding configuration register value.

The PXE boot feature requires ROMMON version 15.0(1r)SG14 on Catalyst 4500-X Series Switches, and ROMMON version 15.1(1r)SG8 on Catalyst 4500-E Series Switches.

For detailed information about the various boot fields, see table [Explanation of Boot Field \(Configuration Register Bits 00 to 03\)](#) in chapter “Configuring the Switch for the First Time” in this book.

PXE Boot Requirements —Configuring the DHCP Server

To send switch startup configuration files, scripts, and ova file in addition to the bootable image, you must configure the DHCP server.

Depending on your existing DHCP server setup (whether on Microsoft Windows or Linux), ensure that you have made the corresponding, requisite settings. See [DHCP Server Settings on Linux, page 6-28](#) or [Microsoft Windows DHCP Server Configuration, page 6-33](#), whichever applies.

Note

After completing DHCP server configuration, manually assign an IP to the switch and ping to check the switch-to-server connectivity.

Observe the following DHCP server configuration guidelines:

- You must provide the gateway, subnet mask, server IP address, and the client IP address. This information is not permanently stored on switch. They are used only to download files and are deleted when the activity is complete.
- Specifics for the start-up configuration file, script file and ova files (applies to DHCP server configuration for Microsoft Windows and Linux):
 - Complete the DHCP Option 43 list with information about the location of configuration, script and ova file to be downloaded.
 - You can specify an HTTP server or a TFTP server location from which to download. Depending on your requirement, specify one or more options— the boot image name, the start-up configuration file name and path, the script file name and path, and the ova file name and path. Ensure that the configuration, script and ova file extensions are `<config-file>.config,<script-file>.script,<container-file>.ova` respectively.
 - If you are opting for Zero-Touch Provisioning, the ova file name must include `_dmi_`. For example, `example_dmi_container.ova`
 - These files should be saved in the root folder.
 - If you are using HTTP to download, you must configure the DNS server information.
- When the DHCP server responds successfully, the output displays `Received DHCP_ACK`.
- If you receive a TFTP timeout error, increase the DHCP timeout by using the ROMMON variable *DhcpTimeout*. The default DHCP timeout is 5 seconds. You can increase it by a maximum of 30 seconds. For example, if **DhcpTimeout=20**, the DHCP timeout increases by 20 seconds. Enter the set command to verify the change.

```
rommon> DhcpTimeout=20
rommon> set
```

- The DHCP options list that the DHCP server sends should not be greater than 255 bytes. If it is, the following error message is displayed:

```
DHCP ERROR: Received Option length is more than maximum supported (255)
```

- The PXE process ignores network information that you configure on the ROMMON, such as IP, gateway, subnet mask etc.
- You can interrupt the autoboot process at any point, by pressing Control +C (switches to the ROMMON mode).
 - For sample output of the autoboot process, using HTTP, see [Autoboot Process Output—Using HTTP, page 6-37](#).
 - For sample output of the autoboot process using TFTP, see [Autoboot Process Output—Using TFTP, page 6-40](#)

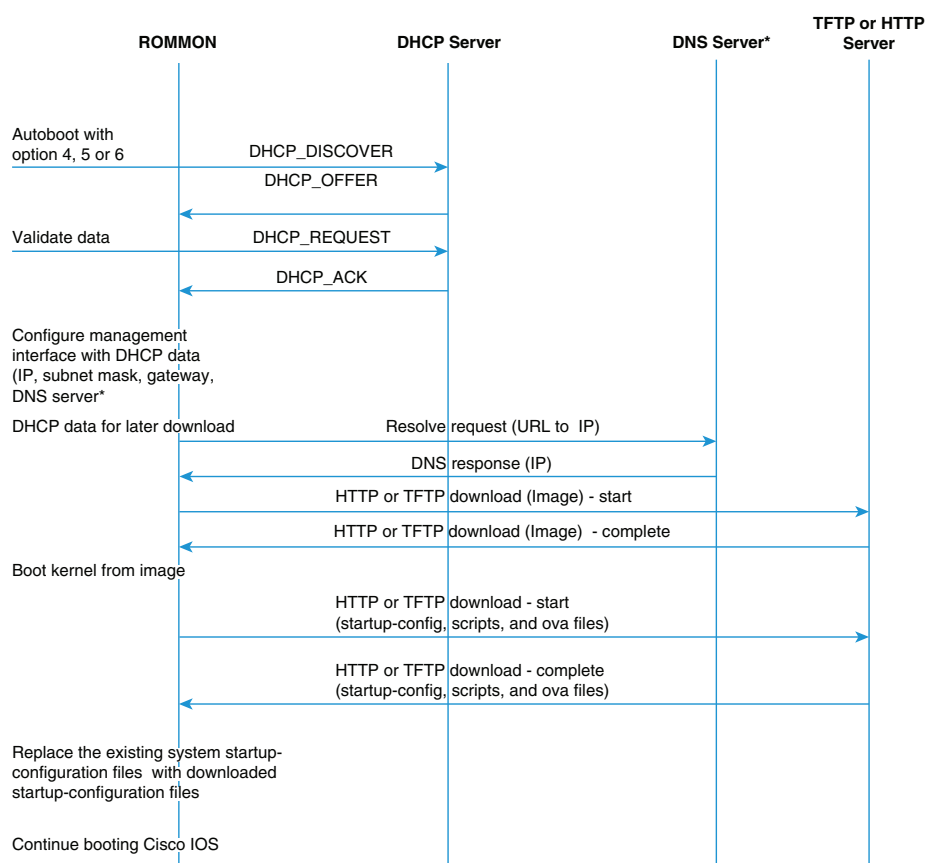

PXE Boot Process Flow

This section outlines the communication process between the DHCP server and the switch and provides the sequence of events followed during the PXE boot (network boot loading) process. This assumes that autoboot is enabled.

1. The switch sends a DHCP discovery packet.
2. The DHCP server responds with an offer containing the TFTP or HTTP server IP address, the offered IP address for the client, the gateway IP address, the boot file name, and the path and names of the OVA, script, and switch configuration files.

3. The switch sends the DHCP request for the IP address.
4. The switch receives the DHCP acknowledgment packet from the server, downloads the image specified in the *filename* variable in the DHCP server, and then boots up with downloaded image.
While booting, the switch receives the Option 43 list from the DHCP server with information about the location of configuration file, script file and ova file to be downloaded.
5. After POST is complete, the switch looks for the startup configuration files, script files, and ova files as mentioned in the Option 43 list received in Step 4. If the files mentioned the Option 43 list are present in the specified location, the switch downloads them.
The script file is downloaded to— bootflash:pxe/scripts folder
The ova file is downloaded to— bootflash:pxe/ova folder.

Figure 6-2 PXE Boot Process Flow

* DNS Server steps do not apply if you are using a TFTP Server

354901

Installing and Activating the DMI Container

This task is mandatory if you have opted for the standard configuration method.

Before you begin, ensure that you have completed the following:

- Downloaded an OVA package that is compatible with the device operating system. The OVA package is available for download in the same location as your system image (.bin) file.
- Ensured that the minimum required disk space - 512 MB, and memory - 256 MB RAM is available on the device for installation and deployment of the DMI container.

To install and activate the DMI by using the virtual services container CLI, perform the following task:

	Command or Action	Purpose
Step 1	enable Example: Switch# enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	virtual-service install name <i>virtual-services-name package file</i> Example: Switch# virtual-service install name dmi package bootflash:/dmi.ova	Installs an OVA package from the specified location onto a device. Ensure that the ova file is located in the root directory of the storage device.
Step 3	configure terminal Example: Switch# configure terminal	Enters the global configuration mode.
Step 4	[no] virtual-service virtual-services-name Example: Switch(config)# virtual-service dmi Switch(config-virt-serv) #	Configures a virtual services container and enters virtual services configuration mode. Observe these guidelines: <ul style="list-style-type: none"> • Use the virtual-services-name defined during installation of the application. • Ensure that installation is complete before proceeding to the next step using the show virtual-service list command.
Step 5	[no] activate Example: Switch(config-virt-serv) # activate	Activates the installed virtual services container.

	Command or Action	Purpose
Step 6	ip shared host-interface <i>interface-id</i> Example: Switch(config-virt-serv)# ip shared host-interface gigabitethernet 3/47	Maps the virtual service container to the interface that you specify. The IP address of the interface you specify here is used for NETCONF and RESTCONF communication. Observe these guidelines: Note You cannot configure a port channel interface as a shared interface. All other interface types are supported. Note If you want to change the shared interface that you have configured, enter the same command with the new interface that you want to use. The no form of this command is not supported.
Step 7	end Example: Switch(config-virt-serv)# exit Switch(config)#	Exits virtual services configuration mode and enters privileged EXEC mode.

Configuring One Platform Kit (OnePK)

OnePK is a software development kit. It enables you to create applications with which to interact directly with Cisco networking devices, and also use a set of controlled API to access networking services.

In the context of Programmability, it is used to enable the VTY service set. The VTY Service allows a onePK application to communicate with a network element, through a virtual terminal.

This task is mandatory if you have opted for the standard configuration method. To enable the requisite, internal OnePK infrastructure, perform the following task:

	Command or Action	Purpose
Step 1	enable Example: Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Switch# configure terminal	Enters the global configuration mode.
Step 3	onep Example: Switch(config)# onep Switch(config-onep)#	Enters the OneP configuration mode.

	Command or Action	Purpose
Step 4	service set vty Example: Switch(config-onep)# service set vty	Enables the VTY service set. The VTY service enables the OneP application to communicate with a network element via a virtual terminal.
Step 5	end Example: Switch# end	Exits the onep configuration mode and enters the privileged EXEC mode.

Providing Privilege Access to Use NETCONF and RESTCONF

This task is mandatory for both zero touch provisioning, and the standard configuration method.

To start working with NETCONF and RESTCONF APIs you must be a user with privilege level 15. To provide this, perform the following task:

	Command or Action	Purpose
Step 1	enable Example: Switch# enable	Enables the privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Switch# configure terminal	Enters the global configuration mode.
Step 3	username name privilege level password password Example: Switch (config)# username example-name privilege 15 password example_password	Establishes a user name-based authentication system. Configure the following keywords: <ul style="list-style-type: none"> privilege level—Sets the privilege level for the user. For the programmability feature, it must be 15. password password—Sets a password to access the CLI view.
Step 4	end Example: Switch# end	Exits global configuration mode and enters privileged EXEC mode.

Enabling the NETCONF Interface

This task is mandatory if you want to use the NETCONF interface and have opted for the standard configuration method:

	Command or Action	Purpose
Step 1	enable Example: Switch# enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Switch# configure terminal	Enters the global configuration mode.
Step 3	netconf-yang Example: Switch(config)# netconf-yang	Enables the NETCONF interface on your network device. After you have completed this step, you can manage network devices through a model based interface. The complete activation of model-based interface processes may require up to 90 seconds.
Step 4	end Example: Switch# end	Exits global configuration mode and enters privileged EXEC mode.

See [Examples for NETCONF RPCs, page 6-14](#).

Enabling Cisco IOS HTTP Services for RESTCONF

This task is mandatory if you want to use the RESTCONF interface and have opted for the standard configuration method.

	Command or Action	Purpose
Step 1	enable Example: Switch# enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: Switch# configure terminal	Enters the global configuration mode.
Step 3	restconf Example: Switch(config)# restconf	Enables the RESTCONF interface on your network device.
Step 4	ip http server or ip http secure-server Example: Switch (config)# ip http server OR Switch (config)# ip http secure-server	<p>The ip http server command enables the HTTP server on your system.</p> <p>The ip http secure-server command enables a secure HTTP (HTTPS) server.</p> <p>Note When enabling an HTTPS server, you should always disable the standard HTTP server to prevent unsecured connections to the same services. Disable the standard HTTP server using the no ip http server command in global configuration mode (this step is precautionary; typically, the HTTP server is disabled by default).</p> <p>Configure only one of the commands.</p>
Step 5	ip http authentication local Example: Switch(config)# ip http authentication local	Indicates that the login user name, password and privilege level access combination specified in the local system configuration (with the username global configuration command) should be used for authentication and authorization.
Step 6	end Example: Switch# end	Exits global configuration mode and enters privileged EXEC mode.

See [Examples for RESTCONF RPCs, page 6-15](#).

Using NETCONF and RESTCONF Protocols

NETCONF uses a simple RPC-based (Remote Procedure Call) mechanism to facilitate communication between a client and a server. The client can be a script or an application running as part of a network manager. The server is typically a network device (switch or router).

NETCONF uses Secure Shell Version 2 (SSHv2) as the transport layer across network devices and RESTCONF uses HTTP.

To use NETCONF and RESTCONF you must complete all the required tasks as per the [Configuring Programmability Components, page 6-4](#) section.

NETCONF and RESTCONF also support capability discovery and model downloads. Supported models are discovered using the ietf-netconf-monitoring model. Revision dates for each model are shown in the capabilities response. Data models are available for optional download from a device using the get-schema rpc. You can use these YANG models to understand or export the data model.

The following shows sample RPCs you can send and the kind of action that is performed.

- [Examples for NETCONF RPCs, page 6-14](#)
- [Examples for RESTCONF RPCs, page 6-15](#)

Examples for NETCONF RPCs

Get the running-configuration of the switch by sending the following RPC:

```
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter>
      <native xmlns="http://cisco.com/ns/yang/ned/ios"/>
    </filter>
  </get-config>
</rpc>
```

Change the description of an interface by sending the following RPC

```
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <native xmlns="http://cisco.com/ns/yang/ned/ios">
        <interface>
          <TenGigabitEthernet>
            <name>4/1</name>
            <description>to_distribution</description>
          </TenGigabitEthernet>
        </interface>
      </native>
    </config>
  </edit-config>
</rpc>
```

Remove the description from an interface by sending the following RPC

```
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <native xmlns="http://cisco.com/ns/yang/ned/ios">
        <interface>
          <TenGigabitEthernet>
            <name>4/1</name>
            <description xc:operation="delete"/>
          </TenGigabitEthernet>
        </interface>
      </native>
    </config>
  </edit-config>
</rpc>
```

Examples for RESTCONF RPCs

Get the TFTP source interface by sending the following RPC:

```
GET http://10.106.30.33:80/restconf/api/running/native/ip/tftp/source-interface
```

Configure the TFTP source interface by sending the following RPC:

```
PATCH
http://10.106.30.33:80/restconf/api/running/native/ip/tftp/source-interface/GigabitEthernet
payload = "{\n  \"GigabitEthernet\": \"2/2\"\n}"
```

Enter an HTTP delete request by sending the following RPC:

```
DELETE http://10.106.30.33:55080/api/running/native/ip/tftp/source-interface/
```

Note

For the HTTP delete request do not use:

```
http://10.106.30.33:80/restconf/api/running/native/ip/tftp/source-interface/
```

Using ODM Models

You use ODM models to retrieve read-only operational state data from the system. For this, you must enable Secure Shell Version 2 (SSHv2), activate the ODM, and set the time interval at which the models will collect information from the system.

Each ODM model has a corresponding parser, which polls the specified operational data according to the specified polling interval in milliseconds. See the following sections:

- [Enabling SSHv2, page 6-17](#)
- [Activating and Deactivating the ODM, page 6-17](#)
- [Enabling the Polling Mode, page 6-19](#)
- [Displaying Supported Parsers and Polling Intervals, page 6-20](#)

The following tables lists the parsers, ODM models, and the kind of operational state data that is polled. By default, polling is enabled.

No.	Parsers	ODM Models	Corresponding show Command and Purpose
1	parse.showArchive	cisco-checkpoint-archive.yang	Corresponds to the show archive command, which displays information about the files saved in the Cisco IOS configuration archive.
2	parse.showACL	cisco-acl-oper.yang (confirm if a footnote is required - pratyusha)	Corresponds to the show ip access-lists command, which displays the contents of all current IP access lists.
3	parse.showVirtualService	cisco-virtual-service.yang	Corresponds to the show virtual-service list command, which displays an overview of resources utilized by the applications
4	parse.showProcessesMemory	cisco-process-memory.yang	Corresponds to the show processes memory command, which displays the amount of memory used by each system process in Cisco IOS, Cisco IOS XE, or Cisco IOS Software Modularity images.
5	parse.showProcessesCPU	cisco-process-cpu.yang	Corresponds to the show processes cpu command, which displays CPU utilization to identify the causes of high CPU utilization.
6	parse.showIpRoute	ietf-routing.yang	Corresponds to the show ip route command, which displays the current state of the routing table to verify the configuration.
7	parse.showInterfaces	ietf-interfaces.yang	Corresponds to the show interfaces command, which displays statistics for all interfaces configured on the device or access server.
8	parse.showBFDneighbors	cisco-bfd-state.yang	Corresponds to the show bfd neighbors command, which displays the active BFD neighbor and displays the routing protocols that BFD has registered.
9	parse.showLLDPneighbors	cisco-lldp-state.yang	Corresponds to the show lldp neighbors command, which displays information about neighbors, including device type, interface type and number, holdtime settings, capabilities, and port ID.
10	parse.showMacAddTable	cisco-mac-address-table.yang	Corresponds to the show mac-address-table command, which displays the MAC address table.
11	parse.showPower	cisco-poe-interfaces.yang	Corresponds to the show power inline command, which displays the PoE state for the switch.
12	parse.showModule	cisco-equipment-module.yang	Corresponds to the show module command, which displays module status.
13	parse.showVersion	cisco-cat4k-version.yang	Corresponds to the show version command, which displays hardware and software information for the system.

No.	Parsers	ODM Models	Corresponding show Command and Purpose
14	parse.showInventory	cisco-inventory-entities.yang	Corresponds to the show inventory command, which displays product identification (PID) information for the hardware
15	parse.showIntTransceiver	cisco-interface-transceiver.yang	Corresponds to the show interfaces transceiver detail command, which displays information about the optical transceivers that have digital optical monitoring (DOM) enabled.
16	parse.showIgmpGroup	cisco-igmpsn-group.yang	Corresponds to the show ip igmp snooping groups command, which displays the member port and the IP address.
17	parse.showFlowMonitor	cisco-flow-monitor.yang	Corresponds to the show flow monitor name cache command, which displays the status and statistics for a Flexible NetFlow flow monitor.
18	showIPslaStatistics	cisco-ip-sla-stats.yang	Corresponds to the show ip sla statistics command, which displays the current operational status and statistics of all IP SLAs operations or a specified operation.

Enabling SSHv2

For information about configuring SSHv2, see

http://www.cisco.com/c/en/us/td/docs/ios-xml/ios/sec_usr_ssh/configuration/xe-3e/sec-usr-ssh-xe-3e-book.html

Activating and Deactivating the ODM

This section contains sample RPCs to check the current status of the ODM, to activate it, and to deactivate it.

Example: Checking the Current Status of the ODM.

In the example below, the ODM is active (value set to true).

Input

```
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter>
      <cisco-ia xmlns="http://cisco.com/yang/cisco-ia">
        <odm-control/>
      </cisco-ia>
    </filter>
  </get>
</rpc>
```

Output

```
NETCONF RETURN
-----
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="101">
  <data>
```

```

    <cisco-ia xmlns="http://cisco.com/yang/cisco-ia">
      <odm-control>true</odm-control>
    </cisco-ia>
  </data>
</rpc-reply>

```

Example: Activating or Starting the ODM

In the example below, the RPC reply (ok) indicates that the ODM is activated successfully.

Input

```

<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <cisco-ia xmlns="http://cisco.com/yang/cisco-ia">
        <odm-control>true</odm-control>
      </cisco-ia>
    </config>
  </edit-config>
</rpc>

```

Output

```

NETCONF RETURN
-----
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="101">
  <ok/>
</rpc-reply>

```

To deactivate or stop the ODM, send the following RPC:

Input

```

<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <cisco-ia xmlns="http://cisco.com/yang/cisco-ia">
        <odm-control>false</odm-control>
      </cisco-ia>
    </config>
  </edit-config>
</rpc>

```

Output

```

NETCONF RETURN
-----
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="101">
  <ok/>
</rpc-reply>

```

Enabling the Polling Mode

This section contains sample RPCs to check the current polling mode, to enable or change it, and to change the polling interval.

Example: Verifying the Currently Polling Mode of the ODM Models

In the example below, polling is enabled. (In the output section, the polling-enable parameter is set to true).

Input

```
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter>
      <cisco-odm xmlns="http://cisco.com/yang/cisco-odm">
        <polling-enable/>
      </cisco-odm>
    </filter>
  </get>
</rpc>
```

Output

```
NETCONF RETURN

<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="101">
  <data>
    <cisco-odm xmlns="http://cisco.com/yang/cisco-odm">
      <polling-enable>true</polling-enable>
    </cisco-odm>
  </data>
</rpc-reply>
```

Example: Enabling or Changing the Polling Mode of the ODM Models

Input

```
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <cisco-odm xmlns="http://cisco.com/yang/cisco-odm">
        <polling-enable>true</polling-enable>
      </cisco-odm>
    </config>
  </edit-config>
</rpc>
```

Output

```
NETCONF RETURN
-----
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="101">
  <ok/>
</rpc-reply>
```

Example: Changing the Polling Interval of a Parser

In the example below, the polling interval of parser **parse.showArchive** is changed to 110000 milliseconds:

Input

```
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <cisco-odm xmlns="http://cisco.com/yang/cisco-odm">
        <actions>
          <action-name>parse.showArchive</action-name>
          <polling-interval>110000</polling-interval>
        </actions>
      </cisco-odm>
    </config>
  </edit-config>
</rpc>
```

Output

```
NETCONF RETURN
-----
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="101">
  <ok/>
</rpc-reply>
```

Displaying Supported Parsers and Polling Intervals

To retrieve information about all the supported parsers and their polling intervals, send the following RPC:

Input

```
<rpc message-id="101" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter>
      <cisco-odm xmlns="http://cisco.com/yang/cisco-odm">
        <actions>
          <action-name/>
          <polling-interval/>
          <mode/>
        </actions>
      </cisco-odm>
    </filter>
  </get>
</rpc>
```

Output

```
NETCONF RETURN
-----
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="101">
  <data>
```

```

<cisco-odm xmlns="http://cisco.com/yang/cisco-odm">
  <actions>
    <action-name>parse.showACL</action-name>
    <polling-interval>120000</polling-interval>
    <mode>poll</mode>
  </actions>
  <actions>
    <action-name>parse.showArchive</action-name>
    <polling-interval>120000</polling-interval>
    <mode>poll</mode>
  </actions>
  <actions>
    <action-name>parse.showBFDneighbors</action-name>
    <polling-interval>120000</polling-interval>
    <mode>poll</mode>
  </actions>
  <actions>
    <action-name>parse.showFlowMonitor</action-name>

Monitoring Programmability

Use these commands in the privileged EXEC mode, to display the Programmability settings you have configured:

Table 6-1 Monitoring Programmability

Show Command	Purpose
debug remotemanagement dmi	<p>Displays the list of applications for which you can debug information. You can choose from the following list of applications</p> <ul style="list-style-type: none"> • ciaauthd—Debug CIA Authorizaition Daemon • ciam—Debug CiaManager • confd—Debug Confd • monit—Debug Monit • nes—Debug Network Element Synchronizer • odm—Debug Operational Data Manager • snmp—Debug SNMP Notification Processor • syncfd—Debug SyncFromDaemon
show onep session all	<p>Displays OneP session information. To verify if NETCONF and RESTCONF interfaces are configured correctly, ensure that these three sessions are listed: NetworkElementSynchronizer, SyncFromDaemon and CiaAuthDaemon. The following is sample output for this command:</p> <p>Switch # show onep session all</p> <pre>ID Username State ReconnectTimer ConnectTime ApplicationName 8145 Connected 0 Thu Jul 28 06:07:05.304 com.cisco.NetworkElementSynchronizer 3234 Connected 0 Thu Jul 28 06:07:06.504 com.cisco.SyncFromDaemon 7249 Connected 0 Thu Jul 28 06:07:07.343 com.cisco.CiaAuthDaemon</pre>
show remotemanagement dmi	<p>Displays the list of applications for which you can display log and status information. You can choose from the following list of applications:</p> <ul style="list-style-type: none"> • ciaauthd—Show CIA Authorization Daemon • ciam—Show CiaManager • confd—Show Confd • genet—Show Mapping Framework • log—Show all DMI logs • monit—Show Monit • nes—Show Network Element Synchronizer • odm—Show Operational Data Manager • snmp—Show SNMP Notification Processor • status—Show status for all DMI applications • syncfd—Show SyncFromDaemon
show virtual-service [global]	Displays available memory, disk space, and CPU allocated for applications.

Table 6-1 Monitoring Programmability

Show Command	Purpose
show virtual-service detail [<i>name virtual-services-name</i>]	Displays a list of resources committed to a specified application, including attached devices.
show virtual-service list	Displays the list of applications installed in the virtual services container. The following is sample output for this command: Switch# show virtual-service list Virtual Service List: Name Status Package Name ----- dmi Activated cat4500e_20160725-212823.ova
show virtual-service storage pool list	Displays an overview of storage locations (pools) used for virtual service containers.
show virtual-service storage volume list	Displays an overview of storage volume information for virtual service containers.
show virtual-service version name <i>virtual-services-name</i> installed	Displays the version of an installed application. For example: Switch# show virtual-service version name dmi installed Virtual service dmi installed version: Name : Netconf-Yang Version : 1.0.0
show virtual-service tech-support	Displays container-based information.
show virtual-service redundancy state	Displays synchronization status
show virtual-service utilization statistics CPU	Displays virtual service CPU utilization statistics.

Troubleshooting Programmability

This section shows sample output for the some of the errors you may encounter while configuring the feature. In some cases a solution is described, and in others, sample configuration output serves as a guideline for correct configuration.

- [File Not Found Errors, page 6-25](#)
- [Startup Configuration Errors, page 6-27](#)
- [Debugging the DMI, page 6-27](#)

File Not Found Errors

If you receive such an error, check the path you have entered for the `filename` field in the DHCP configuration file and make sure that the file exists in your TFTP server. The sample output below shows a successful TFTP session:

```

Filename      : /cat4500e-universalk9.SSA.03.09.00.PR4.46.152-5.0.46.PR4.bin
IP Address    : 192.168.20.16
Loading from TftpServer: 10.106.24.187
TftpBlkSize   : 1468
RxDataPacket  : 130207

Loaded 191143008 bytes successfully.

Startup Configuration Errors

If you encounter errors when you replace the existing startup configuration with a new configuration, the system does not replace the existing startup configuration. You must resolve the errors in the switch start-up configuration file before resuming.

Debugging the DMI

To start debugging the DMI container, perform the following task:

-
- Step 1** Set the logging level to “debug” in cisco-ia.yang model.
 - Step 2** In the privilege EXEC Mode on the switch CLI, enter one of these commands and use NETCONF to read the responses
 - The **debug remotemanagement** command.
 - The **show remotemanagement** command
 - Step 3** To display NETCONF statistical information, such as, the number of sessions, netconf RPCs, packets and so on, use the ietf-netconf-monitoring.yang model.

The following is sample output for the **show remotemanagement command confd log** command:

```

Switch# show remotemanagement dmi confd log
remotemanagement-iosxe-remote-mgmt-8086

***** cia-confd.log *****

```

Sample Configuration and Reference Information

This chapter provides sample configuration for the following :

- [DHCP Server Settings on Linux, page 6-28](#)
- [Configuring DHCP Option 43 \(for Microsoft Windows\), page 6-32](#)
- [Microsoft Windows DHCP Server Configuration, page 6-33](#)
- [Autoboot Process Output, page 6-37](#)

DHCP Server Settings on Linux

The following is sample configuration that is saved in the *dhcpd.conf* file. Use it as a point of reference when you configure DHCP server settings on Linux.

This sample output covers a scenario where different files are sent to multiple devices of the same vendor specific class, but each one of the devices has a different MAC address.

Comments throughout the sample configuration provide guidelines for important steps (sentence starting with #).

Note

You must restart the DHCP service every time you make a change in the *dhcpd.conf* file.

Depending on whether you are using HTTP or TFTP to download files, refer to the corresponding sample configuration file:

- [Using HTTP, page 6-28](#)
- [Using TFTP, page 6-30](#)

}

```

Configuring DHCP Option 43 (for Microsoft Windows)

DHCP Option 43 is used by clients and servers to exchange vendor-specific information. (RFC 2132).

This section describes the DHCP Option 43 configuration information that pertains to sending device configuration files, script files, and .ova files to the switch. It is applicable only if you use OpenDhcpServer as the DHCP server, with Microsoft Windows. Other DHCP servers have their own methods to configure this option and the information is available on the Internet.

To send any file, you must convert the file name along with the extension, to a hexadecimal format and the files must be stored in the TFTP root directory.

<File code><length of filename.ext in hexadecimal value><hex value of the filename.ext>

Use the relevant codes to specify the type of file you want to send

- code 01—A configuration file. For example, to send file `example-config.config`:
43=01:15:65:78:61:6d:70:6c:65:2d:63:6f:6e:66:69:67:2e:63:6f:6e:66:69:67:
- code 02—A script file. For example to send file `example-script.py`:
43=02:11:65:78:61:6d:70:6c:65:2d:73:63:72:69:70:74:2e:70:79
- code 03—An ova file. For example, to send file `example_dmi_container.ova`:
43=03:19:65:78:61:6d:70:6c:65:5f:64:6d:69:5f:63:6f:6e:74:61:69:6e:65:72:2e:6f:76:61

Concatenating all three file names

```
43=01:15:65:78:61:6d:70:6c:65:2d:63:6f:6e:66:69:67:2e:63:6f:6e:66:69:67:02:11:65:78:61:
6d:70:6c:65:2d:73:63:72:69:70:74:2e:70:79:03:19:65:78:61:6d:70:6c:65:5f:64:6d:69:5f:63:
6f:6e:74:61:69:6e:65:72:2e:6f:76:61:ff
```

Microsoft Windows DHCP Server Configuration

The following example shows how to configure the DHCP Server on Microsoft Windows.

Note

The example uses OpenDhcpServer and Solarwinds TFTP server. Information about configuring both is available on the Internet. The use of both applications here is only meant to serve as an example for configuration, and are not product recommendations.

Figure 6-3 Solarwinds TFTP Server

The important sections of this sample configuration are highlighted **bold**:

```
#This is a configuration file.
#Lines starting with punctuation marks are comments.
#This file should be saved in the same folder as the exe file.
#Remove; and replace the sample value with your own to change a setting

[LISTEN_ON]
#Specify the interfaces that the server should listen to. If you have more than one NIC
#card on your server, always specify the cards that will listen to DHCP/DNS requests.
#Requests from different interfaces look for matching DHCP ranges.
#Requests from relay agents look for a matching range to relay the agent IP.
#You can specify up to 125 interfaces
#By default this includes all static interfaces
;198.51.100.2

[LOGGING]
#You can set the LogLevel as None, Errors or All
#We recommend that you set the logging level to Normal, Normal include errors and DHCP
#renewal messages. The default logging level is Normal.
```

```
;LogLevel=None
;LogLevel=Normal
;LogLevel=All
;LogLevel=Debug
```

[REPLICATION_SERVERS]

```
#You can have 2 instances of Open DHCP Servers in a network. Open DHCP Server sends
#replicated inform messages to the other instance of the Open DHCP server and replicates
#leases. The IP address allotted by one server is not realotted by the other server to
#another host. Further when one server goes down, the other can renew the leases, without
#NAK and DISCOVER. You must specify the primary and secondary servers for replication to
#work.Ensure that the primary & secondary server entries are identical on both servers.
#You may copy the entire ini file on both servers and change the
#LISTEN_ON on individual servers, if needed.
;Primary=192.0.2.253
;Secondary=192.0.2.254
```

[HTTP_INTERFACE]

```
#This is http interface to display the lease status. By default, this is the first
#interface, port 6789. You can change it to any network interface.
;HTTPServer=192.51.100.1:6789
#To limit client access, you can specify up to 8 HTTP client IPs here. If no client IPs
#are specified then clients can access the HTTP interface.
#You can also change the title of the HTML page
;HTTPTitle=example-httpserver-url.com
```

```
#Sections below are other DHCP Sections. You can allot clients addresses dynamically from
#the DHCP Range or statically. For static addresses, client section must be created for
#each static client against its MAC Address. BOOTP clients are always static. DHCP Ranges
#are grouped into [RANGE_SET]s, so that range specific options can be specified for a
#group of ranges in one place. The total ranges in all [RANGE_SET]s is also 125 and you
#can also have a maximum of 125 [RANGE_SET]s.
#You can specify one or more ranges in each [RANGE_SET] section, in the specified format.
#Open DHCP Server allots addresses from these ranges. Static Hosts and BootP clients do
#not require ranges. You do not have to specify a [RANGE_SET] or a DHCP_Range if all
#clients are Static.
```

```
#The dynamic address allocation policy is -
```

```
#1)Look to see if a MAC address is specified as static DHCP Client and use that IP
#2)If not found, look for an old, expired or active address of the same host
#3)If not found, look at the requested IP address and check if available
#4)If not found, allot an unused IP address, if available
#5)If not found, allot the expired IP address of the other host.
#From 2) to 6), requests from different interfaces look for matching DHCP ranges
#of interface IP, and requests from relay agents look for matching range to
#relay agent IP.
```

```
#All the ranges in a [RANGE_SET] section can be further restricted with Filter_Mac_Range,
#Filter_Vender_Class and Filter_User_Class. For example, if a MAC range is specified, then
#this section's ranges will only be available to hosts, whose MAC address falls in this
#range. Also if any host has a matching Filter_Mac_Range in any DHCP_RANGE section, then
#other DHCP range sections without a Filter_Mac_Range or without a matching MAC range will
#not be available to it. Each Manufacturer has a fixed MAC Range. The same Mac ranges can
#repeat in many DHCP_RANGE sections.
#For Filter_Vendor_Class (option 60) and Filter_User_Class filter (option 77),
#the range is available only to a matching value of Filter_Vender_Class
#and Filter_User_Class sent in the client request. If the Filter_Vender_Class and
#the Filter_User_Class values do match in one or more ranges, other ranges with missing
#or non-matching values are not available to such clients. You can specify upto 32
#Filter_Mac_Range, Filter_Vender_Class and Filter_User_Class in each [RANGE_SET].
```

```
#Generally you do not have to specify any filters for the relay agent. The range is
#automatically selected based on the relay agent IP and subnet mask of the range. The
#Relay agent always sends it's subnet side IP. This server uses only the DHCP Range, which
#matches this IP. This ensures that correct range is used. This feature
#eliminate the need of additional configuration. For matching purpose, range is
#recalculated using Subnet Mask of range and Relay Agent IP. However if you want
#to manually configure the subnet selection, you can use FilterSubnetSelection in
#a RANGE_SET. If this filter is specified it will be first matched with SubnetSelection
#Option 118 sent by client. If client sends no such option, it will be matched
#with relay Agent IP. If not relay agent IP is sent, Listening Interface's IP
#will be matched. You can also override the Target Relay Agent using TargetRelayAgent
#option.
```

```
[RANGE_SET]
#This is first and simple DHCP range section example,
#If you need range filters, look at example below
DHCPRange=192.0.2.3-192.0.2.250
VendorClass="Example Server"
43=01:15:65:78:61:6d:70:6c:65:2d:63:6f:6e:66:69:67:2e:63:6f:6e:66:69:67:02:11:65:78:61:6d:
70:6c:65:2d:73:63:72:69:70:74:2e:70:79:03:19:65:78:61:6d:70:6c:65:5f:64:6d:69:5f:63:6f:6e:
74:61:69:6e:65:72:2e:6f:76:61:ff
;43="example-config.config"65:78:61:6d:70:6c:65:2d:63:6f:6e:66:69:67:2e:63:6f:6e:66:69:67;

;FilterVendorClass="EXAMPLE 5.0"
;FilterVendorClass="EXAMPLE 5.1"
;FilterVendorClass="EXAMPLE 5.2"
;FilterUserClass="My User Class 4.0"
;FilterUserClass=123,56,87,123,109,0,23,56,156,209,234,56
;FilterUserClass=00:0d:60:c5:4e:0d:60:c5:4e
#You can select RANGE_SET based on FilterSubnetSelection
```

```

;FilterSubnetSelection=198.51.100.1
;FilterSubnetSelection=192.0.2.1
;Ethernet=no

[GLOBAL_OPTIONS]
#These are global DHCP Options and they supplement client specific options and [RANGE_SET]
#options. Options tags start with 1 and go up to 254, you can specify and option like
#1=255.255.255.0, but it may be difficult to remember option tags. Try using Option names
#instead. If a matching name is not found, you can use tag=value (flat options)
#You can also specify the value as byte array or even hex array. Some options that have
#sub-options can be specified only as hex/byte array. If options have client specific
#values, move/copy them to specific static client sections. If any option has a DHCP range
#specific value, move or copy them to [RANGE_SET] sections.
#You may quote string values (must quote if string contain chars like comma, dot or
#colon). For example NDS_Tree_Name="my.NDS.Tree" or 43="this is return string" or use the
#byte array in value like 43=123,56,87,123,109,0,23,56,156,209,234,56 or use the hex
#array in value 43=a6:87:b6:c9:ae:eb:89:09:a4:67:d5

;DomainName="example-httpserver-url.com"
;SubNetMask=255.255.255.0
;DomainServer=198.51.100.3
;Router=192.0.2.254
#AddressTime is default lease time for server
#specify 0 for infinity lease time
;AddressTime=36000
;RenewalTime=0
;RebindingTime=0
#NextServer is PXEBoot TFTP Server
NextServer=198.51.100.2

Configuring the Cisco IOS In-Service Software Upgrade Process

Note

Starting with Cisco IOS 12.2(31)SGA, ISSU is supported on the Catalyst 4500. All line cards are supported.

Operating on redundant systems, the In-Service Software Upgrade (ISSU) process allows Cisco IOS software to be updated or otherwise modified while packet forwarding continues. In most networks, planned software upgrades are a significant cause of downtime. ISSU allows Cisco IOS software to be modified while packet forwarding continues. This increases network availability and reduces downtime caused by planned software upgrades. This document provides information about ISSU concepts and describes the steps taken to perform ISSU in a system.

This section includes these topics:

- [Prerequisites to Performing ISSU, page 7-1](#)
- [About ISSU, page 7-2](#)
- [Performing the ISSU Process, page 7-15](#)
- [Related Documents, page 7-42](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Prerequisites to Performing ISSU

Before performing ISSU, you need to meet these prerequisites:

- Image type of the existing and target image must match. For example, you cannot upgrade from an IP Base image to an Enterprise Services image (and vice versa) without experiencing several minutes of traffic loss.

Note

A similar limitation applies between crypto and non-crypto images.

- The active and the standby supervisor engines must have the same supervisor engine hardware (same model, same memory, NFL daughter card and so on).
- The new and old Cisco IOS software images must be loaded into the file systems (bootflash or compact flash) of both the active and the standby supervisor engines before you begin the ISSU process.

The old image should be available either in bootflash or compact flash and the system should have been booted from one of these locations because the boot variable should not be changed before the ISSU process unfolds.

Note **auto-boot** must be enabled for ISSU to succeed.

- Stateful Switchover (SSO) must be configured and the standby supervisor engine should be in standby hot state.
These commands indicate whether SSO is enabled: **show module**, **show running-config**, **show redundancy state**.
If you do not have SSO enabled, see the *Stateful Switchover* document for further information on how to enable and configure SSO.
- Nonstop Forwarding (NSF) must be configured and working properly. If you do not have NSF enabled, see the *Cisco Nonstop Forwarding* document for further information on how to enable and configure NSF.
- Before you perform ISSU, ensure that the system is configured for redundancy mode SSO and that the file system for both the active and the standby supervisor engines contains the new ISSU-compatible image. The current Cisco IOS version running in the system must also support ISSU.

You can enter various commands on the Catalyst 4500 series switch or the ISSU application on Cisco Feature Navigator to determine supervisor engine versioning and Cisco IOS compatibility.

- If you enter the **no ip routing** command, ISSU falls back from SSO to RPR mode, resulting in traffic loss.
- Autoboot is turned on and the current booted image matches the one specified in the BOOT environmental variable. For details on how to configure and verify these, please refer to "[Modifying the Boot Field and Using the boot Command](#), page 3-28.
- If you enter the **no ip routing** command, ISSU falls back from SSO to RPR mode, resulting in traffic loss.

About ISSU

Note

Do not make any hardware changes while performing ISSU.

Before you perform ISSU, you should understand the following concepts:

- [Stateful Switchover Overview](#), page 7-3
- [NSF Overview](#), page 7-5
- [ISSU Process Overview](#), page 7-6
- [Performing an ISSU Upgrade: 2 Methods](#), page 7-11

- [Changeversion Process, page 7-12](#)
- [Guidelines for Performing ISSU, page 7-13](#)
- [Versioning Capability in Cisco IOS Software to Support ISSU, page 7-13](#)
- [SNMP Support for ISSU, page 7-15](#)
- [Compatibility Verification Using Cisco Feature Navigator, page 7-15](#)

Stateful Switchover Overview

Development of the SSO feature is an incremental step within an overall program to improve the availability of networks constructed with Cisco IOS switches.

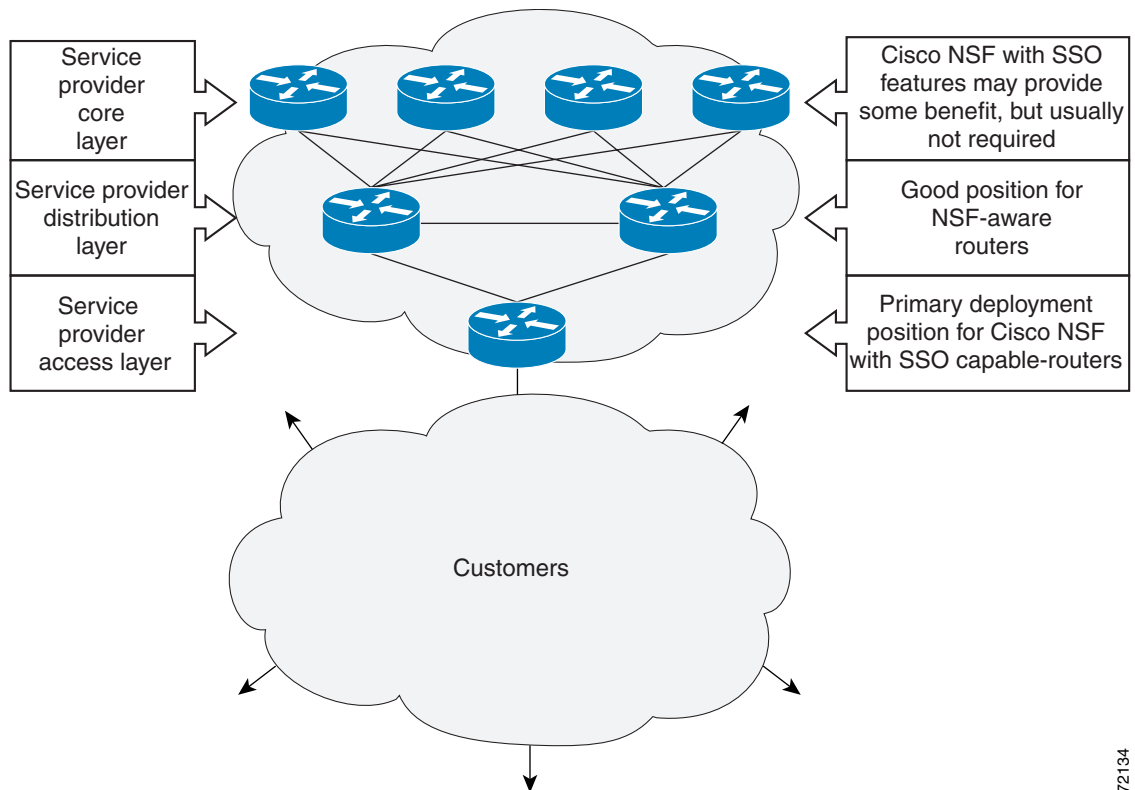

In specific Cisco networking devices that support dual supervisor engines, SSO takes advantage of supervisor engine redundancy to increase network availability. SSO achieves this by establishing one of the supervisor engines as the active processor while the other supervisor engine is designated as the standby processor. Following an initial synchronization between the two supervisor engines, SSO dynamically synchronizes supervisor engine state information between them in real-time.

A switchover from the active to the standby processor occurs when the active supervisor engine fails or is removed from the networking device.

Cisco NSF is used with SSO. Cisco NSF allows the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. With Cisco NSF, peer networking devices do not experience routing flaps, which reduce loss of service outages for customers.

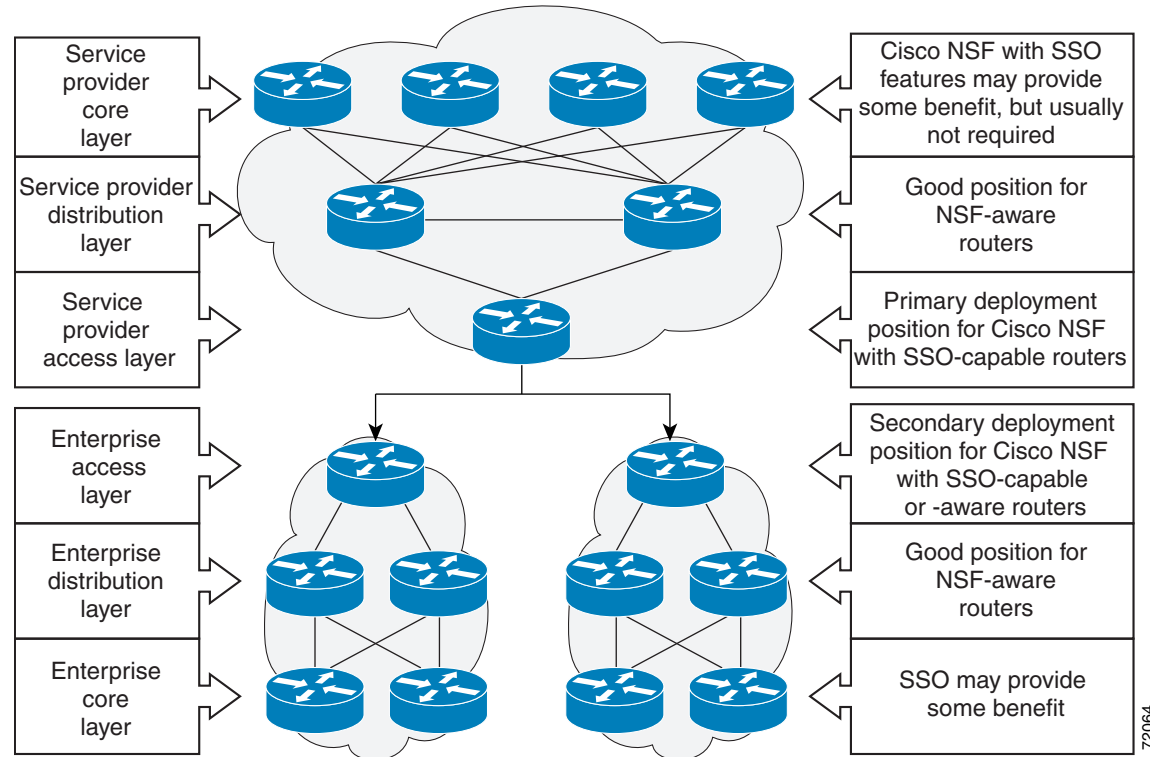

[Figure 7-1](#) illustrates how SSO is typically deployed in service provider networks. In this example, Cisco NSF with SSO is enabled at the access layer (edge) of the service provider network. A fault at this point could result in loss of service for enterprise customers requiring access to the service provider network.

For Cisco NSF protocols that require neighboring devices to participate in Cisco NSF, Cisco NSF-aware software images must be installed on those neighboring distribution layer devices. Depending on your objectives, you may decide to deploy Cisco NSF and SSO features at the core layer of your network. Doing this can help reduce the time to restore network capacity and service for certain failures, which leads to additional availability.

Figure 7-1 Cisco NSF with SSO Network Deployment: Service Provider Networks

72134

Additional levels of availability may be gained by deploying Cisco NSF with SSO at other points in the network where a single point of failure exists. [Figure 7-2](#) illustrates an optional deployment strategy that applies Cisco NSF with SSO at the enterprise network access layer. In this example, each access point in the enterprise network represents another single point of failure in the network design. In the event of a switchover or a planned software upgrade, enterprise customer sessions continue uninterrupted through the network in this example.

Figure 7-2 Cisco NSF with SSO Network Deployment: Enterprise Networks

NSF Overview

Cisco NSF works with the SSO feature in Cisco IOS software. SSO is a prerequisite of Cisco NSF. NSF works with SSO to minimize the amount of time a network is unavailable to its users following a switchover. The main objective of Cisco NSF is to continue forwarding IP packets following a supervisor engine switchover.

Usually, when a networking device restarts, all routing peers of that device detect that the device went down and then came back up. This transition results in what is called a routing flap, which could spread across multiple routing domains. Routing flaps caused by routing restarts create routing instabilities, which are detrimental to the overall network performance. Cisco NSF helps to suppress routing flaps in SSO-enabled devices, thus reducing network instability.

Cisco NSF allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. With Cisco NSF, peer networking devices do not experience routing flaps. Data traffic is forwarded while the standby supervisor engine assumes control from the failed active supervisor engine during a switchover. The ability of physical links to remain up through a switchover and to be kept current with the Forwarding Information Base (FIB) on the active supervisor engine is key to Cisco NSF operation.

ISSU Process Overview

The ISSU process allows you to perform a Cisco IOS software upgrade or downgrade while the system continues to forward packets. (For an illustration of the commands used during the ISSU process, refer to [Figure 7-8 on page 7-11](#).) Cisco IOS ISSU takes advantage of the Cisco IOS high availability infrastructure—Cisco NSF with SSO and hardware redundancy—and eliminates downtime associated with software upgrades or version changes by allowing changes while the system remains in service (see [Figure 7-3](#)).

SSO and NSF mode support configuration and runtime state synchronization from the active to the standby supervisor engine. For this process to happen, the images on both the active and the standby supervisor engines must be the same. When images on active and standby supervisor engines are different ISSU allows the two supervisor engines to be kept in synchronization even when these two versions of Cisco IOS support different sets of features and commands.

Figure 7-3 High Availability Features and Hardware Redundancy in the ISSU Process

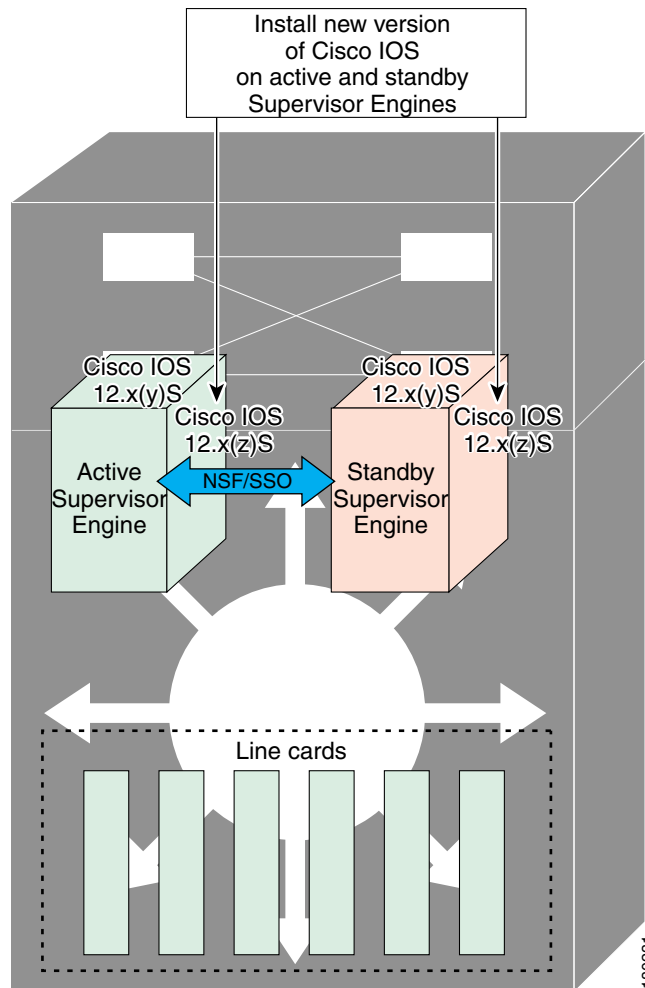

An ISSU-capable switch consists of two supervisor engines (active and standby) and one or more line cards. Before initiating the ISSU process, copy the Cisco IOS software into the file systems of both supervisor engines (see [Figure 7-4](#)).

**Note**

In the following figure, Cisco IOS 12.x(y)S represents the *current* version of Cisco IOS.

Figure 7-4 Install/Copy New Version of Cisco IOS Software on Both Supervisor Engines

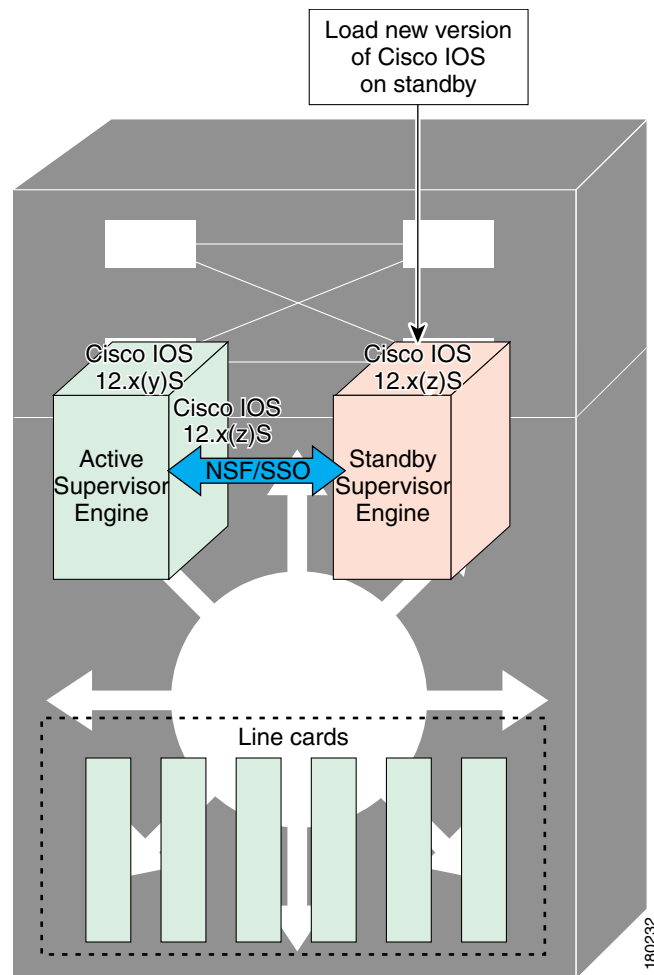

After you have copied the Cisco IOS software to both file systems, load the new version of Cisco IOS software onto the standby supervisor engine (see [Figure 7-5](#)).

**Note**

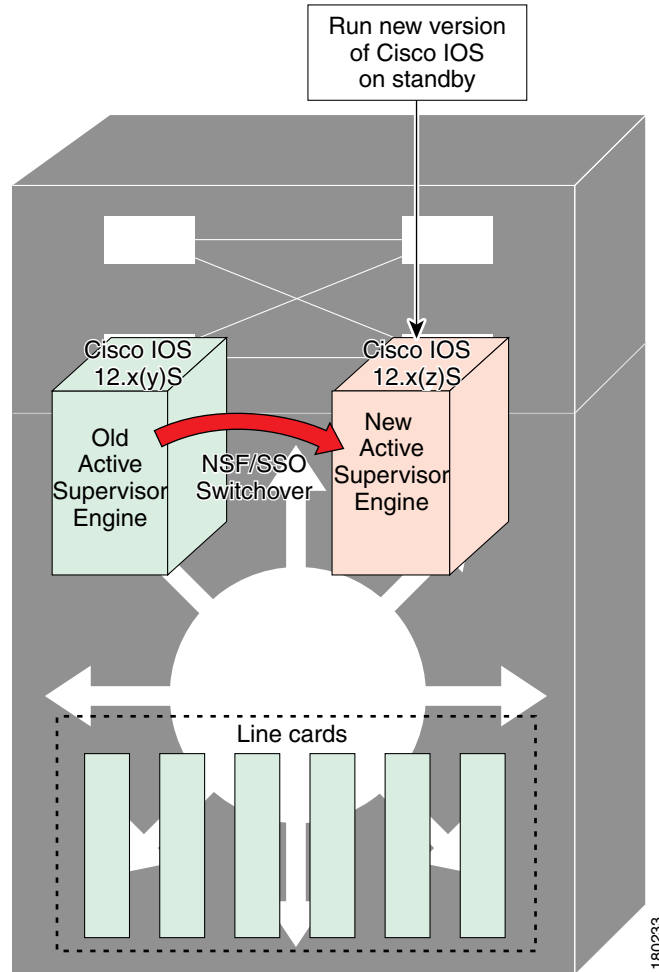

Without the ISSU feature, you cannot have SSO or NSF functioning between the active and standby supervisor engines when they are running two different versions of Cisco IOS image.

Figure 7-5 Load New Version of Cisco IOS Software on the Standby Supervisor Engine

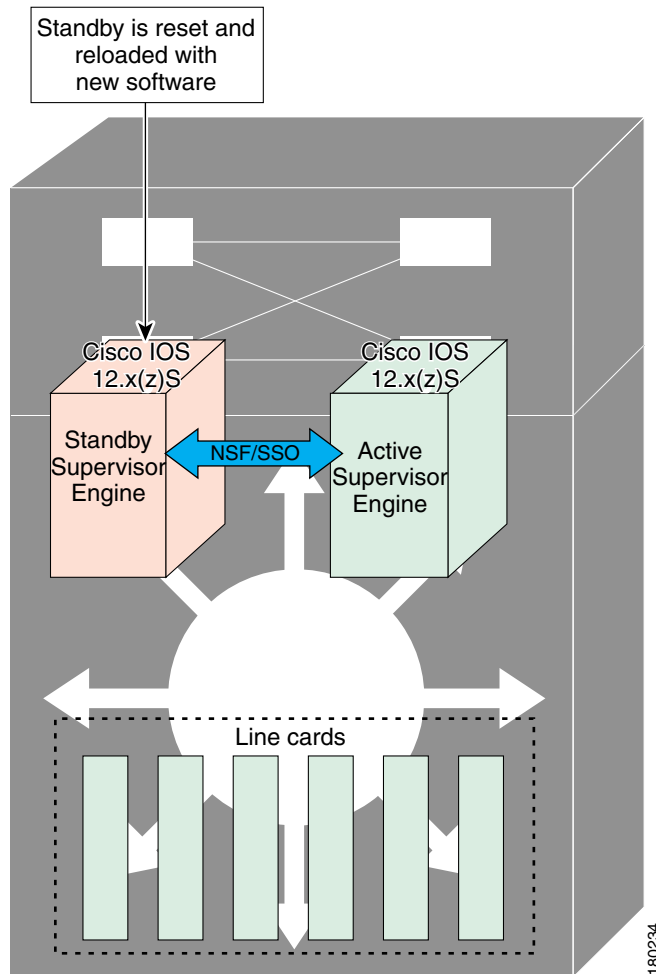

After a switchover (NSF or SSO, not RPR), the standby supervisor engine takes over as the new active supervisor engine (see [Figure 7-6](#)).

Figure 7-6 **Switch Over to Standby Supervisor Engine**

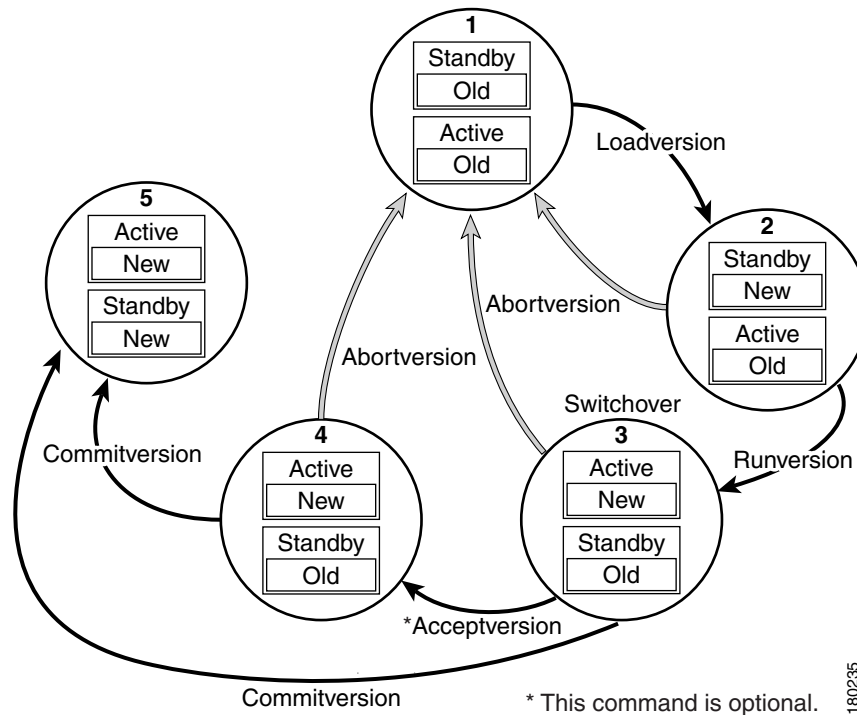

The former active supervisor engine is loaded with an old Cisco IOS image so that if the new active supervisor engine experiences problems, you can abort and conduct a switchover to the former active, which is already running the old image. Next, the former active supervisor engine is loaded with the new version of Cisco IOS software and becomes the new standby supervisor engine (see [Figure 7-7](#)).

Figure 7-7 Load New Standby Supervisor Engine with New Cisco IOS Software

[Figure 7-8](#) shows the steps during the ISSU process.

Figure 7-8 Steps During the ISSU Process

Performing an ISSU Upgrade: 2 Methods

There are two ways to perform an ISSU upgrade: manually, with four commands; or automatically, with one command.

The normal ISSU upgrade process involves issuing four separate ISSU exec commands (**issu loadversion**, **issu runversion**, **issu acceptversion**, **issu commitversion**) along with additional show command invocations to evaluate the success of each command before proceeding. Although the ISSU process is complicated, you should not expect disruption of service. The use of multiple ISSU commands dictates an additional level of care to ensure no service disruption. However, in some scenarios, this upgrade procedure might be cumbersome and of minimal value. A typical example is during a network upgrade that involves performing an ISSU upgrade on a large number of Catalyst 4500 switches. In these cases, we recommend that you first perform the normal (four command) ISSU upgrade procedure on one switch (possibly in a lab environment) to verify successful upgrade. Then, use a single **issu changeversion** command to perform an automatic ISSU on the rest of the Catalyst 4500 switches in the network.

Note

To use the **issu changeversion** command, both old and new IOS versions must support **issu changeversion** functionality.

Changeversion Process

The **issu changeversion** command launches a single-step complete ISSU upgrade cycle. It performs the logic for all four of the standard commands (**issu loadversion**, **issu runversion**, **issu acceptversion**, and **issu commitversion**) without user intervention, streamlining the upgrade through a single CLI step.

Additionally, **issu changeversion** allows the upgrade process to be scheduled for a future time. This enables you to stage a number of systems to perform upgrades sequentially when a potential disruption would be least harmful.

After the standby supervisor engine initializes and the system reaches a terminal state (RPR/SSO), the upgrade process is complete and the BOOT variable is permanently written with the new IOS software software image. Hence, a reset on any RP will keep the system booting the new software image. Console and syslog messages will be generated to notify anyone monitoring the upgrade that the state transition has occurred.

Similar to the normal ISSU upgrade procedure, the in-progress upgrade procedure initiated by the **issu changeversion** command can be aborted with the **issu abortversion** command. If the system detects any problems or detects an unhealthy system during an upgrade, the upgrade might be automatically aborted.

When the **issu runversion** command is entered during the four step manual upgrade process, if any incompatible ISSU clients exist, the upgrade process reports them and their side effects, and allows the user to abort the upgrade. While performing a single-step upgrade process, when the process reaches the runversion state, it will either automatically continue with the upgrade provided the base clients are compatible, or automatically abort because of client incompatibility. If the user wants to continue the upgrade procedure in RPR mode, the user must use the normal ISSU command set and specify the **force** option when entering the **issu loadversion** command.

Changeversion: Quick Option

The **issu changeversion** command provides an optional quick command option that can reduce the time required to perform the automatic ISSU upgrade. When the **quick** command option is applied, the ISSU upgrade state transition differs from that described previously. With this option, the software logic up the loadversion stage remains the same as previously described, and the logic that performs runversion and commitversion is combined. This logic skips the step in the upgrade procedure that loads the old software version on the new standby (old active) supervisor, reducing the time required for the automatic ISSU upgrade by about a third.

Scheduled Changeversion: “in” and “at” Options

issu changeversion provides **in** and **at** command options that enable you to schedule a future automatic ISSU upgrade.

The **at** command option schedules an automatic ISSU upgrade to begin at a specific time. This option specifies an exact time (*hh:mm*, 24 hour format) in the next 24 hours at which the upgrade will occur.

The **in** command option schedules an automatic ISSU upgrade to begin after a certain amount of time has elapsed. This option specifies the number of hours and minutes (*hh:mm* format) that must elapse before an upgrade will occur, with a maximum value of 99:59.

Changeversion Deployment Scenario

The typical **issu changeversion** command usage scenario is for experienced users with a large installed base. These users typically validate a new image using a topology and configuration similar to their production network. The validation process should be done using both the existing multi-command process and the new **issu changeversion** command process. Once users certify an IOS software image and want to roll it out broadly, they can use the single command process to perform an efficient upgrade of their network.

Aborting an In-Progress Changeversion Procedure

The **issu changeversion** command functionality is designed to perform an ISSU software upgrade without user intervention. However, status messages are displayed to the console as the upgrade transitions through the various states. If any anomalies are noticed during the automatic upgrade, perhaps with peers or other parts of the network, you can use the **issu abortversion** command to manually abort the upgrade at any point in the process prior to the commitversion operation.

Guidelines for Performing ISSU

Be aware of the following guidelines while performing the ISSU process:

- Even with ISSU, it is recommended that upgrades be performed during a maintenance window.
- The new features should not be enabled (if they require change of configuration) during the ISSU process.

Note Enabling them will cause the system to enter RPR mode because commands are only supported on the new version.

- In a downgrade scenario, if any feature is not available in the downgrade revision of the Cisco IOS software handle, that feature should be disabled prior to initiating the ISSU process.

Versioning Capability in Cisco IOS Software to Support ISSU

Before the introduction of ISSU, the SSO mode of operation required each supervisor engine to be running the same versions of Cisco IOS software.

Note The operating mode of the system in a redundant HA configuration is determined by exchanging version strings when the standby supervisor engine registers with the active supervisor engine.

The system entered SSO mode only if the versions running on the both supervisor engines were the same. If not, the redundancy mode changes to RPR. With ISSU capability, the implementation allows two different but compatible release levels of Cisco IOS images to interoperate in SSO mode and enables software upgrades while packet forwarding continues. Version checking done before ISSU capability was introduced is no longer sufficient to allow the system to determine the operating mode.

ISSU requires additional information to determine compatibility between software versions. A compatibility matrix is defined, containing information about other images relative to the one in question. This compatibility matrix represents the compatibility of two software versions, one running on the active and the other on the standby supervisor engine, and to allow the system to determine the highest operating mode it can achieve. Incompatible versions cannot progress to SSO operational mode.

Compatibility Matrix

You can perform the ISSU process when the Cisco IOS software on both the active and the standby supervisor engine is capable of ISSU and the old and new images are compatible. The compatibility matrix information stores the compatibility among releases as follows:

- **Compatible**—The base-level system infrastructure and all optional HA-aware subsystems are compatible. An in-service upgrade or downgrade between these versions succeeds with minimal service impact. The matrix entry designates the images to be compatible (C).
- **Base-level compatible**—One or more of the optional HA-aware subsystems is not compatible. An in-service upgrade or downgrade between these versions succeeds; however, some subsystems cannot always maintain state during the transition from the old to the new version of Cisco IOS. The matrix entry designates the images to be base-level compatible (B).

However, you should be able to perform an ISSU upgrade without any functionality loss even if the matrix entry is B. The downgrade may experience some functionality loss if the newer image had additional functionality.

- **Incompatible**—A core set of system infrastructure exists in Cisco IOS that must be able to interoperate in a stateful manner for SSO to function correctly. If any of these required features or subsystems is not interoperable, then the two versions of the Cisco IOS software images are declared to be incompatible. An in-service upgrade or downgrade between these versions is not possible. The matrix entry designates the images to be incompatible (I). The system operates in RPR mode during the period when the versions of Cisco IOS at the active and standby supervisor engines are incompatible.

If you attempt to perform ISSU with a peer that does not support ISSU, the system automatically uses RPR instead.

The compatibility matrix represents the compatibility relationship a Cisco IOS software image has with all of the other Cisco IOS software versions within the designated support window (for example, all of those software versions the image “knows” about) and is populated and released with every image. The matrix stores compatibility information between its own release and prior releases. It is always the newest release that contains the latest information about compatibility with existing releases in the field. The compatibility matrix is available within the Cisco IOS software image and on Cisco.com so that users can determine in advance whether an upgrade can be done using the ISSU process.

To display the compatibility matrix data between two software versions on a given system, enter the **show issu comp-matrix stored** command.

Note

This command is useful *only for verification purposes* because it is available *only after* the ISSU process has started. You might want to check the compatibility matrix prior to starting ISSU. Use the Feature Navigator to obtain the needed information:

<http://tools.cisco.com/ITDIT/CFN/jsp/index.jsp>

SNMP Support for ISSU

SNMP for SSO provides a mechanism for synchronizing the SNMP configurations and the MIBs that support SSO from the active supervisor engine to the standby supervisor engine, assuming that both supervisor engines are running the same version of Cisco IOS software. This assumption is not valid for ISSU.

With ISSU, an SNMP client can handle transformations for the MIBs across two different versions of Cisco IOS, if needed. An SNMP client handles transformation for all MIBs and handles the transmit and receive functionality across the active and standby supervisor engines. During SNMP, a MIB is completely synchronized from the active supervisor engine to the standby supervisor engine only if the versions of the MIB on both Cisco IOS releases are the same.

Compatibility Verification Using Cisco Feature Navigator

The ISSU application on Cisco Feature Navigator allows you to:

- Select an ISSU-capable image
- Identify which images are compatible with that image
- Compare two images and understand the compatibility level of the images (that is, compatible, base-level compatible, and incompatible)
- Compare two images and see the client compatibility for each ISSU client
- Provide links to release notes for the image

Performing the ISSU Process

Unlike SSO, which is a mode of operation for the device and a prerequisite for performing ISSU, the ISSU process is a series of steps performed while the switch is in operation. The steps result in an upgrade to a new or modified Cisco IOS software, and have a minimal impact to traffic.

**Note**

For an illustration of the process flow for ISSU, refer to [Figure 7-8 on page 7-11](#).

This section includes the following topics:

- [Upgrading ISSU to Cisco IOS XE 3.4.0SG/15.1\(2\)SG from a Prior Release, page 7-16](#)
- [Downgrading ISSU from Cisco IOS XE 3.4.0SG/15.1\(2\)SG to a Prior Release, page 7-17](#)
- [Verifying the ISSU Software Installation, page 7-18](#)

- [Switching to the Standby Supervisor Engine, page 7-24 \(required\)](#)
- [Stopping the ISSU Rollback Timer \(Optional\), page 7-26 \(optional\)](#)
- [Loading New Cisco IOS Software on the New Standby Supervisor Engine, page 7-27](#)
- [Aborting a Software Upgrade During ISSU, page 7-34](#)
- [Configuring the Rollback Timer to Safeguard Against Upgrade Issues, page 7-35](#)
- [Displaying ISSU Compatibility Matrix Information, page 7-36](#)

Upgrading ISSU to Cisco IOS XE 3.4.0SG/15.1(2)SG from a Prior Release

Because images prior to Cisco IOS XE 3.4.0SG/15.1(2)SG use the earlier CLI format and Cisco IOS XE 3.4.0SG and 15.1(2)SG images use a newer CLI format, your upgrade consists of the following:

- Upgrading the image on your switch to Cisco IOS XE 3.4.0SG/15.1(2)SG.
- Upgrading mgmtVrf from the earlier CLI format to the later format, removing any IPv6 addresses on the interface.
- Enabling IPv6 address family under mgmtVrf, and reconfigure IPv6 addresses on fa1.

A configuration like the following should exist on pre-Cisco IOS XE 3.4.0SG/15.1(2)SG image:

```
ip vrf mgmtVrf
!
interface FastEthernet1
 ip vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
 ipv6 address 2000::1/64
!
```

Step 1 Perform an ISSU upgrade to a Cisco IOS XE 3.4.0SG/15.1(2)SG image.

Step 2 Run the VRF upgrade command.

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vrf upgrade-cli multi-af-mode common-policies vrf mgmtVrf
You are about to upgrade to the multi-AF VRF syntax commands.
You will lose any IPv6 address configured on interfaces
belonging to upgraded VRFs.

Are you sure ? [yes]:
Number of VRFs upgraded: 1
Switch(config)# exit
```

Your configuration will appear as follows:

```
vrf definition mgmtVrf
!
 address-family ipv4
 exit-address-family
!
interface FastEthernet1
 vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
!
```

Step 3 Configure the switch to enable the IPv6 address family and add the IPv6 address.

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vrf definition mgmtVrf
Switch(config-vrf)# address-family ipv6
Switch(config-vrf-af)# exit
Switch(config-vrf)# exit
Switch(config)# interface fa1
Switch(config-if)# ipv6 address 2000::1/64
```

```
Switch(config-if)# end
```

Your configuration will appear as follows.

```
vrf definition mgmtVrf
!
address-family ipv4
exit-address-family
!
address-family ipv6
exit-address-family
!
interface FastEthernet1
vrf forwarding mgmtVrf
ip address 10.1.1.1 255.255.255.0
speed auto
duplex auto
ipv6 address 2000::1/64
```

Downgrading ISSU from Cisco IOS XE 3.4.0SG/15.1(2)SG to a Prior Release

Because a Cisco IOS XE 3.4.0SG/15.1(2)SG image uses a new CLI format and prior images use earlier CLI formats, the downgrade procedure include the following:

- Downgrading mgmtVrf from new CLI format to older CLI format, removing any IPv6 addresses on the interface.
- Downgrading the image on your switch to a prior release.
- Reconfiguring the IPv6 addresses on fa1.

A configuration like the following will appear on a switch running a Cisco IOS XE 3.4.0SG/15.1(2)SG image:

```
vrf definition mgmtVrf
!
address-family ipv4
exit-address-family
!
address-family ipv6
exit-address-family
!
interface FastEthernet1
vrf forwarding mgmtVrf
ip address 10.1.1.1 255.255.255.0
speed auto
duplex auto
ipv6 address 2000::1/64
!
```

Step 1 Perform a downgrade to a release prior to Cisco IOS XE 3.4.0SG/15.1(2)SG.

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no vrf upgrade-cli multi-af-mode common-policies vrf mgmtVrf
You are about to downgrade to the single-AF VRF syntax commands.
You will lose any IPv6 address configured on interfaces
belonging to downgraded VRFs.

Are you sure ? [yes]:
% ipv6 addresses from all interfaces in VRF mgmtVrf have been removed
```

```
Number of VRFs downgraded: 1
Switch(config)#
```

Your configuration will appear as follows:

```
ip vrf mgmtVrf
!
interface FastEthernet1
 ip vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
!
```

Step 2 Perform an ISSU downgrade to a pre-Cisco IOS XE 3.4.0SG/15.1(2)SGn image.

Step 3 Reconfigure the IPv6 address.

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa1
Switch(config-if)# ipv6 address 2000::1/64
Switch(config-if)# end
Switch#
```

Your configuration will appear as follows.

```
ip vrf mgmtVrf
!
interface FastEthernet1
 ip vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
 ipv6 address 2000::1/64
```

Verifying the ISSU Software Installation

During the ISSU process, five valid states exist: disabled, init, load version, run version, and system reset. Use the **show issu state** command to obtain the current ISSU state:

- Disabled state—The state for the standby supervisor engine while this engine is resetting.
- Init state—The initial state is two supervisor engines, one active and one standby, before the ISSU process is started. It is also the final state after the ISSU process completes.
- Load version (LV) state—The standby supervisor engine is loaded with the new version of Cisco IOS software.
- Run version (RV) state—The **issu runversion** command forces the switchover of the supervisor engines. The newly active supervisor engine now runs the new Cisco IOS software image.
- System reset (SR) state—This state occurs either when you enter the **issu abortversion** command before the Init state is reached, or if the rollback timer expires before you execute the **issu acceptversion** command.

You can verify the ISSU software installation by entering **show** commands, as follows:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# show issu state [detail]	Displays the state of the during the ISSU process.
Step 3	Switch# show redundancy	Displays current or historical status, mode, and related redundancy information about the device.

This example shows how to display the state and the current status of the supervisor engine during the ISSU process:

```
Switch> enable
Switch# show issu state
Switch# show redundancy
```

Verifying Redundancy Mode Before Beginning the ISSU Process

Before you begin the ISSU process, verify the redundancy mode for the system and be sure to configure NSF and SSO.

The following example displays verification that the system is in SSO mode, that slot 1 is the active supervisor engine, and that slot 2 is the standby supervisor engine. Both supervisor engines are running the same Cisco IOS software image.

```
Switch# show redundancy states
    my state = 13 -ACTIVE
    peer state = 8  -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 1

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured)  = Stateful Switchover
Redundancy State               = Stateful Switchover
Maintenance Mode = Disabled
    Manual Swact = enabled
    Communications = Up

    client count = 39
    client_notification_TMR = 240000 milliseconds
        keep_alive TMR = 9000 milliseconds
        keep_alive count = 0
        keep_alive threshold = 18
        RF debug mask = 0x0

Switch# show redundancy
Redundant System Information :
-----
    Available system uptime = 1 minute
    Switchovers system experienced = 0
        Standby failures = 0
        Last switchover reason = none

        Hardware Mode = Duplex
    Configured Redundancy Mode = Stateful Switchover
```

```

Operating Redundancy Mode = Stateful Switchover
Maintenance Mode = Disabled
Communications = Up

Current Processor Information :
-----
      Active Location = slot 1
      Current Software state = ACTIVE
      Uptime in current state = 0 minutes
      Image Version = Cisco IOS Software, Catalyst 4500 L3 Switch Software
(cat4500-ENTSERVICES-M), Version 12.2(31)SGA, RELEASE SOFTWARE (fc1)
Technical Support: http://www.cisco.com/techsupport
Copyright (c) 1986-2006 by Cisco Systems, Inc.
Compiled Tue 05-Sep-06 16:16 by sanjdas
      BOOT = bootflash:old_image,1;
      Configuration register = 0x822

Peer Processor Information :
-----
      Standby Location = slot 2
      Current Software state = STANDBY HOT
      Uptime in current state = 1 minute
      Image Version = Cisco IOS Software, Catalyst 4500 L3 Switch Software
(cat4500-ENTSERVICES-M), Version 12.2(31)SGA, RELEASE SOFTWARE (fc1)
Technical Support: http://www.cisco.com/techsupport

      BOOT = bootflash:old_image,1;
      Configuration register = 0x822

```

Verifying the ISSU State Before Beginning the ISSU Process

Ensure that the active and standby supervisor engines are up and in ISSU Init state and that the boot variables are set and pointing to valid files.

The following example displays the ISSU state before the process begins:

```

Switch# show issu state detail
      Slot = 1
      RP State = Active
      ISSU State = Init
      Boot Variable = bootflash:old_image,1;
      Operating Mode = Stateful Switchover
      Primary Version = N/A
      Secondary Version = N/A
      Current Version = bootflash:old_image

      Slot = 2
      RP State = Standby
      ISSU State = Init
      Boot Variable = bootflash:old_image,1;
      Operating Mode = Stateful Switchover
      Primary Version = N/A
      Secondary Version = N/A
      Current Version = bootflash:old_image

```

The new version of the Cisco IOS software must be present on both of the supervisor engines. The directory information displayed for each of the supervisor engines (or supervisor engines) shows that the new version is present.

```

Switch# dir bootflash:
Directory of bootflash:/

```

```

5 -rwx      13636500   Sep 6 2006 09:32:33 +00:00  old_image
6 -rwx      13636500   Sep 6 2006 09:34:07 +00:00  new_image

61341696 bytes total (1111388 bytes free)

Switch# dir slavebootflash:
Directory of slavebootflash:/

4 -rwx      13636500   Sep 6 2006 09:40:10 +00:00  old_image
5 -rwx      13636500   Sep 6 2006 09:42:13 +00:00  new_image

61341696 bytes total (1116224 bytes free)

```

Loading New Cisco IOS Software on the Standby Supervisor Engine

This task describes how to use ISSU to load a new version of Cisco IOS software to the standby supervisor engine.

Prerequisites

- Ensure that the new version of Cisco IOS software image is already present in the file system of both the active and standby supervisor engines. Also ensure that appropriate boot parameters (BOOT string and config-register) are set for the standby supervisor engine.

Note The switch must boot with the BOOT string setting before the ISSU procedure is attempted.

Note **auto-boot** must be enabled for ISSU to succeed.

- Optionally, perform additional tests and commands to determine the current state of peers and interfaces for later comparison.
- Ensure the system (both active and standby supervisor engines) is in SSO redundancy mode. If the system is in RPR mode rather than SSO mode, you can still upgrade the system using the ISSU CLI commands, but the system experiences extended packet loss during the upgrade.

Refer to the *Stateful Switchover* document for more details on how to configure SSO mode on supervisor engines.

- For ISSU to function, the image names on the active and standby supervisor engines must match.

Perform this task at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# issu loadversion <i>active-slot</i> <i>active-image-new standby-slot standby-image-new</i> [forced]	Starts the ISSU process and (optionally) overrides the automatic rollback when the new Cisco IOS software version is detected to be incompatible. It may take several seconds after the issu loadversion command is entered for Cisco IOS software to load onto the standby supervisor engine and for the standby supervisor engine to transition to SSO mode. This causes the standby supervisor engine to reload with the new image. If you use the forced option, the standby supervisor engine is booted with the new image. After the image is loaded on the standby supervisor engine, if the image is incompatible, the system is forced to the RPR mode. Otherwise the system continues in the SSO mode.
Step 3	Switch# show issu state [detail]	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded and is in SSO mode. It may take several seconds after entering the issu loadversion command for Cisco IOS software to load onto the standby supervisor engine and the standby supervisor engine to transition to SSO mode. If you enter the show issu state command too quickly, you may not see the information you need.
Step 4	Switch# show redundancy [states]	Displays redundancy facility state information.

This example shows how to start the ISSU process, boot the standby supervisor engine in the Standby Hot state, and load the standby supervisor engine slot (2) with the new image:

```
Switch> enable
Switch# issu loadversion 1 bootflash:new_image 2 slavebootflash:new_image
Switch# show issu state detail
      Slot = 1
      RP State = Active
      ISSU State = Load Version
      Boot Variable = bootflash:old_image,12
      Operating Mode = Stateful Switchover
      Primary Version = bootflash:old_image
      Secondary Version = bootflash:new_image
      Current Version = bootflash:old_image

      Slot = 2
      RP State = Standby
      ISSU State = Load Version
      Boot Variable = bootflash:new_image,12;bootflash:old_image,12
      Operating Mode = Stateful Switchover
      Primary Version = bootflash:old_image
      Secondary Version = bootflash:new_image
      Current Version = bootflash:new_image
```

```

Switch# show redundancy states
    my state = 13 -ACTIVE
    peer state = 8  -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 1

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured)  = Stateful Switchover
Redundancy State               = Stateful Switchover
Maintenance Mode = Disabled
    Manual Swact = enabled
    Communications = Up

    client count = 39
    client_notification_TMR = 240000 milliseconds
        keep_alive TMR = 9000 milliseconds
        keep_alive count = 1
        keep_alive threshold = 18
        RF debug mask = 0x0

```

The following example shows how the forced option places the system in RPR mode:

```

Switch> enable
Switch# issu loadversion 1 bootflash:new_image 2 slavebootflash:new_image forced
Switch# show issu state detail
    Slot = 1
        RP State = Active
        ISSU State = Load Version
        Boot Variable = bootflash:old_image,12
        Operating Mode = RPR
        Primary Version = bootflash:old_image
        Secondary Version = bootflash:new_image
        Current Version = bootflash:old_image

    Slot = 2
        RP State = Standby
        ISSU State = Load Version
        Boot Variable = bootflash:new_image,12;bootflash:old_image,12
        Operating Mode = RPR
        Primary Version = bootflash:old_image
        Secondary Version = bootflash:new_image
        Current Version = bootflash:new_image

```

The following example shows the redundancy mode as RPR:

```

Switch# show redundancy states
    my state = 13 -ACTIVE
    peer state = 4  -STANDBY COLD
        Mode = Duplex
        Unit = Primary
        Unit ID = 1

Redundancy Mode (Operational) = RPR
Redundancy Mode (Configured)  = Stateful Switchover
Redundancy State               = RPR
Maintenance Mode = Disabled
    Manual Swact = enabled
    Communications = Up

```

```

client count = 39
client_notification_TMR = 240000 milliseconds
keep_alive TMR = 9000 milliseconds
keep_alive count = 1
keep_alive threshold = 18
RF debug mask = 0x0

```

Switching to the Standby Supervisor Engine

This task describes how to switchover to the standby supervisor engine, which is running the new Cisco IOS software image.

Perform this task at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# issu runversion <i>standby-slot</i> <i>[standby-image-new]</i>	Forces a switchover from the active to the standby supervisor engine and reloads the former active (current standby) supervisor engines with the old image. When you enter the issu runversion command, an SSO switchover is performed, and NSF procedures are invoked if configured.
Step 3	Switch# show issu state <i>[detail]</i>	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that a switchover occurs to slot 2.
Step 4	Switch# show redundancy <i>[states]</i>	Displays redundancy facility state information.

This example shows how to cause a switchover to the former standby supervisor engine (slot 2), reset the former active supervisor engine and reload it with the old image so it becomes the standby supervisor engine:

```

Switch> enable
Switch# issu runversion 2 slavebootflash:new_image
This command will reload the Active unit. Proceed ? [confirm]

```

A switchover occurs at this point. At the new active supervisor engine, after old active supervisor engine comes up as the standby engine, do the following:

```

Switch# show issu state detail
      Slot = 2
      RP State = Active
      ISSU State = Run Version
      Boot Variable = bootflash:new_image,12;bootflash:old_image,12
      Operating Mode = Stateful Switchover
      Primary Version = bootflash:new_image
      Secondary Version = bootflash:old_image
      Current Version = bootflash:new_image

      Slot = 1
      RP State = Standby
      ISSU State = Run Version

```

```

Boot Variable = bootflash:old_image,12
Operating Mode = Stateful Switchover
Primary Version = bootflash:new_image
Secondary Version = bootflash:old_image
Current Version = bootflash:old_image

```

**Note**

The new active supervisor engine is now running the new version of software, and the standby supervisor engine is running the old version of software and is in the standby hot state.

```
Switch# show redundancy states
```

```

my state = 13 -ACTIVE
peer state = 8 -STANDBY HOT
Mode = Duplex
Unit = Secondary
Unit ID = 2

```

```

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
Redundancy State = Stateful Switchover
Maintenance Mode = Disabled
Manual Swact = enabled
Communications = Up

```

```

client count = 39
client_notification_TMR = 240000 milliseconds
keep_alive TMR = 9000 milliseconds
keep_alive count = 1
keep_alive threshold = 18
RF debug mask = 0x0

```

Once **runversion** command completes, the new active supervisor engine is running the new version of software and the previously active supervisor engine now becomes the standby supervisor engine. The standby is reset and reloaded, but remains on the previous version of software and come back online in standbyhot status. The following example shows how to verify these conditions:

```
Switch# show redundancy
```

```
Redundant System Information :
```

```

-----
Available system uptime = 23 minutes
Switchovers system experienced = 1
Standby failures = 0
Last switchover reason = user forced

```

```

Hardware Mode = Duplex
Configured Redundancy Mode = Stateful Switchover
Operating Redundancy Mode = Stateful Switchover
Maintenance Mode = Disabled
Communications = Up

```

```
Current Processor Information :
```

```

-----
Active Location = slot 2
Current Software state = ACTIVE
Uptime in current state = 11 minutes
Image Version = Cisco IOS Software, Catalyst 4500 L3 Switch Software
(cat4500-ENTSERVICES-M), Version 12.2(31)SGA, RELEASE SOFTWARE (fc1)
Technical Support: http://www.cisco.com/techsupport

BOOT = bootflash:old_image,12
Configuration register = 0x822

```

Stopping the ISSU Rollback Timer (Optional)

This optional task describes how to stop the rollback timer.

If you do not run the following procedure before the rollback timer “timeout,” the system automatically aborts the ISSU process and reverts to the original Cisco IOS software version. By default the rollback timer is 45 minutes.

Use the following information to decide what action you should take:

- If you want to retain your switch in this state for an extended period, you need to stop the rollback timer (then validate and run the **acceptversion** command directly).
- If you want to proceed to the following step (running “commitversion”) within the rollback timer window of 45 minutes, you do not need to stop the rollback timer.

**Note**

The **issu acceptversion** command can be optionally executed after the **issu runversion** command.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	Switch# issu acceptversion active-slot [active-image-new]	Halts the rollback timer and ensures the new Cisco IOS ISSU process is not automatically aborted during the ISSU process. Enter the issu acceptversion command within the time period specified by the rollback timer to acknowledge that the supervisor engine has achieved connectivity to the outside world; otherwise, the ISSU process is terminated, and the system reverts to the previous version of Cisco IOS software by switching to the standby supervisor engine.
Step 3	Switch# show issu rollback-timer	Displays the amount of time left before an automatic rollback occurs.

This example displays the timer before you stop it. In the following example, the Automatic Rollback Time information indicates the amount of time remaining before an automatic rollback occurs.

```

Switch> enable
Switch# show issu rollback-timer
Rollback Process State = In progress

```

```
Configured Rollback Time = 45:00
Automatic Rollback Time = 38:30

Switch# issu acceptversion 2 bootflash:new_image
% Rollback timer stopped. Please issue the commitversion command.
Switch# show issu rollback-timer
Rollback Process State = Not in progress
Configured Rollback Time = 45:00
```

Loading New Cisco IOS Software on the New Standby Supervisor Engine

This task explains how to load new version of Cisco IOS software to the new standby supervisor engine. Perform this task at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	Switch# issu commitversion <i>standby-slot-number</i> [<i>standby-image-new</i>]	Allows the new Cisco IOS software image to be loaded into the standby supervisor engine.
Step 3	Switch# show redundancy [states]	Displays redundancy facility state information.
Step 4	Switch# show issu state [detail]	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that a switchover occurs to slot 2.

This example shows how to reset and reload the current standby supervisor engine (slot 1) with the new Cisco IOS software version. After entering the **commitversion** command, the standby supervisor engine boots in the Standby Hot state.

```
Switch> enable
Switch# issu commitversion 1 slavebootflash:new_image
```

Wait till standby supervisor is reloaded with the new image. Then apply the following:

```
Switch# show redundancy states
00:17:12: %RF-5-RF_TERMINAL_STATE: Terminal state reached for (SSO)
    my state = 13 -ACTIVE
    peer state = 8  -STANDBY HOT
        Mode = Duplex
        Unit = Secondary
        Unit ID = 2

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured)  = Stateful Switchover
Redundancy State               = Stateful Switchover
Maintenance Mode = Disabled
    Manual Swact = enabled
    Communications = Up

    client count = 39
    client_notification_TMR = 240000 milliseconds
        keep_alive TMR = 9000 milliseconds
            keep_alive count = 0
            keep_alive threshold = 18
            RF debug mask = 0x0
```

```

Switch# show redundancy
Redundant System Information :
-----
    Available system uptime = 41 minutes
Switchovers system experienced = 1
    Standby failures = 1
    Last switchover reason = user forced

    Hardware Mode = Duplex
Configured Redundancy Mode = Stateful Switchover
Operating Redundancy Mode = Stateful Switchover
    Maintenance Mode = Disabled
    Communications = Up

    Primary Version = N/A
    Secondary Version = N/A
    Current Version = bootflash:new_image

    Slot = 1
    RP State = Standby
    ISSU State = Init
    Boot Variable = bootflash:new_image,12;bootflash:old_image,1;
    Operating Mode = Stateful Switchover
    Primary Version = N/A
    Secondary Version = N/A
    Current Version = bootflash:new_image

```

The ISSU process has been completed. At this stage, any further Cisco IOS software version upgrade or downgrade requires that a new ISSU process be invoked.

Using changeversion to Automate an ISSU Upgrade

This task describes how to use the **issu changeversion** command to perform a one step ISSU upgrade.

Prerequisites

- Ensure that the new version of Cisco IOS software image is already present in the file system of both the active and standby supervisor engines. Also ensure that appropriate boot parameters (BOOT string and config-register) are set for the active and standby supervisor engines
- Optionally, perform additional tests and commands to determine the current state of peers and interfaces for later comparison.
- Ensure the system (both active and standby supervisor engines) is in SSO redundancy mode. If the system is in RPR mode, you can still upgrade the system using the ISSU CLI commands, but the system will experience extended packet loss during the upgrade.'

Refer to the Stateful Switchover document for more details on how to configure SSO mode on supervisor engines (refer to [Chapter 11, “Configuring Supervisor Engine Redundancy Using RPR and SSO on Supervisor Engine 6-E and Supervisor Engine 6L-E”](#)).

- For ISSU to function, the IOS XE software image file names on the active and standby supervisor engines must match.

Perform the following steps at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu changeversion [<i>active-slot</i> <i>active-image-new</i>] [<i>standby-slot</i> <i>standby-image-new</i>] [at <i>hh:mm</i> in <i>hh:mm</i>] [quick]	Initiates a single-step complete upgrade process cycle. Performs the logic of the four standard commands (issu loadversion, issu runversion, issu acceptversion, and issu commitversion) without user intervention. <i>active-slot</i> —Defines the active slot number. <i>new-image</i> —Specifies IOS XE image URL to be upgraded to. <i>standby-slot</i> —Defines the standby slot number. <i>standby-image</i> —Specifies the standby IOS XE image URL. at <i>hh:mm</i> —Schedules an ISSU upgrade to begin in the future. Provides an exact time (<i>hh:mm</i> , 24 hour format) in the next 24 hours when the upgrade will occur. in <i>hh:mm</i> —Schedules an ISSU upgrade to begin in the future. Provides the number of hours and minutes (<i>hh:mm</i> format) that will elapse before an upgrade will occur (99:59 max). quick —Upon switchover, boots the standby supervisor engine with the new, rather than old, image for faster upgrade.

	Command or Action	Purpose
Step 3	Switch# show issu state [detail]	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded and is in SSO mode.
Step 4	Switch# show redundancy [states]	Displays redundancy facility state information.

This example shows how to initiate an ISSU upgrade process using the `issu changeversion` command on slot number 5, the slot for the current active supervisor engine. The `show issu state detail` and `show redundancy` command output is included to show the supervisor state before and after the upgrade procedure.

**Note**

The success messages included in the output below is displayed after some delay because the ISSU upgrade procedure progresses through the ISSU states.

```
Switch> enable
Switch# show issu state detail

Aborting a Software Upgrade During ISSU

You can abort the ISSU process at any stage manually (prior to entering the **issu commitversion** command) by entering the **issu abortversion** command. The ISSU process also aborts on its own if the software detects a failure.

Note

If you enter the **issu abortversion** command before the standby supervisor engine becomes hot, the traffic might be disrupted.

If you abort the process after you enter the **issu loadversion** command, the standby supervisor engine is reset and reloaded with the original software.

If the process is aborted after you enter either the **issu runversion** or **issu acceptversion** command, then a second switchover is performed to the new standby supervisor engine that is still running the original software version. The supervisor engine that had been running the new software is reset and reloaded with the original software version.

Note

Ensure that the standby supervisor engine is fully booted *before* entering the **abortversion** command on an active supervisor engine.

The following task describes how to abort the ISSU process before you complete the ISSU process with the **issu commitversion** command.

Perform the following task on the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# issu abortversion <i>active slot</i> <i>[active-image-new]</i>	Cancels the ISSU upgrade or downgrade process in progress and restores the router to its state before the process had started.

This example shows how to abort the ISSU process on slot number 2, the slot for the current active supervisor engine:

```

Switch> enable
Switch# issu abortversion 2

```

Configuring the Rollback Timer to Safeguard Against Upgrade Issues

Cisco IOS software maintains an ISSU rollback timer, to safeguard against an upgrade that may leave the new active supervisor engine in a state in which communication with the standby supervisor engine is severed.

You may want to configure the rollback timer to fewer than 45 minutes (the default) so that the user need not wait in case the new software is not committed or the connection to the switch was lost while it was in runversion mode. A user may want to configure the rollback timer to more than 45 minutes in order to have enough time to verify the operation of the new Cisco IOS software before committing the new image.

Note

The valid timer value range is from 0 to 7200 seconds (two hours). A value of 0 seconds disables the rollback timer.

Once you are satisfied that the ISSU process has been successful and you want to remain in the current state, you must indicate acceptance by entering the **issu acceptversion** command, which stops the rollback timer. Entering the **issu acceptversion** command is extremely important in advancing the ISSU process.

Entering the **issu commitversion** command at this stage is equal to entering both the **issu acceptversion** and the **issu commitversion** commands. Use the **issu commitversion** command if you do not intend to run in the current state now and are satisfied with the new software version.

Note

The rollback timer can be configured only in the ISSU Init state.

Perform this task to configure the rollback timer:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# issu set rollback-timer <i>hh:mm:ss</i>	Configures the rollback timer value.
Step 4	Switch(config)# exit	Returns the user to privileged EXEC mode.
Step 5	Switch# show issu rollback-timer	Displays the current setting of the ISSU rollback timer.

This example shows how to set the rollback timer to 3600 seconds:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# issu set rollback-timer 3600
% Rollback timer value set to [ 3600 ] seconds

Switch(config)# exit

Switch# show issu rollback-timer
Rollback Process State = Not in progress
Configured Rollback Time = 60:00
```

The rollback timer cannot be set in LV state, as the following example illustrates:

```
Switch# show issu state detail
      Slot = 1
      RP State = Active
      ISSU State = Load Version
      Boot Variable = bootflash:old_image,12
      Operating Mode = RPR
      Primary Version = bootflash:old_image
      Secondary Version = bootflash:new_image
      Current Version = bootflash:old_image

      Slot = 2
      RP State = Standby
      ISSU State = Load Version
      Boot Variable = bootflash:new_image,12;bootflash:old_image,12
      Operating Mode = RPR
      Primary Version = bootflash:old_image
      Secondary Version = bootflash:new_image
      Current Version = bootflash:new_image

Switch# show issu rollback-timer
      Rollback Process State = Not in progress
      Configured Rollback Time = 60:00

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# issu set rollback-timer 20
% ISSU state should be [ init ] to set the rollback timer
```

Displaying ISSU Compatibility Matrix Information

The ISSU compatibility matrix contains information about other software images about the version in question. This compatibility matrix represents the compatibility of the two software versions, one running on the active and the other on the standby supervisor engine, and the matrix allows the system to determine the highest operating mode it can achieve. This information helps the user identify whether to use ISSU.

Perform this task to display information about the ISSU compatibility matrix:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# show issu comp-matrix { negotiated stored xml }	Displays information regarding the ISSU compatibility matrix. <ul style="list-style-type: none"> negotiated—Displays negotiated compatibility matrix information. stored—Displays negotiated compatibility matrix information. xml—Displays negotiated compatibility matrix information in XML format.

This example shows how to display negotiated information regarding the compatibility matrix:

```
Switch> enable
Switch# show issu comp-matrix negotiated
```

```
CardType: WS-C4507R(112), Uid: 2, Image Ver: 12.2(31)SGA
Image Name: cat4500-ENTSERVICES-M
```

12.2(50)SG3       Dynamic(0)
12.2(53)SG        Comp(3)

```

Dynamic(0) was introduced in Cisco IOS Release 12.2(50)SG with the Dynamic Image Version Compatibility (DIVC) feature. With DIVC, Dynamic(0) is stored instead of Incomp(1), Base(2), or Comp(3). Compatibility is determined during runtime when two different DIVC-capable images are running in the active and standby supervisor engines during ISSU.

For Catalyst 4500 switches, a value of Dynamic(0) in the stored compatibility-matrix normally results in Base(2) or Comp(3) upon rollback negotiation between the two images. You never observe Incomp(1) as long as the other image name is present in the stored compatibility matrix.

Displaying ISSU Compatibility Matrix Information

The ISSU compatibility matrix contains information about other IOS XE software releases and the version in question. This compatibility matrix represents the compatibility of the two software versions, one running on the active and the other on the standby supervisor engine, and the matrix allows the system to determine the highest operating mode it can achieve. This information helps the user identify whether to use ISSU.

This task shows how to display information about the ISSU compatibility matrix:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# show issu comp-matrix { negotiated stored xml }	Displays information regarding the ISSU compatibility matrix. <ul style="list-style-type: none"> • negotiated—Displays negotiated compatibility matrix information. • stored—Displays negotiated compatibility matrix information. • xml—Displays negotiated compatibility matrix information in XML format. <p>Note These commands display only the data within IOSd process. Use the show package compatibility to display the information for the whole system.</p>
Step 3	Switch# show package compatibility	Displays information regarding all client compatibility in the system.

This example shows how to display negotiated information regarding the compatibility matrix:

```
Switch> enable
Switch# show issu comp-matrix negotiated

Configuring the Cisco IOS XE In Service Software Upgrade Process

Note

An ISSU upgrade from any release prior to IOS XE 3.6.0E to 3.6.0E or later is unsupported for IOS XE supervisor engines (Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E).

Note

Refer to [Chapter 5, “Configuring Virtual Switching Systems”](#) for details on VSS ISSU.

Note

ISSU is available in Cisco IOS XE Release 3.1.0.SG and later releases.

Operating on redundant systems, the In Service Software Upgrade (ISSU) process allows Cisco IOS XE software to be updated or otherwise modified while packet forwarding continues. In most networks, planned software upgrades are a significant cause of downtime. ISSU allows Cisco IOS XE software to be upgraded while packet forwarding continues. This increases network availability and reduces downtime caused by planned software upgrades. This document provides information about ISSU concepts and describes the steps taken to perform ISSU in a system.

Topics include:

- [Prerequisites to Performing ISSU, page 8-2](#)
- [About Performing ISSU, page 8-3](#)
- [How to Perform the ISSU Process, page 8-16](#)
- [Cisco High Availability Features in Cisco IOS XE 3.1.0SG, page 8-41](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Prerequisites to Performing ISSU

Before performing ISSU, you must meet these prerequisites:

- A permanent “ISSU barrier” exists between pre-IOS XE 3.6.0E and IOS XE 3.6.0 releases: ISSU is supported between versions on the same side of the barrier but it is not supported between versions on opposite sides.

Note

This restriction applies to Catalyst 4500X in a VSS, as well as to Supervisor Engine 7E, Supervisor Engine 7LE, and Supervisor Engine 8E in a VSS or in a redundant chassis.

Four scenarios will illustrate the restriction:

If you are running a release prior to IOS XE 3.6.0E (3.5.1E, for example), you cannot perform an ISSU upgrade to IOS XE 3.6.0E.

If you are running IOS XE 3.6.0E, you cannot perform an ISSU downgrade to IOS XE 3.5.0E.

If you are running IOS XE 3.6.0E, you can perform an ISSU upgrade to IOS XE 3.6.1E (when released).

If you are running a release after IOS XE 3.6.0E (for example, 3.7.0, when released), you cannot perform an ISSU downgrade to IOS XE 3.5.0E.

- The type of the existing and target image must match. You cannot upgrade from a Universal Lite image to a Universal image (and vice versa) without experiencing several minutes of traffic loss. The same restriction applies between crypto and non-crypto images.
- The active and the standby supervisor engines must have the same supervisor engine hardware (same model, same memory, and so on).
- The new and old Cisco IOS XE software images must be loaded into the file systems (bootflash, SD card, or USB) of both the active and the standby supervisor engines before you begin the ISSU process.

The old software image should be available either in bootflash, SD card, or USB and the system should have been booted from one of these locations because the boot variable must be changed before the ISSU process starts.

Note **auto-boot** must be enabled for ISSU to succeed.

- Stateful Switchover (SSO) must be configured and the standby supervisor engine should be in STANDBY HOT state.

These commands indicate whether SSO is enabled: **show module**, **show running-config**, **show redundancy state**.

If you do not have SSO enabled, see the *Stateful Switchover* document for further information on how to enable and configure SSO.

- Nonstop Forwarding (NSF) must be configured and working properly. If you do not have NSF enabled, see the *Cisco Nonstop Forwarding* document for further information on how to enable and configure NSF.
- Before you perform ISSU, ensure that the file system for both the active and the standby supervisor engines contains the new ISSU-compatible IOS XE software. The current Cisco IOS XE version running in the system must also support ISSU.

You can enter various commands on the Catalyst 4500 series switch to determine supervisor engine versioning and Cisco IOS XE software compatibility. Alternatively, you can use the ISSU application on Cisco Feature Navigator to determine this.

- If you enter the **no ip routing** command, ISSU falls back from SSO to RPR mode, resulting in traffic loss.
- Autoboot is turned on and the current booted image matches the one specified in the BOOT environmental variable. For details on how to configure and verify these, please refer to "[Modifying the Boot Field and Using the boot Command](#), page 3-28.
- If you enter the **no ip routing** command, ISSU falls back from SSO to RPR mode, resulting in traffic loss.

About Performing ISSU

Note Do not make any hardware changes while performing ISSU.

Before you perform ISSU, you should understand the following concepts:

- [Stateful Switchover](#), page 8-4
- [NSF](#), page 8-6
- [ISSU Process](#), page 8-7
- [Performing an ISSU Upgrade: 2 Methods](#), page 8-12
- [Changeversion Process](#), page 8-13
- [Guidelines for Performing ISSU](#), page 8-14
- [Compatibility Matrix](#), page 8-14
- [SNMP Support for ISSU](#), page 8-15
- [Compatibility Verification Using Cisco Feature Navigator](#), page 8-15

Stateful Switchover

Development of the SSO feature is an incremental step within an overall program to improve the availability of networks constructed with Cisco IOS XE switches.

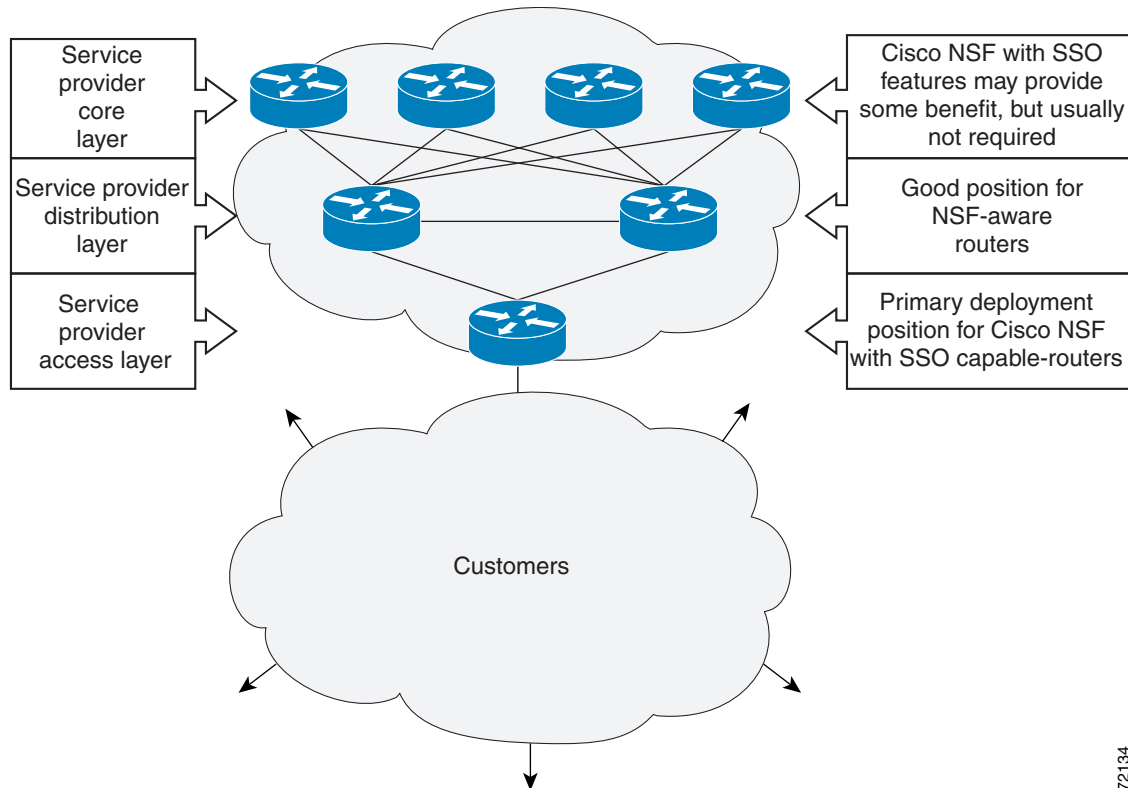

In specific Cisco networking devices that support dual supervisor engines, SSO takes advantage of supervisor engine redundancy to increase network availability. SSO achieves this by establishing one of the supervisor engines as the active processor while the other supervisor engine is designated as the standby processor. Following an initial synchronization between the two supervisor engines, SSO dynamically synchronizes supervisor engine state information between them in real-time.

A switchover from the active to the standby supervisor engine occurs when the active supervisor engine fails or is removed from the networking device.

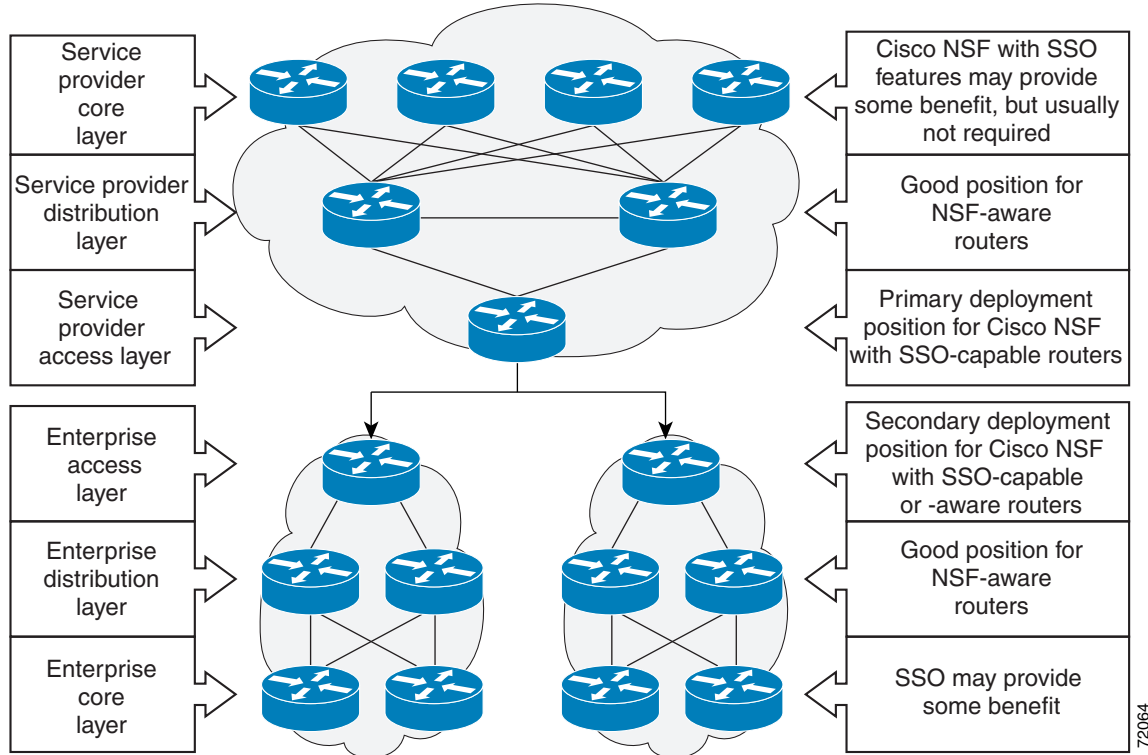

Cisco NSF is used with SSO. Cisco NSF allows the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. With Cisco NSF, peer networking devices do not experience routing flaps, which reduce loss of service outages for customers.

[Figure 8-1](#) illustrates how SSO is typically deployed in service provider networks. In this example, Cisco NSF with SSO is enabled at the access layer (edge) of the service provider network. A fault at this point could result in loss of service for enterprise customers requiring access to the service provider network.

For Cisco NSF protocols that require neighboring devices to participate in Cisco NSF, Cisco NSF-aware software images must be installed on those neighboring distribution layer devices. Depending on your objectives, you may decide to deploy Cisco NSF and SSO features at the core layer of your network. Doing this can help reduce the time required to restore network capacity and service for certain failures, which leads to additional availability.

Figure 8-1 Cisco NSF with SSO Network Deployment: Service Provider Networks

Additional levels of availability may be gained by deploying Cisco NSF with SSO at other points in the network where a single point of failure exists. [Figure 8-2](#) illustrates an optional deployment strategy that applies Cisco NSF with SSO at the enterprise network access layer. In this example, each access point in the enterprise network represents another single point of failure in the network design. In the event of a switchover or a planned software upgrade, enterprise customer sessions would continue uninterrupted through the network in this example.

Figure 8-2 Cisco NSF with SSO Network Deployment: Enterprise Networks

For further information on SSO, see the *Stateful Switchover* document.

NSF

Cisco NSF works with the SSO feature in Cisco IOS XE software. SSO is a prerequisite of Cisco NSF. NSF works with SSO to minimize the amount of time a network is unavailable to its users following a switchover. The main objective of Cisco NSF is to continue forwarding IP packets following a supervisor engine switchover.

Usually, when a networking device restarts, all routing peers of that device detect that the device went down and then came back up. This transition results in what is called a routing flap, which could spread across multiple routing domains. Routing flaps caused by routing restarts create routing instabilities, which are detrimental to the overall network performance. Cisco NSF helps to suppress routing flaps in SSO-enabled devices, thus reducing network instability.

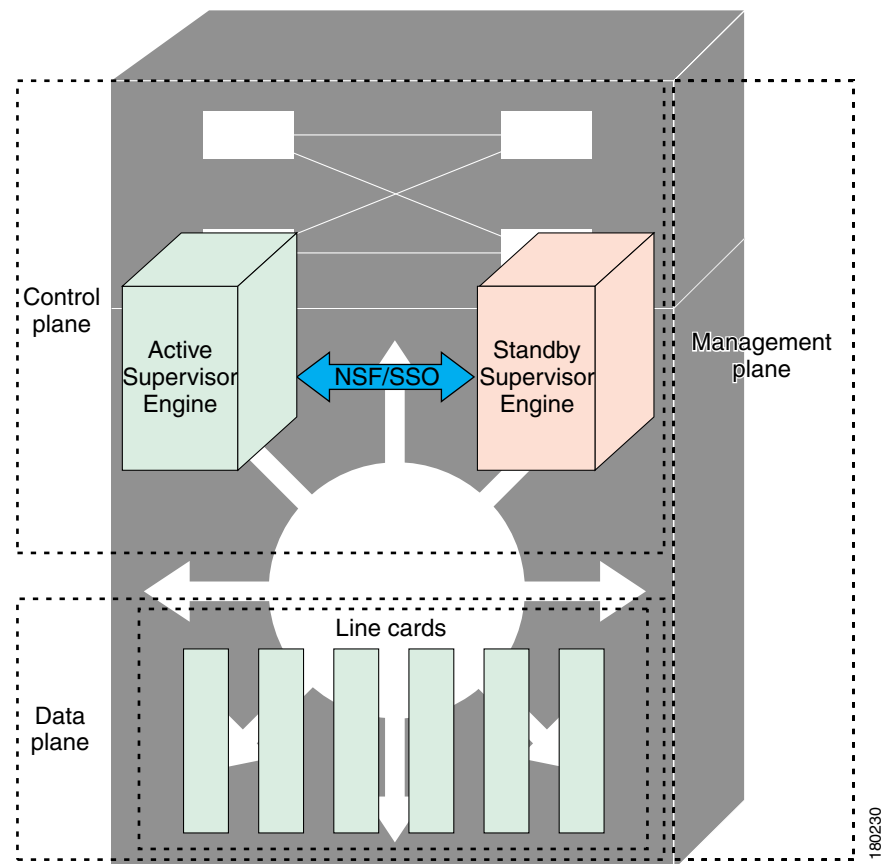

Cisco NSF allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. With Cisco NSF, peer networking devices do not experience routing flaps. Data traffic is forwarded while the standby supervisor engine assumes control from the failed active supervisor engine during a switchover. The ability of physical links to remain up through a switchover and to be kept current with the Forwarding Information Base (FIB) on the active supervisor engine is key to Cisco NSF operation.

ISSU Process

The ISSU process allows you to perform a Cisco IOS XE software upgrade or downgrade while the system continues to forward packets. (For an illustration of the commands used during the ISSU process, refer to [Figure 8-8](#).) Cisco IOS XE ISSU takes advantage of the Cisco IOS XE high availability infrastructure—Cisco NSF with SSO and hardware redundancy—and eliminates downtime associated with software upgrades by allowing changes while the system remains in service (see [Figure 8-3](#)).

SSO and NSF mode support configuration and runtime state synchronization from the active to the standby supervisor engine. For this process, the IOS XE software image on both the active and the standby supervisor engines must be the same. When images on active and standby supervisor engines are different, ISSU allows the two supervisor engines to be kept in synchronization even when these two versions of Cisco IOS XE support different sets of features and commands.

Figure 8-3 High Availability Features and Hardware Redundancy in the ISSU Process

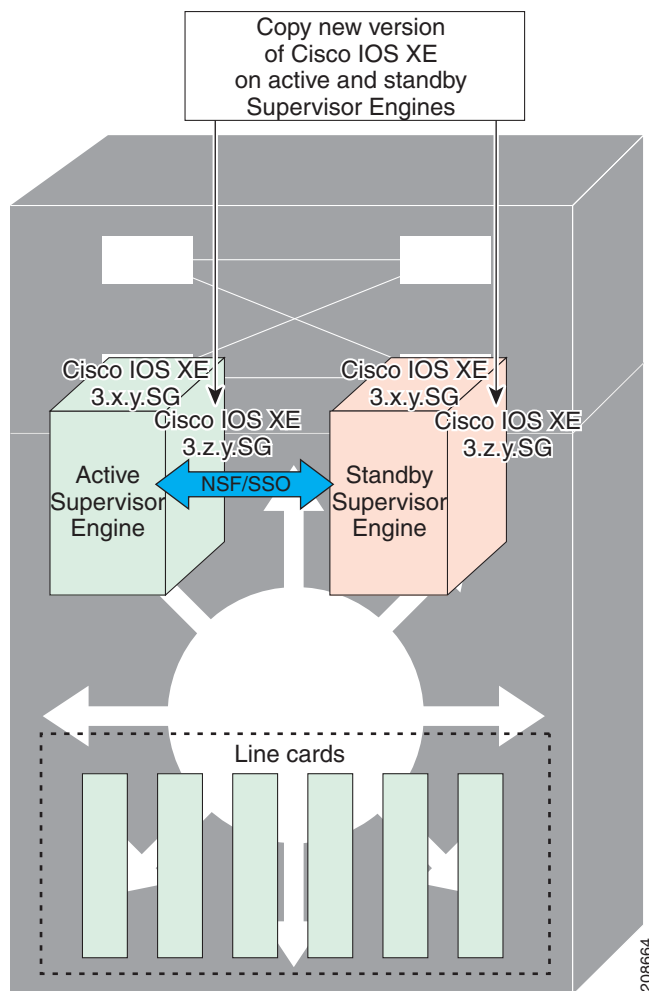

An ISSU-capable switch consists of two supervisor engines (active and standby) and 200 or more linecards. Before initiating the ISSU process, copy the Cisco IOS XE software into the file systems of both supervisor engines (see [Figure 8-4](#)).

**Note**

In the following figure, Cisco IOS XE 3.x.y SG represents the *current* version of Cisco IOS XE 3.z.y SG represents the image you are migrating to.

Figure 8-4 Copy New Version of Cisco IOS XE Software on Both Supervisor Engines

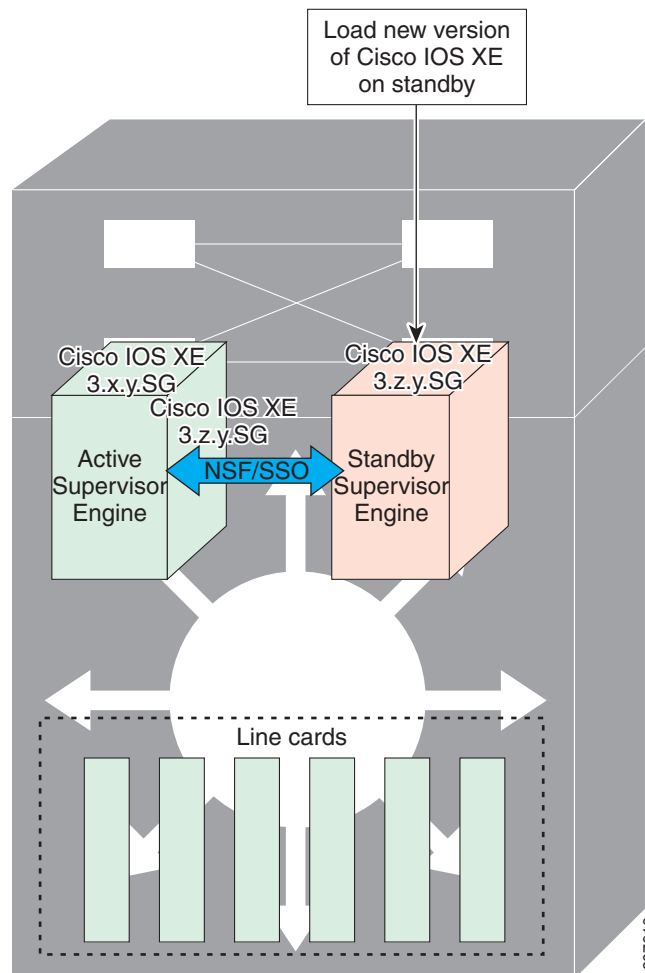

After you have copied the Cisco IOS XE software to both file systems, load the new version of Cisco IOS XE software onto the standby supervisor engine (see [Figure 8-5](#)).

**Note**

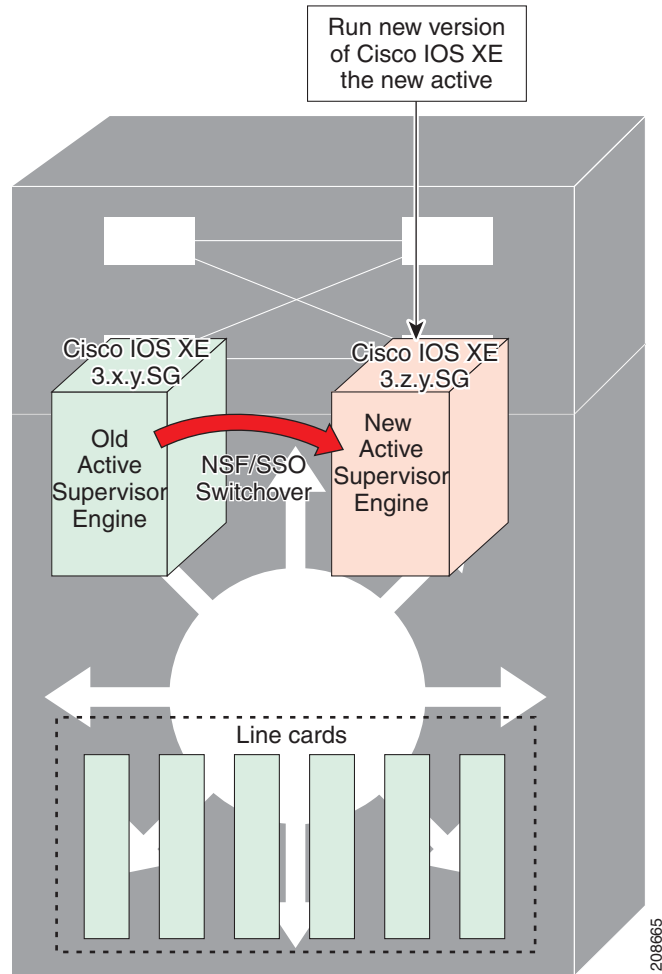

Without the ISSU feature, SSO/NSF cannot function between the active and standby supervisor engines when they are running different versions of the Cisco IOS XE image.

Figure 8-5 Load New Version of Cisco IOS XE Software on the Standby Supervisor Engine

After a switchover (NSF/SSO, not RPR), the standby supervisor engine takes over as the new active supervisor engine (see [Figure 8-6](#)).

Figure 8-6 **Switch Over to Standby Supervisor Engine**

The former active supervisor engine is loaded with an old Cisco IOS XE image so that if the new active supervisor engine experiences problems, you can abort and conduct a switchover to the former active, which is already running the old software image. Next, the former active supervisor engine is loaded with the new version of Cisco IOS XE software and becomes the new standby supervisor engine (see [Figure 8-7](#)).

Figure 8-7 Load New Standby Supervisor Engine with New Cisco IOS XE Software

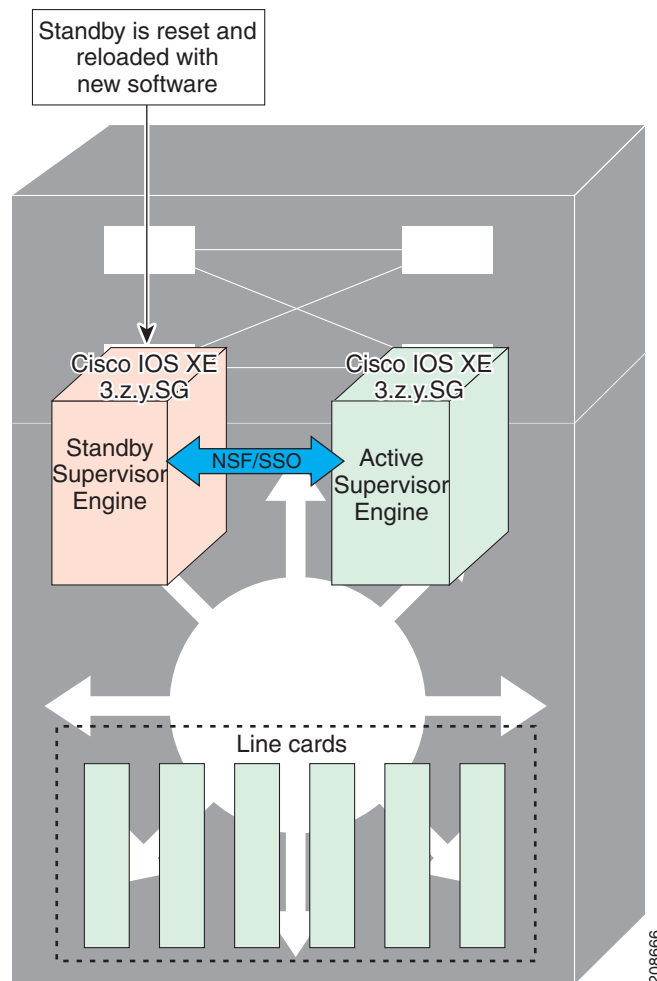

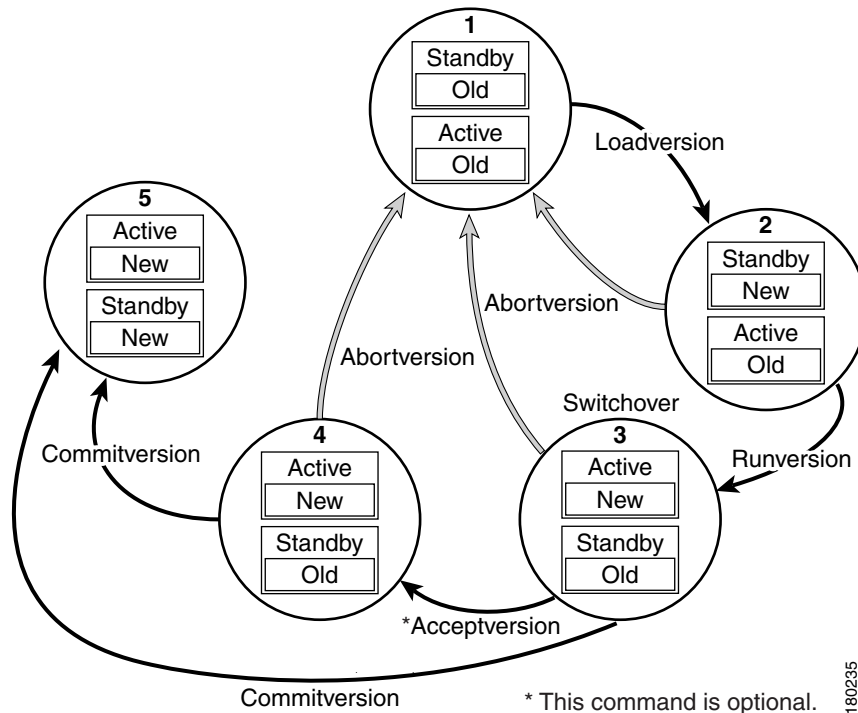

Figure 8-8 shows the steps during the ISSU process.

Figure 8-8 Steps During the ISSU Process

Note **Accept version** stops the rollback timer.

Performing an ISSU Upgrade: 2 Methods

There are two ways to perform an ISSU upgrade: manually, with four commands; or automatically, with one command.

The normal ISSU upgrade process involves issuing four separate ISSU exec commands (**issu loadversion**, **issu runversion**, **issu acceptversion**, **issu commitversion**) along with additional show command invocations to evaluate the success of each command before proceeding. Although the ISSU process is complicated, you should not expect disruption of service. The use of multiple ISSU commands dictates an additional level of care to ensure no service disruption. However, in some scenarios, this upgrade procedure might be cumbersome and of minimal value. A typical example is during a network upgrade that involves performing an ISSU upgrade on a large number of Catalyst 4500 switches. In these cases, we recommend that you first perform the normal (four command) ISSU upgrade procedure on one switch (possibly in a lab environment) to verify successful upgrade. Then, use a single **issu changeversion** command to perform an automatic ISSU on the rest of the Catalyst 4500 switches in the network.

Changeversion Process

The **issu changeversion** command launches a single-step complete ISSU upgrade cycle. It performs the logic for all four of the standard commands (**issu loadversion**, **issu runversion**, **issu acceptversion**, and **issu commitversion**) without user intervention, streamlining the upgrade through a single CLI step.

Additionally, **issu changeversion** allows the upgrade process to be scheduled for a future time. This enables you to stage a number of systems to perform upgrades sequentially when a potential disruption would be least harmful.

After the standby supervisor engine initializes and the system reaches a terminal state (RPR/SSO), the upgrade process is complete and the BOOT variable is permanently written with the new IOS XE software image. Hence, a reset on any RP will keep the system booting the new software image. Console and syslog messages will be generated to notify anyone monitoring the upgrade that the state transition has occurred.

Similar to the normal ISSU upgrade procedure, the in-progress upgrade procedure initiated by the **issu changeversion** command can be aborted with the **issu abortversion** command. If the system detects any problems or detects an unhealthy system during an upgrade, the upgrade might be automatically aborted.

When the **issu runversion** command is entered during the four step manual upgrade process, if any incompatible ISSU clients exist, the upgrade process reports them and their side effects, and allows the user to abort the upgrade. While performing a single-step upgrade process, when the process reaches the runversion state, it will either automatically continue with the upgrade provided the base clients are compatible, or automatically abort because of client incompatibility. If the user wants to continue the upgrade procedure in RPR mode, the user must use the normal ISSU command set and specify the **force** option when entering the **issu loadversion** command.

Changeversion: Quick Option (LV to INIT)

The **issu changeversion** command provides an optional quick command option that can reduce the time required to perform the automatic ISSU upgrade.

When the **quick** command option is applied, the ISSU upgrade state transition differs from that described previously. With this option, the software logic at the loadversion stage remains the same as previously described, and the logic that performs runversion and commitversion is combined. This logic skips the step in the upgrade procedure that loads the old software version on the new standby (old active) supervisor, instead, the new software image is uploaded on the new standby (old active).

This reduces the time required for the automatic ISSU upgrade by about a third (it saves one extra reload time).

Scheduled Changeversion: “in” and “at” Options

issu changeversion provides **in** and **at** command options that enable you to schedule a future automatic ISSU upgrade.

The **at** command option schedules an automatic ISSU upgrade to begin at a specific time. This option specifies an exact time (*hh:mm*, 24 hour format) in the next 24 hours at which the upgrade will occur.

The **in** command option schedules an automatic ISSU upgrade to begin after a certain amount of time has elapsed. This option specifies the number of hours and minutes (*hh:mm* format) that must elapse before an upgrade will occur, with a maximum value of 99:59.

Changeversion Deployment Scenario

The typical **issu changeversion** command usage scenario is for experienced users with a large installed base. These users typically validate a new image using a topology and configuration similar to their production network. The validation process should be done using both the existing multi-command process and the new **issu changeversion** command process. Once users certify an IOS XE software image and want to roll it out broadly, they can use the single command process to perform an efficient upgrade of their network.

Aborting an In-Progress Changeversion Procedure

The **issu changeversion** command functionality is designed to perform an ISSU software upgrade without user intervention. However, status messages are displayed to the console as the upgrade transitions through the various states. If any anomalies are noticed during the automatic upgrade, perhaps with peers or other parts of the network, you can use the **issu abortversion** command to manually abort the upgrade at any point in the process prior to the commitversion operation.

Guidelines for Performing ISSU

Be aware of the following guidelines while performing the ISSU process:

- Even with ISSU, it is recommended that upgrades be performed during a maintenance window.
- The new features should not be enabled (if they require change of configuration) during the ISSU process.

Note

Enabling them will cause the system to enter RPR mode because commands are only supported on the new version.

- In a downgrade scenario, if any feature is not available in the downgrade revision of the Cisco IOS XE software handle, that feature should be disabled prior to initiating the ISSU process.

Compatibility Matrix

ISSU requires additional information to determine compatibility between software versions. Therefore, a compatibility matrix is defined that contains information about other IOS XE software image with respect to the one in question.

This compatibility matrix represents the compatibility of two software versions, one running on the active and the other on the standby supervisor engine, and to allow the system to determine the highest operating mode it can achieve. Incompatible versions will not be able to progress to SSO operational mode.

The compatibility matrix represents the compatibility relationship a Cisco IOS XE software image has with all of the other Cisco IOS XE software versions within the designated support window (for example, all of those software versions the IOS XE software image “knows” about) and is populated and released with every IOS XE software image. The matrix stores compatibility information between its own release and prior releases. It is always the newest release that contains the latest information about compatibility with existing releases in the field. The compatibility matrix is available within the Cisco IOS XE software image and on Cisco.com so that users can determine in advance whether an upgrade can be done using the ISSU process.

You can perform the ISSU process when the old and new Cisco IOS XE software are compatible. The compatibility matrix information stores the compatibility among releases as follows:

- **Compatible**—The base-level system infrastructure and all optional HA-aware subsystems are compatible. An in-service upgrade or downgrade between these versions will succeed with minimal service impact. The matrix entry designates the images to be compatible (C).
- **Base-level compatible**—One or more of the optional HA-aware subsystems is not compatible. An in-service upgrade or downgrade between these versions will succeed; however, some subsystems will not be able to maintain state always during the transition from the old to the new version of Cisco IOS XE. The matrix entry designates the images to be base-level compatible (B).
- **Incompatible**—A core set of system infrastructure exists in Cisco IOS XE that must be able to interoperate in a stateful manner for SSO to function correctly. If any of these required features or subsystems is not interoperable, then the two versions of the Cisco IOS XE software image are declared to be incompatible. An in-service upgrade or downgrade between these versions is not possible. The matrix entry designates the images to be incompatible (I). The system operates in RPR mode during the upgrade process when the versions of Cisco IOS XE at the active and standby supervisor engines are incompatible.
- Cisco IOS XE determines the compatibility between the active and the standby IOS XE software dynamically during STANDBY boot up. The matrix is represented by “x”.

To display the compatibility matrix data between two software versions on a given system, enter the **show issu comp-matrix stored** command.

**Note**

This command is useful *only for verification purposes* because it is available *only after* the ISSU process has started. You might want to check the compatibility matrix prior to starting ISSU. Use the Feature Navigator to obtain the needed information:

<http://tools.cisco.com/ITDIT/CFN/jsp/index.jsp>

SNMP Support for ISSU

SNMP for SSO provides a mechanism for synchronizing the SNMP configurations and the MIBs that support SSO from the active supervisor engine to the standby supervisor engine.

Compatibility Verification Using Cisco Feature Navigator

The ISSU application on Cisco Feature Navigator allows you to:

- Select a specific software bundle.
- Identify which software images are compatible with the selected software image.

- Compare two IOS XE software images and understand the compatibility level of the software images (that is, compatible, base-level compatible, and incompatible), or dynamically determined.
- Compare two software images and see the client compatibility for each ISSU client.
- Provide links to release notes for the software image.

How to Perform the ISSU Process

Unlike SSO, which is a mode of operation for the device and a prerequisite for performing ISSU, the ISSU process is a series of steps performed while the switch is in operation. The steps result in an upgrade to new or modified Cisco IOS XE software, and have a minimal impact to traffic.

Note

For an illustration of the process flow for ISSU, refer to [Figure 8-8 on page 8-12](#).

Upgrading ISSU to Cisco IOS XE 3.4.0SG/15.1(2)SG from a Prior Release

Because images prior to Cisco IOS XE 3.4.0SG/15.1(2)SG use the earlier CLI format and Cisco IOS XE 3.4.0SG and 15.1(2)SG images use a newer CLI format, your upgrade consists of the following:

- Upgrading the image on your switch to Cisco IOS XE 3.4.0SG/15.1(2)SG.
- Upgrading mgmtVrf from the earlier CLI format to the later format, removing any IPv6 addresses on the interface.
- Enabling IPv6 address family under mgmtVrf, and reconfigure IPv6 addresses on fa1.

A configuration like the following should exist on pre-Cisco IOS XE 3.4.0SG/15.1(2)SG image:

```
ip vrf mgmtVrf
!
interface FastEthernet1
 ip vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
 ipv6 address 2000::1/64
```

!

Step 1 Perform an ISSU upgrade to a Cisco IOS XE 3.4.0SG/15.1(2)SG image.

Step 2 Run the VRF upgrade command.

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vrf upgrade-cli multi-af-mode common-policies vrf mgmtVrf
You are about to upgrade to the multi-AF VRF syntax commands.
You will lose any IPv6 address configured on interfaces
belonging to upgraded VRFs.

Are you sure ? [yes]:
Number of VRFs upgraded: 1
Switch(config)# exit
```

Your configuration will appear as follows:

```
vrf definition mgmtVrf
!
 address-family ipv4
 exit-address-family
!
interface FastEthernet1
 vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
!
```

Step 3 Configure the switch to enable the IPv6 address family and add the IPv6 address.

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vrf definition mgmtVrf
Switch(config-vrf)# address-family ipv6
Switch(config-vrf-af)# exit
Switch(config-vrf)# exit
Switch(config)# interface fa1
Switch(config-if)# ipv6 address 2000::1/64
Switch(config-if)# end
```

Your configuration will appear as follows.

```
vrf definition mgmtVrf
!
 address-family ipv4
 exit-address-family
!
 address-family ipv6
 exit-address-family
!
interface FastEthernet1
 vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
 ipv6 address 2000::1/64
```

Downgrading ISSU from Cisco IOS XE 3.4.0SG/15.1(2)SG to a Prior Release

Because a Cisco IOS XE 3.4.0SG/15.1(2)SG image uses a new CLI format and prior images use earlier CLI formats, the downgrade procedure include the following:

- Downgrading mgmtVrf from new CLI format to older CLI format, removing any IPv6 addresses on the interface.
- Downgrading the image on your switch to a prior release.
- Reconfiguring the IPv6 addresses on fa1.

A configuration like the following will appear on a switch running a Cisco IOS XE 3.4.0SG/15.1(2)SG image:

```
vrf definition mgmtVrf
!
 address-family ipv4
 exit-address-family
!
 address-family ipv6
 exit-address-family
!
interface FastEthernet1
 vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
 ipv6 address 2000::1/64
!
```

Step 1 Perform a downgrade to a release prior to Cisco IOS XE 3.4.0SG/15.1(2)SG.

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no vrf upgrade-cli multi-af-mode common-policies vrf mgmtVrf
You are about to downgrade to the single-AF VRF syntax commands.
You will lose any IPv6 address configured on interfaces
belonging to downgraded VRFs.

Are you sure ? [yes]:
% ipv6 addresses from all interfaces in VRF mgmtVrf have been removed
Number of VRFs downgraded: 1
Switch(config)#
```

Your configuration will appear as follows:

```
ip vrf mgmtVrf
!
interface FastEthernet1
 ip vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
!
```

Step 2 Perform an ISSU downgrade to a pre-Cisco IOS XE 3.4.0SG/15.1(2)SGn image.

Step 3 Reconfigure the IPv6 address.

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa1
Switch(config-if)# ipv6 address 2000::1/64
```

```
Switch(config-if)# end
Switch#
```

Your configuration will appear as follows.

```
ip vrf mgmtVrf
!
interface FastEthernet1
 ip vrf forwarding mgmtVrf
 ip address 10.1.1.1 255.255.255.0
 speed auto
 duplex auto
 ipv6 address 2000::1/64
```

Verifying the ISSU Software Installation

During the ISSU process, there are five valid states: disabled, init, load version, run version, and system reset. Use the **show issu state** command to obtain the current ISSU state:

- Disabled state—The state for the standby supervisor engine while this engine is resetting.
- Init state—The initial state for two supervisor engines, one active and one standby, before the ISSU process is started. It is also the final state after the ISSU process completes.
- Load version (LV) state—The standby supervisor engine is loaded with the new version of Cisco IOS XE software.
- Run version (RV) state—The **issu runversion** command forces the switchover of the supervisor engines. The newly active supervisor engine runs the new Cisco IOS XE software image.
- While running ISSU, if both supervisor engines are reset due to power outage, for example, the ISSU context is lost and returns to the init state. Both supervisor engines return to the old software.

You can verify the ISSU software upgrade by entering **show** commands to provide information on the state of the during the ISSU process:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode.
		Enter your password if prompted.
Step 2	Switch# show issu state [detail]	Displays the state of the during the ISSU process.
Step 3	Switch# show redundancy	Displays current or historical status, mode, and related redundancy information about the device.

This example shows how to display the state and the current status of the supervisor engine during the ISSU process:

```
Switch> enable
Switch# show issu state
Switch# show redundancy
```

Verifying Redundancy Mode Before Beginning the ISSU Process

Before you begin the ISSU process, verify the redundancy mode for the system and be sure to configure NSF and SSO.

The following example displays verification that the system is in SSO mode, that slot 3 is the active supervisor engine, and that slot 4 is the standby supervisor engine. Both supervisor engines are running the same Cisco IOS XE software release.

```
Switch# show redundancy state
    my state = 13 -ACTIVE
    peer state = 8 -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 5

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
    Redundancy State = Stateful Switchover
        Manual Swact = enabled

Communications = Up

    client count = 81
    client_notification_TMR = 240000 milliseconds
        keep_alive TMR = 9000 milliseconds
        keep_alive count = 1
    keep_alive threshold = 9
        RF debug mask = 0

Switch# show redundancy
Redundant System Information :

-----
    Available system uptime = 9 hours, 0 minute
Switchovers system experienced = 2
    Standby failures = 1
    Last switchover reason = user_forced

    Hardware Mode = Duplex
    Configured Redundancy Mode = Stateful Switchover
    Operating Redundancy Mode = Stateful Switchover
    Maintenance Mode = Disabled
    Communications = Up

Current Processor Information :
-----
    Active Location = slot 5
    Current Software state = ACTIVE
    Uptime in current state = 7 hours, 31 minutes
        Image Version = Cisco IOS Software, IOS-XE Software, Catalyst 4500 L3
Switch Software (cat4500e-UNIVERSALK9-M), Version 03.06.05a.E RELEASE SOFTWARE (fc1)

Verifying the ISSU State Before Beginning the ISSU Process

Ensure that the active and standby supervisor engines are up and in ISSU Init state and that both supervisor engines are running the same current image.

The following example displays the ISSU state before the process begins:

```
Switch# show issu state detail

      Slot = 5
      RP State = Active
      ISSU State = Init
      Operating Mode = Stateful Switchover
      Current Image = bootflash:old_image
      Pre-ISSU (Original) Image = N/A
      Post-ISSU (Targeted) Image = N/A

      Slot = 6
      RP State = Standby
      ISSU State = Init
      Operating Mode = Stateful Switchover
      Current Image = bootflash:old_image
      Pre-ISSU (Original) Image = N/A
      Post-ISSU (Targeted) Image = N/A
```

The new version of the Cisco IOS XE software must be present on both of the supervisor engines. The directory information displayed for each of the supervisor engines shows that the new version is present.

```
Switch# dir bootflash:
Directory of bootflash:/

29177  -rw-   178623288  Nov 14 2016 00:27:19 -07:00  old_image.bin
29149  -rw-   190288756  Nov 14 2016 00:18:08 -07:00  new_image.bin

820875264 bytes total (450797568 bytes free)

Switch# dir slavebootflash:
Directory of slavebootflash:/

29194  -rw-   190288756  Nov 14 2016 00:31:21 -07:00  new_image.bin
29195  -rw-   178623288  Nov 14 2016 00:36:49 -07:00  old_image.bin

822910976 bytes total (66076672 bytes free)
```

Loading New Cisco IOS XE Software on the Standby Supervisor Engine

This task describes how to use ISSU to load a new version of Cisco IOS XE software to the standby supervisor engine.

Prerequisites

- Ensure that the new version of Cisco IOS XE software image is already present in the file system of both the active and standby supervisor engines. Also ensure that appropriate boot parameters (BOOT string and config-register) are set for the active and standby supervisor engines.

Note **auto-boot** must be enabled for ISSU to succeed.

- Optionally, perform additional tests and commands to determine the current state of peers and interfaces for later comparison.
- Ensure the system (both active and standby supervisor engines) is in SSO redundancy mode. If the system is in RPR mode, you can still upgrade the system using the ISSU CLI commands, but the system will experience extended packet loss during the upgrade.'

Refer to the *Stateful Switchover* document for more details on how to configure SSO mode on supervisor engines.

- For ISSU to function, the IOS XE file names on the active and standby supervisor engines must match.

Perform the following steps at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu loadversion [active-slot] active-image-new [standby-slot] standby-image-new [forced]	Starts the ISSU process and (optionally) overrides the automatic rollback when the new Cisco IOS XE software version is detected to be incompatible. It may take several minutes after entering the issu loadversion command for Cisco IOS XE software to load onto the standby supervisor engine and for the standby supervisor engine to transition to SSO mode. This causes the standby supervisor engine to reload with the new software image. If you use the forced option, the standby supervisor engine is booted with the new software image. After the software image is loaded on the standby supervisor engine, if the software image is incompatible, the system is forced to the RPR mode. Otherwise the system will continue in the SSO mode.

	Command or Action	Purpose
Step 3	Switch# show issu state [detail]	Displays the state of ISSU during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded and is in SSO mode. It may take several minutes after entering the issu loadversion command for Cisco IOS XE software to load onto the standby supervisor engine and the standby supervisor engine to transition to SSO mode. If you enter the show issu state command too quickly, you may not see the information you need.
Step 4	Switch# show redundancy [states]	Displays redundancy facility state information.

This example shows how to start the ISSU process, boot the standby supervisor engine in the Standby Hot state, and load the standby supervisor engine slot (6) with the new IOS XE software image:

```
Switch> enable
Switch# issu loadversion 5 bootflash:new_image 6 slavebootflash:new_image
%issu loadversion executed successfully, Standby is being reloaded

Switch# show issu state detail
          Slot = 5
          RP State = Active
          ISSU State = Load Version
          Operating Mode = Stateful Switchover
          Current Image = bootflash:old_image.bin
          Pre-ISSU (Original) Image = bootflash:old_image.bin
          Post-ISSU (Targeted) Image = bootflash:new_image.bin

          Slot = 6
          RP State = Standby
          ISSU State = Load Version
          Operating Mode = Stateful Switchover
          Current Image = bootflash:new_image.bin
          Pre-ISSU (Original) Image = bootflash:old_image.bin
          Post-ISSU (Targeted) Image = bootflash:new_image.bin

Switch# show redundancy states
  my state = 13 -ACTIVE
  peer state = 8 -STANDBY HOT
    Mode = Duplex
    Unit = Primary
    Unit ID = 5

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
Redundancy State = Stateful Switchover
Manual Swact = enabled

Communications = Up

  client count = 81
  client_notification_TMR = 240000 milliseconds
    keep_alive TMR = 9000 milliseconds
      keep_alive count = 1
      keep_alive threshold = 9
      RF debug mask = 0
```

The following example shows how the forced option places the system in RPR mode:

```
Switch# show issu state detail
          Slot = 5
          RP State = Active
          ISSU State = Load Version
          Operating Mode = Stateful Switchover
          Current Image = bootflash:old_image.bin
          Pre-ISSU (Original) Image = bootflash:old_image.bin
          Post-ISSU (Targeted) Image = bootflash:new_image.bin

          Slot = 6
          RP State = Standby
          ISSU State = Load Version
          Operating Mode = Stateful Switchover
          Current Image = bootflash:new_image.bin
          Pre-ISSU (Original) Image = bootflash:old_image.bin
          Post-ISSU (Targeted) Image = bootflash:new_image.bin
```

The following example shows the redundancy mode as RPR:

```
Switch# show redundancy states
  my state = 13 -ACTIVE
  peer state = 4 -STANDBY COLD
    Mode = Duplex
    Unit = Primary
    Unit ID = 3

  Redundancy Mode (Operational) = RPR
  Redundancy Mode (Configured) = Stateful Switchover
    Redundancy State = RPR
    Manual Swact = enabled
    Communications = Up

  client count = 64
  client_notification_TMR = 240000 milliseconds
    keep_alive TMR = 9000 milliseconds
    keep_alive count = 1
  keep_alive threshold = 18
    RF debug mask = 0

Switch# show redundancy
Redundant System Information :

-----
  Available system uptime = 10 hours, 35 minutes
  Switchovers system experienced = 0
    Standby failures = 3
  Last switchover reason = none

    Hardware Mode = Duplex
  Configured Redundancy Mode = Stateful Switchover
  Operating Redundancy Mode = Stateful Switchover
    Maintenance Mode = Disabled
    Communications = Up

Current Processor Information :
-----
  Active Location = slot 5
  Current Software state = ACTIVE
  Uptime in current state = 10 hours, 34 minutes
```

```

```

Switching to the Standby Supervisor Engine

This task describes how to switchover to the standby supervisor engine, which is running the new Cisco IOS XE software image. Perform the following steps at the active supervisor engine.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu runversion [standby-slot] [standby-image-new]	Forces a switchover from the active to the standby supervisor engine and reloads the former active (current standby) supervisor engines with the old IOS XE image. When you enter the issu runversion command, an SSO switchover will be performed, and NSF procedures will be invoked if so configured.
Step 3	Switch# show issu state [detail]	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that a switchover occurs to slot 6.
Step 4	Switch# show redundancy [states]	Displays redundancy facility state information.

This example shows how to cause a switchover to the former standby supervisor engine (slot 6), reset the former active supervisor engine and reload it with the old IOS XE software image so it becomes the standby supervisor engine:

```

Switch> enable
Switch# issu runversion 6 slavebootflash:new_image
%issu runversion initiated successfully

```

A switchover happens at this point. At the new active supervisor engine, do the following after old active supervisor engine comes up as standby.

```

Switch# show issu state detail
Slot = 6

```

```

RP State = Active
ISSU State = Run Version
Operating Mode = Stateful Switchover
Current Image = bootflash:new_image.bin
Pre-ISSU (Original) Image = bootflash:old_image.bin
Post-ISSU (Targeted) Image = bootflash:new_image.bin

Slot = 5
RP State = Standby
ISSU State = Run Version
Operating Mode = Stateful Switchover
Current Image = bootflash:old_image.bin
Pre-ISSU (Original) Image = bootflash:old_image.bin
Post-ISSU (Targeted) Image = bootflash:new_image.bin

```

**Note**

The new active supervisor engine is now running the new version of software, and the standby supervisor engine is running the old version of software and is in the standby hot state.

```

Switch# show redundancy states
my state = 13 -ACTIVE
peer state = 8 -STANDBY HOT
Mode = Duplex
Unit = Primary
Unit ID = 6

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
Redundancy State = Stateful Switchover
Manual Swact = enabled

Communications = Up

client count = 88
client_notification_TMR = 240000 milliseconds
keep_alive TMR = 9000 milliseconds
keep_alive count = 0
keep_alive threshold = 9
RF debug mask = 0

```

Once Runversion has completed, the new active supervisor engine will be running the new version of software and the previously active supervisor engine will now become the standby supervisor engine. The standby will be reset and reloaded, but it will remain on the previous version of software and come back online in standbyhot status. The following example shows how to verify these conditions:

```

Switch# show redundancy
Redundant System Information :
-----
Available system uptime = 10 hours, 45 minutes
Switchovers system experienced = 1
Standby failures = 0
Last switchover reason = user_forced

Hardware Mode = Duplex
Configured Redundancy Mode = Stateful Switchover
Operating Redundancy Mode = Stateful Switchover
Maintenance Mode = Disabled
Communications = Up

Current Processor Information :
-----

```

```

        Active Location = slot 6
        Current Software state = ACTIVE
        Uptime in current state = 18 minutes
        Image Version = Cisco IOS Software, IOS-XE Software, Catalyst 4500 L3
Switch Software (cat4500e-UNIVERSALK9-M), Version 03.08.03.E RELEASE SOFTWARE (fc2)

        BOOT = bootflash:old_image.bin,12;
        Configuration register = 0x2102

```

Stopping the ISSU Rollback Timer (Optional)

This optional task describes how to stop the rollback timer.

If you do not run the following procedure before the rollback timer “timeout,” the system automatically aborts the ISSU process and reverts to the original Cisco IOS XE software version. By default the rollback timer is 45 minutes.

Use the following information to decide what action you should take:

- If you want to retain your switch in the runversion state for an extended period, you need to stop the rollback timer by entering the **acceptversion** command. Then validate the new software and enter the **commitversion** command (as described in the following section).
- If you want to proceed with the commitversion operation within the rollback timer window of 45 minutes (or the configured value), you do not need to use the **acceptversion** command to stop the roll-back timer.

Note

The **issu acceptversion** command may be optionally executed after the **issu runversion** command.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu acceptversion [<i>active-slot</i>] [<i>active-image-new</i>]	Halts the rollback timer and ensures the new Cisco IOS XE ISSU process is not automatically aborted during the ISSU process. Enter the issu acceptversion command within the time period specified by the rollback timer to acknowledge that the supervisor engine has achieved connectivity to the outside world; otherwise, the ISSU process is terminated, when the rollback timer expires, and the system reverts to the previous version of Cisco IOS XE software by switching to the standby supervisor engine.
Step 3	Switch# show issu rollback-timer	Displays the amount of time left before an automatic rollback will occur.

This example displays the Timer before you stop it. In the following example, the “Automatic Rollback Time” information indicates the amount of time remaining before an automatic rollback will occur.

```
Switch> enable
Switch# show issu rollback-timer
    Rollback Process State = In progress
    Configured Rollback Time = 00:45:00
    Automatic Rollback Time = 00:35:48

Switch# issu acceptversion 6 bootflash:new_image.bin
% Rollback timer stopped. Please issue the commitversion command.

Switch# show issu rollback-timer
    Rollback Process State = Not in progress
    Configured Rollback Time = 00:45:00
```

Loading New Cisco IOS XE Software on the New Standby Supervisor Engine

This task explains how to load new version of Cisco IOS XE software to the new standby supervisor engine.

Perform the following steps at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu commitversion [<i>standby-slot</i>] [<i>standby-image-new</i>]	Allows the new Cisco IOS XE software image to be loaded into the standby supervisor engine.

	Command or Action	Purpose
Step 3	Switch# show redundancy [states]	Displays redundancy facility state information.
Step 4	Switch# show issu state [detail]	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded with the new image.

This example shows how to reset and reload the current standby supervisor engine (slot 1) with the new Cisco IOS XE software version. After you enter the **commitversion** command, the standby supervisor engine boots in the Standby Hot state.

```
Switch> enable
Switch# issu commitversion 5 slavebootflash:new_image
%issu commitversion executed successfully

Switch# show issu state
                        Slot = 6
                        RP State = Active
                        ISSU State = Init

                        Slot = 5
                        RP State = Standby
                        ISSU State = Init
```

Use the following to verify that the standby supervisor engine is reloaded with the new software.

```
Switch# show redundancy states
  my state = 13 -ACTIVE
  peer state = 8 -STANDBY HOT

```

The ISSU process has completed. At this stage, any further Cisco IOS XE software version upgrade or downgrade will require that a new ISSU process be invoked.

Using changeversion to Automate an ISSU Upgrade

This task describes how to use the **issu changeversion** command to perform a one step ISSU upgrade.

Prerequisites

- Ensure that the new version of Cisco IOS XE software image is already present in the file system of both the active and standby supervisor engines. Also ensure that appropriate boot parameters (BOOT string and config-register) are set for the active and standby supervisor engines
- Optionally, perform additional tests and commands to determine the current state of peers and interfaces for later comparison.

- Ensure the system (both active and standby supervisor engines) is in SSO redundancy mode. If the system is in RPR mode, you can still upgrade the system using the ISSU CLI commands, but the system will experience extended packet loss during the upgrade.'

Refer to the Stateful Switchover document for more details on how to configure SSO mode on supervisor engines (refer to [Chapter 10, “Configuring Supervisor Engine Redundancy Using RPR and SSO on Supervisor Engine 6-E and Supervisor Engine 6L-E”](#)).

- For ISSU to function, the IOS XE software image file names on the active and standby supervisor engines must match.

Perform the following steps at the active supervisor engine:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu changeversion [<i>active-slot active-image-new</i>] [<i>standby-slot standby-image-new</i>] [at <i>hh:mm</i> in <i>hh:mm</i>] [quick]	Initiates a single-step complete upgrade process cycle. Performs the logic of the four standard commands (issu loadversion, issu runversion, issu acceptversion, and issu commitversion) without user intervention. <i>active-slot</i> —Defines the active slot number. <i>new-image</i> —Specifies IOS XE image URL to be upgraded to. <i>standby-slot</i> —Defines the standby slot number. <i>standby-image</i> —Specifies the standby IOS XE image URL. at <i>hh:mm</i> —Schedules an ISSU upgrade to begin in the future. Provides an exact time (<i>hh:mm</i> , 24 hour format) in the next 24 hours when the upgrade will occur. in <i>hh:mm</i> —Schedules an ISSU upgrade to begin in the future. Provides the number of hours and minutes (<i>hh:mm</i> format) that will elapse before an upgrade will occur (99:59 max). quick —Upon switchover, boots the standby supervisor engine with the new, rather than old, image for faster upgrade.
Step 3	Switch# show issu state [detail]	Displays the state of the during the ISSU process. At this point in the ISSU process, use this command to check that the standby supervisor engine is loaded and is in SSO mode.
Step 4	Switch# show redundancy [states]	Displays redundancy facility state information.

This example shows how to initiate an ISSU upgrade process using the `issu changeversion` command on slot number 5, the slot for the current active supervisor engine. The `show issu state detail` and `show redundancy` command output is included to show the supervisor state before and after the upgrade procedure.

Note

The success messages included in the output below is displayed after some delay because the ISSU upgrade procedure progresses through the ISSU states.

```

Switch> enable
Switch# show issu state detail
                Slot = 5

```

Aborting a Software Upgrade During ISSU

You can abort the ISSU process at any stage manually (prior to entering the **issu commitversion** command) by entering the **issu abortversion** command. The **issu abortversion** command may also be issued after entering the **issu changeversion** command while the automatic ISSU upgrade is still in progress. The ISSU process also aborts on its own if the software detects a failure.

Note If you enter the **issu abortversion** command before the standby supervisor engine becomes hot, the traffic might be disrupted.

If you abort the process after you issue the **issu loadversion** command, the standby supervisor engine is reset and reloaded with the original software.

If the process is aborted after you enter either the **issu runversion** or **issu acceptversion** command, then a second switchover is performed to the new standby supervisor engine that is still running the original software version. The supervisor engine that had been running the new software is reset and reloaded with the original software version.

Note Ensure that the standby supervisor is fully booted *before* issuing the **abortversion** command on an active supervisor engine.

The following task describes how to abort the ISSU process before you complete the ISSU process with the **issu commitversion** command.

Perform the following task on the active supervisor engine.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# issu abortversion [<i>active slot</i> [<i>active-image-new</i>]]	Cancels the ISSU upgrade or downgrade process in progress and restores the switch to its state before the process had started.

This example shows how to abort the ISSU process on slot number 6, the slot for the current active supervisor engine. In this example, the ISSU upgrade process is in the Runversion state when the **issu abortversion** command is entered:

```
Switch> enable
Switch# show issu state detail
      Slot = 6
      RP State = Active
      ISSU State = Run Version
      Operating Mode = Stateful Switchover
      Current Image = bootflash:x.bin
      Pre-ISSU (Original) Image = bootflash:y.bin
      Post-ISSU (Targeted) Image = bootflash:x.bin

      Slot = 5
      RP State = Standby
      ISSU State = Run Version
      Operating Mode = Stateful Switchover
      Current Image = bootflash:y.bin
      Pre-ISSU (Original) Image = bootflash:y.bin
```

```

Post-ISSU (Targeted) Image = bootflash:x.bin

Switch# issu abortversion 6
% issu abortversion initiated successfully
Switch# show issu state detail

          Slot = 5
          RP State = Active
          ISSU State = Init
          Operating Mode = Stateful Switchover
          Current Image = bootflash:y.bin
    Pre-ISSU (Original) Image = N/A
    Post-ISSU (Targeted) Image = N/A

          Slot = 6
          RP State = Standby
          ISSU State = Init
          Operating Mode = Stateful Switchover
          Current Image = bootflash:y.bin
    Pre-ISSU (Original) Image = N/A
    Post-ISSU (Targeted) Image = N/A

Switch#

```

Configuring the Rollback Timer to Safeguard Against Upgrade Issues

Cisco IOS XE software maintains an ISSU rollback timer, to safeguard against an upgrade that may leave the new active supervisor engine in a state in which communication with the standby supervisor engine is severed.

You may want to configure the rollback timer to fewer than 45 minutes (the default) so that the user need not wait in case the new software is not committed or the connection to the switch was lost while it was in runversion mode. A user may want to configure the rollback timer to more than 45 minutes in order to have enough time to verify the operation of the new Cisco IOS XE software before committing the new software image.

Note

The valid timer value range is from 0 to 7200 seconds (two hours). A value of 0 seconds disables the rollback timer.

Once you are satisfied that the new image at the active supervisor engine has been successful and you want to remain in the current state, you may indicate acceptance by issuing the **issu acceptversion** command, which stops the rollback timer.

Issuing the **issu commitversion** command at this stage is equal to entering both the **issu acceptversion** and the **issu commitversion** commands. Use the **issu commitversion** command if you do not intend to run in the current state for a period of time and are satisfied with the new software version.

Note

The rollback timer can be configured only in the ISSU Init state.

This task explains how to configure the rollback timer:

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# issu set rollback-timer value	Configures the rollback timer value, which can range from 0 to 7200.
Step 4	Switch(config)# exit	Returns the user to privileged EXEC mode.
Step 5	Switch# show issu rollback-timer	Displays the current setting of the ISSU rollback timer.

This example shows how to set the rollback timer to 3600 seconds:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# issu set rollback-timer 3600
% Rollback timer value set to [ 3600 ] seconds

Switch(config)# exit

Switch# show issu rollback-timer
Rollback Process State = Not in progress
Configured Rollback Time = 60:00
```

The Rollback Timer cannot be set in loadversion or runversion state, as the following example illustrates:

```
Switch# show issu state detail
Slot = 5
RP State = Active
ISSU State = Load Version
Operating Mode = Stateful Switchover
Current Image = bootflash:old_image
Pre-ISSU (Original) Image = bootflash:old_image
Post-ISSU (Targeted) Image = bootflash:new_image

Slot = 6
RP State = Standby
ISSU State = Load Version
Operating Mode = Stateful Switchover
Current Image = bootflash:new_image
Pre-ISSU (Original) Image = bootflash:old_image
Post-ISSU (Targeted) Image = bootflash:new_image

Switch# show issu rollback-timer
Rollback Process State = Not in progress
Configured Rollback Time = 60:00

Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# issu set rollback-timer 20
% ISSU state should be [ init ] to set the rollback timer
```

Displaying ISSU Compatibility Matrix Information

The ISSU compatibility matrix contains information about other IOS XE software releases and the version in question. This compatibility matrix represents the compatibility of the two software versions, one running on the active and the other on the standby supervisor engine, and the matrix allows the system to determine the highest operating mode it can achieve. This information helps the user identify whether to use ISSU.

This task shows how to display information about the ISSU compatibility matrix.

	Command or Action	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# show issu comp-matrix { negotiated stored xml }	Displays information regarding the ISSU compatibility matrix. <ul style="list-style-type: none"> • negotiated—Displays negotiated compatibility matrix information. • stored—Displays negotiated compatibility matrix information. • xml—Displays negotiated compatibility matrix information in XML format. <p>Note These commands display only the data within IOSd process. Use the show package compatibility to display the information for the whole system.</p>
Step 3	Switch# show package compatibility	Displays information regarding all client compatibility in the system.

This example shows how to display negotiated information regarding the compatibility matrix:

```
Switch> enable
Switch# show issu comp-matrix negotiated

03.06.05.E    Comp(3)

```

Dynamic Image Version Compatibility (DIVC) feature is supported in IOS XE releases. With DIVC, we store Dynamic(0) rather than Incomp(1), Base(2), or Comp(3), and determine compatibility during run-time when two different DIVC-capable IOS XE software images are running in the active and standby supervisor engines during ISSU.

For Catalyst 4500 switches, a value of Dynamic(0) in the stored compatibility-matrix normally results in Base(2) or Comp(3) upon run-time negotiation between the two IOS XE software images; as of today, you never observe Incomp(1) as long as the other IOS XE name is present in the stored compatibility-matrix.

This example shows how to display negotiated information regarding non-IOSd clients:

```
Switch# show package compatibility
```

```

Cisco High Availability Features in Cisco IOS XE 3.1.0SG

This section provides a list of High Availability software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Configuring Interfaces

This chapter describes how to configure interfaces for the standalone and modular Catalyst 4500 series switches. It also provides guidelines, procedures, and configuration examples.

This chapter includes the following major sections:

- [Restrictions for Configuring Interfaces, page 9-2](#)
- [About Interface Configuration, page 9-2](#)
- [Using the interface Command, page 9-2](#)
- [Configuring a Range of Interfaces, page 9-5](#)
- [Using the Ethernet Management Port, page 9-7](#)
- [Defining and Using Interface-Range Macros, page 9-13](#)
- [Deploying SFP+ in X2 Ports, page 9-14](#)
- [Deploying 10-Gigabit Ethernet and Gigabit Ethernet SFP Ports on Supervisor Engine V-10GE, page 9-14](#)
- [Configuring MultiGigabit Ports on WS-X4748-12X48U+E, page 9-18](#)
- [Invoking Shared-Backplane Uplink Mode on Supervisor Engine 6-E and Supervisor Engine 6L-E, page 9-22](#)
- [Selecting Uplink Mode on a Supervisor Engine 6-E, page 9-23](#)
- [Selecting the Uplink Port on a Supervisor Engine 7L-E, page 9-24](#)
- [Selecting the Uplink Port on a Supervisor Engine 7L-E, page 9-24](#)
- [Configuring Supervisor Engine 7-E Uplink Mode on Supervisor Engine 8-E, page 9-26](#)
- [Supervisor Engine 9-E Uplink Configurations, page 9-29](#)
- [Digital Optical Monitoring Transceiver Support, page 9-32](#)
- [Digital Optical Monitoring Transceiver Support, page 9-32](#)
- [Configuring Optional Interface Features, page 9-32](#)
- [Understanding Online Insertion and Removal, page 9-47](#)
- [Online Insertion and Removal on a WS-4500X-32, page 9-48](#)
- [Monitoring and Maintaining the Interface, page 9-50](#)

**Note**

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Restrictions for Configuring Interfaces

On a Cisco Catalyst 4500E Series Switches with Supervisor Engine 8-E, the management interface receive counter value is unreliable due to deficient functionality in the underlying CPU chip hardware. Fixing this issue requires a new revision of the CPU (when available).

About Interface Configuration

By default, all available interfaces, with the exception of the 40-Gigabit Ethernet (40-GE) interfaces, are enabled. The 10/100-Mbps Ethernet interfaces autonegotiate connection speed and duplex. The 10/100/1000-Mbps Ethernet interfaces negotiate speed, duplex, and flow control. The 1000-Mbps Ethernet interfaces negotiate flow control only. Autonegotiation automatically selects the fastest speed possible on that port for the given pair. If a speed is explicitly stated for an interface, that interface defaults to half duplex unless it is explicitly set for full duplex.

Many features are enabled on a per-interface basis. When you enter the **interface** command, you must specify the following:

- Interface type:
 - Fast Ethernet (keyword **fastethernet**)
 - Gigabit Ethernet (keyword **gigabitethernet**)
 - 10-Gigabit Ethernet (keyword **tengigabitethernet**).
 - 40-Gigabit Ethernet (keyword **fortygigabitethernet**)

Available on Cisco Catalyst 4500E Series Switches with Supervisor Engine 9-E. The corresponding uplink mode (**hw-module uplink mode 80Gig**) must be enabled to use this interface type. When enabled, the 10-GE uplink ports on the supervisor, are not available. See [Selecting the Uplink Mode on Supervisor Engine 9-E, page 9-31](#).

- Slot number—The slot in which the interface module is installed. Slots are numbered starting with 1, from top to bottom.
- Interface number—The interface number on the module. The interface numbers always begin with 1. When you are facing the front of the switch, the interfaces are numbered from left to right.

You can identify interfaces by physically checking the slot/interface location on the switch. You can also use the Cisco IOS **show** commands to display information about a specific interface or all the interfaces.

Using the interface Command

These general instructions apply to all interface configuration processes:

- Step 1** At the privileged EXEC prompt, enter the **configure terminal** command to enter global configuration mode:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)#
```

- Step 2** In global configuration mode, enter the **interface** command. Identify the interface type and the number of the connector on the interface card. The following example shows how to select Fast Ethernet, slot 5, interface 1:

```
Switch(config)# interface fastethernet 5/1
Switch(config-if)#
```

- Step 3** Interface numbers are assigned at the factory at the time of installation or when modules are added to a system. Enter the **show interfaces** EXEC command to see a list of all interfaces installed on your switch. A report is provided for each interface that your switch supports, as shown in this display:

```
Switch(config-if)#Ctrl-Z
Switch#show interfaces
Vlan1 is up, line protocol is down
  Hardware is Ethernet SVI, address is 0004.dd46.7aff (bia 0004.dd46.7aff)

  Keepalive set (10 sec)
  Auto-duplex, Auto-speed
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/2000/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
    0 packets input, 0 bytes, 0 no buffer
    Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
    0 input packets with dribble condition detected
    0 packets output, 0 bytes, 0 underruns
    0 output errors, 0 collisions, 0 interface resets
    0 babbles, 0 late collision, 0 deferred
    0 lost carrier, 0 no carrier
    0 output buffer failures, 0 output buffers swapped out
```

```
GigabitEthernet1/2 is up, line protocol is down
  Hardware is Gigabit Ethernet Port, address is 0004.dd46.7701 (bia 0004.dd46.7701)
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Auto-duplex, Auto-speed
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/2000/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
    0 packets input, 0 bytes, 0 no buffer
    Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
    0 input packets with dribble condition detected
    0 packets output, 0 bytes, 0 underruns
    0 output errors, 0 collisions, 0 interface resets
    0 babbles, 0 late collision, 0 deferred
    0 lost carrier, 0 no carrier
    0 output buffer failures, 0 output buffers swapped out
--More--
<...output truncated...>
```

- Step 4** To begin configuring Fast Ethernet interface 5/5, as shown in the following example, enter the **interface** keyword, interface type, slot number, and interface number in global configuration mode:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/5
Switch(config-if)#
```

Note You do not need to add a space between the interface type and interface number. For example, in the preceding line you can specify either `fastethernet 5/5` or `fastethernet5/5`.

- Step 5** Follow each **interface** command with the interface configuration commands your particular interface requires. The commands you enter define the protocols and applications that run on the interface. The commands are collected and applied to the **interface** command until you enter another **interface** command or press **Ctrl-Z** to exit interface configuration mode and return to privileged EXEC mode.

- Step 6** After you configure an interface, check its status by using the EXEC **show** commands listed in the [“Monitoring and Maintaining the Interface” section on page 9-50](#).

Note Carrier-delay timer modification is not supported on Cisco Catalyst 4500 series switch. A default two second timer is applicable for interface transitions.

Configuring a Range of Interfaces

The interface-range configuration mode allows you to configure multiple interfaces with the same configuration parameters. When you enter the interface-range configuration mode, all command parameters you enter are attributed to all interfaces within that range until you exit interface-range configuration mode.

The following tables show how to configure a range of interfaces with the same configuration—in the default mode and in the 40-GE mode:

Command	Purpose
<pre>Switch(config)# interface range {vlan vlan_ID - vlan_ID} {{fastethernet gigabitethernet tengigabitethernet macro macro_name} slot/interface - interface} [, {vlan vlan_ID - vlan_ID} {{fastethernet gigabitethernet tengigabitethernet macro macro_name} slot/interface - interface}]</pre>	<p>Selects the range of interfaces to be configured. Note the following:</p> <ul style="list-style-type: none"> You are required to enter a space before the dash. You can enter up to five comma-separated ranges. You are not required to enter spaces before or after the comma.

Command	Purpose
<pre>Switch(config)# interface range {vlan vlan_ID - vlan_ID} {{fastethernet gigabitethernet tengigabitethernet fortygigabitethernet macro macro_name} slot/interface - interface} [, {vlan vlan_ID - vlan_ID} {{fastethernet gigabitethernet tengigabitethernet fortygigabitethernet macro macro_name} slot/interface - interface}]</pre>	<p>Selects the range of interfaces to be configured when the 40-Gigabit Ethernet mode is enabled on Supervisor Engine 9-E (hw-module uplink mode 80Gig). Note the following:</p> <ul style="list-style-type: none"> You are required to enter a space before the dash. You can enter up to five comma-separated ranges. You are not required to enter spaces before or after the comma. <p>Note In this mode, the 10-GE uplink ports on Supervisor Engine 9-E are not available, but if there are other 10-GE linecards in the chassis, the tengigabitethernet option is available.</p>

Note

When you use the **interface range** command, you must add a space between the **vlan**, **fastethernet**, **gigabitethernet**, **tengigabitethernet**, **fortygigabitethernet** or **macro** keyword and the dash. For example, the command **interface range fastethernet 5/1 - 5** specifies a valid range; the command **interface range fastethernet 5/1-5** does not contain a valid range command.

**Note**

The **interface range** command works only with VLAN interfaces that have been configured with the **interface vlan** command (the **show running-configuration** command displays the configured VLAN interfaces). VLAN interfaces that are not displayed by the **show running-configuration** command cannot be used with the **interface range** command.

This example shows how to reenable all Fast Ethernet interfaces 5/1 to 5/5:

```
Switch(config)# interface range fastethernet 5/1 - 5
Switch(config-if-range)# no shutdown
Switch(config-if-range)#
*Oct 6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/1, changed state to up
*Oct 6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/2, changed state to up
*Oct 6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/3, changed state to up
*Oct 6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/4, changed state to up
*Oct 6 08:24:35: %LINK-3-UPDOWN: Interface FastEthernet5/5, changed state to up
*Oct 6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/
5, changed state to up
*Oct 6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/
3, changed state to up
*Oct 6 08:24:36: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/
4, changed state to up
Switch(config-if)#
```

This example shows how to use a comma to add different interface type strings to the range to reenable all Fast Ethernet interfaces ranging from 5/1 to 5/5 and both Gigabit Ethernet interfaces 1/1 and 1/2:

```
Switch(config-if)# interface range fastethernet 5/1 - 5, gigabitethernet 1/1 - 2
Switch(config-if)# no shutdown
Switch(config-if)#
*Oct 6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/1, changed state to up
*Oct 6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/2, changed state to up
*Oct 6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/3, changed state to up
*Oct 6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/4, changed state to up
*Oct 6 08:29:28: %LINK-3-UPDOWN: Interface FastEthernet5/5, changed state to up
*Oct 6 08:29:28: %LINK-3-UPDOWN: Interface GigabitEthernet1/1, changed state to
up
*Oct 6 08:29:28: %LINK-3-UPDOWN: Interface GigabitEthernet1/2, changed state to
up
*Oct 6 08:29:29: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/
5, changed state to up
*Oct 6 08:29:29: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/
3, changed state to up
*Oct 6 08:29:29: %LINEPROTO-5-UPDOWN: Line protocol on Interface FastEthernet5/
4, changed state to up
Switch(config-if)#
```

**Note**

If you enter multiple configuration commands while in interface-range configuration mode, each command is run as it is entered (they are not batched together and run after you exit interface-range configuration mode). If you exit interface-range configuration mode while the commands are being run, some commands might not be run on all interfaces in the range. Wait until the command prompt is displayed before exiting interface-range configuration mode.

Using the Ethernet Management Port

This section has this information:

- [Understanding the Ethernet Management Port, page 9-7](#)
- [Supported Features on the Ethernet Management Port, page 9-12](#)
- [Configuring the Ethernet Management Port, page 9-13](#)

Understanding the Ethernet Management Port

The Ethernet management port, also referred to as the *Fa1* or *fastethernet1* port, is a Layer 3 host port to which you can connect a PC. Use the Ethernet management port instead of the switch console port for network management. When managing a switch, connect the PC to the Ethernet management port on a Catalyst 4500 series switch. (Figure 9-1).

Note

When connecting a PC to the Ethernet management port, you must assign an IP address.

Figure 9-1 Connecting a Switch to a PC

By default, the Ethernet management port is enabled. The switch cannot route packets from the Ethernet management port to a network port, and from the network port to the Ethernet port. To obtain these, the Fa1 interface is automatically placed in a separate routing domain (or VRF domain), called *mgmtVrf*. (You observe the *ip Vrf forwarding mgmtVrf* line in the running configuration when you boot up.) For details, read the “[Fa1 Interface and mgmtVrf](#)” section on page 9-8.

Even though the Ethernet management port does not support routing, you might need to enable routing protocols on the port. As illustrated in [Figure 9-2](#), you must enable routing protocols on the Ethernet management port when the PC is multiple hops away from the switch and the packets must pass through multiple Layer 3 devices to reach the PC.

Figure 9-2 Network with Routing Protocols Enabled

The specific implementation of Ethernet management port depends on the redundancy model you are applying.

For details on configuring SSO and ISSU, refer to [Chapter 11, “Configuring Supervisor Engine Redundancy Using RPR and SSO on Supervisor Engine 6-E and Supervisor Engine 6L-E”](#) and [Chapter 7, “Configuring the Cisco IOS In-Service Software Upgrade Process”](#).

Sections include:

- [Fa1 Interface and mgmtVrf, page 9-8](#)
- [SSO Model, page 9-11](#)
- [ISSU Model, page 9-12](#)

Fa1 Interface and mgmtVrf

Caution

The Ethernet management port is intended for out-of-band access only. Like the console port, the Ethernet management port has direct access to critical resources on the switch. Connecting this port to an in-band network might cause performance degradation and vulnerability to a denial of service attack.

Note

A service-policy that is applied to the control-plane interface is not applicable to traffic incoming on the management port.

All features that use fa1 now need to be VRF-aware.

Note

You cannot configure any other interface in the same routing domain and you cannot configure a different routing domain for the Fa1 interface.

On bootstrap the fa1 port assumes the following default configuration.

Images prior to Cisco IOS XE 3.4.0SG/15.1(2)SG use the old VRF definition format for management VRF as shown below.

```
!
ip vrf mgmtVrf
!
interface FastEthernet1
ip vrf forwarding mgmtVrf
```

```
speed auto
duplex auto
!
```

Images starting from Cisco IOS XE 3.4.0SG/15.1(2)SG use the new VRF definition format for management VRF as shown below.

```
!
vrf definition mgmtVrf
!
address-family ipv4
exit-address-family
!
address-family ipv6
exit-address-family
!
interface FastEthernet1
vrf forwarding mgmtVrf
speed auto
duplex auto
!
```

```
Switch# show ip vrf
```

Name	Default RD	Interfaces
mgmtVrf		Fa1

In Cisco IOS XE 3.10.1E/15.2(6)E1 and later releases, use the new VRF definition format for management VRF as shown below.

```
!
vrf definition mgmtVrf
!
address-family ipv4
exit-address-family
!
address-family ipv6
exit-address-family
!
interface FastEthernet1
vrf forwarding mgmtVrf
ip address address
ipv6 address address
speed auto
duplex auto
!
Switch# show ip vrf
Name Default RD Interfaces
mgmtVrf Fa1
```

Because the management port is placed in mgmtVrf, you should be aware of the VRF aware commands required for the following tasks:

- [Ping, page 9-10](#)
- [TraceRoute, page 9-10](#)
- [Telnet, page 9-10](#)
- [TFTP, page 9-11](#)
- [FTP, page 9-11](#)
- [SSH, page 9-11](#)

**Note**

Command usage specific to the mgmtVrf are mentioned below. The additional configuration that is necessary to make the feature work needs to be configured.

**Note**

The following features support IPv6 VRF

Ping

If you want to ping an IP address that is reachable through an fa1 port, enter the following command:

```
Switch# ping vrf mgmtVrf ip address
```

For example:

```
Switch# ping vrf mgmtVrf 20.20.20.1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 20.20.20.1, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/4 ms
```

For Example:

```
IPv6 Management interface for Ping
Switch#ping vrf mgmtVrf 11.27.25.19
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 11.27.25.19, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
Switch#ping vrf mgmtVrf 2031::1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 2031::1, timeout is 2 seconds
```

TraceRoute

```
Switch# traceroute vrf mgmtVrf ip address
```

For example:

Eg: Switch# **traceroute vrf mgmtVrf 20.20.20.1**

```
Type escape sequence to abort.
Tracing the route to 20.20.20.1
 1 20.20.20.1 0 msec 0 msec *
```

For example:

IPv6 Management interface for Traceroute

```
Switch#traceroute vrf mgmtVrf 2031::1
Type escape sequence to abort.
Tracing the route to 2031::1
2031::1 0 msec 0 msec 0 msec
```

Telnet

If you want to Telnet to a remote switch through the Fa1 port, enter the following command:

```
Switch# telnet word /vrf mgmtVrf
word IP address or hostname of a remote system
```

For example :

```
Switch# telnet 20.20.20.1 /vrf mgmtVrf
```

```
Trying 20.20.20.1 ... Open
User Access Verification
Password:
switch> en
Password:
switch#
```

For example:

```
IPv6 Management interface for Telnet
Switch# telnet 2031::1/vrf mgmtVrf
Trying 2031::1 ... Open
User Access Verification
Password:
switch> en
Password:
switch#
```

TFTP

If you want to use Fa1 port for TFTP operation, configure the Fa1 port as the source interface for TFTP as follows:

```
Switch(config)# ip tftp source-interface fastEthernet1
```

FTP

If you want to use an Fa1 port for an FTP operation, configure the Fa1 port as the source interface for FTP as follows:

```
Switch(config)# ip ftp source-interface fastEthernet1
```

SSH

If you want initiate SSH from your switch through the Fa1 port, enter the following command:

```
Switch# ssh -l login name -vrf mgmtVrf ip address
```

For example:

```
Switch# ssh -l xyz -vrf mgmtVrf 20.20.20.1
```

For example:

```
IPv6 Management Interface for SSH:
Switch# ssh -l xyz -vrf mgmtVrf 2031::1
```

SSO Model

On a redundant chassis, management port behavior differs from that of a standard Ethernet port in that each supervisor engine possesses a management port, and only the port on the active supervisor engine is enabled. The management port on the standby supervisor engine is always disabled; it cannot switch any kind of traffic.

When a switchover occurs, the management port of the standby supervisor engine (now, active) is enabled and can be used to switch traffic, while the management port on the “old” active supervisor engine is disabled.

**Note**

The Cisco IOS configuration for the management port is synchronized between the two supervisor engines. Under Cisco IOS, they possess the same IP address. To avoid address overlapping during a switchover on a redundant chassis, you should assign a different IP address on the management port from the one you assigned to the same port in the ROMMON configuration.

ISSU Model

In SSO mode, the running configurations on the active and standby supervisor engines must match. You cannot enable the management port on a redundant chassis if one of the two supervisor engines is running an Cisco IOS image prior to Cisco IOS Release 12.2(50)SG (wherein a management port is not supported).

When you perform an ISSU upgrade or downgrade between Cisco IOS Release 12.2(50)SG and a software image prior to Cisco IOS Release 12.2(50)SG, we automatically disable the management port. The port configuration is restored when both software images running on the supervisor engines are at least Cisco IOS Release 12.2(50)SG. A warning message is also displayed.

Supported Features on the Ethernet Management Port

The Ethernet management port supports these features:

- Express setup
- Network Assistant
- Telnet with passwords
- TFTP
- Secure Shell (SSH)
- DHCP-based autoconfiguration
- SNMP (only the ENTITY-MIB and the IF-MIB)
- IP ping
- Interface features
 - Speed—10 Mb/s, 100 Mb/s, 1000Mb/s, and autonegotiation
 - Duplex mode—Full, half, and autonegotiation
 - Loopback detection
- Cisco Discovery Protocol (CDP)
- IPv4 access control lists (ACLs)
- Routing protocols
- AAA

**Caution**

Before enabling a feature on the Ethernet management port, ensure that the feature is supported. If you try to configure an unsupported feature on an Ethernet management port, the feature might not work properly, and the switch might fail.

Configuring the Ethernet Management Port

To specify the Ethernet management port, enter **fastethernet1**.

To disable the port, use the **shutdown** interface configuration command. To enable the port, use the **no shutdown** interface configuration command.

To determine the link status to the PC, you can monitor the LED for the Ethernet management port:

- The LED is green (on) when the link is active.
- The LED is off when the link is down.
- The LED is amber when there is a POST failure.

To display the link status, use the **show interfaces fastethernet 1** privileged EXEC command.

Defining and Using Interface-Range Macros

You can define an interface-range macro to automatically select a range of interfaces for configuration. Before using the **macro** keyword in the **interface-range** macro command string, you must define the macro.

To define an interface-range macro, enter this command:

This example shows how to define an interface-range macro named **enet_list** to select Fast Ethernet

Command	Purpose
Switch(config)# define interface-range <i>macro_name</i> { vlan <i>vlan_ID</i> - <i>vlan_ID</i> } {{ fastethernet gigabitethernet tengigabitethernet } <i>slot/interface</i> - <i>interface</i> } [, { vlan <i>vlan_ID</i> - <i>vlan_ID</i> } {{ fastethernet gigabitethernet tengigabitethernet } <i>slot/interface</i> - <i>interface</i> }]	Defines the interface-range macro and saves it in the running configuration file.

interfaces 5/1 through 5/4:

```
Switch(config)# define interface-range enet_list fastethernet 5/1 - 4
```

To show the defined interface-range macro configuration, enter this command:

Command	Purpose
Switch# show running-config	Shows the defined interface-range macro configuration.

This example shows how to display the defined interface-range macro named **enet_list**:

```
Switch# show running-config | include define  
define interface-range enet_list FastEthernet5/1 - 4  
Switch#
```

To use an interface-range macro in the **interface range** command, enter this command:

Command	Purpose
Switch(config)# interface range macro <i>name</i>	Selects the interface range to be configured using the values saved in a named interface-range macro.

This example shows how to change to the interface-range configuration mode using the interface-range macro **enet_list**:

```
Switch(config)# interface range macro enet_list
Switch(config-if)#
```

Deploying SFP+ in X2 Ports

Note

This feature is supported on Supervisor Engine 6-E, 6L-E, and WS-X4606-X2-E.

To use an SFP+ in an X2 port to obtain 10-Gigabit Ethernet bandwidth, the Catalyst 4500 series switch supports OneX Convertor modules. When you plug a OneX Convertor module into an X2 port, it converts the X2 port into an SFP+ port into which you can plug in an SFP+. An SFP+ in a OneX Convertor module provides the same functionality as an X2 and maintains the same port numbering.

The output for the **show idprom tengigabitethernet slot/interface** command displays the contents of both the SFP+ and the OneX Convertor module EEPROMs when an SFP+ in a OneX Convertor module is plugged into an X2 port.

Deploying 10-Gigabit Ethernet and Gigabit Ethernet SFP Ports on Supervisor Engine V-10GE

Note

On a Catalyst 4510R series switch, if you enable both the 10-Gigabit Ethernet and Gigabit Ethernet SFP uplink ports, you must reboot the switch. On the Catalyst 4503, 4506, and 4507R series switches, this capability is automatically enabled.

Prior to Cisco IOS Release 12.2(25)SG, you could enable either the dual wire-speed 10-Gigabit Ethernet ports or four alternatively wired Gigabit Ethernet SFP uplink ports.

Beginning with Cisco IOS Release 12.2(25)SG, you could simultaneously deploy the dual 10-Gigabit Ethernet ports and the four Gigabit Ethernet SFP ports on the Catalyst 4503, Catalyst 4506, and Catalyst 4507R chassis.

When you deploy a Catalyst 4510R chassis, one of the following configurations is supported:

- Dual 10-Gigabit Ethernet ports (X2 optics) only.
- Four Gigabit Ethernet ports (SFP optics) only.

- Both the dual 10-Gigabit Ethernet and the four Gigabit Ethernet ports. The tenth slot (Flex-Slot) only supports a 2-port gigabit interface converter (GBIC) line card (WS-X4302-GB) when in this mode.
- You cannot place a line card with a backplane traffic capacity exceeding 6 Gbps in slots 8, 9, and 10 of a Catalyst 4510R-E chassis when used with a Supervisor Engine 6-E or 6L-E.

To select the 10-Gigabit Ethernet or the Gigabit Ethernet SFP uplink port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Establishes global configuration mode.
Step 2	Switch(config)# hw-module uplink select [all gigabitethernet tengigabitethernet]	Selects the port type to enable.

The following example shows how to enable both 10-Gigabit Ethernet and Gigabit Ethernet SFP uplink ports on a Catalyst 4510R series switch:

```
Switch# configure terminal
Switch(config)# hw-module uplink select all
Warning: This configuration mode will place slot 10 in flex slot mode
```

Note

When you modify the uplink mode, you must reboot the switch.

Deploying 10-Gigabit Ethernet or Gigabit Ethernet Ports

To increase the flexibility of X2 ports, Catalyst 4500 series switch support TwinGig Convertor modules. When you plug a TwinGig Convertor module into an X2 hole, it converts a single X2 hole (capable of holding one pluggable X2 optic) into two SFP holes (capable of holding two pluggable SFP optics). This enables you to have 10-Gigabit ports and 1-Gigabit ports on the same line card. It also allows you to use Gigabit ports, and then switch to a 10-Gigabit port, when needed.

This section includes these topics:

- [Port Numbering TwinGig Convertors, page 9-15](#)
- [Limitations on Using a TwinGig Convertor, page 9-16](#)
- [Selecting X2/TwinGig Convertor Model, page 9-16](#)

Port Numbering TwinGig Convertors

When a TwinGig Convertor is enabled or disabled, the number and type of ports on the line card change dynamically. The terminology must reflect this behavior. In Cisco IOS, 10-Gigabit ports are named *10-Gigabit* and 1-Gigabit ports are named *Gigabit*. Starting with Cisco IOS Release 12.2(40)SG, to avoid having two ports named 10-Gigabit1/1 and Gigabit1/1, the 10-Gigabit and 1-Gigabit port numbers are independent. For example, for a WS-X4606-10GE-E module with six X2 holes, the X2 ports are named *10-Gigabit slot-num/<1-6>*, and the SFP ports are named *Gigabit slot-num/<7-18>*.

Figure 9-3 Faceplate for WS-X4606-10GE

In Cisco IOS, ports 1 through 18 always exist. This means that you can apply configurations on them and they display in the CLI output. However, only the X2 or the SFP ports can be active at any particular time. For example, if an X2 is plugged into the second hole, the X2 port 2 is active and SFP ports 9 and 10 are inactive. If a TwinGig Converter is plugged into the second hole, the X2 port 2 is inactive, and the SFP ports 9 and 10 are active. The inactive ports are treated analogously to the inactive ports on Supervisor Engines IV and V-10GE, where at no time are all of the uplinks connected to the switching ASICs.

**Note**

When using both TwinGig and X2 transceivers on the WS-X4606-X2-E module, place ports 1-3 in one group and ports 4-6 in another. (The mode selected with the **show hw-module module port-group** command determines the behavior. See “[Selecting X2/TwinGig Converter Model](#)”.) Mixing within a port group does not work. For example, you cannot have an X2 in port 1 and a TwinGig in port 2 and expect both of them to function.

Limitations on Using a TwinGig Converter

Supervisor Engine 6-E, Supervisor Engine 6L-E, connect ports to the switching engine through a stub ASIC. This stub ASIC imposes some limitations on the ports: Gigabit and 10-Gigabit ports cannot be mixed on a single stub ASIC; they must either be all 10-Gigabit Ethernet (X2), or all Gigabit (TwinGig Converter and SFP). The faceplates of X2 modules show this stub port grouping, either with actual physical grouping with a box drawn around a grouping.

Selecting X2/TwinGig Converter Model

The default configuration mode is X2. If you plan to deploy 10-Gigabit Ethernet interfaces, you do not need to configure anything. However, if you want to deploy Gigabit interfaces (that is, use TwinGig Convertors), you must configure the associated port-group:

To determine how the X2 holes on a module are grouped, enter the **show hw-module module *m* port-group *p*** command.

**Note**

Place a 10-Gigabit Ethernet port that accepts CVR-X2-SFP into 1-Gigabit mode instead of 10-Gigabit Ethernet mode.

If you configure a 10-Gigabit Ethernet port as 1-Gigabit port, an output similar to the following appears:

```
Switch# show hw-module module 5 port-group
Module Port-group Active Inactive
-----
5      1      Gi5/3-6      Te5/1-2
```

If the port is set to the default, 10-Gigabit Ethernet mode, an output similar to the following appears:

```

Switch# show hw-module module 6 port-group
Module Port-group Active Inactive
-----
      6      1   Te6/1-2             Gi6/3-6

Switch# show int status mod 1

Port      Name      Status      Vlan      Duplex  Speed Type
Tel/1      Name      notconnect  1         full    10G  10GBase-LR
Tel/2      Name      connected   1         full    10G  10GBase-LR
Tel/3      Name      notconnect  1         full    10G  No X2
Tel/4      Name      notconnect  1         full    10G  No X2
Tel/5      Name      notconnect  1         full    10G  No X2
Tel/6      Name      notconnect  1         full    10G  No X2
Gi1/7      Name      inactive    1         full    1000 No Gbic
Gi1/8      Name      inactive    1         full    1000 No Gbic
Gi1/9      Name      inactive    1         full    1000 No Gbic
Gi1/10     Name      inactive    1         full    1000 No Gbic
Gi1/11     Name      inactive    1         full    1000 No Gbic
Gi1/12     Name      inactive    1         full    1000 No Gbic
Gi1/13     Name      inactive    1         full    1000 No Gbic
Gi1/14     Name      inactive    1         full    1000 No Gbic
Gi1/15     Name      inactive    1         full    1000 No Gbic
Gi1/16     Name      inactive    1         full    1000 No Gbic
Gi1/17     Name      inactive    1         full    1000 No Gbic
Gi1/18     Name      inactive    1         full    1000 No Gbic
Switch#

```

- To configure the modes of operation for each X2 port group in which you want to deploy Gigabit, enter the **hw-module module *m* port-group *p* select gigabitethernet** command. This configuration is preserved across power cycles and reloads.

To deploy Gigabit Ethernet interfaces using the TwinGig Converter, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Establishes global configuration mode.
Step 2	Switch(config)# hw-module module <i>m</i> port-group <i>p</i> select [gigabitethernet tengigabitethernet]	Selects the mode of operation for each X2 port-group. Default is 10-Gigabit Ethernet (x2).
Step 3	Switch(config)# exit	Exits configuration mode.
Step 4	Switch# show int status mod <i>n</i>	Verifies the setting.

This example shows how to select Gigabit Ethernet interfaces on a WS-X4606-10GE-E using the TwinGig Converter:

```

Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# hw-module module 1 port-group 1 select gigabitethernet
Switch(config)# exit
Switch# show int status mod 1

Port      Name      Status      Vlan      Duplex  Speed Type
Tel/1      Name      inactive    1         full    10G  No X2
Tel/2      Name      inactive    1         full    10G  No X2
Tel/3      Name      inactive    1         full    10G  No X2
Tel/4      Name      notconnect  1         full    10G  No X2
Tel/5      Name      notconnect  1         full    10G  No X2
Tel/6      Name      notconnect  1         full    10G  No X2
Gi1/7      Name      notconnect  1         full    1000 No Gbic
Gi1/8      Name      notconnect  1         full    1000 No Gbic

```

Gi1/9	notconnect	1	full	1000	No	Gbic
Gi1/10	notconnect	1	full	1000	No	Gbic
Gi1/11	notconnect	1	full	1000	No	Gbic
Gi1/12	notconnect	1	full	1000	No	Gbic
Gi1/13	inactive	1	full	1000	No	Gbic
Gi1/14	inactive	1	full	1000	No	Gbic
Gi1/15	inactive	1	full	1000	No	Gbic
Gi1/16	inactive	1	full	1000	No	Gbic
Gi1/17	inactive	1	full	1000	No	Gbic
Gi1/18	inactive	1	full	1000	No	Gbic

Configuring MultiGigabit Ports on WS-X4748-12X48U+E

Cisco's Multigigabit Ethernet technology allows you to leverage 802.11ac Wave 2 speeds on your device. Beginning in Cisco IOS XE Release 3.7.1E, you can configure the WS-X4748-12X48U+E module to auto-negotiate multiple speeds on switch ports, and support 100 Mbps, 1 Gbps, 2.5 Gbps, and 5 Gbps speeds on Category 5e cables, and up to 10 Gbps over Category 6 and Category 6a cables. For more information on supported cables, see [Supported Cable Types and Speed, page 9-20](#).

Beginning in Cisco IOS XE 3.9.1E, by default, downshift is enabled on multigigabit ports. When an interface is unable to establish a high speed link, the line rate is automatically downshifted or reduced to a lower speed. The interface tries up to four times to reestablish a link using the current speed, before downshifting to the next available lower speed. Multigigabit interfaces support downshifting only when the interface speed is set to *auto* on both sides of the link. For information about enabling downshift on WS-X4748-12X48U+E, see [Setting Multigigabit Ethernet Interface Speeds, page 9-35](#).

For more information on 802.11ac Wave 2, see

http://www.cisco.com/c/en/us/products/collateral/wireless/aironet-3600-series/white_paper_c11-713103.html.

This section includes:

- [Module Modes on WS-X4748-12X48U+E Overview, page 9-18](#)
- [Configuring Module Modes on WS-X4748-12X48U+E, page 9-21](#)
- [Upgrading the Line Card FPGA Image on WS-X4748-12X48U+E, page 9-21](#)

For information about setting 2.5G, 5G and 10G interface speeds on WS-X4748-12X48U+E, see [Setting Multigigabit Ethernet Interface Speeds, page 9-35](#).

Module Modes on WS-X4748-12X48U+E Overview

The WS-X4748-12X48U+E module has 48 ports, of which the first 12 ports are 10-Gigabit Ethernet ports and, ports 13 to 48 are GigabitEthernet ports.

Figure 9-4 The WS-X4748-12X48U+E module front panel

1	Ports 1 to 12 - Multigigabit Ethernet ports	2	Ports 13 to 48 - 1 Gigabit Ethernet ports
----------	---	----------	---

You can configure the WS-X4748-12X48U+E module in one of the 3 modes

Mode 1 - Multigigabit Lite (Default)

- Ports 1 to 12 are 100/1000/2.5G/5G/10G Ethernet UPOE ports, oversubscribed 10:1 for 10Gbps port speed.
- Ports 13 to 48 are 10/100/1000 UPOE ports, with no oversubscription.

Mode 2 - Multigigabit Enhanced

- Ports 1 to 12 are 100/1000/2.5G/5G/10G Ethernet UPOE ports, oversubscribed 5:1 for 10Gbps port speed. Ports 1 to 6 share 12G aggregate bandwidth, and ports 7 to 12 share 12G aggregate bandwidth.
- Ports 13 to 24 are inactive (disabled). The LED display for these ports, on the front panel of the device is Off.
- Ports 25 to 48 are 10/100/1000 UPOE ports, with no oversubscription.

Mode 3 - Multigigabit Performance for 10Gbps port speed.

- Ports 1 to 12 are 100/1000/2.5G/5G/10G Ethernet UPOE ports, oversubscribed 2.5:1 for 10Gbps port speed. In this mode, ports 1 to 3, 4 to 6, 7 to 9, 10 to 12 share an aggregate bandwidth of 12G amongst the 3 ports in each group.
- Ports 13 to 48 are inactive (disabled). The LED display for these ports, on the front panel of the device is Off.

Note

10-Gigabit Ethernet, for links up to 100 meters, is supported on Category 6A cables or higher only.

Restrictions for Multigigabit Ports

Note

These restrictions do not apply to ports 13 to 48 that do not support Multigigabit Ethernet

- Ports 1 to 12 do not support 10Mbps speed
- Ports 1 to 12 do not support half-duplex mode for 100Mbps speed.
- Ports 1 to 12 do not support Energy Efficient Ethernet.

Supported Cable Types and Speed

Table 9-1 Cable types and speed

Cable Type	100Mbps	1G	2.5G	5G	10G
Category 5e	Yes	Yes	Yes	Yes	N/A
Category 6	Yes	Yes	Yes	Yes	Yes (55 meters)
Category 6a	Yes	Yes	Yes	Yes	Yes

Supported Hardware and Power Supply

Table 9-2 Supported hardware and power supply

Chassis Type	Supervisor	Power Supply
<ul style="list-style-type: none"> • Cisco Catalyst 4503-E • Cisco Catalyst 4506-E • Cisco Catalyst 4507R+E • Cisco Catalyst 4510R+E 	<ul style="list-style-type: none"> • Supervisor Engine 9-E • Supervisor Engine 8L-E • Supervisor Engine 8-E • Supervisor Engine 7-E • Supervisor Engine 7L-E 	<ul style="list-style-type: none"> • PWR-C45-1300AC • PWR-C45-2800AC • PWR-C45-4200AC • PWR-C45-6000AC • PWR-C45-9000AC • PWR-C45-1400AC¹

1. Power on Ethernet is not supported on PWR-C45-1400AC.

Table 9-3 Hardware and power supply not supported

Chassis Type	Supervisor
<ul style="list-style-type: none"> Cisco Catalyst 4507R-E Cisco Catalyst 4510R-E 	<ul style="list-style-type: none"> Supervisor Engine 6-E, Supervisor Engine 6L-E and earlier.

Configuring Module Modes on WS-X4748-12X48U+E

**Note**

This mode command is applicable only to the selected module. When the mode command is changed for a module, the operation of other modules on the switch is not impacted.

	Command	Purpose
Step 1	Switch# configure terminal	Establishes global configuration mode.
Step 2	Switch(config)# hw-module module <slot> mode <number>	Selects the configuration mode for the selected module.

**Note**

For the selected configuration to be applied, you must reset the module using the **Switch#hw-module module <slot> reset** command.

To verify that the selected configuration is applied, enter the **Switch#show module** command.

The following example shows how to configure an Ethernet mode on WS-X4748-12X48U+E:

```
Switch(config)#hw-module module 3 mode ?
1 Multigigabit lite :12 MultiGigabit ports(10:1 oversubscribed) and 36 1Gigabit ports
2 Multigigabit enhanced :12 MultiGigabit ports(5:1 oversubscribed) and 24 1Gigabit ports
3 Multigigabit performance :12 MultiGigabit ports(2.5:1 oversubscribed) only
```

For information about setting interface speeds to 2.5G, 5G or 10G, see [Setting the Interface Speed, page 9-33](#).

Upgrading the Line Card FPGA Image on WS-X4748-12X48U+E

Beginning in Cisco IOS Release 3.7.1E, a new function to upgrade the line card FPGA on the WS-X4748-12X48U+E module has been introduced to handle oversubscription on multigigabit ports. This upgrade capability allows feature updates or fixes related to the line card FPGA on this module.

**Note**

Before you begin, download the new FPGA image to the bootflash, to a TFTP server, or to a USB drive.

**Caution**

Configuration for this module will be suspended during FPGA upgrade. The module is automatically reset after the upgrade.

To upgrade the line card FPGA on WS-X4748-12X48U+E:

	Command	Purpose
Step 1	Switch# configure terminal	Establishes global configuration mode.
Step 2	Switch(config)# hw-module module <slot> fpga-upgrade image <path:filename>	Upgrades the line card FPGA image on the module.

The following example shows how to upgrade the line card FPGA image:

```
Switch(config)#hw-module slot 1 fpga-upgrade image ?
```

```
bootflash: Path to Linecard FPGA image
tftp: Path to Linecard FPGA image
slot0: Path to Linecard FPGA image
usb0: Path to Linecard FPGA image
```

Invoking Shared-Backplane Uplink Mode on Supervisor Engine 6-E and Supervisor Engine 6L-E

This feature enables you to use all four 10-Gigabit Ethernet ports on the supervisor engines as blocking ports when in redundant mode.

Prior to Cisco IOS Release 12.2(40)SG, Catalyst 4500 Supervisor Engine V-10GE allowed you to enable either the dual wire-speed 10-Gigabit Ethernet ports or four TwinGig convertor based Gigabit Ethernet SFP uplink ports when operating in redundant mode.

Beginning with Cisco IOS Release 12.2(40)SG, you could deploy all four 10-Gigabit Ethernet ports, two blocking ports on an active supervisor engine and two blocking ports on the standby supervisor engine, or all eight Gigabit Ethernet SFP ports, four on the active supervisor and four on the standby supervisor engine. This capability is supported on all Catalyst 4500 and 4500E series chassis.

To enable shared-backplane mode, enter this command:

Command	Purpose
Switch(config)# hw-mod uplink mode shared-backplane	A reload of the active supervisor engine is required to apply the new configuration.

To disable shared-backplane mode, enter this command:

Command	Purpose
Switch(config)# no hw-mod uplink mode shared-backplane	A reload of the active supervisor engine is required to apply the new configuration.

Selecting Uplink Mode on a Supervisor Engine 6-E

You can use the **hw-module uplink mode** command to change the uplink mode to either shared-backplane or tengigabitethernet mode.

Note

Only two 10-Gigabit Ethernet ports or four 1-Gigabit Ethernet ports can be used on the supervisor engine.

Note

When changing the uplink mode using the **hw-module uplink mode shared-backplane** command, you must reload the system. A message appears on the console to reflect this.

To select shared-backplane mode, do the following:

```
Switch(config)# hw-module uplink mode shared-backplane
A reload of the active supervisor is required to apply the new configuration.
Switch(config)# exit
Switch#
```

On a Supervisor Engine 6-E in a 6 or 7-slot chassis (Catalyst 4506-E, 4507R-E, and 4507R+E), the default uplink mode does not allow a WS-X4640-CSFP-E linecard to boot in the last slot because of a hardware limitation. After you use the **hw-module uplink mode tengigabitethernet** command, you must reload the system to enable TenGigabit mode. The configuration is NVGEN'd after you save the running configuration to the startup configuration. You can use the **show run | incl uplink** command to check the uplink configuration before reloading the system. Furthermore, you can enter the **show hw-module uplink** command to display the uplink mode. It reports the current uplink mode, as well as the mode after the system reloads.

In uplink Ten Gigabit mode, the uplink is limited to two Ten Gigabit Ethernet interfaces in non-redundant and in redundant mode; Gigabit Ethernet interfaces are not supported. The WS-X4640-CSFP-E linecard boots in the last slot on 6 and 7-slot chassis. To return to default mode, reload the system from tengigabitethernet mode. SharedBackplane mode can be selected from Default mode, where a system reload is required as well.

The **hw-module module x port-group x select gigabitethernet** command is blocked in uplink TenGigabit mode, preventing you from selecting gigabitethernet mode.

Support for WS-X46490-CSFP-E on a 10-slot Chassis

Starting with Release IOS XE 3.5.0E and IOS 15.2(1)E, the WS-X4640-CSFP-E linecard is supported in a 10-slot chassis for switch mode stand alone and switch mode virtual (VSS). New configurations are saved and reloaded so that the new configuration is applied to the entire switch.

To enable support for WS-X4640-CSFP-E on a 10-slot chassis, enter the following:

```
switch# configuration terminal
switch# hw-module system max-port-num-mode 2
```

To restore the default mode (**Mode 1**), you need to enter the following:

```
switch# configuration terminal
switch# no hw-module system max-port-num-mode 2
```

OR

```
switch# configuration terminal
switch# no hw-module system max-port-num-mode 1
```

OR

```
switch# configuration terminal
switch# hw-module system max-port-num-mode 1
```

Mode 1—a default mode in which the switch is configured to max Vfe subports of 48 per linecard; this configuration does not allow "WS-X4640-CSFP-E" in any of the 8 LC slots.

Mode 2—requires the above configuration to be copied to the startup-config. In this mode, only the first five slots of the chassis are eligible for the line cards. The remaining three slots are unuseable by any other line card including WS-X4640-CSFP-E, effectively reducing a 10-slot chassis to a 7-slot. You can place WS-X4640-CSFP-E in the top five slots, enabling you to use C-Sfp and thereby allow the max 80 ports on each WS-X4640-CSFP-E.

The behavior of a Supervisor Engine 6-E in Mode 2 (which is 10-slot chassis behaving effectively as a 7-slot chassis) matches that of a 7-slot chassis with Supervisor Engine 6-E. In Mode 2, the supervisor engine WS-X45-SUP6-E with the linecard WS-X4640-CSFP-E in the 7th slot will be inactive until an uplink mode change (using the **hw-module uplink mode tengigabitethernet** command) and a reboot. In this case, a syslog is printed to notify the presence of WS-X4640-CSFP-E in the 7th slot to prevent you from performing repetitive reboots.

To display the current mode in which the system is running, enter the following:

```
switch# show hw-module system max-port-num-mode
```

Note

This command is visible only on 10-slot chassis or if 10-slot chassis is present in VSS.

The output of this command is:

```
Active max-port-num-mode configuration is 2
In this mode, last 3 Line card slots shall not be active"
```

In VSS, this output provides the current mode of both active and standby switches.

Limitation and Restrictions on Supervisor Engine 7-E and Supervisor Engine 7L-E

When you use WS-X45-SUP7-E in RPR or SSO mode, only the first two uplinks on each supervisor engine are available. The second two uplinks are unavailable.

Selecting the Uplink Port on a Supervisor Engine 7L-E

With Cisco IOS Release 15.0(2)SG, the SFP+/SFP uplink modes on Supervisor Engine 7L-E (WS-X45-SUP-7L-E) have changed. The number of uplink ports now depends on the supervisor engine mode (single or redundant) and the uplink mode configuration (1-Gigabit or 10-Gigabit). To configure the uplink mode, use the **hw-module uplink select [gigabitethernet/ tengigabitethernet]** command, as follows:

```
Switch(config)# hw-module uplink select?
gigabitethernet      Select the gigabit uplinks
tengigabitethernet   Select the 10G uplinks
```

**Note**

Supervisor Engine 7L-E is not supported on a ten-slot chassis. USB device and SD card support is applicable to Supervisor Engines 9-E, 8-E, and 7-E only.

**Note**

Supervisor Engine 8-E is supported on a 10-slot chassis.

Single Supervisor Mode

In single supervisor mode, WS-X45-SUP-7L-E supports the uplink configuration of at most either two 10-Gigabit or four 1-Gigabit ports ([Table 9-4](#)).

Table 9-4 Uplink Options for Single Supervisor Mode

Supervisor Engine Uplink Ports		Speeds Achievable with the Following Combination of Pluggables (Band Width)
A1	A2	
Choose 10-Gigabit operation through the command line interface.		
SFP+	SFP+	20 Gbps
SFP+	SFP	11 Gbps

SFP+ and SFP can be inserted in any order for lines 2 to 4.

Redundant Supervisor Mode

In redundant supervisor mode, WS-X45-SUP-7L-E supports 1+1 (in 10-Gigabit mode) and 2+2 (in 1-Gigabit mode) ([Table 9-5](#)).

Table 9-5 Uplink Options for Redundant Supervisor Mode

Active Supervisor Uplink Ports				Standby Supervisor Uplink Ports				Speeds Achievable with this Combination of Pluggables
A1	A2	A3	A4	B1	B2	B3	B4	
Choose 10-Gigabit operation through the command line interface.								
SFP+		—	—	SFP+		—	—	20 Gbps
SFP+		—	—	SFP		—	—	11 Gbps
SFP		—	—	SFP+		—	—	11 Gbps
SFP	SFP	—	—	SFP	SFP	—	—	4 Gbps

Limitations and Restrictions on Supervisor Engine 8-E

- When you use Supervisor Engine 8-E in RPR or SSO mode, only the first four uplinks on each supervisor engine are available. The second set of four uplinks are unavailable.

- Memory utilization for the device is calculated using a combination of the **show memory location active** and the **show memory location active-dc** commands. With a daughter card enabled on Supervisor Engine 8-E, the CLI output for the command **show memory location active-dc** shows the value 0 for the config total as no configuration is stored in the daughter card.

Configuring Supervisor Engine 7-E Uplink Mode on Supervisor Engine 8-E

In a ten-slot chassis, by default, Supervisor Engine 8-E supports 80GB uplink bandwidth. The supervisor supports eight active interfaces in non-redundancy mode and the first four active interfaces on both active and standby supervisors, in redundancy mode. Only 47xx series line cards are supported in the tenth slot of the 4510 R+E chassis. The 4510R-E chassis does not support any line cards in the tenth slot, when the daughter card is enabled.

When the daughter card is enabled, Supervisor Engine 8-E restricts uplink bandwidth to 40GB.

For all non-ten-slot chassis (3,6, and 7-slot chassis), Supervisor Engine 8-E mode allows 80GB uplink bandwidth, even with the daughter card enabled.

Supervisor Engine 7-E Mode on Supervisor Engine 8-E

Note

You can configure Supervisor Engine 7-E mode (Sup7-E mode) on Supervisor Engine 8-E in a 10-slot chassis only.

When Sup 7-E mode is enabled, the Supervisor Engine 8-E base board uplink bandwidth is restricted to 40GB as the default configuration in a ten-slot chassis. In non-redundancy mode, the supervisor can support the first four active interfaces. In redundancy mode, this mode supports the first two interfaces on both active and standby supervisors. All line cards are supported in all ten slots in the chassis, with no restriction on the tenth slot.

To enable Sup7-E mode, you must disable the daughter card on the switch.

Supervisor Engine 8-E with Daughter Card Enabled

By default the daughter card is enabled when the supervisor engine is booted in Install Boot mode, and disabled when the supervisor engine is booted in Bundle Boot mode.

When the daughter card is enabled, Supervisor Engine 8-E base board uplink bandwidth is restricted to 40GB as the default configuration in a ten-slot chassis. In non-redundancy mode, the supervisor can support the first four active interfaces. In redundancy mode, the first two interfaces on both the active and the standby supervisors become active. Only 47xx series line cards are supported in the tenth slot of the 4510 R+E chassis. The 4510R-E chassis does not support any line cards in the tenth slot, when the daughter card is enabled.

Supervisor Engine 8-E Uplink Configurations

The following table displays the default uplink configuration for Supervisor Engine 8-E, based on the redundancy mode and whether the daughter card is enabled.

Table 9-6 **Sup 8-E Uplink Configuration Modes**

Supervisor Configuration	Uplink Ports	Wireless Termination/Daughter Card	Linecard/Chassis Restrictions	User Configuration
Single Supervisor (Sup7E Mode)	4x10GE		10-slot Chassis: No restriction	Requires CLI configuration followed by a supervisor engine reload.
			3,6 and 7 Slot Chassis: Configuration not supported	
Single Supervisor	4x10GE	20GE	10-slot Chassis: Restriction on the 10th slot.*	Default configuration in Install Boot mode.
			3,6 and 7 Slot Chassis: No restriction	
Single Supervisor	8x10GE		10-slot Chassis: Restriction on the 10th slot.*	Default configuration in Bundle Boot mode.
			3,6 and 7 Slot Chassis: No restriction	
Single Supervisor	8x10GE		10-slot Chassis: Restriction on the 10th slot.* Wireless/Daughter Card enabled.	Default configuration in Install Boot mode. Requires CLI configuration to force disable the daughter card followed by a supervisor engine reload.
		20GE	3,6 and 7 Slot Chassis: No restriction	Default configuration in Install Boot mode.
Dual Supervisor (Sup 7-E mode)	Active Supervisor: 2x10GE		10-slot Chassis: No restriction	Requires CLI configuration followed by a supervisor engine reload.
	Standby Supervisor: 2x10GE		3,6 and 7 Slot Chassis: Configuration not supported	
Dual Supervisor	Active Supervisor: 2x10GE	20GE	10-slot Chassis: Restriction on the 10th slot.*	Default configuration in Install Boot mode.
	Standby Supervisor: 2x10GE		3,6 and 7 Slot Chassis: Configuration not supported	

Table 9-6 Sup 8-E Uplink Configuration Modes

Supervisor Configuration	Uplink Ports	Wireless Termination/Daughter Card	Linecard/Chassis Restrictions	User Configuration
Dual Supervisor	Active Supervisor: 4x10GE		10-slot Chassis: Restriction on the 10th slot.*	Default configuration in Bundle Boot mode.
	Standby Supervisor: 4x10GE		3,6 and 7 Slot Chassis: No restriction	Requires CLI configuration followed by a supervisor engine reload.
Dual Supervisor	Active Supervisor: 4x10GE	20GE	10-slot Chassis: Restriction on the 10th slot.* Wireless Mode enabled by default.	Default configuration in Install Boot mode. Requires CLI configuration to force disabled the daughter card followed by a supervisor engine reload.
	Standby Supervisor: 4x10GE		3,6 and 7 Slot Chassis: No restriction	Default configuration in Install Boot mode.

*Only 47xx series line cards are supported in the tenth slot of the 4510 R+E chassis. The 4510R-E chassis does not support any line cards in the tenth slot, when the daughter card is enabled.

Restrictions for Configuring Sup 7-E Uplink Mode on Supervisor Engine 8-E

- In Install Boot mode, Supervisor Engine 7-E cannot be configured directly configured as the daughter card is enabled by default.
- Supervisor Engine 7-E mode cannot be configured on a 3, 6, and 7-slot chassis.
- Supervisor Engine 7-E mode is supported only for a symmetric VSS system.

Configuring Supervisor Engine 7-E Mode on Supervisor Engine 8-E

Note

Before you begin, ensure that the daughter card is disabled on the switch.

By default, the daughter card is enabled when the supervisor engine is booted in Install Boot mode and you cannot configure Supervisor Engine 7-E (Sup 7-E) mode until you disable the daughter card on the switch.

Note

Ensure that the supervisor engine is reloaded each time you make uplink configuration changes.

To disable the daughter card, enter the following commands:

	Command	Purpose
Step 1	switch (config)# hw-module daughtercard disable	Disables the daughter card on the switch. Note This command is not available in Bundle Boot mode.
Step 2	Save the configuration and perform a power cycle or reload the supervisor. Then enter: switch# sh hw-module daughtercard	Displays updated daughter card details for Supervisor Engine 8-E, after the supervisor engine is reloaded.

The **no** form of the **hw-module daughtercard disable** command enables the daughter card.

To enable Sup7-E mode on Supervisor Engine 8-E, when the daughter card is disabled, enter the following commands:

	Command	Purpose
Step 1	switch (config)# hw-module uplink mode 40Gig	Configures the uplink mode to 40GB.
Step 2	Save the configuration and perform a power cycle or reload the supervisor. Then enter: switch# show run incl uplink	Displays the uplink configuration for Supervisor Engine 8-E.

The **no** form of the **hw-module uplink mode 40Gig** command restores the default Supervisor Engine 8-E mode.

Supervisor Engine 9-E Uplink Configurations

Starting with Cisco IOS XE Release 3.10.0E, Cisco Catalyst 4500E Series Switches support Supervisor Engine 9-E. This supervisor model provides

- Four 10 Gigabit Ethernet (4 x 10GE) uplink ports.
- Two 40 Gigabit Ethernet (2 x 40GE) uplink ports

Table 9-7 **Sup 9-E Uplink Configuration Modes**

Supervisor Configuration	Uplink Ports	Wireless Termination or Daughter Card	Linecard/Chassis Restrictions	User Configuration
Single Supervisor	4x10GE	—	10-slot Chassis: None 3,6 and 7 Slot Chassis: None	Requires CLI configuration followed by a supervisor engine reload.
Single Supervisor	4x10GE	20GE	10-slot Chassis: Restriction on the 10th slot.* 3,6 and 7 Slot Chassis: None	

Table 9-7 **Sup 9-E Uplink Configuration Modes**

Supervisor Configuration	Uplink Ports	Wireless Termination or Daughter Card	Linecard/Chassis Restrictions	User Configuration
Single Supervisor	2x40GE	—	10-slot Chassis: Restriction on the 10th slot.*	Default configuration in Bundle Boot mode.
			3,6 and 7 Slot Chassis: None	
Single Supervisor	2x40GE	20GE	10-slot Chassis: 10th slot disabled Daughter Card enabled.	Default configuration in Install Boot mode. Requires CLI configuration to force disable the daughter card followed by a supervisor engine reload.
			3,6 and 7 Slot Chassis: None	Default configuration in Install Boot mode.
Dual Supervisor	Active Supervisor: 2x10GE Standby Supervisor: 2x10GE	—	10-slot Chassis: None	Requires CLI configuration followed by a supervisor engine reload.
			7 Slot Chassis: None	
Dual Supervisor	Active Supervisor: 2x10GE Standby Supervisor: 2x10GE	20GE	10-slot Chassis: Restriction on the 10th slot.*	Default configuration in Install Boot mode.
			7 Slot Chassis: None	
Dual Supervisor	Active Supervisor: 1x40GE Standby Supervisor: 1x40GE	—	10-slot Chassis: Restriction on the 10th slot.*	Default configuration in Bundle Boot mode.
			7 Slot Chassis: None	Requires CLI configuration followed by a supervisor engine reload.
Dual Supervisor	Active Supervisor: 1x40GE Standby Supervisor: 1x40GE	20GE	10-slot Chassis: Unsupported (10-slot is disabled)	-
			7 Slot Chassis: None	Default configuration in Install Boot mode.

*Only 47xx series line cards are supported in the tenth slot of the 4510R+E chassis.

Limitations and Restrictions on Supervisor Engine 9-E

- The supervisor is not compatible with the Catalyst 4510R-E and 4507R-E chassis

- When the **hw-module uplink mode 80Gig** command is enabled, the wireless mode is unsupported in the 10th slot of the Catalyst 4510R+E chassis

Selecting the Uplink Mode on Supervisor Engine 9-E

By default, when the supervisor boots, the 4 x 10GE uplinks are available. To boot with 2 x 40GE uplinks, you must enable the 80Gig mode:

1. Check current configuration on the active supervisor. The example shows that the current mode is to boot with 4 x 10GE uplinks:

```
Switch (config)# show hw-module uplink
Active uplink mode configuration is 4X10Gig
```

2. Specify 80Gig in the global configuration mode

```
Switch# configure terminal
Switch(config)# hw-module uplink mode 80Gig
A reload or power-cycle of the active supervisor is required to apply the new
configuration.
Switch(config)#
```

3. Power cycle the active supervisor engine for configuration to take effect:

```
rommon 0 >set
PS1=rommon ! >
RommonVer=15.1(1r)SG(11)
...<output truncated>
cisco WS-C4507R+E (P5040) processor (revision 2) with 4194304K bytes of physical
memory.
Processor board ID FXS1736Q20Q
P5040 CPU at 2.2GHz, Supervisor 9-E
Last reset from Reload
1 Virtual Ethernet interface
48 Gigabit Ethernet interfaces
2 Forty Gigabit Ethernet interfaces
511K bytes of non-volatile configuration memory
...<output truncated>
```

4. Verify current configuration on the active supervisor again. The example shows that the current mode is now 2 x40GE uplinks (a total of 80Gig):

```
Switch# show hw-module uplink
Active uplink mode configuration is 2X40Gig
```

5. You will now be able to configure 40-GE interfaces

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface ?
Bluetooth          Bluetooth interface
FastEthernet        FastEthernet IEEE 802.3
FortyGigabitEthernet Forty Gigabit Ethernet
GigabitEthernet     GigabitEthernet IEEE 802.3z
LISP                Locator/ID Separation Protocol Virtual Interface
Loopback            Loopback interface
Lspvif              LSP virtual interface
Null                Null interface
Port-channel        Ethernet Channel of interfaces
Tunnel              Tunnel interface
Vlan                Catalyst Vlans
range               interface range command
```

```
Switch(config)#interface fortygigabitethernet1/1
Switch (config-if)#
```

The **no** form of the **hw-module uplink mode 80Gig** command restores the default Supervisor Engine 9-E mode (4 x 10GE uplinks).

Digital Optical Monitoring Transceiver Support

Command line interface (CLI) commands (**show inventory**, **show idprom interface**) are used on transceivers to obtain serial number, model name, inventory information.

The following commands are specific to the transceivers that support the DOM capability:

- Displays current values and thresholds for all sensor on a particular interface transceiver:

```
show interfaces int-name transceiver [detail] [threshold]
```

- Enables or disables the *entSensorThresholdNotification* for all sensors in all the transceivers:

```
snmp-server enable trap transceiver
```

- Enables or disables transceiver monitoring:

```
transceiver type all
monitoring
```

Note

This feature is only available when a DOM capable transceiver is present and configured for monitoring. The frequency at which the sensor information is refreshed depends on default values configured in the transceiver EEPROM (Serial Electrically Erasable Programmable Read Only Memory).

Note

For details on transceiver module compatibility, refer to this URL:

http://www.cisco.com/en/US/products/hw/modules/ps5455/products_device_support_tables_list.html

Configuring Optional Interface Features

The following sections describe optional procedures:

- [Configuring Ethernet Interface Speed and Duplex Mode, page 9-32](#)
- [Configuring Flow Control, page 9-38](#)
- [Configuring Jumbo Frame Support, page 9-40](#)
- [Interacting with Baby Giants, page 9-44](#)
- [Configuring the Port Debounce Timer, page 9-44](#)
- [Configuring Auto-MDIX on a Port, page 9-45](#)

Configuring Ethernet Interface Speed and Duplex Mode

Topics include:

- [Speed and Duplex Mode Configuration Guidelines, page 9-33](#)
- [Setting the Interface Speed, page 9-33](#)
- [Setting the Interface Duplex Mode, page 9-35](#)
- [Displaying the Interface Speed and Duplex Mode Configuration, page 9-36](#)
- [Adding a Description for an Interface, page 9-38](#)

Speed and Duplex Mode Configuration Guidelines

Note

You do not configure the client device for autonegotiation. Instead, you configure the switch with the speed, or range of speeds, that you want to autonegotiate.

You can configure the interface speed and duplex mode parameters to **auto** and allow the Catalyst 4500 series switch to negotiate the interface speed and duplex mode between interfaces. If you decide to configure the interface **speed** and **duplex** commands manually, consider the following:

- If you enter the **no speed** command, the switch automatically configures both interface **speed** and **duplex** to **auto**.
- When you set the interface speed to **1000** (Mbps) or **auto 1000**, the duplex mode is full duplex. You cannot change the duplex mode.
- If the interface speed is set to **10** or **100**, the duplex mode is set to half duplex by default unless you explicitly configure it.

On a Catalyst 4500-X switch, the duplex mode is always automatically configured as full duplex (whether you set the interface speed to **10** or **100**). You cannot change this.

Caution

Changing the interface speed and duplex mode configuration might shut down and restart the interface during the reconfiguration.

Setting the Interface Speed

If you set the interface speed to **auto** on a 10/100-Mbps Ethernet interface, speed and duplex are autonegotiated. The forced 10/100 autonegotiation feature allows you to limit interface speed auto negotiation up to 100 Mbps on a 10/100/1000BASE-T port.

To set the port speed for a 10/100-Mbps Ethernet interface, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface fastethernet <i>slot/interface</i>	Specifies the interface to be configured.
Step 2	Switch(config-if)# speed [10 100 auto [10 100]]	Sets the interface speed.

This example shows how to set the interface speed to 100 Mbps on the Fast Ethernet interface 5/4:

```
Switch(config)# interface fastethernet 5/4
Switch(config-if)# speed 100
```

This example shows how to allow Fast Ethernet interface 5/4 to autonegotiate the speed and duplex mode:

```
Switch(config)# interface fastethernet 5/4
Switch(config-if)# speed auto
```

Note The preceding CLI is analogous to **speed auto 10 100**.

This example shows how to limit the interface speed to 10 and 100 Mbps on the Gigabit Ethernet interface 1/1 in auto-negotiation mode:

```
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# speed auto 10 100
```

This example shows how to limit speed negotiation to 100 Mbps on the Gigabit Ethernet interface 1/1:

```
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# speed auto 100
```

Note Turning off autonegotiation on a Gigabit Ethernet interface results in the port being forced into 1000 Mbps and full-duplex mode.

To turn off the port speed autonegotiation for Gigabit Ethernet interface 1/1, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface gigabitethernet1/1	Specifies the interface to be configured.
Step 2	Switch(config-if)# speed nonegotiate	Disables autonegotiation on the interface.

To restore autonegotiation, enter the **no speed nonegotiate** command in the interface configuration mode.

Note For the blocking ports on the WS-X4416 module, do not set the speed to autonegotiate. To set port speed to 10/ 100 Mbps on a 10-Gigabit Ethernet interface (on a 1000Base-T port), perform this task:

	Command	Purpose
Step 1	Switch(config)# interface tengigabitethernet slot/interface	Specifies the interface to be configured.
Step 2	Switch(config-if)# speed [10 100]	Sets the interface speed. Forced 10/100 auto-negotiation is not supported on a 1000Base-T port

To restore autonegotiation (default setting), enter the **no speed** command in the interface configuration mode.

This example shows how to set the interface speed to 100 Mbps on a 10-Gigabit Ethernet interface 2/4:

```
Switch(config)# interface tengigabitethernet 2/4
Switch (config-if)# speed 100
```

Setting Multigigabit Ethernet Interface Speeds

Only ports 1 to 12 on the WS-X4748-12X48U+E module support Multigigabit Ethernet. For more information, see [Configuring MultiGigabit Ports on WS-X4748-12X48U+E, page 9-18](#).

To set port speed to 2500Mbps (2.5Gbps) / 5000Mbps (5Gbps) / 10000Mbps (10Gbps) on a Multigigabit Ethernet interface (on a 1000Base-T port), perform this task:

Note

For Multigigabit Ethernet ports 1 to 12, autonegotiation is enabled by default, and the link is active if both peers are Multigigabit Ethernet ports, and if forced speed is configured.

For 1 Gigabit Ethernet ports 13 to 48, the link is active only if autonegotiation is enabled at least at one end, and forced speed is configured.

	Command	Purpose
Step 1	Switch(config)# interface tengigabitethernet <i>slot/interface</i>	Specifies the interface to be configured.
Step 2	Switch(config-if)# speed [100 1000 2500 5000 10000 auto [100 1000 2500 5000 10000]]	Sets the interface speed. Note 10G speed is supported only on Category 6 and Category 6a cables.
Step 3	Switch(config-if)# [no] downshift disable	By default, downshift is enabled on multigigabit ports. The downshift disable command disables downshift on the specified interface. The no downshift disable command enables downshift on the interface.

This example shows how to set the interface speed to 5G on the Multigigabit Ethernet interface 3/1:

```
Switch(config)# interface tengigabitethernet 3/1
Switch (config-if)# speed 5000
```

This example shows how to allow the Multigigabit Ethernet interface 3/1 to autonegotiate the speed and duplex mode:

```
Switch(config)# interface gigabitethernet 3/1
Switch(config-if)# speed auto
```

This example shows how to limit speed negotiation to 2.5G on the Multigigabit Ethernet interface 3/1:

```
Switch(config)# interface gigabitethernet 3/1
Switch(config-if)# speed auto 2500
```

This example shows how to enable downshift on the Multigigabit Ethernet interface 3/1:

```
Switch(config)# interface gigabitethernet 3/1
Switch(config-if)# speed auto
Switch(config-if)# no disable downshift
```

Setting the Interface Duplex Mode

Note

When the interface is set to 1000 Mbps, you cannot change the duplex mode from full duplex to half duplex.

To set the duplex mode of a Fast Ethernet interface, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface fastethernet <i>slot/interface</i>	Specifies the interface to be configured.
Step 2	Switch(config-if)# duplex [auto full half]	Sets the duplex mode of the interface.

This example shows how to set the interface duplex mode to full on Fast Ethernet interface 5/4:

```
Switch(config)# interface fastethernet 5/4
Switch(config-if)# duplex full
```

Displaying the Interface Speed and Duplex Mode Configuration

To display the interface speed and duplex mode configuration for an interface, enter this command:

Command	Purpose
Switch# show interfaces [fastethernet gigabitethernet tengigabitethernet] <i>slot/interface</i>	Displays the interface speed and duplex mode configuration.

This example shows how to display the interface speed and duplex mode of Fast Ethernet interface 6/1:

```
Switch# show interface fastethernet 6/1
FastEthernet6/1 is up, line protocol is up
  Hardware is Fast Ethernet Port, address is 0050.547a.dee0 (bia 0050.547a.dee0)
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 100Mb/s
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:54, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 50/2000/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
    50 packets input, 11300 bytes, 0 no buffer
    Received 50 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
    0 input packets with dribble condition detected
    1456 packets output, 111609 bytes, 0 underruns
    0 output errors, 0 collisions, 0 interface resets
    0 babbles, 0 late collision, 0 deferred
    1 lost carrier, 0 no carrier
    0 output buffer failures, 0 output buffers swapped out
Switch#
```

This example shows how to display the interface speed and duplex mode of 10-Gigabit Ethernet interface 1/5:

```
Switch# show interface tengigabitethernet 1/5
TenGigabitEthernet1/5 is up, line protocol is up (connected)
  Hardware is Ten Gigabit Ethernet Port, address is 0022.bde2.0f6d (bia 0022.bde2.0f6d)
  MTU 1500 bytes, BW 10000000 Kbit/sec, DLY 10 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 10Gb/s, link type is auto, media type is 10GBase-SR
  input flow-control is on, output flow-control is on
  ARP type: ARPA, ARP Timeout 04:00:00

Switch#
```

Adding a Description for an Interface

You can add a description about an interface to help you remember its function. The description appears in the output of the following commands: **show configuration**, **show running-config**, and **show interfaces**.

To add a description for an interface, enter the following command:

Command	Purpose
Switch(config-if)# description <i>string</i>	Adds a description for an interface.

This example shows how to add a description on Fast Ethernet interface 5/5:

```
Switch(config)# interface fastethernet 5/5
Switch(config-if)# description Channel-group to "Marketing"
```

Configuring Flow Control

Gigabit Ethernet ports use flow control to slow down the transmission of incoming packets. If a buffer on a Gigabit Ethernet port runs out of space, the port transmits a special packet that requests remote ports to delay sending packets for a period of time. The port can also receive this special packet from its link partner for the same purpose. This special packet is called a *pause frame*.

The default settings for Gigabit Ethernet interfaces are as follows:

- Sending pause frames is off—Non-oversubscribed Gigabit Ethernet interfaces.
- Receiving pause frames is desired—Non-oversubscribed Gigabit Ethernet interfaces.
- Sending pause frames is on—Oversubscribed Gigabit Ethernet interfaces.
- Receiving pause frames is desired—Oversubscribed Gigabit Ethernet interfaces

The default settings for 10-Gigabit Ethernet interfaces are as follows:

- Sending pause frames is off.
- Receiving pause frames is on.

Note

desired is not a flow control option on the 10-Gigabit Ethernet interfaces.

To configure flow control, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and specifies the interface to be enabled for flowcontrol.
Step 3	Switch(config-if)# flowcontrol { receive send } { off on desired }	Configures a Gigabit Ethernet port to send or receive pause frames.
Step 4	Switch(config-if)# end	Returns to configuration mode.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.

This example shows how to configure flow control on an oversubscribed Gigabit Ethernet port 7/5:

```
Switch# configure terminal
Switch(config)# interface g7/5
Switch(config-if)# flowcontrol send on
Switch(config-if)# end
Switch)# show interfaces gigabitEthernet 7/5 capabilities
GigabitEthernet7/5
  Model: WS-X4548-GB-RJ45-RJ-45
  Type: 10/100/1000-TX
  Speed: 10,100,1000,auto
  Duplex: half,full,auto
  Trunk encap. type: 802.1Q,ISL
  Trunk mode: on,off,desirable,nonegotiate
  Channel: yes
  Broadcast suppression: percentage(0-100), hw
  Flowcontrol: rx- (off,on,desired),tx- (off,on,desired)

Configuring Jumbo Frame Support

These sections describe jumbo frame support:

- [Ports and Modules That Support Jumbo Frames, page 9-40](#)
- [Jumbo Frame Support, page 9-41](#)
- [Configuring MTU Sizes, page 9-43](#)

Ports and Modules That Support Jumbo Frames

The following ports and modules support jumbo frames:

- Supervisor uplink ports
- WS-C4500X ports
- WS-X4306-GB: all ports
- WS-X4232-GB-RJ: ports 1-2
- WS-X4418-GB: ports 1-2
- WS-X4412-2GB-TX: ports 13-14
- WS-X4506-GB-T
- the 4648-GB-RJ45V
- WS-X4648-GB+RJ45V
- WS-X4648-RJ45V-E
- WS-X4648-RJ45V+E
- WS-X4706-10GE

Jumbo Frame Support

These sections describe jumbo frame support:

- [Maximum Transmission Units, page 9-41](#)
- [Jumbo Frame Support Overview, page 9-41](#)
- [Ethernet Ports, page 9-42](#)
- [VLAN Interfaces, page 9-42](#)

Maximum Transmission Units

The Catalyst 4500 series switch allows you to configure a maximum of 32 different maximum transmission unit (MTU) sizes system wide. This means that the maximum number of different MTU sizes that you can configure with the **system mtu**, **mtu**, **ip mtu**, and **ipv6 mtu** command on all Layer 2 and Layer 3 interfaces combined is 32.

Also, the system stores the IPv4 and IPv6 MTU sizes configured on an interface separately. For every **system mtu** command or per interface **mtu** command, two separate MTU values are stored, one for IPv4 and one for IPv6. This further reduces the number of slots available (out of 32). However, only a single MTU value is stored for each **ip mtu** and **ipv6 mtu** commands.

If the new MTU value you are configuring is already present in the system (that is, configured on some other interface), then no new slot(s) are allocated to store it again.

If the maximum limit of 32 is reached and an attempt is made to configure a new MTU size on a new interface, the system only allows configuration to proceed if the new MTU size has previously been configured on some interface. Otherwise, an error message is displayed and the default MTU size is assigned to the interface being configured.

Jumbo Frame Support Overview

A jumbo frame is a frame larger than the default Ethernet size. Enable jumbo frame support by configuring a larger-than-default MTU size on a port or interface.

Catalyst 4500 series switch Ethernet LAN ports configured with a nondefault MTU size accept frames containing packets with a size between 1500 and 9216 bytes (including Ethernet payload, header and trailer). With a nondefault MTU size configured, the packet size of ingress frames is checked. If the packet is larger than the configured MTU, it is dropped.

For traffic that needs to be routed, the MTU of the egress port is checked. If the MTU is smaller than the packet size, the packet is forwarded to the CPU. If the “do not fragment bit” is not set, it is fragmented. Otherwise, the packet is dropped.

**Note**

Jumbo frame support does not fragment Layer 2 switched packets.

The Catalyst 4500 series switch does not compare the packet size with the MTU at the egress port, but jumbo frames are dropped in ports that do not support them. The frames can be transmitted in ports that do support jumbo frames, even though the MTU is not configured to jumbo size.

**Note**

Jumbo frame support is only configured per interface; jumbo frame support cannot be configured globally.

Ethernet Ports

These sections describe configuring nondefault MTU sizes on Ethernet ports:

- [Ethernet Port Overview, page 9-42](#)
- [Layer 3 and Layer 2 EtherChannels, page 9-42](#)

Ethernet Port Overview

Starting with Cisco IOS Release 12.2(31)SGA, configuring a nondefault MTU size on certain Ethernet ports limits the size of ingress packets. The MTU does not impact the egress packets.

Prior to Cisco IOS Release 12.1(13)EW, you could configure the MTU size only on Gigabit Ethernet.

Layer 3 and Layer 2 EtherChannels

Starting with Release Cisco IOS Release 12.2(31)SGA, you could configure all the interfaces in an EtherChannel provided that they have the same MTU. Changing the MTU of an EtherChannel changes the MTU of all member ports. If the MTU of a member port cannot be changed to the new value, that port is suspended (administratively shut down). A port cannot join an EtherChannel if the port has a different MTU. If a member port of an EtherChannel changes MTU, the member port is suspended.

VLAN Interfaces

If switch ports reside in the same VLAN, either configure all of the switch ports to handle jumbo frames and support the same MTU size, or configure none of them. However, such uniformity of MTU size in the same VLAN is not enforced.

When a VLAN has switch ports with different MTU size, packets received from a port with a larger MTU might be dropped when they are forwarded to a port with a smaller MTU.

If the switch ports in a VLAN have jumbo frames enabled, the corresponding SVI can have jumbo frames enabled. The MTU of an SVI should always be smaller than the smallest MTU among all the switch ports in the VLAN, but this condition is not enforced.

The MTU of a packet is not checked on the ingress side for an SVI; it is checked on the egress side of an SVI. If the MTU of a packet is larger than the MTU of the egress SVI, the packet is sent to the CPU for fragmentation processing. If the “do not fragment” bit is not set, the packet is fragmented. Otherwise, the packet is dropped.

Configuring MTU Sizes

To configure the MTU size, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface {{vlan vlan_ID} {{type ¹ slot/port} {port-channel port_channel_number} slot/port}}	Selects the interface to configure.
Step 2	Switch(config-if)# mtu mtu_size Switch(config-if)# no mtu	Configures the MTU size. Reverts to the default MTU size (1500 bytes).
Step 3	Switch(config-if)# end	Exits configuration interface mode.
Step 4	Switch(config)# end	Exits configuration mode.
Step 5	Switch# show running-config interface [{fastethernet gigabitethernet} slot/port]	Verifies the running configuration.

1. *type* = fastethernet, gigabitethernet, or tengigabitethernet

Note

When you remove a line card, and then reinsert the card, some or all of the MTU values configured on the ports of that line card may be unconfigured. This occurs if the system wide limit of 32 different MTUs is reached while the card is removed. Upon reinserting the line card, the system attempts to reapply the MTU configuration on the ports. If this attempt fails, the MTU values are set to the default.

Note

When configuring the MTU size for VLAN interfaces and Layer 3 and Layer 2 Ethernet ports, note that the supported MTU values are from 1500 to 9198 bytes.

This example shows how to configure the MTU size on Gigabit Ethernet port 1/1:

```
switch# conf terminal
switch(config)# interface gil1/1
switch(config-if)# mtu 9198
switch(config-if)# end
switch(config)# end
switch# show interface gigabitethernet 1/2
GigabitEthernet1/2 is administratively down, line protocol is down
  Hardware is C6k 1000Mb 802.3, address is 0030.9629.9f88 (bia 0030.9629.9f88)
  MTU 9216 bytes, BW 1000000 Kbit, DLY 10 usec,
<...Output Truncated...>
switch#
```

Interacting with Baby Giants

The baby giants feature, introduced in Cisco IOS Release 12.1(12c)EW, uses the global command **system mtu size** to set the global baby giant MTU. This feature also allows certain interfaces to support Ethernet payload size of up to 1552 bytes.

Both the **system mtu** command and the per-interface **mtu** command can operate on interfaces that can support jumbo frames, but the per-interface **mtu** command takes precedence.

For example, before setting the per-interface MTU for interface gi1/1, you enter the **system mtu 1550** command to change the MTU for gi1/1 to 1550 bytes. You enter the per-interface **mtu** command to change the MTU for gi1/1 to 9198 bytes. If you change the baby giant MTU to 1540 bytes with the command **system mtu 1540**, the MTU for gi1/1 remains unchanged at 9198 bytes.

Configuring the Port Debounce Timer

Note

You can only configure port debounce on 10-Gigabit Ethernet ports.

The port debounce timer suppresses notification of short link-down events. Link-down events that are shorter than the port debounce timer are not notified to Layer 2 or Layer 3 protocols, decreasing traffic loss due to network reconfiguration. You can configure the port debounce timer separately on each LAN port.

Caution

Enabling the port debounce timer causes a delay in link down detections, resulting in loss of traffic during the debouncing period. This situation might affect the convergence and reconvergence of some Layer 2 and Layer 3 protocols.

To configure the debounce timer on a port, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface tengigabitethernet slot/port	Selects the port to configure.
Step 2	Switch(config-if)# link debounce [time debounce_time]	Configures the debounce timer.
	Switch(config-if)# no link debounce	Reverts to the default setting.
Step 3	Switch# show interfaces debounce	Verifies the configuration.

Note

The default time is 10ms for E-series supervisor engines and line cards.

When configuring the debounce timer on a port, you can increase the port debounce timer value between 10 milliseconds and 5000 milliseconds on the 10-Gigabit Ethernet ports.

This example shows how to enable the port debounce timer on 10-Gigabit Ethernet port 2/1 and to accept the default value (10 ms):

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
```

```
Switch(config)# interface tenGigabitEthernet 2/1
Switch(config-if)# link debounce
Warning: Enabling debounce feature causes link down detection to be delayed
Switch(config-if)# exit
```

This example shows how to enable the port debounce timer of 5000 ms on 10-Gigabit Ethernet port 2/2 and to verify the setting:

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface tenGigabitEthernet 2/2
Switch(config-if)# link debounce time 5000
Warning: Enabling debounce feature causes link down detection to be delayed
Switch(config-if)# end
Switch#
Switch# show interfaces debounce | include enable
Te2/1      enable      10
Te2/2      enable      5000
Switch#
```

Configuring Auto-MDIX on a Port

When automatic medium-dependent-interface crossover (auto-MDIX) is enabled on an port, the port automatically detects the required cable connection type (straight through or crossover) and configures the connection appropriately. When connecting switches without the auto-MDIX feature, you must use straight-through cables to connect to devices such as servers, workstations, or routers and crossover cables to connect to other switches or repeaters. With auto-MDIX enabled, use either type of cable to connect to other devices; the interface automatically corrects for any incorrect cabling. For more information about cabling requirements, see the hardware installation guide.

Auto-MDIX is enabled by default. When you enable auto-MDIX, you must also set the speed on the port to **auto** so that for the feature to operate correctly. auto-MDIX is supported on copper media ports. It is not supported on fiber media ports.

Note

The following line cards support Auto-MDIX by default, when port auto-negotiation is enabled: WS-X4424-GB-RJ45, WS-X4448-GB-RJ45, WS-X4548-GB-RJ45 and WS-X4412-2GB-T. You cannot disable them with the **mdix** command.

Note

The following line cards do not support Auto-MDIX, neither by default nor by CLI: WS-X4548-GB-RJ45V, WS-X4524-GB-RJ45V, WS-X4506-GB-T, WS-X4148-RJ, WS-X4248-RJ21V, WS-X4248-RJ45V, WS-X4224-RJ45V and WS-X4232-GB-RJ.

Note

The following line cards support Auto-MDIX through the CLI on their copper media ports: WS-X4124-RJ45, WS-X4148-RJ45 (hardware revision 3.0 or higher), and WS-X4232-GB-RJ45 (hardware revision 3.0, or higher), WS-4648-RJ45V+E, WS-X4748-UPOE+E and WS-X4748-RJ45+E (Auto-MDIX support when inline power is disabled on the port).

Table 9-8 shows the link states that results from auto-MDIX settings and correct and incorrect cabling.

Table 9-8 Link Conditions and auto-MDIX Settings

Local Side auto-MDIX	Remote Side auto-MDIX	With Correct Cabling	With Incorrect Cabling
On	On	Link up	Link up
On	Off	Link up	Link up
Off	On	Link up	Link up
Off	Off	Link up	Link down

To configure auto-MDIX on a port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode for the physical interface to be configured.
Step 3	Switch(config-if)# speed auto	Configures the port to autonegotiate speed with the connected device.
Step 4	Switch(config-if)# mdix auto	Enables auto-MDIX on the port.
Step 5	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 6	Switch# show interfaces <i>interface-id</i>	Verifies the configuration of the auto-MDIX feature on the interface.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable auto-MDIX, use the **no mdix auto** interface configuration command.

This example shows how to enable auto-MDIX on a port:

```
Switch# configure terminal
Switch(config)# interface fastethernet 6/5
Switch(config-if)# speed auto
Switch(config-if)# mdix auto
Switch(config-if)# end
```

Displaying the Interface Auto-MDIX Configuration

To display the interface speed and duplex mode configuration for an interface, perform this task:

	Command	Purpose
Step 1	Switch> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	Switch# show interfaces type slot/interface	Displays the interface auto-MDIX configuration setting and operational state.

Depending on how the **speed auto** and the **mdix auto** commands are configured on a supported line card interface, the **show interfaces** command displays the following possible auto-MDIX statuses:

[Table 9-9](#) shows the auto-MDIX setting and operational state and the status of auto-MDIX.

Table 9-9 Auto-MDIX and Operational State

Auto-MDIX Setting and Operational State on an Interface	Description
Auto-MDIX on (operational: on)	Auto-MDIX is enabled and is fully functioning.
Auto-MDIX on (operational: off)	Auto-MDIX is enabled on this interface but it is not functioning. To allow auto-MDIX feature to function properly, you must also set the interface speed to be autonegotiated.
Auto-MDIX off	Auto-MDIX has been disabled with the no mdix auto command.

This example shows how to display the auto-MDIX configuration setting and its operational state on Fast Ethernet interface 6/1:

```
Switch# show interfaces fastethernet 6/1
FastEthernet6/1 is up, line protocol is up (connected)
  Hardware is Fast Ethernet Port, address is 0001.64fe.e5d0 (bia 0001.64fe.e5d0)
  MTU 1500 bytes, BW 100000 Kbit, DLY 100 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 100Mb/s, link type is auto, media type is 10/100BaseTX
  input flow-control is unsupported output flow-control is unsupported
  Auto-MDIX on (operational: on)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input 00:00:16, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/2000/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
    511 packets input, 74464 bytes, 0 no buffer
    Received 511 broadcasts (511 multicasts)
    0 runs, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
    0 input packets with dribble condition detected
    3552 packets output, 269088 bytes, 0 underruns
    0 output errors, 0 collisions, 0 interface resets
    0 babbles, 0 late collision, 0 deferred
    1 lost carrier, 0 no carrier
    0 output buffer failures, 0 output buffers swapped out
Switch#
```

Understanding Online Insertion and Removal

The online insertion and removal (OIR) feature supported on the Catalyst 4500 series switch allows you to remove and replace modules while the system is online. You can shut down the module before removal and restart it after insertion without causing other software or interfaces to shut down.

You do not need to enter a command to notify the software that you are going to remove or install a module. The system notifies the supervisor engine that a module has been removed or installed and scans the system for a configuration change. The OIR process may take up to 70 seconds before the newly

installed module is initialized. Each interface type is verified against the system configuration, after which the system runs diagnostics on the new interface. There is no disruption to normal operation during module insertion or removal.

If you remove a module and then replace it, or insert a different module of the same type into the same slot, no change to the system configuration is needed. An interface of a type that has been configured previously is brought online immediately. If you remove a module and insert a module of a different type, the interface(s) on that module is administratively up with the default configuration for that module.

Online Insertion and Removal on a WS-4500X-32

You must initiate an uplink module removal procedure on a WS-4500X-32 (the Catalyst 4500-X Series Switch) either through a CLI (below) or through the OIR button on the front panel of the uplink.

Note

Unscheduled uplink module removal is not supported because the C4KX-NM-8 module has hardware communication lines to the baseboard that cannot be unplugged in an online state. Communication must be stopped first.

Before removing the uplink module, you must press the OIR button for 5 seconds, and wait for the OIR LED to turn Green. Removing a module without pressing the OIR button causes the system to reboot to ROMMON with the following console error message:

```
Kernel panic - not syncing: Removing a module from switch causes instability.
Rebooting in 15 seconds...
```

Note

No special steps are needed for insertion.

With Cisco Release IOS XE 3.3.0SG and IOS 15.1(1)SG, two CLI's are introduced: **hw-module module number start** and **hw-module module number stop**. For the *number* keyword, the only applicable value for WS-C4500 is 2. With Cisco Release IOS XE 3.3.0SG and IOS 15.1(1)SG, the **start** and **stop** commands are only enabled on the uplink module of WS-4500X-32.

For details, please refer to the hardware portion of the documentation library:

http://www.cisco.com/en/US/products/hw/switches/ps4324/prod_installation_guides_list.html

Shutting down a Module

To shut down a module safely, either enter the **hw-module module stop** command or press the OIR button for 5 seconds.

Note

The **hw-module module stop** command is enabled only on the uplink modules of the WS-C4500X-32.

The following example shows what happens if a module is up and you enter the **hw-module module stop** command:

```
Switch# hw-module module 2 stop
Proceed with module stop? [confirm]
Switch#
*Feb 5 16:34:37.325: %C4K_IOSMODPORTMAN-6-MODULEOFFLINE: Module 2 is offline
Switch# show module
Chassis Type : WS-C4500X-32
```

Power consumed by backplane : 0 Watts

Mod	Ports	Card Type	Model	Serial No.
1	32	4500X-32 10GE (SFP+)	WS-C4900X-32P-10G	JAE153505E9
2	8	Module being held in reset	WS-X4908X-10G-TIM	JAE15340C0J

M	MAC addresses	Hw	Fw	Sw	Status
1	0022.bde2.1061 to 0022.bde2.1080	0.2	15.0(1r)SG(0	0.DEV-0	Ok
2	0022.bde2.1579 to 0022.bde2.1580	0.1			In Reset

Switch#

The following example shows what happens if a module is already stopped and you enter the **hw-module module stop** command:

```
Switch# hw-module module 2 stop
% Module 2 stopped
```

Booting a Module After if it has been Stopped

To bring up a module that has been stopped using the **hw-module module number stop** command or by pressing the **OIR button**, you either enter the **hw-module module number start** command or physically remove and reinsert.

The following example shows what happens if a module has been stopped and you enter this command:

```
Switch# hw-module module 2 start
Switch#
*Feb 5 16:36:27.352: %C4K_IOSMODPORTMAN-6-MODULEINSERTED: Module 2 is inserted
*Feb 5 16:37:15.902: %C4K_IOSMODPORTMAN-6-MODULEONLINE: Module 2 (WS-X4908X-10G-TIM S/N:
JAE15340C0J Hw: 0.1) is online
Switch# show module
Chassis Type : WS-C4500X-32
```

Power consumed by backplane : 0 Watts

Mod	Ports	Card Type	Model	Serial No.
1	32	4500X-32 10GE (SFP+)	WS-C4900X-32P-10G	JAE153505E9
2	8	10GE SFP+	WS-X4908X-10G-TIM	JAE15340C0J

M	MAC addresses	Hw	Fw	Sw	Status
1	0022.bde2.1061 to 0022.bde2.1080	0.2	15.0(1r)SG(0	0.DEV-0	Ok
2	0022.bde2.1579 to 0022.bde2.1580	0.1			Ok

Switch#

The following example shows what happens if a module has not been stopped and you enter this command:

```
Switch# hw-module module 2 start
% Module 2 not stopped
```

Common Scenarios

Table 9-10 lists the common scenarios associated with an OIR on a WS-4500X-32.

Table 9-10 Common Scenarios for OIR on a WS-4500X-32

If you do this or want to do this...	This happens or you need to do this....
Insert a new module for the first time.	The behavior of new module matches that of current linecard.
Pull out an uplink module that was not previously stopped or shut down.	The system reboots to ROMMON.
Press the OIR button accidentally.	Press for less than 5 sec and nothing happens. Press for more than 5 sec and OIR is initiated. The linecard moves to the reset state and the OIR LED turns GREEN.
Change your mind after entering the module stop command or pressing the OIR button.	Enter the module start command or perform a physical OIR. Both actions trigger uplink module restart. If the module is not faulty, it is restored to online state.
Know if the OIR button has taken effect.	The OIR LED on the uplink module turns GREEN and the linecard status LED on the uplink module turns off.
Disable the OIR button and force use of a CLI to initiate an OIR.	Cannot be done.

Monitoring and Maintaining the Interface

The following sections describe how to monitor and maintain the interfaces:

- [Monitoring Interface and Controller Status, page 9-50](#)
- [Clearing and Resetting the Interface, page 9-51](#)
- [Shutting Down and Restarting an Interface, page 9-51](#)
- [Configuring Interface Link Status and Trunk Status Events, page 9-52](#)
- [Resetting the Interface to the Default Configuration, page 9-55](#)

Monitoring Interface and Controller Status

The Cisco IOS software for the Catalyst 4500 series switch contains commands that you can enter at the EXEC prompt to display information about the interface, including the version of the software and the hardware, the controller status, and statistics about the interfaces. The following table lists some of the interface monitoring commands. (You can display the full list of **show** commands by entering the **show ?** command at the EXEC prompt.)

To display information about the interface, enter one of the following commands:

Command	Purpose
Switch# show interfaces [<i>type slot/interface</i>]	Displays the status and configuration of all interfaces or of a specific interface.
Switch# show running-config	Displays the configuration currently running in RAM.
Switch# show protocols [<i>type slot/interface</i>]	Displays the global (system-wide) and interface-specific status of any configured protocol.
Switch# show version	Displays the hardware configuration, software version, the names and sources of configuration files, and the boot images.

This example shows how to display the status of Fast Ethernet interface 5/5:

```
Switch# show protocols fastethernet 5/5
FastEthernet5/5 is up, line protocol is up
Switch#
```

Clearing and Resetting the Interface

To clear the interface counters shown with the **show interfaces** command, enter this command:

Command	Purpose
Switch# clear counters [<i>type slot/interface</i>]	Clears interface counters.

This example shows how to clear and reset the counters on Fast Ethernet interface 5/5:

```
Switch# clear counters fastethernet 5/5
Clear "show interface" counters on this interface [confirm] y
Switch#
*Sep 30 08:42:55: %CLEAR-5-COUNTERS: Clear counter on interface FastEthernet5/5
by vty1 (171.69.115.10)
Switch#
```

The **clear counters** command (without any arguments) clears all the current interface counters from all interfaces.

Note

The **clear counters** command does not clear counters retrieved with SNMP; it clears only those counters displayed with the EXEC **show interfaces** command.

Shutting Down and Restarting an Interface

You can disable an interface, which disables all functions on the specified interface and marks the interface as unavailable on all monitoring command displays. This information is communicated to other network servers through all dynamic routing protocols. The interface is not mentioned in any routing updates.

To shut down an interface and then restart it, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { vlan <i>vlan_ID</i> } { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> } { port-channel <i>port_channel_number</i> }	Specifies the interface to be configured.
Step 2	Switch(config-if)# shutdown	Shuts down the interface.
Step 3	Switch(config-if)# no shutdown	Reenables the interface.

This example shows how to shut down Fast Ethernet interface 5/5:

```
Switch(config)# interface fastethernet 5/5
Switch(config-if)# shutdown
Switch(config-if)#
*Sep 30 08:33:47: %LINK-5-CHANGED: Interface FastEthernet5/5, changed state to a
administratively down
Switch(config-if)#
```

This example shows how to reenabale Fast Ethernet interface 5/5:

```
Switch(config-if)# no shutdown
Switch(config-if)#
*Sep 30 08:36:00: %LINK-3-UPDOWN: Interface FastEthernet5/5, changed state to up
Switch(config-if)#
```

To verify whether an interface is disabled, enter the EXEC **show interfaces** command. An interface that has been shut down appears as “administratively down.”

Configuring Interface Link Status and Trunk Status Events

You can configure interface link status and trunk status events. On the Catalyst 4500 series switch, the following interface logging event notifications are supported both globally and per interface:

- Enable or disable notification on the interface whenever its data link status is changed.
- Enable or disable notification on the trunk interface whenever its trunking status is changed.

Use the **[no] logging event link-status use-global** command to enable or disable the interface link status event. Use the **[no] logging event trunk-status use-global** command to enable or disable the interface trunk status event.

Each interface link status logging event can be configured in one of the following states:

- **logging event link-status**—Link status logging event is enabled explicitly on the interface regardless of the switch global setting.
- **no logging event link-status**—Link status logging event is disabled explicitly on the interface regardless of the switch global setting.
- **logging event link-status use-global**—Default link status logging event configuration on the interface; its configuration should follow the switch global link status logging event setting.

The interface trunk status logging event can be configured in the same configuration states.

Configuring Link Status Event Notification for an Interface

To enable or disable a link status logging event, enter one of the following commands:

Command	Purpose
Switch(config-if)# logging event link-status	Enables interface link status logging.
Switch(config-if)# no logging event link-status	Disables interface link status logging.
Switch(config-if)# logging event link-status use-global	Specifies the global default setting for interface link status logging.

Global Settings

You can also provide a global configuration for the corresponding logging event. A global configuration provides default logging settings for all interfaces. The **[no] logging event link-status global** command lets you enable or disable the interface link status logging for the entire switch. The **[no] logging event trunk-status global** command lets you enable/disable interface trunk status logging for the entire switch.

Each interface link status logging event, if not configured at the interface level, uses the following global logging event setting:

- **logging event link-status global**—Link status logging event is enabled, if not configured on the interface.
- **no logging event link-status global**—Link status logging event is disabled, if not configured on the interface.

The interface trunk status logging event has similar global configurations.

Configuring a Switch Global Link Status Logging Event

To enable or disable the global link status logging event, enter one of the following commands:

Command	Purpose
Switch(config-if)# logging event link-status global	Enables global link status logging.
Switch(config-if)# no logging event link-status global	Disables global link status logging.

Examples

The following example displays a summary of the operating states for the interface logging event using different combinations of global and interface logging settings:

global setting	interface setting	actual logging state
on	on	on
off	on	on
on	off	off
off	off	off
on	default (use-global)	on
off	default (use-global)	off

The following example displays the configuration and logging message output for link status and trunk status logging events:

```
//
// The global link status and trunk status logging events are enabled.
//
Switch# show running | include logging
show running | include logging
logging event link-status global
logging event trunk-status global
Switch#

//
// The interface link status and trunk status logging settings
// are set to default values, which follow regardless of the global
// setting.
//
Switch# show running interface g1/4
Building configuration...

Current configuration: 97 bytes
!
interface GigabitEthernet1/4
 switchport trunk encapsulation dot1q
 switchport mode trunk
end
Switch#

//
// The trunk status logging messages for the interface are
// displayed whenever the interface trunking status is changed.
// Here we change the other end node's trunking encapsulation
// from dot1q to isl.
//
3d00h: %DTP-5-ILGLCFG: Illegal config(on,isl--on,dot1q) on Gi1/4
3d00h: %DTP-5-ILGLCFG: Illegal config(on,isl--on,dot1q) on Gi1/4
3d00h: %DTP-5-ILGLCFG: Illegal config(on,isl--on,dot1q) on Gi1/4

//
// The link and trunk status logging message for the interface
// are displayed whenever the interface link status is changed.
// Here we do a "shut" and "no shut" on the other end link node.
//
3d00h: %DTP-5-NONTRUNKPORTON: Port Gi1/4 has become non-trunk
3d00h: %LINEPROTO-5-UPDOWN: Line protocol on Interface
GigabitEthernet1/4, changed state to down
3d00h: %LINK-3-UPDOWN: Interface GigabitEthernet1/4, changed state to
down
3d00h: %LINK-3-UPDOWN: Interface GigabitEthernet1/4, changed state to up
3d00h: %DTP-5-TRUNKPORTON: Port Gi1/4 has become dot1q trunk
3d00h: %LINEPROTO-5-UPDOWN: Line protocol on Interface
GigabitEthernet1/4, changed state to up
```

Resetting the Interface to the Default Configuration

If you have configured a interface with many command lines and you want to clear all the configuration on that interface, use the **default interface** global configuration command, as follows:

```
Switch(config)# default interface fastEthernet 3/5  
Interface FastEthernet3/5 set to default configuration
```

This command clears all the configurations and shut down the interface:

```
Switch# show run interface fastethernet 3/5  
Building configuration...  
  
Current configuration : 58 bytes  
!  
interface FastEthernet3/5  
  no ip address  
  shutdown  
end
```

Checking Port Status and Connectivity

This chapter describes how to check switch port status and connectivity on the Catalyst 4500 series switch.

This chapter includes the following major sections:

- [Checking Module Status, page 10-1](#)
- [Checking Interfaces Status, page 10-2](#)
- [Displaying MAC Addresses, page 10-3](#)
- [Checking Cable Status Using Time Domain Reflectometer, page 10-3](#)
- [Using Telnet, page 10-5](#)
- [Changing the Logout Timer, page 10-6](#)
- [Monitoring User Sessions, page 10-6](#)
- [Using Ping, page 10-7](#)
- [Using IP Traceroute, page 10-8](#)
- [Using Layer 2 Traceroute, page 10-9](#)
- [Configuring ICMP, page 10-11](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

Checking Module Status

The Catalyst 4500 series switch is a multimodule system. You can see which modules are installed, as well as the MAC address ranges and version numbers for each module, by entering the **show module** command. Use the *mod_num* argument to specify a particular module number and display detailed information on that module.

This example shows how to check module status for all modules on your switch:

```
Switch# show module all
```

Mod	Ports	Card Type	Model	Serial No.
1	2	1000BaseX (GBIC) Supervisor Module	WS-X4014	JAB012345AB
5	24	10/100/1000BaseTX (RJ45)	WS-X4424-GB-RJ45	JAB045304EY
6	48	10/100BaseTX (RJ45)	WS-X4148	JAB023402QK

M	MAC addresses	Hw	Fw	Sw	Stat
1	0004.dd46.9f00 to 0004.dd46.a2ff	0.0	12.1(10r)EW(1.21)	12.1(10)EW(1)	Ok
5	0050.3e7e.1d70 to 0050.3e7e.1d87	0.0			Ok
6	0050.0f10.2370 to 0050.0f10.239f	1.0			Ok

```
Switch#
```

Checking Interfaces Status

You can view summary or detailed information on the switch ports using the **show interfaces status** command. To see summary information on all ports on the switch, enter the **show interfaces status** command with no arguments. Specify a particular module number to see information on the ports on that module only. Enter both the module number and the port number to see detailed information about the specified port.

To apply configuration commands to a particular port, you must specify the appropriate logical module. For more information, see the [“Checking Module Status” section on page 10-1](#).

This example shows how to display the status of all interfaces on a Catalyst 4500 series switch, including transceivers. Output of this command displays “Unapproved GBIC” for non-Cisco transceivers:

```
Switch# show interfaces status
```

Port	Name	Status	Vlan	Duplex	Speed	Type
Gi1/1		notconnect	1	auto	auto	No Gbic
Gi1/2		notconnect	1	auto	auto	No Gbic
Gi5/1		notconnect	1	auto	auto	10/100/1000-TX
Gi5/2		notconnect	1	auto	auto	10/100/1000-TX
Gi5/3		notconnect	1	auto	auto	10/100/1000-TX
Gi5/4		notconnect	1	auto	auto	10/100/1000-TX
Fa6/1		connected	1	a-full	a-100	10/100BaseTX
Fa6/2		connected	2	a-full	a-100	10/100BaseTX
Fa6/3		notconnect	1	auto	auto	10/100BaseTX
Fa6/4		notconnect	1	auto	auto	10/100BaseTX

```
Switch#
```

This example shows how to display the status of interfaces in error-disabled state:

```
Switch# show interfaces status err-disabled
```

Port	Name	Status	Reason
Fa9/4		err-disabled	link-flap

informational error message when the timer expires on a cause

```
-----
5d04h:%PM-SP-4-ERR_RECOVER:Attempting to recover from link-flap err-disable state on Fa9/4
Switch#
```

Displaying MAC Addresses

In addition to displaying the MAC address range for a module using the **show module** command, you can display the MAC address table information of a specific MAC address or a specific interface in the switch using the **show mac-address-table address** and **show mac-address-table interface** commands.

This example shows how to display MAC address table information for a specific MAC address:

```
Switch# show mac-address-table address 0050.3e8d.6400
```

vlan	mac address	type	protocol	qos	ports
200	0050.3e8d.6400	static	assigned	--	Switch
100	0050.3e8d.6400	static	assigned	--	Switch
5	0050.3e8d.6400	static	assigned	--	Switch
4	0050.3e8d.6400	static	ipx	--	Switch
1	0050.3e8d.6400	static	ipx	--	Switch
1	0050.3e8d.6400	static	assigned	--	Switch
4	0050.3e8d.6400	static	assigned	--	Switch
5	0050.3e8d.6400	static	ipx	--	Switch
100	0050.3e8d.6400	static	ipx	--	Switch
200	0050.3e8d.6400	static	ipx	--	Switch
100	0050.3e8d.6400	static	other	--	Switch
200	0050.3e8d.6400	static	other	--	Switch
5	0050.3e8d.6400	static	other	--	Switch
4	0050.3e8d.6400	static	ip	--	Switch
1	0050.3e8d.6400	static	ip	--	Route
1	0050.3e8d.6400	static	other	--	Switch
4	0050.3e8d.6400	static	other	--	Switch
5	0050.3e8d.6400	static	ip	--	Switch
200	0050.3e8d.6400	static	ip	--	Switch
100	0050.3e8d.6400	static	ip	--	Switch

Switch#

This example shows how to display MAC address table information for a specific interface:

```
Switch# show mac-address-table interface gigabit 1/1
```

Multicast Entries

vlan	mac address	type	ports
1	ffff.ffff.ffff	system	Switch, Gi6/1, Gi6/2, Gi6/9, Gi1/1

Switch#

Checking Cable Status Using Time Domain Reflectometer

The Time Domain Reflectometer (TDR) feature allows you to determine if cable is OPEN or SHORT when it is at fault.

Overview

With TDR, you can check the status of copper cables on the 48-port 10/100/1000 BASE-T modules for the Catalyst 4500 series switch. TDR detects a cable fault by sending a signal through the cable and reading the signal that is reflected back. All or part of the signal can be reflected back either by cable defects or by the end of the cable.

**Note**

Four pairs of standard category 5 cable exist. Each pair can assume one of the following states: open (not connected), broken, shorted, or terminated. The TDR test detects all four states and displays the first three as “Fault” conditions, and displays the fourth as “Terminated.” Although the CLI output is shown, the cable length is displayed only if the state is “Faulty.”

TDR feature is supported on the following modules:

WS-X4524-GB-RJ45V

WS-X4548-GB-RJ45

WS-X4548-GB-RJ45V

WS-X4548-GB-RJ45V+

WS-X4548-RJ45V+

WS-X4748-RJ45+E

WS-X4748-RJ45V+E

WS-X4748-UPOE+E

TDR detects a cable fault by sending a signal along its wires and depending on the reflected signal it can determine roughly where a cable fault could be. The variations on how TDR signal is reflected back determine the results on TDR. On cat4k products, we only support cable fault types: OPEN or SHORT. We do display Terminated status in case cable is proper terminated and this is done for illustrative purpose.

Running the TDR Test

To start the TDR test, perform this task:

	Command	Purpose
Step 1	Switch# test cable-diagnostics tdr { interface { <i>interface interface-number</i> }}	Starts the TDR test.
Step 2	Switch# show cable-diagnostics tdr { interface { <i>interface interface-number</i> }}	Displays the TDR test counter information.

This example shows how to start the TDR test on port 1 on module 2:

```
Switch# test cable-diagnostics tdr int gi2/1
Switch#
```

This example shows the message that displays when the TDR test is not supported on a module:

```
Switch# test cable-diagnostics tdr int gi2/1
00:03:15:%C4K_IOSDIAGMAN-4-TESTNOTSUPPORTEDONMODULE: Online cable
diag tdr test is not supported on this module
Switch#
```

This example shows how to display TDR test results for a port:

```
Switch# show cable-diagnostics tdr interface gi4/13
Interface Speed Local pair Cable length Remote channel Status
Gi4/13    0Mbps   1-2      102 +-2m    Unknown      Fault
           3-6      100 +-2m    Unknown      Fault
           4-5      102 +-2m    Unknown      Fault
```

7-8 102 +-2m Unknown Fault

**Note**

After this command is deprecated, use the diagnostic start and the **show diagnostic result** commands to run the TDR test and display the test results.

**Note**

TDR is a port test; the port cannot handle traffic for the duration of the test (generally, 1 minute).

TDR Guidelines

The following guidelines apply to the use of TDR:

- If you connect a port undergoing a TDR test to an Auto-MDIX enabled port, the TDR result might be invalid. In those instances, the port on the WS-X4148-RJ45V should be administratively down before the start of the TDR test.
- If you connect a port undergoing a TDR test to a 100BASE-T port such as that on the WS-X4148-RJ45V, the unused pairs (4-5 and 7-8) is reported as faulty because the remote end does not terminate these pairs.
- Do not change the port configuration while the TDR test is running.
- Due to cable characteristics, you should run the TDR test multiple times to get accurate results.
- Do not change port status (for example, remove the cable at the near or far end) because the results might be inaccurate.
- TDR works best if the test cable is disconnected from the remote port. Otherwise, it might be difficult for you to interpret results correctly.
- TDR operates across four wires. Depending on the cable conditions, the status might show one pair is OPEN or SHORT while all other wire pairs display as faulty. This operation is acceptable because you should declare a cable faulty provided one pair of wires is either OPEN or SHORT.
- TDR intent is to determine how poorly a cable is functioning rather than to locate a faulty cable.
- When TDR locates a faulty cable, you should still use an offline cable diagnosis tool to better diagnose the problem.
- TDR results might differ between runs on different Catalyst 4500 modules because of the resolution difference of TDR implementations. When this occurs, you should refer to offline cable diagnosis tool.

Using Telnet

You can access the switch command-line interface (CLI) using Telnet. In addition, Telnet allows you to access other devices in the network. You can have up to eight simultaneous Telnet sessions.

Before you can open a Telnet session to the switch, you must first set the IP address (and in some cases the default gateway) for the switch. For information about setting the IP address and default gateway, see [Chapter 3, “Configuring the Switch for the First Time.”](#)

**Note**

To establish a Telnet connection to a host by using the hostname, configure and enable DNS.

To establish a Telnet connection to another device on the network from the switch, enter this command:

Command	Purpose
Switch# telnet <i>host</i> [<i>port</i>]	Opens a Telnet session to a remote host.

This example shows how to establish a Telnet connection from the switch to the remote host named labsparc:

```
Switch# telnet labsparc
Trying 172.16.10.3...
Connected to labsparc.
Escape character is '^]'.

UNIX(r) System V Release 4.0 (labsparc)

login:
```

Changing the Logout Timer

The logout timer automatically disconnects a user from the switch when the user is idle for longer than the specified time. To set the logout timer, enter this command:

Command	Purpose
Switch# logoutwarning <i>number</i>	Changes the logout timer value (a timeout value of 0 prevents idle sessions from being disconnected automatically). Use the no keyword to return to the default value.

Monitoring User Sessions

You can display the currently active user sessions on the switch using the **show users** command. The command output lists all active console port and Telnet sessions on the switch.

To display the active user sessions on the switch, enter this command:

Command	Purpose
Switch# show users [<i>all</i>]	Displays the currently active user sessions on the switch.

This example shows the output of the **show users** command when local authentication is enabled for console and Telnet sessions (the asterisk [*] indicates the current session):

```
Switch# show users
  Line      User      Host(s)      Idle      Location
*  0 con 0      idle          00:00:00

  Interface      User      Mode          Idle      Peer Address

Switch# show users all
  Line      User      Host(s)      Idle      Location
```

```

* 0 con 0          idle          00:00:00
  1 vty 0          00:00:00
  2 vty 1          00:00:00
  3 vty 2          00:00:00
  4 vty 3          00:00:00
  5 vty 4          00:00:00

Interface      User      Mode      Idle      Peer Address
Switch#

```

To disconnect an active user session, enter this command:

Command	Purpose
Switch# disconnect { console <i>ip_addr</i> }	Disconnects an active user session on the switch.

This example shows how to disconnect an active console port session and an active Telnet session:

```

Switch> disconnect console
Console session disconnected.
Console> (enable) disconnect tim-nt.bigcorp.com
Telnet session from tim-nt.bigcorp.com disconnected. (1)
Switch# show users
  Session  User      Location
  -----  -
telnet    jake      jake-mac.bigcorp.com
* telnet  suzy      suzy-pc.bigcorp.com
Switch#

```

Using Ping

These sections describe how to use IP ping:

- [Understanding How Ping Works, page 10-7](#)
- [Running Ping, page 10-8](#)

Understanding How Ping Works

The **ping** command allows you to verify connectivity to remote hosts. If you attempt to ping a host in a different IP subnetwork, you must define a static route to the network or configure a router to route between those subnets.

The **ping** command is configurable from normal executive and privileged EXEC mode. Ping returns one of the following responses:

- Normal response—The normal response (*hostname* is alive) occurs in 1 to 10 seconds, depending on network traffic.
- Destination does not respond—If the host does not respond, a No Answer message is returned.
- Unknown host—If the host does not exist, an Unknown Host message is returned.
- Destination unreachable—If the default gateway cannot reach the specified network, a Destination Unreachable message is returned.
- Network or host unreachable—If there is no entry in the route table for the host or network, a Network or Host Unreachable message is returned.

To stop a ping in progress, press **Ctrl-C**.

Running Ping

To ping another device on the network from the switch, enter this command in normal executive and privileged EXEC mode:

Command	Purpose
Switch# ping <i>host</i>	Checks connectivity to a remote host.

This example shows how to ping a remote host from normal executive mode:

```
Switch# ping labsparc
labsparc is alive
Switch> ping 72.16.10.3
12.16.10.3 is alive
Switch#
```

This example shows how to use a **ping** command in privileged EXEC mode to specify the number of packets, the packet size, and the timeout period:

```
Switch# ping
Target IP Address []: 12.20.5.19
Number of Packets [5]: 10
Datagram Size [56]: 100
Timeout in seconds [2]: 10
Source IP Address [12.20.2.18]: 12.20.2.18
!!!!!!!!!!!!

----12.20.2.19 PING Statistics----
10 packets transmitted, 10 packets received, 0% packet loss
round-trip (ms)  min/avg/max = 1/1/1
Switch
```

Using IP Traceroute

These sections describe how to use IP traceroute feature:

- [Understanding How IP Traceroute Works, page 10-8](#)
- [Running IP Traceroute, page 10-9](#)

Understanding How IP Traceroute Works

IP traceroute allows you to identify the path that packets take through the network on a hop-by-hop basis. The command output displays all network layer (Layer 3) devices, such as routers, that the traffic passes through on the way to the destination.

Layer 2 switches can participate as the source or destination of the **trace** command but does not appear as a hop in the **trace** command output.

The **trace** command uses the time to live (TTL) field in the IP header to cause routers and servers to generate specific return messages. Traceroute starts by sending a User Datagram Protocol (UDP) datagram to the destination host with the TTL field set to 1. If a router finds a TTL value of 1 or 0, it

drops the datagram and sends back an Internet Control Message Protocol (ICMP) Time-Exceeded message to the sender. Traceroute determines the address of the first hop by examining the source address field of the ICMP Time-Exceeded message.

To identify the next hop, traceroute sends a UDP packet with a TTL value of 2. The first router decrements the TTL field by 1 and sends the datagram to the next router. The second router sees a TTL value of 1, discards the datagram, and returns the Time-Exceeded message to the source. This process continues until the TTL is incremented to a value large enough for the datagram to reach the destination host or until the maximum TTL is reached.

To determine when a datagram reaches its destination, traceroute sets the UDP destination port in the datagram to a very large value that the destination host is unlikely to be using. When a host receives a datagram with an unrecognized port number, it sends an ICMP Port Unreachable error message to the source. The Port Unreachable error message indicates to traceroute that the destination has been reached.

Running IP Traceroute

To trace the path that packets take through the network, enter this command in EXEC or privileged EXEC mode:

Command	Purpose
Switch# trace [<i>protocol</i>] [<i>destination</i>]	Runs IP traceroute to trace the path that packets take through the network.

This example shows how to use the **trace** command to display the route a packet takes through the network to reach its destination:

```
Switch# trace ip ABA.NYC.mil
```

```
Type escape sequence to abort.
```

```
Tracing the route to ABA.NYC.mil (26.0.0.73)
```

```

```
Switch#
```

Using Layer 2 Traceroute

The Layer 2 traceroute feature allows the switch to identify the physical path that a packet takes from a source device to a destination device. Layer 2 traceroute supports only unicast source and destination MAC addresses. It determines the path by using the MAC address tables of the switches in the path. When the switch detects a device in the path that does not support Layer 2 traceroute, the switch continues to send Layer 2 trace queries and lets them time out.

If you want the switch to trace the path from a host on a source device to a host on a destination device, the switch can identify only the path from the source device to the destination device. It cannot identify the path that a packet takes from source host to the source device or from the destination device to the destination host.

These sections describe how to use the Layer 2 traceroute feature:

- [Layer 2 Traceroute Usage Guidelines, page 10-10](#)
- [Running Layer 2 Traceroute, page 10-11](#)

Layer 2 Traceroute Usage Guidelines

These are the Layer 2 traceroute usage guidelines:

- CDP must be enabled on all the devices in the network. For Layer 2 traceroute to function properly, do not disable CDP.

If any devices in the physical path are transparent to CDP, the switch cannot identify the path through these devices.

Note For more information about enabling CDP, see [Chapter 32, “Configuring Cisco Discovery Protocol.”](#)

- All switches in the physical path must have IP connectivity. When a switch is reachable from another switch, you can test connectivity by using the **ping** command in privileged EXEC mode.
- The maximum number of hops identified in the path is ten.
- You can enter the **traceroute mac** or the **traceroute mac ip** command in privileged EXEC mode on a switch that is not in the physical path from the source device to the destination device. All switches in the path must be reachable from this switch.
- The **traceroute mac** command output shows the Layer 2 path only when the specified source and destination MAC addresses belong to the same VLAN. If you specify source and destination MAC addresses that belong to different VLANs, the Layer 2 path is not identified, and an error message appears.
- If you specify a multicast source or destination MAC address, the path is not identified, and an error message appears.
- If the source or destination MAC address belongs to multiple VLANs, you must specify the VLAN to which both the source and destination MAC addresses belong. If the VLAN is not specified, the path is not identified, and an error message appears.
- The **traceroute mac ip** command output shows the Layer 2 path when the specified source and destination IP addresses belong to the same subnet. When you specify the IP addresses, the switch uses Address Resolution Protocol (ARP) to associate the IP address with the corresponding MAC address and the VLAN ID.
 - If an ARP entry exists for the specified IP address, the switch uses the associated MAC address and identifies the physical path.
 - If an ARP entry does not exist, the switch sends an ARP query and tries to resolve the IP address. If the IP address is not resolved, the path is not identified, and an error message appears.
- When multiple devices are attached to one port through hubs (for example, multiple CDP neighbors are detected on a port), the Layer 2 traceroute feature is not supported. When more than one CDP neighbor is detected on a port, the Layer 2 path is not identified, and an error message appears.
- This feature is not supported in Token Ring VLANs.

Running Layer 2 Traceroute

To display the physical path that a packet takes from a source device to a destination device, enter either one of these commands:

Command	Purpose
Switch# traceroute mac {source-mac-address} {destination-mac-address}	Runs Layer 2 traceroute to trace the path that packets take through the network.

or

Command	Purpose
Switch# traceroute mac ip {source-mac-address} {destination-mac-address}	Runs IP traceroute to trace the path that packets take through the network.

These examples show how to use the **traceroute mac** and **traceroute mac ip** commands to display the physical path a packet takes through the network to reach its destination:

```
Switch# traceroute mac 0000.0201.0601 0000.0201.0201

Configuring ICMP

Internet Control Message Protocol (ICMP) provides many services that control and manage IP connections. ICMP messages are sent by routers or access servers to hosts or other routers when a problem is discovered with the Internet header. For detailed information on ICMP, refer to RFC 792.

Enabling ICMP Protocol Unreachable Messages

If the Cisco IOS software receives a nonbroadcast packet that uses an unknown protocol, it sends an ICMP Protocol Unreachable message back to the source.

Similarly, if the software receives a packet that it is unable to deliver to the ultimate destination because it knows of no route to the destination address, it sends an ICMP Host Unreachable message to the source. This feature is enabled by default.

To enable the generation of ICMP Protocol Unreachable and Host Unreachable messages, enter the following command in interface configuration mode:

Command	Purpose
Switch (config-if)# [no] ip unreachable	Enables ICMP destination unreachable messages. Use the no keyword to disable the ICMP destination unreachable messages.

Caution

If you enter the **no ip unreachable** command, you will break the path MTU discovery functionality. Routers in the middle of the network might be forced to fragment packets.

To limit the rate that Internet Control Message Protocol (ICMP) destination unreachable messages are generated, enter the following command:

Command	Purpose
Switch (config)# [no] ip icmp rate-limit unreachable [df] milliseconds	Limits the rate that ICMP destination messages are generated. Use the no keyword to remove the rate limit and reduce the CPU usage.

Enabling ICMP Redirect Messages

Data routes are sometimes less than optimal. For example, it is possible for the router to be forced to resend a packet through the same interface on which it was received. If this occurs, the Cisco IOS software sends an ICMP Redirect message to the originator of the packet telling the originator that the router is on a subnet directly connected to the receiving device, and that it must forward the packet to another system on the same subnet. The software sends an ICMP Redirect message to the packet's originator because the originating host presumably could have sent that packet to the next hop without involving this device at all. The Redirect message instructs the sender to remove the receiving device from the route and substitute a specified device representing a more direct path. This feature is enabled by default.

However, when Hot Standby Router Protocol (HSRP) is configured on an interface, ICMP Redirect messages are disabled (by default) for the interface. For more information on HSRP, refer to the following URL:

http://www.cisco.com/en/US/docs/ios/ipapp/configuration/guide/ipapp_hsrp_ps6350_TSD_Products_Configuration_Guide_Chapter.html

To enable the sending of ICMP Redirect messages if the Cisco IOS software is forced to resend a packet through the same interface on which it was received, enter the following command in interface configuration mode:

Command	Purpose
Switch (config-if)# [no] ip redirects	Enables ICMP Redirect messages. Use the no keyword to disable the ICMP Redirect messages and reduce CPU usage.

Enabling ICMP Mask Reply Messages

Occasionally, network devices must know the subnet mask for a particular subnetwork in the internetwork. To obtain this information, devices can send ICMP Mask Request messages. These messages are responded to by ICMP Mask Reply messages from devices that have the requested information. The Cisco IOS software can respond to ICMP Mask Request messages if the ICMP Mask Reply function is enabled.

To have the Cisco IOS software respond to ICMP mask requests by sending ICMP Mask Reply messages, enter the following command:

Command	Purpose
Switch (config-if)# [no] ip mask-reply	Enables response to ICMP destination mask requests. Use the no keyword to disable this functionality.

Configuring Supervisor Engine Redundancy Using RPR and SSO on Supervisor Engine 6-E and Supervisor Engine 6L-E

Catalyst 4500 series switches allow a redundant supervisor engine to take over if the active supervisor engine fails. In software, supervisor engine redundancy is enabled by running the redundant supervisor engine in route processor redundancy (RPR) or stateful switchover (SSO) operating mode.

Note

The minimum ROMMON requirement for running SSO is Cisco IOS Release 12.1(20r)EW1 or Cisco IOS Release 12.2(20r)EW1.

This chapter describes how to configure supervisor engine redundancy on the Catalyst 4507R switch.

Note

For information on Cisco nonstop forwarding (NSF) with SSO, see [Chapter 12, “Configuring Cisco NSF with SSO Supervisor Engine Redundancy.”](#)

This chapter contains these major sections:

- [About Supervisor Engine Redundancy, page 11-2](#)
- [About Supervisor Engine Redundancy Synchronization, page 11-4](#)
- [Supervisor Engine Redundancy Guidelines and Restrictions, page 11-5](#)
- [Configuring Supervisor Engine Redundancy, page 11-7](#)
- [Performing a Manual Switchover, page 11-12](#)
- [Performing a Software Upgrade, page 11-13](#)
- [Manipulating Bootflash on the Redundant Supervisor Engine, page 11-14](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Supervisor Engine Redundancy

These sections describe supervisor engine redundancy:

- [Overview, page 11-2](#)
- [RPR Operation, page 11-2](#)
- [SSO Operation, page 11-3](#)

Overview

With supervisor engine redundancy enabled, if the active supervisor engine fails or if a manual switchover is performed, the redundant supervisor engine becomes the active supervisor engine. The redundant supervisor engine has been automatically initialized with the startup configuration of the active supervisor engine, shortening the switchover time (30 seconds or longer in RPR mode, depending on the configuration; subsecond in SSO mode).

In addition to the reduced switchover time, supervisor engine redundancy supports the following:

- Online insertion and removal (OIR) of the redundant supervisor engine.
Supervisor engine redundancy allows OIR of the redundant supervisor engine for maintenance. When the redundant supervisor engine is inserted, the active supervisor engine detects its presence, and the redundant supervisor engine boots into a partially-initialized state in RPR mode and a fully-initialized state in SSO mode.
- Software upgrade. See the [“Performing a Software Upgrade” section on page 11-13](#).
To minimize down time during software changes on the supervisor engine, load the new image on the redundant supervisor engine, and conduct a switchover.

When power is first applied to a switch, the supervisor engine that boots first becomes the active supervisor engine and remains active until a switchover occurs.

A switchover occurs when one or more of the following events take place:

- The active supervisor engine fails (due to either hardware or software function) or is removed.
- A user forces a switchover.
- A user reloads the active supervisor engine.

RPR Operation

RPR is supported in Cisco IOS Release 12.2(12c)EW and later releases. When a redundant supervisor engine runs in RPR mode, it starts up in a partially-initialized state and is synchronized with the persistent configuration of the active supervisor engine.

Note

Persistent configuration includes the following components: startup-config, boot variables, config-register, and VLAN database.

The redundant supervisor engine pauses the startup sequence after basic system initialization, and in the event that the active supervisor engine fails, the redundant supervisor engine becomes the new active supervisor engine.

In a supervisor engine switchover, traffic is disrupted because in the RPR mode all of the physical ports restart since there is no state maintained between supervisor engines relating to module types and statuses. When the redundant supervisor engine completes its initialization, it reads hardware information directly from the module.

SSO Operation

SSO is supported in Cisco IOS Release 12.2(20)EWA and later releases. When a redundant supervisor engine runs in SSO mode, the redundant supervisor engine starts up in a fully-initialized state and synchronizes with the persistent configuration and the running configuration of the active supervisor engine. It subsequently maintains the state on the protocols listed below, and all changes in hardware and software states for features that support stateful switchover are kept in synchronization. Consequently, it offers zero interruption to Layer 2 sessions in a redundant supervisor engine configuration.

Because the redundant supervisor engine recognizes the hardware link status of every link, ports that were active before the switchover remain active, including the uplink ports. However, because uplink ports are physically on the supervisor engine, they will be disconnected if the supervisor engine is removed.

If the active supervisor engine fails, the redundant supervisor engine become active. This newly active supervisor engine uses existing Layer 2 switching information to continue forwarding traffic. Layer 3 forwarding is delayed until the routing tables have been repopulated in the newly active supervisor engine.

SSO supports stateful switchover of the following Layer 2 features. The state of these features is preserved between both the active and redundant supervisor engines:

- 802.3
- 802.3u
- 802.3x (Flow Control)
- 802.3ab (GE)
- 802.3z (Gigabit Ethernet including CWDM)
- 802.3ad (LACP)
- 802.1p (Layer 2 QoS)
- 802.1q
- 802.1X (Authentication)
- 802.1D (Spanning Tree Protocol)
- 802.3af (Inline power)
- PAgP
- VTP
- Dynamic ARP Inspection
- DHCP snooping
- IP source guard
- IGMP snooping (versions 1 and 2)
- DTP (802.1q and ISL)
- MST

- PVST+
- Rapid-PVST
- PortFast/UplinkFast/BackboneFast
- BPDU guard and filtering
- Voice VLAN
- Port security
- Unicast MAC filtering
- ACL (VACLs, PACLS, RACLs)
- QoS (DBL)
- Multicast storm control/broadcast storm control

SSO is compatible with the following list of features. However, the protocol database for these features is not synchronized between the redundant and active supervisor engines:

- 802.1Q tunneling with Layer 2 Protocol Tunneling (L2PT)
- Baby giants
- Jumbo frame support
- CDP
- Flood blocking
- UDLD
- SPAN/RSPAN
- NetFlow

The following features are learned on the redundant supervisor engine if the SSO feature is enabled:

- All Layer 3 protocols on Catalyst 4500 series switches (Switch Virtual Interfaces)

About Supervisor Engine Redundancy Synchronization

During normal operation, the persistent configuration (RPR and SSO) and the running configuration (SSO only) are synchronized by default between the two supervisor engines. In a switchover, the new active supervisor engine uses the current configuration.

Note You cannot enter CLI commands on the redundant supervisor engine console.

These sections describe supervisor engine redundancy synchronization:

- [RPR Supervisor Engine Configuration Synchronization, page 11-4](#)
- [SSO Supervisor Engine Configuration Synchronization, page 11-5](#)

RPR Supervisor Engine Configuration Synchronization

Because the redundant supervisor engine is only partially initialized in RPR mode, it interacts with the active supervisor engine only to receive configuration changes at startup and upon saving the configuration changes.

When a redundant supervisor engine is running in RPR mode, the following events trigger synchronization of the configuration information:

- When the redundant supervisor engine boots, the **auto-sync** command synchronizes the persistent configuration. This command is enabled by default. For details, refer to [“Synchronizing the Supervisor Engine Configurations” section on page 11-11](#).
- When the active supervisor engine detects the redundant supervisor engine, the configuration information is synchronized from the active supervisor engine to the redundant supervisor engine. This synchronization overwrites any existing startup configuration file on the redundant supervisor engine.
- When you make changes to the configuration, you must use the **write** command to save and synchronize the startup configuration of the redundant supervisor engine.

SSO Supervisor Engine Configuration Synchronization

When a redundant supervisor engine runs in SSO mode, the following events trigger synchronization of the configuration information:

- When the active supervisor detects the redundant supervisor engine, synchronization of the persistent and running configuration takes place, allowing the redundant supervisor engine to arrive at a fully-initiated state.
- When real-time changes occur, the active supervisor engine synchronizes the running-config and (or) the persistent configuration (if necessary) with the redundant supervisor engine.
- When you change the configuration, you must use the **write** command to allow the active supervisor engine to save and synchronize the startup configuration of the redundant supervisor engine.

Supervisor Engine Redundancy Guidelines and Restrictions

The following guidelines and restrictions apply to supervisor engine redundancy:

- If SSO mode cannot be established between the active and standby supervisor engines because of an incompatibility in the configuration file, a mismatched command list (MCL) is generated at the active supervisor engine and a reload into RPR mode is forced for the standby supervisor engine. Subsequent attempts to establish SSO, after removing the offending configuration and rebooting the standby supervisor engine with the exact same image, might cause the C4K_REDUNDANCY-2-IOS_VERSION_CHECK_FAIL and ISSU-3-PEER_IMAGE_INCOMPATIBLE messages to appear because the peer image is listed as incompatible. If the configuration problem can be corrected, you can clear the peer image from the incompatible list with the **redundancy config-sync ignore mismatched-commands EXEC** command while the peer is in a standby cold (RPR) state. This action allows the standby supervisor engine to boot in standby hot (SSO) state when it reloads.

Here are the steps:

-
- | | |
|---------------|--|
| Step 1 | Clear the offending configuration (that caused an MCL) while the standby supervisor engine is in standby cold (RPR) state. |
| Step 2 | Enter the redundancy config-sync ignore mismatched-commands EXEC command at the active standby supervisor engine. |
| Step 3 | Perform write memory . |

Step 4 Reload the standby supervisor engine with the **redundancy reload peer** command.

- If you configure Supervisor Engine V-10GE to use both Gigabit Ethernet and 10-Gigabit Ethernet uplinks without WS-X4302-GB in slot 10, module 10 is disabled and you cannot rollback the configuration to use gigabit ports.

Enter the following commands to recover:

```
config t
hw-module uplink select tengigabitethernet // This sets the switch back to default
mode
!
ctrl z
wr me
redundancy reload shelf // The switch will reload with all 10 modules working ok

//The switch reloads

config t
hw-module uplink select gigabitethernet // This sets the switch to the desired link
!
ctrl z
wr me
redundancy reload shelf // The switch reloads with module 10 active with the gigabit
ethernet port(s) ON and the ten gigabit ethernet port(s) Off
```

- RPR requires Cisco IOS Release 12.1(12c)EW, Release 12.1(19)E or later releases. SSO requires Cisco IOS Release 12.2(20)EWA or later releases.
- The Catalyst 4507R switch and the only Catalyst 4500 series switches that support supervisor engine redundancy.
- In Cisco IOS Release 12.2(25)SG and later releases on a Catalyst 4507R series switch, 10-Gigabit Ethernet and Gigabit Ethernet uplinks are concurrently usable.
- Redundancy requires both supervisor engines in the chassis to have the same components (model, memory, NFL daughter card), and to use the same Cisco IOS software image.
-
- The active and redundant supervisor engines in the chassis must be in slots 1 and 2.
- Each supervisor engine in the chassis must have its own flash device and console port connections to operate the switch on its own.
- Each supervisor engine must have a unique console connection. Do not connect a Y cable to the console ports.
- Supervisor engine redundancy does not provide supervisor engine load balancing.
- The Cisco Express Forwarding (CEF) table is cleared on a switchover. As a result, routed traffic is interrupted until route tables reconverge. This reconvergence time is minimal because the SSO feature reduces the supervisor engine redundancy switchover time from 30+ seconds to subsecond, so Layer 3 also has a faster failover time if the switch is configured for SSO.
- Static IP routes are maintained across a switchover because they are configured from entries in the configuration file.
- Information about Layer 3 dynamic states that is maintained on the active supervisor engine is not synchronized to the redundant supervisor engine and is lost on switchover.

- Starting with Cisco IOS Release 12.2, if an unsupported condition is detected (such as when the active supervisor engine is running Cisco IOS Release 12.2(20)EW and the redundant supervisor engine is running Cisco IOS Release 12.1(20)EW), the redundant supervisor engine is reset multiple times and then placed in ROMMON mode. It is important to follow the procedures outlined in the [“Performing a Software Upgrade” section on page 11-13](#).
- If you are running (or upgrading to) Cisco IOS Release 12.2(20)EWA or Cisco IOS Release 12.2(25)EW and are using a single supervisor engine in a redundant chassis (Catalyst 4507R or Catalyst 4510R series switch), and you intend to use routed ports, do one of the following:
 - Use SVIs instead of routed ports.
 - Change the redundancy mode from SSO to RPR.
- Configuration changes made to the redundant supervisor engine through SNMP synchronization and SNMP set operations in SSO mode are not synchronized to the redundant supervisor engine. Even though you can still perform SNMP set operations in SSO mode, you might experience unexpected behavior.

After you configure the switch through SNMP in SSO mode, copy the running-config file to the startup-config file on the active supervisor engine to trigger synchronization of the startup-config file on the redundant supervisor engine. Reload the redundant supervisor engine so that the new configuration is applied on the redundant supervisor engine.

- You cannot perform configuration changes during the startup (bulk) synchronization. If you attempt to make configuration changes during this process, the following message is generated:

```
Config mode locked out till standby initializes
```

- If configuration changes occur at the same time as a supervisor engine switchover, these configuration changes are lost.
- If you remove a line card from a redundant switch and initiate an SSO switchover, and then reinsert the line card, all interfaces are shutdown. The rest of the original line card configuration is preserved.

This situation only occurs if a switch had reached SSO before you removed the line card.

Configuring Supervisor Engine Redundancy

These sections describe how to configure supervisor engine redundancy:

- [Configuring Redundancy, page 11-8](#)
- [Virtual Console for Standby Supervisor Engine, page 11-10](#)
- [Synchronizing the Supervisor Engine Configurations, page 11-11](#)

Configuring Redundancy

To configure redundancy, perform this task:

	Command	Purpose
Step 1	Switch(config)# redundancy	Enters redundancy configuration mode.
Step 2	Switch(config-red)# mode {sso rpr}	Configures SSO or RPR. When this command is entered, the redundant supervisor engine is reloaded and begins to work in SSO or RPR mode.
Step 3	Switch# show running-config	Verifies that SSO or RPR is enabled.
Step 4	Switch# show redundancy [clients counters history states]	Displays the redundancy information (counter, state, and so on) for the active and redundant supervisor engines.

When configuring redundancy, note the following:

- The **sso** keyword is supported in Cisco IOS Release 12.2(20)EWA and later releases.
- The **rpr** keyword is supported in Cisco IOS Release 12.1(12c)EW and later releases.

This example shows how to configure the system for SSO and display the redundancy facility information:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# redundancy
Switch(config-red)# mode sso
Switch(config-red)# end
Switch# show redundancy
Redundant System Information :
-----
        Available system uptime = 2 days, 2 hours, 39 minutes
Switchovers system experienced = 0
        Standby failures = 0
        Last switchover reason = none

        Hardware Mode = Duplex
Configured Redundancy Mode = Stateful Switchover
Operating Redundancy Mode = Stateful Switchover
        Maintenance Mode = Disabled
        Communications = Up

Current Processor Information :
-----
        Active Location = slot 1
        Current Software state = ACTIVE
Uptime in current state = 2 days, 2 hours, 39 minutes
        Image Version = Cisco Internetwork Operating System Software

Switch#

```

This example shows how to display redundancy facility state information:

```

Switch# show redundancy states
my state = 13 -ACTIVE
    peer state = 8 -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 2

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
Redundancy State = Stateful Switchover
Maintenance Mode = Disabled
    Manual Swact = enabled
    Communications = Up

client count = 21
    client_notification_TMR = 240000 milliseconds
        keep_alive TMR = 9000 milliseconds
        keep_alive count = 0
        keep_alive threshold = 18
        RF debug mask = 0x0

Switch#

```

This example shows how to change the system configuration from RPR to SSO mode:

```

Switch(config)# redundancy
Switch(config-red)# mode
Switch(config-red)# mode sso
Changing to sso mode will reset the standby. Do you want to continue?[confirm]
Switch(config-red)# end
Switch#
*Aug 1 13:11:16: %C4K_REDUNDANCY-3-COMMUNICATION: Communication with the peer Supervisor
has been lost
*Aug 1 13:11:16: %C4K_REDUNDANCY-3-SIMPLEX_MODE: The peer Supervisor has been lost

```

This example shows how to change the system configuration from SSO to RPR mode:

```

Switch(config)# redundancy
Switch(config-red)# mode rpr
Changing to rpr mode will reset the standby. Do you want to continue?[confirm]
Switch(config-red)# end
*Aug 1 13:11:16: %C4K_REDUNDANCY-3-COMMUNICATION: Communication with the peer Supervisor
has been lost
*Aug 1 13:11:16: %C4K_REDUNDANCY-3-SIMPLEX_MODE: The peer Supervisor has been lost

```

Virtual Console for Standby Supervisor Engine

Catalyst 4500 series switches can be configured with two supervisor engines to provide redundancy. When the switch is powered, one of the supervisor engines becomes active and remains active until a switchover occurs. The other supervisor engine remains in standby mode.

Each supervisor engine has its own console port. Access to the standby supervisor engine is possible only through the console port of the standby supervisor engine. You must connect to the standby console to access, monitor or debug the standby supervisor.

The virtual console for a standby supervisor Engine enables you to access the standby console from the active supervisor engine without requiring a physical connection to the standby console. It uses IPC over EOBC to communicate with the standby supervisor engine, which emulates the standby console on the active supervisor engine. Only one active standby console session is active at any time.

The virtual console for the standby supervisor engine allows users who are logged onto the active supervisor engine to remotely execute **show** commands on the standby supervisor engine and view the results on the active supervisor engine. Virtual console is available only from the active supervisor engine.

You can access the standby virtual console from the active supervisor engine with the **attach module**, **session module**, or **remote login** commands on the active supervisor engine. You must be in privilege EXEC mode (level 15) to run these commands to access the standby console.

Once you enter the standby virtual console, the terminal prompt automatically changes to *hostname-standby-console* where *hostname* is the configured name of the switch. The prompt is restored back to the original prompt when you exit the virtual console.

You exit the virtual console with the **exit** or **quit** commands. When the inactivity period of the terminal on the active supervisor engine where you logged in exceeds the configured idle time, you are automatically logged out of the terminal on the active supervisor engine. In this instance, the virtual console session is also terminated. Virtual console session is also automatically terminated when the standby is rebooted. After the standby boots up, you need to create another virtual console session.

To log in to the standby supervisor engine using a virtual console, enter the following command:

```
Switch# session module 2
Connecting to standby virtual console
Type "exit" or "quit" to end this session

Switch-standby-console# exit
Switch#
```

If the standby console is not enabled, the following message appears:

```
Switch-standby-console#
Standby console disabled.
Valid commands are: exit, logout
```

Note

The standby virtual console provides the standard features that are available from the supervisor console such as command history, command completion, command help and partial command keywords.

The following limitations apply to the standby virtual console:

- All commands on the virtual console run to completion. It does not provide the auto-more feature; it functions as if the **terminal length 0** command has been executed. It is also noninteractive. You cannot interrupt or abort an executing command by any key sequence on the active supervisor engine. If a command produces considerable output, the virtual console displays it on the supervisor engine screen.

- The virtual console is noninteractive. Because the virtual console does not detect the interactive nature of a command, any command that requires user interaction causes the virtual console to wait until the RPC timer aborts the command.

The virtual console timer is set to 60 seconds. The virtual console returns to its prompt after 60 seconds. During this time, you cannot abort the command from the key board. You must wait for the timer to expire before you continue.

- You cannot use virtual console to view debug and syslog messages that are being displayed on the standby supervisor engine. The virtual console only displays the output of commands that are executed from the virtual console. Other information that is displayed on the real standby console does not appear on the virtual console.

Synchronizing the Supervisor Engine Configurations

To manually synchronize the configurations used by the two supervisor engines, perform this task on the active supervisor engine:

	Command	Purpose
Step 1	Switch(config)# redundancy	Enters redundancy configuration mode.
Step 2	Switch(config-red)# main-cpu	Enters main-cpu configuration submode.
Step 3	Switch(config-r-mc)# auto-sync { startup-config config-register bootvar standard }	Synchronizes the configuration elements.
Step 4	Switch(config-r-mc)# end	Returns to privileged EXEC mode.
Step 5	Switch# copy running-config startup-config	Synchronizes the running configuration in dynamic random-access memory (DRAM) to the startup configuration file in NVRAM. Note This step is not required to synchronize the running configuration file in (DRAM).

Note

Configuration changes made to the active supervisor engine through SNMP are not synchronized to the redundant supervisor engine. For information on how to handle this situation, see the [“Supervisor Engine Redundancy Guidelines and Restrictions”](#) section on page 11-5.

Note

The **auto-sync** command controls the synchronization of the config-reg, bootvar, and startup/private configuration files only. The calendar and VLAN database files are always synchronized when they change. In SSO mode, the running-config is always synchronized.

This example shows how to reenable the default automatic synchronization feature using the **auto-sync standard** command to synchronize the startup-config and config-register configuration of the active supervisor engine with the redundant supervisor engine. Updates for the boot variables are automatic and cannot be disabled.

```
Switch(config)# redundancy
Switch(config-red)# main-cpu
Switch(config-r-mc)# auto-sync standard
Switch(config-r-mc)# end
Switch# copy running-config startup-config
```

**Note**

To manually synchronize individual elements of the standard auto-sync configuration, disable the default automatic synchronization feature.

**Note**

When you configure the auto-sync standard, the individual sync options such as no auto-sync startup-config are ignored.

This example shows how to disable default automatic synchronization and allow only automatic synchronization of the config-registers of the active supervisor engine to the redundant supervisor engine, while disallowing synchronization of the startup configuration:

```
Switch(config)# redundancy
Switch(config-red)# main-cpu
Switch(config-r-mc)# no auto-sync standard
Switch(config-r-mc)# auto-sync config-register
Switch(config-r-mc)# end
```

Performing a Manual Switchover

This section describes how to perform a manual switchover (from the active supervisor engine to the redundant supervisor engine) for test purposes. We recommend that you perform a manual switchover prior to deploying SSO in your production environment.

**Note**

This discussion assumes that SSO has been configured as the redundant mode.

To perform a manual switchover, perform this task on the active supervisor engine:

	Command	Purpose
Step 1	Switch# show redundancy	Verifies that the peer state is in the standby hot state. See the example of the show redundancy states command on page 6-10.
Step 2	Switch# redundancy force-switchover	Launches switchover from the active supervisor engine to the redundant supervisor engine. If the state of the redundant supervisor engine is not standby hot, this command does not execute.

Be aware of these usage guidelines:

- To force a switchover, the redundant supervisor engine must be in a standby hot state. You can verify the state with the **show redundancy** command. If the state is not standby hot, the **redundancy force-switchover** command does not execute.
- Use the **redundancy force-switchover** command, rather than the **reload** command, to initiate a switchover. The **redundancy force-switchover** command first verifies that the redundant supervisor engine is in the correct state. If you enter the **reload** command and the status is not standby hot, the **reload** command resets the current supervisor engine only.

After an initial switchover, there might be occasions when you want to make the supervisor engine in slot 1 of the chassis the active supervisor engine. If the image on supervisor engine 1 is the one you intend to run on both supervisor engines, it is not necessary to reboot the image on the supervisor engine in slot 1 to make it redundant. Instead, you can force another switchover. However, if you want a newer version of the image to run on both supervisor engines, follow the steps under “Performing a Software Upgrade” on page 13. Use the **show module** command to see which slot contains the active supervisor engine, and force another switchover if necessary.

Performing a Software Upgrade

The software upgrade procedure supported by supervisor engine redundancy allows you to reload the Cisco IOS software image on the redundant supervisor engine, and once complete, reload the active supervisor engine once.

The software upgrade procedure supported by supervisor engine redundancy allows you to reload the Cisco IOS software image on the redundant supervisor engine, and once complete, reloads the active supervisor engine once.

The following scenario is not supported: An active supervisor engine running Cisco IOS Release 12.1(x)E, and a standby supervisor engine running Cisco IOS Release 12.2(x)S. The standby supervisor engine resets repeatedly.

If you are trying to upgrade redundant supervisor engines from Cisco IOS Release 12.1(x)E to 12.2(x)S, this requires a full system reboot.

To perform a software upgrade, perform this task:

	Command	Purpose
Step 1	Switch# copy <i>source_device:source_filename</i> slot0:target_filename Or: Switch# copy <i>source_device:source_filename</i> bootflash:target_filename	Copies the new Cisco IOS software image to bootflash on the supervisor engine.
Step 2	Switch# copy <i>source_device:source_filename</i> slaveslot0:target_filename Or: Switch# copy <i>source_device:source_filename</i> slavebootflash:target_filename	Copies the new image to a slave device (such as slavebootflash and slaveslot0).
Step 3	Switch# config terminal Switch(config)# config-register 0x2 Switch(config)# boot system flash <i>device:file_name</i>	Configures the supervisor engines to boot the new image. If your system was configured to autoboot an earlier image, enter the following command string to boot the new image instead: no boot system flash <i>device:old_file_name</i>
Step 4	Switch(config)# redundancy	Enters redundancy configuration mode.
Step 5	Switch(config-red)# main-cpu	Enters main-cpu configuration submode.
Step 6	Switch(config-r-mc)# auto-syn standard	Synchronizes the configuration elements.
Step 7	Switch(config-r-mc)# end	Returns to privileged EXEC mode.

	Command	Purpose
Step 8	Switch# copy running-config start-config	Saves the configuration.
Step 9	Switch# redundancy reload peer	Reloads the redundant supervisor engine and brings it back online (using the new release of the Cisco IOS software). Note Before proceeding to Step 10, ensure that the switch is operating in RPR mode.
Step 10	Switch# redundancy force-switchover	Conducts a manual switchover to the redundant supervisor engine. The redundant supervisor engine becomes the new active supervisor engine using the new Cisco IOS software image. The old active supervisor engine reboots with the new image and becomes the redundant supervisor engine.

This example shows how to perform a software upgrade:

```
Switch# config terminal
Switch(config)# config-register 0x2
Switch(config)# boot system flash slot0:cat4000-i5s-mz.122-20.EWA
Switch(config)# redundancy
Switch(config-red)# main-cpu
Switch(config-r-mc)# auto-syn standard
Switch(config-r-mc)# end
Switch# copy running-config start-config
Switch# redundancy reload peer
Switch# redundancy force-switchover
Switch#
```

This example illustrates how to verify that the running configuration on the active supervisor engine has successfully synchronized with the redundant supervisor engine:

```
Switch# config terminal
Switch(config)# redundancy
Switch(config-red)# main-cpu
Switch(config-r-mc)# auto-sync standard
4d01h: %C4K_REDUNDANCY-5-CONFIGSYNC: The bootvar has been successfully synchronized to the
standby supervisor
4d01h: %C4K_REDUNDANCY-5-CONFIGSYNC: The config-reg has been successfully synchronized to
the standby supervisor
4d01h: %C4K_REDUNDANCY-5-CONFIGSYNC: The startup-config has been successfully synchronized
to the standby supervisor
4d01h: %C4K_REDUNDANCY-5-CONFIGSYNC: The private-config has been successfully synchronized
to the standby supervisor
```

The example above shows that the boot variable, the config-register, and the startup configuration from the active supervisor engine have successfully synchronized to the redundant supervisor engine.

Manipulating Bootflash on the Redundant Supervisor Engine

Note The console port on the redundant supervisor engine is not available.

To manipulate the redundant supervisor engine bootflash, perform one or more of the following commands:

Command	Purpose
Switch# dir slaveslot0: <i>target_filename</i> or Switch# dir slavebootflash: <i>target_filename</i>	Lists the contents of the slot0: device on the redundant supervisor engine. Lists the contents of the bootflash: device on the redundant supervisor engine.
Switch# delete slaveslot0: <i>target_filename</i> or Switch# delete slavebootflash: <i>target_filename</i>	Deletes specific files from the slot0: device on the redundant supervisor engine. Deletes specific files from the bootflash: device on the redundant supervisor engine.
Switch# squeeze slaveslot0: or Switch# squeeze slavebootflash:	Squeezes the slot0: device on the redundant supervisor engine. Squeezes the bootflash: device on the redundant supervisor engine.
Switch# format slaveslot0: or Switch# format slavebootflash:	Formats the slot0: device on the redundant supervisor engine. Formats the bootflash: device on the redundant supervisor engine.
Switch# copy source_device:source_filename slaveslot0:target_filename or Switch# copy source_device:source_filename slavebootflash:target_filename	Copies a file from the active supervisor engine to the slot0: device on the redundant supervisor engine. Copies a file to the bootflash: device on a redundant supervisor engine. Note Source could be the active supervisor engine or a TFTP server.

Configuring Supervisor Engine Redundancy Using RPR and SSO on Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E

Catalyst 4500 series switches allow a standby supervisor engine to take over if the active supervisor engine fails. In software, supervisor engine redundancy is enabled by running the redundant supervisor engine in route processor redundancy (RPR) or stateful switchover (SSO) operating mode.

Note

The minimum ROMMON requirement for running SSO and RPR is 15.0(1r)SG1. VSS default mode is SSO and is not configurable. VSS does not support RPR mode.

This chapter describes how to configure supervisor engine redundancy on the Catalyst 4507R switch.

Note

For information on Cisco nonstop forwarding (NSF) with SSO, see [Chapter 13, “Configuring Cisco NSF with SSO Supervisor Engine Redundancy.”](#)

This chapter contains these major sections:

- [About Supervisor Engine Redundancy, page 12-2](#)
- [About Supervisor Engine Redundancy Synchronization, page 12-4](#)
- [Supervisor Engine Redundancy Guidelines and Restrictions, page 12-5](#)
- [Configuring Supervisor Engine Redundancy, page 12-7](#)
- [Performing a Manual Switchover, page 12-11](#)
- [Performing a Software Upgrade, page 12-12](#)
- [Manipulating Bootflash on the Standby Supervisor Engine, page 12-14](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Supervisor Engine Redundancy

These sections describe supervisor engine redundancy:

- [Overview, page 12-2](#)
- [RPR Operation, page 12-2](#)
- [SSO Operation, page 12-3](#)

Overview

With supervisor engine redundancy enabled, if the active supervisor engine fails or if a manual switchover is performed, the standby supervisor engine becomes the “new” active supervisor engine. The standby supervisor engine has been automatically initialized with the startup configuration of the active supervisor engine, shortening the switchover time (30 seconds or longer in RPR mode, depending on the configuration; subsecond in SSO mode).

In addition to the reduced switchover time, supervisor engine redundancy supports the following:

- Online insertion and removal (OIR) of the supervisor engine.
Supervisor engine redundancy allows OIR of the redundant supervisor engine for maintenance. When the redundant supervisor engine is inserted, the active supervisor engine detects its presence, and the redundant supervisor engine boots into a partially-initialized state in RPR mode and a fully-initialized state in SSO mode.
- Software upgrade. (See the [“Performing a Software Upgrade” section on page 12-12.](#))
To minimize down time during software changes on the supervisor engine, load the new image on the standby supervisor engine, and conduct a switchover.

When power is first applied to a switch, the supervisor engine that boots first becomes the active supervisor engine and remains active until a switchover occurs.

A switchover will occur when one or more of the following events take place:

- The active supervisor engine fails (due to either hardware or software function) or is removed.
- A user forces a switchover.
- A user reloads the active supervisor engine.

[Table 12-1](#) provides information about chassis and supervisor engine support for redundancy.

Table 12-1 Chassis and Supervisor Support

Supported Switches	Supported Supervisor Engines
WS-C4507R-E, WS-C4510R-E, WS-C4507R+E, WS-C4510R+E	Supervisor Engine 9-E (WS-X45-SUP9-E), Supervisor Engine 8L-E (WS-X45-SUP8L-E), Supervisor Engine 8-E (WS-X45-SUP8-E), (WS-X45-SUP7L-E), (WS-X45-SUP7-E),

RPR Operation

RPR is supported in Cisco IOS-XE Release 3.1.0SG and later releases. When a standby supervisor engine runs in RPR mode, it starts up in a partially-initialized state and is synchronized with the persistent configuration of the active supervisor engine.

**Note**

Persistent configuration includes the following components: startup-config, boot variables, config-register, and VLAN database.

The standby supervisor engine pauses the startup sequence after basic system initialization, and in the event that the active supervisor engine fails, the standby supervisor engine becomes the new active supervisor engine.

In a supervisor engine switchover, traffic is disrupted because in the RPR mode all of the physical ports restart since there is no state maintained between supervisor engines relating to module types and statuses. Upon switchover, when the standby supervisor engine completes its initialization, it will read hardware information directly from the module and become the active supervisor engine.

SSO Operation

SSO is supported in Cisco IOS-XE Release 3.1.0SG and later releases. When a standby supervisor engine runs in SSO mode, the standby supervisor engine starts up in a fully-initialized state and synchronizes with the persistent configuration and the running configuration of the active supervisor engine. It subsequently maintains the state on the protocols listed below, and all changes in hardware and software states for features that support stateful switchover are kept in synchronization. Consequently, it offers zero interruption to Layer 2 sessions in a redundant supervisor engine configuration.

Because the standby supervisor engine recognizes the hardware link status of every link, ports that were active before the switchover will remain active, including the uplink ports. However, because uplink ports are physically on the supervisor engine, they will be disconnected if the supervisor engine is removed.

If the active supervisor engine fails, the standby supervisor engine become active. This newly active supervisor engine uses existing Layer 2 switching information to continue forwarding traffic. Layer 3 forwarding will be delayed until the routing tables have been repopulated in the newly active supervisor engine.

After a switchover, Access Point (AP) connected ports take some time to converge. For faster STP convergence of AP connected ports, enable the **spanning-tree portfast edge** interface configuration command on all interfaces that are connected to APs. This enables the workstation or server to allow those devices to connect to the network immediately, rather than waiting for spanning tree to converge.

SSO supports stateful switchover of the following Layer 2 features.

The state of these features is preserved between both the active and standby supervisor engines:

- 802.3
- 802.3u
- 802.3x (Flow Control)
- 802.3ab (GE)
- 802.3z (Gigabit Ethernet including CWDm)
- 802.3ad (LACP)
- 802.1p (Layer 2 QoS)
- 802.1q
- 802.1X (Authentication)

- 802.1D (Spanning Tree Protocol)
- 802.3af (Inline power)
- PAgP
- VTP
- Dynamic ARP Inspection
- DHCP snooping
- IP source guard
- IGMP snooping (versions 1 and 2)
- DTP (802.1q and ISL)
- MST
- PVST+
- Rapid-PVST
- PortFast/UplinkFast/BackboneFast
- BPDU guard and filtering
- Voice VLAN
- Port security
- Unicast MAC filtering
- ACL (VACLs, PACLS, RACLs)
- QoS (DBL)
- Multicast storm control/broadcast storm control

SSO is compatible with the following list of features. However, the protocol database for these features is not synchronized between the standby and active supervisor engines:

- 802.1Q tunneling with Layer 2 Protocol Tunneling (L2PT)
- Baby giants
- Jumbo frame support
- CDP
- Flood blocking
- UDLD
- SPAN/RSPAN
- NetFlow

The following features are learned on the standby supervisor engine if the SSO feature is enabled:

- All Layer 3 protocols on Catalyst 4500 series switches (Switch Virtual Interfaces)

About Supervisor Engine Redundancy Synchronization

During normal operation, the persistent configuration (RPR and SSO) and the running configuration (SSO only) are synchronized by default between the two supervisor engines. In a switchover, the new active supervisor engine uses the current configuration.

**Note**

You cannot enter CLI commands on the standby supervisor engine console.

These sections describe supervisor engine redundancy synchronization:

- [RPR Supervisor Engine Configuration Synchronization, page 12-5](#)
- [SSO Supervisor Engine Configuration Synchronization, page 12-5](#)

RPR Supervisor Engine Configuration Synchronization

Because the standby supervisor engine is only partially initialized in RPR mode, it interacts with the active supervisor engine only to receive configuration changes at startup and upon saving the configuration changes.

When a standby supervisor engine is running in RPR mode, the following events trigger synchronization of the configuration information:

- When the standby supervisor engine boots, the **auto-sync** command synchronizes the persistent configuration. This command is enabled by default. For details, refer to “[Synchronizing the Supervisor Engine Configurations](#)” section on page 12-10.
- When the active supervisor engine detects the standby supervisor engine, the configuration information is synchronized from the active supervisor engine to the standby supervisor engine. This synchronization overwrites any existing startup configuration file on the standby supervisor engine.
- When you make changes to the configuration, you must use the **write** command to save and synchronize the startup configuration to the standby supervisor engine.

SSO Supervisor Engine Configuration Synchronization

When a standby supervisor engine runs in SSO mode, the following events trigger synchronization of the configuration information:

- When the active supervisor detects the standby supervisor engine, synchronization of the persistent and running configuration takes place, allowing the standby supervisor engine to arrive at a fully-initiated state.
- When real-time changes occur, the active supervisor engine synchronizes the running-config and (or) the persistent configuration (if necessary) with the standby supervisor engine.
- When you change the configuration, you must use the **write** command to allow the active supervisor engine to save and synchronize the startup configuration to the standby supervisor engine.

Supervisor Engine Redundancy Guidelines and Restrictions

The following guidelines and restrictions apply to supervisor engine redundancy:

- If SSO mode cannot be established between the active and standby supervisor engines because of an incompatibility in the configuration file, a mismatched command list (MCL) is generated at the active supervisor engine and a reload into RPR mode is forced for the standby supervisor engine. Subsequent attempts to establish SSO, after removing the offending configuration and rebooting the standby supervisor engine with the exact same image, might cause the C4K_REDUNDANCY-2-IOS_VERSION_CHECK_FAIL and

ISSU-3-PEER_IMAGE_INCOMPATIBLE messages to appear because the peer image is listed as incompatible. If the configuration problem can be corrected, you can clear the peer image from the incompatible list with the **redundancy config-sync ignore mismatched-commands EXEC** command while the peer is in a standby cold (RPR) state. This action allows the standby supervisor engine to boot in standby hot (SSO) state when it reloads.

Here are the steps:

-
- | | |
|---------------|--|
| Step 1 | Clear the offending configuration (that caused an MCL) while the standby supervisor engine is in standby cold (RPR) state. |
| Step 2 | Enter the redundancy config-sync ignore mismatched-commands EXEC command at the active standby supervisor engine. |
| Step 3 | Perform write memory . |
| Step 4 | Reload the standby supervisor engine with the redundancy reload peer command. |
-

- RPR and SSO requires Cisco IOS-XE Release 3.1.0SG and later releases.
- WS-C4507R-E, WS-C4510R-E, WS-C4507R+E, and WS-C4510R+E the only Catalyst 4500 series switches that support Supervisor Engine 7-E, Supervisor Engine 7L-E, and Supervisor Engine 8-E redundancy.
- In RPR or SSO mode,
 - with Supervisor Engine 7-E and 7L-E, only the first two uplinks on each supervisor engine are available. The second two uplinks are unavailable.
 - with Supervisor Engine 8-E, only the first four uplinks on each supervisor engine are available provided a 47xx line card is inserted on slot 10. The second set of four uplinks are unavailable. Only the first two uplinks on each supervisor are available unless the requirement is met (i.e., 47xx linecard in 4510 chassis).
- SSO requires both supervisor engines in the chassis to have the same components (model and memory), and to use the same Cisco IOS XE software image.
- The active and standby supervisor engines in the chassis must be in slots 3 and 4 for 7-slot chassis and slot 5 and 6 for 10-slot chassis.
- Each supervisor engine in the chassis must have its own flash device and console port connections to operate the switch on its own.
- Each supervisor engine must have a unique console connection. Do not connect a Y cable to the console ports.
- Supervisor engine redundancy does not provide supervisor engine load balancing.
- The Cisco Express Forwarding (CEF) table is cleared on a switchover. As a result, routed traffic is interrupted until route tables reconverge. This reconvergence time is minimal because the SSO feature reduces the supervisor engine redundancy switchover time from 30+ seconds to subsecond, so Layer 3 also has a faster failover time if the switch is configured for SSO.
- Static IP routes are maintained across a switchover because they are configured from entries in the configuration file.
- Information about Layer 3 dynamic states that is maintained on the active supervisor engine is not synchronized to the standby supervisor engine and is lost on switchover.

- If configuration changes on a redundant switch are made through SNMP set operations, the changes are not synchronized to the standby supervisor engine even in SSO mode. You might experience unexpected behavior.
- After you configure the switch through SNMP in SSO mode, copy the running-config file to the startup-config file on the active supervisor engine to trigger synchronization of the startup-config file to the standby supervisor engine. Then, reload the standby supervisor engine so that the new configuration is applied on the standby supervisor engine.
- You cannot perform configuration changes during the startup (bulk) synchronization. If you attempt to make configuration changes during this process, the following message is generated:

```
Config mode locked out till standby initializes
```

- If configuration changes occur at the same time as a supervisor engine switchover, these configuration changes are lost.
- If you remove a line card from a redundant switch and initiate an SSO switchover, then reinsert the line card, and all interfaces are shutdown. The rest of the original line card configuration is preserved.

This situation only occurs if a switch had reached SSO before you removed the line card.

Configuring Supervisor Engine Redundancy

These sections describe how to configure supervisor engine redundancy:

- [Configuring Redundancy, page 12-7](#)
- [Virtual Console for Standby Supervisor Engine, page 12-9](#)
- [Synchronizing the Supervisor Engine Configurations, page 12-10](#)

Configuring Redundancy

Note

IOS XE software can be booted at three different levels (Enterprise Services, IP Base, and LAN Base), based on the licenses available on the supervisor engine.

To configure redundancy, perform this task:

	Command	Purpose
Step 1	Switch(config)# redundancy	Enters redundancy configuration mode.
Step 2	Switch(config-red)# mode {sso rpr}	Configures SSO or RPR. When this command is entered, the standby supervisor engine is reloaded and begins to work in SSO or RPR mode.
Step 3	Switch# show running-config	Verifies that SSO or RPR is configured.
Step 4	Switch# show redundancy [clients counters history states]	Displays the redundancy information (counter, state, and so on) for the active and standby supervisor engines.

This example shows how to configure the system for SSO and display the redundancy facility information:

```

Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# redundancy
Switch(config-red)# mode sso
Switch(config-red)# end

Switch# show redundancy
Redundant System Information :

-----
        Available system uptime = 10 minutes Switchovers system experienced = 0
        Standby failures = 1
        Last switchover reason = none

        Hardware Mode = Duplex
        Configured Redundancy Mode = Stateful Switchover
        Operating Redundancy Mode = Stateful Switchover
        Maintenance Mode = Disabled
        Communications = Up

Current Processor Information :
-----
        Active Location = slot 3
        Current Software state = ACTIVE
        Uptime in current state = 9 minutes
        Image Version = Cisco IOS Software, Catalyst 4500 L3 Switch Software
        (cat4500e-UNIVERSALK9-M), Version 15.0(100)XO(1.42), INTERIM SOFTWARE Copyright (c)
        1986-2010 by Cisco Systems, Inc.
        Compiled Sun 01-Aug-10 04:12 by gsbuprod
        Configuration register = 0x920

Peer Processor Information :
-----
        Standby Location = slot 4
        Current Software state = STANDBY HOT
        Uptime in current state = 0 minute
        Image Version = Cisco IOS Software, Catalyst 4500 L3 Switch Software
        (cat4500e-UNIVERSALK9-M), Version 15.0(100)XO(1.42), INTERIM SOFTWARE Copyright (c)
        1986-2010 by Cisco Systems, Inc.
        Compiled Sun 01-Aug-10 04:12 by gsbuprod
        Configuration register = 0x920

```

This example shows how to display redundancy facility state information:

```

Switch# show redundancy states
        my state = 13 -ACTIVE
        peer state = 8 -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 3

Redundancy Mode (Operational) = Stateful Switchover
Redundancy Mode (Configured) = Stateful Switchover
Redundancy State = Stateful Switchover
Manual Swact = enabled

Communications = Up

        client count = 64
        client_notification_TMR = 240000 milliseconds
        keep_alive TMR = 9000 milliseconds
        keep_alive count = 1
        keep_alive threshold = 18

```

```
RF debug mask = 0
```

This example shows how to change the system configuration from RPR to SSO mode:

```
Switch(config)# redundancy
Switch(config-red)# mode
Switch(config-red)# mode sso
Changing to sso mode will reset the standby. Do you want to continue?[confirm]
Switch(config-red)# end
Switch#
*Aug 1 13:11:16: %C4K_REDUNDANCY-3-COMMUNICATION: Communication with the peer Supervisor
has been lost
*Aug 1 13:11:16: %C4K_REDUNDANCY-3-SIMPLEX_MODE: The peer Supervisor has been lost
```

This example shows how to change the system configuration from SSO to RPR mode:

```
Switch(config)# redundancy
Switch(config-red)# mode rpr
Changing to rpr mode will reset the standby. Do you want to continue?[confirm]
Switch(config-red)# end
*Aug 1 13:11:16: %C4K_REDUNDANCY-3-COMMUNICATION: Communication with the peer Supervisor
has been lost
*Aug 1 13:11:16: %C4K_REDUNDANCY-3-SIMPLEX_MODE: The peer Supervisor has been lost
```

Virtual Console for Standby Supervisor Engine

Catalyst 4500 series switches can be configured with 2 supervisor engines to provide redundancy. When the switch is powered, one of the supervisor engines becomes active and remains active until a switchover occurs. The other supervisor engine remains in standby mode.

Each supervisor engine has its own console port. Access to the standby supervisor engine is possible only through the console port of the standby supervisor engine. Therefore, you must connect to the standby console to access, monitor or debug the standby supervisor.

Virtual Console for Standby Supervisor Engine enables you to access the standby console from the active supervisor engine without requiring a physical connection to the standby console. It uses IPC over EOBC to communicate with the standby supervisor engine and thus emulate the standby console on the active supervisor engine. Only one standby console session is active at any time.

The Virtual Console for Standby Supervisor Engine allows users who are logged onto the active supervisor engine to remotely execute **show** commands on the standby supervisor engine and view the results on the active supervisor engine. Virtual Console is available only from the active supervisor engine.

You can access the standby virtual console from the active supervisor engine with the **attach module**, **session module**, or **remote login** commands on the active supervisor engine. You must be in privilege EXEC mode (level 15) to run these commands to access the standby console.

Once you enter the standby virtual console, the terminal prompt automatically changes to *hostname-standby-console* where *hostname* is the configured name of the switch. The prompt is restored to the original setting when you exit the virtual console.

You exit the virtual console with the **exit** or **quit** commands. When the inactivity period of the terminal on the active supervisor engine where you logged in exceeds the configured idle time, you are automatically logged out of the terminal on the active supervisor engine. In this instance, the virtual console session is also terminated. Virtual console session is also automatically terminated when the standby is rebooted. After the standby boots up, you need to create another virtual console session.

To log in to the standby supervisor engine using a virtual console, do the following:

```
Switch# session module 4
```

```
Connecting to standby virtual console
Type "exit" or "quit" to end this session
```

```
Switch-standby-console# exit
Switch#
```

If the standby console is not enabled, the following message appears:

```
Switch-standby-console#
Standby console disabled.
Valid commands are: exit, logout
```

Note

The standby virtual console provides the standard features that are available from the supervisor console such as command history, command completion, command help and partial command keywords.

The following limitations apply to the standby virtual console:

- All commands on the virtual console run to completion. It does not provide the auto-more feature; it behaves as if the **terminal length 0** command has been executed. It is also non-interactive. Therefore, a running command cannot be interrupted or aborted by any key sequence on the active supervisor engine. If a command produces considerable output, the virtual console displays it on the supervisor engine screen.
- The virtual console is non-interactive. Because the virtual console does not detect the interactive nature of a command, any command that requires user interaction causes the virtual console to wait until the RPC timer aborts the command.

The virtual console timer is set to 60 seconds. The virtual console returns to its prompt after 60 seconds. During this time, you cannot abort the command from the key board. You must wait for the timer to expire before you continue.

- You cannot use virtual console to view debug and syslog messages that are being displayed on the standby supervisor engine. The virtual console only displays the output of commands that are executed from the virtual console. Other information that is displayed on the real standby console does not appear on the virtual console.

Synchronizing the Supervisor Engine Configurations

To manually synchronize the configurations used by the two supervisor engines, perform this task on the active supervisor engine:

	Command	Purpose
Step 1	Switch(config)# redundancy	Enters redundancy configuration mode.
Step 2	Switch(config-red)# main-cpu	Enters main-cpu configuration submode.
Step 3	Switch(config-r-mc)# auto-sync {startup-config config-register bootvar standard}	Synchronizes the configuration elements.
Step 4	Switch(config-r-mc)# end	Returns to privileged EXEC mode.
Step 5	Switch# copy running-config startup-config	Synchronizes the running configuration in dynamic random-access memory (DRAM) to the startup configuration file in NVRAM.
		Note This step is not required to synchronize the running configuration file in (DRAM).

**Note**

Configuration changes made to the active supervisor engine through SNMP are not synchronized to the redundant supervisor engine. For information on how to handle this situation, see the [“Supervisor Engine Redundancy Guidelines and Restrictions”](#) section on page 12-5.

**Note**

The **auto-sync** command controls the synchronization of the config-reg, bootvar, and startup/private configuration files only. The calendar and VLAN database files are always synchronized when they change. In SSO mode, the running-config is always synchronized.

This example shows how to reenabling the default automatic synchronization feature using the **auto-sync standard** command to synchronize the startup-config and config-register configuration of the active supervisor engine with the standby supervisor engine. Updates for the boot variables are automatic and cannot be disabled.

```
Switch(config)# redundancy
Switch(config-red)# main-cpu
Switch(config-r-mc)# auto-sync standard
Switch(config-r-mc)# end
Switch# copy running-config startup-config
```

**Note**

To manually synchronize individual elements of the standard auto-sync configuration, disable the default automatic synchronization feature.

**Note**

When you configure the auto-sync standard, the individual sync options such as no auto-sync startup-config are ignored.

This example shows how to disable default automatic synchronization and allow only automatic synchronization of the config-registers of the active supervisor engine to the standby supervisor engine, while disallowing synchronization of the startup configuration:

```
Switch(config)# redundancy
Switch(config-red)# main-cpu
Switch(config-r-mc)# no auto-sync standard
Switch(config-r-mc)# auto-sync config-register
Switch(config-r-mc)# end
```

Performing a Manual Switchover

This section describes how to perform a manual switchover (from the active supervisor engine to the standby supervisor engine) for test purposes. We recommend that you perform a manual switchover prior to deploying SSO in your production environment.

**Note**

This discussion assumes that SSO has been configured as the redundant mode.

To perform a manual switchover, perform this task on the active supervisor engine:

	Command	Purpose
Step 1	Switch# show redundancy	Verifies that the peer state is in the standby hot state. See the example of the show redundancy states command on page 6-10.
Step 2	Switch# redundancy force-switchover	Launches switchover from the active supervisor engine to the standby supervisor engine.

Be aware of these usage guidelines:

- force a switchover, the redundant supervisor engine must be in a standby hot (SSO) or standby cold (RPR) state. You can verify the state with the **show redundancy** command. If the state is not standby hot or standby cold, the **redundancy force-switchover** command will not execute.
- Use the **redundancy force-switchover** command, rather than the **reload** command, to initiate a switchover. The **redundancy force-switchover** command will first check that the redundant supervisor engine is in the correct state. If you issue the **reload** command and the status is not standby hot or standby cold, the **reload** command will reset the current supervisor engine and the peer supervisor may not be able to take over because it was not in a terminal state (standby hot or cold).

After a normal switchover, you might want to make the supervisor engine in a lower slot number of the chassis the active supervisor engine. Use the **show module** command to see which slot contains the active supervisor engine, and force another switchover if necessary.

Performing a Software Upgrade

This is useful only if IOS -XE software is running in LAN Base mode. For Enterprise Services or IP Base mode, use ISSU to upgrade software for both RPR and SSO redundant mode.

The software upgrade procedure supported by supervisor engine redundancy allows you to reload the Cisco IOS software image on the redundant supervisor engine, and once complete, reload the active supervisor engine once.

To perform a software upgrade, perform this task:

	Command	Purpose
Step 1	Switch# copy <i>source_device:source_filename</i> <i>slot0:target_filename</i> Or: Switch# copy <i>source_device:source_filename</i> bootflash: <i>target_filename</i>	Copies the new Cisco IOS-XE software image to bootflash on the supervisor engine.
Step 2	Switch# copy <i>source_device:source_filename</i> slaveslot0: <i>target_filename</i> Or: Switch# copy <i>source_device:source_filename</i> slavebootflash: <i>target_filename</i>	Copies the new image to a device on the standby supervisor engine (such as slavebootflash and slaveslot0).

	Command	Purpose
Step 3	Switch# config terminal Switch(config)# config-register 0x2 Switch(config)# boot system flash <i>device:file_name</i>	Configures the supervisor engines to boot the new image. If your system was configured to autoboot an earlier image, issue the following command string to boot the new image instead: no boot system flash device:old_file_name
Step 4	Switch(config)# redundancy	Enters redundancy configuration mode.
Step 5	Switch(config-red)# main-cpu	Enters main-cpu configuration submode.
Step 6	Switch(config-r-mc)# auto-syn standard	Synchronizes the configuration elements.
Step 7	Switch(config-r-mc)# end	Returns to privileged EXEC mode.
Step 8	Switch# copy running-config start-config	Saves the configuration.
Step 9	Switch# redundancy reload peer	Reloads the standby supervisor engine and brings it back online (using the new release of the Cisco IOS-XE software).
Step 10	Switch# redundancy force-switchover	Conducts a manual switchover to the standby supervisor engine. The standby supervisor engine becomes the new active supervisor engine using the new Cisco IOS-XE software image. The old active supervisor engine reboots with the new image and becomes the standby supervisor engine.

This example shows how to perform a software upgrade:

```
Switch# config terminal
Switch(config)# config-register 0x2
Switch(config)# boot system flash
bootflash0:cat4500e-universalk9.SSA.03.01.00.150.1.XO.bin
Switch(config)# redundancy
Switch(config-red)# main-cpu
Switch(config-r-mc)# auto-syn standard
Switch(config-r-mc)# end
Switch# copy running-config start-config
Switch# redundancy reload peer
Switch# redundancy force-switchover
Switch#
```

This example illustrates how to verify that the running configuration on the active supervisor engine has successfully synchronized with the redundant supervisor engine:

```
Switch# config terminal
Switch(config)# redundancy
Switch(config-red)# main-cpu
Switch(config-r-mc)# auto-sync standard
4d01h: %C4K_REDUNDANCY-5-CONFIGSYNC: The bootvar has been successfully synchronized to the
standby supervisor
4d01h: %C4K_REDUNDANCY-5-CONFIGSYNC: The config-reg has been successfully synchronized to
the standby supervisor
4d01h: %C4K_REDUNDANCY-5-CONFIGSYNC: The startup-config has been successfully synchronized
to the standby supervisor
4d01h: %C4K_REDUNDANCY-5-CONFIGSYNC: The private-config has been successfully synchronized
to the standby supervisor
```

The example above shows that the boot variable, the config-register, and the startup configuration from the active supervisor engine have successfully synchronized to the redundant supervisor engine.

Manipulating Bootflash on the Standby Supervisor Engine

Note

The console port on the standby supervisor engine is not available.

To manipulate the standby supervisor engine bootflash, perform one or more of the following tasks:

Command	Purpose
Switch# dir slaveslot0: <i>target_filename</i>	Lists the contents of the slot0: device on the standby supervisor engine.
or Switch# dir slavebootflash: <i>target_filename</i>	Lists the contents of the bootflash: device on the standby supervisor engine.
Switch# delete slaveslot0: <i>target_filename</i>	Deletes specific files from the slot0: device on the standby supervisor engine.
or Switch# delete slavebootflash: <i>target_filename</i>	Deletes specific files from the bootflash: device on the standby supervisor engine.
Switch# squeeze slaveslot0: <i>target_filename</i>	Squeezes the slot0: device on the standby supervisor engine.
or Switch# squeeze slavebootflash: <i>target_filename</i>	Squeezes the bootflash: device on the standby supervisor engine.
Switch# format slaveslot0: <i>target_filename</i>	Formats the slot0: device on the standby supervisor engine.
or Switch# format slavebootflash: <i>target_filename</i>	Formats the bootflash: device on the standby supervisor engine.
Switch# copy source_device:source_filename slaveslot0: <i>target_filename</i>	Copies a file from the active supervisor engine to the slot0: device on the standby supervisor engine.
or Switch# copy source_device:source_filename slavebootflash: <i>target_filename</i>	Copies a file to the bootflash: device on a standby supervisor engine.
	Note Source could be the active supervisor engine or a TFTP server.

Configuring Cisco NSF with SSO Supervisor Engine Redundancy

This chapter describes how to configure supervisor engine redundancy using Cisco nonstop forwarding (NSF) with stateful switchover (SSO).

Note

Starting with Cisco IOS Release 12.2(52)SG, the Catalyst 4500 switch supports VRF lite NSF support with routing protocols OSPF/EIGRP/BGP.

This chapter consists of these sections:

- [About NSF with SSO Supervisor Engine Redundancy, page 13-1](#)
- [Configuring NSF with SSO Supervisor Engine Redundancy, page 13-9](#)
- [Cisco High Availability Features in Cisco IOS XE 3.1.0SG, page 13-17](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About NSF with SSO Supervisor Engine Redundancy

These sections describe supervisor engine redundancy using NSF with SSO:

- [About Cisco IOS NSF-Aware and NSF-Capable Support, page 13-2](#)
- [NSF with SSO Supervisor Engine Redundancy Overview, page 13-3](#)
- [SSO Operation, page 13-4](#)
- [NSF Operation, page 13-4](#)
- [Cisco Express Forwarding, page 13-5](#)
- [Routing Protocols, page 13-5](#)
- [NSF Guidelines and Restrictions, page 13-9](#)

About Cisco IOS NSF-Aware and NSF-Capable Support

Cisco IOS Nonstop Forwarding (NSF) has two primary components:

- NSF-awareness—If neighboring router devices detect that an NSF router can still forward packets when a supervisor engine switchover happens, this capability is referred to as NSF-awareness. Cisco IOS enhancements to the Layer 3 routing protocols (OSPF, BGP, EIGRP and IS-IS) are designed to prevent route-flapping so that the CEF routing table does not time out or the NSF router does not drop routes. An NSF-aware router helps to send routing protocol information to the neighboring NSF router.

Note

OSPF Version2 fast hellos generate false alarms. We recommend that you use Bidirectional Forwarding Detection (BFD) instead.

- NSF-capability—NSF works with SSO to minimize the amount of time that a Layer 3 network is unavailable following a supervisor engine switchover by continuing to forward IP packets. Reconvergence of Layer 3 routing protocols (BGP, EIGRP, OSPF v2, and IS-IS) is transparent to the user and happens automatically in the background. The routing protocols recover routing information from neighbor devices and rebuild the Cisco Express Forwarding (CEF) table.

Note

NSF does not support IPv6.

Note

NSF-capable devices include Catalyst 4500 series switches, Catalyst 6500 series switches, Cisco 7500 series routers, Cisco 10000 series routers, and Cisco 12000 series routers.

A typical topology for NSF and NSF-aware routers is given below.

Figure 13-1 Topology for NSF and NSF-Capable Switches

Starting with Cisco IOS Release 12.2(20)EWA, the Catalyst 4500 series switch supported NSF-awareness for the EIGRP, IS-IS, OSPF, and BGP protocols. Starting with Cisco IOS Release 12.2(31)SG, the Catalyst 4500 series switch supported NSF-awareness for the EIGRP-stub in IP Base image for all supervisor engines. NSF-awareness is turned on by default for EIGRP-stub, EIGRP, IS-IS, and OSPF protocols. You need to turn BGP on manually.

If the supervisor engine is configured for BGP (with the **graceful-restart** command), EIGRP, OSPF, or IS-IS routing protocols, routing updates are automatically sent during the supervisor engine switchover of a neighboring NSF-capable switch (typically a Catalyst 6500 series switch).

Starting with Cisco IOS Release 12.2(31)SG, the Catalyst 4500 series switch supports NSF-capability. [Table 13-1](#) lists the supervisor engines and the associated Catalyst 4500 series switches that are NSF-capable.

Table 13-1 NSF-Capable Supervisor Engines

NSF-Capable Supervisor Engines	Switch Support
Supervisor Engine 6-E (Supervisor Engine 6L-E (WS-X45-SUP7-E), (WS-X45-SUP7L-E), and Supervisor Engine 8-E (WS-X45-SUP8-E)	Catalyst 4500 E-series switch WS-C4507R-E, WS-C4510R-E, WS-C4507R+E, WS-C4510R+E
Supervisor Engine 9-E (WS-X45-SUP9-E)	WS-C4507R+E, WS-C4510R+E

NSF with SSO Supervisor Engine Redundancy Overview

Catalyst 4500 Series Switches support fault resistance by allowing a redundant supervisor engine to take over if the primary supervisor engine fails. NSF works with SSO to minimize the amount of time a network is unavailable to its users following a switchover.

NSF provides these benefits:

- Improved network availability

NSF continues forwarding network traffic and application state information so that user session information is maintained after a switchover.

- Overall network stability

Network stability may be improved with the reduction in the number of route flaps, which were created when routers in the network failed and lost their routing tables.

- Neighboring routers do not detect a link flap

Because the interfaces remain up during a switchover, neighboring routers do not detect a link flap (the link does not go down and come back up).

- Prevents routing flaps

Because SSO continues forwarding network traffic during a switchover, routing flaps are avoided.

- Maintains user sessions established prior to the switchover

Catalyst 4500 series switches also support route processor redundancy (RPR). For information about these redundancy modes, see [Chapter 10, “Configuring Supervisor Engine Redundancy Using RPR and SSO on Supervisor Engine 6-E and Supervisor Engine 6L-E.”](#)

SSO Operation

SSO establishes one of the supervisor engines as active while the other supervisor engine is designated as standby, and then SSO synchronizes information between them. A switchover from the active to the redundant supervisor engine occurs when the active supervisor engine fails, or is removed from the switch, or is manually shut down for maintenance.

In networking devices running SSO, both supervisor engines must be running the same Cisco IOS software version and ROMMON version so that the redundant supervisor engine is always ready to assume control following a fault on the active supervisor engine. SSO switchover also preserves FIB and adjacency entries and can forward Layer 3 traffic after a switchover. Configuration information and data structures are synchronized from the active to the redundant supervisor engine at startup and whenever changes to the active supervisor engine configuration occur. Following an initial synchronization between the two supervisor engines, SSO maintains state information between them, including forwarding information.

During switchover, system control and routing protocol execution is transferred from the active supervisor engine to the redundant supervisor engine.

Note

Use the **[no] service slave-log** configuration command to forward all error messages from the standby supervisor engine to the active engine. By default, this capability is enabled. For details, refer to the *Catalyst 4500 Series Switch Cisco IOS System Error Message Guide*, Release 12.2(37)SG.

NSF Operation

NSF always runs with SSO and provides redundancy for Layer 3 traffic. NSF is supported by the BGP, OSPF, IS-IS, and EIGRP routing protocols and is supported by Cisco Express Forwarding (CEF) for forwarding. The routing protocols have been enhanced with NSF-capability and awareness, which means that routers running these protocols can detect a switchover and take the necessary actions to continue forwarding network traffic and to recover route information from the peer devices. The IS-IS protocol can be configured to use state information that has been synchronized between the active and the redundant supervisor engine to recover route information following a switchover instead of information received from peer devices.

A networking device is NSF-aware if it is running NSF-compatible software. A device is NSF-capable if it has been configured to support NSF; it rebuilds routing information from NSF-aware or NSF-capable neighbors.

Each protocol depends on CEF to continue forwarding packets during switchover while the routing protocols rebuild the Routing Information Base (RIB) tables. After the routing protocols have converged, CEF updates the FIB table and removes stale route entries. CEF then updates the line cards with the new FIB information.

Cisco Express Forwarding

A key element of NSF is packet forwarding. In a Cisco networking device, packet forwarding is provided by Cisco Express Forwarding (CEF). CEF maintains the FIB and uses the FIB information that was current at the time of the switchover to continue forwarding packets during a switchover. This feature reduces traffic interruption during the switchover.

During normal NSF operation, CEF on the active supervisor engine synchronizes its current FIB and adjacency databases with the FIB and adjacency databases on the redundant supervisor engine. Upon switchover of the active supervisor engine, the redundant supervisor engine initially has FIB and adjacency databases that are mirror images of those that were current on the active supervisor engine. For platforms with forwarding engines, CEF keeps the forwarding engine on the redundant supervisor engine current with changes that are sent to it by CEF on the active supervisor engine. The forwarding engine can continue forwarding after a switchover as soon as the interfaces and a data path are available.

As the routing protocols start to repopulate the RIB on a prefix-by-prefix basis, the updates cause prefix-by-prefix updates to CEF, which it uses to update the FIB and adjacency databases. Existing and new entries receive the new version (“epoch”) number, indicating that they have been refreshed. The forwarding information is updated on the forwarding engine during convergence. The supervisor engine signals when the RIB has converged. The software removes all FIB and adjacency entries that have an epoch older than the current switchover epoch. The FIB now represents the newest routing protocol forwarding information.

Routing Protocols

**Note**

Use of the routing protocols require the Enterprise Services Cisco IOS Software image for the Catalyst 4500 series switch.

The routing protocols run only on the active supervisor engine, and they receive routing updates from their neighbor routers. Routing protocols do not run on the standby supervisor engine. Following a switchover, the routing protocols request that the NSF-aware neighbor devices send state information to help rebuild the routing tables. Alternately, the IS-IS protocol can be configured to synchronize state information from the active to the redundant supervisor engine to help rebuild the routing table on the NSF-capable device in environments where neighbor devices are not NSF-aware. NSF supports the BGP, OSPF, IS-IS, and EIGRP protocols.

**Note**

For NSF operation, the routing protocols depend on CEF to continue forwarding packets while the routing protocols rebuild the routing information.

BGP Operation

When an NSF-capable router begins a BGP session with a BGP peer, it sends an OPEN message to the peer. Included in the message is a statement that the NSF-capable device has “graceful” restart capability. Graceful restart is the mechanism by which BGP routing peers avoid a routing flap following a switchover. If the BGP peer has received this capability, it is aware that the device sending the message is NSF-capable. Both the NSF-capable router and its BGP peers need to exchange the graceful restart capability in their OPEN messages at the time of session establishment. If both peers do not exchange the graceful restart capability, the session will not be capable of a graceful restart.

If the BGP session is lost during the supervisor engine switchover, the NSF-aware BGP peer marks all the routes associated with the NSF-capable router as stale; however, it continues to use these routes to make forwarding decisions for a set period of time. This functionality prevents packets from being lost while the newly active supervisor engine is waiting for convergence of the routing information with the BGP peers.

After a supervisor engine switchover occurs, the NSF-capable router reestablishes the session with the BGP peer. In establishing the new session, it sends a new graceful restart message that identifies the NSF-capable router as having restarted.

At this point, the routing information is exchanged between the two BGP peers. After this exchange is complete, the NSF-capable device uses the routing information to update the RIB and the FIB with the new forwarding information. The NSF-aware device uses the network information to remove stale routes from its BGP table; the BGP protocol then is fully converged.

If a BGP peer does not support the graceful restart capability, it ignores the graceful restart capability in an OPEN message but establishes a BGP session with the NSF-capable device. This function allows interoperability with non-NSF-aware BGP peers (and without NSF functionality), but the BGP session with non-NSF-aware BGP peers is not capable of a graceful restart.

**Note**

BGP support in NSF requires that neighbor networking devices be NSF-aware; that is, the devices must have the graceful restart capability and advertise that capability in their OPEN message during session establishment. If an NSF-capable router discovers that a particular BGP neighbor does not have graceful restart capability, it does not establish an NSF-capable session with that neighbor. All other neighbors that have graceful restart capability continue to have NSF-capable sessions with this NSF-capable networking device.

OSPF Operation

**Note**

OSPF Version2 fast hellos generate false alarms. We recommend that you use Bidirectional Forwarding Detection (BFD) instead.

When an OSPF NSF-capable router performs a supervisor engine switchover, it must perform the following tasks in order to resynchronize its link state database with its OSPF neighbors:

- Relearn the available OSPF neighbors on the network without causing a reset of the neighbor relationship
- Reacquire the contents of the link state database for the network

As quickly as possible after a supervisor engine switchover, the NSF-capable router sends an OSPF NSF signal to neighboring NSF-aware devices. Neighbor networking devices recognize this signal as an indicator that the neighbor relationship with this router should not be reset. As the NSF-capable router receives signals from other routers on the network, it can begin to rebuild its neighbor list.

After neighbor relationships are reestablished, the NSF-capable router begins to resynchronize its database with all of its NSF-aware neighbors. At this point, the routing information is exchanged between the OSPF neighbors. Once this exchange is complete, the NSF-capable device uses the routing information to remove stale routes, update the RIB, and update the FIB with the new forwarding information. The OSPF protocols are then fully converged.

**Note**

OSPF support in NSF requires that all neighbor networking devices be NSF-aware. If an NSF-capable router discovers that it has non-NSF -aware neighbors on a particular network segment, it disables NSF capabilities for that segment. Other network segments composed entirely of NSF-capable or NSF-aware routers continue to provide NSF capabilities.

IS-IS Operation

When an IS-IS NSF-capable router performs a supervisor engine switchover, it must perform the following tasks in order to resynchronize its link state database with its IS-IS neighbors:

- Relearn the available IS-IS neighbors on the network without causing a reset of the neighbor relationship
- Reacquire the contents of the link state database for the network

The IS-IS NSF feature offers two options when you configure NSF:

- Internet Engineering Task Force (IETF) IS-IS
- Cisco IS-IS

If neighbor routers on a network segment are running a software version that supports the IETF Internet draft for router restartability, they assist an IETF NSF router that is restarting. With IETF, neighbor routers provide adjacency and link-state information to help rebuild the routing information following a switchover. A benefit of IETF IS-IS configuration is operation between peer devices based on a proposed standard.

**Note**

If you configure IETF on the networking device, but neighbor routers are not IETF-compatible, NSF aborts following a switchover.

If the neighbor routers on a network segment are not NSF-aware, you must use the Cisco configuration option. The Cisco IS-IS configuration transfers both protocol adjacency and link-state information from the active to the redundant supervisor engine. An advantage of Cisco configuration is that it does not rely on NSF-aware neighbors.

IETF IS-IS Configuration

As quickly as possible after a supervisor engine switchover, the NSF-capable router sends IS-IS NSF restart requests to neighboring NSF-aware devices using the IETF IS-IS configuration. Neighbor networking devices recognize this restart request as an indicator that the neighbor relationship with this router should not be reset, but that they should initiate database resynchronization with the restarting router. As the restarting router receives restart request responses from routers on the network, it can begin to rebuild its neighbor list.

After this exchange is complete, the NSF-capable device uses the link-state information to remove stale routes, update the RIB, and update the FIB with the new forwarding information; IS-IS is then fully converged.

The switchover from one supervisor engine to the other happens within seconds. IS-IS reestablishes its routing table and resynchronizes with the network within a few additional seconds. At this point, IS-IS waits for a specified interval before it attempts a second NSF restart. During this time, the new redundant supervisor engine boots up and synchronizes its configuration with the active supervisor engine. The

IS-IS NSF operation waits for a specified interval to ensure that connections are stable before attempting another restart of IS-IS NSF. This functionality prevents IS-IS from attempting back-to-back NSF restarts with stale information.

Cisco IS-IS Configuration

Using the Cisco configuration option, full adjacency and LSP information is saved, or *checkpointed*, to the redundant supervisor engine. Following a switchover, the newly active supervisor engine maintains its adjacencies using the check-pointed data, and can quickly rebuild its routing tables.

Note

Following a switchover, Cisco IS-IS NSF has complete neighbor adjacency and LSP information; however, it must wait for all interfaces to come on line that had adjacencies prior to the switchover. If an interface does not come on line within the allocated interface wait time, the routes learned from these neighbor devices are not considered in routing table recalculation. IS-IS NSF provides a command to extend the wait time for interfaces that, for whatever reason, do not come on line in a timely fashion.

The switchover from one supervisor engine to the other happens within seconds. IS-IS reestablishes its routing table and resynchronizes with the network within a few additional seconds. At this point, IS-IS waits for a specified interval before it attempts a second NSF restart. During this time, the new redundant supervisor engine boots up and synchronizes its configuration with the active supervisor engine. After this synchronization is completed, IS-IS adjacency and LSP data is check-pointed to the redundant supervisor engine; however, a new NSF restart is not attempted by IS-IS until the interval time expires. This functionality prevents IS-IS from attempting back-to-back NSF restarts.

EIGRP Operation

When an EIGRP NSF-capable router initially re-boots after an NSF restart, it has no neighbor and its topology table is empty. The router is notified by the redundant (now active) supervisor engine when it needs to bring up the interfaces, reacquire neighbors, and rebuild the topology and routing tables. The restarting router and its peers must accomplish these tasks without interrupting the data traffic directed toward the restarting router. EIGRP peer routers maintain the routes learned from the restarting router and continue forwarding traffic through the NSF restart process.

To prevent an adjacency reset by the neighbors, the restarting router uses a new Restart (RS) bit in the EIGRP packet header to indicate a restart. The RS bit is set in the hello packets and in the initial INIT update packets during the NSF restart period. The RS bit in the hello packets allows the neighbors to be quickly notified of the NSF restart. Without seeing the RS bit, the neighbor can only detect an adjacency reset by receiving an INIT update or by the expiration of the hello hold timer. Without the RS bit, a neighbor does not know if the adjacency reset should be handled using NSF or the normal startup method.

When the neighbor receives the restart indication, either by receiving the hello packet or the INIT packet, it recognizes the restarting peer in its peer list and maintains the adjacency with the restarting router. The neighbor then sends it topology table to the restarting router with the RS bit set in the first update packet indicating that it is NSF-aware and is helping out the restarting router. The neighbor does not set the RS bit in their hello packets, unless it is also a NSF restarting neighbor.

Note

A router may be NSF-aware but may not be helping the NSF restarting neighbor because booting from a cold start.

If at least one of the peer routers is NSF-aware, the restarting router then receives updates and rebuilds its database. The restarting router must then find out if it had converged so that it can notify the routing information base (RIB). Each NSF-aware router is required to send an end of table (EOT) marker in the last update packet to indicate the end of the table content. The restarting router knows it has converged when it receives the EOT marker. The restarting router can then begin sending updates.

An NSF-aware peer knows when the restarting router had converged when it receives an EOT indication from the restarting router. The peer then scans its topology table to search for the routes with the restarted neighbor as the source. The peer compares the route timestamp with the restart event timestamp to determine if the route is still available. The peer then goes active to find alternate paths for the routes that are no longer available through the restarted router.

When the restarting router has received all EOT indications from its neighbors or when the NSF converge timer expires, EIGRP notifies the RIB of convergence. EIGRP waits for the RIB convergence signal and then floods its topology table to all awaiting NSF-aware peers.

NSF Guidelines and Restrictions

NSF with SSO has these restrictions:

- With aggressive protocol timers (such as, when the default exceeds the timer value), upon switchover, the protocol software running on the new active supervisor engine might not initialize in time to send "hello" packets to its neighboring switches or routers. If the protocol takes longer time to initialize because of other CPU-demanding tasks, then the protocol encounters state transitions and causes a loss in traffic on the order of seconds. We recommend that you do not configure aggressive timers in conjunction with SSO/NSF.
- For NSF operation, you must have SSO configured on the device.
- NSF with SSO supports IP Version 4 traffic and protocols only; NSF with SSO does not support IPv6 traffic.
- The Virtual Redundancy Routing Protocols (VRRP) is not SSO-aware, meaning state information is not maintained between the active and standby supervisor engine during normal operation. VRRP and SSO can coexist but both features work independently. Traffic that relies on VRRP may switch to the VRRP standby in the event of a supervisor engine switchover.
- All neighboring devices participating in BGP NSF must be NSF-capable and configured for BGP graceful restart.
- OSPF NSF for virtual links is not supported.
- All OSPF networking devices on the same network segment must be NSF-aware (running an NSF software image).
- For IETF IS-IS, all neighboring devices must be running an NSF-aware software image.

Configuring NSF with SSO Supervisor Engine Redundancy

The following sections describe the configuration tasks for the NSF feature:

- [Configuring SSO, page 13-10](#)
- [Configuring CEF NSF, page 13-11](#)
- [Verifying CEF NSF, page 13-11](#)
- [Configuring BGP NSF, page 13-11](#)

- [Verifying BGP NSF, page 13-12](#)
- [Configuring OSPF NSF, page 13-13](#)
- [Verifying OSPF NSF, page 13-13](#)
- [Configuring IS-IS NSF, page 13-14](#)
- [Verifying IS-IS NSF, page 13-15](#)
- [Configuring EIGRP NSF, page 13-16](#)
- [Verifying EIGRP NSF, page 13-16](#)

Configuring SSO

You must configure SSO in order to use NSF with any supported protocol.

To configure SSO, perform this task:

	Command	Purpose
Step 1	Switch(config)# redundancy	Enters redundancy configuration mode.
Step 2	Switch(config-red)# mode sso	Configures SSO. When this command is entered, the redundant supervisor engine is reloaded and begins to work in SSO mode.
Step 3	Switch(config-red)# end	Returns to EXEC mode.
Step 4	Switch# show running-config	Verifies that SSO is enabled.
Step 5	Switch# show redundancy states	Displays the operating redundancy mode.

Note

The **sso** keyword is supported in Cisco IOS Release 12.2(20)EWA and later releases.

This example shows how to configure the system for SSO and display the redundancy state:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# redundancy
Switch(config-red)# mode sso
Switch(config-red)# end
Switch# show redundancy states
my state = 13 -ACTIVE
    peer state = 8  -STANDBY HOT
        Mode = Duplex
        Unit = Primary
        Unit ID = 5

Redundancy Mode (Operational) = sso
Redundancy Mode (Configured)  = sso
    Split Mode = Disabled
    Manual Swact = Enabled
    Communications = Up

    client count = 29
    client_notification_TMR = 30000 milliseconds
        keep_alive TMR = 9000 milliseconds
        keep_alive count = 1
```

```

        keep_alive threshold = 18
        RF debug mask = 0x0
Switch#

```

Configuring CEF NSF

The CEF NSF feature operates by default while the networking device is running in SSO mode. No configuration is necessary.

Verifying CEF NSF

To verify that CEF is NSF-capable, enter the **show cef state** command:

```

Switch# show cef state

CEF Status [RP]
CEF enabled/running
dCEF enabled/running
CEF switching enabled/running
CEF default capabilities:
Always FIB switching:      yes
Default CEF switching:     yes
Default dCEF switching:    yes
Update HWIDB counters:    no
Drop multicast packets:    no
.
.
.
CEF NSF capable:           yes
IPC delayed func on SSO:   no
RRP state:
I am standby RRP:          no
My logical slot:           0
RF PeerComm:               no

```

Configuring BGP NSF

Note

You must configure BGP graceful restart on all peer devices participating in BGP NSF.

To configure BGP for NSF, perform this task (repeat this procedure on each of the BGP NSF peer devices):

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.

	Command	Purpose
Step 2	Switch(config)# router bgp <i>as-number</i>	Enables a BGP routing process, which places the switch in switch configuration mode.
Step 3	Switch(config-router)# bgp graceful-restart	<p>Enables the BGP graceful restart capability, starting BGP NSF.</p> <p>If you enter this command after the BGP session has been established, you must restart the session for the capability to be exchanged with the BGP neighbor.</p> <p>Use this command on the restarting switch and all of its peers.</p>

Verifying BGP NSF

To verify BGP NSF, you must check that BGP graceful restart is configured on the SSO-enabled networking device and on the neighbor devices. To verify, follow these steps:

- Step 1** Verify that “bgp graceful-restart” appears in the BGP configuration of the SSO-enabled switch by entering the **show running-config** command:
- ```
Switch# show running-config

.
.
.
router bgp 120
.
.
.
bgp graceful-restart
neighbor 10.2.2.2 remote-as 300
.
.
.
```
- Step 2** Repeat Step 1 on each of the BGP neighbors.
- Step 3** On the SSO device and the neighbor device, verify that the graceful restart function is shown as both advertised and received, and confirm the address families that have the graceful restart capability. If no address families are listed, BGP NSF does not occur either:
- ```
Switch# show ip bgp neighbors x.x.x.x

BGP neighbor is 192.168.2.2, remote AS YY, external link
  BGP version 4, remote router ID 192.168.2.2
  BGP state = Established, up for 00:01:18
  Last read 00:00:17, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh:advertised and received(new)
    Address family IPv4 Unicast:advertised and received
    Address family IPv4 Multicast:advertised and received
    Graceful Restart Capabilty:advertised and received
    Remote Restart timer is 120 seconds
    Address families preserved by peer:
      IPv4 Unicast, IPv4 Multicast
  Received 1539 messages, 0 notifications, 0 in queue
```

```
Sent 1544 messages, 0 notifications, 0 in queue
Default minimum time between advertisement runs is 30 seconds
```

Configuring OSPF NSF

Note

OSPF Version2 fast hellos generate false alarms. We recommend that you use Bidirectional Forwarding Detection (BFD) instead.

All peer devices participating in OSPF NSF must be made OSPF NSF-aware, which happens automatically when you install an NSF software image on the device.

To configure OSPF NSF, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# router ospf <i>processID</i>	Enables an OSPF routing process, which places the switch in router configuration mode.
Step 3	Switch(config-router)# nsf	Enables NSF operations for OSPF.

Verifying OSPF NSF

To verify OSPF NSF, you must check that the NSF function is configured on the SSO-enabled networking device. To verify OSPF NSF, follow these steps:

- Step 1** Verify that 'nsf' appears in the OSPF configuration of the SSO-enabled device by entering the **show running-config** command:

```
Switch# show running-config

route ospf 120
log-adjacency-changes
nsf
network 192.168.20.0 0.0.0.255 area 0
network 192.168.30.0 0.0.0.255 area 1
network 192.168.40.0 0.0.0.255 area 2
.
.
.
```

- Step 2** Enter the **show ip ospf** command to verify that NSF is enabled on the device:

```
Switch> show ip ospf

Routing Process "ospf 1" with ID 192.168.2.1 and Domain ID 0.0.0.1
Supports only single TOS(TOS0) routes
Supports opaque LSA
SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
Minimum LSA interval 5 secs. Minimum LSA arrival 1 secs
Number of external LSA 0. Checksum Sum 0x0
Number of opaque AS LSA 0. Checksum Sum 0x0
```

```

Number of DCbitless external and opaque AS LSA 0
Number of DoNotAge external and opaque AS LSA 0
Number of areas in this router is 1. 1 normal 0 stub 0 nssa
External flood list length 0
Non-Stop Forwarding enabled, last NSF restart 00:02:06 ago (took 44 secs)
Area BACKBONE(0)
Number of interfaces in this area is 1 (0 loopback)
Area has no authentication
SPF algorithm executed 3 times

```

Configuring IS-IS NSF

To configure IS-IS NSF, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# router isis [<i>tag</i>]	Enables an IS-IS routing process, which places the switch in router configuration mode.
Step 3	Switch(config-router)# nsf [cisco ietf]	Enables NSF operation for IS-IS. Enter the ietf keyword to enable IS-IS in a homogeneous network where adjacencies with networking devices supporting IETF draft-based restartability is guaranteed. Enter the cisco keyword to run IS-IS in heterogeneous networks that might not have adjacencies with NSF-aware networking devices.
Step 4	Switch(config-router)# nsf interval [<i>minutes</i>]	(Optional) Specifies the minimum time between NSF restart attempts. The default time between <i>consecutive</i> NSF restart attempts is 5 minutes.
Step 5	Switch(config-router)# nsf t3 { manual [<i>seconds</i>] adjacency }	(Optional) Specifies the time IS-IS waits for the IS-IS database to synchronize before generating overloaded link-state information for itself and flooding that information out to its neighbors. The t3 keyword applies only if you selected IETF operation. When you specify adjacency , the switch that is restarting obtains its wait time from neighboring devices.
Step 6	Switch(config-router)# nsf interface wait <i>seconds</i>	(Optional) Specifies how long an IS-IS NSF restart waits for all interfaces with IS-IS adjacencies to come up before completing the restart. The default is 10 seconds.

Verifying IS-IS NSF

To verify IS-IS NSF, you must check that the NSF function is configured on the SSO-enabled networking device. To verify IS-IS NSF, follow these steps:

- Step 1** Verify that “nsf” appears in the IS-IS configuration of the SSO-enabled device by entering the **show running-config** command. The display shows either the Cisco IS-IS or the IETF IS-IS configuration. The following display indicates that the device uses the Cisco implementation of IS-IS NSF:

```
Switch# show running-config
<...Output Truncated...>
router isis
nsf cisco
<...Output Truncated...>
```

- Step 2** If the NSF configuration is set to **cisco**, enter the **show isis nsf** command to verify that NSF is enabled on the device. Using the Cisco configuration, the display output differs on the active and redundant RPs. The following display shows sample output for the Cisco configuration on the active RP. In this example, note the presence of “NSF restart enabled”:

```
Switch# show isis nsf

NSF is ENABLED, mode 'cisco'

RP is ACTIVE, standby ready, bulk sync complete
NSF interval timer expired (NSF restart enabled)
Checkpointing enabled, no errors
Local state:ACTIVE, Peer state:STANDBY HOT, Mode:SSO
```

The following display shows sample output for the Cisco configuration on the standby RP. In this example, note the presence of “NSF restart enabled”:

```
Switch# show isis nsf

NSF enabled, mode 'cisco'
RP is STANDBY, chkpt msg receive count:ADJ 2, LSP 7
NSF interval timer notification received (NSF restart enabled)
Checkpointing enabled, no errors
Local state:STANDBY HOT, Peer state:ACTIVE, Mode:SSO
```

- Step 3** If the NSF configuration is set to **ietf**, enter the **show isis nsf** command to verify that NSF is enabled on the device. The following display shows sample output for the IETF IS-IS configuration on the networking device:

```
Switch# show isis nsf

NSF is ENABLED, mode IETF
NSF pdb state:Inactive
NSF L1 active interfaces:0
NSF L1 active LSPs:0
NSF interfaces awaiting L1 CSNP:0
Awaiting L1 LSPs:
NSF L2 active interfaces:0
NSF L2 active LSPs:0
NSF interfaces awaiting L2 CSNP:0
Awaiting L2 LSPs:
Interface:Serial3/0/2
  NSF L1 Restart state:Running
  NSF p2p Restart retransmissions:0
  Maximum L1 NSF Restart retransmissions:3
```

```
L1 NSF ACK requested:FALSE
L1 NSF CSNP requested:FALSE
NSF L2 Restart state:Running
NSF p2p Restart retransmissions:0
Maximum L2 NSF Restart retransmissions:3
L2 NSF ACK requested:FALSE
Interface:GigabitEthernet2/0/0
  NSF L1 Restart state:Running
  NSF L1 Restart retransmissions:0
  Maximum L1 NSF Restart retransmissions:3
  L1 NSF ACK requested:FALSE
  L1 NSF CSNP requested:FALSE
  NSF L2 Restart state:Running
  NSF L2 Restart retransmissions:0
  Maximum L2 NSF Restart retransmissions:3
  L2 NSF ACK requested:FALSE
  L2 NSF CSNP requested:FALSE
Interface:Loopback1
  NSF L1 Restart state:Running
  NSF L1 Restart retransmissions:0
  Maximum L1 NSF Restart retransmissions:3
  L1 NSF ACK requested:FALSE
  L1 NSF CSNP requested:FALSE
  NSF L2 Restart state:Running
  NSF L2 Restart retransmissions:0
  Maximum L2 NSF Restart retransmissions:3
  L2 NSF ACK requested:FALSE
  L2 NSF CSNP requested:FALSE
```

Configuring EIGRP NSF

To configure EIGRP NSF, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# router eigrp <i>as-number</i>	Enables an EIGRP routing process, which places the switch in router configuration mode.
Step 3	Switch(config-router)# nsf	Enables EIGRP NSF. Use this command on the “restarting” switch and all of its peers.

Verifying EIGRP NSF

To verify EIGRP NSF, you must check that the NSF function is configured on the SSO-enabled networking device. To verify EIGRP NSF, follow these steps:

- Step 1
- Verify that “nsf” appears in the EIGRP configuration of the SSO-enabled device by entering the **show running-config** command:

```
Switch# show running-config
.
```

```
.
router eigrp 100
  auto-summary
  nsf
..
.
```

Step 2 Enter the **show ip protocols** command to verify that NSF is enabled on the device:

```
Switch# show ip protocols
*** IP Routing is NSF aware ***
Routing Protocol is "eigrp 100"
  Outgoing update filter list for all interfaces is not set
  Incoming update filter list for all interfaces is not set
  Default networks flagged in outgoing updates
  Default networks accepted from incoming updates
  EIGRP metric weight K1=1, K2=0, K3=1, K4=0, K5=0
  EIGRP maximum hopcount 100
  EIGRP maximum metric variance 1
  Redistributing: eigrp 100
  EIGRP NSF-aware route hold timer is 240s
  EIGRP NSF enabled
    NSF signal timer is 20s
    NSF converge timer is 120s
  Automatic network summarization is in effect
  Maximum path: 4
  Routing for Networks:
  Routing Information Sources:
    Gateway         Distance      Last Update
  Distance: internal 90 external 170
```

Cisco High Availability Features in Cisco IOS XE 3.1.0SG

This section provides a list of High Availability software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

Environmental Monitoring and Power Management

Note

Before reading this chapter, read the “Preparing for Installation” section of the *Catalyst 4500 Series Installation Guide*. It is important to ensure that your installation site has enough power and cooling to accommodate the additional electrical load and heat introduced by Power over Ethernet (PoE).

This chapter describes power management and environmental monitoring features in the Catalyst 4500 series switches. It provides guidelines, procedures, and configuration examples.

This chapter consists of the following major sections:

- [About Environmental Monitoring, page 14-1](#)
- [Power Management, page 14-7](#)
- [IEEE 802.3az Energy Efficient Ethernet, page 14-23](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Environmental Monitoring

This section contains the following subsections:

- [Using CLI Commands to Monitor your Environment, page 14-2](#)
- [Displaying Environment Conditions, page 14-2](#)
- [Displaying On Board Failure Logging \(OBFL\) information for 9000W AC, page 14-4](#)
- [Emergency Actions, page 14-5](#)
- [System Alarms, page 14-6](#)

Environmental monitoring of chassis components provides early warning indications of possible component failure. This warning helps you to ensure the safe and reliable operation of your system and avoid network interruptions.

This section describes how to monitor critical system components so that you can identify and rapidly correct hardware-related problems.

Using CLI Commands to Monitor your Environment

Use the **show environment** CLI command to monitor the system. This section gives a basic overview of the command and keywords you need.

Enter the **show environment [alarm | status | temperature]** command to display system status information. Keyword descriptions are listed in [Table 14-1](#).

Table 14-1 *show environment Keyword Descriptions*

Keyword	Purpose
alarm	Displays environmental alarms for the system.
status	Displays field-replaceable unit (FRU) operational status and power and power supply fan sensor information.
temperature	Displays temperature of the chassis.

Displaying Environment Conditions

Supervisor Engine 6-E, Supervisor Engine 6L-E, Supervisor Engine 7-E, and Supervisor Engine 7L-E and their associated line cards support multiple temperature sensors per card. The environment condition output includes the temperature reading from each sensor and the temperature thresholds for each sensor. These line cards support three thresholds: warning, critical, and shutdown.

The following example illustrates how to display the environment condition on a Supervisor Engine 6-E and Supervisor 6L-E. The thresholds appear within parentheses.

```
Switch# show environment
no temperature alarms
```

Module	Sensor	Temperature	Status
2	air inlet	23C (51C, 65C, 68C)	ok
2	air outlet	29C (69C, 83C, 86C)	ok
5	air inlet	38C (51C, 65C, 68C)	ok
5	air outlet	38C (69C, 83C, 86C)	ok
6	air inlet	34C (51C, 65C, 68C)	ok
6	air outlet	37C (69C, 83C, 86C)	ok

Power Supply	Model No	Type	Status	Fan Sensor	Inline Status
PS1	PWR-C45-2800AC	AC 2800W	good	good	good
PS2	none	--	--	--	--

```
Power supplies needed by system : 1
Power supplies currently available : 1
```

```
Chassis Type : WS-C4510R-E
```

Power consumed by backplane : 40 Watts

Switch Bandwidth Utilization : 0%

Supervisor Led Color : Green

Module 2 Status Led Color : Green

Module 5 Status Led Color : Green

Module 6 Status Led Color : Orange

Module 10 Status Led Color : Green

Fantray : Good

Power consumed by Fantray : 80 Watts

The following example illustrates how to display the environment condition on WS-C4506-E with a Supervisor Engine 7-E. The thresholds appear within parentheses.

Switch# **show environment**

Module	Sensor	Temperature	Status
1	Xgstub A	39C (48C,62C,65C)	ok
1	Xgstub B	32C (45C,60C,63C)	ok
1	XPP	47C (62C,75C,78C)	ok
1	VFE2	59C (74C,85C,88C)	ok
1	NFE	44C (63C,75C,78C)	ok
1	CPU	55C (57C,72C,75C)	ok
1	FPGA	37C (52C,66C,69C)	ok
4	Power macro	30C (56C,68C,71C)	ok
4	Air inlet	27C (46C,59C,62C)	ok
4	Xgstub	31C (66C,76C,79C)	ok
4	Air outlet	30C (60C,71C,74C)	ok

Power Supply	Model No	Type	Status	Fan Sensor	Inline Status
PS1	PWR-C45-1300ACV	AC 1300W	good	good	good
PS2	none	--	--	--	--

Power supplies needed by system : 1
Power supplies currently available : 1

Chassis Type : WS-C4506-E

Power consumed by backplane : 0 Watts

Switch Bandwidth Utilization : 0%

Supervisor Led Color : Green

Module 1 Status Led Color : Green

Displaying On Board Failure Logging (OBFL) information for 9000W AC

9000W AC power supplies support logging of voltage sag (input voltage drops below a certain input threshold) and voltage surge (input voltage spikes above a certain input threshold) events.

If a 9000W power supply is installed in the left bay, the **show logging onboard subslot 0 detail** command displays logging information for that power supply.

If a 9000W power supply is installed in the right bay, enter the **show logging onboard subslot 1 detail** command, as follows:

```
Switch# show logging onboard subslot 0 detail
PID: WS-C4506-E , VID: 4 , SN: FOX1347GR85

Emergency Actions

Catalyst 4500 chassis can power down a single card, providing a detailed response to over-temperature conditions on line cards. However, the Catalyst 4500 chassis *cannot* safely operate when the temperature of the supervisor itself exceeds the critical threshold. The supervisor engine turns off the chassis' power supplies to protect itself from overheating. When this happens, you can recover the switch only by cycling the power on and off switches on the power supplies or by cycling the AC or DC inputs to the power supplies.

Critical and shutdown temperature emergencies trigger the same action. [Table 14-2](#) lists temperature emergencies but does not distinguish between critical and shutdown emergencies.

Table 14-2 Emergency and Action

Case 1. Complete fan failure emergency.	Power down the chassis.
Case 2. Temperature emergency on a line card.	Power down the line card.
Case 3. Temperature emergency on the standby supervisor engine.	Power down the standby supervisor engine.

Table 14-2 **Emergency and Action**

Case 1. Complete fan failure emergency.	Power down the chassis.
Case 4. Temperature emergency on the active supervisor engine with the standby supervisor engine in the hot standby or cold standby redundancy state.	Reset the active supervisor engine.
Case 5. Temperature emergency on the active supervisor engine with no standby supervisor engine or with a standby supervisor engine that is not in hot standby or cold standby redundancy state.	Power down the chassis.

In Case 4, the standby supervisor engine takes over when the active engine resets itself. If the temperature emergency remains, the newly active supervisor engine resets the standby supervisor engine.

Case 5 applies to nonredundant chassis and to chassis with a standby supervisor engine that has been shutdown or which has not fully booted.

System Alarms

Any system has two types of alarms: major and minor. A major alarm indicates a critical problem that could lead to system shutdown. A minor alarm is informational—it alerts you to a problem that could become critical if corrective action is not taken.

[Table 14-3](#) lists the possible environment alarms.

Table 14-3 **Possible Environmental Alarms**

A temperature sensor over its warning threshold	minor
A temperature sensor over its critical threshold	major
A temperature sensor over its shutdown threshold	major
A partial fan failure	minor
A complete fan failure	major

Fan failure alarms are issued as soon as the fan failure condition is detected and are canceled when the fan failure condition clears. Temperature alarms are issued as soon as the temperature reaches the threshold temperature and are canceled when the temperature drops more than 5 degree C below the threshold. 5 degree C is a hysteresis value designed to prevent toggling alarms.

An LED on the supervisor engine indicates whether an alarm has been issued.

When the system issues a major alarm, it starts a timer whose duration depends on the alarm. If the alarm is not canceled before the timer expires, the system takes emergency action to protect itself from the effects of overheating. The timer values and the emergency actions depend on the type of supervisor engine.

Note

Refer to the *Catalyst 4500 Series Switch Module Installation Guide* for information on LEDs, including the startup behavior of the supervisor engine system LED.

Table 14-4 describes the alarms.

Table 14-4 Alarms on Supervisor Engine 6-E, Supervisor Engine 6L-E, and Supervisor Engine 7-E

Event	Alarm Type	Supervisor LED Color	Timeout	Description and Action
Card temperature exceeds the critical threshold.	Major	Red	15 min	Syslog message displays when the alarm is issued. See Table 14-2 for the action on timeout.
Card temperature exceeds the shutdown threshold.	Major	Red	30 sec	Syslog message displays when the alarm is issued. See Table 14-2 for the action on timeout.
Supervisor engine fails power-on self-test (POST).	Major	Red	—	Syslog message displays. Supervisor engine fails to come up.
Chassis fan tray fails.	Major	Red	30 sec	Syslog message displays when the alarm is issued. See Table 14-2 for the action on timeout.
Chassis temperature exceeds the warning threshold.	Minor	Orange	—	Syslog message when the alarm is issued.
Chassis fan tray experiences partial failure.	Minor	Orange	—	Syslog message when the alarm is issued.

Power Management

This section describes the power management feature in the Catalyst 4500 series switches. It includes the following topics:

- [Power Management for the Catalyst 4500 series switches, page 14-7](#)
- [Powering Down a Module, page 14-22](#)

Note

For power consumption of all Catalyst 4000/4500 family modules, see [“Appendix A, Specifications,” in the Catalyst 4500 Series Module Installation Guide](#). Enter the **show power** command to display the current power redundancy and the current system power usage.

Power Management for the Catalyst 4500 series switches

This section includes the following subsections:

- [Supported Power Supplies, page 14-8](#)
- [Power Management Modes for the Catalyst 4500 Switch, page 14-9](#)
- [Selecting a Power Management Mode, page 14-10](#)
- [Power Management Limitations in Catalyst 4500 series switches, page 14-10](#)
- [Available Power for Catalyst 4500 Series Switches Power Supplies, page 14-14](#)
- [Special Considerations for the 4200 W AC and 6000 W AC Power Supplies, page 14-15](#)

- [Combined Mode Power Resiliency, page 14-19](#)
- [Special Considerations for the 1400 W DC Power Supply, page 14-21](#)
- [Special Considerations for the 1400 W DC SP Triple Input Power Supply, page 14-22](#)
- [IEEE 802.3az Energy Efficient Ethernet, page 14-23](#)

Supported Power Supplies

You can select from several different power supplies to ensure that you have enough power for the modules installed in your switch.

Note

You should select a power supply based on the modules and the amount of PoE desired using the Cisco Power Calculator:

<http://tools.cisco.com/cpc/>

The choice between 1000 AC and 1400 AC should depend on the type of line cards that the customer plans to use in the chassis.

The Catalyst 4500 series switches support the following power supplies:

- Fixed Wattage—These power supplies always deliver a fixed amount of PoE and system power.
 - 1000 W AC—Supports up to 1050 W of system power. (Not recommended on the Catalyst 4510R switch, PoE not supported)
 - 1400 W AC—Supports up to 1400 W system power. (PoE not supported)
 - 2800 W AC—Supports up to 1400 W of system power and up to 1400 W of PoE.
- Variable Wattage—These power supplies automatically adjust the wattage to accommodate PoE and system power requirements.
 - 1300 W AC—Supports up to 1050 W of system power and 800 W of PoE, limited to a total of 1300 W.
 - 1400 W DC—Supports up to 1400 W of system power and variable amounts of PoE, depending on the input feed to the power supply. See [“Special Considerations for the 1400 W DC Power Supply” section on page 14-21](#) for more information.
 - 1400 W DC Service Provider—Uses up to three lines (12.5 A, 15 A, 15 A) of DC input and delivers varying amounts of system power ranging from 400 W to 1400 W depending on the lines powered. See [“Special Considerations for the 1400 W DC SP Triple Input Power Supply” section on page 14-22](#) for more information. (PoE not supported)
 - 4200 W AC, 6000 W AC, and 9000W AC—Supports varying amounts of system power and PoE depending on the number of inputs powered and input voltage.

Note

All Catalyst 4500 series switch AC-input power supplies require single-phase source AC. The source AC can be out of phase between multiple power supplies or multiple AC-power plugs on the same power supply because all AC power supply inputs are isolated. Each chassis power supply should ideally have its own dedicated branch circuit sized to local and national codes.

When you insert power supplies in your switch, use power supplies that are of the same wattage. Multi-input power supplies such as 1400 W DC triple-input, 4200 W AC, 6000 W AC, and 9000W AC have additional restrictions. Read the sections on special considerations for these power supplies. If you mix power supplies, the switch uses the one with the higher wattage and ignores the other power supply. The power supply status displays as err-disable and the summary displays as all zeros (0) for wattage values in the output for the **show power** command.

The following example shows the output for the **show power** command for mixed power supplies:

```
Switch# show power
Power
Supply  Model No          Type      Status      Fan      Inline
        Sensor      Status
-----  -
PS1     PWR-C45-2800AC         AC 2800W   good       good     good
→ PS2     PWR-C45-1000AC         AC 1000W   err-disable good     n.a.

```

Power Management Modes for the Catalyst 4500 Switch

The Catalyst 4500 series switches support two power management modes:

- **Redundant mode**—Redundant mode uses one power supply as a primary power supply and the second power supply as a back-up. If the primary power supply fails, the second power supply immediately supports the switch without any disruption in the network. Both power supplies must be the same wattage. A single power supply must have enough power to support the switch configuration.
- **Combined mode**—Combined mode uses the power from all installed power supplies to support the switch configuration power requirements. However, combined mode has no power redundancy. If a power supply fails, one or more modules might shut down.

Note On the Catalyst 4510R switch, the 1000 W AC power supply is not enough to support redundant mode for all possible configurations. It is able to support redundant mode for limited configurations that require less than 1050 W.

Note The 1400 W DC power supply supports combined mode for data power. It does not support combined mode for PoE power.

Selecting a Power Management Mode

By default, a switch is set to redundant mode. In the **show power** command, if the **power supplies needed by system** is 1, the switch is in redundant mode; if the **power supplies needed by system** is 2, the switch is in combined mode.

Your switch hardware configuration dictates which power supply or supplies you should use. For example, if your switch configuration requires more power than a single power supply provides, use the combined mode. In combined mode, however, the switch has no power redundancy. Consider the following possibilities:

- The supervisor engine consumes 110 W, the fan boxes for the Catalyst 4503 switch consume 30 W each, the fan boxes for the Catalyst 4506 and Catalyst 4507 switches consume 50 W each, the backplane for the Catalyst 4503 and Catalyst 4506 switches consumes 10 W, and the backplane for the Catalyst 4507 switch consumes 40 W.
- 1000 W can support a fully loaded Catalyst 4503 switch with no powered device support.
- 1300 W can support a fully loaded Catalyst 4503 switch with Cisco powered devices.
- Each PoE port on a WS-X4148-RJ45V module requires 6.3 W. Five fully loaded WS-X4148-RJ45V modules in a switch comprise 240 ports. This configuration requires 1512 W of PoE, plus 300 W for the modules.

Power Management Limitations in Catalyst 4500 series switches

Limitation 1

It is possible to configure a switch that requires more power than the power supplies provide. The two ways you could configure a switch to exceed the power capabilities are as follows:

- The power requirements for the installed modules exceed the power provided by the power supplies. If you insert a single power supply and then set the switch to combined mode, the switch displays this error message:

```
Insufficient power supplies present for specified configuration.
```

This error message also displays in the output for the **show power** command. This error message displays because, by definition, combined mode requires that two working power supplies be installed in your switch.

If the power requirements for the installed modules exceeds the power provided by the power supplies, the switch displays this error message:

```
Insufficient power available for the current chassis configuration.
```

This error message also appears in the **show power** command output.

If you attempt to insert additional modules into your switch and exceed the power supply, the switch immediately places the newly inserted module into reset mode, and the switch displays these error messages:

```
Module has been inserted
Insufficient power supplies operating.
```

Additionally, if you power down a functioning switch and insert an additional module or change the module configuration so that the power requirements exceed the available power, one or more modules enter reset mode when you power on the switch again.

- The power requirements for the PoE exceed the PoE provided by the power supplies.

If you have too many IP phones drawing power from the system, power to IP phones is cut, and some phones may be powered down to reduce the power requirements to match the power supplies.

In the first scenario (power requirements exceed the power supplied), the system attempts to resolve this power usage limitation by evaluating the type and number of modules installed. During the evaluation cycle, beginning from the bottom of the chassis, the system puts the modules that it is unable to support (for lack of power) into reset mode. The supervisor engine and modules for which there is adequate power always remain enabled, with no disruption of network connectivity. Modules placed in reset mode still consume some power and can be removed from the chassis to further reduce power requirements. If you configure the chassis correctly, the system does not enter the evaluation cycle.

A module in reset mode continues to draw power as long as it is installed in the chassis; use the **show power module** command to determine how much power is required to bring the module online.

To compute the power requirements for your system and verify that your system has enough power, add the power consumed by the supervisor engine module(s), the fan box(es), and the installed modules (including PoE). For PoE, total the requirements for all the phones. See the [“Powering Down a Module” section on page 14-22](#) for more information on the power consumption for the various components of your switch.

The 802.3af-compliant PoE modules can consume up to 20 W of PoE to power FPGAs and other hardware components on the module. Be sure to add at least 20 W to your PoE requirements for each 802.3af-compliant PoE module to ensure that the system has adequate power for the PDs connected to the switch.

On the WS-X4148-RJ45V PoE module, PoE consumption cannot be measured. For all PoE calculations, the PoE consumption on this module is presumed to be equal to its administrative PoE.

Use the **show module** command to verify which modules are active and which, if any, have been placed in reset.

The following example shows the **show module** command output for a system with inadequate power for all installed modules. The system does not have enough power for Module 5; the *Status* displays it as *PwrDeny*.

If the PoE that is consumed by the module is more than 50 W above the PoE you allocated using the **power inline consumption default** command, the Status displays as *PwrOver*. If the PoE consumed by the module is more than 50 W above the PoE module limit, the Status displays as *PwrFault*.

```
Switch# show module

Switch#
```

Limitation 2

Certain configurations on the Catalyst 4507R and Catalyst 4510R chassis exceeds the maximum amount of data power available. These configurations include the combination of the follow PIDs:

- 7-slot configuration
- Chassis: WS-C4507R-E, WS-C4510R-E
- Dual supervisor engines: WS-X45-Sup6-E and WS-X45-Sup6L-E
- One or more: WS-X4448-GB-RJ45 or WS-X4148-FX-MT

To maximize the 10/100/1000 port density of 7- and 10- slot chassis, install WS-X4548-GB-RJ45 line cards instead of WS-X4448-GB-RJ45 line cards. If WS-X4448-GB-RJ45 line cards are required, two options are available:

- Option 1
Only four line card slots can be used on the Catalyst 4507R and six line card slots on the Catalyst 4510R chassis.
- Option 2
When all slots are required, only one WS-X4448-GB-RJ45 line card can be used.

To maximize the 100-BASE-FX port density of 7- and 10- slot chassis, install WS-X4248-FE-SFP line cards with FX optics instead of WS-X4148-FX-MT line cards. If WS-X4148-FX-MT line cards are required, two options are available:

- Option 1
Only four line card slots can be used on the Cat4507R and six line card slots on the Catalyst 4510R chassis.
- Option 2
When all slots are required only one WS-X4448-GB-RJ45 line card can be used.

Configuring Redundant Mode on Catalyst 4500 series switches

By default, the power supplies in a Catalyst 4500 series switch are set to operate in redundant mode. To effectively use redundant mode, follow these guidelines:

- Use two power supplies of the same type.
- If you have the power management mode set to redundant mode and only one power supply installed, your switch accepts the configuration but operates without redundancy.

Caution

If you have power supplies with different types or different wattages installed in your switch, the switch does not recognize one of the power supplies and does not have power redundancy.

- For fixed power supplies, choose a power supply that is powerful enough to support the switch configuration.
- For variable power supplies, choose a power supply that provides enough power so that the chassis and PoE requirements are less than the maximum available power. Variable power supplies automatically adjust the power resources at startup to accommodate the chassis and PoE requirements. Modules are brought up first, followed by IP phones.
- The maximum available power for chassis and PoE for each power supply are listed in [Table 14-5 on page 14-14](#).

To configure redundant mode on your Catalyst 4500 series switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# power redundancy-mode redundant	Sets the power management mode to redundant mode.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show power supplies	Verifies the power redundancy mode for the switch.

The following example shows how to set the power management mode to redundant mode:

```
Switch (config)# power redundancy-mode redundant
Switch (config)# end
Switch#
```

The following example shows how to display the current power redundancy mode. The power supplies needed by system:1 indicates that the switch is in redundant mode.

```
Switch# show power supplies
Power supplies needed by system:1
Switch#
```

An option in the combined mode provides a form of redundancy available with only the 4200 W AC and 6000 W AC power supplies. Refer to the section “Combined Mode Power Resiliency” on page 19.

Configuring Combined Mode on Catalyst 4500 series switches

If your switch configuration requires more power than a single power supply can provide, set the power management mode to combined mode. Combined mode utilizes the available power for both power supplies; however, your switch has no power redundancy.

To effectively use combined mode, follow these guidelines:

- Use power supplies of the same type and wattage (fixed or variable and AC or DC).
- If you use power supplies with different types or wattages, the switch utilizes only one of the power supplies.
- For variable power supplies, choose a power supply that provides enough power so that the chassis and PoE requirements are less than the maximum available power. Variable power supplies automatically adjust the power resources at startup to accommodate the chassis and PoE requirements.
- If you have the power management mode set to combined mode and only one power supply installed, your switch accepts the configuration, but power is available from only one power supply.
- When your switch is configured to combined mode, the total available power is not the mathematical sum of the individual power supplies. The power supplies have a predetermined current sharing ratio. See [Table 14-5 on page 14-14](#) for more information.
- The maximum available power for chassis and PoE for each power supply are listed in [Table 14-5 on page 14-14](#).

To configure combined mode on your Catalyst 4500 series switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# power redundancy-mode combined	Sets the power management mode to combined mode.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show power supplies	Verifies the power redundancy mode for the switch.

The following example shows how to set the power management mode to combined mode:

```
Switch(config)# power redundancy-mode combined
Switch(config)# end
Switch#
```

The following example shows how to display the current power redundancy mode. The power supplies needed by system: 2 indicates that the switch is in combined mode.

```
Switch# show power supplies
Power supplies needed by system:2
Switch#
```

Available Power for Catalyst 4500 Series Switches Power Supplies

Table 14-5 lists the power available for use in the various Catalyst 4500 series switches power supplies. When your switch is configured to combined mode, the total available power is not the mathematical sum of the individual power supplies. The power supplies have a sharing ratio predetermined by the hardware. In combined mode, the total power available is $P + (P * \text{sharing-ratio})$, where P is the amount of power in the power supply.

Table 14-5 Available Power for Switch Power Supplies

Power Supply	Redundant Mode (W)	Combined Mode (W)	Sharing Ratio
1000 W AC	Chassis ¹ = 1050 PoE = 0	Chassis = 1667 PoE = 0	2/3
1300 W AC	Chassis (max) = 1050 PoE (max) = 800 Chassis + PoE + Backplane \leq 1300	Chassis (min) = 767 PoE (max) = 1333 Chassis (max) = 1667 PoE (min) = 533 Chassis + PoE + Backplane \leq 2200	2/3
1400 W DC	Chassis (min) = 200 Chassis (max) = 1360 $\text{PoE (max)}^2 = (\text{DC Input}^3 - [\text{Chassis (min)} + \text{Backplane}] / 0.75) * 0.96$	Chassis = 2267 ⁴ PoE ⁵	Chassis—2/3 PoE—0

Table 14-5 Available Power for Switch Power Supplies (continued)

Power Supply	Redundant Mode (W)	Combined Mode (W)	Sharing Ratio
1400 W AC	Chassis = 1360 PoE = 0 ⁶	Chassis = 2473 PoE = 0	9/11
2800 W AC	Chassis = 1360 PoE = 1400	Chassis = 2473 PoE = 2333	Chassis ⁷ —9/11 PoE ⁸ —2/3

1. Chassis power includes power for the supervisor engine(s), all line cards, and the fan tray.
2. The efficiency for the 1400 W DC power supply is 0.75, and 0.96 is applied to PoE.
3. DC input can vary for the 1400 W DC power supply and is configurable. For more information, see “Special Considerations for the 1400 W DC Power Supply” on page 21.
4. Not available for PoE.
5. Not available for PoE.
6. No voice power.
7. Data-only.
8. Inline power.

Special Considerations for the 4200 W AC and 6000 W AC Power Supplies

The 4200 W AC and 6000 W AC power supply has two inputs: each can be powered at 110 or 220 V.

The 9000 W AC power supply has three inputs: each can be powered at 110 or 220V.

The output of the **show power** command for the 4200 W AC, 6000 W AC, and 9000W AC power supplies are similar to that of 1400 W DC triple-input power supply (that is, the status of the submodules (multiple inputs) is displayed). With these power supplies, you can distinguish submodule “failed” versus “off,” and the status of the submodules (good, bad, or off):

```
Switch# show power
Power
Supply  Model No          Type      Status      Fan      Inline
        -----
PS1     PWR-C45-4200ACV      AC 4200W  good        good      good
PS1-1                   220V      good
PS1-2                   off
PS2     PWR-C45-4200ACV      AC 4200W  bad/off     good      bad/off
PS2-1                   220V      good
PS2-2                   220V      bad

Power supplies needed by system      : 1
Power supplies currently available   : 2

Power Summary
(in Watts)      Used      Maximum
-----
System Power (12V)      140      1360

Power Summary (in Watts)	Used	Maximum Available
-----	----	-----
System Power (12V)	1323	2646
Inline Power (-50V)	0	6022
Backplane Power (3.3V)	40	67
-----	----	-----

As with other power supplies, the two power supplies must be of the same type (6000 W AC or 4200 W AC or 1400 W DC). Otherwise, the right power supply is put in err-disable state and the left one is selected. In addition, all the inputs to the chassis must be at the same voltage. In redundant mode, the inputs to the left and right power supplies must be identical. If the left and right power supplies are powered in redundant mode, the power values is based on the power supply with the higher output wattage.

**Note**

When the system is powered with a 4200 W, 6000 W, or 9000W power supply either in 110 V or 220 V combined mode operation, the available power is determined by the configuration of the system (the type of line cards, the number of line cards, number of ports consuming inline power, etc.) and does not reflect the absolute maximum power.

**Note**

In a matched redundant power supply configuration, if a power supply submodule fails, the other (good) power supply provides power to its full capability.

Table 14-6 illustrates how the 4200 W AC power supply is evaluated in redundant mode.

Table 14-6 Output Power in Redundant Mode for the 4200 W AC Power Supply

Power Supply	12 V (data) (W)	-50V (PoE) (W)	Total Power (W) ¹
110 V AC	660	922	1050
110 V AC + 110 V AC	1460	2000	2100
220 V AC	1460	2500	2100
220 V AC + 220 V AC	1960	5000	4200

1. Power supply outputs' drawing should not exceed the total power.

In combined mode, all the inputs to the chassis must be at the same voltage.

Table 14-7 illustrates how the 4200 W AC power supply is evaluated in combined mode.

Table 14-7 Output Power in Combined Mode for the 4200 W AC Power Supply

Power Supply	12 V (data) (W)	-50 V (PoE) (W)	Total Power (W) ¹
Both sides at 110 V AC	1188	1531	1700
Both sides at 110 V AC + 110 V AC	2448	3071	3570
One side at 110 V AC + 110 V AC, the other at 110 V AC	1818	2301	2660
Both sides at 220 V AC	2448	3071	3570
Both sides at 220 V AC + 220 V AC	2448	6142	7070
Both sides at 220 V AC + 220 V AC, the other at 220 V AC	2447	4607	5320

1. Power supply outputs' drawing should not exceed the total power.

Table 14-8 illustrates how the 6000 W AC power supply is evaluated in redundant mode.

Table 14-8 Output Power in Redundant Mode for the 6000 W AC Power Supply

Power Supply	12 V (data) (W)	-50V (PoE) (W)	Total Power (W) ¹
110 V AC	850	922	1050
110 V AC + 110 V AC	1700	1850	2100
220 V AC	2200	2400	3000
220 V AC + 220 V AC	2200	4800	6000

1. Power supply outputs' drawing should not exceed the total power.

In combined mode, all the inputs to the chassis must be at the same voltage.

Table 14-9 illustrates how the 6000 W AC power supply is evaluated in combined mode.

Table 14-9 Combined Mode Output for the 6000 W AC Power Supply

Power Supply	12 V (data) (W)	-50 V (PoE) (W)	Total Power (W) ¹
Both sides at 110 V AC	1530	1531	1710
Both sides at 110 V AC + 110 V AC	3060	3071	3590
One side at 110 V AC + 110 V AC, the other at 110 V AC	2295	2301	2680
Both sides at 220 V AC	3960	3984	5140
Both sides at 220 V AC + 220 V AC	3960	7968	10170
Both sides at 220 V AC + 220 V AC, the other at 220 V AC	2970	5976	7610

1. Power supply outputs' drawing should not exceed the total power.

Table 14-10 illustrates how the 9000 W AC power supply is evaluated in redundant mode.

Table 14-10 Power Output in Redundant Mode for the 9000 W AC Power Supply

Power Supply	12V (data) (W)	-50V (PoE) (W)	¹ Total Power (W)
110VAC	960	1000	1100
110VAC + 110 VAC	1460	2000	2200
110VAC + 110 V AC+ 110VAC	1460	2500	3300
220VAC	1460	2500	3000
220VAC + 220VAC	1960	5000	6000
220VAC + 220VAC + 220VAC	1960	7500	9000

1. Power supply output drawings should not exceed the total power.

Table 14-11 illustrates how the 9000 W AC power supply is evaluated in combined mode.

Table 14-11 Power Output in Combined Mode for the 9000 W AC Power Supply

Power Supply	12V (data) (W)	-50V (PoE) (W)	¹ Total Power (W)
Both sides at 110 VAC	1594	1660	1790
Both sides at 110VAC + 110VAC	2424	3320	3610
Both sides at 110VAC + 110VAC + 110VAC	2424	4150	5420
One side at 110VAC + 110VAC + 110VAC, the other at 110VAC + 110VAC	2020	3458	4510
One side at 110VAC + 110VAC + 110VAC, the other at 110VAC	1615	2767	3600
One side at 110VAC + 110VAC, the other at 110VAC	1818	2490	2700
Both sides at 220VAC	2424	4150	4930
Both sides at 220VAC + 220VAC	3763	8300	10140
Both sides at 220VAC + 220VAC + 220VAC	3763	14400	17210
One side at 220VAC + 220VAC + 220VAC, the other at 220VAC + 220VAC	2940	11250	13430
One side at 220VAC + 220VAC + 220VAC, the other at 220VAC	2169	8300	9900
One side at 220VAC + 220VAC, the other at 220VAC	2646	6225	7410

1. Power supply output drawings should not exceed the total power.

Combined Mode Power Resiliency

Note

This feature only applies in combined mode when both power supply bays contain the 4200 W AC or 6000 W AC power supply.

Using the combined mode power resiliency feature, you can limit the power usage to a maximum of two or three (configurable) inputs for 4000W and 6000W power supplies. For 9000W power supplies, you can limit the power usage to a maximum of 2 to 5 inputs, since the 9000W is a triple input power supply.

With two 4200 W AC or 6000 W AC power supplies, a maximum of four inputs are available. With two 9000W, a maximum of six inputs are available. This feature allows you to cap the power usage to that of two/three inputs or four/five inputs. If one of the power supplies fails, no loss of power occurs because you have capped its usage to a smaller number of inputs.

To configure the combined mode resiliency feature, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# power redundancy combined max inputs {2 3}	If a 9000W AC power supply is detected, this limits the power usage to four or five inputs.
	OR	
	Switch(config)# power redundancy combined max inputs {2 3}	If a 9000W AC power supply is not detected, limits the power usage to two or three inputs.
Step 3	Switch(config)# end	Exits configuration mode.

If you have **max inputs 3** configured with four “good” (220 V) inputs and you limit the user to 5500 W instead of 7600 W and one subunit fails or is powered off, you have three quality inputs providing 5500 W and the chassis is powered at the same rate as it was prior to the failure event:

```
Switch# configuration terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# power redundancy combined max inputs 3
Switch(config)# end
Switch#
14:32:01: %SYS-5-CONFIG_I: Configured from console by console
```

Here is the output of the **show power** command prior to invoking this feature:

```
Switch# show power
sh power
Power
Supply  Model No          Type      Status      Fan      Inline
-----  -
PS1      PWR-C45-4200ACV    AC 4200W  good        good      good
PS1-1    110V               good
PS1-2    110V               good
```

```

PS2      PWR-C45-4200ACV  AC 4200W  good      good      good
PS2-1                    110V  good
PS2-2                    110V  good

```

```

Power supplies needed by system : 1
Power supplies currently available : 2

```

```

Power Summary
(in Watts)      Used      Maximum
-----
System Power (12V)  140      1360
Inline Power (-50V)   0      1850
Backplane Power (3.3V) 0       40
-----
Total            140 (not to exceed Total Maximum Available = 2100)

```

Here is the output after invoking this feature. The combined mode was indicated before **Power supplies needed = 2** in the output of the **show power** command, combined mode is now indicated by the phrase **Power supplies needed by system: 2 Maximum Inputs = 3**.

```
Switch# show power
```

```

sh power
Power
Supply Model No      Type      Status      Fan      Inline
-----
PS1      PWR-C45-4200ACV  AC 4200W  good      good      good
PS1-1                    110V  good
PS1-2                    110V  good
PS2      PWR-C45-4200ACV  AC 4200W  good      good      good
PS2-1                    110V  good
PS2-2                    110V  good

```

```

Power supplies needed by system : 2 Maximum Inputs = 3
Power supplies currently available : 2

```

```

Power Summary
(in Watts)      Used      Maximum
-----
System Power (12V)  140      2400
Inline Power (-50V)   0      2000
Backplane Power (3.3V) 0       40
-----
Total            140 (not to exceed Total Maximum Available = 2728)

```

```
Switch#
```

Here's another example of combined mode resiliency with 9000W power supply with a maximum of six active inputs, limited to 3 inputs:

```
Switch# show power
```

```

Power
Supply Model No      Type      Status      Fan      Inline
-----
PS1      PWR-C45-9000ACV  AC 9000W  good      good      good
PS1-1                    220V  good
PS1-2                    220V  good
PS1-3                    220V  good
PS2      PWR-C45-9000ACV  AC 9000W  good      good      good
PS2-1                    220V  good
PS2-2                    220V  good
PS2-3                    220V  good

```

```

Power supplies needed by system : 2 Maximum Inputs = 3

```

Power supplies currently available : 2

Power Summary (in Watts)	Used	Maximum Available
-----	----	-----
System Power (12V)	1323	2646
Inline Power (-50V)	0	6022
Backplane Power (3.3V)	40	67
-----	----	-----
Total	1363	(not to exceed Total Maximum Available = 7412)

Special Considerations for the 1400 W DC Power Supply

Caution

Do not mix the 1400 W DC power supply with any other power supply, even for a hot swap or other short-term emergency. Doing so can seriously damage your switch.

Keep in mind the following guidelines when using a 1400 W DC power supply with your Catalyst 4500 series switch:

- The 1400 W DC power supply works with a variety of DC sources. The DC input can vary from 300 W to 7500 W. Refer to the power supply documentation for additional information.
- The supervisor engine cannot detect the DC source plugged into the 1400 W DC power supply. If you are using the 1400 W DC power supply, use the **power dc input** command to set the DC input power. For more information on this command, see the [“Configuring the DC Input for a Power Supply” section on page 14-21](#).
- The software automatically adjusts between system power (for modules, backplane, and fans) and PoE. Although PoE is 96 percent efficient, system power has only 75 percent efficiency. For example, each 120 W of system power requires 160 W from the DC input. This requirement is reflected in the **“Power Used”** column of the output for the **show power available** command.
- The 1400 W DC power supply has a separate power on or off switch for PoE. The power supply fan status and main power supply status are tied together. If either of them fails, both the power supply and its fan report as bad/off. You should verify that the main power is on before turning on the power for the inline switch. In addition, you should verify that the power for the inline switch is off before turning off the main power.

Configuring the DC Input for a Power Supply

To configure the DC input power for the 1400 W DC power supply or a power shelf, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# power dc input watts	Sets the capacity of the DC input source.
Step 3	Switch(config)# end	Exits configuration mode.

The same configuration is applied to both power slots. For example, if you set the **dc power input** to 1000 W, the switch expects 1000 W as the external DC source for both slot 1 and slot 2 (if present).

The following example shows how to set the external DC power source to 1000 W:

```
Switch# configure terminal
Switch (config)# power dc input 1000
```

```
Switch (config)# end
Switch#
```

If you use the 1400 W DC SP power supply in combined mode, the inputs do not have to match.

Special Considerations for the 1400 W DC SP Triple Input Power Supply

Unlike the 1400 W DC power supply, the 1400 W DC SP power supply has submodules (multiple inputs) that can be powered on or off. With Cisco IOS Release 12.2(25)EW, the output of the **show power** command is modified to display the status of these submodules:

```
Switch# show power
Power
Supply Model No          Type      Status      Fan      Inline
-----
PS1      PWR-C45-1400DC        DCSP1400W good        good      n.a.
PS1-1    12.5A                 good
PS1-2    15.0A                 bad
PS1-3    15.0A                 off

PS2      none                  --        --        --        --
```

Observer the following guidelines when using a 1400 W DC SP power supply with your Catalyst 4500 series switch:

- When you use two 48 V power rails to drive two power supplies, you might use cross-wiring to connect the power supplies (to rails) to minimize the inrush current drawn during an initial power up. In this situation, you should configure the switch in combined mode before you take a rail down for maintenance.
- Ordinarily, when configured for redundancy, two power supplies must be matched (have identical inputs). For example, you might provide power to inputs 1 and 3 on both PS1 and PS2. If power supplies are mismatched upon bootup, the right (second) power supply is in err-disable state.

In a matched redundant power supply configuration, if a power supply submodule fails, the other (good) power supply provides power to its full capability.

Powering Down a Module

If your system does not have enough power for all modules installed in the switch, you can power down a module, and place it in low-power mode. To power down a module, perform this task:

Command	Purpose
Switch(config)# no hw-module module num power	Turns power down to the specified module by placing it in low power mode.

To power on a module that has been powered down, perform this task:

Command	Purpose
Switch(config)# hw-module module num power	Turns power on to the specified module.

This example shows how to power down module 6:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# no hw-module module 6 power
Switch(config)# end
Switch#
```

**Note**

After you enter **no hw-mod mod x power** command and OIR the linecard, the configuration persists and is valid for any slot in the chassis it is applied to. You observe the same behavior in the active and standby supervisor engines

IEEE 802.3az Energy Efficient Ethernet

**Note**

EEE is supported on WS-X4748-UPOE+E and WS-X4748-RJ45-E.

Energy Efficient Ethernet is an extension of the IEEE 802.3 standard that provides a mechanism and a standard for reducing energy usage without reducing the vital function of network interfaces. EEE defines the signaling necessary for energy savings during periods where no data is sent on the interface.

EEE defines support for physical layer devices (PHYs) to operate in Low Power Idle (LPI) mode. When enabled, EEE supports QUIET times during low link utilization allowing both sides of a link to disable portions of each PHY's operating circuitry and save power. This functionality is provided per port and is not enabled by default. To avoid issues with EEE functionality on any port during run-time, Cisco provides the **power efficient-ethernet auto** command to enable or disable EEE.

Because EEE relies on Auto Negotiation pulse to determine whether to activate EEE, the port must initially enable auto negotiation. Furthermore, EEE is the correct action provided the speed is auto 100M, auto 1000M, or auto 100M and 1000M. 10M (either auto or forced mode) does not require EEE for power saving.

For more details, see the URL:

http://www.cisco.com/en/US/prod/collateral/switches/ps5718/ps4324/white_paper_c11-676336.pdf

Sections include:

- [Determining EEE Capability, page 14-23](#)
- [Enabling EEE, page 14-24](#)
- [Determining EEE Status, page 14-24](#)

Determining EEE Capability

To determine whether a line card supports EEE, use the **show interface capabilities module *module*** command, as follows:

```
Switch# show interface capabilities module 3
GigabitEthernet3/1
Model: WS-X4748-NGPOE+E-RJ-45
Type: 10/100/1000-TX
Speed: 10,100,1000,auto
Duplex: half,full,auto
Auto-MDIX: yes
EEE: yes ( 100-Tx and 1000-T auto mode )
```

Enabling EEE

To enable EEE on a given port, use the **power efficient-ethernet auto** command.

	Command	Purpose
Step 1	Switch# configure terminal	Enters configuration mode.
Step 2	Switch(config)# interface <i>interface</i>	Enters interface configuration mode and specifies the port to be configured.
Step 3	Switch(config-if)# power efficient-ethernet auto	Enables EEE.
Step 4	Switch(config-if)# exit	Exits global configuration mode.

The following example shows how to enable EEE:

```
Switch# conf t
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# power efficient-ethernet auto
Switch(config-if)# exit
```

Determining EEE Status

To determine EEE status use the **show platform software interface *interface* status** command:

The following example determines EEE status:

```
Switch(config)# show platform software interface g2/1 status
Switch Phyport Gi2/1 Software Status
EEE: Disabled
```

EEE status can have the following values:

- EEE: N/A**—The port is not capable of EEE.
- EEE: Disabled**—The port EEE is disabled.
- EEE: Disagreed**—The port EEE is not set because a remote link partner might be incompatible with EEE; either it is not EEE capable, or it’s EEE setting is incompatible.
- EEE: Operational**—The port EEE is enabled and operating.

Configuring Power over Ethernet

Note

Before reading this chapter, read the “Preparing for Installation” section of the *Catalyst 4500 Series Installation Guide*. You must ensure that your installation site has enough power and cooling to accommodate the additional electrical load and heat introduced by PoE.

This chapter describes how to configure Power over Ethernet (PoE) on the Catalyst 4500 series switch.

This chapter contains the following sections:

- [Feature Information for Power over Ethernet, page 15-18](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Power over Ethernet

The Catalyst 4500 series switch provides Power over Ethernet (PoE) support for both Cisco Prestandard PoE and the IEEE 802.3af standard (ratified in 2003). PoE is supported by all Catalyst 4500 series chassis and requires a PoE module and power supply. The amount of PoE power available depends on the PoE capabilities of individual power supplies. Support for PoE enables the system to power inline devices, such as IP phones, IP video phones, and wireless access points over standard copper cabling (Category 5, 5e, or 6 cabling).

In addition, with PoE, you do not need to provide wall power for each PoE enabled device. This eliminates the cost for additional electrical cabling that is otherwise necessary for connected devices. Moreover, PoE enables you to isolate critical devices on a single power system, enabling the entire system to be supported by UPS backup.

You typically deploy a Catalyst 4500 series switch in one of two deployment scenarios. The first scenario is data-only, which requires power to operate the switch and the associated modules. The second scenario supports data and PoE (also termed “inline power”) for deployments where the attached device derives power from the Ethernet port.

Catalyst 4500 series switches can sense if a powered device is connected to a PoE module. They can supply PoE to the powered device if there is no power on the circuit. (If there is power on the circuit, the switch does not supply it.) The powered device can also be connected to an AC power source and supply its own power to the voice circuit.

Note

You should select the amount of PoE desired using the Cisco Power Calculator:

<http://tools.cisco.com/cpc/>

Hardware Requirements

To power a device using PoE, your chassis must use at least one of the power supplies listed in [Table 15-1](#), and connect the device to at least one of the switching modules listed in [Table 15-1](#).

Table 15-1 **Hardware Requirements**

Switching Modules	Power Supplies
WS-X4148-RJ45V	PWR-C45-1300ACV=

WS-X4648-RJ45V+E	

Power Management Modes

If your switch has a module capable of providing PoE to end stations, you can set each interface on the module to automatically detect and apply PoE if the end station requires power.

The Catalyst 4500 series switch has three PoE modes:

- **auto**—PoE interface. The supervisor engine directs the switching module to power up the interface *only* if the switching module discovers the phone and the switch has enough power. You can specify the maximum wattage that is allowed on the interface. If you do not specify a wattage, then the switch delivers no more than the hardware-supported maximum value. This mode has no effect if the interface is not capable of providing PoE.
- **static**—High priority PoE interface. The supervisor engine preallocates power to the interface, even when nothing is connected, guaranteeing that power exists for the interface. You can specify the maximum wattage that is allowed on the interface. If you do not specify a wattage, then the switch preallocates the hardware-supported maximum value. If the switch does not have enough power for the allocation, the command fails. The supervisor engine directs the switching module to power up the interface *only* if the switching module discovers the powered device.
- **never**—Data interface only. The supervisor engine never powers up the interface, even if an unpowered phone is connected. This mode is only needed when you want to make sure power is never applied to a PoE-capable interface.

The switch can measure the actual PoE consumption for an 802.3af-compliant PoE module, and displays this in the **show power module** command.

PoE consumption cannot be measured on the WS-X4148-RJ45V PoE module. For all PoE calculations, the PoE consumption on this module is presumed to be equal to its administrative PoE.

For more information, see the [“Displaying the PoE Consumed by a Module” section on page 15-8](#).

For most users, the default configuration of “auto” works well, providing plug-and-play capability. No further configuration is required. However, to make an interface higher priority or data only, or to specify a maximum wattage, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet } <i>slot/port</i>	Selects the interface to configure.
Step 2	Switch(config-if)# power inline { auto [max <i>milli-watts</i>] never static [max <i>milli-watts</i>]}	<p>The auto keyword sets the interface to automatically detect and supply power to the powered device. it is the default configuration.</p> <p>The static keyword sets the interface to higher priority than auto.</p> <p>If necessary, use the max keyword to specify the maximum wattage allowed on the interface (4000 to 15400 milliwatts for most switching modules. As of Cisco IOS Release 12.2(44)SG, the WS-X4648-RJ45V+E can support up to 30 W available per-port and the WS-X4648-RJ45V-E supports up to 20 W. For more information, see “The WS-X4648-RJ45V-E, WS-X4648-RJ45V+E, and WS-X4548-RJ45V+ switching modules support IEEE 802.3af PoE as well as the Cisco proprietary Inline Power standard. With Cisco IOS Release 12.2(44)SG, the WS-X4648-RJ45V+E line card can also support the IEEE 802.3at standard with up to 30 W available per-port. The WS-X4648-RJ45V-E line card also supports up to 20 W. The WS-X4548-RJ45V+ switching module is supported with Cisco IOS Release 12.2(50)SG and can provide up to 30 W of inline power per-port.” on page 16).</p> <p>Use the never keyword to disable detection and power for the PoE capable interface.</p>
Step 3	Switch(config-if)# end	Exits configuration mode.
Step 4	Switch# show power inline { fastethernet gigabitethernet } <i>slot/port</i>	Displays the PoE state for the switch.

Note

If you set a non-PoE-capable interface to automatically detect and apply power, an error message indicates that the configuration is not valid.

The following example shows how to set the Fast Ethernet interface 4/1 to automatically detect PoE and send power through that interface, and to verify the PoE configuration:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 4/1
Switch(config-if)# power inline auto
Switch(config-if)# end
Switch# show power inline fastethernet 4/1
Available:677(w) Used:11(w) Remaining:666(w)
```

Interface	Admin	Oper	Power(Watts)		Device	Class
			From PS	To Device		
Fa4/1	auto	on	11.2	10.0	Ieee PD	0

Interface	AdminPowerMax (Watts)	AdminConsumption (Watts)
-----------	--------------------------	-----------------------------

```
-----  
Fa4/1                15.4                10.0  
Switch#
```

The following example shows how to configure an interface so that it never supplies power through the interface:

```
Switch# configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch(config)# interface fastethernet 5/2  
Switch(config-if)# power inline never  
Switch(config-if)# end  
Switch#
```

Intelligent Power Management

All Catalyst 4500 PoE-capable modules use Intelligent Power Management to provide power on each interface. When a powered device (PD) is attached to a PoE-capable port, the port detects the PD and provision power accordingly. If a Cisco PD is used, the switch and PD negotiate power using CDP packets to determine the precise amount of power needed by the PD. If the PD is 802.3af compatible, the difference between what is mandated by the 802.3af class and what is actually needed by the PD is returned to the power budget for use by additional devices. In this way, power negotiation enables customers to stretch their power budget and use it more effectively.

Power negotiation also enables the interoperability of newer Cisco powered devices with older legacy PoE-capable ports from Cisco. Newer Cisco PDs do not consume more than what the switch port can provide.

Configuring Power Consumption for Powered Devices on an Interface

By default, when the switch detects a powered device on an interface, it assumes the powered device consumes the maximum the port can provide (7 W on a legacy PoE module and 15.4W on the IEEE PoE modules introduced in Cisco IOS Release 12.2(18)EW). When the switch receives a CDP packet from the powered device, the wattage automatically adjusts downward to the specific amount required by that device. Normally, this automatic adjustment works well, and no further configuration is required or recommended. However, you can specify the powered device's consumption for a particular interface to provide extra functionality from your switch. This behavior is useful when CDP is disabled or not available.

Note

When manually configuring the consumption for powered devices, you need to account for the power loss over the cable between the switch and the powered device.

Note

The **inline power consumption** command overrides the power allocated to the port through IEEE/Cisco phone discovery and CDP/LLDP power negotiation. To guarantee safe operation of the system, ensure that the value configured here is no less than the actual power requirement of the attached device. If the power drawn by the inline powered devices exceeds the capability of the power supply, it could trip the power supply.

To change the power consumption of a single powered device, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet } <i>slot/port</i>	Selects the interface to configure.
Step 2	Switch(config-if)# [no] power inline consumption <i>milli-watts</i>	Sets the PoE consumption (in milliwatts) of the powered device connected to a specific interface. The power consumption can range from 4000 to 15,400. To reenable the automatic adjustment of consumption, either use the no keyword or specify 15,400 milliwatts.
Step 3	Switch(config-if)# end	Exits configuration mode.
Step 4	Switch# show power inline consumption { fastethernet gigabitethernet } <i>slot/port</i>	Displays the PoE consumption for the interface.

This example shows how to set the PoE consumption to 5000 milliwatts for interface gi 7/1 regardless what is mandated by the 802.3af class of the discovered device, or by any CDP packet received from the powered device. This example also verifies the PoE consumption on interface gi 7/1.

The following output displays the initial power consumption of the interface:

```
Switch# show power inline gi 7/1
Available:627(w)  Used:267(w)  Remaining:360(w)

Interface Admin  Oper          Power(Watts)      Device           Class
          From PS    To Device
-----
Gi7/1      auto    on           7.9              7.0             IP Phone 7941    3

Interface  AdminPowerMax  AdminConsumption
          (Watts)      (Watts)
-----
Gi7/1                        15.4              15.4

Switch# config terminal
Enter configuration commands, one per line.  End with CNTL/Z.
Switch(config)# int gi 7/1
Switch(config-if)# power inline consumption 5000
Switch(config-if)# exit
Switch(config)# exit
```

The following output displays the power consumption after entering the **power inline consumption** command on the interface:

```
Switch# show power inline gi 7/1
Available:627(w)  Used:265(w)  Remaining:362(w)

Interface Admin  Oper          Power(Watts)      Device           Class
          From PS    To Device
-----
Gi7/1      auto    on           5.6              5.0             Ieee PD          3
```

Interface	AdminPowerMax (Watts)	AdminConsumption (Watts)
-----	-----	-----
Gi7/1	15.4	5.0

Displaying the Operational Status for an Interface

Each interface has an operational status which reflects the PoE status for an interface. The operational status for an interface is defined as one of the following:

- on—Power is supplied by the port.
- off—Power is not supplied by the port. If a powered device is connected to an interface with external power, the switch does not recognize the powered device. The “Device” column in the **show power inline** command displays as n/a.
- Power-deny—The supervisor engine does not have enough power to allocate to the port, or the power that is configured for the port is less than the power required by the port; power is not being supplied by the port.
- err-disable—The port is unable to provide power to the connected device that is configured in static mode.
- faulty—The port failed diagnostics tests.

To view the operational status for an interface, use the **show power inline** command.

This example shows how to display the operational status for all interfaces on module 3:

```
Switch# show power inline module 3
Available:677(w)  Used:117(w)  Remaining:560(w)
```

Displaying all PoE Detection and Removal Events

Starting with Cisco IOS Release 15.0(2)SG2/XE 3.2.2SG, a Catalyst 4500 series switch can display all PoE detection and removal events.

To enable PoE event logging, you use the **power inline logging global** command:

```
Switch# conf terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# power inline logging global
Switch(config)# int gigabitEthernet 5/5
Switch(config-if)# shut
Switch(config-if)#
*Oct 17 12:02:48.407: %ILPOWER-5-IEEE_DISCONNECT: Interface Gi5/5: PD removed
Switch(config-if)# no shut
Switch(config-if)#
*Oct 17 12:02:54.915: %ILPOWER-7-DETECT: Interface Gi5/5: Power Device detected: IEEE PD
```

Displaying the PoE Consumed by a Module

A Catalyst 4500 series switch can measure the actual PoE consumption for an 802.3af-compliant PoE module. You can observe this consumption by using **show power module** and **show power detail** commands. For all PoE calculations, presume that the PoE consumption on the WS-X4148-RJ45V module equals its administrative PoE.

The 802.3af-compliant PoE modules can consume up to 20 W of PoE to power FPGAs and other hardware components on the module. To ensure that the system has sufficient power for the PDs connected to the switch, add at least 20 W to your PoE requirements for each 802.3af-compliant PoE module.

The following example uses the **show power module** command to display the PoE consumption for an 802.3af-compliant module:

Switch# **show power module**

Watts Used of System Power (12V)						
Mod	Model	currently	out of reset	in reset		
1	WS-X4013+TS	330	330	330		
2	WS-X4548-GB-RJ45V	60	60	20		
3	WS-X4548-GB-RJ45V	60	60	20		
--	Fan Tray	30	--	--		
Total		480	450	370		

Watts used of Chassis Inline Power (-50V)						
Mod	Model	PS	Device	PS	Device	Efficiency
2	WS-X4548-GB-RJ45V	138	123	73	65	89
3	WS-X4548-GB-RJ45V	0	0	22	20	89
Total		138	123	95	85	

Watts used of Module Inline Power (12V -> -50V)						
Mod	Model	PS	Device	PS	Device	Efficiency
1	WS-X4013+TS	128	128	63	63	100

Switch#

The Inline Power Oper column displays the amount of PoE consumed by the powered devices that are attached to the module, in addition to the PoE consumed by the FPGAs and other hardware components on the module.

The Inline Power Admin column displays only the amount of PoE allocated by the powered devices attached to the module.

Note

The operating PoE consumption for an 802.3af-compliant module can be non-zero, even when no powered devices are attached to the module, because of the PoE consumed by FPGAs and other hardware components on the module. In addition, the operating PoE can vary because of fluctuations in the PoE consumed by the hardware components.

The following example uses the **show power detail** and **show power inline** commands to display the PoE consumption for an 802.3af-compliant module:

Switch# **show power detail**

Power Supply	Model No	Type	Status	Fan Sensor	Inline Status
PS1	PWR-C45-1300ACV	AC 1300W	good	good	good
PS2	none	--	--	--	--

PoE Policing and Monitoring

Note

This functionality is supported on the WS-X4548-RJ45V+, WS-X4648-RJ45V-E, and WS-X4648-RJ45V+E line cards.

PoE policing protects a switch from faulty inline powered devices that may draw more current than they were designed for. When a device is connected to a port, a line card detects the type of device connected and allocates the appropriate amount of power. It sets a PoE policing threshold to a value 5 percent greater than the allocated power. If the device consumes more power than specified by the policing threshold for a more than 1 second, the port shuts down. Depending on the policing action configured, the port may then be error-disabled, or a message might be logged to the console and the port restarted.

PoE monitoring lets you display the true power consumption of inline powered devices attached to the switch, allowing you determine your actual power consumption.

This section includes these topics:

- [PoE Policing Modes, page 15-13](#)
- [Configuring Power Policing on an Interface, page 15-13](#)
- [Displaying Power Policing on an Interface, page 15-14](#)
- [Configuring Errdisable Recovery, page 15-15](#)

PoE Policing Modes

PoE policing comprises two modes, which determine the action to take on the interface after a port shuts down because of an inline-power policing violation:

- **Logging** — An error message is logged to the console and the interface restarts; the device powers up.
- **Errdisable** (Default) — In addition to logging an error message to the console, the interface is placed in an errdisable state so that the device attached to the port does not receive inline-power until you restart the port or configure an errdisable autorecovery mechanism.

Note

After an inline-power policing violation occurs and the port shuts down, PoE policing automatically turns on again when the port restarts. If the connected device exceeds its allocated power again, the port once again shuts down.

Configuring Power Policing on an Interface

The default policing levels are determined by the discovery and power allocation methods (listed in order of priority):

- Configured consumption values, in case any exist
- CDP allocated values (for Cisco devices using CDP)
- Allocated power from IEEE discovery (for devices using this mechanism)

To activate default PoE policing, enter the following:

```
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# int g2/1
Switch(config-if)# power inline police
Switch(config-if)# end
Switch# show power inline police g2/1
Available:800(w) Used:32(w) Remaining:768(w)
```

Interface	Admin State	Oper State	Admin Police	Oper Police	Cutoff Power	Oper Power
-----	-----	-----	-----	-----	-----	-----
Gi2/1	auto	on	errdisable	ok	17.2	16.7

The default action for power policing is to set the port to errdisable; the **power inline police** command is equivalent to the **power inline police action errdisable** command, as the above example illustrates. The following example illustrates how to configure the logging policing action:

```
Switch# conf t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# int g2/1
Switch(config-if)# power inline police action log
Switch(config-if)# end
Switch# show power inline police g2/1
Available:800(w) Used:32(w) Remaining:768(w)
```

Interface	Admin State	Oper State	Admin Police	Oper Police	Cutoff Power	Oper Power
-----	-----	-----	-----	-----	-----	-----
Gi2/1	auto	on	log	ok	17.2	16.7

When a PD consumes more than its allocated power, the port shuts down and a warning message similar to the following appears on the console.

For the WS-X4648-GB-RJ45V and WS-X4648-GB-RJ45V+:

```
*Sep 12 09:15:28.583: %C4K_ETHPORTMAN-3-INLINEPOWEROVERDRAWN: Inline powered device
connected on port Gi3/25 exceeded its policed threshold.
```

For the WS-X4548-RJ45V+:

```
*Sep 26 09:23:21.355: %C4K_SWITCHMANAGER-3-INLINEPOWEROVERDRAWN: Inline powered device
connected on port Gi2/1 exceeded its policed threshold.
```

For actions of Log type, the port restarts itself and the device reboots. In contrast, when the action is to set the port in an errdisable state, a log message similar to the following appears:

```
*Sep 26 09:30:20.463: %PM-4-ERR_DISABLE: inline-power error detected on Gi2/1, putting
Gi2/1 in err-disable state
```

```
Switch# show power inline police g2/1
Available:800(w) Used:16(w) Remaining:784(w)
```

Interface	Admin State	Oper State	Admin Police	Oper Police	Cutoff Power	Oper Power
-----	-----	-----	-----	-----	-----	-----
Gi2/1	auto	errdisable	errdisable	overdrawn	0.0	0.0

Displaying Power Policing on an Interface

You can display power policing on an interface, on a module, or for all the PoE-capable line cards in a chassis.

The following example shows output for the **show power inline police** command:

```
Switch# show power inline police
Available:623(w) Used:6(w) Remaining:617(w)
```

Interface	Admin State	Oper State	Admin Police	Oper Police	Cutoff Power	Oper Power
-----	-----	-----	-----	-----	-----	-----
Gi2/1	auto	off	none	n/a	n/a	0.0
Gi2/2	auto	on	none	n/a	n/a	16.7
Gi2/3	auto	off	errdisable	n/a	0.0	0.0
Gi2/4	auto	on	errdisable	ok	16.6	11.4
Gi2/5	auto	on	log	ok	16.6	11.2
Gi2/6	auto	on	errdisable	overdrawn	0.0	0.0

The following table lists the interface and the status.

Interface Configuration	State
Gi2/1	No PD connected, no policing configured.
Gi2/2	PD connected, no policing configured.
Gi2/3	No PD connected, policing configured (is enabled when PD is connected). Policing action is errdisable.
Gi2/4	PD connected, policing configured. Configured policing action is errdisable. Port is currently operating within policing limits.
Gi2/5	PD connected, policing configured. Configured policing action is log. Port is currently operating within policing limits.
Gi2/6	PD connected, policing configured. Configured policing action is errdisable. Port is currently in errdisable state as it has overdrawn its policed power level.

If you enter the **show power inline** command at the global level (**show power inline police**), the last line of the output under the Oper Power field displays the total of true inline power consumption of all devices connected to the switch.

Configuring Errdisable Recovery

By default, errdisable auto recovery for inline-power is disabled; when an interface is placed in an errdisable state because of an inline-power policing violation, it remains in that state. You must enter **shut** and then **no shut** on the affected interface to revive it.

The errdisable autorecovery mechanism allows you to configure a timer for errdisable recovery so that when an interface enters errdisable state (after the timer expires), the interface returns from the errdisable state.

errdisable detection

By default, errdisable detection for inline-power is enabled, as the following example illustrates:

```
Switch# show errdisable detect
ErrDisable Reason    Detection    Mode
-----
inline-power         Enabled      port
```

Note

If detection is disabled (through the **errdisable detect cause inline-power** command), the port is not placed in errdisable state when it exceeds its power policing threshold.

errdisable recovery

By default, errdisable recovery for inline-power is disabled. To enable errdisable recovery, enter the **errdisable detect cause line-power** command:

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# errdisable detect cause inline-power
Switch(config)# end
```

```
Switch# show errdisable recovery
ErrDisable Reason          Timer Status
-----
inline-power              Enabled
```

The WS-X4648-RJ45V-E, WS-X4648-RJ45V+E, and WS-X4548-RJ45V+ switching modules support IEEE 802.3af PoE as well as the Cisco proprietary Inline Power standard. With Cisco IOS Release 12.2(44)SG, the WS-X4648-RJ45V+E line card can also support the IEEE 802.3at standard with up to 30 W available per-port. The WS-X4648-RJ45V-E line card also supports up to 20 W. The WS-X4548-RJ45V+ switching module is supported with Cisco IOS Release 12.2(50)SG and can provide up to 30 W of inline power per-port.

For these switching modules, the valid milliwatt ranges for the **power inline** command have been increased appropriately for the module, as the following table illustrates:

Line card	Standard	Max Power/Port	Cisco IOS Release
WS-X4648-RJ45V-E	IEEE 802.3af	20 W	12.2(44)SG
	IEEE 802.3at		
WS-X4648-RJ45V+E	IEEE 802.3af	30 W	12.2(44)SG
	IEEE 802.3at		
WS-X4548-RJ45V+	IEEE 802.3af	30 W	12.2(50)SG
	IEEE 802.3at		

The default power inline configurations usually are sufficient; no additional configuration is required even for high power-consumption Cisco powered devices (for example, a Cisco AP1250 Wireless Access Point). When a high-power consumption device is attached to a port on a WS-X4648-RJ45V-E or WS-X4648-RJ45V+E line card, the switch and device negotiate power using CDP packets to automatically determine the extended amount of power needed by the device.

Depending on the deployment requirements and design, you specify a specific configuration with the **power inline** command.

The following example shows how to pre-allocate PoE allocation to 16500 mW for Gi 2/1, regardless of what is mandated either by the 802.3af class of the discovered device or by any CDP packet that is received from the powered device:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 2/1
Switch(config-if)# power inline static max 16500
Switch(config-if)# end
Switch#
```

Configuring Universal PoE

Note

This feature is only available on Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, and 7-E.

Although IEEE 802.at only provides for power up to 30W per port, the WS-X4748-UPOE+E module can provide up to 60W using the spare pair of an RJ45 cable (wires 4,5,7,8) with the signal pair (wires 1,2,3,6). Power on the spare pair is enabled when the switch port and end-device mutually identify

themselves as Universal PoE (UPOE) capable using CDP or LLDP and the end-device requests for power on the spare pair to be enabled. When the spare pair is powered, the end-device can negotiate up to 60W power from the switch using CDP or LLDP.

If the end-device is PoE capable on both signal and spare pairs but does not support the CDP or LLDP extensions required for UPOE, then the following configuration automatically enables power on both signal and spare pairs from the switch port:

	Command	Purpose
Step 1	Switch # interface terminal	Changes mode to global configuration.
Step 2	Switch(config)# interface { fastethernet gigabitethernet } <i>slot/port</i>	Selects the interface to configure.
Step 3	Switch(config-if)# power inline four-pair forced	To automatically enables power on both signal and spare pairs from a switch port.
Step 4	Switch(config-if)# shutdown	Shuts down the port.
Step 5	Switch(config-if)# no	Boots the port.
Step 6	Switch(config-if)# end	Exits configuration mode.
Step 7	Switch# show platform software interface { fastethernet gigabitethernet } <i>slot/port</i> status	Displays EEE status.

The following example shows how to automatically enable power on both signal and spare pairs from switch port gigabit ethernet 2/1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 2/1
Switch(config-if)# power inline four-pair forced
Switch(config-if)# shutdown
Switch(config-if)# no shutdown
Switch(config-if)# end
Switch#
```

Do not enter this command if the end-device is incapable of sourcing inline power on the spare pair or if the end-device supports the CDP or LLDP extensions for UPOE.

Configuring Catalyst 4500 Series Switches with Cisco Network Assistant

This chapter describes how to install Network Assistant on the workstation and configure Catalyst 4500 series switch to communicate with Network Assistant. It also describes how to create communities and clusters, which are two technologies used by Network Assistant to manage a group of network devices, including the Catalyst 4500 series switch.

This chapter contains these topics:

- [About Network Assistant, page 16-2](#)
- [Network Assistant-Related Parameters and Their Defaults, page 16-2](#)
- [Network Assistant CLI Commands, page 16-3](#)
- [Configuring Your Switch for Network Assistant, page 16-4](#)
- [Managing a Network Using Community, page 16-6](#)
- [Converting a Cluster into a Community, page 16-10](#)
- [Managing a Network Using Cluster, page 16-11](#)
- [Configuring Network Assistant in Community or Cluster Mode, page 16-13](#)

Note

The Network Assistant is not bundled with an online software image on Cisco.com. You can download the Network Assistant at this location:

<http://www.cisco.com/en/US/products/ps5931/index.html>

For information on software and hardware requirements, installing Network Assistant, launching Network Assistant, and connecting Network Assistant to a device refer to *Getting Started with Cisco Network Assistant*, available at the URL:

http://www.cisco.com/en/US/products/ps5931/prod_installation_guides_list.html.

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Network Assistant

Network Assistant is a free network management tool that allows you to configure and manage Catalyst 4500 series switches using a graphical user interface (GUI). Network Assistant works in both secure and unsecure environments. Network Assistant manages standalone devices or groups of devices or switches (in communities or clusters) from anywhere in your intranet. Using Network Assistant, you can perform multiple configuration tasks without having to remember commands.

Community Overview

A *community* is a device group that can contain up to 20 connected network devices. Network Assistant uses the Cisco Discovery Protocol (CDP) automatic discovery capability to find eligible network devices and to add them to a community. When a network device is added to a community, it becomes a member device. Network Assistant manages, configures, and monitors each member on an individual basis; therefore, each member must have an IP address assigned to it.

When you use communities, you need to have an HTTP server, and you need to configure an IP address on each switch.

Clustering Overview

A *switch cluster* is a set of up to 16 connected, cluster-capable Catalyst switches that are managed as a single entity. The switches in the cluster use the switch clustering technology so that you can configure and troubleshoot a group of different Catalyst 4500 series switch platforms through a single IP address.

Using switch clusters simplifies the management of multiple switches, regardless of their physical location and platform families.

Note

By default, Network Assistant in clustering mode discovers up to seven hops away.

In a switch cluster, one switch must be the *cluster commander switch*, and up to 15 other switches can be *cluster member switches*. The total number of switches in a cluster cannot exceed 16 switches. The cluster command switch is the single point of access used to configure, manage, and monitor the cluster member switches. Cluster members can belong to only one cluster at a time.

Note

Always choose Catalyst 4500 series switches as the cluster command switch.

Network Assistant-Related Parameters and Their Defaults

Table 16-1 lists the Network Assistant-related configuration parameters on a Catalyst 4500 series switch.

Table 16-1 Network Assistant-Related Configuration on Catalyst 4500 Series Switches

Parameters	Default Value	Recommended Value
Authentication	Disabled	Optional
IP address	Depends on community or discovery option ¹	User selectable
IP HTTP port number	80	Optional ²
IP HTTPS port number	443	Optional ³
IP HTTP server	Disabled	Enabled ⁴
Cluster run	Disabled	Enabled ⁵

1. You need to set an IP address in each switch for community device discovery and for the cluster commander.
2. Port number on the Network Assistant and the Catalyst 4500 series switch must match.
3. You can only change this value for a cluster of devices. Port number on the Network Assistant and on the Catalyst 4500 series switch must match. Value can be changed to any non-default number above 1024.
4. Required for Network Assistant to access the device.
5. Enabled only if you want to manage a cluster of devices.

Network Assistant CLI Commands

Table 16-2 describes the Network Assistant-related CLI commands.

Table 16-2 CLI Commands

Command	Functions
<code>[no] cluster enable</code>	Names the cluster.
<code>[no] cluster run</code>	Enables clustering. Note This command is used strictly for clustering.
<code>[no] ip http server</code>	Configures the HTTP on a switch.
<code>[no] ip http port <i>port_number</i></code>	Configures the HTTP port.
<code>[no] ip domain-name <i>domain_name</i></code>	Configures the domain on the switch.
<code>[no] ip http secure-server</code>	Configures and enable HTTPS on a switch.
<code>[no] ip http secure-port <i>port_number</i></code>	Configures the HTTPS port.
<code>[no] ip http max-connections <i>connection_number</i></code>	Configures the maximum concurrent connections to the HTTP server.
<code>[no] ip http timeout-policy <i>idle idle_time life life_time requests requests</i></code>	Configures the HTTPS port. A idle value of 180 seconds is recommended. A life value of 180 seconds is recommended. The recommended maximum number of requests allowed is 25.

Table 16-2 CLI Commands (continued)

Command	Functions
<code>line vty</code>	Configures additional VTYs for use by Cisco Network Assistant.
<code>show version</code>	Displays the Cisco IOS release.
<code>show running-config</code>	Displays the switch configuration.
<code>vtp domain</code>	Creates a VTP domain to manage VLANs.
<code>vtp mode</code>	Sets the behavior for VTP management of the VLANs.

Configuring Your Switch for Network Assistant

This section includes the following topics:

- [\(Minimum\) Required Configuration, page 16-4](#)
- [\(Additional\) Configuration Required to Use Community, page 16-5](#)
- [\(Additional\) Configuration Required to Use Clustering, page 16-5](#)

(Minimum) Required Configuration

If you use the default configuration, access the Catalyst 4500 series switch and enter the **ip http server** (for HTTP) or **ip http secure-server** (for HTTPS) global configuration command.

To configure the Catalyst 4500 series switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip http server or Switch(config)# ip domain-name <i>domain_name</i>	(HTTP only) Enables the HTTP server on the switch. By default, the HTTP server is disabled. Enables the domain name on the switch to configure HTTPS.
Step 3	Switch(config)# ip http secure-server	Enables the HTTPS server on the switch. By default, the HTTPS server is disabled.
Step 4	Switch(config)# ip http max-connections <i>connection_number</i>	Configures the maximum concurrent connections to the HTTP server. <i>A connection_number of 16 is recommended.</i>

	Command	Purpose
Step 5	Switch(config)# ip http timeout-policy idle <i>idle_time life life_time requests requests</i>	Configures the HTTPS port. The idle keyword specifies the maximum amount of time a connection can stay idle. A idle value of 180 seconds is recommended. The life keyword specifies the maximum amount of time a connection can stay open since it was established. A life value of 180 seconds is recommended. The requests keyword specifies the maximum amount of requests on a connection. The recommended maximum number of requests allowed is 25.
Step 6	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 7	Switch# show running-config	Verifies the configuration.

**Note**

If you have enabled clustering, disable clustering before configuring a community (see [Table 16-2](#)).

(Additional) Configuration Required to Use Community

If you plan to use community, define an IP address on each switch.

To configure a switch to use community, perform this task:

	Command	Purpose
Step 1	Switch# configuration terminal	Enters global configuration mode.
Step 2	Switch(config)# interface { vlan <i>vlan_ID</i> { fastethernet gigabitethernet } <i>slot/interface</i> Port-channel <i>number</i> }	Selects an interface.
Step 3	Switch(config-if)# ip address ip_address <i>address_mask</i>	(Optional) Assigns an IP address to the Catalyst 4500 series. Note This step is mandatory if the switch is part of community or is a cluster command switch. This step is optional if the switch is a cluster member candidate.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-config	Verifies the configuration.

(Additional) Configuration Required to Use Clustering

If you plan to use clustering, enter the **cluster run** global configuration command on each device and enter the **ip address** interface configuration command on the cluster commander.

To configure a switch to use clustering, perform this task:

	Command	Purpose
Step 1	Switch# configuration terminal	Enters global configuration mode.
Step 2	Switch(config)# cluster run	Enables clustering.
		 Note Enable clustering on all switches that are part of the potential cluster.
Step 3	Switch(config)# cluster enable	Names the cluster.
Step 4	Switch(config)# interface { vlan <i>vlan_ID</i> { fastethernet gigabitethernet } <i>slot/interface</i> Port-channel <i>number</i> }	Selects an interface.
Step 5	Switch(config-if)# ip address <i>ip_address address_mask</i>	(Optional) Assigns an IP address to the Catalyst 4500 series switch cluster master.
		 Note This step is mandatory if the switch is part of a community or is a cluster command switch. This step is optional if the switch is a cluster member candidate.
Step 6	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 7	Switch# show running-config	Verifies the configuration.

Managing a Network Using Community

This section describes how to use communities to manage devices (including Catalyst 4500 series switches, routers, access points, and PIX firewalls) using the Network Assistant application.

Note

Access points have been eliminated from the device limits. There is no current limit for the number of access points that can be managed by CNA.

Note

The **Add to Community** dialog box displays any number of devices, but can only select 20 devices. If you try to add a twenty-first device, the dialog box displays the twenty-first device and prompts you to select the unwanted device.

Some devices like routers and access points do not support clustering. CNA 2.0 introduces a logical grouping for such devices, which are called *communities*. This grouping supports the auto discovery protocol using CDP. Any device that cannot support CDP can be added as a managed device manually by specifying the IP address.

Note

For complete procedures for using Network Assistant to configure switch communities, refer to *Getting Started with Cisco Network Assistant*, available at:

http://www.cisco.com/en/US/products/ps5931/prod_installation_guides_list.html.

This section describes the guidelines and requirements you should understand before you create a community. This section contains the following topics:

- [Candidate and Member Requirements, page 16-7](#)
- [Automatic Discovery of Candidates and Members, page 16-7](#)
- [Community Names, page 16-8](#)
- [Hostnames, page 16-8](#)
- [Passwords, page 16-8](#)
- [Access Modes in Network Assistant, page 16-9](#)
- [Community Information, page 16-9](#)
- [Adding Devices, page 16-9](#)

Candidate and Member Requirements

Candidates are network devices that have IP addresses but are not part of a community. *Members* are network devices that are currently part of a community.

To join a community, a candidate must meet these requirements:

- An IP address has been obtained.
- Cisco Discovery Protocol (CDP) version 2 is enabled (the default) (if you want the device to be auto-discovered).
- HTTP (or HTTPS) is enabled.

Note A cluster member can be added to a community, but the reverse is not possible.

Note If a cluster commander is added to a community, the other member devices of the cluster are not added automatically. The cluster members must be added to the community on an individual basis in order to be managed.

Automatic Discovery of Candidates and Members

Network Assistant forms a community using CDP to locate or discover all the available devices in the network. Beginning with the IP address for a starting device and the port numbers for HTTP (or HTTPS) protocols, Network Assistant uses CDP to compile a list of community candidates that neighbor the starting device. Network Assistant can discover candidate and member devices across multiple networks and VLANs as long as they have valid IP addresses.

Note By default, Network Assistant in community mode discovers up to four hops away.

See the [“Candidate and Member Requirements” section on page 16-7](#) for a list of requirements that network devices must meet in order to be discovered.

**Note**

Do not disable CDP on candidates, members, or on any network devices that you might want Network Assistant to discover.

**Note**

PIX firewalls do not support the CDP, so they are not automatically shown as neighbors in the Topology view. They are shown only after you add them to a community with the Create Community or Modify Community window. To see a PIX firewall link to another community member, you must add the link manually by selecting ADD Link in the Topology popup menu.

You can edit the list of discovered devices to fit your needs and add them to the community. As each device is added to the community, its neighbors are discovered and added to the list of candidate devices. If Network Assistant fails to discover a device, you can add it manually through the IP management IP address.

Community Names

When you apply the community configuration information to the list of member devices, Network Assistant requests that you enter a name (or IP address) for the community. You need to assign a name to the community before you can manage it. Network Assistant saves the name to your PC.

The community name can consist of the characters 0 through 9, a through z and A through Z, with spaces allowed between the characters.

**Note**

You can connect to a cluster only through an IP address. When you select a name the name is always for the community.

Hostnames

You do not need to assign a hostname to a starting device or a community member. However, we recommend that you do assign a hostname because Network Assistant does not assign one by default. If a discovered device does have a hostname, Network Assistant saves it to your PC as identifying information for that device along with its IP address, communication protocol, and designated protocol port.

Passwords

Although you do not need to assign a password to a device if it will become a community member, we recommend that you do so.

Community members can have different passwords.

Communication Protocols

Network Assistant uses the HTTP or HTTPS protocols to communicate with network devices. It attempts communication with HTTP or HTTPS when using CDP to discover candidate devices.

Access Modes in Network Assistant

When Network Assistant is connected to a community or cluster, two access modes are available: read-write and read-only, depending on the password.

Community Information

Network Assistant saves all community configuration information and individual device information such as IP address, hostname, and communication protocol to your local PC. When Network Assistant connects to a community, it uses the locally saved data to rediscover the member devices.

If you attempt to use a different PC to manage an existing community, the member device information is not available. You need to create the community again and add the same member devices.

Adding Devices

You can add members to a community using these methods:

- Use the Devices Found window on Network Assistant to add devices that you discovered to a new community.
 - In the Devices Found window, select the candidate devices that you want to add.
To add more than one candidate, press **Ctrl** and make your choices, or press **Shift** and choose the first and last device in a range.
 - Click **Add**.
- Use the Modify Community window to add devices to an existing community.
 - Choose **Application > Communities** to open the Communities window.
 - In the Communities window, select the name of the community to which you want to add a device, and click **Modify**.
 - To add a single device manually, enter the IP address for the desired device in the Modify Community window, and click **Add**.
 - To discover candidate devices, enter the IP address for the starting device, and click **Discover**.
 - Select a candidate device from the list, click **Add**, and click **OK**.
 - To add more than one candidate, press **Ctrl** and make your choices, or press **Shift** and choose the first and last device in a range.
- Add a device using the Topology view.
 - If the Topology view is not displayed, choose **View window> Topology** from the feature bar.
 - Right-click a candidate icon, and select **Add to Community**.

Candidates are cyan; members are green. To add more than one candidate, press **Ctrl** and left-click the candidates that you want to add.

When a community has 20 members, the **Add to Community** option is not available for that community. You must remove a member before adding a new one.

**Note**

If you are logged into a community and you delete that community from some other CNA instance, then unless you close that community session, you can perform all the configurations through that session. After you close that session (which deletes the community), you cannot connect to that community.

Converting a Cluster into a Community

The Cluster Conversion wizard helps you convert a cluster into a community. When you complete the conversion, you can immediately manage the device group as a community. The benefits of managing a community is that the communication with the devices in a community is more secure (through multiple passwords and HTTPS) than in a cluster. Moreover, device availability is greater, and the range of devices that can be members is broader.

**Note**

The Cluster Conversion wizard does not alter your cluster definition. This means that you can still manage the devices as a cluster.

To launch the Cluster Conversion Wizard, follow these steps:

-
- Step 1** Start Network Assistant and connect to an existing cluster through its commander IP address.
- Step 2** In the feature bar, choose **Configure > Cluster > Cluster Conversion Wizard**.
- You see the query “or you want to convert this cluster to a community?”
- Step 3** Select **Yes** to proceed or **No** if you want to manually bring up the Cluster Conversion Wizard.
- If you select **Yes**, the Welcome screen appears, providing information about clusters, communities, and their benefits.
- A table appears listing the devices in the cluster starting with those that have no IP address and subnet mask. Be aware that all the devices in the cluster must have an IP address and subnet mask to be members of a community.
-
- Note** If a device has more than one interface with an IP address and subnet mask, you see more than one interface listed when you click in the cell. You can choose a different interface from the one originally shown.
-
- Step 4** In the IP Address column, enter an IP address for each device that does not have one.
- Step 5** In the Subnet Mask column, click in the cell for each device that does not have a subnet mask and select one.
- Step 6** Enter a name for the community.
- Step 7** Click **Finish** to begin the conversion.
- When the conversion completes, Network Assistant restarts and automatically connects to the newly created community.
-

**Note**

If you have enabled clustering, you should disable clustering before configuring a community (see [Table 16-2](#)).

Managing a Network Using Cluster

This section describes how to use clustering to create and manage Catalyst 4500 series switches using the standalone Network Assistant application or the command-line interface (CLI).

Use clustering to group the switches in your network. You must enter the **cluster run** command on each switch to be managed. The major advantage is that you can manage 16 devices with one IP address.

**Note**

Clustering is the auto-discovering mechanism used in CNA 1.0.

**Note**

For complete procedures for using Network Assistant to configure switch clusters, refer to *Getting Started with Cisco Network Assistant*, available at:

http://www.cisco.com/en/US/products/ps5931/prod_installation_guides_list.html.

This section contains the following topics:

- [Understanding Switch Clusters, page 16-11](#)
- [Using the CLI to Manage Switch Clusters, page 16-13](#)

Understanding Switch Clusters

These sections describes these topics:

- [Cluster Command Switch Requirements, page 16-11](#)
- [Network Assistant and VTY, page 16-12](#)
- [Candidate Switch and Cluster Member Switch Requirements, page 16-12](#)

Cluster Command Switch Requirements

A cluster command switch must meet these requirements:

- Uses Cisco IOS Release 12.2(20)EWA or later.
- Has an IP address.
- Cisco Discovery Protocol (CDP) version 2 is enabled (the default).
- Uses cluster-capable software and has clustering enabled.
- IP HTTP (or HTTPS) server is enabled.

**Note**

On a Catalyst 4500 series switch, neither HTTP or HTTPS is enabled by default.

- Has 16 VTY lines.

Note On a Catalyst 4500 series switch, the default is 4 lines. You configure the switch to set the value to 16.

- Is not a command or cluster member switch of another cluster.

Note If your switch cluster contains a Catalyst 4500 series switch, the cluster command switch must also be a Catalyst 4500 series switch.

Network Assistant and VTY

Network Assistant uses virtual terminal (VTY) lines to communicate with the cluster command device. Catalyst 4500 series switches have 5 VTY lines configured by default. Network Assistant can use an additional 8 lines. You should configure the maximum number of lines (or at least, $8 + 5 = 13$) so that Network Assistant can communicate with the switch and not use VTY lines that might be needed for Telnet.

You can configure the Catalyst 4500 series switch to support an appropriate number of VTY lines with the **line vty** configuration command. For example, the **line vty 6 15** command configures the switch to include 9 VTY lines.

Note If your existing VTY lines have nondefault configurations, you might want to apply those configurations to the new VTY lines.

Candidate Switch and Cluster Member Switch Requirements

Candidate switches are cluster-capable switches that are not part of a cluster. Cluster member switches are switches that are currently part of a switch cluster. Although not required, a candidate or cluster member switch can have its own IP address and password.

Note The hostname of a candidate should not be in the form [a-zA-Z0-9]-*n*, where *n* is 0 to 16. These names are reserved.

To join a cluster, a candidate switch must meet these requirements:

- Running cluster-capable software and has clustering enabled.
- Has CDP version 2 enabled.
- Has HTTP server enabled.

Note Even when HTTP is enabled on the commander switch, communication between the commander switch and member switch is still carried over HTTP.

- Has 16 VTY lines.
- Is not a command or cluster member switch of another cluster.
- Is connected to the cluster command switch through at least one common VLAN.

We recommend that you configure the Catalyst 4500 candidate and cluster member switches with an SVI on the VLAN connection to the cluster command switch.

Using the CLI to Manage Switch Clusters

You can configure cluster member switches from the CLI by first logging in to the cluster command switch. Enter the **rcommand** user EXEC command and the cluster member switch number to start a Telnet session (through a console or Telnet connection) and to access the cluster member switch CLI. The command mode changes and the Cisco IOS commands operate as usual. Enter the **exit** privileged EXEC command on the cluster member switch to return to the command-switch CLI.

This example shows how to log in to member-switch 3 from the command-switch CLI:

```
switch# rcommand 3
```

If you do not know the member-switch number, enter the **show cluster members** privileged EXEC command on the cluster command switch. For more information about the **rcommand** command and all other cluster commands, refer to the command reference guide.

The Telnet session accesses the member-switch CLI at the same privilege level as on the cluster command switch. The Cisco IOS commands will operate as usual. For instructions on configuring the switch for a Telnet session, see the [“Accessing the CLI Through Telnet”](#) section on page 2-2.

Note

CISCO-CLUSTER_MIB is not supported.

Configuring Network Assistant in Community or Cluster Mode

This section provides a detailed explanation of the CLI used to configure Network Assistant to work in a community or cluster. Network Assistant communicates with a Catalyst 4500 series switch by sending Cisco IOS commands over an HTTP (or HTTPS) connection.

This section includes the following topics:

- [Configuring Network Assistant on a Networked Switch in Community Mode, page 16-13](#)
- [Configuring Network Assistant in a Networked Switch in Cluster Mode, page 16-17](#)

Configuring Network Assistant on a Networked Switch in Community Mode

To configure Network Assistant on a networked switch in community mode, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# enable password <i>name</i>	Enables password protection of configuration mode.
Step 3	Switch(config)# vtp domain <i>name</i>	Creates a VTP domain to manage VLAN.
Step 4	Switch(config)# vlan <i>vlan_id</i>	Creates a VLAN.
Step 5	Switch(config-vlan)# interface { vlan <i>vlan_ID</i> { fastethernet gigabitethernet } <i>slot/interface</i> port-channel <i>number</i> }	Selects the interface that connects to your CNA-enabled PC.

	Command	Purpose
Step 6	Switch(config-if)# switchport access vlan <i>vlan_id</i>	Enables the selected interface to be in the specified VLAN.
Step 7	Switch(config-if)# interface { vlan <i>vlan_ID</i> slot/interface Port-channel <i>number</i> }	Select the VLAN instance for configuration.
Step 8	Switch(config-if)# ip address <i>ip_address</i>	Assigns an IP address to the SVI.
Step 9	Switch(config-if)# no shutdown	Enables the interface.
Step 10	Switch(config-if)# ip http server	Starts the HTTP server so that Network Assistant can talk to the switch.
Step 11	Switch(config)# ip domain-name <i>domain_name</i>	Enables the domain name on the switch to configure HTTPS.
Step 12	Switch(config)# ip http secure-server	Enables the HTTPS server on the switch. By default, the HTTPS server is disabled.
Step 13	Switch(config)# ip http max-connections <i>connection_number</i>	Configures the maximum concurrent connections to the HTTP server. <i>A connection_number</i> of 16 is recommended.
Step 14	Switch(config)# ip http timeout-policy idle <i>idle_time</i> life <i>life_time</i> requests <i>requests</i>	Configures the HTTPS port. The idle keyword specifies the maximum amount of time a connection can stay idle. A idle value of 180 seconds is recommended. The life keyword specifies the maximum amount of time a connection can stay open since it was established. A life value of 180 seconds is recommended. The requests keyword specifies the maximum number of requests on a connection. A requests value of 25 recommended.
Step 15	Switch(config-if)# ip http secure-server	(Optionally) Enables the switch to accept HTTPS connections from Network Assistant.
Step 16	Switch(config)# ip route <i>a.b.c</i>	Establishes the route to the default router, usually supplied by the local Internet provider. Note This line represents the only difference between the configuration for a standalone and a networked switch.
Step 17	Switch(config)# line con 0	Selects the console port to perform the configuration.
Step 18	Switch(config-line)# exec-timeout <i>x y</i>	Configures an automatic session logout if no keyboard input or output is displayed on the terminal.
Step 19	Switch(config-line)# password <i>password</i>	Specifies a password for the console port.
Step 20	Switch(config-line)# login	Allows login to the console port.
Step 21	Switch(config-line)# line vty <i>x y</i>	Creates additional VTY lines for CNA to access the switch.
Step 22	Switch(config-line)# password <i>password</i>	Specifies a password for the switch.
Step 23	Switch(config-line)# login	Allows login to the switch.
Step 24	Switch(config-line)# line vty <i>x y</i>	Creates additional VTY lines for CNA to access the switch.
Step 25	Switch(config-line)# password <i>password</i>	Specifies a password for the switch.
Step 26	Switch(config-line)# login	Allows login to the switch.

	Command	Purpose
Step 27	Switch(config-line)# end	Returns to privileged EXEC mode.
Step 28	Switch# show running-config	Verifies the configuration.

This example shows how to configure Network Assistant on a networked switch in community mode:

```
Switch# configure terminal
Switch(config)# vtp domain cnadoc
Changing VTP domain name from cisco to cnadoc
Switch(config)# vlan 2
Switch(config-vlan)# exit
Switch(config)# interface GigabitEthernet 2/1
Switch(config-if)# switchport access vlan 2
Switch(config-if)# exit
Switch(config)# interface vlan 2
Switch(config-if)# ip address 123.123.123.1 255.255.255.0
Switch(config-if)# no shutdown
Switch(config-if)# exit
Switch(config)# ip http server
Switch(config)# ip domain-name cisco.com
Switch(config)# ip http secure-server
Switch(config)# ip http max-connections 16
Switch(config)# ip http timeout-policy idle 180 life 180 requests 25
Switch(config)# ip route 0.0.0.0 0.0.0.0 123.123.123.2
Switch(config)# line con 0
Switch(config-line)# exec-timeout 0 0
Switch(config-line)# password keepout
Switch(config-line)# login
Switch(config-line)# line vty 5 15
Switch(config-line)# password keepout
Switch(config-line)# login
Switch(config-line)# line vty 5 15
Switch(config-line)# end
Switch# show running-config

Configuring Network Assistant in a Networked Switch in Cluster Mode

To configure Network Assistant on a networked switch in cluster mode, perform this task on the switch:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# enable password <i>name</i>	Enables password protection of configuration mode.
Step 3	Switch(config)# vtp domain <i>name</i>	Creates a VTP domain to manage VLANs and names.
Step 4	Switch(config)# cluster run	Launches the cluster on the cluster commander.
Step 5	Switch(config)# cluster enable <i>cluster_name</i>	Makes the switch the cluster commander.
Step 6	Switch(config)# vlan <i>vlan_id</i>	Creates a VLAN.

	Command	Purpose
Step 7	Switch(config-vlan)# interface { vlan <i>vlan_ID</i> { fastethernet gigabitethernet } <i>slot/interface</i> Port-channel <i>number</i> }	Selects the interface that connects to your CNA-enabled PC.
Step 8	Switch(config-if)# switchport access vlan <i>vlan_id</i>	Enables the physical port to be in the specified VLAN.
Step 9	Switch(config-if)# interface { vlan <i>vlan_ID</i> <i>slot/interface</i> Port-channel <i>number</i> }	Select the VLAN instance for configuration.
Step 10	Switch(config-if)# ip address <i>ip_address</i>	Assigns an IP address to the SVI.
Step 11	Switch(config-if)# no shut	Enables the interface.
Step 12	Switch(config-if)# ip http server	Starts the HTTP server so that Network Assistant can talk to the switch.
Step 13	Switch(config)# ip http secure-server	(Optionally) Enables the switch to accept HTTPS connections from Network Assistant.
Step 14	Switch(config)# ip route <i>a.b.c</i>	Establishes the route to the default router, usually supplied by the local Internet provider. Note This line represents the only difference between the configuration for a standalone and a networked switch.
Step 15	Switch(config)# line con 0	Selects the console port to perform the configuration.
Step 16	Switch(config-line)# exec-timeout <i>x y</i>	Configures an automatic session logout if no keyboard input or output is displayed on the terminal.
Step 17	Switch(config-line)# password <i>password</i>	Specifies a password for the console port.
Step 18	Switch(config-line)# login	Allows login to the console port.
Step 19	Switch(config-line)# line vty <i>x y</i>	Creates additional VTY lines for CNA to access the switch.
Step 20	Switch(config-line)# password <i>password</i>	Specifies a password for the switch.
Step 21	Switch(config-line)# login	Allows login to the switch.
Step 22	Switch(config-line)# line vty <i>x y</i>	Creates additional VTY lines for CNA to access the switch.
Step 23	Switch(config-line)# password <i>password</i>	Specifies a password for the switch.
Step 24	Switch(config-line)# login	Allows login to the switch.
Step 25	Switch(config-line)# end	Returns to privileged EXEC mode.
Step 26	Switch# show running-config include http	Verifies that the HTTP server is enabled.

This example shows how to configure Network Assistant on a networked switch in cluster mode:

```
Switch# configure terminal
Switch(config)# vtp domain cnadoc
Switch(config)# cluster run
Switch(config)# cluster enable cnadoc
Switch(config)# vlan 10
Switch(config-vlan)# interface GigabitEthernet 2/1
Switch(config-if)# switchport access vlan 10
Switch(config-if)# interface vlan10
Switch(config-if)# ip address aa.bb.cc.dd
Switch(config-if)# no shut
Switch(config-if)# ip http server
Switch(config-if)# ip http secure-server
Switch(config)# ip route 0.0.0.0 0.0.0.0 123.123.123.2
```

```
Switch(config)# line con 0
Switch(config-line)# exec-timeout 0 0
Switch(config-line)# password keepout
Switch(config-line)# login
Switch(config-line)# line vty 5 15
Switch(config-line)# password keepout
Switch(config-line)# login
Switch(config-line)# line vty 5 15
Switch(config-line)# end
Switch# show running-config

Configuring VLANs, VTP, and VMPS

This chapter describes VLANs on Catalyst 4500 series switches. It also describes how to enable the VLAN Trunking Protocol (VTP) and to configure the Catalyst 4500 series switch as a VMPS client.

This chapter includes the following major sections:

- [VLANs, page 17-1](#)
- [VLAN Trunking Protocol, page 17-7](#)
- [VLAN Membership Policy Server, page 17-20](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

VLANs

This section includes the following major subsections:

- [About VLANs, page 17-1](#)
- [VLAN Configuration Guidelines and Restrictions, page 17-3](#)
- [VLAN Default Configuration, page 17-4](#)
- [Configuring VLANs, page 17-5](#)

About VLANs

A VLAN is a group of devices on one or more LANs that are configured to communicate as if they were attached to the same wire, when in fact they are located on a number of different LAN segments. Because VLANs are based on logical instead of physical connections, they are extremely flexible.

Note

VTP version 3 updates do not pass through promiscuous trunk ports.

VLANs define broadcast domains in a Layer 2 network. A broadcast domain is the set of all devices that receives broadcast frames originating from any device within the set. Broadcast domains are typically bounded by switches because switches do not forward broadcast frames. Layer 2 switches create broadcast domains based on the configuration of the switch. Switches are multiport bridges that allow you to create multiple broadcast domains. Each broadcast domain is like a distinct virtual bridge within a switch.

You can define one or many virtual bridges within a switch. Each virtual bridge you create in the switch defines a new broadcast domain (VLAN). Traffic cannot pass directly to another VLAN (between broadcast domains) within the switch or between two switches. To interconnect two different VLANs, you must use switches or Layer 3 switches. See the [“About Layer 3 Interfaces” section on page 36-1](#) for information on inter-VLAN routing on Catalyst 4500 series switches.

Figure 17-1 shows an example of three VLANs that create logically defined networks.

Figure 17-1 Sample VLANs

VLANs are often associated with IP subnetworks. For example, all of the end stations in a particular IP subnet belong to the same VLAN. Traffic between VLANs must be routed. You must assign LAN interface VLAN membership on an interface-by-interface basis (termed interface-based or static VLAN membership).

You can set the following parameters when you create a VLAN in the management domain:

- VLAN number
- VLAN name
- VLAN type
- VLAN state (active or suspended)
- Maximum transmission unit (MTU) for the VLAN
- Security Association Identifier (SAID)

- VLAN number to use when translating from one VLAN type to another

**Note**

When the software translates from one VLAN type to another, it requires a different VLAN number for each media type.

VLAN Configuration Guidelines and Restrictions

Follow these guidelines and restrictions when creating and modifying VLANs in your network:

- Before creating a VLAN, put the Catalyst 4500 series switch in VTP server mode or VTP transparent mode. If the Catalyst 4500 series switch is a VTP server, you must define a VTP domain. For information on configuring VTP, see the [“VLAN Trunking Protocol” section on page 17-7](#).
- You cannot use the **end** command in VLAN database mode.
- You cannot use **Ctrl-Z** to exit VLAN database mode.
- If a switch running MSTP and configured with all possible VLANs (4094) is in the path of two HSRP peers with the timeout set below 500 ms, HSRP flaps.

Workarounds:

- Use fewer VLANs.
- Set the timers greater than 600 ms.
- Enter the **no igmp snooping** (globally) and **access-list hardware capture mode VLAN** commands

VLAN Ranges

**Note**

You must enable the extended system ID to use 4094 VLANs. See the [“Understanding the Bridge ID” section on page 23-2](#).

With Cisco IOS Release 12.2(31)SGA and later, Catalyst 4500 series switches support 4096 VLANs in compliance with the IEEE 802.1Q standard. These VLANs are organized into three ranges: reserved, normal, and extended.

Some of these VLANs are propagated to other switches in the network when you use the VLAN Trunking Protocol (VTP). The extended-range VLANs are not propagated, so you must configure extended-range VLANs manually on each network device.

[Table 17-1](#) describes the uses for VLAN ranges.

Table 17-1 **VLAN Ranges**

VLANs	Range	Usage	Propagated by VTP
0, 4095	Reserved	For system use only. You cannot see or use these VLANs.	—
1	Normal	Cisco default. You cannot delete this VLAN.	Yes
2–1001	Normal	Used for Ethernet VLANs; you can create, use, and delete these VLANs.	Yes

Table 17-1 VLAN Ranges

VLANs	Range	Usage	Propagated by VTP
1002–1005	Normal	Cisco defaults for FDDI and Token Ring. You cannot delete VLANs 1002–1005.	Yes
1006–4094	Extended	<p>For Ethernet VLANs only. When configuring extended-range VLANs, note the following:</p> <ul style="list-style-type: none"> Layer 3 ports and some software features require internal VLANs. Internal VLANs are allocated from 1006 and up. You cannot use a VLAN that has been allocated for such use. To display the VLANs used internally, enter the show vlan internal usage command. Switches running the Catalyst operating system do not support configuration of VLANs 1006-1024. If you configure VLANs 1006-1024, ensure that the VLANs do not extend to any switches running Catalyst operating system software. You must enable the extended system ID to use extended range VLANs. 	No

Configurable Normal-Range VLAN Parameters

Note

Ethernet VLANs 1 and 1006 through 4094 use only default values.

You can configure the following parameters for VLANs 2 through 1001:

- VLAN name
- VLAN type
- VLAN state (active or suspended)
- SAID
- STP type for VLANs

VLAN Default Configuration

Table 17-2 shows the default VLAN configuration values.

Table 17-2 Ethernet VLAN Defaults and Ranges

Parameter	Default	Valid Values
VLAN ID	1	1–4094
VLAN name	VLANx, where x is a number assigned by the software.	No range
802.1Q SAID	100,001	1–4,294,967,294
MTU size	1500	1500–18,190

Table 17-2 Ethernet VLAN Defaults and Ranges (continued)

Parameter	Default	Valid Values
Translational bridge 1	1002	0–1005
Translational bridge 2	1003	0–1005
VLAN state	active	active; suspend; shutdown

**Note**

Catalyst 4500 series switches do not support Token Ring or FDDI media. The switch does not forward FDDI, FDDI-NET, TrCRF, or TrBRF traffic, but it does propagate the VLAN configuration by using VTP. The software reserves parameters for these media types, but they are not supported.

Configuring VLANs

**Note**

Before you configure VLANs, you must use VLAN Trunking Protocol (VTP) to maintain global VLAN configuration information for your network. For complete information on VTP, see the [“VLAN Trunking Protocol” section on page 7](#).

**Note**

VLANs support a number of parameters that are not discussed in detail in this section. For complete information, refer to the command reference guide.

**Note**

The VLAN configuration is stored in the **vlan.dat** file, which is stored in nonvolatile memory. You can cause inconsistency in the VLAN database if you manually delete the **vlan.dat** file. If you want to modify the VLAN configuration or VTP, use the commands described in the following sections and in the command reference guide.

The following sections describe how to configure VLANs:

- [Configuring VLANs in Global Configuration Mode, page 17-5](#)
- [Assigning a Layer 2 LAN Interface to a VLAN, page 17-7](#)

Configuring VLANs in Global Configuration Mode

If the switch is in VTP server or transparent mode (see the [“VLAN Trunking Protocol” section on page 17-7](#)), you can configure VLANs in global and VLAN configuration modes. When you configure VLANs in global and config-vlan configuration modes, the VLAN configuration is saved in the **vlan.dat** files, not the **running-config** or **startup-config** files. To display the VLAN configuration, enter the **show vlan** command.

If the switch is in VLAN transparent mode, use the **copy running-config startup-config** command to save the VLAN configuration to the **startup-config** file. After you save the running configuration as the startup configuration, the **show running-config** and **show startup-config** commands display the VLAN configuration.

When the switch boots, if the VTP domain name and VTP mode in the **startup-config** and **vlan.dat** files do not match, the switch uses the configuration in the **vlan.dat** file.

You use the interface configuration command mode to define the port membership mode and add and remove ports from a VLAN. The results of these commands are written to the **running-config** file, and you can display the contents of the file by entering the **show running-config** command. Beginning with Cisco IOS Release 15.2(2)E and Cisco IOS XE Release 3.6E, if the VTP mode is off or transparent, VLAN configuration is saved to the **startup-config** file, even when the configuration is not applied to the interface.

User-configured VLANs have unique IDs from 1 to 4094. To create a VLAN, enter the **vlan** command with an unused ID. To verify whether a particular ID is in use, enter the **show vlan id ID** command. To modify a VLAN, enter the **vlan** command for an existing VLAN.

See the “[VLAN Default Configuration](#)” section on page 17-4 for the list of default parameters that are assigned when you create a VLAN. If you do not use the **media** keyword when specifying the VLAN type, the VLAN is an Ethernet VLAN.

To create a VLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# vlan <i>vlan_ID</i> Switch(config-vlan)#	<p>Adds an Ethernet VLAN.</p> <p>Note You cannot delete the default VLANs for these media types: Ethernet VLAN 1 and FDDI or Token Ring VLANs 1002 to 1005.</p> <p>When you delete a VLAN, any LAN interfaces configured as access ports assigned to that VLAN become inactive. They remain associated with the VLAN (and thus inactive) until you assign them to a new VLAN.</p> <p>Use the no keyword to delete a VLAN.</p> <p>When the prompt shows Switch(config-vlan)#; you are in vlan-configuration mode. If you want to change any of the parameters for the newly created VLAN, use this mode.</p>
Step 3	Switch(config-vlan)# end	Returns to enable mode from vlan-configuration mode.
Step 4	Switch# show vlan [<i>id</i> <i>name</i>] <i>vlan_name</i>	Verifies the VLAN configuration.

When you create or modify an Ethernet VLAN, note the following:

- Because Layer 3 ports and some software features require internal VLANs allocated from 1006 and up, configure extended-range VLANs starting with 4094 and work downward.
- You can configure extended-range VLANs only in global configuration mode. You cannot configure extended-range VLANs in VLAN database mode.
- Layer 3 ports and some software features use extended-range VLANs. If the VLAN you are trying to create or modify is being used by a Layer 3 port or a software feature, the switch displays a message and does not modify the VLAN configuration.
- When you create VLANs with the VLAN configuration command, they are automatically added to the existing VTP domain; no action is required of the user.

This example shows how to create an Ethernet VLAN in global configuration mode and verify the configuration:

```
Switch# configure terminal
Switch(config)# vlan 3
Switch(config-vlan)# end
Switch# show vlan id 3
```

VLAN Name	Status	Ports
3 VLAN0003	active	

VLAN	Type	SAID	MTU	Parent	RingNo	BridgeNo	Stp	BrdgMode	Trans1	Trans2
3	enet	100003	1500	-	-	-	-	-	0	0

Primary	Secondary	Type	Interfaces

```
Switch#
```

Assigning a Layer 2 LAN Interface to a VLAN

A VLAN created in a management domain remains unused until you assign one or more LAN interfaces to the VLAN.

Note

Make sure you assign LAN interfaces to a VLAN of the proper type. Assign Fast Ethernet, Gigabit Ethernet, and 10-Gigabit Ethernet interfaces to Ethernet-type VLANs.

To assign one or more LAN interfaces to a VLAN, complete the procedures in the [“Configuring Ethernet Interfaces for Layer 2 Switching”](#) section on page 19-5.

VLAN Trunking Protocol

This section describes the VLAN Trunking Protocol (VTP) on the Catalyst 4500 series switches, and includes the following major subsections:

- [About VTP, page 17-7](#)
- [VTP Configuration Guidelines and Restrictions, page 17-12](#)
- [VTP Default Configuration, page 17-13](#)
- [Configuring VTP, page 17-13](#)

About VTP

VTP is a Layer 2 messaging protocol that maintains VLAN configuration consistency by managing the addition, deletion, and renaming of VLANs within a VTP domain. A VTP domain (also called a VLAN management domain) is made up of one or more network devices that share the same VTP domain name and that are interconnected with trunks. VTP minimizes misconfigurations and configuration inconsistencies that can result in a number of problems, such as duplicate VLAN names, incorrect VLAN-type specifications, and security violations.

Before you create VLANs, you must decide whether you want to use VTP in your network. With VTP, you can make configuration changes centrally on one or more network devices and have those changes automatically communicated to all the other network devices in the network. For details on configuring VLANs, see the [“VLANs”](#) section on page 17-1

These sections describe how VTP works:

- [Understanding the VTP Domain, page 17-8](#)
- [Understanding VTP Modes, page 17-8](#)
- [Understanding VTP Advertisements, page 17-9](#)
- [Understanding VTP Versions, page 17-9](#)
- [Understanding VTP Pruning, page 17-10](#)

Understanding the VTP Domain

A VTP domain is made up of one or more interconnected network devices that share the same VTP domain name. A network device can be configured to be in only one VTP domain. You make global VLAN configuration changes for the domain using either the command-line interface (CLI) or Simple Network Management Protocol (SNMP).

By default, the Catalyst 4500 series switch is in VTP server mode and the domain is set to NULL until the switch receives an advertisement for a domain over a trunk link or you configure a management domain. You cannot create or modify VLANs on a VTP server until the management domain name is specified or learned.

If the switch receives a VTP advertisement over a trunk link, it inherits the management domain name and the VTP configuration revision number. The switch ignores advertisements with a different management domain name or an earlier configuration revision number.

If you configure the switch as VTP transparent, you can create and modify VLANs, but the changes affect only the individual switch.

When you make a change to the VLAN configuration on a VTP server, the change is propagated to all network devices in the VTP domain. VTP advertisements are transmitted out all Inter-Switch Link (ISL) and IEEE 802.1Q trunk connections.

VTP maps VLANs dynamically across multiple LAN types with unique names and internal index associations. Mapping eliminates unnecessary device administration for network administrators.

Understanding VTP Modes

You can configure a Catalyst 4500 series switch to operate in any one of these VTP modes:

- **Server**—In VTP server mode, you can create, modify, and delete VLANs and specify other configuration parameters (such as VTP version and VTP pruning) for the entire VTP domain. VTP servers advertise their VLAN configuration to other network devices in the same VTP domain and synchronize their VLAN configuration with other network devices based on advertisements received over trunk links. VTP server is the default mode.

Note In VTP version 3, manipulation of VLANs can be done only to primary servers.

- **Client**—VTP clients behave the same way as VTP servers, but you cannot create, change, or delete VLANs on a VTP client.
- **Transparent**—VTP transparent network devices do not participate in VTP. A VTP transparent network device does not advertise its VLAN configuration and does not synchronize its VLAN configuration based on received advertisements. However, in VTP version 2, transparent network devices do forward VTP advertisements that they receive on their trunking LAN interfaces.

- Off—In VTP off mode, a network device functions in the same manner as a VTP transparent device except that it does not forward VTP advertisements.

**Note**

Catalyst 4500 series switches automatically change from VTP server mode to VTP client mode if the switch detects a failure while writing configuration to NVRAM. If this happens, the switch cannot be returned to VTP server mode until the NVRAM is functioning.

Understanding VTP Advertisements

Each network device in the VTP domain sends periodic advertisements out each trunking LAN interface to a reserved multicast address. VTP advertisements are received by neighboring network devices, which update their VTP and VLAN configurations as necessary.

The following global configuration information is distributed in VTP advertisements:

- VLAN IDs (ISL and 802.1Q)
- Emulated LAN names (for ATM LANE)
- 802.10 SAID values (FDDI)
- VTP domain name
- VTP configuration revision number
- VLAN configuration, including maximum transmission unit (MTU) size for each VLAN
- Frame format

Understanding VTP Versions

VTP Version 2

If you use VTP in your network, you must decide whether to use VTP version 2 or version 3.

**Note**

Catalyst 4500 series switches do not support Token Ring or FDDI media. The switch does not forward FDDI, FDDI-Net, Token Ring Concentrator Relay Function (TrCRF), or Token Ring Bridge Relay Function (TrBRF) traffic, but it does propagate the VLAN configuration by using VTP.

VTP version 2 supports the following features, which are not supported in version 1:

- Token Ring support—Supports Token Ring LAN switching and VLANs (TrBRF and TrCRF).
- Unrecognized Type-Length-Value (TLV) support—A VTP server or client propagates configuration changes to its other trunks, even for TLVs it is not able to parse. The unrecognized TLV is saved in NVRAM.
- Version-dependent transparent mode—In VTP version 1 and version 2, a VTP transparent network device forwards VTP messages in transparent mode without checking the version.
- Consistency checks—In VTP version 2, VLAN consistency checks (such as VLAN names and values) are performed only when you enter new information through the CLI or SNMP. Consistency checks are not performed when new information is obtained from a VTP message or when information is read from NVRAM. If the digest on a received VTP message is correct, its information is accepted without consistency checks.

VTP Version 3

VTP version 3 supports the following features not supported in version 1 or version 2:

- Hidden password support—Supports the option of configuring the password as **hidden** or **secret**.
When the **hidden** keyword is specified, that password must be reentered if a takeover command is issued in the domain. The secret key generated from the password string is saved in the `const_nvram:vlan.dat` file. When configured with this option, the password does not appear in plain text in the configuration. Instead, the secret key associated with the password is saved in hexadecimal format in the running configuration. If the **hidden** keyword is not specified, the password is saved in clear text in the `const_nvram:vlan.dat` file as in VTP version 1 and VTP version 2.
When the **secret** keyword is specified, the password secret key can be directly configured.
- Extended VLAN database propagation support—In VTP version 2, VLAN configuration information is propagated only for VLANs numbered 1 to 1000. In VTP version 3, information also is propagated for extended-range VLANs (VLANs numbered 1006 to 4094).
- On Catalyst 4500 series switches running VTP version 1, VTP version 2, or VTP version 3, default VLANs 1 and 1002 to 1005 cannot be modified.

Note VTP pruning continues to apply only to VLANs numbered 1 to 1000.

- Propagation of any database in a domain—In addition to propagating VLAN database information, VTP can propagate Multiple Spanning Tree (MST) protocol database information.
- Disabling VTP—When VTP is disabled on a trunking port, it applies to all VTP instances on that port. When VTP is disabled globally, the setting applies to all the trunking ports in the system.
- In VTP version 1 and VTP version 2, the role of a VTP server is to back up the database to NVRAM and to allow the administrator to change database information. VTP version 3 introduces the roles of VTP primary server and VTP secondary server. A VTP primary server is used to update the database information. The updates sent out are honored by all the devices in the system. A VTP secondary server can only back up to its NVRAM the VTP configuration received by using updates from the VTP primary server.

The status of primary and secondary servers is a runtime status and is not a configurable option. By default, all devices are initiated as secondary servers. Primary server status is needed only when database updates are needed, and is obtained when the administrator issues a takeover message in the domain. See the [“Starting a Takeover” section on page 17-18](#).

Primary server status is lost upon reload of the device, or when switchover or domain parameters change. Secondary servers back up the configuration and continue to propagate it. Because of that, you may have a working VTP domain without any primary servers.

Understanding VTP Pruning

VTP pruning enhances network bandwidth use by reducing unnecessary flooded traffic, such as broadcast, multicast, and unicast packets. VTP pruning increases available bandwidth by restricting flooded traffic to those trunk links that the traffic must use to access the appropriate network devices. By default, VTP pruning is disabled.

For VTP pruning to be effective, all devices in the management domain must either support VTP pruning or, on devices that do not support VTP pruning, you must manually configure the VLANs allowed on trunks.

Figure 17-2 shows a switched network without VTP pruning enabled. Interface 1 on Switch 1 and Interface 2 on Switch 4 are assigned to the Red VLAN. A broadcast is sent from the host connected to Switch 1. Switch 1 floods the broadcast and every network device in the network receives it, even though Switches 3, 5, and 6 have no interfaces in the Red VLAN.

You can enable pruning globally on the Catalyst 4500 series switch (see the “Enabling VTP Pruning” section on page 17-15).

Figure 17-2 Flooding Traffic without VTP Pruning

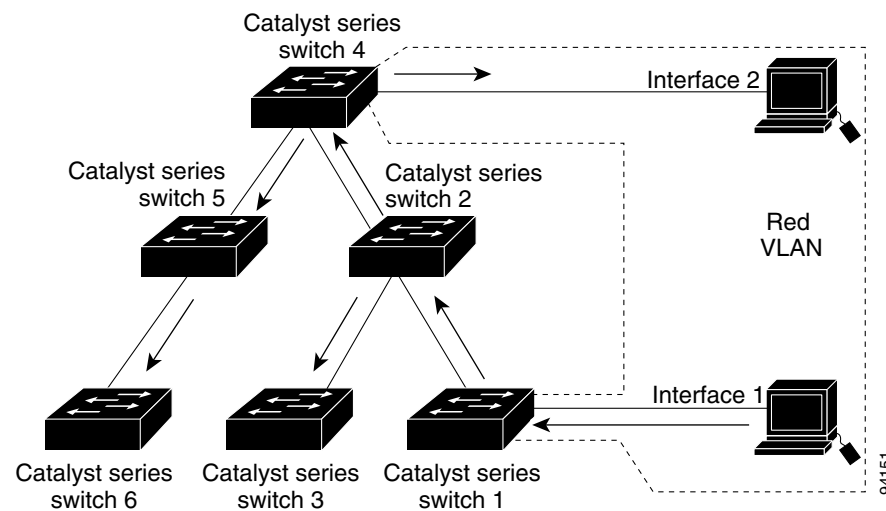

Figure 17-3 shows the same switched network with VTP pruning enabled. The broadcast traffic from Switch 1 is not forwarded to Switches 3, 5, and 6 because traffic for the Red VLAN has been pruned on the links indicated (Interface 5 on Switch 2 and Interface 4 on Switch 4).

Figure 17-3 Flooding Traffic with VTP Pruning

Enabling VTP pruning on a VTP server enables pruning for the entire management domain. VTP pruning takes effect several seconds after you enable it. By default, VLANs 2 through 1000 are eligible for pruning. VTP pruning does not prune traffic from pruning-eligible VLANs. VLAN 1 is always ineligible for pruning; traffic from VLAN 1 cannot be pruned.

To configure VTP pruning on a trunking LAN interface, use the **switchport trunk pruning vlan** command. VTP pruning operates when a LAN interface is trunking. You can set VLAN pruning eligibility regardless of whether VTP pruning is enabled or disabled for the VTP domain, whether any given VLAN exists, and regardless of whether the LAN interface is currently trunking.

VTP Configuration Guidelines and Restrictions

Follow these guidelines and restrictions when implementing VTP in your network:

- Supervisor engine redundancy does not support nondefault VLAN data file names or locations. Do not enter the **vtp file *file_name*** command on a switch that has a redundant supervisor engine.
- Before installing a redundant supervisor engine, enter the **no vtp file** command to return to the default configuration.
- When a VTP version 3 device on a trunk port receives messages from a VTP version 2 device, it sends a scaled-down version of the VLAN database on that particular trunk in a VTP version 2 format. A VTP version 3 device does not send out VTP version 2 formatted packets on a trunk port unless it first receives VTP version 2 packets on that trunk.
- Even when a VTP version 3 device detects a VTP version 2 device on a trunk port, it continues to send VTP version 3 packets in addition to VTP version 2 packets, to allow co-existence of two kinds of neighbors off the trunk.
- A VTP version 3 device does not accept configuration information from a VPT version 2 or version 1 device.
- Unlike in VPT version 2, when VTP is configured to be version 3, this does not configure all the version-3-capable devices in the domain to start behaving as VPT version 3 systems.
- When a VTP version 1 device, capable of version 2 or version 3, receives a VTP version 3 packet, the device is configured as a VTP version 2 device provided a VTP version 2 conflict does not exist.
- Devices that are only VTP version 1 capable cannot interoperate with VTP version 3 devices.
- In a Token Ring environment, you must enable VTP version 2 or version 3 for Token Ring VLAN switching to function properly.
- Two VPT version 3 regions can only communicate in transparent mode over a VTP version 1 or VTP version 2 region.
- All network devices in a VTP domain must run the same VTP version.
- You must configure a password on each network device in the management domain when VTP is in secure mode.

Caution

If you configure VTP in secure mode and you do not assign a management domain password to each network device in the domain, the management domain does not function properly.

- A VTP version 2-capable network device can operate in the same VTP domain as a network device running VTP version 1 if VTP version 2 is disabled on the VTP version 2-capable network device (VTP version 2 is disabled by default).
- Do not enable VTP version 2 on a network device unless all of the network devices in the same VTP domain are version 2-capable. When you enable VTP version 2 on a server, all of the version 2-capable network devices in the domain enable VTP version 2.
- Enabling or disabling VTP pruning on a VTP server enables or disables VTP pruning for the entire management domain.

- Configuring VLANs as eligible for pruning on a Catalyst 4500 series switch affects pruning eligibility for those VLANs on that switch only, not on all network devices in the VTP domain.
- The VLAN database is saved in the NVRAM file in a format compliant with the VTP version running on the system. Since older images supporting only VTP version 2 do not recognize the VTP version 3 file format, the NVRAM VLAN database information is lost if the system is downgraded from a new image supporting VTP to one that does not.

VTP Default Configuration

Table 17-3 shows the default VTP configuration.

Table 17-3 VTP Default Configuration

Feature	Default Value
VTP domain name	Null
VTP mode	Server
VTP version 2 enable state	Version 2 is disabled
VTP password	None
VTP pruning	Disabled

The default VTP mode for newly manufactured Catalyst 4500 Series Switches supervisor engines is transparent. Deleting `vlan.dat` or entering the `erase cat4000_flash:` command, and resetting the switch changes the VTP mode to server.

Configuring VTP

These sections describe how to configure VTP:

- [Configuring VTP Global Parameters, page 17-13](#)
- [Configuring the VTP Mode, page 17-16](#)
- [Starting a Takeover, page 17-18](#)
- [Displaying VTP Statistics, page 17-19](#)
- [Displaying VTP Devices in a Domain, page 17-19](#)

Configuring VTP Global Parameters

These sections describe configuring the VTP global parameters:

- [Configuring a VTP Password, page 17-14](#)
- [Enabling VTP Pruning, page 17-15](#)
- [Enabling the VTP Version Number, page 17-15](#)

Note

You can enter the VTP global parameters in either global configuration mode or in EXEC mode.

Configuring a VTP Password

To configure the VTP global parameters, use these commands:

Command	Purpose
Switch(config)# vtp password <i>password_string</i> [hidden secret]	Sets a password, which can be from 8 to 64 characters long, for the VTP domain. In VTP version 3 the keywords hidden and secret are available. <ul style="list-style-type: none"> If the hidden keyword is used, the secret key generated from the password string is saved in the const_nvram:vlan.dat file. If a takeover command is issued, that password must be reentered. If the secret keyword is used, the password secret key can be directly configured. The secret password must contain 32 hexadecimal characters.
Switch(config)# no vtp password	Clears the password.

This example shows one way to configure a VTP password in global configuration mode:

```
Switch# configure terminal
Switch(config)# vtp password myPassword
Setting device VLAN database password to myPassword.
Switch#
```

This example shows how to configure a VTP password in EXEC mode:

```
Switch# vtp password myPassword
Setting device VLAN database password to myPassword.
Switch#
```

Note

The password is not stored in the running-config file.

This example shows how to configure a **hidden** password:

```
Switch# configure terminal
Switch(config)# vtp password myPassword hidden
Generating the secret associated to the password.
Switch(config)#
```

This example shows how the password myPassword is displayed when it is configured with the **hidden** keyword.

```
Switch# show vtp password
VTP Password: 89914640C8D90868B6A0D8103847A733
Switch#
```

Enabling VTP Pruning

To enable VTP pruning in the management domain, perform this task:

	Command	Purpose
Step 1	Switch(config)# vtp pruning	Enables VTP pruning in the management domain.
Step 2	Switch# show vtp status include pruning	(Optional) Verifies the configuration.

This example shows one way to enable VTP pruning in the management domain:

```
Switch# configure terminal
Switch(config)# vtp pruning
Pruning switched ON
```

This example shows how to enable VTP pruning in the management domain with any release:

```
Switch# vtp pruning
Pruning switched ON
```

This example shows how to verify the configuration:

```
Switch# show vtp status | include Pruning
VTP Pruning Mode: Enabled
Switch#
```

For information about configuring prune eligibility, see the [“Understanding VTP Pruning” section on page 17-10](#).

Enabling the VTP Version Number

VTP version 2 is disabled by default on VTP version-2-capable network devices. When you enable VTP version 2 on a network device, every VTP version-2-capable network device in the VTP domain enables version 2.

Caution

VTP version 1 and VTP version 2 are not interoperable on network devices in the same VTP domain. Every network device in the VTP domain must use the same VTP version. Do not enable VTP version 2 unless every network device in the VTP domain supports version 2.

Note

In a Token Ring environment, you must enable VTP version 2 or VTP version 3 for Token Ring VLAN switching to function properly on devices that support Token Ring interfaces.

To enable the VTP version, perform this task:

	Command	Purpose
Step 1	Switch(config)# vtp version {1 2 3}	Enables the VTP version.
Step 2	Switch# show vtp status include {v1 v2 v3}	(Optional) Verifies the configuration.

This example shows one way to enable VTP version 2:

```
Switch# configure terminal
Switch(config)# vtp version 2
V2 mode enabled.
Switch(config)#
```

This example shows how to enable VTP version 2 with any release:

```
Switch# vtp version 2
V2 mode enabled.
Switch#
```

This example shows how to verify the configuration:

```
Switch# show vtp status | include V2
VTP V2 Mode: Enabled
Switch#
```

Configuring the VTP Mode

To configure the VTP mode, perform this task:

	Command	Purpose
Step 1	Switch(config)# vtp mode {client server transparent off}	Configures the VTP mode.
Step 2	Switch(config)# vtp domain <i>domain_name</i>	(Optional; for server mode only) Defines the VTP domain name, which can be up to 32 characters long. VTP server mode requires a domain name. If the switch has a trunk connection to a VTP domain, the switch learns the domain name from the VTP server in the domain. Note You cannot clear the domain name.
Step 3	Switch(config)# end	Exits VLAN configuration mode.
Step 4	Switch# show vtp status	(Optional) Verifies the configuration.

Note

When VTP is disabled, you can enter VLAN configuration commands in configuration mode instead of the VLAN database mode and the VLAN configuration is stored in the startup configuration file.

This example shows how to configure the switch as a VTP server:

```
Switch# configure terminal
Switch(config)# vtp mode server
Setting device to VTP SERVER mode.
Switch(config)# vtp domain Lab_Network
Setting VTP domain name to Lab_Network
Switch(config)# end
Switch#
```

This example shows how to configure the switch as a VTP client:

```
Switch# configure terminal
Switch(config)# vtp mode client
Setting device to VTP CLIENT mode.
Switch(config)# end
Switch#
```

This example shows how to disable VTP on the switch:

```
Switch# configure terminal
Switch(config)# vtp mode transparent
Setting device to VTP TRANSPARENT mode.
Switch(config)# end
Switch#
```

This example shows how to disable VTP on the switch and to disable VTP advertisement forwarding:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vtp mode off
Setting device to VTP OFF mode.
Switch(config)# end
Switch#
```

This example shows an example of the VTP configuration parameters when the device is running VTP version 1:

```
Switch# show vtp status
VTP Version capable           : 1 to 3
VTP version running          : 1
VTP Domain Name               : Lab_Network
VTP Pruning Mode              : Enabled
VTP Traps Generation          : Disabled
Device ID                     : 0016.9c6d.5300
Configuration last modified by 127.0.0.12 at 10-18-07 10:12:42
Local updater ID is 127.00.12 at 10-18-07 10:2:42

Feature VLAN:
-----
VTP Operating Mode            : Server
Maximum number of existing VLANs : 5
Configuration Revision        : 1
MD5 digest                    : 0x92 0xF1 0xE8 0x52 0x2E 0x5C 0x36 0x10 0x70 0x61 0xB8
                                0x24 0xB6 0x93 0x21 0x09

Switch#
```

This example shows an example of the VTP configuration parameters when the device is running VTP version 2:

```
Switch# show vtp status
VTP Version capable           : 1 to 3
VTP version running          : 2
VTP Domain Name               : Lab_Network
VTP Pruning Mode              : Disabled
VTP Traps Generation          : Disabled
Device ID                     : 0012.44dc.b800
Configuration last modified by 127.0.0.12 at 10-18-07 10:38:45
Local updater ID is 127.0.0.12 on interface EO 0/0 (first interface found)

Feature VLAN:
-----
VTP Operating Mode            : Server
Maximum VLANs supported locally: 1005
Number of existing VLANs      : 1005
Configuration Revision        : 1
MD5 digest                    : 0x2E 0x6B 0x99 0x58 0xA2 0x4F 0xD5 0x15 0x70 0x61 0xB8
                                0x24 0xB6 0x93 0x21 0x09

Switch#
```

This example shows an example of the VTP configuration parameters when the device is running VTP version 3:

```
Switch# show vtp status
VTP Version capable      : 1 to 3
VTP version running      : 3
VTP Domain Name          : Lab_Network
VTP Pruning Mode         : Disabled
VTP Traps Generation     : Disabled
Device ID                : 0012.44dc.b800

Feature VLAN:
-----
VTP Operating Mode       : Server
Number of existing VLANs : 1005
Number of existing extended VLANs: 3074
Configuration Revision   : 18
Primary ID               : 0012.4371.9ec0
Primary Description      :
Switch#
```

Starting a Takeover

This process applies to VTP version 3 only. To start a takeover, perform this task:

Command	Purpose
Switch# vtp primary-server [vlan mst] [force]	<p>Changes the operational state of a switch from a secondary to a primary server and advertises the configuration to the whole domain. (If the password for this device is configured with the hidden keyword, the user is prompted to re-enter it.)</p> <p>Note Using the force keyword overwrites the configuration of any conflicting servers. If not using the force keyword, you are prompted for confirmation before proceeding with the takeover.</p> <p>Specify where to direct the takeover by selecting the appropriate feature (vlan or mst). If no feature is selected, the takeover is directed to the VLAN database.</p>

This example shows how to start a takeover and direct it to the **vlan** database:

```
Switch# vtp primary-server vlan
Enter VTP password:password
This system is becoming primary for feature vlan

VTP Feature Conf Revision Primary Server Device ID      Description
-----
MST          Yes    4          0012.4371.9ec0=0012.4371.9ec0 R1
Do you want to continue? (confirm)
Switch#
```

Displaying VTP Statistics

To display VTP statistics, including VTP advertisements sent and received and VTP errors, perform this task:

Command	Purpose
Switch# show vtp counters	Displays VTP statistics.

This example shows how to display VTP statistics:

```
Switch# show vtp counters
VTP statistics:
Summary advertisements received      : 7
Subset advertisements received      : 5
Request advertisements received     : 0
Summary advertisements transmitted : 997
Subset advertisements transmitted   : 13
Request advertisements transmitted   : 3
Number of config revision errors    : 0
Number of config digest errors      : 0
Number of V1 summary errors         : 0

VTP pruning statistics:

Trunk          Join Transmitted Join Received      Summary advts received from
-----          -----          -----          non-pruning-capable device
Fa5/8          43071          42766          5
```

Displaying VTP Devices in a Domain

To display information for all the VTP devices in a domain, perform this task:

Command	Purpose
Switch# show vtp devices [conflicts]	<p>Gathers and displays information for all the VTP devices in the domain.</p> <p>Note No information is gathered or displayed from switches set to vtp modes off or to transparent for a particular feature.</p> <p>The conflicts keyword (optional) displays the information of devices that have conflicting primary servers.</p>

This example shows how to display information for VTP devices in a domain:

```
Switch# show vtp devices
Retrieving information from the VTP domain, please wait for 5 seconds.
VTP Feature Conf Revision Primary Server Device ID      Device Description
-----
VLAN          No    18      0016.9c6d.5300 0012.011a.0d00    R2

MST           Yes    4       0012.4371.9ec0=0012.4371.9ec0    R1

Switch#
```

VLAN Membership Policy Server

This section describes how to configure dynamic port VLAN membership through the VLAN Membership Policy Server (VMPS), and includes the following subsections:

- [About VMPS, page 17-20](#)
- [Overview of VMPS Clients, page 17-22](#)
- [Dynamic Port VLAN Membership Configuration Example, page 17-28](#)
- [VMPS Database Configuration File Example, page 17-31](#)

About VMPS

These subsections describe what a VMPS server does and how it operates:

- [Understanding the VMPS Server, page 17-20](#)
- [Security Modes for VMPS Server, page 17-21](#)
- [Fallback VLAN, page 17-22](#)
- [Illegal VMPS Client Requests, page 17-22](#)

Understanding the VMPS Server

A VLAN Membership Policy Server (VMPS) provides a centralized server for selecting the VLAN for a port dynamically based on the MAC address of the device connected to the port. When the host moves from a port on one switch in the network to a port on another switch in the network, that switch dynamically assigns the new port to the proper VLAN for that host.

A Catalyst 4500 series switch running Cisco IOS software does not support the functionality of a VMPS. It can only function as a VLAN Query Protocol (VQP) client, which communicates with a VMPS through the VQP. For VMPS functionality, you need to use a Catalyst 4500 series switch (or Catalyst 6500 series switch) running Catalyst operating system (OS) software.

VMPS uses a UDP port to listen to VQP requests from clients, so, it is not necessary for VMPS clients to know if the VMPS resides on a local or remote device on the network. Upon receiving a valid request from a VMPS client, a VMPS server searches its database for an entry of a MAC-address to VLAN mapping.

In response to a request, the VMPS takes one of the following actions:

- If the assigned VLAN is restricted to a group of ports, the VMPS verifies the requesting port against this group and responds as follows:

- If the VLAN is allowed on the port, the VMPS sends the VLAN name to the client in response.
- If the VLAN is not allowed on the port and the VMPS is not in secure mode, the VMPS sends an “access-denied” response.
- If the VLAN is not allowed on the port and the VMPS is in secure mode, the VMPS sends a “port-shutdown” response.
- If the VLAN in the database does not match the current VLAN on the port and active hosts exist on the port, the VMPS sends an “access-denied” (open), a “fallback VLAN name” (open with fallback VLAN configured), a “port-shutdown” (secure), or a “new VLAN name” (multiple) response, depending on the secure mode setting of the VMPS.

If the switch receives an “access-denied” response from the VMPS, the switch continues to block traffic from the MAC address to or from the port. The switch continues to monitor the packets directed to the port and sends a query to the VMPS when it identifies a new address. If the switch receives a “port-shutdown” response from the VMPS, the switch disables the port. The port must be manually reenabled by using the CLI, Cisco Visual Switch Manager (CVSM), or SNMP.

You can also use an explicit entry in the configuration table to deny access to specific MAC addresses for security reasons. If you enter the **none** keyword for the VLAN name, the VMPS sends an “access-denied” or “port-shutdown” response.

Security Modes for VMPS Server

VMPS operates in three different modes. The way a VMPS server responds to illegal requests depends on the mode in which the VMPS is configured:

- [Open Mode, page 17-21](#)
- [Secure Mode, page 17-21](#)
- [Multiple Mode, page 17-22](#)

Open Mode

If no VLAN is assigned to this port, VMPS verifies the requesting MAC address against this port:

- If the VLAN associated with this MAC address is allowed on the port, the VLAN name is returned to the client.
- If the VLAN associated with this MAC address is not allowed on the port, the host receives an “access denied” response.

If a VLAN is already assigned to this port, VMPS verifies the requesting MAC address against this port:

- If the VLAN associated with this MAC address in the database does not match the current VLAN assigned on the port, and a fallback VLAN name is configured, VMPS sends the fallback VLAN name to the client.
- If a VLAN associated with this MAC address in the database does not match the current VLAN assigned on the port, and a fallback VLAN name is not configured, the host receives an “access denied” response.

Secure Mode

If no VLAN is assigned to this port, VMPS verifies the requesting MAC address against this port:

- If the VLAN associated with this MAC address is allowed on the port, the VLAN name is returned to the client.

- If the VLAN associated with this MAC address is not allowed on the port, the port is shut down.

If a VLAN is already assigned to this port, VMPS verifies the requesting MAC address against this port:

- If a VLAN associated with this MAC address in the database does not match the current VLAN assigned on the port, the port is shutdown, even if a fallback VLAN name is configured.

Multiple Mode

Multiple hosts (MAC addresses) can be active on a dynamic port if they are all in the same VLAN. If the link fails on a dynamic port, the port returns to the unassigned state. Any hosts that come online through the port are checked again with VMPS before the port is assigned to a VLAN.

If multiple hosts connected to a dynamic port belong to different VLANs, the VLAN matching the MAC address in the last request is returned to the client provided that multiple mode is configured on the VMPS server.

Note

Although Catalyst 4500 series and Catalyst 6500 series switches running Catalyst operating system software support VMPS in all three operation modes, the User Registration Tool (URT) supports open mode only.

Fallback VLAN

You can configure a fallback VLAN name on a VMPS server.

If no VLAN has been assigned to this port, VMPS compares the requesting MAC address to this port:

- If you connect a device with a MAC address that is not in the database, the VMPS sends the fallback VLAN name to the client.
- If you do not configure a fallback VLAN name and the MAC address does not exist in the database, the VMPS sends an “access-denied” response.

If a VLAN is already assigned to this port, VMPS compares the requesting MAC address to this port:

- If the VMPS is in secure mode, it sends a “port-shutdown” response, whether a fallback VLAN has been configured on the server.

Illegal VMPS Client Requests

Two examples of illegal VMPS client requests are as follows:

- When a MAC-address mapping is not present in the VMPS database and “no fall back” VLAN is configured on the VMPS.
- When a port is already assigned a VLAN (and the VMPS mode is not “multiple”) but a second VMPS client request is received on the VMPS for a different MAC-address.

Overview of VMPS Clients

The following subsections describe how to configure a switch as a VMPS client and configure its ports for dynamic VLAN membership.

The following topics are included:

- [Understanding Dynamic VLAN Membership, page 17-23](#)

- [Default VMPS Client Configuration, page 17-23](#)
- [Configuring a Switch as a VMPS Client, page 17-24](#)
- [Administering and Monitoring the VMPS, page 17-27](#)
- [Troubleshooting Dynamic Port VLAN Membership, page 17-28](#)

Understanding Dynamic VLAN Membership

When a port is configured as “dynamic,” it receives VLAN information based on the MAC-address that is on the port. The VLAN is not statically assigned to the port; it is dynamically acquired from the VMPS based on the MAC-address on the port.

A dynamic port can belong to one VLAN only. When the link becomes active, the switch does not forward traffic to or from this port until the port is assigned to a VLAN. The source MAC address from the first packet of a new host on the dynamic port is sent to the VMPS as part of the VQP request, which attempts to match the MAC address to a VLAN in the VMPS database. If there is a match, the VMPS sends the VLAN number for that port. If there is no match, the VMPS either denies the request or shuts down the port (depending on the VMPS security mode setting). See the [“About VMPS” section on page 17-20](#) for a complete description of possible VMPS responses.

Multiple hosts (MAC addresses) can be active on a dynamic port if all are in the same VLAN. If the link goes down on a dynamic port, the port returns to the unassigned state and does not belong to a VLAN. Any hosts that come online through the port are checked again with the VMPS before the port is assigned to a VLAN.

For this operation to work, the client device must be able to reach the VMPS. A VMPS client sends VQP requests as UDP packets, trying a certain number of times before giving up. For details on how to set the retry interval, refer to section “Configuring the Retry Interval” on page 26.

The VMPS client also periodically reconfirms the VLAN membership. For details on how to set the reconfirm frequency, refer to section “Administering and Monitoring the VMPS” on page 27.

A maximum of 50 hosts are supported on a given port at any given time. Once this maximum is exceeded, the port is shut down, irrespective of the operating mode of the VMPS server.

**Note**

The VMPS shuts down a dynamic port if more than 50 hosts are active on that port.

Default VMPS Client Configuration

[Table 17-4](#) shows the default VMPS and dynamic port configuration on client switches.

Table 17-4 **Default VMPS Client and Dynamic Port Configuration**

Feature	Default Configuration
VMPS domain server	None
VMPS reconfirm interval	60 minutes
VMPS server retry count	3
Dynamic ports	None configured

Configuring a Switch as a VMPS Client

This section contains the following topics:

- [Configuring the IP Address of the VMPS Server, page 17-24](#)
- [Configuring Dynamic Access Ports on a VMPS Client, page 17-24](#)
- [Reconfirming VLAN Memberships, page 17-25](#)
- [Configuring Reconfirmation Interval, page 17-26](#)
- [Reconfirming VLAN Memberships, page 17-25](#)

Configuring the IP Address of the VMPS Server

To configure a Catalyst 4500 series switch as a VMPS client, you must enter the IP address or hostname of the switch acting as the VMPS.

To define the primary and secondary VMPS on a Catalyst 4500 series switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# vmps server {ipaddress hostname} primary	Specifies the IP address or hostname of the switch acting as the primary VMPS server.
Step 3	Switch(config)# vmps server {ipaddress hostname}	Specifies the IP address or hostname of the switch acting as a secondary VMPS server.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show vmps	Verifies the VMPS server entry.

This example shows how to define the primary and secondary VMPS devices:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vmps server 172.20.128.179 primary
Switch(config)# vmps server 172.20.128.178
Switch(config)# end
```

Note

You can configure up to four VMPS servers using this CLI on the VMPS client.

```
Switch# show vmps
VQP Client Status:
-----
VMPS VQP Version: 1
Reconfirm Interval: 60 min
Server Retry Count: 3
VMPS domain server: 172.20.128.179 (primary, current)
                   172.20.128.178

Reconfirmation status
-----
VMPS Action:          No Dynamic Port
```

Configuring Dynamic Access Ports on a VMPS Client

To configure a dynamic access port on a VMPS client switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface	Enters interface configuration mode and specifies the port to be configured.
Step 3	Switch(config-if)# switchport mode access	Sets the port to access mode.
Step 4	Switch(config-if)# switchport access vlan dynamic	Configures the port as eligible for dynamic VLAN access.
Step 5	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 6	Switch# show interface interface switchport	Verifies the entry.

This example shows how to configure a dynamic access port and to verify the entry:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa1/1
Switch(config-if)# switchport mode access
Switch(config-if)# switchport access vlan dynamic
Switch(config-if)# end

Switch# show interface fa1/1 switchport
Name: Fa0/1
Switchport: Enabled
Administrative mode: dynamic auto
Operational Mode: dynamic access
Administrative Trunking Encapsulation: isl
Operational Trunking Encapsulation: isl
Negotiation of Trunking: Disabled
Access Mode VLAN: 0 ((Inactive))
Trunking Native Mode VLAN: 1 (default)
Trunking VLANs Enabled: NONE
Pruning VLANs Enabled: NONE
```

Voice Ports

If a VVID (voice VLAN ID) is configured on a dynamic access port, the port can belong to both an access VLAN and a voice VLAN. Consequently, an access port configured for connecting an IP phone can have separate VLANs for the following:

- Data traffic to and from the PC that is connected to the switch through the access port of the IP phone (access VLAN)
- Voice traffic to and from the IP phone (voice VLAN)

Reconfirming VLAN Memberships

To confirm the dynamic port VLAN membership assignments that the switch has received from the VMPS, perform this task:

	Command	Purpose
Step 1	Switch# vmps reconfirm	Reconfirms dynamic port VLAN membership.
Step 2	Switch# show vmps	Verifies the dynamic VLAN reconfirmation status.

Configuring Reconfirmation Interval

VMPS clients periodically reconfirm the VLAN membership information received from the VMPS. You can set the number of minutes the VMPS client waits before reconfirming the VLAN-to-MAC-address assignments.

To configure the reconfirmation interval, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# vmips reconfirm <i>minutes</i>	Specifies the number of minutes between reconfirmations of the dynamic VLAN membership.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show vmips	Verifies the dynamic VLAN reconfirmation status.

This example shows how to change the reconfirmation interval to 60 minutes and verify the change:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vmips reconfirm 60
Switch(config)# end
Switch# show vmips
VQP Client Status:
-----
VMPS VQP Version: 1
Reconfirm Interval: 60 min
Server Retry Count: 10
VMPS domain server: 172.20.130.50 (primary, current)

Reconfirmation status
-----
VMPS Action: No Host
```

Configuring the Retry Interval

You can set the number of times that the VMPS client attempts to contact the VMPS before querying the next server.

To configure the retry interval, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# vmips retry <i>count</i>	Specifies the retry count for the VPQ queries. Default is 3. Range is from 1 to 10.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show vmips	Verifies the retry count.

This example shows how to change the retry count to 5 and to verify the change:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vmips retry 5
Switch(config)# end
```

```

Switch# show vmps
VQP Client Status:
-----
VMPS VQP Version: 1
Reconfirm Interval: 60 min
Server Retry Count: 5
VMPS domain server: 172.20.130.50 (primary, current)

Reconfirmation status
-----
VMPS Action:          No Host

```

Administering and Monitoring the VMPS

You can display the following information about the VMPS with the **show vmps** command:

VQP Version	The version of VQP used to communicate with the VMPS. The switch queries the VMPS using VQP Version 1.
Reconfirm Interval	The number of minutes the switch waits before reconfirming the VLAN-to-MAC-address assignments.
Server Retry Count	The number of times VQP resends a query to the VMPS. If no response is received after this many tries, the switch starts to query the secondary VMPS.
VMPS Domain Server	The IP address of the configured VLAN membership policy servers. The switch currently sends queries to the one marked “current.” The one marked “primary” is the primary server.
VMPS Action	The result of the most-recent reconfirmation attempt. This action can occur automatically when the reconfirmation interval expired, or you can force it by entering the vmps reconfirm command or its CVSM or SNMP equivalent.

The following example shows how to display VMPS information:

```

Switch# show vmps
VQP Client Status:
-----
VMPS VQP Version: 1
Reconfirm Interval: 60 min
Server Retry Count: 3
VMPS domain server:

Reconfirmation status
-----
VMPS Action:          other

```

The following example shows how to display VMPS statistics:

```

Switch# show vmps statistics
VMPS Client Statistics
-----
VQP  Queries:          0
VQP  Responses:        0
VMPS  Changes:          0
VQP  Shutdowns:        0
VQP  Denied:           0

```

```
VQP Wrong Domain:          0
VQP Wrong Version:         0
VQP Insufficient Resource: 0
```

**Note**

Refer to command reference guide for details on VMPS statistics.

Troubleshooting Dynamic Port VLAN Membership

VMPS errdisables a dynamic port under the following conditions:

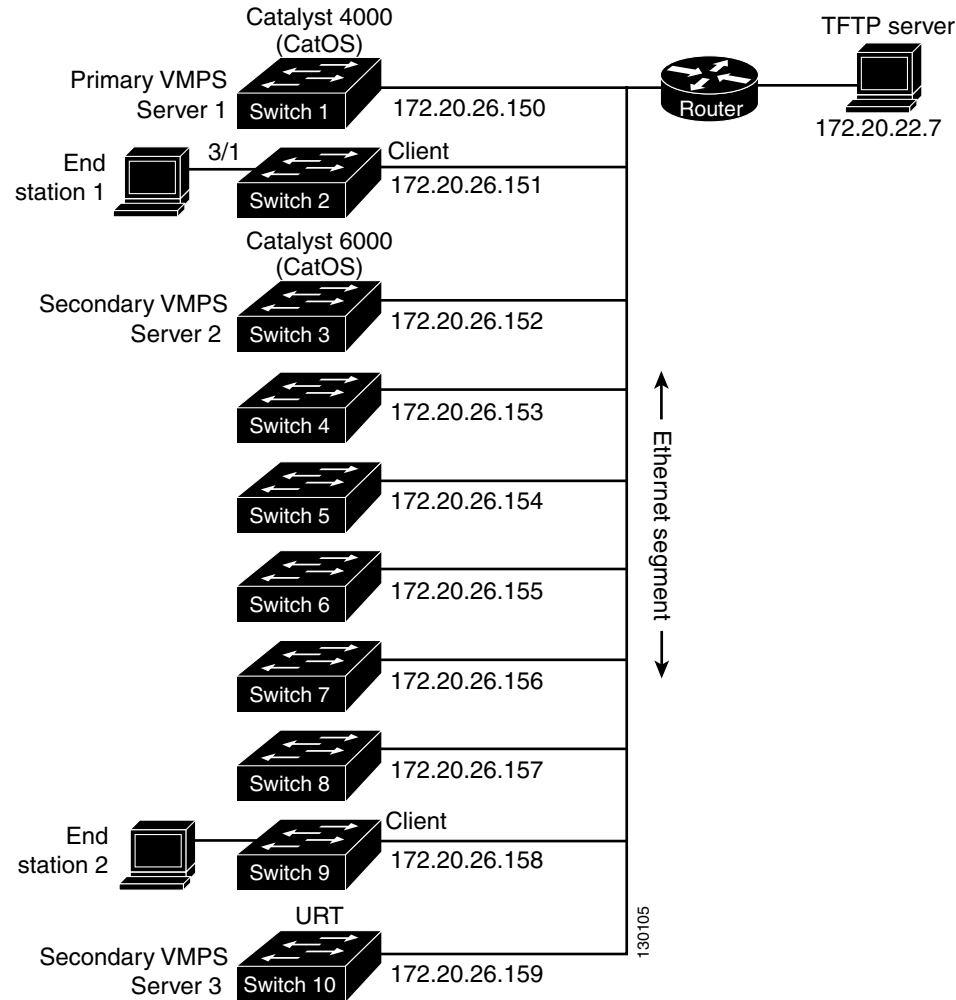

- The VMPS is in secure mode, and it does not allow the host to connect to the port. The VMPS errdisables the port to prevent the host from connecting to the network.
- More than 50 active hosts reside on a dynamic port.

For information on how to display the status of interfaces in error-disabled state, refer to [Chapter 10, “Checking Port Status and Connectivity.”](#) To recover an errdisabled port, use the **errdisable recovery cause vmps** global configuration command.

Dynamic Port VLAN Membership Configuration Example

[Figure 17-4 on page 17-29](#) shows a network with a VMPS servers and VMPS client switches with dynamic ports. In this example, these assumptions apply:

- The VMPS server and the VMPS client are separate switches.
- The Catalyst 4000 family Switch 1 (running Catalyst Operating System) is the primary VMPS server.
- The Catalyst 6000 family Switch 3 (running Catalyst Operating System) and the URT are secondary VMPS servers.
- End stations are connected to these clients:
 - Catalyst 4500 series XL Switch 2 (running Catalyst Cisco IOS)
 - Catalyst 4500 series XL Switch 9 (running Catalyst Cisco IOS)
- The database configuration file is called Bldg-G.db and is stored on the TFTP server with the IP address 172.20.22.7.

Figure 17-4 *Dynamic Port VLAN Membership Configuration*

Two topologies are possible. Figure 17-5 illustrates a topology with one end station attached directly to a Catalyst 4500 series switch operating as a VMPS client. Figure 17-6 illustrates a topology with an end station attached to a Cisco IP Phone, which is attached to a Catalyst 4500 series switch.

Figure 17-5 *Topology with an End Station Attached Directly to a Catalyst 4500 Series Switch Operating as a VMPS Client*

Figure 17-6 *Topology with an End Station Attached to a Cisco IP Phone that is Attached to a Catalyst 4500 Series Switch*

In the following procedure, the Catalyst 4500 and Catalyst 6500 series switches (running Catalyst Operating System) are the VMPS servers. Use this procedure to configure the Catalyst 4500 series switch clients in the network:

Step 1 Configure the VMPS server addresses on Switch 2, the client switch.

- a. Starting from privileged EXEC mode, enter global configuration mode:

```
switch# configuration terminal
```

- b. Enter the primary VMPS server IP address:

```
switch(config)# vmps server 172.20.26.150 primary
```

- c. Enter the secondary VMPS server IP addresses:

```
switch(config)# vmps server 172.20.26.152
```

- d. To verify your entry of the VMPS IP addresses, return to privileged EXEC mode:

```
switch(config)# exit
```

- e. Display VMPS information configured for the switch:

```
switch# show vmps
VQP Client Status:
-----
VMPS VQP Version: 1
Reconfirm Interval: 60 min
Server Retry Count: 3
VMPS domain server: 172.20.26.152
                    172.20.26.150 (primary, current)
```

Step 2 Configure port Fa0/1 on Switch 2 as a dynamic port.

- a. Return to global configuration mode:

```
switch# configure terminal
```

- b. Enter interface configuration mode:

```
switch(config)# interface fa2/1
```

- c. Configure the VLAN membership mode for static-access ports:

```
switch(config-if)# switchport mode access
```

- d. Assign the port dynamic VLAN membership:

```
switch(config-if)# switchport access vlan dynamic
```

- e. Return to privileged EXEC mode:

```
switch(config-if)# exit
switch#
```

Step 3 Connect End Station 2 on port Fa2/1. When End Station 2 sends a packet, Switch 2 sends a query to the primary VMPS server, Switch 1. Switch 1 responds with the VLAN ID for port Fa2/1. If spanning-tree PortFast mode is enabled on Fa2/1, port Fa2/1 connects immediately and begins forwarding.

Step 4 Set the VMPS reconfirmation period to 60 minutes. The reconfirmation period is the number of minutes the switch waits before reconfirming the VLAN to MAC address assignments.

```
switch# config terminal
switch(config)# vmps reconfirm 60
```

Step 5 Confirm the entry from privileged EXEC mode:

```
switch# show vmps
VQP Client Status:
-----
VMPS VQP Version: 1
Reconfirm Interval: 60 min
Server Retry Count: 3
VMPS domain server:

Reconfirmation status
-----
VMPS Action: No Dynamic Port
```

Step 6 Repeat Steps 1 and 2 to configure the VMPS server addresses, and assign dynamic ports on each VMPS client switch.

VMPS Database Configuration File Example

This example shows a sample VMPS database configuration file as it appears on a VMPS server. A VMPS database configuration file is an ASCII text file that is stored on a TFTP server accessible to the switch that functions as the VMPS server.

```
!vmips domain <domain-name>
! The VMPS domain must be defined.
!vmips mode {open | secure}
! The default mode is open.
!vmips fallback <vlan-name>
!vmips no-domain-req {allow | deny}
!
! The default value is allow.

Configuring IP Unnumbered Interface

This chapter discusses the IP Unnumbered Interface feature, which allows you to enable IP processing on an interface without assigning an explicit IP address.

This chapter contains these sections:

- [About IP Unnumbered Interface Support, page 18-1](#)
- [IP Unnumbered Configuration Guidelines and Restrictions, page 18-3](#)
- [Configuring IP Unnumbered Interface Support with DHCP Server, page 18-4](#)
- [Configuring IP Unnumbered Interface Support with Connected Host Polling, page 18-6](#)
- [Displaying IP Unnumbered Interface Settings, page 18-7](#)
- [Troubleshooting IP Unnumbered Interface, page 18-8](#)
- [Related Documents, page 18-8](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About IP Unnumbered Interface Support

Before you configure VLANs and LAN interfaces with IP unnumbered interfaces, you should understand the following concepts:

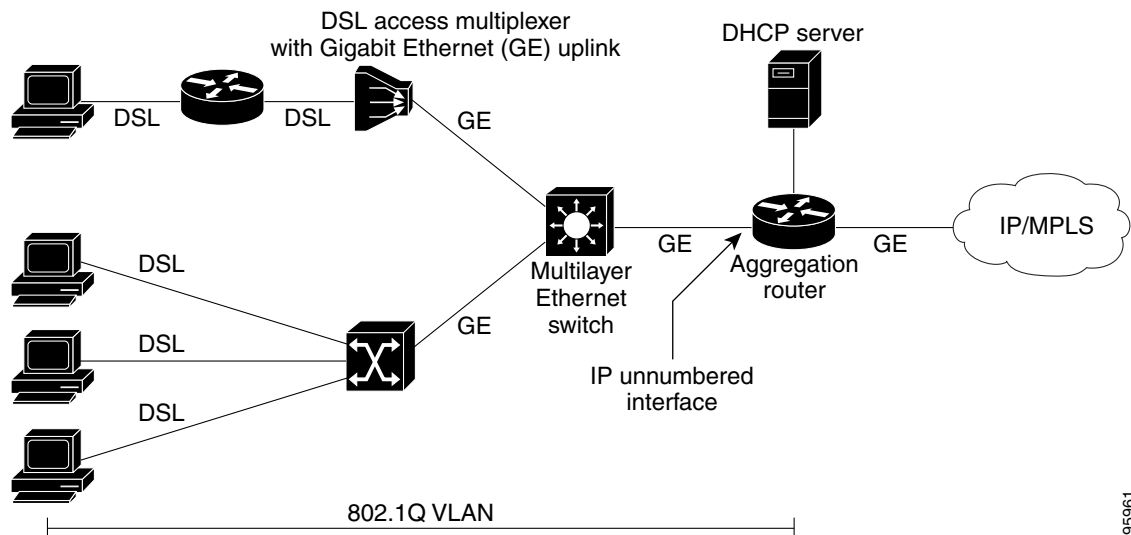

- [IP Unnumbered Interface Support with DHCP Server and Relay Agent, page 18-2](#)
- [DHCP Option 82, page 18-2](#)
- [IP Unnumbered Interface with Connected Host Polling, page 18-3](#)

IP Unnumbered Interface Support with DHCP Server and Relay Agent

The IP unnumbered interface configuration allows you to enable IP processing on an interface without assigning it an explicit IP address. The IP unnumbered interface can “borrow” the IP address from another interface that is already configured on the Catalyst 4500 series switch, which conserves network and address space. When used with the DHCP server/relay agent, this feature allows a host address assigned by the DHCP server to be learned dynamically at the DHCP relay agent.

Figure 18-1 shows a sample network topology implementing the IP Unnumbered Interface feature. In this topology, IP routes are dynamically established by the aggregation switch when the DHCP server assigns IP addresses to the hosts.

Figure 18-1 Sample Network Topology Using the VLANs over IP Unnumbered Interfaces Feature

95961

DHCP Option 82

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. Configuration parameters and other control information are carried in tagged data items that are stored in the options field of the DHCP message. The data items are also called *options*. Option 82 is organized as a single DHCP option that contains information known by the relay agent.

The IP Unnumbered Interface feature communicates information to the DHCP server using a suboption of the DHCP relay agent information option called *agent remote ID*. The information sent in the agent remote ID includes an IP address identifying the relay agent and information about the interface and the connection over which the DHCP request entered. The DHCP server can use this information to make IP address assignments and security policy decisions.

Figure 18-2 shows the agent remote ID suboption format that is used with the IP Unnumbered Interfaces feature.

Figure 18-2 **Format of the Agent Remote ID Suboption**

Table 18-1 describes the agent remote ID suboption fields displayed in Figure 18-2.

Table 18-1 **Agent Remote ID Suboption Field Descriptions**

Field	Description
Type	Format type. The value 2 specifies the format for use with this feature. (1 byte)
Length	Length of the Agent Remote ID suboption, not including the type and length fields. (1 byte)
Reserved	Reserved. (2 bytes)
NAS IP Address	IP address of the interface specified by the ip unnumbered command. (4 bytes)
Interface	Physical interface. This field has the following format: slot (4 bits) module (1 bit) port (3 bits). For example, if the interface name is interface ethernet 2/1/1, the slot is 2, the module is 1, and the port is 1. (1 byte)
Reserved	Reserved. (1 byte)
VLAN ID	VLAN identifier for the Ethernet interface. (2 bytes)

IP Unnumbered Interface with Connected Host Polling

Note

This feature option is applicable to LAN and VLAN interfaces only.

In some cases, the host IP address is assigned statically. The IP Unnumbered Interfaces feature can learn the static host IP address dynamically.

IP Unnumbered Configuration Guidelines and Restrictions

When using (or configuring) IP Unnumbered Interface, consider these guidelines and restrictions:

- For IP Unnumbered Interfaces, the following features are not supported:
 - Dynamic routing protocols
 - HSRP/VRRP
 - Static ARP
 - Unnumbered Interface and Numbered Interface in different VRFs

- The option to add *dhcp host routes* as connected routes is available in Cisco IOS. When using connected mode, however, the **clear ip route *** command deletes the dhcp host connected routes permanently.

Workarounds:

- For a layer 3 interface (SVI), enter **shut** then **no shut**.
- To enable IP unnumbered to use static routes, enter the **ip dhcp route static** command.
- IP Redirect is not sent by an interface configured with IP Unnumbered Interface.
- IP Unnumbered Interface is unable to forward multicast source packets.

Configuring IP Unnumbered Interface Support with DHCP Server

Note

DHCP must be configured and operational before you perform this task.

This section contains the following procedures:

- [Configuring IP Unnumbered Interface Support on LAN and VLAN Interfaces, page 18-4](#)
- [Configuring IP Unnumbered Interface Support on a Range of Ethernet VLANs, page 18-5](#)

Configuring IP Unnumbered Interface Support on LAN and VLAN Interfaces

To configure IP unnumbered interface support on a single LAN or VLAN interface, perform this task.

	Command	Purpose
Step 1	Switch# enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# interface [<i>fastethernet</i> <i>gigabitethernet</i> <i>tengigabitethernet</i> <i>vlan</i> <i>vlan</i> <i>port-channel</i> <i>loopback</i>]	Enters interface configuration mode and the interface to be configured as a tunnel port.
Step 4	Switch(config-if)# ip unnumbered <i>type number</i>	Enables IP processing on an interface without assigning an explicit IP address to the interface. The <i>type</i> and <i>number</i> arguments specify another interface on which the switch has an assigned IP address. The interface specified cannot be another unnumbered interface.
Step 5	Switch(config-if)# exit	Returns to global configuration mode.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.
Step 7	Switch# show running-config	Verifies that IP unnumbered support has been configured correctly.

In the following example, Ethernet VLAN 10 is configured as an IP unnumbered interfaces:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface vlan 10
Switch(config-if)# ip unnumbered Loopback 0
```

Configuring IP Unnumbered Interface Support on a Range of Ethernet VLANs

To configure IP unnumbered interface support on a range of Ethernet VLAN interfaces, perform this task:

	Command or Action	Purpose
Step 1	Switch# enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# interface range {{ fastethernet gigabitethernet vlan <i>vlan</i> } <i>slot/interface</i> { fastethernet gigabitethernet vlan <i>vlan</i> } <i>slot/interface</i> macro <i>macro-name</i> }	Executes commands on multiple interfaces at the same time. A hyphen must be entered with a space on either side to separate the range information.
Step 4	Switch(config-if)# ip unnumbered <i>type number</i>	Enables IP processing on an interface without assigning an explicit IP address to the interface. The <i>type</i> and <i>number</i> arguments specify another interface on which the switch has an assigned IP address. The specified interface cannot be another unnumbered interface.
Step 5	Switch(config-if)# exit	Returns to global configuration mode.
Step 6	Switch(config)# end	Returns to privileged EXEC mode.
Step 7	Switch# show running-config	Verifies that IP unnumbered support has been configured correctly.

In the following example, VLANs in the range from 1 to 10 are configured as IP unnumbered interfaces, sharing IP address of Fast Ethernet 3/1:

```
Switch> enable
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface range vlan 1 - 10
Switch(config-if)# ip unnumbered fastethernet 3/1
Switch(config-if)# exit
Switch(config)# end
```

Configuring IP Unnumbered Interface Support with Connected Host Polling

To configure IP unnumbered interface support with connected host polling, perform this task:

	Command	Purpose
Step 1	Switch# enable	Enables privileged EXEC mode. Enter your password if prompted.
Step 2	Switch# configure terminal	Enters global configuration mode.
Step 3	Switch(config)# interface vlan <i>vlan-id</i>	Enters interface configuration mode and the interface to be configured as a tunnel port.
Step 4	Switch(config-if)# ip unnumbered <i>type number</i> poll	Enables IP processing and connected host polling on an interface without assigning an explicit IP address to the interface <i>type</i> and <i>number</i> specify another interface on which the switch has an assigned IP address. The interface specified cannot be another unnumbered interface. The <i>type</i> argument can have the values: <i>loopback</i> , <i>fastethernet</i> , <i>gigabitethernet</i> , <i>svi</i> , and <i>portchannel</i> .
Step 5	Switch(config-if)# exit	Returns to global configuration mode.
Step 6	Switch(config)# ip arp poll queue <10-10000>	Configures the global backlog queue of host addresses to be discovered. Default for the queue size is 1000.
Step 7	Switch(config)# ip arp poll rate <10-10000>	Configures the maximum number of ARP requests sent over unnumbered interfaces. Default number of ARP requests is 1000 packet per second.
Step 8	Switch(config)# end	Returns to privileged EXEC mode.
Step 9	Switch# show running-config	Verifies that IP unnumbered support has been configured correctly.

The following example shows how to enable IP processing and connected host polling on Fast Ethernet interface 6/2. It also shows how to set the global backlog queue to 2000 and the maximum number of ARP requests to 500:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastEthernet 6/2
Switch(config-if)# no switchport
Switch(config-if)# ip unnumbered loopback 0 poll
Warning: dynamic routing protocols will not work on non-point-to-point interfaces with IP
unnumbered configured.
Switch(config-if)# exit
Switch(config)# ip arp poll queue 2000
Switch(config)# ip arp poll rate 500
Switch(config)# end
```

Displaying IP Unnumbered Interface Settings

Use the **show ip interface unnumbered** command to display status of an unnumbered interface with connected host polling for the switch.

To display **status of an unnumbered interface**, enter this command:

Command	Purpose
Switch# show ip interface [type number] unnumbered [detail]	Displays the status of unnumbered interface with connected host polling for the Catalyst 4500 series switch.

The following example shows how to display the status of unnumbered interfaces with connected host polling:

```
Switch# show ip interface loopback 0 unnumbered detail
Number of unnumbered interfaces with polling: 1
Number of IP addresses processed for polling: 2
10.1.1.7
10.1.1.8
Number of IP addresses in queue for polling: 2 (high water mark: 3)
10.1.1.17
10.1.1.18
```

To display key statistic for the backlog of unnumbered interfaces with connected host polling for the switch, perform this task:

Command	Purpose
Switch# show ip arp poll [detail]	Displays key statistic for the backlog of unnumbered interfaces with connected host polling for the switch.

The following example shows how to display key statistic for the backlog of unnumbered interfaces with connected host polling:

```
Switch# show ip arp poll
Number of IP addresses processed for polling: 439
Number of IP addresses in queue for polling: 3 (high water mark: 0, max: 1000)
Number of requests dropped:
  Queue was full: 0
  Request was throttled by incomplete ARP: 0
  Duplicate request was found in queue: 0
```

To clear the key statistic for the backlog of unnumbered interfaces, use the **clear ip arp poll statistic** command, as follows:

```
Switch# clear ip arp poll statistic
Switch# show ip arp poll
Number of IP addresses processed for polling: 0
Number of IP addresses in queue for polling: 0 (high water mark: 0, max: 1000)
Number of requests dropped:
  Queue was full: 0
  Request was throttled by incomplete ARP: 0
  Duplicate request was found in queue: 0
```

Troubleshooting IP Unnumbered Interface

To understand how to debug connect host polling, see the Cisco IOS documentation of the **debug arp** command on cisco.com.

When an IP unnumbered interface shares the IP address of a loopback interface whose prefix is advertised in an OSPF network, you must modify the loopback interface as a point-to-point interface. Otherwise, only the loopback interface host route is advertised to an OSPF neighbor.

```
Switch(config)# int loopback 0
Switch(config-if)# ip address
Switch(config-if)# ip address 10.1.0.1 255.255.0.0
Switch(config-if)# ip ospf network point-to-point
Switch(config-if)# end
```

Configuring Layer 2 Ethernet Interfaces

This chapter describes how to use the command-line interface (CLI) to configure Fast Ethernet and Gigabit Ethernet interfaces for Layer 2 switching on Catalyst 4500 series switches. It also provides guidelines, procedures, and configuration examples. The configuration tasks in this chapter apply to Fast Ethernet and Gigabit Ethernet interfaces on any module, including the uplink ports on the supervisor engine.

This chapter includes the following major sections:

- [About Layer 2 Ethernet Switching, page 19-1](#)
- [Default Layer 2 Ethernet Interface Configuration, page 19-4](#)
- [Layer 2 Interface Configuration Guidelines and Restrictions, page 19-4](#)
- [Configuring Ethernet Interfaces for Layer 2 Switching, page 19-5](#)

Note

To configure Layer 3 interfaces, see [Chapter 36, “Configuring Layer 3 Interfaces.”](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Layer 2 Ethernet Switching

The following sections describe how Layer 2 Ethernet switching works on Catalyst 4500 series switches:

- [Layer 2 Ethernet Switching, page 19-2](#)
- [VLAN Trunks, page 19-3](#)
- [Layer 2 Interface Modes, page 19-3](#)

Layer 2 Ethernet Switching

Catalyst 4500 series switches support simultaneous, parallel connections between Layer 2 Ethernet segments. Switched connections between Ethernet segments last only for the duration of the packet. New connections can be made between different segments for successive packets.

**Note**

With Cisco IOS Release 12.1(13)EW, the Catalyst 4500 series switches can handle packets of 1600 bytes, rather than treat them as “oversized” and discard them. This size is larger than the usual IEEE Ethernet Maximum Transmission Unit (MTU) (1518 bytes) and 802.1q MTU (1522 bytes). The ability to handle larger packets is required to support two nested 802.1q headers and Multiprotocol Label Switching (MPLS) on a network.

The Catalyst 4500 series switch solves congestion problems caused by high-bandwidth devices and a large number of users by assigning each device (for example, a server) to its own 10-, 100-, or 1000-Mbps segment. Because each Ethernet interface on the switch represents a separate Ethernet segment, servers in a properly configured switched environment achieve full access to the bandwidth.

Because collisions are a major bottleneck in Ethernet networks, an effective solution is full-duplex communication. Normally, Ethernet operates in half-duplex mode, which means that stations can either receive or transmit. In full-duplex mode, two devices can transmit and receive at the same time. When packets can flow in both directions simultaneously, effective Ethernet bandwidth doubles to 20 Mbps for 10-Mbps interfaces and to 200 Mbps for Fast Ethernet interfaces. Gigabit Ethernet interfaces on the Catalyst 4500 series switch are full-duplex mode only, providing 2-Gbps effective bandwidth.

Switching Frames Between Segments

Each Ethernet interface on a Catalyst 4500 series switch can connect to a single workstation or server, or to a hub through which workstations or servers connect to the network.

On a typical Ethernet hub, all ports connect to a common backplane within the hub, and the bandwidth of the network is shared by all devices attached to the hub. If two devices establish a session that uses a significant level of bandwidth, the network performance of all other stations attached to the hub is degraded.

To reduce degradation, the switch treats each interface as an individual segment. When stations on different interfaces need to communicate, the switch forwards frames from one interface to the other at wire speed to ensure that each session receives full bandwidth.

To switch frames between interfaces efficiently, the switch maintains an address table. When a frame enters the switch, it associates the MAC address of the sending station with the interface on which it was received.

Building the MAC Address Table

The Catalyst 4500 series switch builds the MAC address table by using the source address of the frames received. When the switch receives a frame for a destination address not listed in its MAC address table, it floods the frame to all interfaces of the same VLAN except the interface that received the frame. When the destination device replies, the switch adds its relevant source address and interface ID to the address table. The switch then forwards subsequent frames to a single interface without flooding to all interfaces.

The address table can store at least 32,000 address entries without flooding any entries. The switch uses an aging mechanism, defined by a configurable aging timer, so if an address remains inactive for a specified number of seconds, it is removed from the address table.

VLAN Trunks

A trunk is a point-to-point link between one or more Ethernet switch interfaces and another networking device such as a router or a switch. Trunks carry the traffic of multiple VLANs over a single link and allow you to extend VLANs across an entire network.

Only 802.1Q trunking encapsulations is available on all Catalyst 4500 Ethernet interfaces.

Note Ports 3 to 18 are blocking Gigabit ports on the WS-X4418-GB module. Ports 1 to 12 are blocking Gigabit ports on the WS-X4412-2GB-T module.

You can configure a trunk on a single Ethernet interface or on an EtherChannel bundle. For more information about EtherChannel, see [Chapter 27, “Configuring EtherChannel and Link State Tracking.”](#)

Layer 2 Interface Modes

[Table 19-1](#) lists the Layer 2 interface modes and describes how they function on Ethernet interfaces.

Table 19-1 *Layer 2 Interface Modes*

Mode	Purpose
switchport mode access	Puts the interface into permanent nontrunking mode and negotiates to convert the link into a nontrunking link. The interface becomes a nontrunk interface even if the neighboring interface does not change.
switchport mode dynamic desirable	Makes the interface actively attempt to convert the link to a trunking link. The interface becomes a trunk interface if the neighboring interface is set to trunk , desirable , or auto mode.
switchport mode dynamic auto	Makes the interface convert the link to a trunking link if the neighboring interface is set to trunk or desirable mode. It is the default mode for all Ethernet interfaces.
switchport mode trunk	Puts the interface into permanent trunking mode and negotiates to convert the link into a trunking link. The interface becomes a trunk interface even if the neighboring interface does not change.
switchport nonegotiate	Puts the interface into permanent trunking mode but prevents the interface from generating DTP frames. You must configure the neighboring interface manually as a trunk interface to establish a trunking link.

Note

DTP is a point-to-point protocol. However, some internetworking devices might forward DTP frames improperly. To avoid this problem, ensure that interfaces connected to devices that do not support DTP are configured with the **access** keyword if you do not intend to trunk across those links. To enable trunking to a device that does not support DTP, use the **nonegotiate** keyword to cause the interface to become a trunk without generating DTP frames.

Default Layer 2 Ethernet Interface Configuration

Table 19-2 shows the Layer 2 Ethernet interface default configuration.

Table 19-2 Layer 2 Ethernet Interface Default Configuration

Feature	Default Value
Interface mode	switchport mode dynamic auto
Trunk encapsulation	switchport trunk encapsulation negotiate
Allowed VLAN range	VLANs 1–1005
VLAN range eligible for pruning	VLANs 2–1001
Default VLAN (for access ports)	VLAN 1
Native VLAN (for 802.1Q only trunks)	VLAN 1
STP ¹	Enabled for all VLANs
STP port priority	128
STP port cost	<ul style="list-style-type: none"> • 100 for 10-Mbps Ethernet LAN ports • 19 for 10/100-Mbps Fast Ethernet ports • 19 for 100-Mbps Fast Ethernet ports • 4 for 1000-Mbps Gigabit Ethernet ports • 2 for 10,000-Mbps 10-Gigabit Ethernet LAN ports

1. STP = Spanning Tree Protocol

Layer 2 Interface Configuration Guidelines and Restrictions

When using (or configuring) Layer 2 interfaces, consider these guidelines and restrictions:

- In a network of Cisco switches connected through 802.1Q trunks, the switches maintain one instance of spanning tree for each VLAN allowed on the trunks. Non-Cisco 802.1Q switches maintain only one instance of spanning tree for all VLANs allowed on the trunks.

When you connect a Cisco switch to a non-Cisco device through an 802.1Q trunk, the Cisco switch combines the spanning tree instance of the native VLAN of the trunk with the spanning tree instance of the non-Cisco 802.1Q switch. However, spanning tree information for each VLAN is maintained by Cisco switches separated by a cloud of non-Cisco 802.1Q switches. The non-Cisco 802.1Q cloud separating the Cisco switches is treated as a single trunk link between the switches.

- Make sure the native VLAN for an 802.1Q trunk is the same on both ends of the trunk link. If the VLAN on one end of the trunk is different from the VLAN on the other end, spanning tree loops might result.
- Disabling spanning tree on any VLAN of an 802.1Q trunk can cause spanning tree loops.

Configuring Ethernet Interfaces for Layer 2 Switching

The following sections describe how to configure Layer 2 switching on a Catalyst 4500 series switch:

- [Configuring an Ethernet Interface as a Layer 2 Trunk, page 19-5](#)
- [Configuring an Interface as a Layer 2 Access Port, page 19-7](#)
- [Clearing Layer 2 Configuration, page 19-8](#)

Configuring an Ethernet Interface as a Layer 2 Trunk

Note

The default for Layer 2 interfaces is **switchport mode dynamic auto**. If the neighboring interface supports trunking and is configured to trunk mode or dynamic desirable mode, the link becomes a Layer 2 trunk.

To configure an interface as a Layer 2 trunk, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Specifies the interface to configure.
Step 2	Switch(config-if)# shutdown	(Optional) Shuts down the interface to prevent traffic flow until configuration is complete.
Step 3	Switch(config-if)# switchport trunk encapsulation { dot1q negotiate }	(Optional) Specifies the encapsulation. Note You must enter this command with the dot1q keyword to support the switchport mode trunk command, which is not supported by the default mode (negotiate).
Step 4	Switch(config-if)# switchport mode { dynamic { auto desirable } trunk }	Configures the interface as a Layer 2 trunk. (Required only if the interface is a Layer 2 access port or to specify the trunking mode.)
Step 5	Switch(config-if)# switchport access vlan <i>vlan_num</i>	(Optional) Specifies the access VLAN, which is used if the interface stops trunking. The access VLAN is not used as the native VLAN. Note The <i>vlan_num</i> parameter is either a single VLAN number from 1 to 1005 or a range of VLANs described by two VLAN numbers, the lesser one first, separated by a dash. Do not enter any spaces between comma-separated <i>vlan</i> parameters or in dash-specified ranges.
Step 6	Switch(config-if)# switchport trunk native vlan <i>vlan_num</i>	For 802.1Q trunks, specifies the native VLAN. Note If you do not set the native VLAN, the default is used (VLAN 1).
Step 7	Switch(config-if)# switchport trunk allowed vlan { add except all remove } <i>vlan_num[,vlan_num[,vlan_num[,...]]]</i>	(Optional) Configures the list of VLANs allowed on the trunk. All VLANs are allowed by default. You cannot remove any of the default VLANs from a trunk.

	Command	Purpose
Step 8	Switch(config-if)# switchport trunk pruning vlan {add except none remove} vlan_num[,vlan_num[,vlan_num[,...]]	(Optional) Configures the list of VLANs allowed to be pruned from the trunk (see the “VLAN Trunking Protocol” section on page 17-7). The default list of VLANs allowed to be pruned contains all VLANs, except for VLAN 1.
Step 9	Switch(config-if)# no shutdown	Activates the interface. (Required only if you shut down the interface.)
Step 10	Switch(config-if)# end	Exits interface configuration mode.
Step 11	Switch# show running-config interface {fastethernet gigabitethernet tengigabitethernet} slot/port	Displays the running configuration of the interface.
Step 12	Switch# show interfaces [fastethernet gigabitethernet tengigabitethernet] slot/port switchport	Displays the switch port configuration of the interface.
Step 13	Switch# show interfaces [{fastethernet gigabitethernet tengigabitethernet} slot/port] trunk	Displays the trunk configuration of the interface.

This example shows how to configure the Fast Ethernet interface 5/8 as an 802.1Q trunk. This example assumes that the neighbor interface is configured to support 802.1Q trunking and that the native VLAN defaults to VLAN 1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/8
Switch(config-if)# shutdown
Switch(config-if)# switchport mode dynamic desirable
Switch(config-if)# switchport trunk encapsulation dot1q
Switch(config-if)# no shutdown
Switch(config-if)# end
Switch# exit
```

This example shows how to verify the running configuration:

```
Switch# show running-config interface fastethernet 5/8
Building configuration...
Current configuration:
!
interface FastEthernet5/8
 switchport mode dynamic desirable
 switchport trunk encapsulation dot1q
end
```

This example shows how to verify the switch port configuration:

```
Switch# show interfaces fastethernet 5/8 switchport
Name: Fa5/8
Switchport: Enabled
Administrative Mode: dynamic desirable
Operational Mode: trunk
Administrative Trunking Encapsulation: negotiate
Operational Trunking Encapsulation: dot1q
Negotiation of Trunking: Enabled
Access Mode VLAN: 1 (default)
Trunking Native Mode VLAN: 1 (default)
Trunking VLANs Enabled: ALL
Pruning VLANs Enabled: 2-1001
```

This example shows how to verify the trunk configuration:

```
Switch# show interfaces fastethernet 5/8 trunk

Port      Mode           Encapsulation  Status        Native vlan
Fa5/8     desirable      n-802.1q       trunking      1

Port      Vlans allowed on trunk
Fa5/8     1-1005

Port      Vlans allowed and active in management domain
Fa5/8     1-6,10,20,50,100,152,200,300,303-305,349-351,400,500,521,524,570,801-802,850,917,999,1002-1005

Port      Vlans in spanning tree forwarding state and not pruned
Fa5/8     1-6,10,20,50,100,152,200,300,303-305,349-351,400,500,521,524,570,801-802,850,917,999,1002-1005

Switch#
```

Configuring an Interface as a Layer 2 Access Port

Note

If you assign an interface to a VLAN that does not exist, the interface is not operational until you create the VLAN in the VLAN database (see the [“Configuring VLANs in Global Configuration Mode”](#) section on page 17-5).

To configure an interface as a Layer 2 access port, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Specifies the interface to configure.
Step 2	Switch(config-if)# shutdown	(Optional) Shuts down the interface to prevent traffic flow until configuration is complete.
Step 3	Switch(config-if)# switchport	Configures the interface for Layer 2 switching: <ul style="list-style-type: none"> You must enter the switchport command once without any keywords to configure the interface as a Layer 2 port before you can enter additional switchport commands with keywords. Required only if you previously entered the no switchport command for the interface.
Step 4	Switch(config-if)# switchport mode access	Configures the interface as a Layer 2 access port.
Step 5	Switch(config-if)# switchport access vlan <i>vlan_num</i>	Places the interface in a VLAN.
Step 6	Switch(config-if)# no shutdown	Activates the interface. (Required only if you had shut down the interface.)
Step 7	Switch(config-if)# end	Exits interface configuration mode.

	Command	Purpose
Step 8	Switch# show running-config interface { fastethernet gigabitethernet } <i>slot/port</i>	Displays the running configuration of the interface.
Step 9	Switch# show interfaces [{ fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>] switchport	Displays the switch port configuration of the interface.

This example shows how to configure the Fast Ethernet interface 5/6 as an access port in VLAN 200:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fastethernet 5/6
Switch(config-if)# shutdown
Switch(config-if)# switchport mode access
Switch(config-if)# switchport access vlan 200
Switch(config-if)# no shutdown
Switch(config-if)# end
Switch# exit
```

This example shows how to verify the running configuration:

```
Switch# show running-config interface fastethernet 5/6
Building configuration...
!
Current configuration :33 bytes
interface FastEthernet 5/6
  switchport access vlan 200
  switchport mode access
end
```

This example shows how to verify the switch port configuration:

```
Switch# show interface fastethernet 5/6 switchport
Name:Fa5/6
Switchport:Enabled
Administrative Mode:dynamic auto
Operational Mode:static access
Administrative Trunking Encapsulation:negotiate
Operational Trunking Encapsulation:native
Negotiation of Trunking:On
Access Mode VLAN:1 (default)
Trunking Native Mode VLAN:1 (default)
Administrative private-vlan host-association:none
Administrative private-vlan mapping:none
Operational private-vlan:none
Trunking VLANs Enabled:ALL
Pruning VLANs Enabled:2-1001
Switch#
```

Clearing Layer 2 Configuration

To clear the Layer 2 configuration on an interface, perform this task:

	Command	Purpose
Step 1	Switch(config)# default interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Specifies the interface to clear.
Step 2	Switch(config-if)# end	Exits interface configuration mode.

	Command	Purpose
Step 3	Switch# show running-config interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Displays the running configuration of the interface.
Step 4	Switch# show interfaces [{ fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>] switchport	Displays the switch port configuration of the interface.

This example shows how to clear the Layer 2 configuration on the Fast Ethernet interface 5/6:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# default interface fastethernet 5/6
Switch(config)# end
Switch# exit
```

This example shows how to verify that the Layer 2 configuration was cleared:

```
Switch# show running-config interface fastethernet 5/6
Building configuration...
Current configuration:
!
interface FastEthernet5/6
end
```

This example shows how to verify the switch port configuration:

```
Switch# show interfaces fastethernet 5/6 switchport
Name: Fa5/6
Switchport: Enabled
Switch#
```

Configuring EVC-Lite

This document describes how to configure EVC-Lite, which is a lite version of the Ethernet Virtual Connections (EVC) feature on Supervisor Engine 7L-E. The associated command pages are also provided.

The document details:

- [About EVC-Lite, page 20-1](#)
- [How to Configure EVC-Lite, page 20-2](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About EVC-Lite

Ethernet virtual circuits (EVCs) define a Layer 2 bridging architecture that supports Ethernet services. An EVC is defined by the Metro-Ethernet Forum (MEF) as an association between two or more user network interfaces that identifies a point-to-point or multipoint-to-multipoint path within the service provider network. An EVC is a conceptual service pipe within the service provider network. A bridge domain is a local broadcast domain that exists separately from VLANs.

A Catalyst 4500 series switch comprises of two bridge domains (BDs), BD 0 and BD 1. By default, all ports belong to BD 0 and you can move them to BD 1 manually.

EVC-Lite supports 8K VLANs using the existing support of 8K Internal VLANs, segregated under the two BDs, where each BD has its own representation of 4K VLANs.

A system can have two types of VLAN's: EVC-Lite and non EVC-Lite (the default). Ordinary VLANs are VLANs without awareness of any BDs (the situation that exists when the feature is not enabled). EVC-Lite VLANs are treated differently in different bridge domains (e.g the same VLAN 2 is treated differently in BD 0 and BD 1).

A port can support both EVC-Lite and non EVC-Lite VLANs. EVC-Lite VLANs that are part of BD 1 are mapped to an internal VLAN ID as VLAN ID + 4096. Remaining VLANs are not mapped internally.

How to Configure EVC-Lite

Step 1 Create a VLAN:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vlan vlan-ID
Switch(config-vlan)# exit
```

Step 2 Configure the VLAN as an EVC-Lite VLAN:

```
Switch(config)# vlan configuration vlan_ID
Switch(config-vlan-config)# evc-lite
Switch(config-vlan-config)# exit
```

Step 3 Associate the EVC-Lite VLAN to an interface:

```
Switch(config)# interface gigabitEthernet slot/port
Switch(config-if)# switchport mode trunk
Switch(config-if)# switchport trunk allowed vlan vlan_ID
```

Step 4 Enable the interface with bridge-domain {0|1}:

```
Switch(config-if)#?
Interface configuration commands:
-----
      evc-lite          set the interface in evc-lite mode
--More--
Switch(config-if)# evc-lite bridge-domain bridge-domain
Switch(config-if)# exit
```

This sequence creates an EVC-Lite VLAN and associates it to an interface. The same VLAN can be associated with multiple interfaces, although each interface can have only one bridge-domain. On a Catalyst 4500 series switch, we can have two BDs (0 and 1). Because each BD supports 4K VLAN's, we can support 8K VLANs. An EVC-Lite VLAN can be associated with the BD 0 and 1 interfaces. However, traffic flowing on this VLAN under BD 1 will never flow under BD 0 and vice-versa.

This example shows how to configure VLAN 10 as EVC-Lite, enable interface GigabitEthernet 7/1 in BD 1, and display configured EVC-Lite VLANs and ports in BD 1:

```
Switch(config)# vlan configuration 10
Switch(config-vlan-config)# evc-lite
Switch(config-vlan-config)# exit
Switch# show running-config | begin vlan configuration
vlan configuration 10
    evc-lite

Switch(config)# interface gigabitEthernet 7/1
Switch(config-if)# switchport mode trunk
Switch(config-if)# evc-lite bridge-domain 1
Switch(config-if)# exit
Switch# show run interface gigabitEthernet 7/1
Building configuration...

Current configuration : 119 bytes
!
interface GigabitEthernet7/1
    switchport mode trunk
    evc-lite bridge-domain 1
end
```

```
Switch# show evc-lite
evc-lite vlans: 10
Ports in bridge-domain 1: Gi7/1
```

**Note**

Because a port channel can only accommodate member links belonging to the BD of the port-channel, the **show evc-lite** command displays only the port-channel instead of all the member links.

Configuring SmartPort Macros

This chapter describes how to configure and apply SmartPort and Static SmartPort macros on a Catalyst 4500 series switch. This chapter consists of these sections:

- [About SmartPort Macros and Static SmartPort, page 21-1](#)
- [Configuring SmartPort Macros, page 21-2](#)
- [Displaying SmartPort Macros, page 21-12](#)
- [Configuring Static SmartPort Macros, page 21-13](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About SmartPort Macros and Static SmartPort

SmartPort macros provide a convenient way to save and share common configurations. Use SmartPort macros to enable features and settings based on the location of a switch in the network and for mass configuration deployments across the network.

Each SmartPort macro is a set of CLI commands that you define. SmartPort macro sets do not contain new CLI commands; each SmartPort macro is a group of existing CLI commands.

When you apply a SmartPort macro on an interface, the CLI commands contained within the macro are configured on the interface. When the macro is applied to an interface, the existing interface configurations are not lost. The new commands are added to interface and are saved in the running configuration file.

In addition to SmartPort macros, static SmartPort macros provide port configuration that you manually apply based on the device connected to the port. When you apply a static SmartPort macro the CLI commands within the macro are added to the existing port configuration. When there is a link-down event on the port, the switch does not remove the static macro.

Cisco-default SmartPort macros are embedded in the switch software (see [Table 21-1](#)). You can display these macros and the commands they contain by using the **show parser macro** user EXEC command.

Table 21-1 *Cisco-Default SmartPort Macros*

Macro Name ¹	Description
cisco-global	Use this global configuration macro to enable rapid PVST+, loop guard, and dynamic port error recovery for link state failures.
cisco-desktop	Use this interface configuration macro for increased network security and reliability when connecting a desktop device, such as a PC, to a switch port.
cisco-phone	Use this interface configuration macro when connecting a desktop device such as a PC with a Cisco IP Phone to a switch port. This macro is an extension of the cisco-desktop macro and provides the same security and resiliency features, but with the addition of dedicated voice VLANs to ensure proper treatment of delay-sensitive voice traffic.
cisco-switch	Use this interface configuration macro when connecting an access switch and a distribution switch or between access switches connected using GigaStack modules or GBICs.
cisco-router	Use this interface configuration macro when connecting the switch and a WAN router.

1. Cisco-default SmartPort macros vary depending on the software version running on your switch.

Cisco also provides a collection of pretested, Cisco-recommended baseline configuration templates for Catalyst switches. The online reference guide templates provide the CLI commands that you use to create SmartPort macros based on the use of the port. Use the configuration templates to create SmartPort macros to build and deploy Cisco-recommended network designs and configurations.

Configuring SmartPort Macros

You can create a new SmartPort macro or use an existing macro as a template to create a new macro that is specific to your application. After you create the macro, you can apply it to an interface or a range of interfaces.

This section includes information about these topics:

- [Passing Parameters Through the Macro, page 21-2](#)
- [Default SmartPort Macro Configuration, page 21-3](#)
- [SmartPort Macro Configuration Guidelines, page 21-6](#)
- [Creating SmartPort Macros, page 21-7](#)
- [Applying SmartPort Macros, page 21-8](#)

Passing Parameters Through the Macro

Some commands might not be sufficiently generic for all the interfaces; for example, VLAN ID for Layer 2 interfaces and the IP address for Layer 3 interface. Retaining such commands in macro definitions requires that you change the value of such parameters (such as VLAN ID or IP address) before applying the macro to different interfaces. Alternatively, it requires that you create different macros for each possible value of its parameters.

The macro infrastructure can be enhanced to support accepting parameters while applying a macro. The parameters are passed as *keyword-value* pairs.

The CLI limits the number of keyword-value pairs to a maximum of three, where the first parameter must be the keyword, the second is its corresponding value, and the third parameter is the keyword for the second keyword-value pair. Here is an example of how to pass parameters to a command macro:

```
Switch(config)# macro name parameter-test  
Enter macro commands one per line. End with the character '@'.  
switchport mode access  
switchport access vlan $VLANID  
switchport port-security  
switchport port-security maximum $MAXHOST
```

If the above macro is applied to some interface without parameters, the invalid commands fail. Instead, you should apply the macro with appropriate keyword-value pair parameters, as follows:

```
Switch(config-if)# macro apply parameter-test $VLANID 1 $MAXHOST 5
```

The above command applies the macro after replacing \$VLANID with 1 and \$MAXHOST with 5. Be aware that you can specify any string in the macro as a keyword.

Macro Parameter Help

It is often difficult to remember the macro keywords while applying a macro to an interface or switch. Macros can contain the definitions for mandatory keywords. If you apply a macro without those keyword values, the commands are considered invalid and they fail.

You can enhance the macro infrastructure to provide help on keywords defined in macros. While creating a macro, you can specify a help string (as a comment) to list the mandatory keywords for that macro.

The following example illustrates how to specify the help string for the keywords:

```
Switch(config)# macro name test  
switchport access vlan $VLANID  
switchport port-security maximum $MAX  
#macro keywords $VLANID $MAX
```

Help string can be anywhere in the macro. The following example illustrates an alternate way to specify the help string:

```
Switch(config)# macro name test  
switchport access vlan $VLANID  
#macro keywords $VLANID  
switchport port-security maximum $MAX  
#macro keywords $MAX
```

Default SmartPort Macro Configuration

This section illustrates the default configurations for the four supported macros. These macros can only be viewed and applied; they cannot be modified by the user.

- [cisco-global, page 21-4](#)
- [cisco-desktop, page 21-4](#)
- [cisco-phone, page 21-4](#)
- [cisco-router, page 21-5](#)
- [cisco-switch, page 21-5](#)

cisco-global

This is the example for the cisco-global macro:

```
# Enable dynamic port error recovery for link state failures.
errdisable recovery cause link-flap
errdisable recovery interval 60

# VTP requires Transparent mode for future 802.1x Guest VLAN
# and current Best Practice
vtp domain [smartports]
vtp mode transparent

# Enable aggressive mode UDLD on all fiber uplinks
udld aggressive

# Enable Rapid PVST+ and Loopguard
spanning-tree mode rapid-pvst
spanning-tree loopguard default
spanning-tree extend system-id
```

cisco-desktop

This is the example for the cisco-desktop macro:

```
# Basic interface - Enable data VLAN only
# Recommended value for access vlan (AVID) should not be 1
switchport access vlan $AVID
switchport mode access
# Enable port security limiting port to a single
# MAC address -- that of desktop
switchport port-security
# Ensure port-security age is greater than one minute
# and use inactivity timer
# "Port-security maximum 1" is the default and will not
# Show up in the config
switchport port-security violation restrict
switchport port-security aging time 2
switchport port-security aging type inactivity
# Configure port as an edge network port
spanning-tree portfast
spanning-tree bpduguard enable
```

cisco-phone

This is the example for the cisco-phone macro:

```
# VoIP enabled interface - Enable data VLAN
# and voice VLAN (VVID)
# Recommended value for access vlan (AVID) should not be 1\
switchport access vlan $AVID
switchport mode access
# Update the Voice VLAN (VVID) value which should be
# different from data VLAN
# Recommended value for voice vlan (VVID) should not be 1
switchport voice vlan $VVID
# Enable port security limiting port to a 2 MAC
# addressess -- One for desktop and two for phone
switchport port-security
switchport port-security maximum 2
# Ensure port-security age is greater than one minute
# and use inactivity timer
```

```
switchport port-security violation restrict
switchport port-security aging time 2
switchport port-security aging type inactivity
# Enable auto-qos to extend trust to attached Cisco phone
auto qos voip cisco-phone
# Configure port as an edge network port
spanning-tree portfast
spanning-tree bpduguard enable@
```

cisco-router

This is the example for the cisco-router macro:

```
# Access Uplink to Distribution
switchport trunk encapsulation dot1q
# Define unique Native VLAN on trunk ports
# Recommended value for native vlan (NVID) should not be 1
switchport trunk native vlan $NVID
# Update the allowed VLAN range (VRANGE) such that it
# includes data, voice and native VLANs
# switchport trunk allowed vlan $VRANGE
# Hardcode trunk and disable negotiation to
# speed up convergence
# Hardcode speed and duplex to router
switchport mode trunk
switchport nonegotiate
speed 100
duplex full
# Configure qos to trust this interface
auto qos voip trust
qos trust dscp
# Ensure fast access to the network when enabling the interface.
# Ensure that switch devices cannot become active on the interface.
spanning-tree portfast
spanning-tree bpduguard enable
```

cisco-switch

This is the example for the cisco-switch macro:

```
# Access Uplink to Distribution
switchport trunk encapsulation dot1q
# Define unique Native VLAN on trunk ports
# Recommended value for native vlan (NVID) should not be 1
switchport trunk native vlan $NVID
# Update the allowed VLAN range (VRANGE) such that it
# includes data, voice and native VLANs
# switchport trunk allowed vlan $VRANGE
# Hardcode trunk and disable negotiation to
# speed up convergence
switchport mode trunk
switchport nonegotiate
# Configure qos to trust this interface
auto qos voip trust
# 802.1w defines the link as pt-pt for rapid convergence
spanning-tree link-type point-to-point
```

SmartPort Macro Configuration Guidelines

Follow these guidelines when configuring macros on your switch:

- If a command fails when you apply a macro, either due to a syntax error or to a configuration error, the macro continues to apply the remaining commands to the interface.
- **cisco-global** needs to be applied at the global configuration mode. We recommend that you apply this macro before any other interface level macro.
- Specific keywords are required when you apply the system-defined macros (**cisco-desktop**, **cisco-phone**, **cisco-switch**, and **cisco-router**) on an interface.
- When using the **cisco-phone** macro to apply port security, the port security maximum is 2 (**switchport port-security maximum 2**).
- At most, three keyword-value pairs are allowed per system-defined macro.
- When creating a macro, do not use the **exit** or **end** commands or change the command mode by using **interface interface-id**. This could cause commands that follow **exit**, **end**, or **interface interface-id** to execute in a different command mode.
- When creating a macro, ensure that all CLI commands are in the same configuration mode.
- When creating a macro that requires the assignment of unique values, use the **parameter value** keywords to designate values specific to the interface. Keyword matching is case sensitive. All matching occurrences of the keyword are replaced with the corresponding value. Any full match of a keyword, even if it is part of a larger string, is considered a match and is replaced by the corresponding value.
- Macro names are case sensitive. For example, the commands **macro name Sample-Macro** and **macro name sample-macro** result in two separate macros.
- Some macros might contain keywords that require a parameter value. Use the **macro global apply macro-name ?** global configuration command or the **macro apply macro-name ?** interface configuration command to display a list of any required values in the macro. If you apply a macro without entering the keyword values, the commands are invalid and are not applied.
- When a macro is applied globally to a switch or to a switch interface, all existing configuration on the interface is retained. It is helpful when applying an incremental configuration.
- If you modify a macro definition by adding or deleting commands, the changes are not reflected on the interface where the original macro was applied. You need to reapply the updated macro on the interface to apply the new or changed commands.
- Use the **macro global trace macro-name** global configuration command or the **macro trace macro-name** interface configuration command to apply and debug a macro to find any syntax or configuration errors. If a command fails because of a syntax error or a configuration error, the macro continues to apply the remaining commands.
- Some CLI commands are specific to certain interface types. If a macro is applied to an interface that does not accept the configuration, the macro fails the syntax check or the configuration check, and the switch returns an error message.
- Applying a macro to an interface range is the same as applying a macro to a single interface. When you use an interface range, the macro is applied sequentially to each interface within the range. If a macro command fails on one interface, it is still applied to the remaining interfaces.

- When you apply a macro to a switch or a switch interface, the macro name is automatically added to the macro description of the switch or interface. You can display the applied commands and macro names by using the **show parser macro description** user EXEC command.
- The user-configurable macro has a buffer that can take commands and comments up to 3000 characters. Each new line takes two characters, and empty lines are counted as is.

Cisco-default SmartPort macros are embedded in the switch software (see [Table 21-1](#)). You can display these macros and the commands they contain by using the **show parser macro** user EXEC command.

Follow these guidelines when you apply a Cisco-default SmartPort macro on an interface:

- Display all macros on the switch by using the **show parser macro** user EXEC command. Display the contents of a specific macro by using the **show parser macro macro-name** user EXEC command.
- Keywords that begin with \$ mean that a unique parameter value is required. Append the Cisco-default macro with the required values by using the **parameter value** keywords.

The Cisco-default macros use the \$ character to help identify required keywords. There is no restriction on using the \$ character to define keywords when you create a macro.

Creating SmartPort Macros

To create a SmartPort macro, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# macro name <i>macro-name</i>	<p>Creates a macro definition, and enter a macro name. A macro definition can contain up to 3000 characters.</p> <p>Enter the macro commands with one command per line. Use the @ character to end the macro. Use the # character at the beginning of a line to enter comment text within the macro.</p> <p>Macro names are case sensitive. For example, the commands macro name Sample-Macro and macro name sample-macro result in two separate macros.</p> <p>We recommend that you do not use the exit or end commands or change the command mode by using interface interface-id in a macro. This could cause any commands following exit, end, or interface interface-id to execute in a different command mode. For best results, all commands in a macro should be in the same configuration mode.</p> <p>Note The no form of the macro name global configuration command only deletes the macro definition. It does not affect the configuration of those interfaces on which the macro is already applied.</p>
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show parser macro name <i>macro-name</i>	Verifies that the macro was created.

Applying SmartPort Macros

To apply a SmartPort macro, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# macro global { apply trace } <i>macro-name</i> [parameter { <i>value</i> }] [parameter { <i>value</i> }] [parameter { <i>value</i> }]	<p>Applies each individual command defined in the macro to the switch by entering macro global apply macro-name. Specify macro global trace macro-name to apply and debug a macro to find any syntax or configuration errors.</p> <p>(Optional) Specify unique parameter values that are specific to the switch. You can enter up to three keyword-value pairs. Parameter keyword matching is case sensitive. All matching occurrences of the keyword are replaced with the corresponding value.</p> <p>Some macros might contain keywords that require a parameter value. Use the macro global apply macro-name ? command to display a list of any required values in the macro. If you apply a macro without entering the keyword values, the commands are invalid and are not applied.</p>
Step 3	Switch(config)# macro global description <i>text</i>	(Optional) Enters a description about the macro that is applied to the switch.
Step 4	Switch(config-if)# interface <i>interface-id</i>	(Optional) Enters interface configuration mode, and specify the interface on which to apply the macro.
Step 5	Switch(config-if)# default interface <i>interface-id</i>	(Optional) Clears all configuration from the specified interface.
Step 6	Switch(config-if)# macro { apply trace } <i>macro-name</i> [parameter { <i>value</i> }] [parameter { <i>value</i> }] [parameter { <i>value</i> }]	<p>Applies each individual command defined in the macro to the interface by entering macro apply macro-name. Specify macro trace macro-name to apply and debug a macro to find any syntax or configuration errors.</p> <p>(Optional) Specify unique parameter values that are specific to the interface. You can enter up to three keyword-value pairs. Parameter keyword matching is case sensitive. All matching occurrences of the keyword are replaced with the corresponding value.</p> <p>Some macros might contain keywords that require a parameter value. Use the macro apply macro-name ? command to display a list of any required values in the macro. If you apply a macro without entering the keyword values, the commands are invalid and are not applied.</p> <p>For example, here is how you apply this command:</p> <pre>Switch(config-if)# macro apply cisco-phone ? WORD Keyword to replace with a value e.g. \$AVID, \$VVID <cr></pre>
Step 7	Switch(config-if)# macro description <i>text</i>	(Optional) Enters a description about the macro that is applied to the interface.
Step 8	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 9	Switch# show parser macro description [interface <i>interface-id</i>]	Verifies that the macro is applied to the interface.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

You can delete a global macro-applied configuration on a switch only by entering the **no** version of each command that is in the macro. You can delete a macro-applied configuration on an interface by entering the **default interface** *interface-id* interface configuration command.

The **no** form of the **macro name** global configuration command deletes only the macro definition. It does not affect the configuration of those interfaces on which the macro is already applied. You can delete a macro-applied configuration on an interface by entering the **default interface** *interface-id* interface configuration command. Alternatively, you can create an *anti-macro* for an existing macro that contains the **no** form of all the corresponding commands in the original macro and apply the anti-macro to the interface.

The following sections describe how to apply and display the attachments on each of the supported macros:

- [cisco-global, page 21-9](#)
- [cisco-desktop, page 21-9](#)
- [cisco-phone, page 21-10](#)
- [cisco-switch, page 21-11](#)
- [cisco-router, page 21-11](#)

cisco-global

This example shows how to use the system-defined macro **cisco-global**:

```
Switch(config)# macro global apply cisco-global
Changing VTP domain name from gsg-switch to [smartports]
Setting device to VTP TRANSPARENT mode.
Switch(config)# end
Switch# show parser macro name cisco-global
Macro name : cisco-global
Macro type : default global
# Enable dynamic port error recovery for link state failures.
errdisable recovery cause link-flap
errdisable recovery interval 60

# VTP requires Transparent mode for future 802.1x Guest VLAN
# and current Best Practice vtp domain [smartports] vtp mode transparent

# Enable aggressive mode UDLD on all fiber uplinks udld aggressive

# Enable Rapid PVST+ and Loopguard
spanning-tree mode rapid-pvst
spanning-tree loopguard default
spanning-tree extend system-id
```

cisco-desktop

This example shows how to use the system-defined macro **cisco-desktop** to assign a value of 35 to the access VLAN of the Fast Ethernet interface 2/9.

Note

This macro requires the **\$AVID** keyword, which is the access VLAN of the port.

```
Switch(config)# interface fastethernet2/9
Switch(config-if)# macro apply cisco-desktop $AVID 35
Switch(config-if)# end
```

```

Switch# show parser macro name cisco-desktop
Macro name : cisco-desktop
Macro type : customizable

# Basic interface - Enable data VLAN only
# Recommended value for access vlan (AVID) should not be 1
switchport access vlan $AVID [access_vlan_id]
switchport mode access
# Enable port security limiting port to a single
# MAC address -- that of desktop
switchport port-security
# Ensure port-security age is greater than one minute
# and use inactivity timer
# "Port-security maximum 1" is the default and will not
# Show up in the config
switchport port-security violation restrict
switchport port-security aging time 2
switchport port-security aging type inactivity
# Configure port as an edge network port
spanning-tree portfast
spanning-tree bpduguard enable
Switch# show parser macro description
Interface      Macro Description
-----
Fa2/9          cisco-desktop
-----

```

cisco-phone

This example shows how to use the system-defined macro **cisco-phone** to assign a value of 35 to the access VLAN and 56 to the voice VLAN on the Fast Ethernet interface 2/9.

Note

This macro requires the **\$AVID** and **\$VVID** keywords, which are the access and voice VLANs of the port.

```

Switch(config)# interface fastethernet2/9
Switch(config-if)# macro apply cisco-phone
Switch(config-if)# macro description cisco-phone $AVID 35 $VVID 56
Switch(config-if)# end
Switch# show parser macro name cisco-phone
Macro name : cisco-phone
Macro type : customizable

# VoIP enabled interface - Enable data VLAN
# and voice VLAN (VVID)
# Recommended value for access vlan (AVID) should not be 1\
switchport access vlan $AVID [access_vlan_id]
switchport mode access
# Update the Voice VLAN (VVID) value which should be
# different from data VLAN
# Recommended value for voice vlan (VVID) should not be 1
switchport voice vlan $VVID [voice_vlan_id]
# Enable port security limiting port to a 2 MAC
# addressess -- One for desktop and one for phone
switchport port-security
switchport port-security maximum 2
# Ensure port-security age is greater than one minute
# and use inactivity timer
switchport port-security violation restrict
switchport port-security aging time 2

```

```

switchport port-security aging type inactivity
# Enable auto-qos to extend trust to attached Cisco phone
auto qos voip cisco-phone
# Configure port as an edge network port
spanning-tree portfast
spanning-tree bpduguard enable@

```

```
Switch# show parser macro description
```

```
Interface      Macro Description
```

```
-----
Fa2/9          cisco-phone
-----
```

cisco-switch

This example shows how to use the system-defined macro **cisco-switch** to assign a value of 38 to the native VLAN on the Fast Ethernet interface 2/9.

Note

This macro requires the **\$NVID** keyword, which is the native VLANs of the port.

```

Switch(config)# interface fastethernet2/9
Switch(config-if)# macro apply cisco-switch
Switch(config-if)# macro description cisco-switch $NVID 38
Switch(config-if)# end
Switch# show parser macro name cisco-switch
Macro name : cisco-switch
Macro type : customizable

```

```

# Access Uplink to Distribution
switchport trunk encapsulation dot1q
# Define unique Native VLAN on trunk ports
# Recommended value for native vlan (NVID) should not be 1
switchport trunk native vlan $NVID [native_vlan_id]
# Update the allowed VLAN range (VRANGE) such that it
# includes data, voice and native VLANs
# switchport trunk allowed vlan $VRANGE [vlan_range]
# Hardcode trunk and disable negotiation to
# speed up convergence
switchport mode trunk
switchport nonegotiate
# Configure qos to trust this interface
auto qos voip trust
# 802.1w defines the link as pt-pt for rapid convergence
spanning-tree link-type point-to-point

```

```
Switch# show parser macro description
```

```
Interface      Macro Description
```

```
-----
Fa2/9          cisco-switch
-----
```

cisco-router

This example shows how to use the system-defined macro **cisco-router** to assign a value of 451 to the native VLAN on the Fast Ethernet interface 2/9.

Note

This macro requires the **\$NVID** keyword, which is the native VLANs of the port.

```
Switch(config)# interface fastethernet2/9
Switch(config-if)# macro apply cisco-router
Switch(config-if)# macro description cisco-router $NVID 45I
Switch(config-if)# end
Switch# show parser macro name cisco-router
Macro name : cisco-router
Macro type : customizable

# Access Uplink to Distribution
switchport trunk encapsulation dot1q
# Define unique Native VLAN on trunk ports
# Recommended value for native vlan (NVID) should not be 1
switchport trunk native vlan $NVID [native_vlan_id]
# Update the allowed VLAN range (VRANGE) such that it
# includes data, voice and native VLANs
# switchport trunk allowed vlan $VRANGE [vlan_range]
# Hardcode trunk and disable negotiation to
# speed up convergence
# Hardcode speed and duplex to router
switchport mode trunk
switchport nonegotiate
speed 100
duplex full
# Configure qos to trust this interface
auto qos voip trust
qos trust dscp
# Ensure fast access to the network when enabling the interface.
# Ensure that switch devices cannot become active on the interface.
spanning-tree portfast
spanning-tree bpduguard enable

Switch# show parser macro description
Interface      Macro Description
-----
Fa2/9          cisco-router
-----
```

Displaying SmartPort Macros

To display the SmartPort macros, use one or more of the privileged EXEC commands in [Table 21-2](#).

Table 21-2 *Commands for Displaying SmartPort Macros*

Command	Purpose
<code>show parser macro</code>	Displays all configured macros.
<code>show parser macro name <i>macro-name</i></code>	Displays a specific macro.
<code>show parser macro brief</code>	Displays the configured macro names.
<code>show parser macro description [<i>interface interface-id</i>]</code>	Displays the macro description for all interfaces or for a specified interface.

Configuring Static SmartPort Macros

This section describes how to configure and enable static SmartPort macros:

- [Default SmartPort Macro Configuration, page 21-3](#)
- [SmartPort Macro Configuration Guidelines, page 21-6](#)
- [Applying Static SmartPort Macros, page 21-14](#)

Default Static SmartPort Configuration

No static SmartPort macros are enabled on the switch.

Table 21-3 **Default Static SmartPort Macros**

Macro Name ¹	Description
cisco-global	Use this global configuration macro to enable rapid PVST+, loop guard, and dynamic port error recovery for link state failures.
cisco-desktop	Use this interface configuration macro for increased network security and reliability when connecting a desktop device, such as a PC, to a switch port.
cisco-phone	Use this interface configuration macro when connecting a desktop device such as a PC with a Cisco IP Phone to a switch port. This macro is an extension of the cisco-desktop macro and provides the same security and resiliency features, but with the addition of dedicated voice VLANs to ensure proper treatment of delay-sensitive voice traffic.
cisco-switch	Use this interface configuration macro when connecting an access switch and a distribution switch or between access switches connected by using small form-factor pluggable (SFP) modules.
cisco-router	Use this interface configuration macro when connecting the switch and a WAN router.

1. Cisco-default SmartPort macros vary, depending on the software version running on your switch.

Static SmartPort Configuration Guidelines

- When a macro is applied globally to a switch or to a switch interface, all existing configuration on the interface is retained. It is helpful when applying an incremental configuration.
- If a command fails because of a syntax or a configuration error, the macro continues to apply the remaining commands. Use the **macro global trace macro-name** global configuration command or the **macro trace macro-name** interface configuration command to apply and debug a macro to find any syntax or configuration errors.
- Some CLI commands are specific to certain interface types. If you apply a macro to an interface that does not accept the configuration, the macro fails the syntax or the configuration check, and the switch returns an error message.
- Applying a macro to an interface range is the same as applying a macro to a single interface. When you use an interface range, the macro is applied sequentially to each interface within the range. If a macro command fails on one interface, it is still applied to the remaining interfaces.
- When you apply a macro to a switch or a switch interface, the macro name is automatically added to the switch or interface. You can display the applied commands and macro names by using the **show running-config** user EXEC command.

Applying Static SmartPort Macros

To apply a static SmartPort macro, perform these steps, beginning in privileged EXEC mode:

	Command	Purpose
Step 1	show parser macro	Displays the Cisco-default staticSmartPort macros embedded in the switch software.
Step 2	show parser macro name <i>macro-name</i>	Displays the specific macro that you want to apply.
Step 3	configure terminal	Enters global configuration mode.
Step 4	macro global { apply trace } <i>macro-name</i> [parameter { <i>value</i> }] [parameter { <i>value</i> }] [parameter { <i>value</i> }]	<p>Applies each individual command defined in the macro to the switch by entering macro global apply macro-name. Specify macro global trace macro-name to apply and to debug a macro to find any syntax or configuration errors.</p> <p>Append the macro with the required values by using the parameter value keywords. Keywords that begin with \$ require a unique parameter value.</p> <p>Use the macro global apply macro-name ? command to display a list of any required values for the macro. If you apply a macro without entering the keyword values, the commands are invalid and are not applied.</p> <p>(Optional) Specify unique parameter values that are specific to the switch. You can enter up to three keyword-value pairs. Parameter keyword matching is case sensitive. The corresponding value replaces all matching occurrences of the keyword.</p>
Step 5	interface <i>interface-id</i>	(Optional) Enters interface configuration mode, and specify the interface on which to apply the macro.
Step 6	default interface <i>interface-id</i>	(Optional) Clears all configuration from the specified interface.
Step 7	macro { apply trace } <i>macro-name</i> [parameter { <i>value</i> }] [parameter { <i>value</i> }] [parameter { <i>value</i> }]	<p>Applies each individual command defined in the macro to the port by entering macro global apply macro-name. Specify macro global trace macro-name to apply and to debug a macro to find any syntax or configuration errors.</p> <p>Append the macro with the required values by using the parameter value keywords. Keywords that begin with \$ require a unique parameter value.</p> <p>Use the macro global apply macro-name ? command to display a list of any required values for the macro. If you apply a macro without entering the keyword values, the commands are invalid and are not applied.</p> <p>(Optional) Specify unique parameter values that are specific to the switch. You can enter up to three keyword-value pairs. Parameter keyword matching is case sensitive. The corresponding value replaces all matching occurrences of the keyword.</p>
Step 8	end	Returns to privileged EXEC mode.
Step 9	show running-config interface <i>interface-id</i>	Verifies that the macro is applied to an interface.
Step 10	copy running-config startup-config	(Optional) Saves your entries in the configuration file.

You can only delete a global macro-applied configuration on a switch by entering the **no** version of each command in the macro. You can delete a macro-applied configuration on a port by entering the **default interface interface-id** interface configuration command.

This example shows how to display the **cisco-desktop** macro, to apply the macro and to set the access VLAN ID to 25 on an interface:

```
Switch# show parser macro cisco-desktop
-----
Macro name : cisco-desktop
Macro type : default

# Basic interface - Enable data VLAN only
# Recommended value for access vlan (AVID) should not be 1
switchport access vlan $AVID
switchport mode access

# Enable port security limiting port to a single
# MAC address -- that of desktop
switchport port-security
switchport port-security maximum 1

# Ensure port-security age is greater than one minute
# and use inactivity timer
switchport port-security violation restrict
switchport port-security aging time 2
switchport port-security aging type inactivity

# Configure port as an edge network port
spanning-tree portfast
spanning-tree bpduguard enable
-----
Switch# configure terminal
Switch(config)# interface gigabitethernet1/0/4
Switch(config-if)# macro apply cisco-desktop $AVID 25
```

Configuring Cisco IOS Auto Smartport Macros

This chapter describes how to configure macros on the Catalyst 4500 series switches.

This chapter includes the following major sections:

- [About Auto Smartport Macros, page 22-1](#)
- [Configuring Auto Smartport Macros, page 22-3](#)
- [Displaying Auto Smartport, page 22-14](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Auto Smartport Macros

Auto Smartport macros dynamically configure ports based on the device type detected on the port. When the switch detects a new device on a port, it applies the appropriate Auto Smartport macro. When a link-down event occurs on the port, the switch removes the macro. For example, when you connect a Cisco IP phone to a port, Auto Smartport automatically applies the Cisco IP phone macro. The Cisco IP phone macro enables quality of service (QoS), security features, and a dedicated voice VLAN to ensure proper treatment of delay-sensitive voice traffic.

Auto Smartport uses event triggers to map devices to macros. The most common event triggers are based on Cisco Discovery Protocol (CDP) messages received from connected devices. The detection of a device (Cisco IP phone, Cisco wireless access point, Cisco switch, or Cisco router) invokes an event trigger for that device.

Note

Although Auto SmartPort detects the Cisco switch it does not invoke the event trigger automatically. The event trigger needs to be manually invoked to map the switch to macros.

Link Layer Discovery Protocol (LLDP) is used to detect devices that do not support CDP. Other mechanisms used as event triggers include the 802.1X authentication result and MAC-address learned.

System built-in event triggers exist for various devices based mostly on CDP and LLDP messages (Table 22-1) and some MAC address. (Through Cisco IOS Release 12.2(54)SG, DMP is detected using the MAC address. Starting with Cisco IOS Release 15.0(2)SG, DMP is also detected using CDP.) These triggers are enabled as long as Auto Smartport is enabled.

You can also define your own trigger. User-defined triggers can be CDP/LLDP-based, a group of MAC addresses, or the value of the attribute-value (AV) pair for the **auto-smart-port** keyword.

The Auto Smartport macros are groups of CLI commands. Detection of devices on a port triggers the application of the macro for the device. (For example, detecting a CISCO_PHONE event on a port triggers the switch to apply the commands in the CISCO_PHONE_AUTO_SMARTPORT macro.) System built-in macros exist for various devices, and, by default, system built-in triggers are mapped to the corresponding built-in macros. You can change the mapping of built-in triggers or macros as needed.

A macro basically applies or removes a set of CLIs on an interface based on the link status. In a macro, the link status is checked. If the link is up, then a set of CLIs is applied; if the link is down, the set is removed (the **no** format of the CLIs are applied). The part of the macro that applies the set of CLIs is termed *macro*. The part that removes the CLIs (the **no** format of the CLIs) are termed *antimacro*.

Besides creating user-defined triggers, you can also create user-defined macros and map one to the other among all triggers (both built-in and user-defined) and all macros (both built-in and user-defined). Use the Cisco IOS scripting capability to create the macros. Cisco IOS scripting is a BASH-like language syntax for command automation and variable replacement.

The four detection mechanisms adhere to the following order of priority:

- If 802.1X authentication is configured on a port, an authentication response-based trigger is applied, and other triggers are ignored.
- If 802.1X authentication fails and the CDP/LLDP fallback mechanism is configured, CDP/LLDP triggers for phone devices only; if no fallback mechanism is configured, or a device is not a phone device, nothing is triggered.
- If 802.1X authentication is configured on a port, a MAC address-based trigger is never triggered.
- If 802.1X authentication is not configured on a port, CDP/LLDP has priority over a MAC address-based trigger with a hold-off timer applied for MAC-address based trigger. Between CDP/LLDP, there is no particular order; whichever one arrives first is triggered.

Device Classifier

Starting with Cisco Release IOS XE 3.3.0SG and IOS 15.1(1)SG, the device classifier (DC) feature is enabled by default on the Catalyst 4500 series switch.

The DC collects information from MAC-OUI and protocols such as CDP, LLDP, and DHCP to identify devices. You must enable CDP and LLDP on the switch. To make DHCP options information available to the DC, you must enable the DHCP snooping feature on the switch. The device attributes collected from these protocols are evaluated against a set of profiles available to the DC to find the best match. The best-matched profile is used for device identification.

Devices that do not send CDP, LLDP or DHCP traffic may not be properly identified by the device classifier.

Device-classifier uses profile definitions—built-in and default profiles. The built-in profiles contain the device profiles that are known to the Auto Smartport module, comprising a limited set of Cisco devices. They are built into Cisco IOS and cannot be changed. The default profiles are stored as a text file in nonvolatile storage and allow the DC to identify a much larger set of devices. The default profiles are updated as part of the Cisco IOS archive download.

When a new device is detected, the corresponding shell trigger executes the Auto Smartport configuration macro. Auto Smartport has built-in mappings for a large set of devices. You can use the commands described in the [“Configuring Mapping Between User-Defined Triggers and Built-in Macros” section on page 22-10](#) to create new mappings. You can create the trigger mappings based on the profile name or device name that is provided by the DC.

Device Visibility Mode

The DC function is enabled on the switch by default. You can disable it by using the **no macro auto monitor** global configuration command. The DC feature provides **show** commands to display the devices that are connected to the switch. It also provides information about the physical port to which the device is connected, along with device MAC address and other vendor information. Only directly connected devices, such as another Layer 2 switch, are classified on nonaccess ports. On access ports that are connected to hubs, device classification is limited to 32 devices.

When you enable Auto Smartport, the DC is automatically enabled.

Configuring Auto Smartport Macros

The following topics are included:

- [Enabling Auto Smartport Macros, page 22-3](#)
- [Auto Smartport Configuration Guidelines, page 22-5](#)
- [Configuring Auto Smartport Built-in Macro Parameters, page 22-6](#)
- [Configuring Mapping Between Event Triggers and Built-in Macros, page 22-8](#)
- [Configuring User-Defined Event Triggers, page 22-9](#)
- [Configuring Mapping Between User-Defined Triggers and Built-in Macros, page 22-10](#)
- [Configuring Auto Smartport User-Defined Macros, page 22-11](#)

Enabling Auto Smartport Macros

Note

By default, Auto Smartport is disabled globally. To disable Auto Smartport macros on a specific port, use the **no macro auto global processing** interface command before enabling Auto Smartport globally.

To enable Auto Smartport globally, use the **macro auto global processing** global configuration command.

To enable Auto Smartport macros, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# [no] macro auto global processing [cdp lldp]	Enables Auto Smartport on the switch globally. Note Starting with Release 15.0(2)SG, the fallback option has been deprecated. Use no macro auto global processing to disable Auto Smartport globally. Note The macro auto processing command turns Auto Smartport on or off on the interface level. The default is on.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config	Verifies that Auto Smartport is enabled.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **show shell functions** and the **show shell triggers** privileged EXEC command to display the event triggers, the built-in macros, and the built-in macro default values.

This example shows how enable Auto Smartport on the switch and how to disable the feature on a specific interface:

```
Switch(config)# macro auto global processing
Switch(config)# interface interface_id
Switch(config-if)# no macro auto processing
```

Auto Smartport Default Configuration

By default, Cisco IOS shell is enabled and Auto Smartport is disabled globally.

Table 22-1 shows the Auto Smartport built-in event triggers that are embedded in the switch software by default.

Table 22-1 Auto Smartport Built-in Event Trigger Macros

Event Trigger Name	Description
CISCO_PHONE_EVENT	System detects that a phone device is connected to an interface.
CISCO_SWITCH_EVENT	System detects that a switch is connected to an interface.
CISCO_ROUTER_EVENT	System detects that a router is connected to an interface.
CISCO_WIRELESS_AP_EVENT	System detects that a wireless application is connected to an interface.
CISCO_WIRELESS_LIGHTWEIGHT_AP_EVENT	System detects that a wireless lightweight application is connected to an interface.
CISCO_DMP_EVENT	System detects that a digital media player is connected to an interface.
CISCO_IPVSC_EVENT	System detects that an IP video surveillance camera is connected to an interface.

Table 22-2 shows the Auto Smartport built-in macros that are embedded in the switch software.

Table 22-2 Auto Smartport Built-in Macros

Macro Name	Description
CISCO_PHONE_AUTO_SMARTPORT	Use this macro for Cisco IP phone device. It enables QoS, port security, Address Resolution Protocol (ARP) inspection (dynamic ARP inspection), IP source guard, DHCP snooping, storm control and spanning tree protection on the port.
CISCO_SWITCH_AUTO_SMARTPORT	Use this macro to apply the switch macro for Cisco switches. It enables trunking on the port.
CISCO_ROUTER_AUTO_SMARTPORT	Use this macro to apply the router macro for Cisco routers. It enables QoS, trunking, and spanning-tree protection on the port.
CISCO_AP_AUTO_SMARTPORT	Use this macro to apply the wireless access point (AP) macro for Cisco APs. It enables support for an autonomous wireless access point and QoS on the port.
CISCO_LWAP_AUTO_SMARTPORT	Use this macro to apply the lightweight wireless access point macro for Cisco lightweight wireless APs. It enables QoS, port security, dynamic ARP inspection, IP source guard, DHCP snooping, storm control, and spanning tree protection on the port.
CISCO_IP_CAMERA_AUTO_SMARTPORT	Use this macro for a Cisco IP surveillance camera device. It enables QoS, port security, and access VLAN on the port.
CISCO_DMP_AUTOSMARTPORT	Use this macro for a Cisco digital media player device. It enables QoS, port security, and access VLAN on the port.

Note

By default, the built-in event triggers are mapped to the built-in macros.

Auto Smartport Configuration Guidelines

Auto Smartport guidelines include the following:

- To avoid system conflicts when Auto Smartport macros are applied, remove all port configuration except for 802.1X authentication.
- If the macro conflicts with the original configuration, some macro commands might not be applied, or some antimacro commands might not be applied. (The antimacro is the portion of the applied macro that removes it at link down.)

Note

Failure of one command in the macro halts the application of the entire macro.

For example, if 802.1X authentication is enabled, you cannot remove switchport-mode access configuration. You must remove the 802.1X authentication before removing the configuration.

- A port should not be a member of an EtherChannel when applying Auto Smartport macros.
If Auto Smartport is not yet enabled globally, disable Auto Smartport on all the EtherChannel ports before enabling it globally. If Auto Smartport is already enabled, shut down the port and disable it before adding the port to an EtherChannel.

Note

If an Auto Smartport macro is applied on an interface, EtherChannel configuration usually fails because of conflict with the auto-QoS configuration applied by the macro.

- The built-in macro default data VLAN is VLAN 1. The default voice VLAN is VLAN 2. You should modify the built-in macro default values if your switch uses different VLANs. To view all built-in macro default values, use the **show shell functions** privileged EXEC command.
- To detect non-Cisco devices for 802.1X authentication or MAB, configure the RADIUS server to support the Cisco AV pair **auto-smart-port=event trigger**. You must configure a user-defined trigger with the value returned in the AV pair for **auto-smart-port**.
- For stationary devices that do not support CDP, MAB, or 802.1X authentication, such as network printers, we recommend that you disable Auto Smartport on the port.
- If authentication is enabled on a port, the switch ignores CDP unless the **fallback cdp** keyword is in the **macro auto global processing** global configuration command.
- The order of CLI commands within the macro and the corresponding antimacro can differ.
- Before converting a port into an Layer 3 interface, enter the **no macro auto processing** command. This prevents Auto Smartport from applying macros on the interface. If Layer 3 is already configured, enter the **no macro auto processing** command on the Layer 3 interface enable Auto Smartport globally.
- Auto Smartport macros and Smartport cannot coexist on an interface.
- A switch applies a macro in accordance with the LLDP advertisement from the attached device. If the device does not identify itself properly, the wrong macro is applied. Consult the specific device documentation to ensure the device's firmware is current.
- The LWAP's WLC software version must be 6.0.188 (=> Cisco IOS 12.4(21a)JA2) or later to make it detectable as LWAP by AutoSmartport.
- As of Cisco IOS Release 12.2(54)SG, Auto Smartport does not support macros that apply EtherChannel configurations. Interfaces that belong to EtherChannel groups are treated as standard interfaces. You can apply macros on individual interfaces based on the device type but the CLIs in the macro (for example, auto-QoS) might conflict with an EtherChannel configuration. We recommend that you disable Auto Smartport on interfaces belonging to EtherChannels before you enable Auto Smartport globally. If Auto Smartport is already enabled, disable Auto Smartport on the interfaces before configuring EtherChannel.
- When a Cisco switch is detected on the Auto Smartport, you have to manually map the event trigger to either a built-in macro or user-defined macro. You need to also match the event trigger to the device PID.

Configuring Auto Smartport Built-in Macro Parameters

The switch automatically maps from built-in event triggers to built-in macros. You can replace the built-in macro default values with values that are specific to your switch.

To configure Auto Smartport built-in macros parameters, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.

Command	Purpose
Step 2 Switch(config)# macro auto execute <i>event trigger builtin built-in</i> <i>macro name [parameter=value]</i> <i>[parameter=value]</i>	Defines mapping from an event trigger to a built-in macro. Specify an <i>event trigger</i> value: <ul style="list-style-type: none"> CISCO_PHONE_EVENT CISCO_SWITCH_EVENT CISCO_ROUTER_EVENT CISCO_WIRELESS_AP_EVENT CISCO_WIRELESS_LIGHTWEIGHT_AP_EVENT CISCO_DMP_EVENT CISCO_IPVSC_EVENT WORD—Apply a user-defined event trigger. Specify a <i>built-in macro name</i> value: <ul style="list-style-type: none"> CISCO_PHONE_AUTO_SMARTPORT (Optional) Specify the parameter values: \$ACCESS_VLAN=(1) and \$VOICE_VLAN=(2). CISCO_SWITCH_AUTO_SMARTPORT (Optional) Specify the parameter values: \$NATIVE_VLAN=(1). CISCO_ROUTER_AUTO_SMARTPORT (Optional) Specify the parameter values: \$NATIVE_VLAN=(1). CISCO_AP_AUTO_SMARTPORT (Optional) Specify the parameter values: \$NATIVE_VLAN=(1). CISCO_LWAP_AUTO_SMARTPORT (Optional) Specify the parameter values: \$ACCESS_VLAN=(1). CISCO_DMP_AUTO_SMARTPORT CISCO_IP_CAMERA_AUTO_SMARTPORT (Optional) <i>parameter=value</i> —Replace default values that begin with \$. Enter new values in the form of name value pair separated by a space: [<i>name1=value1 name2=value2...</i>]. Default values are shown in parenthesis.
Step 3 Switch(config)# end	Returns to privileged EXEC mode.
Step 4 Switch# show running-config	Verifies your entries.
Step 5 Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

The **no macro auto execute event trigger** {[**builtin** *built-in macro name* [*parameter=value*]] | [*parameter=value*] {*function contents*}} command deletes the mapping.

This example shows how to use two built-in Auto Smartport macros for connecting Cisco switches and Cisco IP phones to the switch. This example modifies the default voice VLAN, access VLAN, and native VLAN for the trunk interface:

```
Switch# configure terminal
Switch(config)# macro auto execute CISCO_PHONE_EVENT builtin CISCO_PHONE_AUTO_SMARTPORT
ACCESS_VLAN=10 VOICE_VLAN=20
Switch(config)#
Switch(config)#
```

```

Switch(config)#!!! the next command enables auto smart ports globally
Switch(config)# macro auto global processing fallback cdp
Switch(config)#
Switch(config)# exit

Switch#
Switch# show running-config interface gigabitethernet2/7
Building configuration...

Current configuration : 284 bytes
!
switchport access vlan 10
switchport mode access
switchport voice vlan 2
switchport port-security maximum 2
switchport port-security
switchport port-security aging time 2
switchport port-security violation restrict
switchport port-security aging type inactivity
auto qos voip cisco-phone
qos trust device cisco-phone
neighbor device type phone
macro description CISCO_PHONE_EVENT
spanning-tree portfast
spanning-tree bpduguard enable
service-policy input AutoQos-VoIP-Input-Cos-Policy
service-policy output AutoQos-VoIP-Output-Policy
end

```

Note

You can also use the **macro auto device** command to simplify changing the parameters for a built-in function for a device type.

Configuring Mapping Between Event Triggers and Built-in Macros

Note

You need to perform this task when a Cisco switch is connected to the Auto Smartport.

To map event trigger to a built-in macros, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# macro auto execute event trigger builtin <i>built-in macro name</i>	Specifies a user-defined event trigger and a macro name. This action configures mapping from an event trigger to a built-in Auto Smartports macro .
Step 3	Switch(config)# macro auto trigger event trigger	Invokes the user-defined event trigger.
Step 4	Switch(config)# device <i>device_ID</i>	Matches the event trigger to the device identifier.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# show shell triggers	Displays the event triggers on the switch.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to map a event trigger called CISCO_SWITCH_EVENT to the built-in macro CISCO_SWITCH_AUTO_SMARTPORT.

```
Switch(config)# macro auto execute CISCO_SWITCH_EVENT builtin CISCO_SWITCH_AUTO_SMARTPORT
Switch(config)# macro auto trigger CISCO_SWITCH_EVENT
Switch(config)# device cisco WS-C3560CX-8PT-S
Switch(config)# exit
```

Configuring User-Defined Event Triggers

You can configure two types of event triggers: user-defined and MAC address-based.

The following sections describe these triggers:

- [802.1X-Based Event Trigger, page 22-9](#)
- [MAC Address-Based Event Trigger, page 22-10](#)

802.1X-Based Event Trigger

When using MAB or 802.1X authentication to trigger Auto Smartport macros, you need to create an event trigger that corresponds to the Cisco AV pair (**auto-smart-port=event trigger**) sent by the RADIUS server.

To configure an event trigger, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# shell trigger <i>identifier description</i>	Specifies the event trigger identifier and description. The identifier should have no spaces or hyphens between words.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show shell triggers	Displays the event triggers on the switch.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no shell trigger identifier** global configuration command to delete the event trigger.

The following example shows how to define a user-defined trigger:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# shell trigger RADIUS_MAB_EVENT MAC_AuthBypass Event
Switch(config)#
```

MAC Address-Based Event Trigger

To configure a MAC address group as an event trigger, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# macro auto mac-address <i>group</i>	Specifies a group of MAC address as an event trigger. Changes mode to config-mac-addr-grp. You can then add or remove the MAC address or Organizational Unique Identifier (OUI) from the group. The <i>group</i> value defines the user-defined trigger.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show shell triggers	Displays the event triggers on the switch.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no macro auto mac-address-group** *grp_name* to delete the event trigger.

Configuring Mapping Between User-Defined Triggers and Built-in Macros

You need to map the user-defined trigger to either a built-in macro or user-defined macro.

To map a user-defined trigger to a built-in macros, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# macro auto execute event trigger builtin <i>built-in macro</i> <i>name</i> [<i>parameter=value</i>] [<i>parameter=value</i>]	Specifies a user-defined event trigger and a macro name. This action replaces built-in macro default values, and configures mapping from an event trigger to a built-in Auto Smartport macros. Note When performing a mapping, you must provide parameter values. For example, you must specify \$ACCESS_VLAN=(1) and \$VOICE_VLAN=(2) for the macro CISCO_PHONE_AUTO_SMARTPORT.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show shell triggers	Displays the event triggers on the switch.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to map a user-defined event trigger called RADIUS_MAB_EVENT to the built-in macro CISCO_PHONE_AUTO_SMARTPORT with access VLAN set to 10, and how to verify the entries.

This procedure shows how to map a user-defined trigger to a built-in macro:

-
- Step 1** Connect the device to a MAB-enabled switch port.
 - Step 2** On the RADIUS server, set the attribute-value pair to auto-smart-port=RADIUS_MAB_EVENT.

Step 3 On the switch, create the event trigger RADIUS_MAB_EVENT.

The switch recognizes the attribute-value pair=RADIUS_MAB_EVENT response from the RADIUS server and applies the macro CISCO_PHONE_AUTO_SMARTPORT, as in the following example:

```
Switch(config)# macro auto execute RADIUS_MAB_EVENT builtin CISCO_PHONE_AUTO_SMARTPORT
ACCESS_VLAN=10
Switch(config)# exit
Switch# show shell triggers
User defined triggers
-----
Trigger Id: RADIUS_MAB_EVENT
Trigger description: MAC_AuthBypass Event
Trigger environment:
Trigger mapping function: CISCO_PHONE_AUTO_SMARTPORT
<output truncated>
```

Configuring Auto Smartport User-Defined Macros

The Cisco IOS shell provides basic scripting capabilities for configuring the user-defined Auto Smartport macros. These macros can contain multiple lines and can include any CLI command. You can also define variable substitution, conditionals, functions, and triggers within the macro.

Inside a user-defined macro, besides parameters specified through **macro auto execute trigger parameter-name=value ..**, you also can use the following variables published by EEM ([Table 22-3](#)):

Table 22-3 Variables Published by EEM

Parameter Name	Meaning
\$INTERFACE	Name of the interface where the trigger event is detected.
\$LINKUP	Indicates whether the interface is up or down (true/false).
\$TRIGGER	Name of the trigger event that is raised (for example, CISCO_PHONE_EVENT).
\$AUTH_ENABLED	Indicates whether 802.1X authentication is configured on the interface (true/false).

To map an event trigger to a user-defined macro, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# macro auto execute event trigger [parameter=value] {function contents}	Specifies a user-defined macro that maps to an event trigger. Specify an <i>event trigger</i> value: <ul style="list-style-type: none"> • CISCO_PHONE_EVENT • CISCO_SWITCH_EVENT • CISCO_ROUTER_EVENT • CISCO_WIRELESS_AP_EVENT • CISCO_WIRELESS_LIGHTWEIGHT_AP_EVENT • WORD Applies a user-defined event trigger. • CISCO_DMP_EVENT • CISCO_IPVSC_EVENT <i>function contents</i> —Specifies a user-defined macro to associate with the trigger. Enter the macro contents within braces. Begin the Cisco IOS shell commands with the left brace and end the command grouping with the right brace. (Optional) <i>parameter=value</i> —Replaces default values that begin with \$, enter new values in the form of name value pair separated by a space: [name1=value1 name2=value2...].
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config	Verifies your entries.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to map a user-defined event trigger called Cisco Digital Media Player (DMP) to a user-defined macro.

-
- Step 1** Connect the DMP to an 802.1X- or MAB-enabled switch port.
- Step 2** On the RADIUS server, set the attribute-value pair to **auto-smart-port** =MY_MEDIAPLAYER_EVENT.
- Step 3** On the switch, create the event trigger CISCO_DMP_EVENT, and map it to the user-defined macro commands shown below.

The switch recognizes the attribute-value pair=CISCO_DMP_EVENT response from the RADIUS server and applies the macro associated with this event trigger.

The following example shows the macro portion of the automacro:

```
Switch(config)# shell trigger CISCO_DMP_EVENT Cisco DMP player
Switch(config)# macro auto execute CISCO_DMP_EVENT {
if [[ $LINKUP -eq YES ]]; then
conf t
    interface $INTERFACE
        macro description $TRIGGER
        switchport access vlan 1
        switchport mode access
        switchport port-security
        switchport port-security maximum 1
        switchport port-security violation restrict
        switchport port-security aging time 2
        switchport port-security aging type inactivity
        spanning-tree portfast
        spanning-tree bpduguard enable
    exit
fi
```

The following represents the anti-macro portion of the automacro:

```
if [[ $LINKUP -eq NO ]]; then
conf t
interface $INTERFACE
    no macro description $TRIGGER
    no switchport access vlan 1
    if [[ $AUTH_ENABLED -eq NO ]]; then
        no switchport mode access
    fi
    no switchport port-security
    no switchport port-security maximum 1
    no switchport port-security violation restrict
    no switchport port-security aging time 2
    no switchport port-security aging type inactivity
    no spanning-tree portfast
    no spanning-tree bpduguard enable
    exit
fi
}
Switch(config)# end
```

Table 22-4 lists the supported shell keywords you can apply in your macros and antimacro statements.

Table 22-4 Supported Cisco IOS Shell Keywords

Command	Description
{	Begin the command grouping.
}	End the command grouping.
[[Use as a conditional construct.
]]	Use as a conditional construct.
else	Use as a conditional construct.
-eq	Use as a conditional construct.
fi	Use as a conditional construct.
if	Use as a conditional construct.
then	Use as a conditional construct.
-z	Use as a conditional construct.

Table 22-4 Supported Cisco IOS Shell Keywords (continued)

Command	Description
\$	Variables that begin with the \$ character are replaced with a parameter value.
#	Use the # character to enter comment text.

Table 22-5 lists the shell keywords that are not supported in macros and antimacros.

Table 22-5 Unsupported Cisco IOS Shell Reserved Keywords

Command	Description
	Pipeline.
case	Conditional construct.
esac	Conditional construct.
for	Looping construct.
function	Shell function.
in	Conditional construct.
select	Conditional construct.
time	Pipeline.
until	Looping construct.
while	Looping construct.

Displaying Auto Smartport

To display the Auto Smartport and static Smartport macros, use one or more of the privileged EXEC commands in Table 22-6.

Table 22-6 Commands for Displaying *Auto Smartport* and *Static Smartport* Macros

Command	Purpose
<code>show macro auto monitor clients</code>	Displays the clients using the device classifier facility on the switch.
<code>show macro auto monitor device</code>	Displays the devices connected to a switch and their associated properties.
<code>show macro auto monitor type</code>	Displays all the device types recognized by the device classifier.
<code>show parser macro</code>	Displays all static Smartport macros.
<code>show parser macro name <i>macro-name</i></code>	Displays a specific static Smartport macro.
<code>show parser macro brief</code>	Displays the static Smartport macro names.
<code>show parser macro description [<i>interface interface-id</i>]</code>	Displays the static Smartport macro description for all interfaces or for a specified interface.
<code>show shell</code>	Displays information about Auto Smartport event triggers and macros.

This example shows how to use the **show macro auto monitor device** privileged EXEC command with the optional **mac-address** keyword to view summary information about the connected device with the specified MAC address:

```
Switch# show macro auto monitor device mac-address 001f.9e90.1250
MAC_Address      Port_Id      Profile Name
=====
001f.9e90.1250   Gi1/0/4      Cisco-AP-Aironet-1130
=====
```

This example shows how to use the **show macro auto monitor type** privileged EXEC command with no optional keywords to view the devices recognized by the device classifier:

```
Switch# show macro auto monitor type table
Valid      Type      Profile Name      min Conf      ID
=====
Valid      Default   Apple-Device      10            0
Valid      Default   Aruba-Device      10            1
Valid      Default   Avaya-Device      10            2

This example shows how to use the **show shell triggers** privileged EXEC command to view the event triggers in the switch software:

```
Switch# show shell triggers
```

```
User defined triggers
```

```
-----
```

```
Built-in triggers
```

```
-----
```

```
Trigger Id: CISCO_PHONE_EVENT
```

```
Trigger description: Event for ip-phone macro
```

```
Trigger environment: ACCESS_VLAN=1 VOICE_VLAN=2
```

```
Trigger mapping function: CISCO_PHONE_AUTO_SMARTPORT
```

```
Trigger Id: CISCO_ROUTER_EVENT
```

```
Trigger description: Event for router macro
```

```
Trigger environment: NATIVE_VLAN=1
```

```
Trigger mapping function: CISCO_ROUTER_AUTO_SMARTPORT
```

```
Trigger Id: CISCO_SWITCH_EVENT
```

```

Trigger description: Event for switch macro
Trigger environment: NATIVE_VLAN=1
Trigger mapping function: CISCO_SWITCH_AUTO_SMARTPORT

Trigger Id: CISCO_WIRELESS_AP_EVENT
Trigger description: Event for Wireless Access Point macro
Trigger environment: NATIVE_VLAN=1
Trigger mapping function: CISCO_AP_AUTO_SMARTPORT

Trigger Id: CISCO_WIRELESS_LIGHTWEIGHT_AP_EVENT
Trigger description: Event for Wireless Lightweight Access Point macro
Trigger environment: NATIVE_VLAN=1
Trigger mapping function: CISCO_LWAP_AUTO_SMARTPORT

```

This example shows how to use the **show shell functions** privileged EXEC command to view the built-in macros in the switch software:

```

Switch# show shell functions
#User defined functions:

#Built-in functions:
function CISCO_AP_AUTO_SMARTPORT () {
    if [[ $LINKUP -eq YES ]]; then
        conf t
            interface $INTERFACE
                macro description $TRIGGER
                switchport trunk encapsulation dot1q
                switchport trunk native vlan $NATIVE_VLAN
                switchport trunk allowed vlan ALL
                switchport mode trunk
                switchport nonegotiate
                auto qos voip trust
                mls qos trust cos
            exit
        end
    fi
    if [[ $LINKUP -eq NO ]]; then
        conf t
            interface $INTERFACE
                no macro description
                no switchport nonegotiate
                no switchport trunk native vlan $NATIVE_VLAN
                no switchport trunk allowed vlan ALL
                no auto qos voip trust

Configuring STP and MST

This chapter describes how to configure the Spanning Tree Protocol (STP). This chapter also describes how to configure the IEEE 802.1s Multiple Spanning Tree (MST) protocol. MST is an IEEE standard derived from Cisco's proprietary Multi-Instance Spanning-Tree Protocol (MISTP) implementation. With MST, you can map a single spanning-tree instance to several VLANs.

It includes the following major sections:

- [About STP, page 23-1](#)
- [Default STP Configuration, page 23-7](#)
- [Configuring STP, page 23-7](#)
- [About MST, page 23-22](#)
- [MST Configuration Restrictions and Guidelines, page 23-28](#)
- [Configuring MST, page 23-28](#)
- [About MST-to-PVST+ Interoperability \(PVST+ Simulation\), page 23-35](#)
- [Configuring PVST+ Simulation, page 23-36](#)
- [About Detecting Unidirectional Link Failure, page 23-40](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About STP

STP is a Layer 2 link management protocol that provides path redundancy while preventing undesirable loops in the network. For a Layer 2 Ethernet network to function properly, only one active path can exist between any two stations. A loop-free subset of a network topology is called a spanning tree. The operation of a spanning tree is transparent to end stations, which cannot detect whether they are connected to a single LAN segment or a switched LAN of multiple segments.

Beginning in Cisco IOS Release 15.2(4)E and Cisco IOS Release 3.8.0E, Catalyst 4500 series switches by default, use STP (the IEEE 802.1w RSTP) on all VLANs. By default, a single spanning tree runs on each configured VLAN (provided you do not manually disable the spanning tree). You can enable and disable a spanning tree on a per-VLAN basis.

When you create fault-tolerant internetworks, you must have a loop-free path between all nodes in a network. The spanning tree algorithm calculates the best loop-free path throughout a switched Layer 2 network. Switches send and receive spanning tree frames at regular intervals. The switches do not forward these frames, but use the frames to construct a loop-free path.

Multiple active paths between end stations cause loops in the network. If a loop exists in the network, end stations might receive duplicate messages and switches might learn end station MAC addresses on multiple Layer 2 interfaces. These conditions result in an unstable network.

A spanning tree defines a tree with a root switch and a loop-free path from the root to all switches in the Layer 2 network. A spanning tree forces redundant data paths into a standby (blocked) state. If a network segment in the spanning tree fails and a redundant path exists, the spanning tree algorithm recalculates the spanning tree topology and activates the standby path.

When two ports on a switch are part of a loop, the spanning tree port priority and port path cost setting determine which port is put in the forwarding state and which port is put in the blocking state. The spanning tree port priority value represents the location of an interface in the network topology and how well located it is to pass traffic. The spanning tree port path cost value represents media speed.

These sections describe STP:

- [Understanding the Bridge ID, page 23-2](#)
- [Bridge Protocol Data Units, page 23-3](#)
- [Election of the Root Bridge, page 23-4](#)
- [STP Timers, page 23-4](#)
- [Creating the STP Topology, page 23-5](#)
- [STP Port States, page 23-5](#)
- [MAC Address Allocation, page 23-6](#)
- [STP and IEEE 802.1Q Trunks, page 23-6](#)
- [Per-VLAN Rapid Spanning Tree, page 23-6](#)

Understanding the Bridge ID

Each VLAN on each network device has a unique 64-bit bridge ID consisting of a bridge priority value, an extended system ID, and an STP MAC address allocation.

Bridge Priority Value

The bridge priority value determines whether a given redundant link is given priority and considered part of a given span in a spanning tree. Preference is given to lower values, and if you want to manually configure a preference, assign a lower bridge priority value to a link than to its redundant possibility. With Cisco IOS releases prior to 12.1(12c)EW, the bridge priority is a 16-bit value (see [Table 23-1](#)). With Cisco IOS Release 12.1(12c)EW and later releases, the bridge priority is a 4-bit value when the extended system ID is enabled (see [Table 23-2](#)). See the “[Configuring the Bridge Priority of a VLAN](#)” section on [page 23-17](#).

Extended System ID

Extended system IDs are VLAN IDs between 1025 and 4096. Cisco IOS Releases 12.1(12c)EW and later releases support a 12-bit extended system ID field as part of the bridge ID (see [Table 23-2](#)). Chassis that support only 64 MAC addresses always use the 12-bit extended system ID. On chassis that support 1024 MAC addresses, you can enable use of the extended system ID. STP uses the VLAN ID as the extended system ID. See the “[Enabling the Extended System ID](#)” section on page 23-9.

Table 23-1 Bridge Priority Value with the Extended System ID Disabled

Bridge Priority Value															
Bit 16	Bit 15	Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Bit 9	Bit 8	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1
32768	16384	8192	4096	2048	1024	512	256	128	64	32	16	8	4	2	1

Table 23-2 Bridge Priority Value and Extended System ID with the Extended System ID Enabled

Bridge Priority Value				Extended System ID (Set Equal to the VLAN ID)											
Bit 16	Bit 15	Bit 14	Bit 13	Bit 12	Bit 11	Bit 10	Bit 9	Bit 8	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1
32768	16384	8192	4096	VLAN ID											

STP MAC Address Allocation

A Catalyst 4500 series switch chassis has either 64 or 1024 MAC addresses available to support software features like STP. Enter the **show module** command to view the MAC address range on your chassis.

Cisco IOS Release 12.1(12c)EW and later releases support chassis with 64 or 1024 MAC addresses. For chassis with 64 MAC addresses, STP uses the extended system ID plus a MAC address to make the bridge ID unique for each VLAN.

Earlier releases support chassis with 1024 MAC addresses. With earlier releases, STP uses one MAC address per-VLAN to make the bridge ID unique for each VLAN.

Bridge Protocol Data Units

The following elements determine the stable active spanning tree topology of a switched network:

- The unique bridge ID (bridge priority and MAC address) associated with each VLAN on each switch
- The spanning tree path cost (or bridge priority value) to the root bridge
- The port identifier (port priority and MAC address) associated with each Layer 2 interface

Bridge protocol data units (BPDUs) contain information about the transmitting bridge and its ports, including the bridge and MAC addresses, bridge priority, port priority, and path cost. The system computes the spanning tree topology by transmitting BPDUs among connecting switches, and in one direction from the root switch. Each configuration BPDU contains at least the following:

- The unique bridge ID of the switch that the transmitting switch believes to be the root switch
- The spanning tree path cost to the root
- The bridge ID of the transmitting bridge
- The age of the message

- The identifier of the transmitting port
- Values for the *hello*, *forward delay*, and *max-age* protocol timers

When a switch transmits a BPDU frame, all switches connected to the LAN on which the frame is transmitted receive the BPDU. When a switch receives a BPDU, it does not forward the frame but instead uses the information in the frame to calculate a BPDU and, if the topology changes, initiate a BPDU transmission.

A BPDU exchange results in the following:

- One switch is elected as the root bridge.
- The shortest distance to the root bridge is calculated for each switch based on the path cost.
- A designated bridge for each LAN segment is selected. It is the switch closest to the root bridge through which frames are forwarded to the root.
- A root port is selected. It is the port providing the best path from the bridge to the root bridge.
- Ports included in the spanning tree are selected.

Election of the Root Bridge

For each VLAN, the switch with the highest bridge priority (the lowest numerical priority value) is elected as the root bridge. If all switches are configured with the default priority value (32,768), the switch with the lowest MAC address in the VLAN becomes the root bridge.

The spanning tree root bridge is the logical center of the spanning tree topology in a switched network. All paths that are not required to reach the root bridge from anywhere in the switched network are placed in spanning tree blocking mode.

A spanning tree uses the information provided by BPDUs to elect the root bridge and root port for the switched network, as well as the root port and designated port for each switched segment.

STP Timers

Table 23-3 describes the STP timers that affect the performance of the entire spanning tree.

Table 23-3 **Spanning Tree Protocol Timers**

Variable	Description
<i>hello_time</i>	Determines how often the switch broadcasts hello messages to other switches.
<i>forward_time</i>	Determines how long each of the listening and learning states last before the port begins forwarding.
<i>max_age</i>	Determines the amount of time that protocol information received on a port is stored by the switch.

Creating the STP Topology

The goal of the spanning tree algorithm is to make the most direct link the root port. When the spanning tree topology is calculated based on default parameters, the path between source and destination end stations in a switched network might not be optimal according to link speed. For instance, connecting higher-speed links to a port that has a higher number than the current root port can cause a root-port change.

In [Figure 23-1](#), Switch A is elected as the root bridge. (This could happen if the bridge priority of all the switches is set to the default value [32,768] and Switch A has the lowest MAC address.) However, due to traffic patterns, the number of forwarding ports, or link types, Switch A might not be the ideal root bridge. By increasing the STP port priority (lowering the numerical value) of the ideal switch so that it becomes the root bridge, you force a spanning tree recalculation to form a new spanning tree topology with the ideal switch as the root.

Figure 23-1 Spanning Tree Topology

RP = Root Port
DP = Designated Port

For example, assume that one port on Switch B is a fiber-optic link, and another port on Switch B (an unshielded twisted-pair [UTP] link) is the root port. Network traffic might be more efficient over the high-speed fiber-optic link. By changing the spanning tree port priority on the fiber-optic port to a higher priority (lower numerical value) than the priority set for the root port, the fiber-optic port becomes the new root port.

STP Port States

Propagation delays can occur when protocol information passes through a switched LAN. As a result, topology changes can take place at different times and at different places in a switched network. When a Layer 2 interface transitions directly from nonparticipation in the spanning tree topology to the forwarding state, it can create temporary data loops. Ports must wait for new topology information to propagate through the switched LAN before starting to forward frames. They must allow the frame lifetime to expire for frames that have been forwarded under the old topology.

Each Layer 2 interface on a switch that uses spanning tree exists in one of the following five states:

- **Blocking**—In this state, the Layer 2 interface does not participate in frame forwarding.
- **Listening**—This state is the first transitional state after the blocking state when spanning tree determines that the Layer 2 interface should participate in frame forwarding.
- **Learning**—In this state, the Layer 2 interface prepares to participate in frame forwarding.
- **Forwarding**—In this state, the Layer 2 interface forwards frames.

- Disabled—In this state, the Layer 2 interface does not participate in spanning tree and does not forward frames.

MAC Address Allocation

The supervisor engine has a pool of 1024 MAC addresses that are used as the bridge IDs for the VLAN spanning trees. Use the **show module** command to view the MAC address range (allocation range for the supervisor) that the spanning tree uses for the algorithm.

MAC addresses for the Catalyst 4506 switch are allocated sequentially, with the first MAC address in the range assigned to VLAN 1, the second MAC address in the range assigned to VLAN 2, and so forth. For example, if the MAC address range is 00-e0-1e-9b-2e-00 to 00-e0-1e-9b-31-ff, the VLAN 1 bridge ID is 00-e0-1e-9b-2e-00, the VLAN 2 bridge ID is 00-e0-1e-9b-2e-01, the VLAN 3 bridge ID is 00-e0-1e-9b-2e-02, and so on. On other Catalyst 4500 series platforms, all VLANs map to the same MAC address rather than mapping to separate MAC addresses.

STP and IEEE 802.1Q Trunks

802.1Q VLAN trunks impose some limitations on the spanning tree strategy for a network. In a network of Cisco switches connected through 802.1Q trunks, the switches maintain one instance of spanning tree for each VLAN allowed on the trunks. However, non-Cisco 802.1Q switches maintain only one instance of spanning tree for all VLANs allowed on the trunks.

When you connect a Cisco switch to a non-Cisco device (that supports 802.1Q) through an 802.1Q trunk, the Cisco switch combines the spanning tree instance of the 802.1Q native VLAN of the trunk with the spanning tree instance of the non-Cisco 802.1Q switch. However, all per-VLAN spanning tree information is maintained by Cisco switches separated by a network of non-Cisco 802.1Q switches. The non-Cisco 802.1Q network separating the Cisco switches is treated as a single trunk link between the switches.

**Note**

For more information on 802.1Q trunks, see [Chapter 19, “Configuring Layer 2 Ethernet Interfaces.”](#)

Per-VLAN Rapid Spanning Tree

Beginning in Cisco IOS XE Release 3.8.0E and Cisco IOS Release 15.2(4)E, Per-VLAN Rapid Spanning Tree (PVRST+) is the default STP mode on Catalyst 4500 Series Switches.

Per-VLAN Rapid Spanning Tree is the same as PVST+, although PVRST+ utilizes a rapid STP based on IEEE 802.1w rather than 802.1D to provide faster convergence. PVRST+ uses roughly the same configuration as PVST+ and needs only minimal configuration. In PVRST+, dynamic CAM entries are flushed immediately on a per-port basis when any topology change is made. UplinkFast and BackboneFast are enabled but not active in this mode, because the functionality is built into the Rapid STP. PVRST+ provides for rapid recovery of connectivity following the failure of a bridge, bridge port, or LAN.

Like per-VLAN Spanning Tree (PVST+), per-VLAN Rapid Spanning Tree (PVRST+) instances are equal to the number of vlans configured on the switch and can go up to a maximum of 4094 instances.

For enabling information, see “Enabling Per-VLAN Rapid Spanning Tree” on page 20.

Default STP Configuration

Table 23-4 shows the default spanning tree configuration.

Table 23-4 Spanning Tree Default Configuration Values

Feature	Default Value
Enable state	Spanning tree enabled for all VLANs
Bridge priority value	32,768
Spanning tree port priority value (configurable on a per-interface basis—used on interfaces configured as Layer 2 access ports)	128
Spanning tree port cost (configurable on a per-interface basis—used on interfaces configured as Layer 2 access ports)	<ul style="list-style-type: none"> 10-Gigabit Ethernet: 2 Gigabit Ethernet: 4 Fast Ethernet: 19
Spanning tree VLAN port priority value (configurable on a per-VLAN basis—used on interfaces configured as Layer 2 trunk ports)	128
Spanning tree VLAN port cost (configurable on a per-VLAN basis—used on interfaces configured as Layer 2 trunk ports)	<ul style="list-style-type: none"> 10-Gigabit Ethernet: 2 Gigabit Ethernet: 4 Fast Ethernet: 19
Hello time	2 sec
Forward delay time	15 sec
Maximum aging time	20 sec

Configuring STP

The following sections describe how to configure spanning tree on VLANs:

- [Enabling STP, page 23-8](#)
- [Enabling the Extended System ID, page 23-9](#)
- [Configuring the Root Bridge, page 23-9](#)
- [Configuring a Secondary Root Switch, page 23-12](#)
- [Configuring STP Port Priority, page 23-13](#)
- [Configuring STP Port Cost, page 23-15](#)
- [Configuring the Bridge Priority of a VLAN, page 23-17](#)
- [Configuring the Hello Time, page 23-17](#)
- [Configuring the Maximum Aging Time for a VLAN, page 23-18](#)
- [Configuring the Forward-Delay Time for a VLAN, page 23-19](#)
- [Disabling Spanning Tree Protocol, page 23-20](#)
- [Enabling Per-VLAN Rapid Spanning Tree, page 23-20](#)

**Note**

The spanning tree commands described in this chapter can be configured on any interface except those configured with the **no switchport** command.

Enabling STP

**Note**

By default, spanning tree is enabled on all the VLANs.

You can enable a spanning tree on a per-VLAN basis. The switch maintains a separate instance of spanning tree for each VLAN (except on VLANs on which you have disabled a spanning tree).

To enable a spanning tree on a per-VLAN basis, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# spanning-tree vlan <i>vlan_ID</i>	Enables spanning tree for VLAN <i>vlan_id</i> . The <i>vlan_ID</i> value can range from 1 to 4094.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show spanning-tree vlan <i>vlan_ID</i>	Verifies that spanning tree is enabled.

This example shows how to enable a spanning tree on VLAN 200:

```
Switch# configure terminal
Switch(config)# spanning-tree vlan 200
Switch(config)# end
Switch#
```

**Note**

Because spanning tree is enabled by default, entering a **show running** command to view the resulting configuration does not display the command you entered to enable spanning tree.

This example shows how to verify that spanning tree is enabled on VLAN 200:

```
Switch# show spanning-tree vlan 200
```

```
VLAN200 is executing the ieee compatible Spanning Tree protocol
Bridge Identifier has priority 32768, address 0050.3e8d.6401
Configured hello time 2, max age 20, forward delay 15
Current root has priority 16384, address 0060.704c.7000
Root port is 264 (FastEthernet5/8), cost of root path is 38
Topology change flag not set, detected flag not set
Number of topology changes 0 last change occurred 01:53:48 ago
Times: hold 1, topology change 24, notification 2
      hello 2, max age 14, forward delay 10
Timers: hello 0, topology change 0, notification 0
```

```
Port 264 (FastEthernet5/8) of VLAN200 is forwarding
Port path cost 19, Port priority 128, Port Identifier 129.9.
Designated root has priority 16384, address 0060.704c.7000
Designated bridge has priority 32768, address 00e0.4fac.b000
Designated port id is 128.2, designated path cost 19
Timers: message age 3, forward delay 0, hold 0
Number of transitions to forwarding state: 1
```

```
BPDU: sent 3, received 3417
```

```
Switch#
```

Enabling the Extended System ID

Note

The extended system ID is enabled permanently on chassis that support 64 MAC addresses.

Use the **spanning-tree extend system-id** command to enable the extended system ID on chassis that support 1024 MAC addresses. See the [“Understanding the Bridge ID” section on page 23-2](#).

To enable the extended system ID, perform this task:

	Command	Purpose
Step 1	Switch(config) # spanning-tree extend system-id	Enables the extended system ID.
		Disables the extended system ID. Note You cannot disable the extended system ID on chassis that support 64 MAC addresses or when you have configured extended range VLANs (see Table 23-4 on page 23-7).
Step 2	Switch(config) # end	Exits configuration mode.
Step 3	Switch# show spanning-tree vlan <i>vlan_ID</i>	Verifies the configuration.

Note

When you enable or disable the extended system ID, the bridge IDs of all active STP instances are updated, which might change the spanning tree topology.

This example shows how to enable the extended system ID:

```
Switch# configure terminal
Switch(config)# spanning-tree extend system-id
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show spanning-tree summary | include extended
Extended system ID is enabled.
```

Configuring the Root Bridge

A Catalyst 4500 series switch maintains an instance of spanning tree for each active VLAN configured on the switch. A bridge ID, consisting of the bridge priority and the bridge MAC address, is associated with each instance. For each VLAN, the switch with the lowest bridge ID becomes the root bridge for that VLAN. Whenever the bridge priority changes, the bridge ID also changes, resulting in the recomputation of the root bridge for the VLAN.

To configure a switch to become the root bridge for the specified VLAN, use the **spanning-tree vlan *vlan-ID* root** command to modify the bridge priority from the default value (32,768) to a significantly lower value. The bridge priority for the specified VLAN is set to 8192 if this value causes the switch to become the root for the VLAN. If any bridge for the VLAN has a priority lower than 8192, the switch sets the priority to 1 less than the lowest bridge priority.

For example, assume that all the switches in the network have the bridge priority for VLAN 100 set to the default value of 32,768. Entering the **spanning-tree vlan 100 root primary** command on a switch sets the bridge priority for VLAN 100 to 8192, causing this switch to become the root bridge for VLAN 100.

Note

The root switch for each instance of spanning tree should be a backbone or distribution switch. Do not configure an access switch as the spanning tree primary root.

Use the **diameter** keyword to specify the Layer 2 network diameter (the maximum number of bridge hops between any two end stations in the network). When you specify the network diameter, a switch automatically picks an optimal hello time, forward delay time, and maximum age time for a network of that diameter. This action can significantly reduce the spanning tree convergence time.

Use the **hello-time** keyword to override the automatically calculated hello time.

Note

We recommend that you avoid manually configuring the hello time, forward delay time, and maximum age time after configuring the switch as the root bridge.

To configure a switch as the root switch, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] spanning-tree vlan <i>vlan_ID</i> root primary [diameter <i>hops</i> [hello-time <i>seconds</i>]]	Configures a switch as the root switch.
		Use the no keyword to restore the defaults.
Step 2	Switch(config)# end	Exits configuration mode.

This example shows how to configure a switch as the root bridge for VLAN 10, with a network diameter of 4:

```
Switch# configure terminal
Switch(config)# spanning-tree vlan 10 root primary diameter 4
Switch(config)# end
Switch#
```

This example shows how the configuration changes when a switch becomes a spanning tree root. This configuration is the one before the switch becomes the root for VLAN 1:

```
Switch# show spanning-tree vlan 1

VLAN1 is executing the ieee compatible Spanning Tree protocol
Bridge Identifier has priority 32768, address 0030.94fc.0a00
Configured hello time 2, max age 20, forward delay 15
Current root has priority 32768, address 0001.6445.4400
Root port is 323 (FastEthernet6/3), cost of root path is 19
Topology change flag not set, detected flag not set
Number of topology changes 2 last change occurred 00:02:19 ago
    from FastEthernet6/1
Times: hold 1, topology change 35, notification 2
    hello 2, max age 20, forward delay 15
```

```

Timers:hello 0, topology change 0, notification 0, aging 300

Port 323 (FastEthernet6/3) of VLAN1 is forwarding
  Port path cost 19, Port priority 128, Port Identifier 129.67.
  Designated root has priority 32768, address 0001.6445.4400
  Designated bridge has priority 32768, address 0001.6445.4400
  Designated port id is 129.67, designated path cost 0
  Timers:message age 2, forward delay 0, hold 0
  Number of transitions to forwarding state:1
  BPDU:sent 3, received 91

Port 324 (FastEthernet6/4) of VLAN1 is blocking
  Port path cost 19, Port priority 128, Port Identifier 129.68.
  Designated root has priority 32768, address 0001.6445.4400
  Designated bridge has priority 32768, address 0001.6445.4400
  Designated port id is 129.68, designated path cost 0
  Timers:message age 2, forward delay 0, hold 0
  Number of transitions to forwarding state:0
  BPDU:sent 1, received 89

```

You can set the switch as the root:

```

Switch# configure terminal
Switch(config)# spanning-tree vlan 1 root primary
Switch(config)# spanning-tree vlan 1 root primary
VLAN 1 bridge priority set to 8192
VLAN 1 bridge max aging time unchanged at 20
VLAN 1 bridge hello time unchanged at 2
VLAN 1 bridge forward delay unchanged at 15
Switch(config)# end

```

This configuration is the one after the switch becomes the root:

```

Switch# show spanning-tree vlan 1

VLAN1 is executing the ieee compatible Spanning Tree protocol
  Bridge Identifier has priority 8192, address 0030.94fc.0a00
  Configured hello time 2, max age 20, forward delay 15
  We are the root of the spanning tree
  Topology change flag set, detected flag set
  Number of topology changes 3 last change occurred 00:00:09 ago
  Times: hold 1, topology change 35, notification 2
         hello 2, max age 20, forward delay 15
  Timers:hello 0, topology change 25, notification 0, aging 15

Port 323 (FastEthernet6/3) of VLAN1 is forwarding
  Port path cost 19, Port priority 128, Port Identifier 129.67.
  Designated root has priority 8192, address 0030.94fc.0a00
  Designated bridge has priority 8192, address 0030.94fc.0a00
  Designated port id is 129.67, designated path cost 0
  Timers:message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state:1
  BPDU:sent 9, received 105

Port 324 (FastEthernet6/4) of VLAN1 is listening
  Port path cost 19, Port priority 128, Port Identifier 129.68.
  Designated root has priority 8192, address 0030.94fc.0a00
  Designated bridge has priority 8192, address 0030.94fc.0a00
  Designated port id is 129.68, designated path cost 0
  Timers:message age 0, forward delay 5, hold 0
  Number of transitions to forwarding state:0
  BPDU:sent 6, received 102

Switch#

```

Because the bridge priority is now set at 8192, this switch becomes the root of the spanning tree.

Configuring a Secondary Root Switch

When you configure a switch as the secondary root, the spanning tree bridge priority is modified from the default value (32,768) to 16,384. This means that the switch is likely to become the root bridge for the specified VLANs if the primary root bridge fails (assuming the other switches in the network use the default bridge priority of 32,768).

You can run this command on more than one switch to configure multiple backup root switches. Use the same network diameter and hello time values that you used when configuring the primary root switch.

We recommend that you avoid manually configuring the hello time, forward delay time, and maximum age time after configuring the switch as the root bridge.

To configure a switch as the secondary root switch, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] spanning-tree vlan vlan_ID root secondary [diameter hops [hello-time seconds]]	Configures a switch as the secondary root switch. Use the no keyword to restore the defaults.
Step 2	Switch(config)# end	Exits configuration mode.

This example shows how to configure the switch as the secondary root switch for VLAN 10, with a network diameter of 4:

```
Switch# configure terminal
Switch(config)# spanning-tree vlan 10 root secondary diameter 4
VLAN 10 bridge priority set to 16384
VLAN 10 bridge max aging time set to 14
VLAN 10 bridge hello time unchanged at 2
VLAN 10 bridge forward delay set to 10
Switch(config)# end
Switch#
```

This example shows how to verify the configuration of VLAN 1:

```
Switch#sh spanning-tree vlan 1

VLAN0001
  Spanning tree enabled protocol ieee

```

Configuring STP Port Priority

In the event of a loop, a spanning tree considers port priority when selecting an interface to put into the forwarding state. You can assign higher priority values to interfaces that you want a spanning tree to select first and lower priority values to interfaces that you want a spanning tree to select last. If all interfaces have the same priority value, a spanning tree puts the interface with the lowest interface number in the forwarding state and blocks other interfaces. The possible priority range is 0 through 240, configurable in increments of 16 (the default is 128).

Note

The Cisco IOS software uses the port priority value when the interface is configured as an access port and uses VLAN port priority values when the interface is configured as a trunk port.

To configure the spanning tree port priority of an interface, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface {{ fastethernet gigabitethernet tengigabitethernet } slot/port} { port-channel port_channel_number}	Specifies an interface to configure.
Step 2	Switch(config-if)# [no] spanning-tree port-priority port_priority	Configures the port priority for an interface. The <i>port_priority</i> value can be from 0 to 240, in increments of 16. Use the no keyword to restore the defaults.
Step 3	Switch(config-if)# [no] spanning-tree vlan vlan_ID port-priority port_priority	Configures the VLAN port priority for an interface. The <i>port_priority</i> value can be from 0 to 240, in increments of 16. Use the no keyword to restore the defaults.
Step 4	Switch(config-if)# end	Exits configuration mode.
Step 5	Switch# show spanning-tree interface {{ fastethernet gigabitethernet } slot/port} { port-channel port_channel_number} show spanning-tree vlan vlan_ID	Verifies the configuration.

This example shows how to configure the spanning tree port priority of a Fast Ethernet interface:

```

Switch# configure terminal
Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree port-priority 100
Switch(config-if)# end
Switch#

```

This example shows how to verify the configuration of a Fast Ethernet interface when it is configured as an access port:

```

Switch# show spanning-tree interface fastethernet 3/1

Vlan                Role Sts Cost        Prio.Nbr Status

```

```

-----

Switch#

```

This example shows how to display the details of the interface configuration when the interface is configured as an access port:

```

Switch# show spanning-tree interface fastethernet 3/1 detail
Port 129 (FastEthernet3/1) of VLAN0001 is forwarding
  Port path cost 19, Port priority 128, Port Identifier 128.129.
  Designated root has priority 32768, address 0003.6b10.e800
  Designated bridge has priority 32768, address 0003.6b10.e800
  Designated port id is 128.129, designated path cost 0
  Timers:message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state:1
  Link type is point-to-point by default
  BPDU:sent 187, received 1

Port 129 (FastEthernet3/1) of VLAN1002 is forwarding
  Port path cost 19, Port priority 128, Port Identifier 128.129.
  Designated root has priority 32768, address 0003.6b10.ebe9
  Designated bridge has priority 32768, address 0003.6b10.ebe9
  Designated port id is 128.129, designated path cost 0
  Timers:message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state:1
  Link type is point-to-point by default
  BPDU:sent 94, received 2

Port 129 (FastEthernet3/1) of VLAN1003 is forwarding
  Port path cost 19, Port priority 128, Port Identifier 128.129.
  Designated root has priority 32768, address 0003.6b10.ebea
  Designated bridge has priority 32768, address 0003.6b10.ebea
  Designated port id is 128.129, designated path cost 0
  Timers:message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state:1
  Link type is point-to-point by default
  BPDU:sent 94, received 2

Port 129 (FastEthernet3/1) of VLAN1004 is forwarding
  Port path cost 19, Port priority 128, Port Identifier 128.129.
  Designated root has priority 32768, address 0003.6b10.ebeb
  Designated bridge has priority 32768, address 0003.6b10.ebeb
  Designated port id is 128.129, designated path cost 0
  Timers:message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state:1
  Link type is point-to-point by default
  BPDU:sent 95, received 2

Port 129 (FastEthernet3/1) of VLAN1005 is forwarding
  Port path cost 19, Port priority 128, Port Identifier 128.129.
  Designated root has priority 32768, address 0003.6b10.ebec
  Designated bridge has priority 32768, address 0003.6b10.ebec
  Designated port id is 128.129, designated path cost 0
  Timers:message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state:1
  Link type is point-to-point by default
  BPDU:sent 95, received 2
Switch#

```

**Note**

The **show spanning-tree port-priority** command displays only information for ports with an active link. If there is no port with an active link, enter a **show running-config interface** command to verify the configuration.

This example shows how to configure the spanning tree VLAN port priority of a Fast Ethernet interface:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree vlan 200 port-priority 64
Switch(config-if)# end
Switch#
```

This example shows how to verify the configuration of VLAN 200 on the interface when it is configured as a trunk port:

```
Switch# show spanning-tree vlan 200
<...output truncated...>

Port 264 (FastEthernet5/8) of VLAN200 is forwarding
Port path cost 19, Port priority 64, Port Identifier 129.8.
  Designated root has priority 32768, address 0010.0d40.34c7
  Designated bridge has priority 32768, address 0010.0d40.34c7
  Designated port id is 128.1, designated path cost 0
  Timers: message age 2, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  BPDU: sent 0, received 13513

<...output truncated...>
Switch#
```

Configuring STP Port Cost

The default value for spanning tree port path cost is derived from the interface media speed. In the event of a loop, spanning tree considers port cost when selecting an interface to put into the forwarding state. You can assign lower cost values to interfaces that you want spanning tree to select first, and higher cost values to interfaces that you want spanning tree to select last. If all interfaces have the same cost value, spanning tree puts the interface with the lowest interface number in the forwarding state and blocks other interfaces. The possible cost range is 1 through 200,000,000 (the default is media-specific).

Spanning tree uses the port cost value when the interface is configured as an access port and uses VLAN port cost values when the interface is configured as a trunk port.

To configure the spanning tree port cost of an interface, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface {{fastethernet gigabitethernet tengigabitethernet} slot/port} {port-channel port_channel_number}	Specifies an interface to configure.
Step 2	Switch(config-if)# [no] spanning-tree cost port_cost	Configures the port cost for an interface. The <i>port_cost</i> value can be from 1 to 200,000,000. Use the no keyword to restore the defaults.

	Command	Purpose
Step 3	Switch(config-if)# [no] spanning-tree vlan <i>vlan_ID cost port_cost</i>	Configures the VLAN port cost for an interface. The <i>port_cost</i> value can be from 1 to 200,000,000. Use the no keyword to restore the defaults.
Step 4	Switch(config-if)# end	Exits configuration mode.
Step 5	Switch# show spanning-tree interface { fastethernet gigabitethernet } <i>slot/port</i> { port-channel <i>port_channel_number</i> } show spanning-tree vlan <i>vlan_ID</i>	Verifies the configuration.

This example shows how to change the spanning tree port cost of a Fast Ethernet interface:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree cost 18
Switch(config-if)# end
Switch#
```

This example shows how to verify the configuration of the interface when it is configured as an access port:

```
Switch# show spanning-tree interface fastethernet 5/8
Port 264 (FastEthernet5/8) of VLAN200 is forwarding
  Port path cost 18, Port priority 100, Port Identifier 129.8.
  Designated root has priority 32768, address 0010.0d40.34c7
  Designated bridge has priority 32768, address 0010.0d40.34c7
  Designated port id is 128.1, designated path cost 0
  Timers: message age 2, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  BPDU: sent 0, received 13513
Switch#
```

This example shows how to configure the spanning tree VLAN port cost of a Fast Ethernet interface:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree vlan 200 cost 17
Switch(config-if)# end
Switch#
```

This example shows how to verify the configuration of VLAN 200 on the interface when it is configured as a trunk port:

```
Switch# show spanning-tree vlan 200
<...output truncated...>
Port 264 (FastEthernet5/8) of VLAN200 is forwarding
  Port path cost 17, Port priority 64, Port Identifier 129.8.
  Designated root has priority 32768, address 0010.0d40.34c7
  Designated bridge has priority 32768, address 0010.0d40.34c7
  Designated port id is 128.1, designated path cost 0
  Timers: message age 2, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  BPDU: sent 0, received 13513

<...output truncated...>
Switch#
```

**Note**

The **show spanning-tree** command displays only information for ports with an active link (green light is on). If there is no port with an active link, you can issue a **show running-config** command to confirm the configuration.

Configuring the Bridge Priority of a VLAN

**Note**

Exercise care when configuring the bridge priority of a VLAN. In most cases, we recommend that you enter the **spanning-tree vlan *vlan_ID* root primary** and the **spanning-tree vlan *vlan_ID* root secondary** commands to modify the bridge priority.

To configure the spanning tree bridge priority of a VLAN, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] spanning-tree vlan <i>vlan_ID</i> priority <i>bridge_priority</i>	Configures the bridge priority of a VLAN. The <i>bridge_priority</i> value can be from 1 to 65,534. Use the no keyword to restore the defaults.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show spanning-tree vlan <i>vlan_ID</i> bridge [brief]	Verifies the configuration.

This example shows how to configure the bridge priority of VLAN 200 to 33,792:

```
Switch# configure terminal
Switch(config)# spanning-tree vlan 200 priority 33792
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show spanning-tree vlan 200 bridge brief
Vlan                Bridge ID      Hello Time  Max Age  Fwd Delay  Protocol
-----
VLAN200             33792 0050.3e8d.64c8  2    20    15    ieee
Switch#
```

Configuring the Hello Time

**Note**

Exercise care when configuring the hello time. In most cases, we recommend that you use the **spanning-tree vlan *vlan_ID* root primary** and the **spanning-tree vlan *vlan_ID* root secondary** commands to modify the hello time.

To configure the spanning tree hello time of a VLAN, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] spanning-tree vlan <i>vlan_ID</i> hello-time <i>hello_time</i>	Configures the hello time of a VLAN. The <i>hello_time</i> value can be from 1 to 10 seconds. Use the no keyword to restore the defaults.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show spanning-tree vlan <i>vlan_ID</i> bridge [brief]	Verifies the configuration.

This example shows how to configure the hello time for VLAN 200 to 7 seconds:

```
Switch# configure terminal
Switch(config)# spanning-tree vlan 200 hello-time 7
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show spanning-tree vlan 200 bridge brief

Vlan                Bridge ID      Hello Time  Max Age  Fwd Delay  Protocol
-----
VLAN200             49152 0050.3e8d.64c8    7       20       15    ieee
Switch#
```

Configuring the Maximum Aging Time for a VLAN

Note

Exercise care when configuring aging time. In most cases, we recommend that you use the **spanning-tree vlan *vlan_ID* root primary** and the **spanning-tree vlan *vlan_ID* root secondary** commands to modify the maximum aging time.

To configure the spanning tree maximum aging time for a VLAN, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] spanning-tree vlan <i>vlan_ID</i> max-age <i>max_age</i>	Configures the maximum aging time of a VLAN. The <i>max_age</i> value can be from 6 to 40 seconds. Use the no keyword to restore the defaults.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show spanning-tree vlan <i>vlan_ID</i> bridge [brief]	Verifies the configuration.

This example shows how to configure the maximum aging time for VLAN 200 to 36 seconds:

```
Switch# configure terminal
Switch(config)# spanning-tree vlan 200 max-age 36
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show spanning-tree vlan 200 bridge brief
Hello Max Fwd
Vlan          Bridge ID    Time Age Delay Protocol
-----
VLAN200      49152 0050.3e8d.64c8  2  36  15  ieee
Switch#
```

Configuring the Forward-Delay Time for a VLAN

Note

Exercise care when configuring forward-delay time. In most cases, we recommend that you use the **spanning-tree vlan *vlan_ID* root primary** and the **spanning-tree vlan *vlan_ID* root secondary** commands to modify the forward delay time.

To configure the spanning tree forward delay time for a VLAN, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] spanning-tree vlan <i>vlan_ID</i> forward-time <i>forward_time</i>	Configures the forward time of a VLAN. The <i>forward_time</i> value can be from 4 to 30 seconds. Use the no keyword to restore the defaults.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show spanning-tree vlan <i>vlan_ID</i> bridge [brief]	Verifies the configuration.

This example shows how to configure the forward delay time for VLAN 200 to 21 seconds:

```
Switch# configure terminal
Switch(config)# spanning-tree vlan 200 forward-time 21
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show spanning-tree vlan 200 bridge brief
Hello Max Fwd
Vlan          Bridge ID    Time Age Delay Protocol
-----
VLAN200      49152 0050.3e8d.64c8  2  20  21  ieee
Switch#
```

This example shows how to display spanning tree information for the bridge:

```
Switch# show spanning-tree bridge
Hello Max Fwd
Vlan          Bridge ID    Time Age Dly Protocol
-----
VLAN200      49152 0050.3e8d.64c8  2  20  15  ieee
VLAN202      49152 0050.3e8d.64c9  2  20  15  ieee
VLAN203      49152 0050.3e8d.64ca  2  20  15  ieee
VLAN204      49152 0050.3e8d.64cb  2  20  15  ieee
VLAN205      49152 0050.3e8d.64cc  2  20  15  ieee
VLAN206      49152 0050.3e8d.64cd  2  20  15  ieee
Switch#
```

Disabling Spanning Tree Protocol

To disable spanning tree on a per-VLAN basis, perform this task:

	Command	Purpose
Step 1	Switch(config)# no spanning-tree vlan <i>vlan_ID</i>	Disables spanning tree on a per-VLAN basis.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show spanning-tree vlan <i>vlan_ID</i>	Verifies that spanning tree is disabled.

This example shows how to disable spanning tree on VLAN 200:

```
Switch# configure terminal
Switch(config)# no spanning-tree vlan 200
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show spanning-tree vlan 200
Spanning tree instance for VLAN 200 does not exist.
Switch#
```

Enabling Per-VLAN Rapid Spanning Tree

Per-VLAN Rapid Spanning Tree (PVRST+) uses the existing PVST+ framework for configuration purposes and for interaction with other features. It also supports some of the PVST+ extensions.

Note

Beginning in Cisco IOS XE Release 3.8.0E and Cisco IOS Release 15.2(4)E, Per-VLAN Rapid Spanning Tree (PVRST+) is the default STP mode on Catalyst 4500 Series Switches.

To enable PVRST+, perform this task:

:

	Command	Purpose
Step 1	Switch(config)# [no] spantree mode rapid-pvst	Enables PVRST+.
Step 2	Switch(config)# interface <i>interface/port</i>	Switches to interface configuration mode.
Step 3	Switch(config-if)# spanning-tree link-type point-to-point	Sets the link-type to point-to-point mode for the port.
Step 4	Switch(config-if)# exit	Exits interface mode.
Step 5	Switch(config)# exit	Exits configuration mode.
Step 6	Switch(config-if)# clear spantree detected-protocols <i>mod/port</i>	Detects any legacy bridges on the port
Step 7	Switch# show spanning-tree summary totals	Verifies the PVRST+ configuration.

The following example shows how to configure PVRST+:

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# spanning-tree mode rapid-pvst
Switch(config)# int fa 6/4
```

```
Switch(config-if)# spanning-tree link-type point-to-point
Switch(config-if)# end
Switch(config)# end
Switch#
23:55:32:%SYS-5-CONFIG_I:Configured from console by console
Switch# clear spanning-tree detected-protocols
```

The following example shows how to verify the configuration:

```
Switch# show spanning-tree summary totals
Switch is in rapid-pvst mode
Root bridge for:VLAN0001
Extended system ID          is disabled
Portfast Default            is disabled
PortFast BPDU Guard Default is disabled
Portfast BPDU Filter Default is disabled
Loopguard Default           is disabled
EtherChannel misconfig guard is enabled
UplinkFast                  is disabled
BackboneFast                is disabled
Pathcost method used         is short
Name                         Blocking Listening Learning Forwarding STP Active
-----
1 vlan                       0          0          0          2          2
Switch#
```

Specifying the Link Type

Rapid connectivity is established only on point-to-point links. Spanning tree views a point-to-point link as a segment connecting only two switches running the spanning tree algorithm. Because the switch assumes that all full-duplex links are point-to-point links and that half-duplex links are shared links, you can avoid explicitly configuring the link type. To configure a specific link type, use the **spanning-tree linktype** command.

Restarting Protocol Migration

A switch running both MSTP and RSTP supports a built-in protocol migration process that enables the switch to interoperate with legacy 802.1D switches. If this switch receives a legacy 802.1D configuration BPDU (a BPDU with the protocol version set to 0), it sends only 802.1D BPDUs on that port. When an MSTP switch receives a legacy BPDU, it can also detect the following:

- A port is at the boundary of a region
- An MST BPDU (version 3) that is associated with a different region
- An RST BPDU (version 2)

The switch, however, does not automatically revert to the MSTP mode if it no longer receives 802.1D BPDUs because it cannot determine whether or not the legacy switch has been removed from the link unless the legacy switch is the designated switch. A switch also might continue to assign a boundary role to a port when the switch to which it is connected has joined the region.

To restart the protocol migration process on the entire switch (that is, to force renegotiation with neighboring switches), use the **clear spanning-tree detected-protocols** commands in privileged EXEC mode. To restart the protocol migration process on a specific interface, enter the **clear spanning-tree detected-protocols interface** command in interface-id privileged EXEC mode.

About MST

The following sections describe how MST works on a Catalyst 4500 series switch:

- [IEEE 802.1s MST, page 23-22](#)
- [IEEE 802.1w RSTP, page 23-23](#)
- [MST-to-SST Interoperability, page 23-24](#)
- [Common Spanning Tree, page 23-25](#)
- [MST Instances, page 23-26](#)
- [MST Configuration Parameters, page 23-26](#)
- [MST Regions, page 23-26](#)
- [Message Age and Hop Count, page 23-28](#)

IEEE 802.1s MST

MST extends the IEEE 802.1w rapid spanning tree (RST) algorithm to multiple spanning trees. This extension provides both rapid convergence and load balancing in a VLAN environment. MST converges faster than per-VLAN Spanning Tree Plus (PVST+) and is backward compatible with 802.1D STP, 802.1w (Rapid Spanning Tree Protocol [RSTP]), and the Cisco PVST+ architecture.

MST allows you to build multiple spanning trees over trunks. You can group and associate VLANs to spanning tree instances. Each instance can have a topology independent of other spanning tree instances. This architecture provides multiple forwarding paths for data traffic and enables load balancing. Network fault tolerance is improved because a failure in one instance (forwarding path) does not affect other instances.

In large networks, you can more easily administer the network and use redundant paths by locating different VLAN and spanning tree instance assignments in different parts of the network. A spanning tree instance can exist only on bridges that have compatible VLAN instance assignments. You must configure a set of bridges with the same MST configuration information, which allows them to participate in a specific set of spanning tree instances. Interconnected bridges that have the same MST configuration are referred to as an *MST region*.

MST uses the modified RSTP, MSTP. MST has the following characteristics:

- MST runs a variant of spanning tree called Internal Spanning Tree (IST). IST augments Common Spanning Tree (CST) information with internal information about the MST region. The MST region appears as a single bridge to adjacent single spanning tree (SST) and MST regions.
- A bridge running MST provides interoperability with SST bridges as follows:
 - MST bridges run IST, which augments CST information with internal information about the MST region.
 - IST connects all the MST bridges in the region and appears as a subtree in the CST that includes the whole bridged domain. The MST region appears as a virtual bridge to adjacent SST bridges and MST regions.
 - The Common and Internal Spanning Tree (CIST) is the collection of the following: ISTs in each MST region, the CST that interconnects the MST regions, and the SST bridges. CIST is identical to an IST inside an MST region and identical to a CST outside an MST region. The STP, RSTP, and MSTP together elect a single bridge as the root of the CIST.

- MST establishes and maintains additional spanning trees within each MST region. These spanning trees are termed MST instances (MSTIs). The IST is numbered 0, and the MSTIs are numbered 1, 2, 3, and so on. Any MSTI is local to the MST region and is independent of MSTIs in another region, even if the MST regions are interconnected.

MST instances combine with the IST at the boundary of MST regions to become the CST as follows:

- Spanning tree information for an MSTI is contained in an MSTP record (M-record).

M-records are always encapsulated within MST bridge protocol data units (BPDUs). The original spanning trees computed by MSTP are called M-trees, which are active only within the MST region. M-trees merge with the IST at the boundary of the MST region and form the CST.

- MST provides interoperability with PVST+ by generating PVST+ BPDUs for the non-CST VLANs.
- MST supports some of the PVST+ extensions in MSTP as follows:
 - UplinkFast and BackboneFast are not available in MST mode; they are part of RSTP.
 - PortFast is supported.
 - BPDU filter and BPDU guard are supported in MST mode.
 - Loop guard and root guard are supported in MST. MST preserves the VLAN 1 disabled functionality except that BPDUs are still transmitted in VLAN 1.
 - MST switches operate as if MAC reduction is enabled.
 - For private VLANs (PVLANS), you must map a secondary VLAN to the same instance as the primary.

IEEE 802.1w RSTP

RSTP, specified in 802.1w, supersedes STP specified in 802.1D, but remains compatible with STP. You configure RSTP when you configure the MST feature. For more information, see the [“Configuring MST” section on page 23-28](#).

RSTP provides the structure on which the MST operates, significantly reducing the time to reconfigure the active topology of a network when its physical topology or configuration parameters change. RSTP selects one switch as the root of a spanning-tree-connected active topology and assigns port roles to individual ports of the switch, depending on whether that port is part of the active topology.

RSTP provides rapid connectivity following the failure of a switch, switch port, or a LAN. A new root port and the designated port on the other side of the bridge transition to the forwarding state through an explicit handshake between them. RSTP allows switch port configuration so the ports can transition to forwarding directly when the switch reinitializes.

RSTP provides backward compatibility with 802.1D bridges as follows:

- RSTP selectively sends 802.1D-configured BPDUs and Topology Change Notification (TCN) BPDUs on a per-port basis.
- When a port initializes, the migration delay timer starts and RSTP BPDUs are transmitted. While the migration delay timer is active, the bridge processes all BPDUs received on that port.
- If the bridge receives an 802.1D BPDU after a port’s migration delay timer expires, the bridge assumes it is connected to an 802.1D bridge and starts using only 802.1D BPDUs.
- When RSTP uses 802.1D BPDUs on a port and receives an RSTP BPDU after the migration delay expires, RSTP restarts the migration delay timer and begins using RSTP BPDUs on that port.

RSTP Port Roles

In RSTP, the port roles are defined as follows:

- **Root**—A forwarding port elected for the spanning tree topology.
- **Designated**—A forwarding port elected for every switched LAN segment.
- **Alternate**—An alternate path to the root bridge to that provided by the current root port.
- **Backup**—A backup for the path provided by a designated port toward the leaves of the spanning tree. Backup ports can exist only where two ports are connected together in a loopback mode or bridge with two or more connections to a shared LAN segment.
- **Disabled**—A port that has no role within the operation of spanning tree.

The system assigns port roles as follows:

- A root port or designated port role includes the port in the active topology.
- An alternate port or backup port role excludes the port from the active topology.

RSTP Port States

The port state controls the forwarding and learning processes and provides the values of discarding, learning, and forwarding. [Table 23-5](#) shows the STP port states and RSTP port states.

Table 23-5 Comparison Between STP and RSTP Port States

Operational Status	STP Port State	RSTP Port State	Port Included in Active Topology
Enabled	Blocking ¹	Discarding ²	No
Enabled	Listening	Discarding	No
Enabled	Learning	Learning	Yes
Enabled	Forwarding	Forwarding	Yes
Disabled	Disabled	Discarding	No

1. IEEE 802.1D port state designation.

2. IEEE 802.1w port state designation. Discarding is the same as blocking in MST.

In a stable topology, RSTP ensures that every root port and designated port transitions to the forwarding state while all alternate ports and backup ports are always in the discarding state.

MST-to-SST Interoperability

A virtual bridged LAN may contain interconnected regions of SST and MST bridges. [Figure 23-2](#) shows this relationship.

Figure 23-2 Network with Interconnected SST and MST Regions

To STP running in the SST region, an MST region appears as a single SST or pseudobridge, which operates as follows:

- Although the values for root identifiers and root path costs match for all BPDUs in all pseudobridges, a pseudobridge differs from a single SST bridge as follows:
 - The pseudobridge BPDUs have different bridge identifiers. This difference does not affect STP operation in the neighboring SST regions because the root identifier and root cost are the same.
 - BPDUs sent from the pseudobridge ports may have significantly different message ages. Because the message age increases by one second for each hop, the difference in the message age is measured in seconds.
- Data traffic from one port of a pseudobridge (a port at the edge of a region) to another port follows a path entirely contained within the pseudobridge or MST region. Data traffic belonging to different VLANs might follow different paths within the MST regions established by MST.
- The system prevents looping by doing either of the following:
 - Blocking the appropriate pseudobridge ports by allowing one forwarding port on the boundary and blocking all other ports.
 - Setting the CST partitions to block the ports of the SST regions.

Common Spanning Tree

CST (802.1Q) is a single spanning tree for all the VLANs. On a Catalyst 4500 series switch running PVST+, the VLAN 1 spanning tree corresponds to CST. On a Catalyst 4500 series switch running MST, IST (instance 0) corresponds to CST.

MST Instances

We support 65 instances including instance 0. Each spanning tree instance is identified by an instance ID that ranges from 0 to 4094. Instance 0 is mandatory and is always present. Rest of the instances are optional.

MST Configuration Parameters

The MST configuration includes these three parts:

- Name—A 32-character string (null padded) that identifies the MST region.
- Revision number—An unsigned 16-bit number that identifies the revision of the current MST configuration.

**Note**

You must set the revision number when required as part of the MST configuration. The revision number is not incremented automatically each time you commit the MST configuration.

- MST configuration table—An array of 4096 bytes. Each byte, interpreted as an unsigned integer, corresponds to a VLAN. The value is the instance number to which the VLAN is mapped. The first byte that corresponds to VLAN 0 and the 4096th byte that corresponds to VLAN 4095 are unused and always set to zero.

You must configure each byte manually. Use SNMP or the CLI to perform the configuration.

MST BPDUs contain the MST configuration ID and the checksum. An MST bridge accepts an MST BPDU only if the MST BPDU configuration ID and the checksum match its own MST region configuration ID and checksum. If either value is different, the MST BPDU is considered to be an SST BPDU.

MST Regions

These sections describe MST regions:

- [MST Region Overview, page 23-26](#)
- [Boundary Ports, page 23-27](#)
- [IST Master, page 23-27](#)
- [Edge Ports, page 23-27](#)
- [Link Type, page 23-28](#)

MST Region Overview

Interconnected bridges that have the same MST configuration are referred to as an MST region. There is no limit on the number of MST regions in the network.

To form an MST region, bridges can be either of the following:

- An MST bridge that is the only member of the MST region.
- An MST bridge interconnected by a LAN. A LAN's designated bridge has the same MST configuration as an MST bridge. All the bridges on the LAN can process MST BPDUs.

If you connect two MST regions with different MST configurations, the MST regions do the following:

- Load balance across redundant paths in the network. If two MST regions are redundantly connected, all traffic flows on a single connection with the MST regions in a network.
- Provide an RSTP handshake to enable rapid connectivity between regions. However, the handshaking is not as fast as between two bridges. To prevent loops, all the bridges inside the region must agree upon the connections to other regions. This situation introduces a delay. We do not recommend partitioning the network into a large number of regions.

Boundary Ports

A boundary port is a port that connects to a LAN, the designated bridge of which is either an SST bridge or a bridge with a different MST configuration. A designated port knows that it is on the boundary if it detects an STP bridge or receives an agreement message from an RST or MST bridge with a different configuration.

At the boundary, the role of MST ports do not matter; their state is forced to be the same as the IST port state. If the boundary flag is set for the port, the MSTP Port Role selection mechanism assigns a port role to the boundary and the same state as that of the IST port. The IST port at the boundary can take up any port role except a backup port role.

IST Master

The IST master of an MST region is the bridge with the lowest bridge identifier and the least path cost to the CST root. If an MST bridge is the root bridge for CST, then it is the IST master of that MST region. If the CST root is outside the MST region, then one of the MST bridges at the boundary is selected as the IST master. Other bridges on the boundary that belong to the same region eventually block the boundary ports that lead to the root.

If two or more bridges at the boundary of a region have an identical path to the root, you can set a slightly lower bridge priority to make a specific bridge the IST master.

The root path cost and message age inside a region stay constant, but the IST path cost is incremented and the IST remaining hops are decremented at each hop. Enter the **show spanning-tree mst** command to display the information about the IST master, path cost, and remaining hops for the bridge.

Edge Ports

A port that is connected to a nonbridging device (for example, a host or a switch) is an edge port. A port that connects to a hub is also an edge port if the hub or any LAN that is connected to it does not have a bridge. An edge port can start forwarding as soon as the link is up.

MST requires that you configure each port connected to a host. To establish rapid connectivity after a failure, you need to block the non-edge designated ports of an intermediate bridge. If the port connects to another bridge that can send back an agreement, then the port starts forwarding immediately. Otherwise, the port needs twice the forward delay time to start forwarding again. You must explicitly configure the ports that are connected to the hosts and switches as edge ports while using MST.

To prevent a misconfiguration, the PortFast operation is turned off if the port receives a BPDU. You can display the configured and operational status of PortFast by using the **show spanning-tree mst interface** command.

Link Type

Rapid connectivity is established only on point-to-point links. You must configure ports explicitly to a host or switch. However, cabling in most networks meets this requirement. By entering the **spanning-tree linktype** command to treating all full-duplex links as point-to-point links, you can avoid explicit configuration.

Message Age and Hop Count

IST and MST instances do not use the message age and maximum age timer settings in the BPDU. IST and MST use a separate hop count mechanism that is very similar to the IP time-to live (TTL) mechanism. You can configure each MST bridge with a maximum hop count. The root bridge of the instance sends a BPDU (or M-record) with the remaining hop count that is equal to the maximum hop count. When a bridge receives a BPDU (or M-record), it decrements the received remaining hop count by one. The bridge discards the BPDU (M-record) and ages out the information held for the port if the count reaches zero after decrementing. The nonroot bridges propagate the decremented count as the remaining hop count in the BPDUs (M-records) they generate.

The message age and maximum age timer settings in the RST portion of the BPDU remain the same throughout the region, and the same values are propagated by the region's designated ports at the boundary.

MST Configuration Restrictions and Guidelines

Follow these restrictions and guidelines to avoid configuration problems:

- Do not disable spanning tree on any VLAN in any of the PVST bridges.
- Do not use PVST bridges as the root of CST.
- Do not connect switches with access links because access links may partition a VLAN.
- Ensure that all PVST root bridges have lower, (numerically higher) priority than the CST root bridge.
- Ensure that trunks carry all of the VLANs mapped to an instance or do not carry any VLANs at all for this instance.
- Complete any MST configuration that incorporates a large number of either existing or new logical VLAN ports during a maintenance window because the complete MST database gets reinitialized for any incremental change (such as adding new VLANs to instances or moving VLANs across instances).

Configuring MST

The following sections describe how to configure MST:

- [Enabling MST, page 23-29](#)

- [Configuring MST Instance Parameters, page 23-30](#)
- [Configuring MST Instance Port Parameters, page 23-31](#)
- [Restarting Protocol Migration, page 23-32](#)
- [Displaying MST Configurations, page 23-32](#)

Enabling MST

To enable and configure MST on a switch, perform this task:

	Command	Purpose
Step 1	Switch(config)# spanning-tree mode mst	Enters MST mode.
Step 2	Switch(config)# spanning-tree mst configuration	Enters MST configuration submenu. Use the no keyword to clear the MST configuration.
Step 3	Switch(config-mst)# show current	Displays the current MST configuration.
Step 4	Switch(config-mst)# name name	Sets the MST region name.
Step 5	Switch(config-mst)# revision revision_number	Sets the MST configuration revision number.
Step 6	Switch(config-mst)# instance instance_number vlan vlan_range	Maps the VLANs to an MST instance. If you do not specify the vlan keyword, use the no keyword to unmap all the VLANs that were mapped to an MST instance. If you specify the vlan keyword, use the no keyword to unmap a specified VLAN from an MST instance.
Step 7	Switch(config-mst)# show pending	Displays the new MST configuration to be applied.
Step 8	Switch(config-mst)# end	Applies the configuration and exit MST configuration submenu.
Step 9	Switch# show spanning-tree mst configuration	Displays the current MST configuration.

This example show how to enable MST:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# spanning-tree mode mst

Switch(config)# spanning-tree mst configuration

Switch(config-mst)# show current

Configuring MST Instance Parameters

To configure MST instance parameters, perform this task:

	Command	Purpose
Step 1	Switch(config)# spanning-tree mst X priority Y	Configures the priority for an MST instance.
Step 2	Switch(config)# spanning-tree mst X root [primary secondary]	Configures the bridge as root for an MST instance.
Step 3	Switch(config)# Ctrl-Z	Exits configuration mode.
Step 4	Switch# show spanning-tree mst	Verifies the configuration.

This example shows how to configure MST instance parameters:

```
Switch(config)# spanning-tree mst 1 priority ?
<0-61440>  bridge priority in increments of 4096

Switch(config)# spanning-tree mst 1 priority 1
% Bridge Priority must be in increments of 4096.
% Allowed values are:
```

```

0      4096  8192  12288 16384 20480 24576 28672
32768 36864 40960 45056 49152 53248 57344 61440

Switch(config)# spanning-tree mst 1 priority 49152
Switch(config)#

Switch(config)# spanning-tree mst 0 root primary
mst 0 bridge priority set to 24576
mst bridge max aging time unchanged at 20
mst bridge hello time unchanged at 2
mst bridge forward delay unchanged at 15
Switch(config)# ^Z
Switch#

Switch# show spanning-tree mst

Configuring MST Instance Port Parameters

To configure MST instance port parameters, perform this task:

	Command	Purpose
Step 1	Switch(config-if)# spanning-tree mst x cost y	Configures the MST instance port cost.
Step 2	Switch(config-if)# spanning-tree mst x port-priority y	Configures the MST instance port priority.
Step 3	Switch(config-if)# Ctrl-Z	Exits configuration mode.
Step 4	Switch# show spanning-tree mst x interface y	Verifies the configuration.

This example shows how to configure MST instance port parameters:

```

Switch(config)# interface fastethernet 4/4
Switch(config-if)# spanning-tree mst 1 ?
cost          Change the interface spanning tree path cost for an instance
port-priority Change the spanning tree port priority for an instance

Switch(config-if)# spanning-tree mst 1 cost 1234567

```

```
Switch(config-if)# spanning-tree mst 1 port-priority 240
Switch(config-if)# ^Z

Switch# show spanning-tree mst 1 interface fastethernet 4/4

```

Restarting Protocol Migration

RSTP and MST have built-in compatibility mechanisms that allow them to interact properly with other regions or other versions of IEEE spanning-tree. For example, an RSTP bridge connected to a legacy bridge can send 802.1D BPDUs on one of its ports. Similarly, when an MST bridge receives a legacy BPDU or an MST BPDU associated with a different region, it is also to detect that a port is at the boundary of a region.

Unfortunately, these mechanisms cannot always revert to the most efficient mode. For example, an RSTP bridge designated for a legacy 802.1D stays in 802.1D mode even after the legacy bridge has been removed from the link. Similarly, an MST port still assumes that it is a boundary port when the bridge(s) to which it is connected have joined the same region. To force a Catalyst 4500 series switch to renegotiate with the neighbors (that is, to restart protocol migration), you must enter the **clear spanning-tree detected-protocols** command, as follows:

```
Switch# clear spanning-tree detected-protocols fastethernet 4/4
Switch#
```

Displaying MST Configurations

To display MST configurations, perform this task:

	Command	Purpose
Step 1	Switch# show spanning-tree mst configuration	Displays the active region configuration information.
Step 2	Switch# show spanning-tree mst [detail]	Displays detailed MST protocol information.
Step 3	Switch# show spanning-tree mst <i>instance-id</i> [detail]	Displays information about a specific MST instance.
Step 4	Switch# show spanning-tree mst interface <i>interface</i> [detail]	Displays information for a given port.
Step 5	Switch# show spanning-tree mst <i>instance-id</i> interface <i>interface</i> [detail]	Displays MST information for a given port and a given instance.
Step 6	Switch# show spanning-tree vlan <i>vlan_ID</i>	Displays VLAN information in MST mode.

The following examples show how to display spanning tree VLAN configurations in MST mode:

```
Switch(config)# spanning-tree mst configuration
Switch(config-mst)# instance 1 vlan 1-10
Switch(config-mst)# name cisco
Switch(config-mst)# revision 1
Switch(config-mst)# Ctrl-D

About MST-to-PVST+ Interoperability (PVST+ Simulation)

The PVST+ simulation feature enables seamless interoperability between MST and Rapid PVST+. You can enable or disable this per port, or globally. PVST+ simulation is enabled by default.

However, you may want to control the connection between MST and Rapid PVST+ to protect against accidentally connecting an MST-enabled port to a Rapid PVST+-enabled port. Because Rapid PVST+ is the default STP mode, you may encounter many Rapid PVST+-enabled connections.

Disabling this feature causes the switch to stop the MST region from interacting with PVST+ regions. The MST-enabled port moves to a PVST peer inconsistent (blocking) state once it detects it is connected to a Rapid PVST+-enabled port. This port remains in the inconsistent state until the port stops receiving Shared Spanning Tree Protocol (SSTP) BPDUs, and then the port resumes the normal STP transition process.

You can for instance, disable PVST+ simulation, to prevent an incorrectly configured switch from connecting to a network where the STP mode is not MSTP (the default mode is PVST+).

Observe these guidelines when you configure MST switches (in the same region) to interact with PVST+ switches:

- Configure the root for all VLANs inside the MST region as shown in this example:

```

Switch# show spanning-tree mst interface gigabitethernet 1/1

GigabitEthernet1/1 of MST00 is root forwarding
Edge port: no (trunk) port guard : none (default)
Link type: point-to-point (auto) bpdu filter: disable (default)
Boundary : boundary (PVST) bpdu guard : disable (default)
Bpdus sent 10, received 310

```

Instance	Role	Sts	Cost	Prio.	Nbr Vlans mapped
0	Root	FWD	20000	128.1	1-2, 4-2999, 4000-4094
3	Boun	FWD	20000	128.1	3, 3000-3999

The ports that belong to the MST switch at the boundary simulate PVST+ and send PVST+ BPDUs for all the VLANs.

If you enable loop guard on the PVST+ switches, the ports might change to a loop-inconsistent state when the MST switches change their configuration. To correct the loop-inconsistent state, you must disable and re-enable loop guard on that PVST+ switch.

- Do not locate the root for some or all of the VLANs inside the PVST+ side of the MST switch because when the MST switch at the boundary receives PVST+ BPDUs for all or some of the VLANs on its designated ports, root guard sets the port to the blocking state.
- When you connect a PVST+ switch to two different MST regions, the topology change from the PVST+ switch does not pass beyond the first MST region. In such a case, the topology changes are propagated only in the instance to which the VLAN is mapped. The topology change stays local to the first MST region, and the Cisco Access Manager (CAM) entries in the other region are not flushed. To make the topology change visible throughout other MST regions, you can map that VLAN to IST or connect the PVST+ switch to the two regions through access links.
- When you disable the PVST+ simulation, note that the PVST+ peer inconsistency can also occur while the port is already in other states of inconsistency. For example, the root bridge for all STP instances must all be in either the MST region or the Rapid PVST+ side. If the root bridge for all STP instances are not on one side or the other, the software moves the port into a PVST+ simulation-inconsistent state.

Note We recommend that you put the root bridge for all STP instances in the MST region.

Configuring PVST+ Simulation

PVST+ simulation is enabled by default. This means that all ports automatically interoperate with a connected device that is running in Rapid PVST+ mode. If you disabled the feature and want to re-configure it, refer to the following tasks.

To enable PVST+ simulation globally, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters the global configuration mode.
Step 2	Switch(config)# [no] spanning-tree mst simulate pvst global	Enables PVST+ simulation globally. To prevent the switch from automatically interoperating with a connecting switch that is running Rapid PVST+, enter the no version of the command.

This example shows how to prevent the switch from automatically interoperating with a connecting switch that is running Rapid PVST+:

```
Switch# configure terminal
Switch(config)# no spanning-tree mst simulate pvst global
```

To enable PVST+ simulation on a port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters the global configuration mode.
Step 2	Switch(config)# interface {type slot/port}	Selects a port to configure.
Step 3	Switch(config-if)# spanning-tree mst simulate pvst	Enables PVST+ simulation on the specified interface. To prevent a specified interface from automatically interoperating with a connecting switch that is not running MST, enter the spanning-tree mst simulate pvst disable command.

This example shows how to prevent a port from automatically interoperating with a connecting device that is running Rapid PVST+:

```
Switch(config)# interface gi3/13
Switch(config-if)# spanning-tree mst simulate pvst disable
```

The following sample output shows the system message you receive when a SSTP BPDU is received on a port and PVST+ simulation is disabled:

```
Message
SPANTREE_PVST_PEER_BLOCK: PVST BPDU detected on port %s [port number].
```

```
Severity
Critical
```

```
Explanation
A PVST+ peer was detected on the specified interface on the switch. PVST+ simulation
feature is disabled, as a result of which the interface was moved to the spanning tree
Blocking state.
```

```
Action
Identify the PVST+ switch from the network which might be configured incorrectly.
```

The following sample output shows the system message you receive when peer inconsistency on the interface is cleared:

```
Message
SPANTREE_PVST_PEER_UNBLOCK: Unblocking port %s [port number].
```

```
Severity
Critical
```

```
Explanation
The interface specified in the error message has been restored to normal spanning tree
state.
```

```
Action
None.
```

This example shows the spanning tree status when port Gi3/14 has been configured to disable PVST+ simulation and is currently in the peer type inconsistent state:

```
Switch# show spanning-tree
VLAN0010
  Spanning tree enabled protocol mstp
    Root ID    Priority    32778
              Address     0002.172c.f400
              This bridge is the root
              Hello Time  2 sec  Max Age 20 sec  Forward Delay 15 sec

    Bridge ID  Priority    32778 (priority 32768 sys-id-ext 10)
              Address     0002.172c.f400
              Hello Time  2 sec  Max Age 20 sec  Forward Delay 15 sec
              Aging Time 300

```

This example shows the spanning tree summary when PVST+ simulation is enabled in the MSTP mode:

```
Switch# show spanning-tree summary
Switch is in mst mode (IEEE Standard)
Root bridge for: MST0
EtherChannel misconfig guard is enabled
Extended system ID          is enabled
Portfast Default            is disabled
PortFast BPDU Guard Default is disabled
Portfast BPDU Filter Default is disabled
Loopguard Default           is disabled
UplinkFast                  is disabled
BackboneFast                 is disabled
Pathcost method used         is long
PVST Simulation Default      is enabled
```

Name	Blocking	Listening	Learning	Forwarding	STP Active
MST0	2	0	0	0	2
1 mst	2	0	0	0	2

This example shows the spanning tree summary when PVST+ simulation is disabled in any STP mode:

```
Switch# show spanning-tree summary
Switch is in mst mode (IEEE Standard)
Root bridge for: MST0
EtherChannel misconfig guard is enabled
Extended system ID          is enabled
Portfast Default            is disabled
PortFast BPDU Guard Default is disabled
Portfast BPDU Filter Default is disabled
Loopguard Default           is disabled
UplinkFast                  is disabled
BackboneFast                 is disabled
Pathcost method used         is long
PVST Simulation Default      is disabled
```

Name	Blocking	Listening	Learning	Forwarding	STP Active
MST0	2	0	0	0	2
1 mst	2	0	0	0	2

This example shows the spanning tree summary when the switch is not in MSTP mode, that is, the switch is in PVST or Rapid-PVST mode. The output string displays the current STP mode:

```
Switch# show spanning-tree summary
Switch is in rapid-pvst mode
Root bridge for: VLAN0001, VLAN2001-VLAN2002
EtherChannel misconfig guard is enabled
Extended system ID is enabled
Portfast Default is disabled
PortFast BPDU Guard Default is disabled
Portfast BPDU Filter Default is disabled
Loopguard Default is disabled
UplinkFast is disabled
BackboneFast is disabled
Pathcost method used is short
PVST Simulation Default is enabled but inactive in rapid-pvst mode
```

Name	Blocking	Listening	Learning	Forwarding	STP Active
VLAN0001	2	0	0	0	2
VLAN2001	2	0	0	0	2
VLAN2002	2	0	0	0	2
3 vlans	6	0	0	0	6

This example shows the interface details when PVST+ simulation is globally enabled, or the default configuration:

```
Switch# show spanning-tree interface gi3/13 detail
Port 269 (GigabitEthernet3/13) of VLAN0002 is forwarding
  Port path cost 4, Port priority 128, Port Identifier 128.297.
  Designated root has priority 32769, address 0013.5f20.01c0
  Designated bridge has priority 32769, address 0013.5f20.01c0
  Designated port id is 128.297, designated path cost 0
  Timers: message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default
  PVST Simulation is enabled by default
  BPDU: sent 132, received 1
```

This example shows the interface details when PVST+ simulation is globally disabled:

```
Switch# show spanning-tree interface gi3/13 detail
Port 269 (GigabitEthernet3/13) of VLAN0002 is forwarding
  Port path cost 4, Port priority 128, Port Identifier 128.297.
  Designated root has priority 32769, address 0013.5f20.01c0
  Designated bridge has priority 32769, address 0013.5f20.01c0
  Designated port id is 128.297, designated path cost 0
  Timers: message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default
  PVST Simulation is disabled by default
  BPDU: sent 132, received 1
```

This example shows the interface details when PVST+ simulation is explicitly enabled on the port:

```
Switch# show spanning-tree interface gi3/13 detail
Port 269 (GigabitEthernet3/13) of VLAN0002 is forwarding
  Port path cost 4, Port priority 128, Port Identifier 128.297.
  Designated root has priority 32769, address 0013.5f20.01c0
  Designated bridge has priority 32769, address 0013.5f20.01c0
  Designated port id is 128.297, designated path cost 0
  Timers: message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
```

```

Link type is point-to-point by default
PVST Simulation is enabled
BPDU: sent 132, received 1

```

This example shows the interface details when the PVST+ simulation feature is disabled and a PVST Peer inconsistency has been detected on the port:

```

Switch# show spanning-tree interface gi3/13 detail
Port 269 (GigabitEthernet3/13) of VLAN0002 is broken (PVST Peer Inconsistent)
  Port path cost 4, Port priority 128, Port Identifier 128.297.
  Designated root has priority 32769, address 0013.5f20.01c0
  Designated bridge has priority 32769, address 0013.5f20.01c0
  Designated port id is 128.297, designated path cost 0
  Timers: message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default
  PVST Simulation is disabled
  BPDU: sent 132, received 1

```

About Detecting Unidirectional Link Failure

The dispute mechanism that detects unidirectional link failures is included in the IEEE 802.1D-2004 RSTP and IEEE 802.1Q-2005 MSTP standard, and requires no user configuration.

The switch checks the consistency of the port role and state in the BPDUs it receives, to detect unidirectional link failures that could cause bridging loops. When a designated port detects a conflict, it keeps its role, but reverts to a discarding (blocking) state because disrupting connectivity in case of inconsistency is preferable to opening a bridging loop.

For example, in [Figure 23-3](#), Switch A is the root bridge and Switch B is the designated port. BPDUs from Switch A are lost on the link leading to switch B.

Since Rapid PVST+ (802.1w) and MST BPDUs include the role and state of the sending port, Switch A detects (from the inferior BPDU), that switch B does not react to the superior BPDUs it sends, because switch B has the role of a designated port and not the root bridge.

As a result, switch A blocks (or keeps blocking) its port, thus preventing the bridging loop.

Figure 23-3 Detecting Unidirectional Link Failure

92722

Note these guidelines and limitations relating to the dispute mechanism:

- It works only on switches running RSTP or MST, because the dispute mechanism requires reading the role and state of the port initiating the BPDUs.

- It may result in loss of connectivity. For example, in Figure 23-4, Bridge A cannot transmit on the port it elected as a root port. As a result of this situation, there is loss of connectivity (r1 and r2 are designated, a1 is root and a2 is alternate). There is only a one way connectivity between A and R.

Figure 23-4 Loss of Connectivity

- It may cause permanent bridging loops on shared segments. For example, in Figure 23-5, suppose that bridge R has the best priority, and that port b1 cannot receive any traffic from the shared segment 1 and sends inferior designated information on segment 1. Both r1 and a1 can detect this inconsistency. However, with the current dispute mechanism, only r1 will revert to discarding while the root port a1 opens a permanent loop. However, this problem does not occur in Layer 2 switched networks that are connected by point-to-point links.

Figure 23-5 Bridging Loops on Shared Segments

This example shows the spanning tree status when port Gi3/14 has been configured to disable PVST+ simulation and the port is currently in the peer type inconsistent state:

```
Switch# show spanning-tree
VLAN0010
  Spanning tree enabled protocol rstp
    Root ID    Priority    32778
              Address     0002.172c.f400
              This bridge is the root
              Hello Time  2 sec    Max Age 20 sec    Forward Delay 15 sec
    Bridge ID  Priority    32778 (priority 32768 sys-id-ext 10)
              Address     0002.172c.f400
              Hello Time  2 sec    Max Age 20 sec    Forward Delay 15 sec
              Aging Time 300
Interface      Role Sts Cost      Prio.Nbr Type
-----
Gi3/14        Desg BKN 4        128.270   P2p Dispute
```

This example shows the interface details when a dispute condition is detected:

```
Switch# show spanning-tree interface gi3/13 detail
Port 269 (GigabitEthernet3/13) of VLAN0002 is designated blocking (dispute)
  Port path cost 4, Port priority 128, Port Identifier 128.297.
  Designated root has priority 32769, address 0013.5f20.01c0
  Designated bridge has priority 32769, address 0013.5f20.01c0
  Designated port id is 128.297, designated path cost 0
  Timers: message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state: 1
  Link type is point-to-point by default
  BPDU: sent 132, received 1
```

Configuring Flex Links and MAC Address-Table Move Update

Flex Links provide a fast and simplified Layer 2 Link redundancy mechanism. This chapter describes how to configure Flex Links on the Catalyst 4500 series switch. It also describes how to configure the MAC address-table move update (MMU) feature, also referred to as the Flex Links bidirectional fast convergence feature.

The chapter consists of these sections:

- [About Flex Links, page 24-1](#)
- [Configuring Flex Links, page 24-5](#)
- [Monitoring Flex Links and the MAC Address-Table Move Update, page 24-12](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Flex Links

This section describes this information:

- [Flex Links, page 24-1](#)
- [VLAN Flex Links Load Balancing and Support, page 24-2](#)
- [Flex Links Failover Actions, page 24-3](#)

Flex Links

Flex Links are a pair of Layer 2 interfaces (switch ports or port channels) where one interface is configured to act as a backup to the other. Users can disable STP and still retain basic link redundancy. Flex Links are typically configured in service provider or enterprise networks where customers do not want to run STP on some interfaces.

**Note**

The Catalyst 4500 series switch supports a maximum of 16 Flex Links.

You configure Flex Links on one Layer 2 interface (the active link) by assigning another Layer 2 interface as the Flex Link or backup link. When one of the links is up and forwarding traffic, the other link is in standby mode, ready to begin forwarding traffic if the other link fails. At any given time, only one of the interfaces is in the forwarding state and forwarding traffic. If the primary link fails, the standby link starts forwarding traffic. When the active link reactivates, it enters standby mode and does not forward traffic. STP is disabled on Flex Links interfaces.

In [Figure 24-1](#), ports 1 and 2 on switch A are connected to uplink switches B and C. Because they are configured as Flex Links, only one of the interfaces is forwarding traffic; the other is in standby mode. If port 1 is the active link, it begins forwarding traffic between port 1 and switch B; the link between port 2 (the backup link) and switch C is not forwarding traffic. If port 1 shuts down, port 2 activates and starts forwarding traffic to switch C. When port 1 reactivates, it enters standby mode and does not forward traffic; port 2 continues forwarding traffic.

You can also choose to configure a preemption mechanism, specifying the preferred port for forwarding traffic. In [Figure 24-1](#), for example, you can configure the Flex Links pair with preemption mode so that after port 1 reactivates in the scenario, and it has greater bandwidth than port 2, port 1 begins forwarding after a duration equal to the preemption delay; and port 2 becomes the standby. You do this by entering the interface configuration **switchport backup interface preemption mode bandwidth** and **switchport backup interface preemption delay** commands.

Figure 24-1 Flex Links Configuration Example

If a primary (forwarding) link shuts down, a trap notifies the network management stations. If the standby link shuts down, a trap notifies the users.

Flex Links are supported only on Layer 2 ports and port channels. Flex Links are compatible with promiscuous trunks. It is not supported on isolated PVLAN trunks.

VLAN Flex Links Load Balancing and Support

VLAN Flex Links load balancing allows you to configure a Flex Links pair so that both ports simultaneously forward the traffic for mutually exclusive VLANs. For example, if Flex Links ports are configured for 1 to 100 VLANs, the traffic of the first 50 VLANs can be forwarded on one port and the rest on the other port. If one of the ports fail, the other active port forwards all the traffic. When the failed port reactivates, it resumes forwarding traffic in the preferred VLANs. In addition to providing the redundancy, this Flex Links pair can be used for load balancing. Also, Flex Links VLAN load balancing also does not impose any restrictions on uplink switches ([Figure 24-2](#)).

Figure 24-2 VLAN Flex Links Load Balancing Configuration Example**Note**

A static MAC address must point to a Flex Links interface that is forwarding for given VLAN. For example, if a backup interface is forwarding VLAN X, then a static MAC address in VLAN X must point to the backup interface. Misconfiguration might cause unexpected results.

Flex Links Failover Actions

When a Flex Links primary fails, the following important actions are taken:

- Detects link failure.
- Moves static unicast MAC addresses that are configured on the primary link to the standby link.
- Moves dynamic unicast MAC addresses that are learned on the primary link to the standby link.
- Moves the standby link to a forwarding state.
- Transmits MAC address-table move updates over a new active link, if you enter the **mac move update transmit** command.
- Transmits dummy multicast packets over a new active interface.

**Note**

Local administrative shut down or a link that starts forwarding again due to preemption is not considered a link failure. In those cases, flush the dynamic hosts and not move them.

Static MAC addresses configured on a Flex Links member interface are moved over to the backup, if it fails. Static MAC addresses configured on a Flex Links member interface are restored when it starts forwarding again.

**Note**

The **show mac address-table** command always shows static MAC addresses as associated with the interface on which it was configured even if it may have been moved to the standby link because of a Flex Links failover.

MAC Address-Table Move Update

In [Figure 24-3](#), ports 1 and 2 on switch A are connected to uplink switches B and D through a Flex Links pair. Port 1 is forwarding traffic, and port 2 is in the blocking state. Traffic from the PC to the server is forwarded from port 1 to port 3. The MAC address of the PC was learned on port 3 of switch C. Traffic from the server to the PC is forwarded from port 3 to port 1.

If port 1 shuts down, port 2 starts forwarding traffic. If there is no traffic from PC to the server after failover to port 2, switch C does not learn MAC address of the PC on port 4. As a result, switch C keeps forwarding traffic from the server to the PC out of port 3. There is traffic loss from server to PC because port 1 is down. This problem is alleviated by sending out a dummy multicast packet with source MAC address of the PC over port 2. Switch C learns the PC MAC address on port 4 and start forwarding traffic from server to the PC out of port 4. One dummy multicast packet is sent out for every MAC address, which is the default Flex Links behavior. The MAC address-table move update (MMU) feature may be enabled to further expedite downstream convergence. MMUs are special packets that carry multiple MAC addresses. Switch A is configured to transmit these packets and switches B, C, and D are configured to receive such packets. If MMU transmit is enabled on Switch A, MAC move updates are transmitted before dummy multicast packets over port 2. Switch D processes and floods MMUs over to Switch C. Switch C processes these packets, and moves the MAC addresses contained within the packets from port 3 to port 4. Because one packet carries multiple MAC addresses, downstream convergence is faster.

Figure 24-3 MAC Address-Table Move Update Example

Configuring Flex Links

These sections contain this configuration information:

- [Default Configuration, page 24-5](#)
- [Configuration Guidelines, page 24-5](#)
- [Configuring Flex Links, page 24-6](#)
- [Configuring VLAN Load Balancing on Flex Links, page 24-8](#)

Default Configuration

The following is the default Flex Links configuration:

- Flex Links are not configured on any interface.
- Preemption mode is off.
- If preemption is enabled, preemption delay is 35 seconds.

Configuration Guidelines

Follow these guidelines to configure Flex Links and associated features:

- You can configure only one Flex Link backup link for any active link, and it must be a different interface from the active interface.
- An interface can belong to only one Flex Links pair. An interface can be a backup link for only one active link, but an active link cannot belong to another Flex Links pair.
- Neither of the links can be a port that belongs to an EtherChannel. However, you can configure two port channels (EtherChannel logical interfaces) as Flex Links. Moreover, you can configure a port channel and a physical interface as Flex Links, with either the port channel or the physical interface as the active link.
- The types (Fast Ethernet, Gigabit Ethernet, or port channel) of the backup link and the active link can differ. However, you should configure both Flex Links with similar characteristics so that no loops exist or changes occur in behavior if the standby link begins to forward traffic.
- STP is disabled on Flex Links ports. A Flex Links port does not participate in STP, even if the VLANs present on the port are configured for STP. When STP is not enabled, ensure that no loops exist in the configured topology.
- Configure any static MAC addresses on a Flex Links member interface after enabling Flex Links.

Follow these guidelines to configure VLAN load balancing on the Flex Links feature. For Flex Links VLAN load balancing, you must choose the preferred VLANs on the backup interface.

Set **switchport backup interface interface-id preempt mode** to forced. A default value of 35 seconds is used as the delay timeout. You cannot configure **switchport backup interface interface-id preempt mode** on the interface. So, mode **bandwidth** and **off** cannot be configured.

Adjust the delay time with the **switchport backup interface interface-id preempt delay delay-time** command.

Configuring Flex Links

To configure a pair of Flex Links, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(conf)# interface <i>interface-id</i>	Specifies the interface, and enters interface configuration mode. The interface might be a physical Layer 2 interface or a port channel (logical interface). The port channel range is 1 to 64.
Step 3	Switch(conf-if)# switchport backup interface <i>interface-id</i>	Configures a physical Layer 2 interface (or port channel) as part of a Flex Links pair with the interface. When one link is forwarding traffic, the other interface is in standby mode.
Step 4	Switch(conf-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show interface [<i>interface-id</i>] switchport backup	Verifies the configuration.
Step 6	Switch# copy running-config startup config	(Optional) Saves your entries in the switch startup configuration file.

To disable a Flex Links backup interface, enter the **no switchport backup interface** *interface-id* interface configuration command.

This example shows how to configure an interface with a backup interface and to verify the configuration:

```
Switch# configure terminal
Switch(conf)# interface fastethernet1/1
Switch(conf-if)# switchport backup interface fastethernet1/2
Switch(conf-if)# end
Switch# show interface switchport backup
Switch Backup Interface Pairs:

Active Interface      Backup Interface      State
-----
FastEthernet1/1      FastEthernet1/2      Active Up/Backup Standby
FastEthernet1/3      FastEthernet1/4      Active Up/Backup Standby
Port-channel1        GigabitEthernet1/1    Active Up/Backup Standby
```

To configure a preemption scheme for a pair of Flex Links, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(conf)# interface <i>interface-id</i>	Specifies the interface, and enters interface configuration mode. The interface might be a physical Layer 2 interface or a port channel (logical interface). The port channel range is 1 to 64.
Step 3	Switch(conf-if)# switchport backup interface <i>interface-id</i>	Configures a physical Layer 2 interface (or port channel) as part of a Flex Links pair with the interface. When one link is forwarding traffic, the other interface is in standby mode.

	Command	Purpose
Step 4	Switch(conf-if)# switchport backup interface <i>interface-id</i> preemption mode [forced bandwidth off]	Configures a preemption mechanism and delay for a Flex Links interface pair. You can configure the preemption mode as: <ul style="list-style-type: none"> • forced—The active interface always preempts the backup. • bandwidth—The interface with higher bandwidth always acts as the active interface. • off—No preemption occurs from active to backup.
Step 5	Switch(conf-if)# switchport backup interface <i>interface-id</i> preemption delay <i>delay-time</i>	Configures the delay time until a port preempts another port. Note Setting a delay time requires forced or bandwidth mode.
Step 6	Switch(conf)# end	Returns to privileged EXEC mode.
Step 7	Switch# show interface [<i>interface-id</i>] switchport backup	Verifies the configuration.
Step 8	Switch# copy running-config startup config	(Optional) Saves your entries in the switch startup configuration file.

To remove a preemption scheme, enter the **no switchport backup interface** *interface-id* **preemption mode** interface configuration command. To reset the delay time to the default, enter the **no switchport backup interface** *interface-id* **preemption delay** interface configuration command.

This example shows how to configure preemption mode as bandwidth for a backup interface pair and to verify the configuration:

```
Switch# configure terminal
Switch(conf)# interface gigabitethernet1/0/1
Switch(conf-if)# switchport backup interface gigabitethernet1/2
Switch(conf-if)# switchport backup interface gigabitethernet1/2 preemption mode forced
Switch(conf-if)# switchport backup interface gigabitethernet1/2 preemption delay 50
Switch(conf-if)# end
Switch# show interface switchport backup detail
Active Interface      Backup Interface      State
-----
GigabitEthernet1/21  GigabitEthernet1/2    Active Down/Backup Down
Interface Pair       : Gi1/21, Gi1/2
Preemption Mode      : forced
Preemption Delay     : 50 seconds
Bandwidth : 10000 Kbit (Gi1/1), 10000 Kbit (Gi1/2)
Mac Address Move Update Vlan : auto
```

<output truncated>

Configuring VLAN Load Balancing on Flex Links

To configure VLAN load balancing on Flex Links, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Specifies the interface, and enters interface configuration mode. The interface might be a physical Layer 2 interface or a port channel (logical interface). The port channel range is 1 to 48.
Step 3	Switch(config-if)# switchport backup interface <i>interface-id</i> prefer vlan <i>vlan-range</i>	Configures a physical Layer 2 interface (or port channel) as part of a Flex Links pair with the interface, and specifies the VLANs carried on the interface. The VLAN ID range is 1 to 4094.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show interfaces [<i>interface-id</i>] switchport backup	Verifies the configuration.
Step 6	Switch# copy running-config startup config	(Optional) Saves your entries in the switch startup configuration file.

To disable the VLAN load balancing feature, enter the **no switchport backup interface prefer vlan** interface configuration command.

In this example, VLANs 1 to 50, 60, and 100 to 120 are configured on the switch:

```
Switch(config)# interface fastethernet 1/6
Switch(config-if)# switchport backup interface fastethernet 1/0/8 prefer vlan 60,100-120
```

When both interfaces are up, Fast Ethernet port 1/0/8 forwards traffic for VLANs 60 and 100 to 120 and Fast Ethernet port 1/0/6 forwards traffic for VLANs 1 to 50.

```
Switch# show interfaces switchport backup
Switch Backup Interface Pairs:
```

Active Interface	Backup Interface	State
FastEthernet1/6	FastEthernet1/8	Active Up/Backup Standby

```
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
```

When a Flex Links interface shuts down, VLANs preferred on this interface are moved to the peer interface of the Flex Links pair. In this example, if interface 1/6 shuts down, interface 1/8 carries all VLANs of the Flex Links pair.

```
Switch# show interfaces switchport backup
Switch Backup Interface Pairs:
```

Active Interface	Backup Interface	State
FastEthernet1/6	FastEthernet1/8	Active Down/Backup VLB all

```
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
```

When a Flex Links interface becomes active, VLANs preferred on this interface are blocked on the peer interface and moved to the forwarding state on the interface that has just come up. In this example, if interface Fast Ethernet port 1/6 becomes active, VLANs preferred on this interface are blocked on the peer interface Fast Ethernet port 1/8 and forwarded on Fast Ethernet port 1/6.

```
Switch# show interfaces switchport backup
Switch Backup Interface Pairs:
```

Active Interface	Backup Interface	State
FastEthernet1/6	FastEthernet1/8	Active VLB cfg/Backup VLB cfg

```
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
```

```
Switch# show interfaces switchport backup detail
Switch Backup Interface Pairs:
```

Active Interface	Backup Interface	State
FastEthernet1/6	FastEthernet1/8	Active VLB cfg/Backup VLB cfg

```
Vlans Preferred on Active Interface: 1-50
Vlans Preferred on Backup Interface: 60, 100-120
Preemption Mode : off
Bandwidth : 10000 Kbit (Fa1/6), 100000 Kbit (Fa1/8)
Mac Address Move Update Vlan : auto
```

Configuring MAC Address-Table Move Update

These sections contain this configuration information:

- [Default Configuration, page 24-5](#)
- [Configuration Guidelines, page 24-5](#)
- [Configuring MAC Address-Table Move Update, page 24-9](#)

Default Configuration

By default, the MAC address-table move update feature is disabled.

Configuration Guidelines

Follow these guidelines to configure the MAC address-table move update feature:

- Enable **mac address-table move transmit** on the switch with Flex Links configured to send MAC address-table move updates.
- Enable **mac address-table move receive** on all upstream switches to process MAC address-table move updates.

Configuring the MAC Address-Table Move Update Feature

This section describes the following tasks:

- [Configuring a Switch to Send MAC Address-Table Move Updates, page 24-10](#)
- [Configuring a Switch to Receive MAC Address-Table Move Updates, page 24-11](#)

Configuring a Switch to Send MAC Address-Table Move Updates

To configure an access switch to send MAC address-table move updates, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(conf)# interface <i>interface-id</i>	Specifies the interface, and enters interface configuration mode. The interface might be a physical Layer 2 interface or a port channel (logical interface). The port channel range is 1 to 64.
Step 3	Switch(conf-if)# switchport backup interface <i>interface-id</i> or Switch(conf-if)# switchport backup interface <i>interface-id</i> mmu primary vlan <i>vlan-id</i>	Configures a physical Layer 2 interface (or port channel), as part of a Flex Links pair with the interface. The MAC address-table move update VLAN is the lowest VLAN ID on the interface. Configures a physical Layer 2 interface (or port channel) and specifies the VLAN ID on the interface, which is used for sending the MAC address-table move update. When one link is forwarding traffic, the other interface is in standby mode.
Step 4	Switch(conf-if)# end	Returns to global configuration mode.
Step 5	Switch(conf)# mac address-table move update transmit	Enables the access switch to send MAC address-table move updates to other switches in the network if the primary link shuts down and the switch starts forwarding traffic through the standby link.
Step 6	Switch(conf)# end	Returns to privileged EXEC mode.
Step 7	Switch# show mac address-table move update	Verifies the configuration.
Step 8	Switch# copy running-config startup config	(Optional) Saves your entries in the switch startup configuration file.

To disable the MAC address-table move update feature on the access switch, enter the **no mac address-table move update transmit** interface configuration command. To display the MAC address-table move update information, enter the **show mac address-table move update** command.

This example shows how to configure an access switch to send MAC address-table move update messages and to verify the configuration:

```
Switch# configure terminal
Switch(conf)# interface fastethernet1/1
Switch(conf-if)# switchport backup interface fastethernet1/0/2 mmu primary vlan 2
Switch(conf-if)# end
Switch(conf)# mac address-table move update transmit
Switch(conf)# end
Switch# show mac-address-table move update
```

```

Switch-ID : 01d0.2bfc.3180
Dst mac-address : 0180.c200.0010
Vlans/Macs supported : 4096/55000
Default/Current settings: Rcv Off/Off, Xmt Off/On
Max packets per min : Rcv 100, Xmt 120
Rcv packet count : 0
Rcv conforming packet count : 0
Rcv invalid packet count : 0
Rcv packet count this min : 0
Rcv threshold exceed count : 0

Xmt packet count this min : 0
Xmt threshold exceed count : 0
Xmt pak buf unavail cnt : 0
Xmt last interface : fa1/2

```

Configuring a Switch to Receive MAC Address-Table Move Updates

To configure a switch to receive and process MAC address-table move update messages, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(conf)# mac address-table move update receive	Enables the switch to receive and process the MAC address-table move updates.
Step 3	Switch(conf)# end	Returns to privileged EXEC mode.
Step 4	Switch# show mac address-table move update	Verifies the configuration.
Step 5	Switch# copy running-config startup config	(Optional) Saves your entries in the switch startup configuration file.

To disable the MAC address-table move update feature on the access switch, enter the **no mac address-table move update receive** configuration command. To display the MAC address-table move update information, enter the **show mac address-table move update** command.

This example shows how to configure a switch to receive and process MAC address-table move update messages:

```

Switch# configure terminal
Switch(conf)# mac address-table move update receive
Switch(conf)# end

```

Monitoring Flex Links and the MAC Address-Table Move Update

Table 24-1 shows the commands for monitoring the Flex Links configuration and the MAC address-table move update information.

Table 24-1 Flex Links and MAC Address-Table Move Update Monitoring Commands

Command	Purpose
Switch# show interface [<i>interface-id</i>] switchport backup	Displays the Flex Link backup interface configured for an interface or all the configured Flex Links and the state of each active and backup interface (up or standby mode).
Switch# show mac address-table move update	Displays the MAC address-table move update information on the switch.

Configuring Resilient Ethernet Protocol

This chapter describes how to use Resilient Ethernet Protocol (REP) on the Catalyst 4500 Series switch. REP is a Cisco proprietary protocol that provides an alternative to Spanning Tree Protocol (STP) to control network loops, handle link failures, and improve convergence time. REP controls a group of ports connected in a segment, ensures that the segment does not create any bridging loops, and responds to link failures within the segment. REP provides a basis for constructing more complex networks and supports VLAN load balancing.

This chapter includes these sections:

- [About REP, page 25-1](#)
- [Configuring REP, page 25-7](#)
- [Monitoring REP, page 25-14](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About REP

One REP segment is a chain of ports connected to each other and configured with a segment ID. Each segment consists of standard (non-edge) segment ports and two user-configured edge ports. A switch can have no more than two ports that belong to the same segment, and each segment port can have only one external neighbor. A segment can go through a shared medium, but on any link only two ports can belong to the same segment. REP is supported only on Layer 2 trunk and PVLAN promiscuous trunk interfaces.

[Figure 25-1](#) shows an example of a segment consisting of six ports spread across four switches. Ports E1 and E2 are configured as edge ports. When all ports are operational (as in the segment on the left), a single port is blocked, shown by the diagonal line. When there is a failure in the network, as shown in the diagram on the right, the blocked port returns to the forwarding state to minimize network disruption.

Figure 25-1 REP Open Segments

The segment shown in Figure 25-1 is an open segment; there is no connectivity between the two edge ports. The REP segment cannot cause a bridging loop and it is safe to connect the segment edges to any network. All hosts connected to switches inside the segment have two possible connections to the rest of the network through the edge ports, but only one connection is accessible at any time. If a failure causes a host to be unable to access its usual gateway, REP unblocks all ports to ensure that connectivity is available through the other gateway.

The segment shown in Figure 25-2, with both edge ports located on the same switch, is a ring segment. In this configuration, there is connectivity between the edge ports through the segment. With this configuration, you can create a redundant connection between any two switches in the segment.

Figure 25-2 REP Ring Segment

REP segments have these characteristics:

- If all ports in the segment are operational, one port (referred to as the *alternate* port) is in the blocked state for each VLAN. If VLAN load balancing is configured, two ports in the segment control the blocked state of VLANs.
- If one or more ports in a segment is not operational, causing a link failure, all ports forward traffic on all VLANs to ensure connectivity.
- In case of a link failure, the alternate ports are unblocked as quickly as possible. When the failed link comes back up, a logically blocked port per-VLAN is selected with minimal disruption to the network.

You can construct almost any type of network based on REP segments. REP also supports VLAN load balancing, controlled by the primary edge port but occurring at any port in the segment.

In access ring topologies, the neighboring switch might not support REP, as shown in [Figure 25-3](#). Starting with Cisco IOS Release 15.0(2)SG, you can configure the non-REP facing ports (E1 and E2) as edge no-neighbor ports. These ports inherit all properties of edge ports, and you can configure them the same as any edge port, including configuring them to send STP or REP topology change notices to the aggregation switch. In this case the STP topology change notice (TCN) that is sent is a multiple spanning-tree (MST) STP message.

Figure 25-3 Edge No-Neighbor Ports

REP has these limitations:

- You must configure each segment port; an incorrect configuration can cause forwarding loops in the networks.
- REP can manage only a single failed port within the segment; multiple port failures within the REP segment cause loss of network connectivity.
- You should configure REP only in networks with redundancy. Configuring REP in a network without redundancy causes loss of connectivity.

To use REP effectively, you should understand the following topics:

- [Link Integrity, page 25-4](#)
- [Fast Convergence, page 25-4](#)
- [VLAN Load Balancing, page 25-4](#)
- [Spanning Tree Interaction, page 25-6](#)
- [REP Ports, page 25-6](#)

Link Integrity

REP does not use an end-to-end polling mechanism between edge ports to verify link integrity. It implements local link failure detection. When enabled on an interface, the REP Link Status Layer (LSL) detects its REP-aware neighbor and establishes connectivity within the segment. All VLANs are blocked on an interface until it detects the neighbor. After the neighbor is identified, REP determines which neighbor port should become the alternate port and which ports should forward traffic.

Each port in a segment has a unique port ID. The port ID format is similar to that used by the spanning tree algorithm: a port number (unique on the bridge), associated to a MAC address (unique in the network). When a segment port is coming up, its LSL starts sending packets that include the segment ID and the port ID. The port is declared as operational after it performs a three-way handshake with a neighbor in the same segment. A segment port does not become operational if these situations occur:

- No neighbor has the same segment ID.
- More than one neighbor has the same segment ID.
- The neighbor does not acknowledge the local port as a peer.

Each port creates an adjacency with its immediate neighbor. Once the neighbor adjacencies are created, the ports negotiate to determine one blocked port for the segment, the alternate port. All other ports become unblocked. By default, REP packets are sent to a BPDU class MAC address. The packets can also be sent to the Cisco multicast address, which at present is used only to send blocked port advertisement (BPA) messages when there is a failure in the segment. The packets are dropped by devices not running REP.

Fast Convergence

Because REP runs on a physical link basis and not a per-VLAN basis, only one hello message is required for all VLANs, reducing the load on the protocol. We recommend that you create VLANs consistently on all switches in a given segment and configure the same allowed VLANs on the REP trunk and PVLAN promiscuous trunk ports. To avoid the delay introduced by relaying messages in software, REP also allows some packets to be flooded to a regular multicast address. These messages operate at the hardware flood layer (HFL) and are flooded to the whole network, not just the REP segment. Switches that do not belong to the segment treat them as data traffic. You can control flooding of these messages by configuring a dedicated administrative VLAN for the whole domain.

The estimated convergence recovery time is less than 200 milliseconds for the local segment.

VLAN Load Balancing

One edge port in the REP segment acts as the primary edge port; the other as the secondary edge port. It is the primary edge port that always participates in VLAN load balancing in the segment. REP VLAN balancing is achieved by blocking some VLANs at a configured alternate port and all other VLANs at the primary edge port. When you configure VLAN load balancing, you can specify the alternate port in one of three ways:

- By entering the port ID of the interface.
To identify the port ID of a port in the segment, enter the **show interface rep detail** interface configuration command for the port.
- By entering the neighbor offset number of a port in the segment, which identifies the downstream neighbor port of an edge port.

The neighbor offset number range is -256 to +256; a value of 0 is invalid. The primary edge port has an offset number of 1; positive numbers above 1 identify downstream neighbors of the primary edge port. Negative numbers indicate the secondary edge port (offset number -1) and its downstream neighbors.

**Note**

You configure offset numbers on the primary edge port by identifying a port's downstream position from the primary (or secondary) edge port. You never enter an offset value of 1 because that is the offset number of the primary edge port itself.

Figure 25-4 shows neighbor offset numbers for a segment where E1 is the primary edge port and E2 is the secondary edge port. The red numbers inside the ring are numbers offset from the primary edge port; the black numbers outside of the ring show the offset numbers from the secondary edge port. Note that you can identify all ports (except the primary edge port) by either a positive offset number (downstream position from the primary edge port) or a negative offset number (downstream position from the secondary edge port). If E2 became the primary edge port, its offset number is then 1 and E1 is then -1.

- By entering the **preferred** keyword to select the port that you previously configured as the preferred alternate port with the **rep segment preferred** interface configuration command.

Figure 25-4 Neighbor Offset Numbers in a Segment

When the REP segment is complete, all VLANs are blocked. When you configure VLAN load balancing, it is triggered in one of two ways:

- You can manually trigger VLAN load balancing at any time by entering the **rep preempt segment segment-id** privileged EXEC command on the switch that has the primary edge port.
- You can configure a preempt delay time by entering the **rep preempt delay seconds** interface configuration command. After a link failure and recovery, VLAN load balancing begins after the configured preemption time period elapses. Note that the delay timer restarts if another port fails before the time has elapsed.

**Note**

When VLAN load balancing is configured, it does not start working until triggered by either manual intervention or a link failure and recovery.

When VLAN load balancing is triggered, the primary edge port then sends out a message to alert all interfaces in the segment about the preemption. When the message is received by the secondary edge port, it is reflected into the network to notify the alternate port to block the set of VLANs specified in the message and to notify the primary edge port to block the remaining VLANs.

You can also configure a particular port in the segment to block all VLANs. VLAN load balancing is initiated only by the primary edge port and is not possible if the segment is not terminated by an edge port on each end. The primary edge port determines the local VLAN load balancing configuration.

To reconfigure load balancing, you reconfigure the primary edge port. When you change the load balancing configuration, the primary edge port again waits for the **rep preempt segment** command or for the configured preempt delay period after a port failure and recovery before executing the new configuration. If you change an edge port to a regular segment port, the existing VLAN load balancing status does not change. Configuring a new edge port might cause a new topology configuration.

Spanning Tree Interaction

REP does not interact with STP, but can coexist with it. A port that belongs to a segment is removed from spanning tree control and STP BPDUs are not accepted or sent from segment ports. STP can not run on a segment.

To migrate from an STP ring configuration to REP segment configuration, begin by configuring a single port in the ring as part of the segment and continue by configuring contiguous ports to minimize the number of segments. Each segment always contains a blocked port, so multiple segments means multiple blocked ports and a potential loss of connectivity. When the segment has been configured in both directions up to the location of the edge ports, you then configure the edge ports.

REP Ports

Ports in REP segments take one of three roles or states: Failed, Open, or Alternate.

- A port configured as a regular segment port starts as a failed port.
- Once the neighbor adjacencies are determined, the port transitions to alternate port state, blocking all VLANs on the interface. Blocked port negotiations occur and when the segment settles, one blocked port remains in the alternate role and all other ports become open ports.
- When a failure occurs in a link, all ports move to the failed state. When the alternate port receives the failure notification, it changes to the open state, forwarding all VLANs.

A regular segment port converted to an edge port, or an edge port converted to a regular segment port, does not always result in a topology change. If you convert an edge port into a regular segment port, VLAN load balancing is not implemented unless it has been configured. For VLAN load balancing, you must configure two edge ports in the segment.

A segment port that is reconfigured as a spanning tree port restarts according the spanning tree configuration (by default, a designated blocking port). If PortFast is configured or if STP is disabled, the port goes into the forwarding state.

Configuring REP

A segment is a collection of ports connected one to the other in a chain and configured with a segment ID. To configure REP segments, you should configure the REP administrative VLAN and then add the ports to the segment using interface configuration mode. You should configure two edge ports in the segment, with one of them the primary edge port and the other by default the secondary edge port. A segment has only one primary edge port. If you configure two ports in a segment as the primary edge port, for example ports on different switches, the REP selects one of them to serve as the segment primary edge port. You can also optionally configure where to send segment topology change notices (STCNs) and VLAN load balancing.

This section includes this information:

- [Default REP Configuration, page 25-7](#)
- [REP Configuration Guidelines, page 25-7](#)
- [Configuring the REP Administrative VLAN, page 25-8](#)
- [Configuring REP Interfaces, page 25-10](#)
- [Setting Manual Preemption for VLAN Load Balancing, page 25-13](#)
- [Configuring SNMP Traps for REP, page 25-14](#)

Default REP Configuration

REP is disabled on all interfaces. When enabled, the interface is a regular segment port unless it is configured as an edge port.

When REP is enabled, the task of sending segment topology change notices (STCNs) is disabled, all the VLANs are blocked, and the default administrative VLAN is VLAN 1.

When VLAN load balancing is enabled, the default is manual pre-emption with the delay timer disabled. If VLAN load balancing is not configured, the default after manual pre-emption is to block all the VLANs in the primary edge port.

REP Configuration Guidelines

Follow these guidelines when configuring REP:

- We recommend that you begin by configuring one port and then configure the contiguous ports to minimize the number of segments and the number of blocked ports.
- If more than two ports in a segment fail when no external neighbors are configured, one port goes into a forwarding state for the data path to help maintain connectivity during configuration. In the **show rep interface privileged EXEC** command output, the Port Role for this port shows as *Fail Logical Open*; the Port Role for the other failed port shows as *Fail No Ext Neighbor*. When the external neighbors for the failed ports are configured, the ports go through the alternate port state transitions and eventually go to an open state or remain as the alternate port, based on the alternate port election mechanism.
- REP ports must be Layer 2 dot1Q trunk or PVLAN promiscuous trunk ports.
- Be careful when configuring REP through a Telnet connection. Because REP blocks all VLANs until another REP interface sends a message to unblock it, you might lose connectivity to the switch if you enable REP in a Telnet session that accesses the switch through the same interface.

- You cannot run REP and STP on the same segment or interface.
- If you connect an STP network to the REP segment, be sure that the connection is at the segment edge. An STP connection that is not at the edge could cause a bridging loop because STP does not run on REP segments. All STP BPDUs are dropped at REP interfaces.
- You must configure all trunk and PVLAN promiscuous trunk ports in the segment with the same set of allowed VLANs, or a misconfiguration occurs.
- REP ports follow these rules:
 - If REP is enabled on two ports on a switch, both ports must be either regular segment ports or edge ports.
 - If only one port on a switch is configured in a segment, the port should be an edge port.
 - If two ports on a switch belong to the same segment, both ports must be edge ports or both ports must be regular segment ports.
 - If two ports on a switch belong to the same segment, they must be both edge ports, both regular segment ports, or one regular port and one edge no-neighbor port. An edge port and regular segment port on a switch cannot belong to the same segment.
 - If two ports on a switch belong to the same segment and one is configured as an edge port and one as a regular segment port (a misconfiguration), the edge port is treated as a regular segment port.
- REP interfaces come up in a blocked state and remains in a blocked state until notified that it is safe to unblock. You need to be aware of this to avoid sudden connection losses.
- REP sends all LSL PDUs in untagged frames on the native VLAN. The BPA message sent to the Cisco multicast address is sent on the administration VLAN, which is VLAN 1 by default.
- REP ports can not be configured as one of these port types:
 - SPAN destination port
 - Private VLAN port
 - Tunnel port
 - Access port
- REP is supported on EtherChannels, but not on an individual port that belongs to an EtherChannel.
- There is a maximum of 384 REP segments per switch.

Configuring the REP Administrative VLAN

To avoid the delay introduced by relaying messages in software for link-failure notification or VLAN-blocking notification during load balancing, REP floods packets at the hardware flood layer (HFL) to a regular multicast address. These messages are flooded to the whole network, not just the REP segment. You can control message flooding by configuring an administrative VLAN for the entire domain, or for a particular segment.

Follow these guidelines when configuring a REP administrative VLAN:

- If you do not configure an administrative VLAN, the default is VLAN 1.
- You can create any number of administrative VLANs as long as it is per segment.
- The administrative VLAN cannot be a Remote Switched Port Analyzer (RSPAN) VLAN.

To configure the REP administrative VLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# rep admin vlan <i>vlan-id</i>	Specifies the administrative VLAN ID for the entire domain (all segments). The VLAN ID range is 2 to 4094. The default is VLAN 1. To specify the administrative VLAN ID per segment, enter the rep admin vlan <i>vlan-id segment segment-id</i> global configuration command. To set the admin VLAN ID to 1, enter the no rep admin vlan global configuration command.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show interface [<i>interface-id</i>] rep detail	Verifies configuration on the specified REP interface.
Step 5	Switch# copy running-config startup config	(Optional) Saves your entries in the switch startup configuration file.

This example shows how to configure the administrative VLAN as VLAN 100 and verify the configuration by entering the **show interface rep detail** command on one of the REP interfaces:

```
Switch# configure terminal
Switch (config)# rep admin vlan 100
Switch (config)# end

Switch# show interface gigabitethernet1/1 rep detail
GigabitEthernet1/1 REP enabled
Segment-id: 2 (Edge)
PortID: 00010019E7144680
Preferred flag: No
Operational Link Status: TWO_WAY
Current Key: 0002001121A2D5800E4D
Port Role: Open
Blocked Vlan: <empty>
Admin-vlan: 100
Preempt Delay Timer: disabled
Load-balancing block port: none
Load-balancing block vlan: none
STCN Propagate to: none
LSL PDU rx: 3322, tx: 1722
HFL PDU rx: 32, tx: 5
BPA TLV rx: 16849, tx: 508
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
EPA-ELECTION TLV rx: 118, tx: 118
EPA-COMMAND TLV rx: 0, tx: 0
EPA-INFO TLV rx: 4214, tx: 4190
```

This example shows how to create an administrative VLAN per segment. Here VLAN ID 2 is configured as the administrative VLAN only for REP segment 2. All remaining segments have VLAN 1 as the administrative VLAN.

```
Switch# configure terminal
Switch (config)# rep admin vlan 2 segment 2
Switch (config)# end
```

Configuring REP Interfaces

For REP operation, you need to enable it on each segment interface and identify the segment ID. This step is required and must be done before other REP configuration. You must also configure a primary and secondary edge port on each segment. All other steps are optional.

To enable and configure REP on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Specifies the interface, and enter interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 48.
Step 3	Switch(config-if)# switchport mode trunk or, switchport mode private-vlan trunk promiscuous	<p>Configures the Layer 2 interface as a Layer 2 trunk port.</p> <p>Configures the Layer 2 interface as a PVLAN promiscuous trunk port.</p> <p>For information on command options for PVLAN promiscuous trunk ports, refer to “Configuring a Layer 2 Interface as a Promiscuous PVLAN Trunk Port” on page 21.</p> <p>Note With REP, only the switchport mode private-vlan trunk promiscuous command is supported; other PVLAN trunk related configurations <i>are not</i> supported.</p>

	Command	Purpose
Step 4	<pre>Switch(config-if)# rep segment segment-id [edge [no-neighbor] [primary]] [preferred]</pre>	<p>Enables REP on the interface, and identifies a segment number. The segment ID range is from 1 to 1024. These optional keywords are available.</p> <p>Note You must configure two edge ports, including one primary edge port for each segment.</p> <ul style="list-style-type: none"> Enter edge to configure the port as an edge port. Entering edge without the primary keyword configures the port as the secondary edge port. Each segment has only two edge ports. (Optional) Enter no-neighbor to configure a port with no external REP neighbors as an edge port. The port inherits all properties of edge ports. You can configure them as you would any edge port. (Optional) On an edge port, enter primary to configure the port as the primary edge port, the port on which you can configure VLAN load balancing. <p>Note Although each segment can have only one primary edge port, if you configure edge ports on two different switches and enter the primary keyword on both switches, the configuration is allowed. However, REP selects only one of these ports as the segment primary edge port. You can identify the primary edge port for a segment by entering the show rep topology privileged EXEC command.</p> <ul style="list-style-type: none"> (Optional) Enter preferred to indicate that the port is the preferred alternate port or the preferred port for VLAN load balancing. <p>Note Configuring a port as preferred does not guarantee that it becomes the alternate port; this only provides a slight advantage among equal contenders. The alternate port is usually a previously failed port.</p>
Step 5	<pre>Switch(config-if)# rep stcn {interface interface-id segment id-list stp}</pre>	<p>(Optional) Configures the edge port to send segment topology change notices (STCNs).</p> <ul style="list-style-type: none"> Enter interface <i>interface-id</i> to designate a physical interface or port channel to receive STCNs. Enter segment <i>id-list</i> to identify one or more segments to receive STCNs. The range is 1 to 1024. Enter stp to send STCNs to STP networks.

	Command	Purpose
Step 6	Switch(config-if)# rep block port { id <i>port-id</i> <i>neighbor_offset</i> preferred } vlan { <i>vlan-list</i> all }	<p>(Optional) Configures VLAN load balancing on the primary edge port, identify the REP alternate port in one of three ways, and configure the VLANs to be blocked on the alternate port.</p> <ul style="list-style-type: none"> Enter the id <i>port-id</i> to identify the alternate port by port ID. The port ID is automatically generated for each port in the segment. You can view interface port IDs by entering the show interface interface-id rep [detail] privileged EXEC command. Enter a <i>neighbor_offset</i> number to identify the alternate port as a downstream neighbor from an edge port. The range is from -256 to 256, with negative numbers indicating the downstream neighbor from the secondary edge port. A value of 0 is invalid. Enter -1 to identify the secondary edge port as the alternate port. For an example of neighbor offset numbering, see Figure 25-4 on page 25-5. <p>Note Because you enter this command at the primary edge port (offset number 1), you never enter an offset value of 1 to identify an alternate port.</p> <ul style="list-style-type: none"> Enter preferred to select the regular segment port previously identified as the preferred alternate port for VLAN load balancing. Enter vlan <i>vlan-list</i> to block one VLAN or a range of VLANs. Enter vlan all to block all VLANs. <p>Note Enter this command only on the REP primary edge port.</p>
Step 7	Switch(config-if)# rep preempt delay <i>seconds</i>	<p>(Optional) You must enter this command and configure a preempt time delay if you want VLAN load balancing to automatically trigger after a link failure and recovery. The time delay range is 15 to 300 seconds. The default is manual preemption with no time delay.</p> <p>Note Enter this command only on the REP primary edge port.</p>
Step 8	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 9	Switch# show interface [<i>interface-id</i>] rep [detail]	Verifies the REP interface configuration.
Step 10	Switch# copy running-config startup config	(Optional) Saves your entries in the switch startup configuration file.

Enter the **no** form of each command to return to the default configuration. Enter the **show rep topology** privileged EXEC command to see which port in the segment is the primary edge port.

This example shows how to configure an interface as the primary edge port for segment 1, to send STCNs to segments 2 through 5, and to configure the alternate port as the port with port ID 0009001818D68700 to block all VLANs after a preemption delay of 60 seconds after a segment port failure and recovery.

```
Switch# configure terminal
Switch(config)# interface gigabitethernet1/1
Switch(config-if)# rep segment 1 edge primary
Switch(config-if)# rep stcn segment 2-5
Switch(config-if)# rep block port 0009001818D68700 vlan all
Switch(config-if)# rep preempt delay 60
Switch(config-if)# end
```

This example shows how to configure the same configuration when the interface has no external REP neighbor:

```
Switch# configure terminal
Switch (config)# interface gigabitethernet1/1
Switch (config-if)# rep segment 1 edge no-neighbor primary
Switch (config-if)# rep stcn segment 2-5
Switch (config-if)# rep block port 0009001818D68700 vlan all
Switch (config-if)# rep preempt delay 60
Switch (config-if)# rep lsl-age-timer 6000
```

This example shows how to configure the VLAN blocking configuration shown in Figure 25-5. The alternate port is the neighbor with neighbor offset number 4. After manual preemption, VLANs 100 to 200 are blocked at this port and all other VLANs are blocked at the primary edge port E1 (Gigabit Ethernet port 1/1).

```
Switch# configure terminal
Switch (config)# interface gigabitethernet1/1
Switch (config-if)# rep segment 1 edge primary
Switch (config-if)# rep block port 4 vlan 100-200
Switch (config-if)# end
```

Figure 25-5 Example of VLAN Blocking

Setting Manual Preemption for VLAN Load Balancing

If you do not enter the **rep preempt delay** *seconds* interface configuration command on the primary edge port to configure a preemption time delay, the default is to manually trigger VLAN load balancing on the segment. Be sure that all other segment configuration has been completed before manually preempting VLAN load balancing. When you enter the **rep preempt segment** command, a confirmation message appears before the command is executed because preemption can cause network disruption.

To manually trigger VLAN load balancing on a segment on the switch that has the segment primary edge port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Specifies the interface, and enter interface configuration mode. The interface can be a physical Layer 2 interface or a port channel (logical interface). The port-channel range is 1 to 48.

	Command	Purpose
Step 3	Switch(config-if)# rep preempt segment <i>segment-id</i>	Manually triggers VLAN load balancing on the segment. You must confirm the command before it is executed.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show rep topology	Displays REP topology information.

Configuring SNMP Traps for REP

To configure the switch to send REP-specific traps to notify the SNMP server of link operational status changes and port role changes, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# snmp mib rep trap-rate <i>value</i>	Enables the switch to send REP traps, and set the number of traps sent per second. The range is from 0 to 1000. The default is 0 (no limit imposed; a trap is sent at every occurrence).
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show running-config	Verifies the REP trap configuration.
Step 5	Switch# copy running-config startup config	(Optional) Saves your entries in the switch startup configuration file.

To remove the trap, enter the **no snmp mib rep trap-rate** global configuration command.

This example configures the switch to send REP traps at a rate of 10 per second:

```
Switch(config)# snmp mib rep trap-rate 10
```

Monitoring REP

To monitor REP, enter the following privileged EXEC commands ([Table 25-1](#)).

Table 25-1 REP Monitoring Commands

Command	Purpose
Switch# show interface [<i>interface-id</i>] rep [<i>detail</i>]	Displays REP configuration and status for a specified interface or for all interfaces.
Switch# show rep topology [<i>segment segment-id</i>] [<i>archive</i>] [<i>detail</i>]	Displays REP topology information for a segment or for all segments, including the primary and secondary edge ports in the segment.

Configuring Optional STP Features

This chapter describes the Spanning Tree Protocol (STP) features supported on the switch. It also provides guidelines, procedures, and configuration examples. To configure STP, see [Chapter 23, “Configuring STP and MST.”](#)

This chapter includes the following major sections:

- [About Root Guard, page 26-2](#)
- [Enabling Root Guard, page 26-2](#)
- [About Loop Guard, page 26-3](#)
- [Enabling Loop Guard, page 26-5](#)
- [About EtherChannel Guard, page 26-6](#)
- [Enabling EtherChannel Guard \(Optional\), page 26-6](#)
- [About STP PortFast Port Types, page 26-7](#)
- [Enabling PortFast Port Types, page 26-8](#)
- [About Bridge Assurance, page 26-11](#)
- [Configuring Bridge Assurance, page 26-13](#)
- [About BPDU Guard, page 26-15](#)
- [Enabling BPDU Guard, page 26-15](#)
- [About PortFast Edge BPDU Filtering, page 26-16](#)
- [Enabling PortFast Edge BPDU Filtering, page 26-17](#)
- [About UplinkFast, page 26-19](#)
- [Enabling UplinkFast, page 26-20](#)
- [About BackboneFast, page 26-21](#)
- [Enabling BackboneFast, page 26-23](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Root Guard

Spanning Tree root guard forces an interface to become a designated port, to protect the current root status and prevent surrounding switches from becoming the root switch.

When you enable root guard on a per-port basis, it is automatically applied to all of the active VLANs to which that port belongs. When you disable root guard, it is disabled for the specified port and the port automatically goes into the listening state.

When a switch that has ports with root guard enabled detects a new root, the ports enter the root-inconsistent state. The switch no longer detects a new root and its ports automatically go into the listening state.

Enabling Root Guard

To enable root guard on a Layer 2 access port (to force it to become a designated port), perform this task:

	Command	Purpose
Step 1	Switch(config)# interface {{fastethernet gigabitethernet tengigabitethernet} slot/port}	Specifies an interface to configure.
Step 2	Switch(config-if)# [no] spanning-tree guard root	Enables root guard. Use the no keyword to disable root guard.
Step 3	Switch(config-if)# end	Exits configuration mode.
Step 4	Switch# show spanning-tree	Verifies the configuration.

This example shows how to enable root guard on Fast Ethernet interface 5/8:

```
Switch(config)# interface fastethernet 5/8
Switch(config-if)# spanning-tree guard root
Switch(config-if)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show running-config interface fastethernet 5/8
Building configuration...

Current configuration: 67 bytes
!
interface FastEthernet5/8
  switchport mode access
  spanning-tree guard root
end

Switch#
```

This example shows how to determine whether any ports are in root inconsistent state:

```
Switch# show spanning-tree inconsistentports
```

Name	Interface	Inconsistency
VLAN0001	FastEthernet3/1	Root Inconsistent
VLAN0001	FastEthernet3/2	Root Inconsistent
VLAN1002	FastEthernet3/1	Root Inconsistent
VLAN1002	FastEthernet3/2	Root Inconsistent
VLAN1003	FastEthernet3/1	Root Inconsistent
VLAN1003	FastEthernet3/2	Root Inconsistent
VLAN1004	FastEthernet3/1	Root Inconsistent
VLAN1004	FastEthernet3/2	Root Inconsistent
VLAN1005	FastEthernet3/1	Root Inconsistent
VLAN1005	FastEthernet3/2	Root Inconsistent

```
Number of inconsistent ports (segments) in the system :10
```

About Loop Guard

Loop guard helps prevent bridging loops that could occur because of a unidirectional link failure on a point-to-point link. When enabled globally, loop guard applies to all point-to-point ports on the system. Loop guard detects root ports and blocked ports and ensures that they keep receiving BPDUs from their designated port on the segment. If a loop-guard-enabled root or blocked port stop receiving BPDUs from its designated port, it transitions to the blocking state, assuming there is a physical link error on this port. The port recovers from this state as soon as it receives a BPDU.

You can enable loop guard on a per-port basis. When you enable loop guard, it is automatically applied to all of the active instances or VLANs to which that port belongs. When you disable loop guard, it is disabled for the specified ports. Disabling loop guard moves all loop-inconsistent ports to the listening state.

If you enable loop guard on a channel and the first link becomes unidirectional, loop guard blocks the entire channel until the affected port is removed from the channel. [Figure 26-1](#) shows loop guard in a triangular switch configuration.

Figure 26-1 Triangular Switch Configuration with Loop Guard

55772

Figure 26-1 illustrates the following configuration:

- Switches A and B are distribution switches.
- Switch C is an access switch.
- Loop guard is enabled on ports 3/1 and 3/2 on Switches A, B, and C.

Enabling loop guard on a root switch has no effect but provides protection when a root switch becomes a nonroot switch.

Follow these guidelines when using loop guard:

- Do not enable loop guard on PortFast edge-enabled or dynamic VLAN ports.
- Do not enable loop guard if root guard is enabled.

Loop guard interacts with other features as follows:

- Loop guard does not affect the functionality of UplinkFast or BackboneFast.
- Enabling loop guard on ports that are not connected to a point-to-point link does not work.
- Root guard forces a port to always be the root port. Loop guard is effective only if the port is a root port or an alternate port. You cannot enable loop guard and root guard on a port at the same time.
- Loop guard uses the ports known to spanning tree. Loop guard can take advantage of logical ports provided by the Port Aggregation Protocol (PAgP). However, to form a channel, all the physical ports grouped in the channel must have compatible configurations. PAgP enforces uniform configurations of root guard or loop guard on all the physical ports to form a channel.
 - Spanning tree always chooses the first operational port in the channel to send the BPDUs. If that link becomes unidirectional, loop guard blocks the channel, even if other links in the channel are functioning properly.
 - If a set of ports that are already blocked by loop guard are grouped together to form a channel, spanning tree loses all the state information for those ports and the new channel port may obtain the forwarding state with a designated role.
 - If a channel is blocked by loop guard and the channel breaks, spanning tree loses all the state information. The individual physical ports may obtain the forwarding state with the designated role, even if one or more of the links that formed the channel are unidirectional.

**Note**

You can enable UniDirectional Link Detection (UDLD) to help isolate the link failure. A loop may occur until UDLD detects the failure, but loop guard is not able to detect it.

- Loop guard has no effect on a disabled spanning tree instance or a VLAN.

Enabling Loop Guard

You can enable loop guard globally or per-port.

Loop Guard can be enabled only on network and normal spanning tree port types.

To enable loop guard globally on the switch, perform this task:

	Command	Purpose
Step 1	Switch(config)# spanning-tree loopguard default	Enables loop guard globally on the switch.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show spanning tree interface 4/4	Verifies the configuration impact on a port.

This example shows how to enable loop guard globally:

```
Switch(config)# spanning-tree loopguard default
Switch(config)# Ctrl-Z
```

This example shows how to verify the previous configuration of port 4/4:

```
Switch# show spanning-tree interface fastethernet 4/4 detail
Port 196 (FastEthernet4/4) of VLAN0010 is forwarding
  Port path cost 1000, Port priority 160, Port Identifier 160.196.
  Designated root has priority 32768, address 00d0.00b8.140a
  Designated bridge has priority 32768, address 00d0.00b8.140a
  Designated port id is 160.196, designated path cost 0
  Timers:message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state:1
  The port is in the portfast mode by portfast trunk configuration
  Link type is point-to-point by default
  Bpdu filter is enabled
  Loop guard is enabled by default on the port
  BPDU:sent 0, received 0
```

To enable loop guard on an interface, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface {type slot/port} {port-channel port_channel_number}	Selects an interface to configure.
Step 2	Switch(config-if)# spanning-tree guard loop	Configures loop guard.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show spanning tree interface 4/4	Verifies the configuration impact on that port.

This example shows how to enable loop guard on port 4/4:

```
Switch(config)# interface fastEthernet 4/4
Switch(config-if)# spanning-tree guard loop
Switch(config-if)# ^Z
```

This example shows how to verify the configuration impact on port 4/4:

```
Switch# show spanning-tree interface fastEthernet 4/4 detail
Port 196 (FastEthernet4/4) of VLAN0010 is forwarding
  Port path cost 1000, Port priority 160, Port Identifier 160.196.
  Designated root has priority 32768, address 00d0.00b8.140a
  Designated bridge has priority 32768, address 00d0.00b8.140a
  Designated port id is 160.196, designated path cost 0
  Timers:message age 0, forward delay 0, hold 0
  Number of transitions to forwarding state:1
  The port is in the portfast mode by portfast trunk configuration
  Link type is point-to-point by default
  Bpdu filter is enabled
  Loop guard is enabled on the port
  BPDU:sent 0, received 0
Switch#
```

About EtherChannel Guard

EtherChannel guard allows you to detect an EtherChannel misconfiguration between the switch and a connected device. A misconfiguration can occur if the interfaces of a switch are manually configured in an EtherChannel, and one or more interfaces on the other device are not. For EtherChannel configuration guidelines, see the [“EtherChannel Configuration Guidelines and Restrictions” section on page 27-6](#).

Note

EtherChannel guard applies only to EtherChannels in forced mode (that is, manually configured) rather than through PAgP or LACP.

If the switch detects a misconfiguration on the other device, EtherChannel guard error-disables all interfaces in the EtherChannel bundle, and displays an error message.

You can enable this feature with the **spanning-tree etherchannel guard misconfig** global configuration command.

Enabling EtherChannel Guard (Optional)

You can enable EtherChannel guard to detect an EtherChannel misconfiguration if your switch is running PVST+, rapid PVST+, or MSTP.

To enable EtherChannel guard, perform this task:

	Command	Purpose
Step 1	Switch(config)# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# spanning-tree etherchannel guard misconfig	Enables EtherChannel guard.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch(config)# show spanning-tree summary	Verifies your entries.
Step 5	Switch(config)# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable the EtherChannel guard feature, use the **no spanning-tree etherchannel guard misconfig** global configuration command.

Use the **show interfaces status err-disabled** privileged EXEC command to show which switch ports are disabled because of an EtherChannel misconfiguration. On the remote device, you can enter the **show etherchannel summary** privileged EXEC command to verify the EtherChannel configuration.

After the configuration is corrected, enter the **shutdown** and **no shutdown** interface configuration commands on the port-channel interfaces that were misconfigured.

About STP PortFast Port Types

You can configure a spanning tree port as an edge port, a network port, or a normal port. A port can be in only one of these states at a given time. The default spanning tree port type is normal. You can configure the port type either globally or per interface.

Depending on the type of device to which the interface is connected, you can configure a spanning tree port as one of these port types:

- A PortFast edge port—is connected to a Layer 2 host. This can be either an access port or an edge trunk port (**portfast edge trunk**). This type of port interface immediately transitions to the forwarding state, bypassing the listening and learning states. Use PortFast edge on Layer 2 access ports connected to a single workstation or server to allow those devices to connect to the network immediately, rather than waiting for spanning tree to converge.

Even if the interface receives a bridge protocol data unit (BPDU), spanning tree does not place the port into the blocking state. Spanning tree sets the port's operating state to *non-port fast* even if the configured state remains *port fast edge* and starts participating in the topology change.

Note If you configure a port connected to a Layer 2 switch or bridge as an edge port, you might create a bridging loop.

- A PortFast network port—is connected only to a Layer 2 switch or bridge.
Bridge Assurance is enabled only on PortFast network ports. For more information, see [About Bridge Assurance, page 26-11](#).

Note If you configure a port that is connected to a Layer 2 host as a spanning tree network port, the port will automatically move into the blocking state.

- A PortFast normal port—is the default type of spanning tree port.

Note

Beginning with Cisco IOS Release 15.2(4)E, or IOS XE 3.8.0E, if you enter the **spanning-tree portfast** [trunk] command in the global or interface configuration mode, the system automatically saves it as **spanning-tree portfast edge** [trunk].

Enabling PortFast Port Types

- [Configuring the PortFast Default State Globally, page 26-8](#)
- [Configuring a PortFast Edge Port on a Specified Interface, page 26-8](#)
- [Configuring a PortFast Network Port on a Specified Interface, page 26-10](#)

Configuring the PortFast Default State Globally

To configure the default PortFast state, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 1	Switch(config)# spanning-tree portfast [edge network normal] default	Configures the default state for all interfaces on the switch. You have these options: <ul style="list-style-type: none"> • (Optional) edge—Configures all interfaces as edge ports. This assumes all ports are connected to hosts/servers. • (Optional) network—Configures all interfaces as spanning tree network ports. This assumes all ports are connected to switches and bridges. Bridge Assurance is enabled on all network ports by default. • (Optional) normal—Configures all interfaces as normal spanning tree ports. These ports can be connected to any type of device. • default—The default port type is normal.
Step 2	Switch(config)# end	Exits configuration mode.

Configuring a PortFast Edge Port on a Specified Interface

Interfaces configured as edge ports immediately transition to the forwarding state, without passing through the blocking or learning states, on linkup. To configure an edge port on a specified interface, perform this task:

Note

Because the purpose of this type of port is to minimize the time that access ports must wait for spanning tree to converge, it is most effective when used on access ports. If you enable PortFast edge on a port connecting to another switch, you risk creating a spanning tree loop.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface {{ fastethernet gigabitethernet tengigabitethernet } slot/port } { port-channel port_channel_number }	Specifies an interface to configure.

	Command	Purpose
Step 3	Switch(config-if)# spanning-tree portfast edge [trunk]	Enables edge behavior on a Layer 2 access port connected to an end workstation or server. (Optional) trunk —Enables edge behavior on a trunk port. Use this keyword if the link is a trunk. Use this command only on ports that are connected to end host devices that terminate VLANs and from which the port should never receive STP BPDUs. Such end host devices include workstations, servers, and ports on routers that are not configured to support bridging. Use the no version of the command to disable PortFast edge.
Step 4	Switch(config-if)# end	Exits global configuration mode
Step 5	Switch# show running interface {{ fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> } { port-channel <i>port_channel_number</i> }	Verifies the configuration.
Step 6	Switch# show spanning-tree interface {{ fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> } { port-channel <i>port_channel_number</i> } portfast edge	Displays spanning-tree PortFast information for the specified interface.

This example shows how to enable edge behavior on GigabitEthernet interface 5/7 and verify configuration:

```
Switch# configure terminal
Switch(config)# interface fastethernet 5/7
Switch(config-if)# spanning-tree portfast edge
Switch(config-if)# end
Switch#

Switch# show running-config interface fastethernet 5/7
Building configuration...
Current configuration:
!
interface GigabitEthernet5/7
 no ip address
 switchport
 switchport access vlan 200
 switchport mode access
 spanning-tree portfast edge
end
```

This example shows how you can display that port GigabitEthernet 5/8 is currently in the edge state:

```
Switch# show spanning-tree vlan 200
VLAN0200
Spanning tree enabled protocol rstp
Root ID Priority 2
Address 001b.2a68.5fc0
Cost 3
Port 125 (GigabitEthernet5/9)
Hello Time 2 sec Max Age 20 sec Forward Delay 15 sec

Bridge ID Priority 2 (priority 0 sys-id-ext 2)
Address 7010.5c9c.5200
Hello Time 2 sec Max Age 20 sec Forward Delay 15 sec
Aging Time 0 sec
```

Interface	Role	Sts	Cost	Prio.	Nbr	Type
-----	-----	-----	-----	-----	-----	-----
Gi5/7	Desg	FWD	4	128.1	P2p	Edge

Configuring a PortFast Network Port on a Specified Interface

Ports that are connected to Layer 2 switches and bridges can be configured as network ports.

Note Bridge Assurance is enabled only on PortFast network ports. For more information, see [About Bridge Assurance, page 26-11](#)

To configure a port as a network port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface {{fastethernet gigabitethernet tengigabitethernet} slot/port} {port-channel port_channel_number}	Specifies an interface to configure.
Step 3	Switch(config-if)# spanning-tree portfast network	Configures the port as a network port. If you have enabled Bridge Assurance globally, it automatically runs on a spanning tree network port. Use the no keyword to disable PortFast.
Step 4	Switch(config-if)# end	Exits configuration mode.
Step 5	Switch# show running interface {{fastethernet gigabitethernet tengigabitethernet} slot/port} {port-channel port_channel_number}	Verifies the configuration.

This example shows how to configure GigabitEthernet interface 5/8 as a network port and verify configuration:

```
Switch# configure terminal
Switch(config)# interface gigabitethernet 5/8
Switch(config-if)# spanning-tree portfast network
Switch(config-if)# end
Switch#

Switch# show running-config interface gigabitethernet 5/8
Building configuration...
Current configuration:
!
interface GigabitEthernet5/8
 no ip address
 switchport
 switchport access vlan 200
 switchport mode access
 spanning-tree portfast network
end
```

About Bridge Assurance

You can use Bridge Assurance to help prevent looping conditions that are caused by unidirectional links (one-way traffic on a link or port), or a malfunction in a neighboring switch. Here, a malfunction refers to a switch that is not able to run STP any more, while still forwarding traffic (a brain dead switch).

BPDUs are sent out on all operational network ports, including alternate and backup ports, for each hello time period. Bridge Assurance monitors the receipt of BPDUs on point-to-point links on all network ports. When a port does not receive BPDUs within the allotted hello time period, the port is put into a blocked state (the same as a port inconsistent state, which stops forwarding of frames). When the port resumes receipt of BPDUs, the port resumes normal spanning tree operations.

Note Only Rapid PVST+ and MST spanning tree protocols support Bridge Assurance. PVST+ does not support Bridge Assurance.

This example shows how Bridge Assurance protects your network from bridging loops. Here, [Figure 26-2](#) shows a normal STP topology, and [Figure 26-3](#) demonstrates a potential network problem when the device fails (brain dead) and Bridge Assurance is not enabled on the network.

Figure 26-2 Network with Normal STP Topology

Figure 26-3 Network Loop Due to a Malfunctioning Switch

Figure 26-4 shows the network with Bridge Assurance enabled, and the STP topology progressing normally with bidirectional BDPUs issuing from every STP network port. Figure 26-5 shows how the potential network problem shown in Figure 26-3 does not occur when you have Bridge Assurance enabled on your network.

Figure 26-4 Network with STP Topology Running Bridge Assurance

Figure 26-5 Network Problem Averted with Bridge Assurance Enabled

The system generates syslog messages when a port is block or unblocked. The following sample outputs show the log that is generated for each of these states:

Blocked port:

```
Sep 17 09:48:16.249 PDT: %SPANTREE-2-BRIDGE_ASSURANCE_BLOCK: Bridge Assurance blocking
port GigabitEthernet5/8 on VLAN0200. (stack-dut-R4-4)
```

Unblocked Port:

```
Sep 17 09:48:58.426 PDT: %SPANTREE-2-BRIDGE_ASSURANCE_UNBLOCK: Bridge Assurance
unblocking port GigabitEthernet5/8 on VLAN0200. (stack-dut-R4-4)
```

Observe these guidelines when configuring Bridge Assurance:

- It can be enabled or disabled globally.
- It applies to all operational network ports, including alternate and backup ports.
- Only Rapid PVST+ and MST spanning tree protocols support Bridge Assurance. PVST+ does not support Bridge Assurance.
- For Bridge Assurance to work properly, it must be supported and configured on both ends of a point-to-point link. If the device on one side of the link has Bridge Assurance enabled and the device on the other side does not, then the connecting port is blocked (a Bridge Assurance inconsistent state). We recommend that you enable Bridge Assurance throughout your network.
- To enable Bridge Assurance on a port, BPDU filtering and BPDU Guard must be disabled.
- You can enable Bridge Assurance in conjunction with Loop Guard.
- You can enable Bridge Assurance in conjunction with Root Guard. The latter is designed to provide a way to enforce the root bridge placement in the network.

Configuring Bridge Assurance

	Command	Purpose
Step 1	Switch # configure terminal	Enters the global configuration mode.
Step 2	Switch(config)# spanning-tree bridge assurance	Enables Bridge Assurance on all network ports on the switch. Bridge Assurance is enabled by default. Use the no version of the command to disable the feature. Disabling Bridge Assurance causes all configured network ports to behave as normal spanning tree ports.
Step 3	Switch(config-if)# end	Exits configuration mode.
Step 4	Switch# show spanning-tree summary	Displays spanning tree information and shows if Bridge Assurance is enabled

This example show how to display spanning tree information and verify if Bridge Assurance is enabled. Look for these details in the output:

- Portfast Default—Network
- Bridge Assurance—Enabled

```
Switch# show spanning-tree summary
Switch is in rapid-pvst mode
Root bridge for: VLAN0199-VLAN0200, VLAN0128
EtherChannel misconfig guard      is enabled
Extended system ID                is enabled
Portfast Default                  is network
Portfast Edge BPDU Guard Default  is disabled
Portfast Edge BPDU Filter Default is disabled
Loopguard Default                 is enabled
PVST Simulation Default           is enabled but inactive in rapid-pvst mode
Bridge Assurance                  is enabled
UplinkFast                        is disabled
BackboneFast                      is disabled
```

Configured Pathcost method used is short

Name	Blocking	Listening	Learning	Forwarding	STP Active
VLAN0199	0	0	0	5	5
VLAN0200	0	0	0	4	4
VLAN0128	0	0	0	4	4
3 vlans	0	0	0	13	13

This example shows how to verify if GigabitEthernet 5/8 (configured as a network port), is in a normal state. (From the **show spanning-tree summary** output above, we know that Bridge Assurance is enabled on GigabitEthernet 5/8).

Switch# **show spanning-tree vlan**

Sep 17 09:51:36.370 PDT: %SYS-5-CONFIG_I: Configured from console by console2

VLAN0200

About BPDU Guard

Spanning Tree BPDU guard shuts down PortFast edge-configured interfaces that receive BPDUs, rather than putting them into the spanning tree blocking state.

When configured globally, BPDU Guard is only effective on ports in the operational PortFast edge state. In a valid configuration, PortFast edge-configured interfaces do not receive BPDUs. Reception of a BPDU by a PortFast edge-configured interface signals an invalid configuration, such as connection of an unauthorized device.

BPDU guard provides a secure response to invalid configurations, because the administrator must manually put the interface back in service.

Note

When the BPDU guard feature is enabled, spanning tree applies the BPDU guard feature to all PortFast-configured interfaces. BPDU Guard shuts down that interface if a BPDU is received, regardless of the PortFast port type configuration.

Note

To prevent the port from shutting down, use the **errdisable detect cause bpduguard shutdown vlan** global configuration command to shut down only the offending VLAN on the port where the violation occurred.

Enabling BPDU Guard

Enabling BPDU Guard Globally

To globally enable BPDU guard on edge ports that receive BPDUs, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	
Step 2	Switch(config)# spanning-tree portfast edge bpduguard default	Enables BPDU Guard globally by default on all edge ports of the switch. Use the no version of the command to disable BPDU guard.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show spanning-tree summary	Verifies the BPDU configuration.

This example shows how to enable BPDU guard:

```
Switch(config)# spanning-tree portfast edge bpduguard default
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show spanning-tree summary
Root bridge for: Bridge VLAN0025
EtherChannel misconfiguration guard is enabled
```

```
Extended system ID                is enabled
PortFast Edge BPDU Guard Default  is enabled
Portfast Edge BPDU Filter Default is disabled
Portfast Default                  is edge
Bridge Assurance                  is enabled
Loopguard                        is disabled
UplinkFast                       is disabled
BackboneFast                     is disabled
Pathcost method used is short

Name                               Blocking Listening Learning Forwarding STP Active
-----
2 vlans                           0           0           0           3           3
```

Enabling BPDU Guard on a Specified Interface

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface {{fastethernet gigabitethernet tengigabitethernet} slot/port} {port-channel port_channel_number}	Specifies an interface to configure.
Step 3	Switch(config-if)# spanning-tree portfast edge bpduguard default	Enables BPDU Guard on the specified edge port. Use the no keyword to disable BPDU guard.
Step 4	Switch(config)# end	Exits configuration mode.
Step 5	Switch# show spanning-tree summary	Verifies the BPDU configuration.

About PortFast Edge BPDU Filtering

Cisco IOS Release 12.2(31)SGA and later support PortFast edge BPDU filtering, which allows the administrator to prevent the system from sending or even receiving BPDUs on specified ports.

When configured globally, PortFast edge BPDU filtering applies to all operational PortFast edge ports. Ports in an operational PortFast edge state are supposed to be connected to hosts that typically drop BPDUs. If an operational PortFast edge port receives a BPDU, it immediately loses its operational PortFast edge status. In that case, PortFast edge BPDU filtering is disabled on this port and STP resumes sending BPDUs on this port.

PortFast edge BPDU filtering can also be configured on a per-port basis. When PortFast edge BPDU filtering is explicitly configured on a port, it does not send any BPDUs and drops all BPDUs it receives.

Caution

Explicitly configuring PortFast edge BPDU filtering on a port that is not connected to a host can result in bridging loops, because the port ignores any BPDU it receives and goes to the forwarding state.

When you enable PortFast edge BPDU filtering globally and set this port configuration as the default for PortFast edge BPDU filtering (see the [“Enabling BackboneFast” section on page 26-23](#)), PortFast enables or disables PortFast edge BPDU filtering.

If the port configuration is not set to default, then the PortFast edge configuration does not affect PortFast edge BPDU filtering. Table 26-1 lists all the possible PortFast edge BPDU filtering combinations. PortFast edge BPDU filtering allows access ports to move directly to the forwarding state as soon as the end hosts are connected.

Table 26-1 PortFast Edge BPDU Filtering Port Configurations

Per-Port Configuration	Global Configuration	PortFast Edge State	PortFast Edge BPDU Filtering State
Default	Enable	Enable	Enable ¹
Default	Enable	Disable	Disable
Default	Disable	Not applicable	Disable
Disable	Not applicable	Not applicable	Disable
Enable	Not applicable	Not applicable	Enable

1. The port transmits at least 10 BPDUs. If this port receives any BPDUs, then PortFast edge and PortFast edge BPDU filtering are disabled.

Enabling PortFast Edge BPDU Filtering

Enabling PortFast Edge BPDU Filtering Globally

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# spanning-tree portfast edge bpdupfilter default	Enables BPDU filtering globally by default on all edge ports of the switch. Use the no prefix to disable BPDU filtering by default on all edge ports of the switch.
Step 3	Switch# show spanning-tree summary totals	Verifies the BPDU configuration.

This example shows how to enable PortFast edge BPDU filtering as default on all edge ports and verify the configuration in PVST+ mode :

```
Switch(config)# spanning-tree portfast edge bpdupfilter default
Switch(config)# exit
```

```
Switch# show spanning-tree summary totals
Root bridge for: Bridge VLAN0025
EtherChannel misconfiguration guard is enabled
Extended system ID           is enabled
PortFast Edge BPDU Guard Default is disabled
Portfast Edge BPDU Filter Default is enabled
Portfast Default              is edge
Bridge Assurance               is enabled
Loopguard                     is disabled
UplinkFast                    is disabled
BackboneFast                   is disabled
Pathcost method used is long
```

```
Name                Blocking Listening Learning Forwarding STP Active
```

2 vlans	0	0	0	3	3
---------	---	---	---	---	---

Note

For PVST+ information, see [Chapter 23, “Configuring STP and MST.”](#)

Enabling PortFast Edge BPDU Filtering on a Specified Interface

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface {{ fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> } {port-channel port_channel_number}	Specifies an interface to configure.
Step 3	Switch(config-if)# spanning-tree bpdufilter [enable disable]	Enables or Disables BPDU filtering.
Step 4	Switch# show spanning-tree interface { <i>type slot/port</i> }	Verifies the configuration.

This example shows how to enable PortFast edge BPDU filtering on port 4/4:

```
Switch(config)# interface fastethernet 4/4
Switch(config-if)# spanning-tree bpdufilter enable
Switch(config-if)# end
```

This example shows how to verify that PortFast edge BPDU filtering is enabled:

```
Switch# show spanning-tree interface fastethernet 4/4

Vlan          Role Sts Cost      Prio.Nbr Status
-----
VLAN0010      Desg FWD 1000     160.196 Edge P2p
```

This example shows more detail on the port:

```
Switch# show spanning-tree interface fastEthernet 4/4 detail
Port 196 (FastEthernet4/4) of VLAN0002 is forwarding
Port path cost 4, Port priority 128, Port Identifier 128.269.
Designated root has priority 32770, address 0002.172c.f400
Designated bridge has priority 32770, address 0002.172c.f400
Designated port id is 128.269, designated path cost 0
Timers: message age 0, forward delay 0, hold 0
Number of transitions to forwarding state: 1
Link type is point-to-point by default
Loop guard is enabled by default on the port
The port is in portfast edge trunk mode
Link type is point-to-point by default
BPDU:sent 2183, received 0
Switch#
```

About UplinkFast

Note

UplinkFast is most useful in wiring-closet switches. This feature might not be useful for other types of applications.

Spanning Tree UplinkFast provides fast convergence after a direct link failure and uses uplink groups to achieve load balancing between redundant Layer 2 links. Convergence is the speed and ability of a group of internetworking devices running a specific routing protocol to agree on the topology of an internetwork after a change in that topology. An uplink group is a set of Layer 2 interfaces (per VLAN), only one of which is forwarding at any given time. Specifically, an uplink group consists of the root port (which is forwarding) and a set of blocked ports, except for self-looping ports. The uplink group provides an alternate path in case the currently forwarding link fails.

Figure 26-6 shows an example of a topology with no link failures. Switch A, the root switch, is connected directly to Switch B over link L1 and to Switch C over link L2. The Layer 2 interface on Switch C that is connected directly to Switch B is in the blocking state.

Figure 26-6 UplinkFast Before Direct Link Failure

If Switch C detects a link failure on the currently active link L2 on the root port (a direct link failure), UplinkFast unblocks the blocked port on Switch C and transitions it to the forwarding state without going through the listening and learning states, as shown in Figure 26-7. This switchover takes approximately one to five seconds.

Figure 26-7 UplinkFast After Direct Link Failure

Enabling UplinkFast

UplinkFast increases the bridge priority to 49,152 and adds 3000 to the spanning tree port cost of all interfaces on the switch, making it unlikely that the switch becomes the root switch. The *max_update_rate* value represents the number of multicast packets transmitted per second (the default is 150 packets per second [pps]).

UplinkFast cannot be enabled on VLANs that have been configured for bridge priority. To enable UplinkFast on a VLAN with bridge priority configured, restore the bridge priority on the VLAN to the default value by entering a **no spanning-tree vlan *vlan_ID* priority** command in global configuration mode.

Note

When you enable UplinkFast, it affects all VLANs on the switch. You cannot configure UplinkFast on an individual VLAN.

To enable UplinkFast, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] spanning-tree uplinkfast [max-update-rate <i>max_update_rate</i>]	Enables UplinkFast. Use the no keyword to disable UplinkFast and restore the default rate, use the command.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show spanning-tree vlan <i>vlan_ID</i>	Verifies that UplinkFast is enabled on that VLAN.

This example shows how to enable UplinkFast with a maximum update rate of 400 pps:

```
Switch(config)# spanning-tree uplinkfast max-update-rate 400
Switch(config)# exit
Switch#
```

This example shows how to verify which VLANS have UplinkFast enabled:

```
Switch# show spanning-tree uplinkfast
UplinkFast is enabled
```

Station update rate set to 150 packets/sec.

```

About BackboneFast

BackboneFast is a complementary technology to UplinkFast. UplinkFast is designed to quickly respond to failures on links directly connected to leaf-node switches, but it does not help with indirect failures in the backbone core. BackboneFast optimizes the topology based on the Max Age setting. It allows the default convergence time for indirect failures to be reduced from 50 seconds to 30 seconds. However, it never eliminates forward delays and offers no assistance for direct failures.

Note

BackboneFast should be enabled on every switch in your network.

Sometimes a switch receives a BPDU from a designated switch that identifies the root bridge and the designated bridge as the same switch. Because this should not happen, the BPDU is considered inferior.

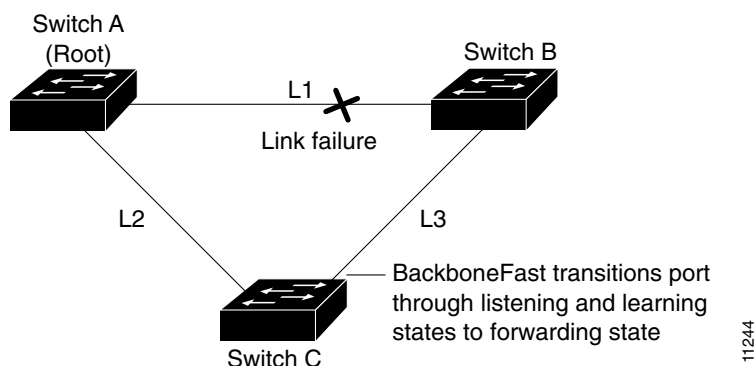

BPDU is considered inferior when a link from the designated switch has lost its link to the root bridge. The designated switch transmits the BPDU with the information that it is now the root bridge as well as the designated bridge. The receiving switch ignores the inferior BPDU for the time defined by the Max Age setting.

After receiving inferior BPDUs, the receiving switch tries to determine if there is an alternate path to the root bridge.

- If the port that the inferior BPDUs are received on is already in blocking mode, then the root port and other blocked ports on the switch become alternate paths to the root bridge.
- If the inferior BPDUs are received on a root port, then all presently blocking ports become the alternate paths to the root bridge. Also, if the inferior BPDUs are received on a root port and no other blocking ports exist on the switch, the receiving switch assumes that the link to the root bridge is down and the time defined by the Max Age setting expires, which turns the switch into the root switch.

If the switch finds an alternate path to the root bridge, it uses this new alternate path. This new path, and any other alternate paths, are used to send a Root Link Query (RLQ) BPDU. When BackboneFast is enabled, the RLQ BPDUs are sent out as soon as an inferior BPDU is received. This process can enable faster convergence in the event of a backbone link failure.

Figure 26-8 shows an example of a topology with no link failures. Switch A, the root switch, connects directly to Switch B over link L1 and to Switch C over link L2. In this example, because switch B has a lower priority than A but higher than C, switch B becomes the designated bridge for L3. Consequently, the Layer 2 interface on Switch C that connects directly to Switch B must be in the blocking state.

Figure 26-8 BackboneFast Before Indirect Link Failure

Next, assume that L1 fails. Switch A and Switch B, the switches directly connected to this segment, instantly know that the link is down. The blocking interface on Switch C must enter the forwarding state for the network to recover. However, because L1 is not directly connected to Switch C, Switch C does not start sending any BPDUs on L3 under the normal rules of STP until the time defined by the Max Age setting has expired.

In an STP environment without BackboneFast, if L1 should fail, Switch C cannot detect this failure because it is not connected directly to link L1. However, because Switch B is directly connected to the root switch over L1, Switch B detects the failure and elects itself the root. Switch B begins sending configuration BPDUs to Switch C, listing itself as the root.

The following actions also occur when you use BackboneFast to eliminate the time defined by the Max Age setting (20-second) delay:

1. When Switch C receives the inferior configuration BPDUs from Switch B, Switch C infers that an indirect failure has occurred.
2. Switch C then sends out an RLQ.
3. Switch A receives the RLQ. Because Switch A is the root bridge, it replies with an RLQ response, listing itself as the root bridge.
4. When Switch C receives the RLQ response on its existing root port, it knows that it still has a stable connection to the root bridge. Because Switch C originated the RLQ request, it does not need to forward the RLQ response on to other switches.
5. BackboneFast allows the blocked port on Switch C to move immediately to the listening state without waiting for the time defined by the Max Age setting for the port to expire.
6. BackboneFast transitions the Layer 2 interface on Switch C to the forwarding state, providing a path from Switch B to Switch A.

This switchover takes approximately 30 seconds, twice the Forward Delay time if the default forward delay time of 15 seconds is set.

Figure 26-9 shows how BackboneFast reconfigures the topology to account for the failure of link L1.

Figure 26-9 BackboneFast after Indirect Link Failure

If a new switch is introduced into a shared-medium topology as shown in [Figure 26-10](#), BackboneFast is not activated, because the inferior BPDUs did not come from the recognized designated bridge (Switch B). The new switch begins sending inferior BPDUs that say it is the root switch. However, the other switches ignore these inferior BPDUs, and the new switch learns that Switch B is the designated bridge to Switch A, the root switch.

Figure 26-10 Adding a Switch in a Shared-Medium Topology

Enabling BackboneFast

Note

For BackboneFast to work, you must enable it on all switches in the network. BackboneFast is supported for use with third-party switches but it is not supported on Token Ring VLANs.

To enable BackboneFast, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] spanning-tree backbonefast	Enables BackboneFast. Use You can use the no keyword to disable BackboneFast.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show spanning-tree backbonefast	Verifies that BackboneFast is enabled.

This example shows how to enable BackboneFast:

```
Switch(config)# spanning-tree backbonefast
Switch(config)# end
Switch#
```

This example shows how to verify that BackboneFast is enabled:

```
Switch# show spanning-tree backbonefast
BackboneFast is enabled
```

```
BackboneFast statistics
-----
Number of transition via backboneFast (all VLANs) : 0
Number of inferior BPDUs received (all VLANs)    : 0
Number of RLQ request PDUs received (all VLANs)  : 0

Configuring EtherChannel and Link State Tracking

This chapter describes how to use the command-line interface (CLI) to configure EtherChannel on the Layer 2 or Layer 3 interfaces of the switch. It also provides guidelines, procedures, and configuration examples.

EtherChannel provides automatic recovery for the loss of a link by redistributing the load across the remaining links. If a link fails, EtherChannel redirects traffic from the failed link to the remaining links in the channel without intervention. This chapter also describes how to configure link-state tracking.

This chapter includes the following major sections:

- [About EtherChannel, page 27-1](#)
- [EtherChannel Configuration Guidelines and Restrictions, page 27-6](#)
- [Configuring EtherChannel, page 27-7](#)
- [Displaying EtherChannel to a Virtual Switch System, page 27-20](#)
- [Understanding Link-State Tracking, page 27-23](#)
- [Configuring Link-State Tracking, page 27-26](#)

Note

The commands in the following sections can be used on all Ethernet interfaces of the switch, including the uplink ports on the supervisor engine.

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About EtherChannel

EtherChannel bundles up to eight individual Ethernet links into a single logical link that provides an aggregate bandwidth of up to 800 Mbps (Fast EtherChannel), 8 Gbps (Gigabit EtherChannel), or 80 Gbps (10 Gigabit EtherChannel) between a Catalyst 4500 or 4500X Series Switch and another switch or host.

**Note**

Because some linecards have a maximum bandwidth capacity toward the backplane, they can limit the aggregate bandwidth of an EtherChannel when all the EtherChannel members belong to the same linecard.

The switch supports a maximum of 254 EtherChannels on standalone switches, and 256 EtherChannels in virtual switching system (VSS) mode. You can form an EtherChannel with up to eight compatibly configured Ethernet interfaces across modules on a Catalyst 4500 series switch. All interfaces in each EtherChannel must be the same speed and must be configured as either Layer 2 or Layer 3 interfaces.

**Note**

The network device to which a Catalyst 4500 series switch is connected may impose its own limits on the number of interfaces in an EtherChannel.

If a segment within an EtherChannel fails, traffic previously carried over the failed link switches to the remaining segments within the EtherChannel. When the segment fails, an SNMP trap is sent, identifying the switch, the EtherChannel, and the failed link. Inbound broadcast and multicast packets on one segment in an EtherChannel are blocked from returning on any other segment of the EtherChannel.

**Note**

The port channel link failure switchover for the Catalyst 4500 series switch was measured at 50 milliseconds, which provides SONET-like link failure switchover time.

These subsections describe how EtherChannel works:

- [Port Channel Interfaces, page 27-2](#)
- [Configuring EtherChannels, page 27-2](#)
- [Load Balancing, page 27-6](#)

Port Channel Interfaces

Each EtherChannel has a numbered port channel interface. A configuration applied to the port channel interface affects all physical interfaces assigned to that interface.

**Note**

QoS does not propagate to members. The defaults, QoS cos = 0 and QoS dscp = 0, apply on the port channel. Input or output policies applied on individual interfaces are ignored.

After you configure an EtherChannel, the configuration that you apply to the port channel interface affects the EtherChannel; the configuration that you apply to the physical interfaces affects only the interface where you apply the configuration. To change the parameters of all ports in an EtherChannel, apply configuration commands to the port channel interface (such commands can be STP commands or commands to configure a Layer 2 EtherChannel as a trunk).

Configuring EtherChannels

These subsections describe how EtherChannels are configured:

- [EtherChannel Configuration Overview, page 27-3](#)
- [Manual EtherChannel Configuration, page 27-3](#)

- [PAgP EtherChannel Configuration, page 27-4](#)
- [IEEE 802.3ad LACP EtherChannel Configuration, page 27-5](#)

EtherChannel Configuration Overview

You can configure EtherChannels manually or use the Port Aggregation Control Protocol (PAgP) or the Link Aggregation Control Protocol (LACP) (Cisco IOS Release 12.2(31)SGA and later), to form EtherChannels. The EtherChannel protocols allow ports with similar characteristics to form an EtherChannel through dynamic negotiation with connected network devices. PAgP is a Cisco-proprietary protocol and LACP is defined in IEEE 802.3ad.

PAgP and LACP do not interoperate. Ports configured to use PAgP cannot form EtherChannels with ports configured to use LACP and vice versa.

[Table 27-1](#) lists the user-configurable EtherChannel modes.

Table 27-1 *EtherChannel Modes*

Mode	Description
on	Mode that forces the LAN port to channel unconditionally. In the on mode, a usable EtherChannel exists only when a LAN port group in the on mode is connected to another LAN port group in the on mode. Because ports configured in the on mode do not negotiate, there is no negotiation traffic between the ports.
auto	PAgP mode that places a LAN port into a passive negotiating state in which the port responds to PAgP packets it receives but does not initiate PAgP negotiation.
desirable	PAgP mode that places a LAN port into an active negotiating state in which the port initiates negotiations with other LAN ports by sending PAgP packets.
passive	LACP mode that places a port into a passive negotiating state in which the port responds to LACP packets it receives but does not initiate LACP negotiation.
active	LACP mode that places a port into an active negotiating state in which the port initiates negotiations with other ports by sending LACP packets.

Manual EtherChannel Configuration

Manually configured EtherChannel ports do not exchange EtherChannel protocol packets. A manually configured EtherChannel forms only when you configure all ports compatibly in the EtherChannel.

Auto-LAG

You can automatically create EtherChannels on ports connected to a switch, using auto-LAG. By default, auto-LAG is disabled globally, but is enabled on all port interfaces. To configure auto-LAG on your switch, ensure that you enable auto-LAG globally.

When auto-LAG is enabled globally:

- All port interfaces participate in the creation of auto EtherChannels if the partner port interfaces have EtherChannel configured on them. For more information, see [Table 27-1Supported auto-LAG configuration on actor and partner devices, page 27-4](#).
- Ports that are already part of manual EtherChannels cannot participate in creation of auto EtherChannels.

- When auto-LAG is disabled on a port interface that is already a part of an auto created EtherChannel, the port interface will unbundle from the auto EtherChannel.

The following table shows the supported auto-LAG configurations between the actor and partner devices:

Table 27-1 Supported auto-LAG configuration on actor and partner devices

Actor/Partner	Active	Passive	Auto
Active	Yes	Yes	Yes
Passive	Yes	No	Yes
Auto	Yes	Yes	Yes

On disabling auto-LAG globally, all auto created Etherchannels become manual EtherChannels. You cannot add any configurations in an existing auto created EtherChannel. To add an new configuration, convert the auto-created EtherChannel into a manual EtherChannel using the **port-channel channel-number persistent** command.

Note

Auto-LAG uses the LACP protocol to create an auto EtherChannel. Only one EtherChannel can be automatically created with the unique partner devices.

Auto-LAG Configuration Guidelines

Follow these guidelines when configuring auto-LAG:

- When auto-LAG is enabled globally and on the port interface, and you do not want the port interface to become a member of the auto EtherChannel, disable the auto-LAG on the port interface.
- A port interface does not bundle to an auto EtherChannel when it is already a member of a manual EtherChannel. To allow it to bundle with the auto EtherChannel, first unbundle the manual EtherChannel on the port interface.
- When auto-LAG is enabled and an auto EtherChannel is created, you can create multiple EtherChannels manually with the same partner device. But by default, the port tries to create auto EtherChannel with the partner device.
- Auto-LAG is supported only on Layer 2 EtherChannels. It is not supported on Layer 3 interfaces and Layer 3 EtherChannels.

PAgP EtherChannel Configuration

PAgP supports the automatic creation of EtherChannels by exchanging PAgP packets between LAN ports. PAgP packets are exchanged only between ports in **auto** and **desirable** modes.

The protocol learns the capabilities of LAN port groups dynamically and informs the other LAN ports. Once PAgP identifies correctly matched Ethernet links, it facilitates grouping the links into an EtherChannel. The EtherChannel is then added to the spanning tree as a single bridge port.

Both the **auto** and **desirable** modes allow PAgP to negotiate between LAN ports to determine if they can form an EtherChannel, based on criteria such as port speed and trunking state. Layer 2 EtherChannels also use VLAN numbers.

LAN ports can form an EtherChannel when they are in different PAgP modes if the modes are compatible. For example:

- A LAN port in **desirable** mode can form an EtherChannel successfully with another LAN port that is in **desirable** mode.
- A LAN port in **desirable** mode can form an EtherChannel with another LAN port in **auto** mode.
- A LAN port in **auto** mode cannot form an EtherChannel with another LAN port that is also in **auto** mode because neither port initiates negotiation.

IEEE 802.3ad LACP EtherChannel Configuration

Cisco IOS Release 12.2(31)SGA and later releases support IEEE 802.3ad LACP EtherChannels. LACP supports the automatic creation of EtherChannels by exchanging LACP packets between LAN ports. LACP packets are exchanged only between ports in **passive** and **active** modes.

The protocol learns the capabilities of LAN port groups dynamically and informs the other LAN ports. Once LACP identifies correctly matched Ethernet links, it facilitates grouping the links into an EtherChannel. The EtherChannel is then added to the spanning tree as a single bridge port.

Both the **passive** and **active** modes allow LACP to negotiate between LAN ports to determine if they can form an EtherChannel, based on criteria such as port speed and trunking state. Layer 2 EtherChannels also use VLAN numbers.

LAN ports can form an EtherChannel when they are in different LACP modes as long as the modes are compatible. For example:

- A LAN port in **active** mode can form an EtherChannel successfully with another LAN port that is in **active** mode.
- A LAN port in **active** mode can form an EtherChannel with another LAN port in **passive** mode.
- A LAN port in **passive** mode cannot form an EtherChannel with another LAN port that is also in **passive** mode, because neither port initiates negotiation.

LACP uses the following parameters:

- LACP system priority—You may configure an LACP system priority on each switch running LACP. The system priority can be configured automatically or through the CLI. See the [“Configuring the LACP System Priority and System ID”](#) section on page 27-16. LACP uses the system priority with the switch MAC address to form the system ID and also during negotiation with other systems.

Note The LACP system ID is the combination of the LACP system priority value and the MAC address of the switch.

- LACP port priority—You must configure an LACP port priority on each port configured to use LACP. The port priority can be configured automatically or through the CLI. See the [“Configuring Layer 2 EtherChannels”](#) section on page 27-11. LACP uses the port priority with the port number to form the port identifier.
- LACP administrative key—LACP automatically configures an administrative key value equal to the channel group identification number on each port configured to use LACP. The administrative key defines the ability of a port to aggregate with other ports. A port’s ability to aggregate with other ports is determined by these factors:
 - Port physical characteristics, such as data rate, duplex capability, and point-to-point or shared medium
 - Configuration restrictions that you establish

LACP tries to configure the maximum number of compatible ports in an EtherChannel up to the maximum allowed by the hardware (eight ports). If a port cannot be actively included in a channel, it is not included automatically if a channeled port fails.

You can change the LACP timer rate to modify the duration of the LACP timeout. Use the `lACP rate` command to set the rate at which LACP control packets are sent to an LACP-supported interface. You can change the timeout rate from the default rate (30 seconds) to the fast rate (1 second). This command is supported only on LACP-enabled interfaces. To configure the LACP fast time rate, see *Configuring the LACP Fast Timer Rate*.

ISSU and stateful switchover cannot be guaranteed with LACP fast timers.

Note Standby and “sub-channeling” are not supported in LACP and PagP.

Load Balancing

EtherChannel can balance the traffic load across the links in the channel by reducing part of the binary pattern formed from the addresses or ports in the frame to a numerical value that selects one of the links in the channel. To balance the load, EtherChannel uses MAC addresses, IP addresses, or Layer 4 port numbers, and either the message source or message destination, or both.

Use the option that provides the greatest variety in your configuration. For example, if the traffic on a channel is going only to a single MAC address, using the destination MAC address always chooses the same link in the channel; using source addresses or IP addresses might result in better load balancing.

Note Load balancing can only be configured globally. As a result, all channels (manually configured, PagP, or LACP) use the same load-balancing method.

For additional information on load balancing, see the [“Configuring EtherChannel Load Balancing” section on page 27-18](#).

EtherChannel Configuration Guidelines and Restrictions

If improperly configured, some EtherChannel interfaces are disabled automatically to avoid network loops and other problems. Follow these guidelines and restrictions to avoid configuration problems:

- All Ethernet interfaces on all modules support EtherChannel (maximum of eight interfaces) with no requirement that interfaces be physically contiguous or on the same module.
- Configure all interfaces in an EtherChannel to operate at the same speed and duplex mode.
- Enable all interfaces in an EtherChannel. Disabling an interface in an EtherChannel is treated as a link failure, and its traffic is transferred to one of the remaining interfaces in the EtherChannel.
- An EtherChannel does not form if one of the interfaces is a Switched Port Analyzer (SPAN) destination port.
- For Layer 3 EtherChannels:
 - Assign Layer 3 addresses to the port channel logical interface, not to the physical interfaces in the channel.
- For Layer 2 EtherChannels:

- Assign all interfaces in the EtherChannel to the same VLAN, or configure them as trunks.
- If you configure an EtherChannel from trunk interfaces, verify that the trunking mode and the native VLAN is the same on all the trunks. Interfaces in an EtherChannel with different trunk modes or different native VLANs can have unexpected results.
- An EtherChannel supports the same allowed range of VLANs on all the interfaces in a trunking Layer 2 EtherChannel. If the allowed ranges differ for selected interface differ, they do not form an EtherChannel.
- Interfaces with different Spanning Tree Protocol (STP) port path costs can form an EtherChannel as long they are otherwise compatibly configured. Setting different STP port path costs does not make interfaces incompatible for the formation of an EtherChannel.
- After you configure an EtherChannel, any configuration that you apply to the port channel interface affects the EtherChannel; any configuration that you apply to the physical interfaces affects only the interface you configure.

Storm Control is an exception to this rule. For example, you cannot configure Storm Control on some of the members of an EtherChannel; Storm Control must be configured on all or none of the ports. If you configure Storm Control on only some of the ports, those ports are dropped from the EtherChannel interface (put in suspended state). You should configure Storm Control at the port channel interface level, and not at the physical interface level.

- A physical interface with port security enabled can join a Layer 2 EtherChannel only if port security is also enabled on the EtherChannel; otherwise the command is rejected by the CLI.
- You cannot configure a 802.1X port in an EtherChannel.

Configuring EtherChannel

These sections describe how to configure EtherChannel:

- [Configuring Layer 3 EtherChannels, page 27-7](#)
- [Configuring Layer 2 EtherChannels, page 27-11](#)
- [Configuring LACP Standalone or Independent Mode, page 27-13](#)
- [Configuring LACP Port Channel Min-links, page 27-14](#)
- [Configuring the LACP System Priority and System ID, page 27-16](#)
- [Configuring EtherChannel Load Balancing, page 27-18](#)
- [Removing an Interface from an EtherChannel, page 27-19](#)
- [Removing an EtherChannel, page 27-20](#)

**Note**

Ensure that the interfaces are configured correctly. See the “[EtherChannel Configuration Guidelines and Restrictions](#)” section on page 27-6.

Configuring Layer 3 EtherChannels

To configure Layer 3 EtherChannels, create the port channel logical interface and then put the Ethernet interfaces into the port channel.

These sections describe Layer 3 EtherChannel configuration:

- [Creating Port Channel Logical Interfaces, page 27-8](#)
- [Configuring Physical Interfaces as Layer 3 EtherChannels, page 27-8](#)

Creating Port Channel Logical Interfaces

Note

To move an IP address from a physical interface to an EtherChannel, you must delete the IP address from the physical interface before configuring it on the port channel interface.

To create a port channel interface for a Layer 3 EtherChannel, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface port-channel <i>port_channel_number</i>	Creates the port channel interface. The value for <i>port_channel_number</i> can range from 1 to 254 for a standalone switch, and from 1 to 256 for switches in VSS mode.
Step 2	Switch(config-if)# ip address <i>ip_address mask</i>	Assigns an IP address and subnet mask to the EtherChannel.
Step 3	Switch(config-if)# end	Exits configuration mode.
Step 4	Switch# show running-config interface port-channel <i>port_channel_number</i>	Verifies the configuration.

This example shows how to create port channel interface 1:

```
Switch# configure terminal
Switch(config)# interface port-channel 1
Switch(config-if)# ip address 172.32.52.10 255.255.255.0
Switch(config-if)# end
```

This example shows how to verify the configuration of port channel interface 1:

```
Switch# show running-config interface port-channel 1
Building configuration...

Current configuration:
!
interface Port-channel1
 ip address 172.32.52.10 255.255.255.0
 no ip directed-broadcast
end

Switch#
```

Configuring Physical Interfaces as Layer 3 EtherChannels

To configure physical interfaces as Layer 3 EtherChannels, perform this task for each interface:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Selects a physical interface to configure.
Step 2	Switch(config-if)# no switchport	Makes this a Layer 3 routed port.
Step 3	Switch(config-if)# no ip address	Ensures that no IP address is assigned to the physical interface.
Step 4	Switch(config-if)# channel-group <i>port_channel_number</i> mode { active on auto passive desirable }	Configures the interface in a port channel and specifies the PAgP or LACP mode. If you use PAgP, enter the keywords auto or desirable . If you use LACP, enter the keywords active or passive .
Step 5	Switch(config-if)# end	Exits configuration mode.
Step 6	Switch# show running-config interface port-channel <i>port_channel_number</i> Switch# show running-config interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> Switch# show interfaces { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> etherchannel Switch# show etherchannel 1 port-channel	Verifies the configuration.

This example shows how to configure Fast Ethernet interfaces 5/4 and 5/5 into port channel 1 with PAgP mode **desirable**:

```
Switch# configure terminal
Switch(config)# interface range fastethernet 5/4 - 5 (Note: Space is mandatory.)
Switch(config-if)# no switchport
Switch(config-if)# no ip address
Switch(config-if)# channel-group 1 mode desirable
Switch(config-if)# end
```

Note

See the “[Configuring a Range of Interfaces](#)” section on page 9-5 for information about the **range** keyword.

The following two examples show how to verify the configuration of Fast Ethernet interface 5/4:

```
Switch# show running-config interface fastethernet 5/4
Building configuration...
```

```
Current configuration:
!
interface FastEthernet5/4
 no ip address
 no switchport
 no ip directed-broadcast
 channel-group 1 mode desirable
end
```

```
Switch# show interfaces fastethernet 5/4 etherchannel
Port state      = EC-Enbld Up In-Bndl Usr-Config
```

```

Channel group = 1          Mode = Desirable      Gcchange = 0
Port-channel  = Po1       GC   = 0x00010001     Pseudo-port-channel = Po1
Port index    = 0         Load = 0x55

Flags: S - Device is sending Slow hello.  C - Device is in Consistent state.
      A - Device is in Auto mode.         P - Device learns on physical port.
Timers: H - Hello timer is running.       Q - Quit timer is running.
      S - Switching timer is running.     I - Interface timer is running.

Switch#

```

Configuring Layer 2 EtherChannels

To configure Layer 2 EtherChannels, configure the Ethernet interfaces with the **channel-group** command. This operation creates the port channel logical interface.

Note

Cisco IOS software creates port channel interfaces for Layer 2 EtherChannels when you configure Layer 2 Ethernet interfaces with the **channel-group** command.

To configure Layer 2 Ethernet interfaces as Layer 2 EtherChannels, perform this task for each interface:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Selects a physical interface to configure.
Step 2	Switch(config-if)# channel-group <i>port_channel_number</i> mode { active on auto passive desirable }	Configures the interface in a port channel and specifies the PAGP or LACP mode. If you use PAGP, enter the keywords auto or desirable . If you use LACP, enter the keywords active or passive .
Step 3	Switch(config-if)# end	Exits configuration mode.
Step 4	Switch# show running-config interface { fastethernet gigabitethernet } <i>slot/port</i> Switch# show interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> etherchannel	Verifies the configuration.

This example shows how to configure Fast Ethernet interfaces 5/6 and 5/7 into port channel 2 with PAGP mode **desirable**:

```

Switch# configure terminal
Switch(config)# interface range fastethernet 5/6 - 7 (Note: Space is mandatory.)
Switch(config-if-range)# channel-group 2 mode desirable
Switch(config-if-range)# end
Switch# end

```

Note

See the [“Configuring a Range of Interfaces”](#) section on page 9-5 for information about the **range** keyword.

This example shows how to verify the configuration of port channel interface 2:

```
Switch# show running-config interface port-channel 2
Building configuration...
```

```
Current configuration:
!
interface Port-channel2
 switchport access vlan 10
 switchport mode access
end
```

```
Switch#
```

The following two examples show how to verify the configuration of Fast Ethernet interface 5/6:

```
Switch# show running-config interface fastethernet 5/6
Building configuration...
```

```
Current configuration:
!
interface FastEthernet5/6
 switchport access vlan 10
 switchport mode access
 channel-group 2 mode desirable
end
```

```
Switch# show interfaces fastethernet 5/6 etherchannel
Port state      = EC-Enbld Up In-Bndl Usr-Config
Channel group = 1          Mode = Desirable      Gcchange = 0
Port-channel   = Po1       GC      = 0x00010001
Port indx      = 0         Load = 0x55
```

```
Flags: S - Device is sending Slow hello.  C - Device is in Consistent state.
       A - Device is in Auto mode.        P - Device learns on physical port.
       d - PAgP is down.
```

```
Timers: H - Hello timer is running.      Q - Quit timer is running.
        S - Switching timer is running.  I - Interface timer is running.
```

Local information:

Port	Flags	State	Timers	Hello Interval	Partner Count	PAgP Priority	Learning Method	Group Ifindex

    1      00      Fa5/6
    0      00      Fa5/7

Time since last port bundled:    00h:23m:33s    Fa5/6

Switch#

```

Configuring LACP Standalone or Independent Mode

This feature is particularly relevant when a port (A) in a Layer 2 LACP EtherChannel is connected to an unresponsive port (B) on the peer. When LACP standalone is disabled on the EtherChannel, all traffic arriving on A is blocked (the default behavior on a switch). In some scenarios, you might want to allow management traffic on such ports. You can do this by enabling LACP standalone (or independent) mode.

Note

This **port-channel standalone-disable** command only applies to Layer 2 EtherChannels

Note

LACP Standalone Disable is enabled by default.

To configure the LACP Standalone or Independent mode, perform this task:

	Command	Purpose
Step 1	Switch(config)# no port-channel standalone-disable	Enables the LACP standalone or independent mode.
	Switch(config)# port-channel standalone-disable	Reverts to the default.
Step 2	Switch(config-if)# end	Exits configuration mode.
Step 3	Switch# show running configuration {fastethernet gigabitethernet} slot/port port-channel port_channel_number	Verifies the configuration.

This example shows how to configure the LACP Standalone mode:

```

Switch# configure terminal
Switch(config)# interface port-channel 1
Switch(config-if)# switchport
Switch(config-if)# exit
Switch(config)# int gi3/1
Switch(config-if)# channel-group 1 mode active
Switch(config-if)# exit
Switch(config)# interface port-channel 1
Switch(config-if)# no port-channel standalone-disable
Ports of Po12 already in suspend (S) mode require a shut/no shut.
Switch(config-if)# end

```

This example shows how to verify the configuration of port channel interface 1:

```

Switch# show running-config interface port-channel 1

```

```
Building configuration...

Current configuration:
!
interface Port-channel1
  switchport
  no port-channel standalone-disable
end

Switch#
```

This example shows how to verify the state of port channel interface 1:

```
Switch# show etherchannel 1 port-channel
      Port-channels in the group:
      -----
Port-channel: Po13      (Primary Aggregator)
-----
Age of the Port-channel   = 0d:00h:07m:57s
Logical slot/port        = 11/13           Number of ports = 0
Port state                = Port-channel Ag-Not-Inuse
Protocol                  = LACP
Port security             = Disabled
Standalone                = Enabled (independent mode)
Switch#
```

Configuring LACP Port Channel Min-links

Beginning in Cisco IOS Release 15.2(4)E, and Cisco IOS XE Release 3.8.0E, you can specify the minimum number of active ports that must be in the link-up state and bundled in an EtherChannel for the port channel interface to transition to the link-up state. Using EtherChannel min-links, you can prevent low-bandwidth LACP EtherChannels from becoming active. Port channel min-links also cause LACP EtherChannels to become inactive if they have too few active member ports to supply the required minimum bandwidth.

Note

For a Multichassis EtherChannel (MEC), the LACP *min-links* command argument defines the minimum number of physical links in each chassis for the MEC to be operational.

To configure the minimum number of links that are required for a port channel, perform the following task:

	Command	Purpose
Step 1	Switch(config)# interface port-channel <i>channel-number</i>	Enters interface configuration mode for a port-channel. The valid range for <i>channel-number</i> is 1 to 256.

	Command	Purpose
Step 2	Switch(config-if)# port-channel min-links <i>min-links-number</i>	Specifies the minimum number of member ports that must be in the link-up state and bundled in the EtherChannel for the port channel interface to transition to the link-up state. The valid range for <i>min-links-number</i> is 2 to 8. For a switch in VSS mode, when setting up min-links, ensure that the port-channel consists of the same number of min-links on the active switch and on the standby switch. For example, if you set min-links to 2 for a port-channel, ensure that there are 2 links, each, available on the active and the standby switch.
Step 3	Switch# end	Returns to privileged EXEC mode

This example shows how to configure LACP port channel min-links:

```
Switch# configure terminal
Switch(config)# interface port-channel 25
switch(config-if)# port-channel min-links 3
Switch# show etherchannel 25 summary
switch# end
```

For a switch in VSS mode, when the minimum links requirement on a port channel is not met, the local ports in the EtherChannel are assigned m state, and all traffic is redirected out through the virtual switch link, via the member ports of the port channel on the peer switch, for example:

```
Switch# show etherchannel 25 summary
Flags: D - down P - bundled in port-channel
I - stand-alone s - suspended
H - Hot-standby (LACP only)
R - Layer3 S - Layer2
U - in use N - not in use, no aggregation
f - failed to allocate aggregator
M - not in use, no aggregation due to minimum links not met
m- not in use, port not aggregated due to minimum links not met
u - unsuitable for bundling
w - waiting to be aggregated
d - default port
Number of channel-groups in use: 125
Number of aggregators: 125
Group Port-channel Protocol Ports
-----+-----+-----+-----+-----+-----
25 Po25(RU) LACP Gi1/3/1(D) Gi1/3/2(m) Gi2/2/25(P) Gi2/2/26(P)
```

When the minimum links requirement is not met in standalone switches, the port channel is flagged and assigned the SM/SN or RM/RN state, for example:

```
Switch# show etherchannel 25 summary
Flags: D - down P - bundled in port-channel
I - stand-alone s - suspended
H - Hot-standby (LACP only)
R - Layer3 S - Layer2
U - in use N- not in use, no aggregation
f - failed to allocate aggregator
M - not in use, no aggregation due to minimum links not met
m- not in use, port not aggregated due to minimum links not met
u - unsuitable for bundling
```

```

w - waiting to be aggregated
d - default port
Number of channel-groups in use: 125
Number of aggregators: 125
Group Port-channel Protocol Ports
-----+-----+-----+-----+-----+-----
25 Po25(RM) LACP Gi1/3/1(D) Gi1/3/2(D) Gi2/2/25(D) Gi2/2/26(w)

```

Configuring the LACP System Priority and System ID

The LACP system ID is the LACP system priority value combined with the MAC address of the switch. To configure the LACP system priority and system ID, perform this task:

	Command	Purpose
Step 1	Switch(config)# lACP system-priority <i>priority_value</i>	(Optional for LACP) Sets the LACP system priority and system ID. Valid values are 1 through 65535. Higher numbers have lower priority. The default is 32768.
	Switch(config)# no system port-priority	Reverts to the default.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show lACP sys-id	Verifies the configuration.

This example shows how to configure the LACP system priority:

```

Switch# configure terminal
Switch(config)# lACP system-priority 23456
Switch(config)# end
Switch# show module

Mod  Ports Card Type                               Model                Serial No.
-----+-----+-----+-----+-----+-----
1      2  1000BaseX (GBIC) Supervisor(active)    WS-X4014              JAB063808YZ
2     48  10/100BaseTX (RJ45)                    WS-X4148-RJ           JAB0447072W
3     48  10/100BaseTX (RJ45)V                    WS-X4148-RJ45V        JAE061704J6
4     48  10/100BaseTX (RJ45)V                    WS-X4148-RJ45V        JAE061704ML

M MAC addresses                               Hw  Fw      Sw              Status
-----+-----+-----+-----+-----+-----
1 0005.9a39.7a80 to 0005.9a39.7a81 2.1 12.1(12r)EW 12.1(13)EW(0.26) Ok
2 0002.fd80.f530 to 0002.fd80.f55f 0.1                               Ok
3 0009.7c45.67c0 to 0009.7c45.67ef 1.6                               Ok
4 0009.7c45.4a80 to 0009.7c45.4aaf 1.6                               Ok

```

This example shows how to verify the configuration:

```

Switch# show lACP sys-id
23456,0050.3e8d.6400
Switch#

```

The system priority is displayed first, followed by the MAC address of the switch.

Configuring LACP Fast Rate Timer

You can change the LACP timer rate to modify the duration of the LACP timeout. Use the **lacp rate** command to set the rate at which LACP control packets are received by an LACP-supported interface. You can change the timeout rate from the default rate (30 seconds) to the fast rate (1 second). This command is supported only on LACP-enabled interfaces.

	Command	Purpose
Step 4	Switch# configure terminal	Enters configuration mode.
Step 5	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Selects the interface to configure.
Step 6	Switch(config-if)# lacp rate { normal fast }	Configures the rate at which LACP control packets are received by an LACP-supported interface. To reset the timeout rate to its default, use the no lacp rate command.

This example shows how to configure the LACP rate:

```
Switch# configure terminal
Switch(config)# interface gigabitEthernet 2/1
Switch(config-if)# lacp rate fast
Switch(config-if)# exit
```

The **show lacp internal** command displays similar output:

```
Flags: S - Device is requesting Slow LACPDU
F - Device is requesting Fast LACPDU
A - Device is in Active mode P - Device is in Passive mode
Channel group 25
LACP port Admin Oper Port Port
Port Flags State Priority Key Key Number State
Tel/49 FA bndl 32768 0x19 0x19 0x32 0x3F
Tel/50 FA bndl 32768 0x19 0x19 0x33 0x3F
Tel/51 FA bndl 32768 0x19 0x19 0x34 0x3F
Tel/52 FA bndl 32768 0x19 0x19 0x35 0x3F
```

The **show lacp counters** command displays similar output

```
Switch# show lacp counters
LACPDU Marker Marker Response LACPDU
Port Sent Recv Sent Recv Sent Recv Pkts Err
-----
Channel group: 24
Tel/1/27 2 2 0 0 0 0 0
Te2/1/25 2 2 0 0 0 0 0
```

Configuring Auto-LAG Globally

Note

By default, auto-LAG is disabled globally, on your device.

To configure auto-LAG globally, perform this task:

	Command	Purpose
Step 1	Switch(config)# port-channel auto	Configures auto-LAG globally on the device.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show etherchannel auto	Displays the EtherChannel created automatically.

Configuring Auto-LAG on a Port Interface

To configure auto-LAG globally, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface <i>interface-id</i>	Specifies the port interface to be enabled for auto-LAG, and enters interface configuration mode.
Step 2	Switch(config-if)# channel-group auto	(Optional) Enables auto-LAG feature on individual port interface. By default, the auto-LAG feature is enabled on the port.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show etherchannel auto	Displays the EtherChannel created automatically.

Configuring Persistence with Auto-LAG

To convert the automatically created EtherChannel back to a manual one, perform this task:

	Command	Purpose
Step 1	Switch# port-channel <i>channel-number</i> persistent	Specifies the port interface to be enabled for auto-LAG, and enters interface configuration mode.
Step 2	Switch(config-if)# channel-group auto	Converts the auto created EtherChannel into a manual one and allows you to add configuration on the EtherChannel.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show etherchannel summary	Displays EtherChannel information.

Configuring EtherChannel Load Balancing

Note

Load balancing can only be configured globally. As a result, all channels (manually configured, PagP, or LACP) use the same load-balancing method.

To configure EtherChannel load balancing, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] port-channel load-balance { src-mac dst-mac src-dst-mac src-ip dst-ip src-dst-ip src-port dst-port src-dst-port }	Configures EtherChannel load balancing. Use the no keyword to return EtherChannel load balancing to the default configuration.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show etherchannel load-balance	Verifies the configuration.

The load-balancing keywords indicate these values:

- **src-mac**—Source MAC addresses
- **dst-mac**—Destination MAC addresses
- **src-dst-mac**—Source and destination MAC addresses
- **src-ip**—Source IP addresses
- **dst-ip**—Destination IP addresses
- **src-dst-ip**—Source and destination IP addresses (Default)
- **src-port**—Source Layer 4 port
- **dst-port**—Destination Layer 4 port
- **src-dst-port**—Source and destination Layer 4 port

This example shows how to configure EtherChannel to use source and destination IP addresses:

```
Switch# configure terminal
Switch(config)# port-channel load-balance src-dst-ip
Switch(config)# end
Switch#
```

This example shows how to verify the configuration:

```
Switch# show etherchannel load-balance
EtherChannel Load-Balancing Configuration:
    src-dst-ip

EtherChannel Load-Balancing Addresses Used Per-Protocol:
Non-IP: Source XOR Destination MAC address
IPv4: Source XOR Destination IP address
IPv6: Source XOR Destination IP address
Switch#
```

Removing an Interface from an EtherChannel

To remove an Ethernet interface from an EtherChannel, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Selects a physical interface to configure.
Step 2	Switch(config-if)# no channel-group	Removes the interface from the port channel interface.

	Command	Purpose
Step 3	Switch(config-if)# end	Exits configuration mode.
Step 4	Switch# show running-config interface {fastethernet gigabitethernet tengigabitethernet} slot/port Switch# show interface {fastethernet gigabitethernet tengigabitethernet} slot/port etherchannel	Verifies the configuration.

This example shows how to remove Fast Ethernet interfaces 5/4 and 5/5 from port channel 1:

```
Switch# configure terminal
Switch(config)# interface range fastethernet 5/4 - 5 (Note: Space is mandatory.)
Switch(config-if)# no channel-group 1
Switch(config-if)# end
```

Removing an EtherChannel

If you remove an EtherChannel, the member ports are shut down and removed from the channel group.

Note

If you want to change an EtherChannel from Layer 2 to Layer 3, or Layer 3 to Layer 2, you must remove the EtherChannel and recreate it in the desired configuration.

To remove an EtherChannel, perform this task:

	Command	Purpose
Step 1	Switch(config)# no interface port-channel port_channel_number	Removes the port channel interface.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show etherchannel summary	Verifies the configuration.

This example shows how to remove port channel 1:

```
Switch# configure terminal
Switch(config)# no interface port-channel 1
Switch(config)# end
```

Displaying EtherChannel to a Virtual Switch System

Catalyst 4500 series switches support enhanced PAgP. If a Catalyst 4500 series switch is connected to a Catalyst 6500 series Virtual Switch System (VSS) by using a PAgP EtherChannel, the Catalyst 4500 series switch automatically serve as a VSS client, using enhanced PAgP on this EtherChannel for dual-active detection. This VSS client feature has no impact on the performance of Catalyst 4500 series switch and does not require any user configuration.

This section includes these topics:

- [Understanding VSS Client, page 27-21](#)
- [Displaying EtherChannel Links to VSS, page 27-23](#)

Understanding VSS Client

This section describes these topics:

- [Virtual Switch System, page 27-21](#)
- [Dual-Active Scenarios, page 27-21](#)
- [Dual-Active Detection Using Enhanced PAgP, page 27-21](#)

Virtual Switch System

The Cisco Catalyst 6500 Series VSS 1440 allows for the combination of two Cisco Catalyst 6500 Series switches into a single, logical network entity from the network control-plane and management perspectives. Within the Cisco VSS, one chassis is designated as the active virtual switch, acting as the single management point of the entire system, and the other is designated as the standby virtual switch. These two chassis are bound together by a special link, called Virtual Switch Link (VSL), which carries the internal signaling and control information between them.

Dual-Active Scenarios

One of the failure scenarios in a VSS is called *dual-active*, which occurs when the VSL fails completely. Neither virtual switch knows of the other's status. From the perspective of the active virtual switch, the standby chassis is lost. The standby virtual switch also views the active chassis as failed and transitions to active state by using an SSO switchover. Two active virtual switches exist in the network with identical configurations, causing duplicate IP addresses and bridge identifiers. This scenario has adverse effects on the network topology and traffic if it persists.

Dual-Active Detection Using Enhanced PAgP

One method for detecting a dual-active scenario is based on enhanced PAgP (PAgP+). Specifically, the VSS sends regularly scheduled PAgP messages with Type-Length-Values (TLVs) containing the ID of the current active virtual switch ([Figure 27-1](#)). When the VSL fails completely, the standby virtual switch immediately sends asynchronous PAgP messages with TLVs containing its own ID on all port channels enabled for enhanced PAgP dual-active detection ([Figure 27-2](#)). The remote switch (the VSS client) connected to both VSS components by using EtherChannel links, compares every received active ID with its stored active ID. If they match, the remote switch sends TLVs containing its stored active ID back to the VSS in its regularly scheduled PAgP messages. If they do not match, the remote switch stores the new active ID and immediately transmits asynchronous PAgP messages with TLVs containing the new active ID. Upon receiving the new active ID from the remote switch, the original active virtual switch detects the dual-active scenario and takes appropriate actions.

Figure 27-1 Enhanced PAgP in VSS Normal Operation**Figure 27-2** Enhanced PAgP in VSS Dual-active Scenario

As a remote switch, the Catalyst 4500 series switch supports stateful VSS client. In particular, the ID of the current active virtual switch is synchronized from the active supervisor engine to the redundant supervisor engine of the Catalyst 4500 series switch. This ensures that dual-active detection is not disrupted even when the active supervisor engine switches over to the redundant supervisor engine.

Displaying EtherChannel Links to VSS

To display the dual-active detection capability of a configured PAgP port channel, enter the **show pagp port_channel_number dual-active** command.

The command provides the following information:

- A switch uses enhanced PAgP for dual-active detection.
You should always see Yes after PAgP dual-active detection enabled on a Catalyst 4500 switch.
- The configured PAgP EtherChannel is connected to a Catalyst 6500 switch VSS.
You see N/A below Partner Version if this EtherChannel is *not* connected to a VSS. Otherwise, you see the version of enhanced PAgP dual-active detection implemented in the VSS.
- This switch is capable of detecting dual-active scenarios in the connected VSS.
You see Yes below Dual-Active Detect Capable if and only if the configured EtherChannel is connected to a Catalyst 6500 series VSS that uses the same version of enhanced PAgP dual-active detection.

Note

You can also see the name of the neighboring switch (Partner Name) and the ports to which this EtherChannel is connected (Partner Port).

If a Catalyst 4500 switch is connected to a Catalyst 6500 series VSS with the same version of enhanced PAgP dual-active detection, the switch can detect a dual-active scenario:

```
Switch# show pagp 1 dual-active
```

```
PAgP dual-active detection enabled: Yes
```

```
PAgP dual-active version: 1.1
```

```
Channel group 1
```

Port	Dual-Active Detect Capable	Partner Name	Partner Port	Partner Version
Gi6/5	Yes	VSS	Gi1/8/1	1.1
Gi6/6	Yes	VSS	Gi2/8/1	1.1

If a Catalyst 4500 switch is not connected to a Catalyst 6500 series VSS, the switch cannot detect a dual-active scenario:

```
Switch# show pagp 1 dual-active
```

```
PAgP dual-active detection enabled: Yes
```

```
PAgP dual-active version: 1.1
```

```
Channel group 1
```

Port	Dual-Active Detect Capable	Partner Name	Partner Port	Partner Version
Gi6/5	No	Switch	Fa6/5	N/A
Gi6/6	No	Switch	Fa6/6	N/A

Understanding Link-State Tracking

Link-state tracking, also known as trunk failover, is a feature that binds the link state of multiple interfaces. For example, link-state tracking provides redundancy in the network when used with server NIC adapter teaming. When server network adapters are configured in a primary or secondary relationship known as teaming, if the link is lost on the primary interface, connectivity is transparently changed to the secondary interface.

Figure 27-3 on page 27-25 shows a network configured with link-state tracking. To enable link-state tracking, create a link-state group, and specify the interfaces that are assigned to the link-state group. An interface can be an aggregation of ports (an EtherChannel), a single physical port in access or trunk mode, or a routed port. In a link-state group, these interfaces are bundled together. The downstream interfaces are bound to the upstream interfaces. Interfaces connected to servers are referred to as downstream interfaces, and interfaces connected to distribution switches and network devices are referred to as upstream interfaces.

The configuration in Figure 27-3 ensures that the network traffic flow is balanced as follows:

- For links to switches and other network devices
 - Server 1 and server 2 use switch A for primary links and switch B for secondary links.
 - Server 3 and server 4 use switch B for primary links and switch A for secondary links.
- Link-state group 1 on switch A
 - Switch A provides primary links to server 1 and server 2 through link-state group 1. Port 1 is connected to server 1, and port 2 is connected to server 2. Port 1 and port 2 are the downstream interfaces in link-state group 1.
 - Port 5 and port 6 are connected to distribution switch 1 through link-state group 1. Port 5 and port 6 are the upstream interfaces in link-state group 1.
- Link-state group 2 on switch A
 - Switch A provides secondary links to server 3 and server 4 through link-state group 2. Port 3 is connected to server 3, and port 4 is connected to server 4. Port 3 and port 4 are the downstream interfaces in link-state group 2.
 - Port 7 and port 8 are connected to distribution switch 2 through link-state group 2. Port 7 and port 8 are the upstream interfaces in link-state group 2.
- Link-state group 2 on switch B
 - Switch B provides primary links to server 3 and server 4 through link-state group 2. Port 3 is connected to server 3, and port 4 is connected to server 4. Port 3 and port 4 are the downstream interfaces in link-state group 2.
 - Port 5 and port 6 are connected to distribution switch 2 through link-state group 2. Port 5 and port 6 are the upstream interfaces in link-state group 2.
- Link-state group 1 on switch B
 - Switch B provides secondary links to server 1 and server 2 through link-state group 1. Port 1 is connected to server 1, and port 2 is connected to server 2. Port 1 and port 2 are the downstream interfaces in link-state group 1.
 - Port 7 and port 8 are connected to distribution switch 1 through link-state group 1. Port 7 and port 8 are the upstream interfaces in link-state group 1.

In a link-state group, the upstream ports can become unavailable or lose connectivity because the distribution switch or router fails, the cables are disconnected, or the link is lost. These are the interactions between the downstream and upstream interfaces when link-state tracking is enabled:

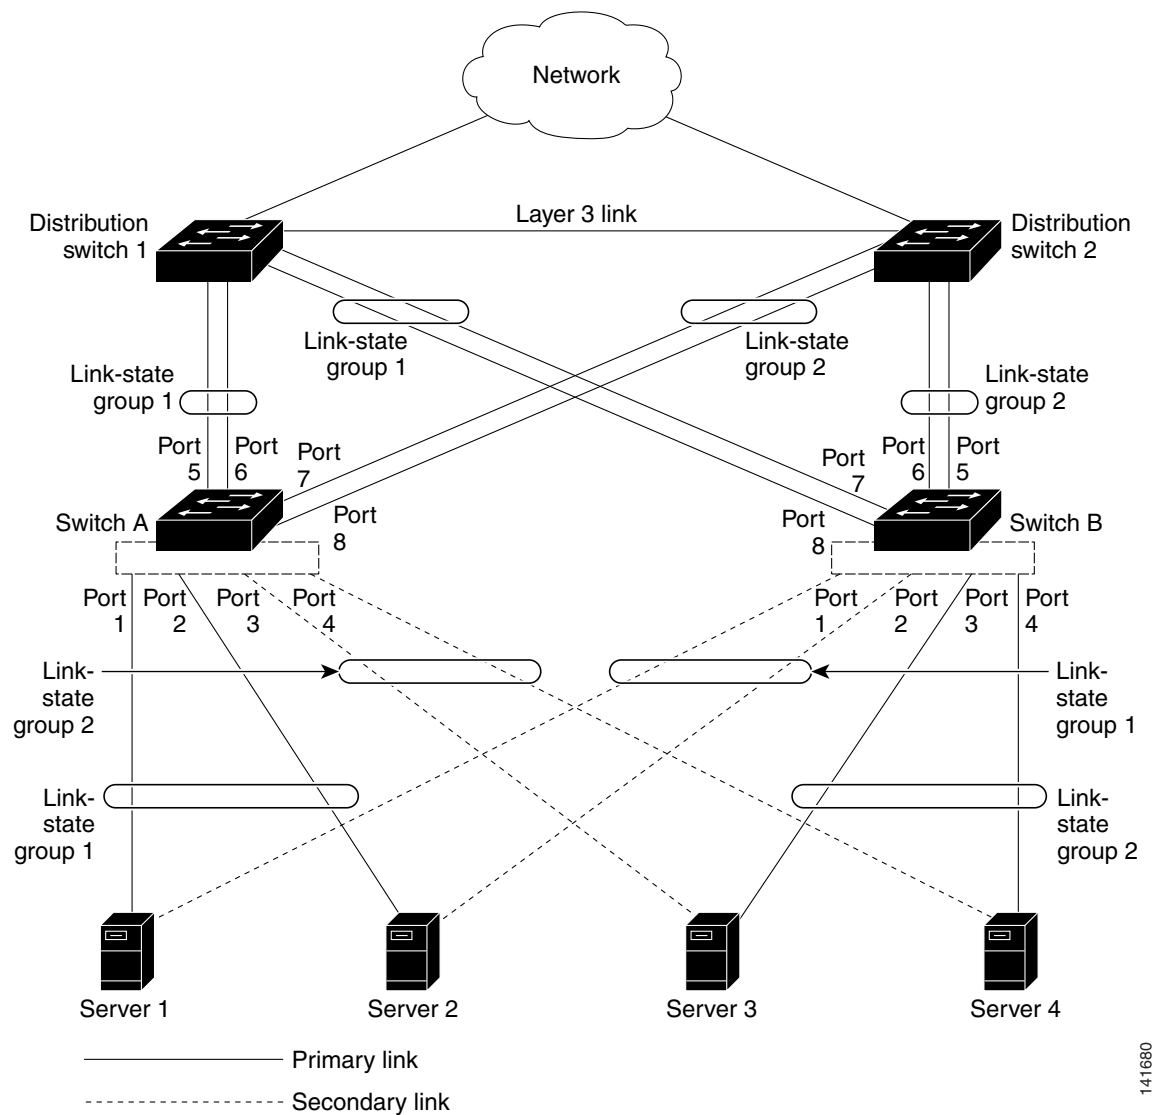

- If any of the upstream interfaces are in the link-up state, the downstream interfaces can change to or remain in the link-up state.
- If all of the upstream interfaces become unavailable, link-state tracking automatically puts the downstream interfaces in the error-disabled state. Connectivity to and from the servers is automatically changed from the primary server interface to the secondary server interface.

As an example of a connectivity change from link-state group 1 to link-state group 2 on switch A, see [Figure 27-3 on page 27-25](#). If the upstream link for port 6 is lost, the link states of downstream ports 1 and 2 do not change. However, if the link for upstream port 5 is also lost, the link state of the downstream ports changes to the link-down state. Connectivity to server 1 and server 2 is then changed from link-state group 1 to link-state group 2. The downstream ports 3 and 4 do not change state because they are in link-group 2.

- If the link-state group is configured, link-state tracking is disabled, and the upstream interfaces lose connectivity, the link states of the downstream interfaces remain unchanged. The server does not recognize that upstream connectivity has been lost and does not failover to the secondary interface.

You can recover a downstream interface link-down condition by removing the failed downstream port from the link-state group. To recover multiple downstream interfaces, disable the link-state group.

Figure 27-3 Typical Link-State Tracking Configuration

141680

Configuring Link-State Tracking

These sections describe how to configure link-state tracking ports:

- [Default Link-State Tracking Configuration, page 27-26](#)
- [Link-State Tracking Configuration Guidelines, page 27-26](#)
- [Configuring Link-State Tracking, page 27-26](#)
- [Displaying Link-State Tracking Status, page 27-27](#)

Default Link-State Tracking Configuration

No link-state groups are defined, and link-state tracking is not enabled for any group.

Link-State Tracking Configuration Guidelines

Follow these guidelines to avoid configuration problems:

- An interface that is defined as an upstream interface cannot also be defined as a downstream interface in the same or different link-state group. The reverse is also true.
- We recommend that you add the upstream interfaces to the link state group before adding the downstream interfaces. it is because when a downstream interface is added to a link state group without an upstream interface, the downstream interface is put in error-disabled state until an upstream interfaces is added to the group.
- An interface cannot be a member of more than one link-state group.
- You can configure up to 20 link-state groups per switch.
- If a SPAN destination port is configured as a downstream interface, it is error disabled when all upstream interfaces in its group are down. When an upstream interface is configured as a SPAN destination port, it is considered as a link down event on the interface.

Configuring Link-State Tracking

To configure a link-state group and to assign an interface to a group, perform this task beginning in privileged EXEC mode:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# link state track <i>number</i>	Creates a link-state group, and enables link-state tracking. The group number range is 1 to 20; the default is 1.
Step 3	Switch(config)# interface <i>interface-id</i>	Specifies a physical interface or range of interfaces to configure, and enters interface configuration mode. Valid interfaces include switch ports in access mode or trunk mode (IEEE 802.1q), routed ports, or multiple ports bundled into an EtherChannel interface (static or LACP), in trunk mode.

	Command	Purpose
Step 4	Switch(config-if)# link state group <i>[number]</i> { upstream downstream }	Specifies a link-state group, and configures the interface as either an upstream or downstream interface in the group. The group number range is from 1 to 20; the default is 1.
Step 5	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 6	Switch# show running-config	Verifies your entries.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to create a link-state group and configure the interfaces:

```
Switch# configure terminal
Switch(config)# link state track 1
Switch(config)# interface gigabitethernet3/1
Switch(config-if)# link state group 1 upstream
Switch(config-if)# interface gigabitethernet3/3
Switch(config-if)# link state group 1 upstream
Switch(config-if)# interface gigabitethernet3/5
Switch(config-if)# link state group 1 downstream
Switch(config-if)# interface gigabitethernet3/7
Switch(config-if)# link state group 1 downstream
Switch(config-if)# end
```

To disable a link-state group, use the **no link state track *number*** global configuration command.

Displaying Link-State Tracking Status

To display the link-state group information, enter the **show link state group** command. Enter this command without keywords to display information about all link-state groups.

Enter the group number to display information specific to the group. Enter the **detail** keyword to display detailed information about the group.

it is an example of output from the **show link state group 1** command:

```
Switch> show link state group 1
Link State Group: 1 Status: Enabled, Down
```

it is an example of output from the **show link state group detail** command:

```
Switch> show link state group detail
(Up):Interface up (Dwn):Interface Down (Dis):Interface disabled
Link State Group: 1 Status: Enabled, Down
Upstream Interfaces : Gi3/5(Dwn) Gi3/6(Dwn)
Downstream Interfaces : Gi3/1(Dis) Gi3/2(Dis) Gi3/3(Dis) Gi3/4(Dis)
Link State Group: 2 Status: Enabled, Down
Upstream Interfaces : Gi3/15(Dwn) Gi3/16(Dwn) Gi3/17(Dwn)
Downstream Interfaces : Gi3/11(Dis) Gi3/12(Dis) Gi3/13(Dis) Gi3/14(Dis)
(Up):Interface up (Dwn):Interface Down (Dis):Interface disabled
```

Configuring IGMP Snooping and Filtering, and MVR

This chapter describes how to configure Internet Group Management Protocol (IGMP) snooping on the switch, including an application of local IGMP snooping, Multicast VLAN Registration (MVR). It also includes procedures for controlling multicast group membership by using IGMP filtering.

This chapter consists of the following major sections:

- [About IGMP Snooping, page 28-1](#)
- [Configuring IGMP Snooping, page 28-5](#)
- [Displaying IGMP Snooping Information, page 28-14](#)
- [Understanding Multicast VLAN Registration, page 28-20](#)
- [Configuring MVR, page 28-23](#)
- [Displaying MVR Information, page 28-29](#)
- [Configuring IGMP Filtering, page 28-30](#)
- [Displaying IGMP Filtering Configuration, page 28-34](#)

Note

To support Cisco Group Management Protocol (CGMP) client devices, configure the switch as a CGMP server. For more information, see the Cisco IOS 15.0M configuration guides at this location: http://www.cisco.com/en/US/products/ps10591/products_installation_and_configuration_guides_list.html

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About IGMP Snooping

This section includes the following subsections:

- [Immediate-Leave Processing, page 28-3](#)
- [IGMP Configurable-Leave Timer, page 28-4](#)

- [IGMP Snooping Querier, page 28-4](#)
- [Explicit Host Tracking, page 28-4](#)

**Note**

Quality of service does not apply to IGMP packets.

IGMP snooping allows a switch to snoop or capture information from IGMP packets transmitted between hosts and a router. Based on this information, a switch adds or deletes multicast addresses from its address table, which enables (or disables) multicast traffic from flowing to individual host ports. IGMP snooping supports all versions of IGMP: IGMPv1, IGMPv2, and IGMPv3.

In contrast to IGMPv1 and IGMPv2, IGMPv3 snooping provides immediate-leave processing by default. It provides explicit host tracking (EHT) and allows network administrators to deploy SSM functionality on Layer 2 devices that support IGMPv3. See the [“Explicit Host Tracking” section on page 28-4](#). In subnets where IGMP is configured, IGMP snooping manages multicast traffic at Layer 2. You can configure interfaces to dynamically forward multicast traffic only to those interfaces that are interested in receiving it by using the **switchport** keyword.

IGMP snooping restricts traffic in MAC multicast groups 0100.5e00.0001 to 01-00-5e-ff-ff-ff. IGMP snooping does not restrict Layer 2 multicast packets generated by routing protocols.

**Note**

For more information on IP multicast and IGMP, refer to RFC 1112, RFC 2236, RFC 3376 (for IGMPv3).

IGMP (configured on a router) periodically sends out IGMP general queries. A host responds to these queries with IGMP membership reports for groups that it is interested in. When IGMP snooping is enabled, the switch creates one entry per-VLAN in the Layer 2 forwarding table for each Layer 2 multicast group from which it receives an IGMP join request. All hosts interested in this multicast traffic send IGMP membership reports and are added to the forwarding table entry.

Layer 2 multicast groups learned through IGMP snooping are dynamic. However, you can statically configure Layer 2 multicast groups using the **ip igmp snooping static** command. If you specify group membership statically, your setting supersedes any automatic manipulation by IGMP snooping. Multicast group membership lists can contain both user-defined and IGMP snooping settings.

Groups with IP addresses in the range 224.0.0.0 to 224.0.0.255, which map to the multicast MAC address range 0100.5E00.0001 to 0100.5E00.00FF, are reserved for routing control packets. These groups are flooded to all forwarding ports of the VLAN with the exception of 224.0.0.22, which is used for IGMPv3 membership reports.

**Note**

If a VLAN experiences a spanning-tree topology change, IP multicast traffic floods on all VLAN ports where PortFast is not enabled, as well as on ports with the **no igmp snooping tcn flood** command configured for a period of TCN query count.

For a Layer 2 IGMPv2 host interface to join an IP multicast group, a host sends an IGMP membership report for the IP multicast group. For a host to leave a multicast group, it can either ignore the periodic IGMP general queries or it can send an IGMP leave message. When the switch receives an IGMP leave message from a host, it sends out an IGMP group-specific query to determine whether any devices connected to that interface are interested in traffic for the specific multicast group. The switch then updates the table entry for that Layer 2 multicast group so that only those hosts interested in receiving multicast traffic for the group are listed.

In contrast, IGMPv3 hosts send IGMPv3 membership reports (with the **allow** group record mode) to join a specific multicast group. When IGMPv3 hosts send membership reports (with the **block** group record) to reject traffic from all sources in the previous source list, the last host on the port is removed by immediate-leave if EHT is enabled.

Immediate-Leave Processing

IGMP snooping immediate-leave processing allows the switch to remove an interface from the forwarding-table entry without first sending out IGMP group-specific queries to the interface. The VLAN interface is pruned from the multicast tree for the multicast group specified in the original IGMP leave message. Immediate-leave processing ensures optimal bandwidth management for all hosts on a switched network, even when multiple multicast groups are being used simultaneously.

When a switch with IGMP snooping enabled receives an IGMPv2 or IGMPv3 leave message, it sends an IGMP group-specific query from the interface where the leave message was received to determine when other hosts are attached to that interface that are interested in joining the MAC multicast group. If the switch does not receive an IGMP join message within the query response interval, the interface is removed from the port list of the (MAC-group, VLAN) entry in the Layer 2 forwarding table.

**Note**

By default all IGMP joins are forwarded to all multicast router ports.

With immediate-leave processing enabled on the VLAN, an interface can be removed immediately from the port list of the Layer 2 entry when the IGMP leave message is received, unless a multicast router was learned on the port.

**Note**

When using IGMPv2 snooping, use immediate-leave processing only on VLANs where just one host is connected to each interface. If immediate-leave processing is enabled on VLANs where multiple hosts are connected to an interface, some hosts might be dropped inadvertently. When using IGMPv3, immediate-leave processing is enabled by default, and due to explicit host tracking, the switch can detect when a port has single or multiple hosts maintained by the switch for IGMPv3 hosts. As a result, the switch can perform immediate-leave processing when it detects a single host behind a given port.

**Note**

IGMPv3 is interoperable with older versions of IGMP.

To display the IGMP version on a particular VLAN, use the **show ip igmp snooping querier vlan** command.

To display whether the switch supports IGMPv3 snooping, use the **show ip igmp snooping vlan** command.

To enable immediate-leave for IGMPv2, use the **ip igmp snooping immediate-leave** command.

**Note**

Immediate-leave processing is enabled by default for IGMPv3.

IGMP Configurable-Leave Timer

Immediate-leave processing cannot be used on VLANs where multiple hosts may be connected to a single interface. To reduce leave latency in such a scenario, IGMPv3 provides a configurable leave timer.

In Cisco IOS Release 12.2(25)SG and earlier, the IGMP snooping leave time was based on query response time. If membership reports were not received by the switch before the query response time of the query expired, a port was removed from the multicast group membership.

In Cisco IOS Release 12.2(31)SG and later, you can configure the length of time that the switch waits after sending a group-specific query to determine if hosts are still interested in a specific multicast group. The IGMP leave response time can be configured from 100 to 5000 milliseconds. The timer can be set either globally or per-VLAN. The VLAN configuration of the leave time overrides the global configuration.

For configuration steps, see the [“Configuring the IGMP Leave Timer” section on page 28-9](#).

IGMP Snooping Querier

IGMP Snooping Querier support was introduced in Cisco IOS Release 12.2(50)SG. This is a Layer 2 feature required to support IGMP snooping in a VLAN where PIM and IGMP are not configured because the multicast traffic does not require routing.

In a network where IP multicast routing is configured, the IP multicast router acts as the IGMP querier by sending general queries. If the IP-multicast traffic in a VLAN only needs to be Layer 2-switched, an IP-multicast router is not required. Without an IP-multicast router on the VLAN, you must configure another switch as the IGMP querier so that it can send queries.

When enabled, the IGMP snooping querier sends out periodic IGMPv2 queries that trigger IGMP report messages from the switch that requests IP multicast traffic. IGMP snooping listens to these IGMP reports to establish appropriate forwarding.

On switches that use IGMP to report interest in IP multicast traffic, configure at least one switch as the IGMP snooping querier in each supported VLAN.

You can configure a switch to generate IGMP queries on a VLAN regardless of whether IP multicast routing is enabled.

Explicit Host Tracking

Explicit host tracking (EHT) monitors group membership by tracking hosts that are sending IGMPv3 membership reports. This tracking enables a switch to detect host information associated with the groups of each port. EHT also enables the user to track the membership and various statistics.

EHT enables a switch to track membership on a per-port basis. Consequently, a switch is aware of the hosts residing on each port and can perform immediate-leave processing when there is only one host behind a port.

To determine whether EHT is enabled on a VLAN, use the **show ip igmp snoop vlan** command.

Configuring IGMP Snooping

**Note**

When configuring IGMP, configure the VLAN in the VLAN database mode. See [Chapter 17](#), “Configuring VLANs, VTP, and VMPS.”

IGMP snooping allows switches to examine IGMP packets and make forwarding decisions based on their content.

These sections describe how to configure IGMP snooping:

- [Default IGMP Snooping Configuration, page 28-5](#)
- [Enabling IGMP Snooping Globally, page 28-6](#)
- [Enabling IGMP Snooping on a VLAN, page 28-6](#)
- [Configuring Learning Methods, page 28-7](#)
- [Configuring a Static Connection to a Multicast Router, page 28-8](#)
- [Enabling IGMP Immediate-Leave Processing, page 28-8](#)
- [Configuring the IGMP Leave Timer, page 28-9](#)
- [Configuring IGMP Snooping Querier, page 28-10](#)
- [Configuring Explicit Host Tracking, page 28-11](#)
- [Configuring a Host Statically, page 28-11](#)
- [Suppressing Multicast Flooding, page 28-12](#)

Default IGMP Snooping Configuration

[Table 28-1](#) shows the IGMP snooping default configuration values.

Table 28-1 IGMP Snooping Default Configuration Values

Feature	Default Value
IGMP snooping	Enabled
Multicast routers	None configured
Explicit Host Tracking	Enabled for IGMPv3; Not available for IGMPv2
Immediate-leave processing	Enabled for IGMPv3; Disabled for IGMPv2
Report Suppression	Enabled
IGMP snooping learning method	PIM/DVMRP ¹

1. PIM/DVMRP = Protocol Independent Multicast/Distance Vector Multicast Routing Protocol

Enabling IGMP Snooping Globally

To enable IGMP snooping globally, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# [no] ip igmp snooping	Enables IGMP snooping. Use the no keyword to disable IGMP snooping.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show ip igmp snooping include	Verifies the configuration.

This example shows how to enable IGMP snooping globally and verify the configuration:

```
Switch# configure terminal
Switch(config)# ip igmp snooping
Switch(config)# end
Switch# show ip igmp snooping
Global IGMP Snooping configuration:
-----
IGMP snooping           : Enabled
IGMPv3 snooping         : Enabled
Report suppression      : Enabled
TCN solicit query       : Disabled
TCN flood query count    : 2

Vlan 1:
-----
IGMP snooping           : Enabled
IGMPv2 immediate leave   : Disabled
Explicit host tracking    : Enabled
Multicast router learning mode : pim-dvmrp
CGMP interoperability mode : IGMP_ONLY

Vlan 2:
-----
IGMP snooping           : Enabled
IGMPv2 immediate leave   : Disabled
Explicit host tracking    : Enabled
Multicast router learning mode : pim-dvmrp
CGMP interoperability mode : IGMP_ONLY
```

Enabling IGMP Snooping on a VLAN

To enable IGMP snooping on a VLAN, perform this task:

	Command	Purpose
Step 1	Switch(config)# [no] ip igmp snooping vlan vlan_ID	Enables IGMP snooping. Use the no keyword to disable IGMP snooping.
Step 2	Switch(config)# end	Exits configuration mode.
Step 3	Switch# show ip igmp snooping vlan vlan_ID	Verifies the configuration.

This example shows how to enable IGMP snooping on VLAN 2 and verify the configuration:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 2
Switch(config)# end
Switch# show ip igmp snooping vlan 2
Global IGMP Snooping configuration:
-----
IGMP snooping           : Enabled
IGMPv3 snooping         : Enabled
Report suppression      : Enabled
TCN solicit query       : Disabled
TCN flood query count    : 2

Vlan 2:
-----
IGMP snooping           : Enabled
IGMPv2 immediate leave  : Disabled
Explicit host tracking   : Enabled
Multicast router learning mode : pim-dvmrp
CGMP interoperability mode : IGMP_ONLY
```

Configuring Learning Methods

The following sections describe IGMP snooping learning methods:

- [Configuring PIM/DVMRP Learning, page 28-7](#)
- [Configuring CGMP Learning, page 28-7](#)

Configuring PIM/DVMRP Learning

To configure IGMP snooping to learn from PIM/DVMRP packets, perform this task:

Command	Purpose
Switch(config)# ip igmp snooping vlan <i>vlan_ID</i> mrouter learn [cgmp pim-dvmrp]	Specifies the learning method for the VLAN.

This example shows how to configure IP IGMP snooping to learn from PIM/DVMRP packets:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 1 mrouter learn pim-dvmrp
Switch(config)# end
Switch#
```

Configuring CGMP Learning

To configure IGMP snooping to learn from CGMP self-join packets, perform this task:

Command	Purpose
Switch(config)# ip igmp snooping vlan <i>vlan_ID</i> mrouter learn [cgmp pim-dvmrp]	Specifies the learning method for the VLAN.

This example shows how to configure IP IGMP snooping to learn from CGMP self-join packets:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 1 mrouter learn cgmp
Switch(config)# end
Switch#
```

Configuring a Static Connection to a Multicast Router

To configure a static connection to a multicast router, enter the **ip igmp snooping vlan mrouter interface** command on the switch.

To configure a static connection to a multicast router, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip igmp snooping vlan <i>vlan_ID</i> mrouter interface <i>interface_num</i>	Specifies a static connection to a multicast router for the VLAN. Note The interface to the router must be in the VLAN where you are entering the command. The router and the line protocol must be up.
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show ip igmp snooping mrouter vlan <i>vlan_ID</i>	Verifies the configuration.

This example shows how to configure a static connection to a multicast router:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 200 mrouter interface fastethernet 2/10
Switch# show ip igmp snooping mrouter vlan 200
vlan  ports
-----+-----
 200   Fa2/10
Switch#
```

Enabling IGMP Immediate-Leave Processing

When you enable IGMP immediate-leave processing on a VLAN, a switch removes an interface from the multicast group when it detects an IGMPv2 leave message on that interface.

Note

For IGMPv3, immediate-leave processing is enabled by default with EHT.

To enable immediate-leave processing on an IGMPv2 interface, perform this task:

Command	Purpose
Switch(config)# ip igmp snooping vlan <i>vlan_ID</i> immediate-leave	Enables immediate-leave processing in the VLAN. Note This command applies only to IGMPv2 hosts.

This example shows how to enable IGMP immediate-leave processing on interface VLAN 200 and to verify the configuration:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 200 immediate-leave
Configuring immediate leave on vlan 200
Switch(config)# end
Switch# show ip igmp interface vlan 200 | include immediate leave
Immediate leave                : Disabled
Switch(config)#
```

Configuring the IGMP Leave Timer

Follows these guidelines when configuring the IGMP leave timer:

- You can configure the leave time globally or per-VLAN.
- Configuring the leave time on a VLAN overrides the global setting.
- The default leave time is 1000 milliseconds.
- The IGMP configurable leave time is only supported on hosts running IGMP Version 2.
- The actual leave latency in the network is usually the configured leave time. However, the leave time *might* vary around the configured time, depending on real-time CPU load conditions, network delays and the amount of traffic sent through the interface.

To enable the IGMP configurable-leave timer, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip igmp snooping last-member-query-interval time	Configures the IGMP leave timer globally. The range is 100 to 5000 milliseconds. The default is 1000 seconds. To globally reset the IGMP leave timer to the default setting, use the global configuration command no ip igmp snooping last-member-query-interval .
Step 3	Switch(config)# ip igmp snooping vlan vlan_ID last-member-query-interval time	(Optional) Configures the IGMP leave time on the VLAN interface. The range is 100 to 5000 milliseconds. To remove the configured IGMP leave-time setting from the specified VLAN, use the global configuration command no ip igmp snooping vlan vlan-id last-member-query-interval Note Configuring the leave time on a VLAN overrides the globally configured timer.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# show ip igmp snooping	(Optional) Displays the configured IGMP leave time.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable the IGMP configurable-leave timer and to verify the configuration:

```
Switch# configure terminal
Switch(config)# ip igmp snooping last-member-query-interval 200
Switch(config)# ip igmp snooping vlan 10 last-member-query-interval 500
Switch(config)# end
```

```
Switch# show ip igmp snooping show ip igmp snooping
Global IGMP Snooping configuration:
-----

IGMP snooping           : Enabled
IGMPv3 snooping         : Enabled
Report suppression      : Enabled
TCN solicit query       : Disabled
TCN flood query count    : 2
Last Member Query Interval : 200

Vlan 1:
-----
IGMP snooping           : Enabled
IGMPv2 immediate leave  : Disabled
Explicit host tracking   : Enabled
Multicast router learning mode : pim-dvmrp
Last Member Query Interval : 200
CGMP interoperability mode : IGMP_ONLY

Vlan 10:
-----
IGMP snooping           : Enabled
IGMPv2 immediate leave  : Disabled
Explicit host tracking   : Enabled
Multicast router learning mode : pim-dvmrp
Last Member Query Interval : 500
CGMP interoperability mode : IGMP_ONLY

Switch#
```

Configuring IGMP Snooping Querier

The IGMP Snooping Querier feature can be enabled either globally or per-VLAN.

Note

The IGMP snooping querier is disabled by default.

To configure IGMP Snooping Querier, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# [no] ip igmp snooping [vlan vlan_id] querier	Enables IGMP Snooping Querier.
Step 3	Switch(config)# [no] ip igmp snooping [vlan vlan_id] querier address abcd	Configures the IGMP Snooping Querier source IP address.
Step 4	Switch(config)# [no] ip igmp snooping [vlan vlan_id] querier version [1 2]	Configures IGMP Snooping Querier IGMP version.
Step 5	Switch(config)# ip igmp snooping [vlan vlan_id] querier query-interval interval	Configures IGMP Snooping Querier query interval.
Step 6	Switch(config)# ip igmp snooping [vlan vlan_id] querier max-response-time value	Configures IGMP Snooping Querier query maximum response time.
Step 7	Switch(config)# ip igmp snooping [vlan vlan_id] querier timer expiry value	Configures IGMP Snooping Querier expiry time out.

	Command	Purpose
Step 8	Switch(config)# ip igmp snooping [vlan vlan_id] querier tcq query count value	Configures IGMP Snooping Querier tcq query count.
Step 9	Switch(config)# ip igmp snooping [vlan vlan_id] querier tcq query interval value	Configures IGMP Snooping Querier tcq query interval.
Step 10	Switch(config) # end	Returns to privileged EXEC mode.

For an example of how to display Snooping Querier information, refer to the [“Displaying IGMP Snooping Querier Information”](#) section on page 28-19.

Configuring Explicit Host Tracking

For IGMPv3, EHT is enabled by default and can be disabled on a per-VLAN basis.

To disable EHT processing on a VLAN, perform this task:

Command	Purpose
Switch(config)# [no] ip igmp snooping vlan vlan_ID explicit-tracking	Enables EHT on a VLAN. The no keyword disables EHT.

This example shows how to disable IGMP EHT on VLAN 200 and to verify the configuration:

```
Switch# configure terminal
Switch(config)# no ip igmp snooping vlan 200 explicit-tracking
Switch(config)# end
Switch# show ip igmp snooping vlan 200 | include Explicit host tracking
Explicit host tracking           : Disabled
```

Configuring a Host Statically

Hosts normally join multicast groups dynamically, but you can also configure a host statically on an interface.

To configure a host statically on an interface, perform this task:

Command	Purpose
Switch(config-if)# ip igmp snooping vlan vlan_ID static mac_address interface interface_num	Configures a host statically in the VLAN. Note This command cannot be configured to receive traffic for specific source IP addresses.

This example shows how to configure a host statically in VLAN 200 on interface Fast Ethernet 2/11:

```
Switch# configure terminal
Switch(config)# ip igmp snooping vlan 200 static 0100.5e02.0203 interface fastethernet
2/11
Configuring port FastEthernet2/11 on group 0100.5e02.0203 vlan 200
Switch(config)# end
```

Suppressing Multicast Flooding

An IGMP snooping-enabled switch floods multicast traffic to all ports in a VLAN when a spanning-tree topology change notification (TCN) is received. Multicast flooding suppression enables a switch to stop sending such traffic. To support flooding suppression, the following interface and global commands were introduced in Cisco IOS Release 12.1(11b)EW:

- **[no | default] ip igmp snooping tcn flood** (interface command)
- **[no | default] ip igmp snooping tcn flood query count [1 - 10]** (global command)
- **[no | default] ip igmp snooping tcn query solicit** (global command)

Prior to Cisco IOS Release 12.1(11b)EW, when a spanning tree topology change notification (TCN) was received by a switch, the multicast traffic was flooded to all the ports in a VLAN for a period of three IGMP query intervals. This was necessary for redundant configurations. In Cisco IOS Release 12.1(11b)EW, the default time period the switch waits before multicast flooding stops was changed to two IGMP query intervals.

This flooding behavior is undesirable if the switch that does the flooding has many ports that are subscribed to different groups. The traffic could exceed the capacity of the link between the switch and the end host, resulting in packet loss.

With the **no ip igmp snooping tcn flood** command, you can disable multicast flooding on a switch interface following a topology change. Only the multicast groups that have been joined by a port are sent to that port, even during a topology change.

With the **ip igmp snooping tcn flood query count** command, you can enable multicast flooding on a switch interface for a short period of time following a topology change by configuring an IGMP query threshold.

Typically, if a topology change occurs, the spanning tree root switch issues a global IGMP leave message (referred to as a “query solicitation”) with the group multicast address 0.0.0.0. When a switch receives this solicitation, it floods this solicitation on all ports in the VLAN where the spanning tree change occurred. When the upstream router receives this solicitation, it immediately issues an IGMP general query.

With the **ip igmp snooping tcn query solicit** command, you can now direct a non-spanning tree root switch to enter the same query solicitation.

The following sections provide additional details on the new commands and illustrate how you can use them.

IGMP Snooping Interface Configuration

A topology change in a VLAN may invalidate previously learned IGMP snooping information. A host that was on one port before the topology change may move to another port after the topology change. When the topology changes, the Catalyst 4500 series switch takes special actions to ensure that multicast traffic is delivered to all multicast receivers in that VLAN.

When the spanning tree protocol is running in a VLAN, a spanning tree topology change notification (TCN) is issued by the root switch in the VLAN. A Catalyst 4500 series switch that receives a TCN in a VLAN for which IGMP snooping has been enabled immediately enters into multicast flooding mode for a period of time until the topology restabilizes and the new locations of all multicast receivers are learned.

While in multicast flooding mode, IP multicast traffic is delivered to all ports in the VLAN, and not restricted to those ports on which multicast group members have been detected.

Starting with Cisco IOS Release 12.1(11b)EW, you can manually prevent IP multicast traffic from being flooded to a switch port by using the **no ip igmp snooping tcn flood** command on that port.

For trunk ports, the configuration applies to all VLANs.

By default, multicast flooding is enabled. Use the **no** keyword to disable flooding, and use **default** to restore the default behavior (flooding is enabled).

To disable multicast flooding on an interface, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Selects the interface to configure.
Step 2	Switch(config-if)# no ip igmp snooping tcn flood	Disables multicast flooding on the interface when TCNs are received by the switch. To enable multicast flooding on the interface, enter this command: default ip igmp snooping tcn flood
Step 3	Switch(config)# end	Exits configuration mode.
Step 4	Switch# show running interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i>	Verifies the configuration.

This example shows how to disable multicast flooding on interface Fast Ethernet 2/11:

```
Switch(config)# interface fastethernet 2/11
Switch(config-if)# no ip igmp snooping tcn flood
Switch(config-if)# end
Switch#
```

IGMP Snooping Switch Configuration

By default, flooding mode persists until the switch receives two IGMP general queries. You can change this period of time by using the **ip igmp snooping tcn flood query count** *n* command, where *n* is a number between 1 and 10.

This command operates at the global configuration level.

The default number of queries is 2. The **no** and **default** keywords restore the default.

To establish an IGMP query threshold, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip igmp snooping tcn flood query count <n>	Modifies the number of IGMP queries the switch waits for before it stops flooding multicast traffic. To return the switch to the default number of IGMP queries, enter this command: default ip igmp snooping tcn flood query count.
Step 2	Switch(config)# end	Exits configuration mode.

This example shows how to modify the switch to stop flooding multicast traffic after four queries:

```
Switch(config)# ip igmp snooping tcn flood query count 4
Switch(config)# end
Switch#
```

When a spanning tree root switch receives a topology change in an IGMP snooping-enabled VLAN, the switch issues a query solicitation that causes an Cisco IOS router to send out one or more general queries. The new command **ip igmp snooping tcn query solicit** causes the switch to send the query solicitation whenever it notices a topology change, even if that switch is not the spanning tree root.

This command operates at the global configuration level.

By default, query solicitation is disabled unless the switch is the spanning tree root. The **default** keyword restores the default behavior.

To direct a switch to send a query solicitation, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip igmp snooping tcn query solicit	Configures the switch to send a query solicitation when a TCN is detected. To stop the switch from sending a query solicitation (if it is not a spanning tree root switch), enter the no ip igmp snooping tcn query solicit command.
Step 2	Switch(config)# end	Exits configuration mode.

This example shows how to configure the switch to send a query solicitation upon detecting a TCN:

```
Switch(config)# ip igmp snooping tcn query solicit
Switch(config)# end
Switch#
```

Displaying IGMP Snooping Information

The following sections show how to display IGMP snooping information:

- [Displaying Querier Information, page 28-15](#)
- [Displaying IGMP Host Membership Information, page 28-15](#)
- [Displaying Group Information, page 28-16](#)
- [Displaying Multicast Router Interfaces, page 28-17](#)

- [Displaying MAC Address Multicast Entries, page 28-18](#)
- [Displaying IGMP Snooping Information on a VLAN Interface, page 28-18](#)
- [Configuring IGMP Filtering, page 28-30](#)

Displaying Querier Information

To display querier information, perform this task:

Command	Purpose
Switch# show ip igmp snooping querier [vlan <i>vlan_ID</i>]	Displays multicast router interfaces.

This example shows how to display the IGMP snooping querier information for all VLANs on the switch:

```
Switch# show ip igmp snooping querier
Vlan      IP Address      IGMP Version      Port
-----
2         10.10.10.1      v2                 Router
3         172.20.50.22    v3                 Fa3/15
```

This example shows how to display the IGMP snooping querier information for VLAN 3:

```
Switch# show ip igmp snooping querier vlan 3
Vlan      IP Address      IGMP Version      Port
-----
3         172.20.50.22    v3                 Fa3/15
```

Displaying IGMP Host Membership Information

Note

By default, EHT maintains a maximum of 1000 entries in the EHT database. Once this limit is reached, no additional entries are created. To create additional entries, clear the database with the **clear ip igmp snooping membership vlan** command.

To display host membership information, perform this task:

Command	Purpose
Switch# show ip igmp snooping membership [interface <i>interface_num</i>] [vlan <i>vlan_ID</i>] [reporter <i>a.b.c.d</i>] [source <i>a.b.c.d</i> group <i>a.b.c.d</i>]	Displays EHT information. Note This command is valid only if EHT is enabled on the switch.

This example shows how to display host membership information for VLAN 20 and to delete the EHT database:

```
Switch# show ip igmp snooping membership vlan 20
#channels: 5
#hosts : 1
Source/Group Interface Reporter Uptime Last-Join Last-Leave
```

```

40.40.40.2/224.10.10.10 Gi4/1 20.20.20.20 00:23:37 00:06:50 00:20:30
40.40.40.3/224.10.10.10 Gi4/2 20.20.20.20 00:23:37 00:06:50 00:20:30

```

```
Switch# clear ip igmp snooping membership vlan 20
```

This example shows how to display host membership for interface gi4/1:

```

Switch# show ip igmp snooping membership interface gi4/1
#channels: 5
#hosts : 1
Source/Group Interface Reporter Uptime Last-Join Last-Leave

40.40.40.2/224.10.10.10 Gi4/1 20.20.20.20 00:23:37 00:06:50 00:20:30
40.40.40.4/224.10.10.10Gi4/1 20.20.20.20 00:39:42 00:09:17 -

```

This example shows how to display host membership for VLAN 20 and group 224.10.10.10:

```

Switch# show ip igmp snooping membership vlan 20 source 40.40.40.2 group 224.10.10.10
#channels: 5
#hosts : 1
Source/Group Interface Reporter Uptime Last-Join Last-Leave

40.40.40.2/224.10.10.10 Gi4/1 20.20.20.20 00:23:37 00:06:50 00:20:30

```

Displaying Group Information

To display detailed IGMPv3 information associated with a group, perform one of the following tasks:

Command	Purpose
Switch# show ip igmp snooping groups [vlan <i>vlan_ID</i>]	<p>Displays groups, the type of reports that were received for the group (Host Type), and the list of ports on which reports were received.</p> <p>The report list includes neither the multicast router ports nor the complete forwarding port set for the group. It lists the ports on which the reports have been received.</p> <p>To display the complete forwarding port set for the group, display the CLI output for the MAC address that maps to this group by using the show mac-address-table multicast command.</p>
Switch# show ip igmp snooping groups [vlan <i>vlan_ID</i> <i>a.b.c.d</i>] [<i>summary/sources/hosts</i>]	<p>Displays information specific to a group address, providing details about the current state of the group with respect to sources and hosts.</p> <p>Note This command applies only to full IGMPv3 snooping support and can be used for IGMPv1, IGMPv2, or IGMPv3 groups.</p>
Switch# show ip igmp snooping groups [vlan <i>vlan_ID</i>] [<i>count</i>]	Displays the total number of group addresses learned by the system on a global or per-VLAN basis.

This example shows how to display the host types and ports of a group in VLAN 1:

```
Switch# show ip igmp snooping groups vlan 10 226.6.6.7
Vlan      Group      Version  Ports
-----
10        226.6.6.7    v3       Fa7/13, Fa7/14
Switch>
```

This example shows how to display the current state of a group with respect to a source IP address:

```
Switch# show ip igmp snooping groups vlan 10 226.6.6.7 sources
Source information for group 226.6.6.7:
Timers: Expired sources are deleted on next IGMP General Query

SourceIP      Expires    Uptime      Inc Hosts  Exc Hosts
-----
2.0.0.1       00:03:04   00:03:48    2          0
2.0.0.2       00:03:04   00:02:07    2          0
Switch>
```

This example shows how to display the current state of a group with respect to a host MAC address:

```
Switch# show ip igmp snooping groups vlan 10 226.6.6.7 hosts
IGMPv3 host information for group 226.6.6.7
Timers: Expired hosts are deleted on next IGMP General Query

Host (MAC/IP)  Filter mode  Expires    Uptime      # Sources
-----
175.1.0.29     INCLUDE     stopped    00:00:51     2
175.2.0.30     INCLUDE     stopped    00:04:14     2
```

This example shows how to display summary information for an IGMPv3 group:

```
Switch# show ip igmp snooping groups vlan 10 226.6.6.7 summary
Group Address (Vlan 10)      : 226.6.6.7
Host type                    : v3
Member Ports                 : Fa7/13, Fa7/14
Filter mode                  : INCLUDE
Expires                      : stopped
Sources                      : 2
Reporters (Include/Exclude)  : 2/0
```

This example shows how to display the total number of group addresses learned by the system globally:

```
Switch# show ip igmp snooping groups count
Total number of groups: 54
```

This example shows how to display the total number of group addresses learned on VLAN 5:

```
Switch# show ip igmp snooping groups vlan 5 count
Total number of groups: 30
```

Displaying Multicast Router Interfaces

When you enable IGMP snooping, the switch automatically learns to which interface the multicast routers are connected.

To display multicast router interfaces, perform this task:

Command	Purpose
Switch# show ip igmp snooping mrouter vlan <i>vlan_ID</i>	Displays multicast router interfaces.

This example shows how to display the multicast router interfaces in VLAN 1:

```
Switch# show ip igmp snooping mrouter vlan 1
vlan                ports
-----+-----
  1                Gi1/1,Gi2/1,Fa3/48,Router
Switch#
```

Displaying MAC Address Multicast Entries

To display MAC address multicast entries for a VLAN, perform this task:

Command	Purpose
Switch# show mac-address-table multicast vlan <i>vlan_ID</i> [<i>count</i>]	Displays MAC address multicast entries for a VLAN.

This example shows how to display MAC address multicast entries for VLAN 1:

```
Switch# show mac-address-table multicast vlan 1
Multicast Entries
vlan    mac address      type    ports
-----+-----
  1     0100.5e01.0101    igmp    Switch,Gi6/1
  1     0100.5e01.0102    igmp    Switch,Gi6/1
  1     0100.5e01.0103    igmp    Switch,Gi6/1
  1     0100.5e01.0104    igmp    Switch,Gi6/1
  1     0100.5e01.0105    igmp    Switch,Gi6/1
  1     0100.5e01.0106    igmp    Switch,Gi6/1
Switch#
```

This example shows how to display a total count of MAC address entries for VLAN 1:

```
Switch# show mac-address-table multicast vlan 1 count
Multicast MAC Entries for vlan 1:    4
Switch#
```

Displaying IGMP Snooping Information on a VLAN Interface

To display IGMP snooping information on a VLAN, perform this task:

Command	Purpose
Switch# show ip igmp snooping vlan <i>vlan_ID</i>	Displays IGMP snooping information on a VLAN interface.

This example shows how to display IGMP snooping information on VLAN 5:

```
Switch# show ip igmp snooping vlan 5
Global IGMP Snooping configuration:
-----
IGMP snooping                :Enabled
IGMPv3 snooping support      :Full
Report suppression           :Enabled
TCN solicit query             :Disabled
TCN flood query count         :2

Vlan 5:
-----
IGMP snooping                :Enabled
Immediate leave               :Disabled
Explicit Host Tracking        :Disabled
Multicast router learning mode :pim-dvmrp
CGMP interoperability mode     :IGMP_ONLY
```

Displaying IGMP Snooping Querier Information

To display IGMP Snooping Querier information, perform this task:

Command	Purpose
Switch# show ip igmp snooping querier [vlan <i>vlan_ID</i>] [detail]	Displays the IGMP Snooping Querier state.

This example shows how to display Snooping Querier information:

```
switch# show ip igmp snooping querier vlan 2 detail
IP address          : 1.2.3.4
IGMP version         : v2
Port                : Router/Switch
Max response time    : 12s

Global IGMP switch querier status
-----
admin state          : Enabled
admin version         : 2
source IP address     : 1.2.3.4
query-interval (sec)  : 130
max-response-time (sec) : 10
querier-timeout (sec) : 100
tcn query count       : 2
tcn query interval (sec) : 10
```

```

Vlan 2:  IGMP switch querier status
-----
admin state                : Enabled
admin version              : 2
source IP address          : 1.2.3.4
query-interval (sec)       : 55
max-response-time (sec)    : 12
querier-timeout (sec)      : 70
tcn query count            : 10
tcn query interval (sec)   : 8
operational state          : Querier
operational version        : 2
tcn query pending count    : 0

```

Understanding Multicast VLAN Registration

When a network involves multi-VLAN's, subscribers to a multicast group may exist in more than one VLAN (i.e., the broadcast of multiple television channels over a service provider network). The multicast router must replicate the multicast data transmission to the same group in the every subscriber VLANs. The number of multicast stream replication is directly proportional to the subscriber VLANs. This results in using more than the required bandwidth.

Multicast VLAN Registration (MVR) overcomes this inefficiency by conserving network bandwidth. MVR allows a subscriber on a port to subscribe and unsubscribe to a multicast stream on the network-wide single "multicast VLAN," while subscribers remain in separate VLANs. It also isolates the streams from the subscriber VLANs for bandwidth and security reasons.

Note

Only Layer 2 ports participate in MVR.

Note

You need to configure subscriber ports as *MVR receiver ports* and router or data-source ports as *MVR source ports*.

Note

Only one MVR multicast VLAN per switch is supported.

MVR assumes that subscriber ports subscribe and unsubscribe (join and leave) these multicast streams by sending out IGMP join and leave messages. These messages can originate from an IGMP v2 compatible host with an Ethernet connection. Although MVR and IGMP snooping use the same underlying mechanism, the two features operate independently. You can enable or disable one without affecting the behavior of the other. However, if IGMP snooping and MVR are both enabled, MVR reacts only to join and leave messages from multicast groups configured under MVR. Join and leave messages from all other multicast groups are managed by IGMP snooping.

You can set the switch to operate MVR in compatible or dynamic mode:

- In *compatible* mode, a multicast router learned or configured is not required for MVR traffic to egress MVR source ports. All the MVR traffic is forwarded to the source ports. The IGMP reports that are received by the receiver ports are not forwarded to the mrouter or source ports.

- In *dynamic* mode, the interface on which the multicast router is learned or configured will receive MVR traffic. The receiver ports from where the MVR hosts have explicitly joined either by IGMP reports or by MVR static configuration will receive the MVR data traffic. The IGMP reports are forwarded to all the multicast VLAN (mVLAN) mrouter ports.

Using MVR in a Multicast Television Application

In a multicast television application, a PC or a television with a set-top box can receive the multicast stream. Multiple set-top boxes or PCs can be connected to one subscriber port, which is a switch port configured as an MVR receiver port. [Figure 28-1](#) is an example configuration. DHCP assigns an IP address to the set-top box or the PC. When a subscriber selects a channel, the set-top box or PC sends an IGMP report to Switch A to join the appropriate multicast. If the IGMP report matches one of the configured IP multicast group addresses, the switch CPU modifies the hardware address table to include this receiver port and VLAN as a forwarding destination of the specified multicast stream when it is received from the multicast VLAN. Uplink ports that send and receive multicast data to and from the multicast VLAN are called MVR *source* ports.

Figure 28-1 Multicast VLAN Registration Example

When a subscriber changes channels or turns off the television, the set-top box sends an IGMP leave message for the multicast stream. The switch CPU sends a MAC-based general query through the receiver port VLAN. If there is another set-top box in the VLAN still subscribing to this group, that set-top box must respond within the maximum response time specified in the query. If the CPU does not receive a response, it eliminates the receiver port as a forwarding destination for this group.

Without Immediate Leave, when the switch receives an IGMP leave message from a subscriber on a receiver port, it sends out an IGMP query on that port and waits for IGMP group membership reports. If no reports are received in a configured time period, the receiver port is removed from multicast group membership. With Immediate Leave, an IGMP query is not sent from the receiver port on which the IGMP leave was received. Once the leave message is received, the receiver port is removed from multicast group membership, which speeds up leave latency. Enable Immediate Leave feature only on receiver ports to which a single receiver device is connected.

Because MVR multicast traffic is sent only on mVLANs, duplicating television-channel multicast traffic for subscribers on different VLANs is unnecessary. The IGMP leave and join messages are in the VLAN to which the subscriber port is assigned. The access layer switch (Switch A) modifies the forwarding behavior to allow traffic forwarding from the multicast VLAN to the subscriber port in a different VLAN. This is done by selectively allowing traffic to cross between the two VLANs.

IGMP reports are sent to the same IP multicast group address as the multicast data. The Switch A CPU must capture all IGMP join and leave messages from the receiver ports and forward them to the multicast VLAN of the source (uplink) port, based on the MVR mode.

Configuring MVR

These sections include basic MVR configuration information:

- [Default MVR Configuration, page 28-23](#)
- [MVR Configuration Guidelines and Limitations, page 28-23](#)
- [Configuring MVR Global Parameters, page 28-24](#)
- [Configuring MVR on Access Ports, page 28-26](#)
- [Configuring MVR on a Trunk Port, page 28-27](#)
- [Displaying MVR Information, page 28-29](#)

Default MVR Configuration

**Note**

Enabling the **MVR** command will set all the MVR default parameters.

[Table 28-2](#) shows the default MVR configuration.

Table 28-2 **Default MVR Configuration**

Feature	Default Setting
MVR	Disabled globally
Multicast addresses	None configured
Query response time	5 (tenths of a second)
Multicast VLAN	VLAN 1
Mode	Compatible
Interface (per port) default	Neither a receiver nor a source port
Immediate Leave	Disabled on all ports

MVR Configuration Guidelines and Limitations

Follow these guidelines when configuring MVR:

- Ports can be configured as either a *source port* or a *receiver port*.
 - Ports connected to subscribers are configured as receiver ports.

- Router ports or ports that are connected to another MVR switch are configured as source ports.
- Compatible mode

A source port configuration is required for those ports that must receive MVR traffic, even when there is no JOIN request from that port. All the MVR traffic received on the mVLAN on any port is forwarded to all source and receiver ports. (The receiver port should have been joined either by IGMP report or through static configurations).
- Dynamic mode

Source port configuration is not required, unless there is a port connected to another Layer 2 switch that runs MVR on the same mVLAN as this switch. Configure such ports as *source* ports. All MVR traffic received on the mVLAN on any ports is forwarded to the receiver or source ports that are joined either by IGMP report or through static configurations.
- Only one MVR VLAN can be configured.
- Although receiver ports that are connected to subscribers can be on different VLANs, they should not belong to the mVLAN.
- mRouter ports should not be configured as receiver ports.
- Both trunk and access ports can be configured as either source or receiver ports.
- The maximum number of MVR groups is fixed at 1500.
- MVR cannot coexist with a PVLAN; do not configure MVR on a PVLAN.
- The IGMPSN group MAC address can alias with an MVR group's MAC address.

For example, 225.1.1.1 and 226.1.1.1 are IP addresses whose MAC addresses match to the same multicast MAC address (0100.5e01.0101). If 225.1.1.1 is configured as an MVR group then 225.1.1.1 is handled by MVR and 226.1.1.1 is handled by IGMPSN.

If the 226.1.1.1 host is present on the MVR trunk receiver, IGMPSN might not handle the forwarding for 226.1.1.1. Instead, the switch treats 226.1.1.1 as an MVR group and MVR handles forwarding on the mVLAN. You should not connect the hosts *interested* in MVR aliased groups on the MVR trunk receiver port. (By *interested* we mean that a host sends a JOIN request for a multicast group in order to receive the traffic or stream for that group.) This limitation applies only to MVR trunk receiver ports.
- MVR and multicast-routing cannot co-exist on the same switch. If you try to enable MVR while multicast routing or a multicast routing protocol are enabled, your operation is cancelled and you receive an error message. If you enable multicast routing or a multicast routing protocol while MVR is enabled, MVR is disabled and you receive a warning message.
- MVR can coexist with IGMP snooping on a switch.
- MVR is not supported with IPv6 multicast groups.
- MVR supports only IGMPv2 messages; MVR group reports derived from other versions are dropped.

Configuring MVR Global Parameters

If you select the default settings, you do not need to set the optional MVR parameters. If you want to change the default parameters (except for the MVR VLAN), you must first enable MVR.

To configure MVR parameters, perform these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# mvr	Enables MVR on the switch.
Step 3	Switch(config)# mvr group <i>ip-address [count]</i>	Configures an IP multicast address on the switch or uses the count parameter to configure a contiguous series of MVR group addresses (maximum of 1500 groups).
Step 4	Switch(config)# mvr querytime <i>value</i>	(optional) Defines the maximum wait time for IGMP report memberships on a receiver port before removing the port from multicast group membership.
Step 5	Switch(config)# mvr vlan <i>vlan-id</i>	Specifies the VLAN in which multicast data is received; all source ports must belong to this VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. The default is VLAN 1.
Step 6	Switch(config)# mvr mode { dynamic compatible }	Specifies the MVR mode of operation.
Step 7	Switch(config)# end	Returns to privileged EXEC mode.
Step 8	Switch# show mvr OR show mvr members	Verifies the configuration.
Step 9	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To return a switch to the default settings, use the **no mvr [mode | group ip-address | querytime | vlan]** global configuration commands.

The following example shows how to enable and verify MVR:

```
Switch(config)# mvr
Switch(config)# mvr vlan 100
Switch(config)# mvr group 225.1.1.1
Switch(config)# mvr querytime 10
Switch(config)# mvr mode dynamic
Switch(config)# end
Switch# show mvr
MVR Running: TRUE
MVR multicast VLAN: 100
MVR Max Multicast Groups: 1500
MVR Current multicast groups: 1
MVR Global query response time: 10 (tenths of sec)
MVR Mode: dynamic
Switch# show mac address-table
Multicast Entries
  vlan      mac address      type      ports
-----+-----+-----+-----
100        0100.5e01.0101      igmp Fa2/1

Switch# show platform hardware mac-address-table address 0100.5e01.0101
Flags are:
-----
D - Drop
ND - Do not drop
Index  Mac Address      Vlan  Type      SinglePort/RetIndex/AdjIndex
-----
40048  0100.5E01.0101    100   Ret       104444

Switch# show platform hardware ret chain index 104444
RetIndex 104444
```

```
RetWordIndex: 522220 Link: 1048575(0xFFFFF) FieldsCnt: 1
SuppressRxVlanBridging: true
Vlan: 100 BridgeOnly: N Fa2/1(8)
```

**Note**

Fa2/1 is an mrouter port.

Configuring MVR on Access Ports

To configure the access port, perform these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# mvr	Enables MVR on the switch.
Step 3	Switch(config)# interface interface-id	Enters interface configuration mode, and enter the type and number of the Layer 2 port to configure.
Step 4	Switch(config-if)# switch mode access	Change the interface to access mode.
Step 5	Switch(config-if)# switch access vlan value	Assign the VLAN to the port.
Step 6	Switch(config-if)# mvr type {source receiver}	Configures an MVR port as source or receiver: source —Subscribers cannot be directly connected to source ports. All source ports on a switch belong to the single multicast VLAN. receiver —Configure a port as a receiver port if it is a subscriber port and should only receive multicast data. It does not receive data unless it becomes a member of the multicast group, either statically or through IGMP leave and join messages. Receiver ports cannot belong to the multicast VLAN. The mrouter port should not be configured as the receiver port. Non-MVR port is the default configuration.
Step 7	Switch(config-if)# mvr vlan vlan-id group [ip-address]	(Optional) Statically configures a port to receive multicast traffic sent to the multicast VLAN and the IP multicast address. Receiver ports can also dynamically join multicast groups by using IGMP join and leave messages.
Step 8	Switch(config-if)# mvr immediate	(Optional) Enables the Immediate-Leave feature of MVR on the port.
Step 9	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 10	Switch# show mvr [interface members]	Verifies the configuration.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To return the interface to its default settings, use the **no mvr [type | immediate | vlan vlan-id | group]** interface configuration commands.

This example shows how to configure MVR "source and receiver" access ports:

```
Switch(config)# int fastEthernet 2/2
Switch(config-if)# switchport mode access
Switch(config-if)# switchport access vlan 200
Switch(config-if)# mvr type receiver
```

```
Switch(config-if)# exit
Switch(config)# interface fastEthernet 2/3
Switch(config-if)# switchport mode access
Switch(config-if)# switchport access vlan 100
Switch(config-if)# mvr type source
```

To verify the configuration, enter the **show mvr** command:

```
Switch# show mvr interface
Port          Type      Mode      VLAN      Status      Immediate Leave
-----
Fa2/2         RECEIVER Access     200        ACTIVE/UP    DISABLED
Fa2/3         SOURCE    Access     100        ACTIVE/UP    DISABLED
```

Dynamic Mode:

```
Switch# show mvr members
MVR Group IP      Status      Members      VLAN      Membership
```

Compatible Mode:

```
Switch# show mvr members
MVR Group IP      Status      Members      VLAN      Membership
-----
225.1.1.1         ACTIVE/UP    Fa2/3        100        Static
```

Configuring MVR on a Trunk Port

To configure MVR on a trunk port, perform these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# mvr	Enables MVR on the switch.
Step 3	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode, and enters the type and number of the Layer 2 port to configure.
Step 4	Switch(config-if)# switchport mode trunk	Change the interface to trunk mode
Step 5	Switch(config-if)# mvr type receiver	Specifies that the trunk port is an MVR receiver port.
Step 6	Switch(config-if)# mvr vlan <i>mvr-vlan-id</i> receiver vlan <i>receiver-vlan-id</i>	Enables this trunk port to distribute MVR traffic arriving from the MVR VLAN to the VLAN on the trunk identified by the receiver VLAN. Note This command is not accepted unless you first enter the mvr type receiver command.
Step 7	Switch(config-if)# mvr vlan <i>vlan-id</i> group <i>ip-address</i> receiver <i>vlan-id</i>	(Optional) Configures the trunk port to be a static member of the group on the receiver VLAN.
Step 8	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 9	Switch# show mvr [interface members]	Verifies the configuration.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to configure MVR “receiver” VLANs on trunk ports:

```
Switch(config)# interface fastEthernet 2/1
Switch(config-if)# switchport mode trunk
Switch(config-if)# mvr type source
```

```
Switch(config)# interface fastEthernet 2/4
Switch(config-if)# switchport mode trunk
Switch(config-if)# mvr type receiver
Switch(config-if)# mvr vlan 100 receiver vlan 300
```

```
Switch# show mvr interface
```

Port	Type	Mode	VLAN	Status	Immediate Leave
Fa2/1	SOURCE	Trunk	100	ACTIVE/UP	DISABLED
Fa2/2	RECEIVER	Access	200	ACTIVE/UP	DISABLED
Fa2/3	SOURCE	Access	100	ACTIVE/UP	DISABLED
Fa2/4	RECEIVER	Trunk	300	ACTIVE/UP	DISABLED

Compatible Mode

```
Switch# show mvr members
```

MVR Group IP	Status	Members	VLAN	Membership
225.1.1.1	ACTIVE/UP	Fa2/1	100	Static
225.1.1.1	ACTIVE/UP	Fa2/3	100	Static

Dynamic Mode

```
Switch# show mvr members
```

MVR Group IP	Status	Members	VLAN	Membership
--------------	--------	---------	------	------------

Displaying MVR Information

You can display MVR information for the switch or a specified interface. Use the following commands in privileged EXEC mode:

Table 28-3 *Commands for Displaying MVR Information*

show mvr	<p>Displays MVR status:</p> <ul style="list-style-type: none"> • whether MVR is enabled or disabled • the multicast VLAN • the maximum (1500) and current (0 to 1500) number of multicast groups • the query response time • the MVR mode
show mvr interface [<i>interface-id</i>] [members [<i>vlan</i> <i>vlan-id</i>]]	<p>Displays all MVR interfaces and their MVR configurations. Interface specific MVR information can be obtained as well.</p> <p>Type—Receiver or Source</p> <p>Status—One of these:</p> <ul style="list-style-type: none"> – ACTIVE/INACTIVE means the port is part/not part of VLAN. – UP/DOWN means that the port is forwarding/non-forwarding. <p>Immediate Leave—Enabled or Disabled</p> <p>If the members keyword is entered, it displays all multicast group members on this port. If a VLAN is identified, it displays all multicast group members on the VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.</p>
show mvr members [<i>ip-address</i>]	This displays all receiver and source ports that are members of all MVR IP multicast groups or the specified MVR IP multicast group address.

The following examples show how to display MVR information for either the switch or an interface on the switch:

```
Switch# show mvr
MVR Running: TRUE
MVR multicast vlan: 10022
MVR Max Multicast Groups: 1500
MVR Current multicast groups: 1
MVR Global query response time: 10 (tenths of sec)
MVR Mode: dynamic
```

```
Switch# show mvr interface
```

Port	Type	Mode	VLAN	Status	Immediate Leave
Fa2/1	SOURCE	Trunk	100	ACTIVE/UP	DISABLED
Fa2/2	RECEIVER	Access	200	ACTIVE/UP	DISABLED
Fa2/3	SOURCE	Access	100	ACTIVE/UP	DISABLED
Fa2/4	RECEIVER	Trunk	300	ACTIVE/UP	DISABLED

```
Switch# show mvr interface
interface
```

```
Switch# show mvr interface fastEthernet 2/2
```

Port	Type	Mode	VLAN	Status	Immediate Leave
Fa2/2	RECEIVER	Access	200	ACTIVE/UP	DISABLED

```
Switch# show mvr interface fastEthernet 2/2 members
MVR Group IP          VLAN          Membership  Status
-----
225.1.1.1             vlan 200      DYNAMIC     ACTIVE/UP

Switch# show mvr interface fastEthernet 2/2 members vlan 200
MVR Group IP          VLAN          Membership  Status
-----
225.1.1.1             vlan 200      DYNAMIC     ACTIVE/UP

Switch# show mvr members
MVR Group IP          Status          Members          VLAN          Membership
-----
225.1.1.1             ACTIVE/UP       Fa2/2            200           Dynamic

Switch# show mvr members 225.1.1.1
MVR Group IP          Status          Members          VLAN          Membership
-----
225.1.1.1             ACTIVE/UP       Fa2/2            200           Dynamic
```

Configuring IGMP Filtering

This section includes the following subsections:

- [Default IGMP Filtering Configuration, page 28-30](#)
- [Configuring IGMP Profiles, page 28-31](#)
- [Applying IGMP Profiles, page 28-32](#)
- [Setting the Maximum Number of IGMP Groups, page 28-33](#)

Note

The IGMP filtering feature works for IGMPv1 and IGMPv2 only.

In some environments (like metropolitan or multiple-dwelling unit (MDU) installations), an administrator might want to control the multicast groups to which a user on a switch port can belong. This allows the administrator to control the distribution of multicast services, such as IP/TV, based on some type of subscription or service plan.

With IGMP filtering, an administrator can apply this type of control. With this feature, you can filter multicast joins on a per-port basis by configuring IP multicast profiles and associating them with individual switch ports. An IGMP profile can contain one or more multicast groups and specifies whether access to the group is permitted or denied. If an IGMP profile denying access to a multicast group is applied to a switch port, the IGMP join report requesting the stream of IP multicast traffic is dropped, and the port is not allowed to receive IP multicast traffic from that group. If the filtering action permits access to the multicast group, the IGMP report from the port is forwarded for normal processing.

IGMP filtering controls only IGMP membership join reports and has no relationship to the function that directs the forwarding of IP multicast traffic.

You can also set the maximum number of IGMP groups that a Layer 2 interface can join with the **ip igmp max-groups** *n* command.

Default IGMP Filtering Configuration

[Table 28-4](#) shows the default IGMP filtering configuration.

Table 28-4 **Default IGMP Filtering Settings**

Feature	Default Setting
IGMP filters	No filtering
IGMP maximum number of IGMP groups	No limit
IGMP profiles	None defined

Configuring IGMP Profiles

To configure an IGMP profile and to enter IGMP profile configuration mode, use the **ip igmp profile** global configuration command. From the IGMP profile configuration mode, you can specify the parameters of the IGMP profile to be used for filtering IGMP join requests from a port. When you are in IGMP profile configuration mode, you can apply these keywords:

- **deny**—Specifies that matching addresses are denied (the default condition).
- **exit**—Exits from igmp-profile configuration mode.
- **no**—Negates a command or sets its defaults.
- **permit**—Specifies that matching addresses are permitted.
- **range**—Specifies a range of IP addresses for the profile. You can enter a single IP address or a range with starting and ending addresses.

By default, no IGMP profiles are configured. When a profile is configured with neither the **permit** nor the **deny** keyword, the default is to deny access to the range of IP addresses.

To create an IGMP profile for a port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ip igmp profile <i>profile number</i>	Enters IGMP profile configuration mode and assigns a number to the profile you are configuring. The range is from 1 to 4,294,967,295.
Step 3	Switch(config-igmp-profile)# permit deny	(Optional) Sets the action to permit or deny access to the IP multicast address. If no action is configured, the default for the profile is to deny access.
Step 4	Switch(config-igmp-profile)# range <i>ip multicast address</i>	Enters the IP multicast address or range of IP multicast addresses to which access is being controlled. If entering a range, enter the low IP multicast address, a space, and the high IP multicast address. Use the range command multiple times to enter multiple addresses or ranges of addresses.
Step 5	Switch(config-igmp-profile)# end	Returns to privileged EXEC mode.
Step 6	Switch# show ip igmp profile <i>profile-number</i>	Verifies the profile configuration.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To delete a profile, use the **no ip igmp profile** *profile-number* global configuration command.

To delete an IP multicast address or range of IP multicast addresses, use the **no range ip multicast address** IGMP profile configuration command.

This example shows how to create IGMP profile 4 (allowing access to the single IP multicast address) and how to verify the configuration. If the action were to deny (the default), it does not appear in the output of the **show ip igmp profile** command.

```
Switch# configure terminal
Switch(config)# ip igmp profile 4
Switch(config-igmp-profile)# permit
Switch(config-igmp-profile)# range 229.9.9.0
Switch(config-igmp-profile)# end
Switch# show ip igmp profile 4
IGMP Profile 4
    permit
    range 229.9.9.0 229.9.9.0
```

Applying IGMP Profiles

To control access as defined in an IGMP profile, use the **ip igmp filter** interface configuration command to apply the profile to the appropriate interfaces. You can apply a profile to multiple interfaces, but each interface can only have one profile applied to it.

Note

You can apply IGMP profiles to Layer 2 ports only. You cannot apply IGMP profiles to routed ports (or SVIs) or to ports that belong to an EtherChannel port group.

To apply an IGMP profile to a switch port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode, and enters the physical interface to configure, for example, fastethernet2/3 . The interface must be a Layer 2 port that does not belong to an EtherChannel port group.
Step 3	Switch(config-if)# ip igmp filter <i>profile number</i>	Applies the specified IGMP profile to the interface. The profile number can be from 1 to 4,294,967,295.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running configuration interface <i>interface-id</i>	Verifies the configuration.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove a profile from an interface, use the **no ip igmp filter** command.

This example shows how to apply IGMP profile 4 to an interface and to verify the configuration:

```
Switch# configure terminal
Switch(config)# interface fastethernet2/12
Switch(config-if)# ip igmp filter 4
Switch(config-if)# end
```

```

Switch# show running-config interface fastethernet2/12
Building configuration...

Current configuration : 123 bytes
!
interface FastEthernet2/12
 no ip address
 shutdown
 snmp trap link-status
 ip igmp max-groups 25
 ip igmp filter 4
end

```

Setting the Maximum Number of IGMP Groups

You can set the maximum number of IGMP groups that a Layer 2 interface can join by using the **ip igmp max-groups** interface configuration command. Use the **no** form of this command to set the maximum back to the default, which is no limit.

Note

This restriction can be applied to Layer 2 ports only. You cannot set a maximum number of IGMP groups on routed ports (or SVIs) or on ports that belong to an EtherChannel port group.

To apply an IGMP profile on a switch port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode, and enter the physical interface to configure, for example, gigabitethernet1/1 . The interface must be a Layer 2 port that does not belong to an EtherChannel group.
Step 3	Switch(config-if)# ip igmp max-groups <i>number</i>	Sets the maximum number of IGMP groups that the interface can join. The range is from 0 to 4,294,967,294. By default, no maximum is set. To remove the maximum group limitation and return to the default of no maximum, use the no ip igmp max-groups command.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# show running-configuration interface <i>interface-id</i>	Verifies the configuration.
Step 6	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to limit the number of IGMP groups that an interface can join to 25:

```

Switch# configure terminal
Switch(config)# interface fastethernet2/12
Switch(config-if)# ip igmp max-groups 25
Switch(config-if)# end
Switch# show running-config interface fastethernet2/12
Building configuration...

Current configuration : 123 bytes
!

```

```
interface FastEthernet2/12
no ip address
shutdown
snmp trap link-status
ip igmp max-groups 25
ip igmp filter 4
end
```

Displaying IGMP Filtering Configuration

You can display IGMP profile and maximum group configuration for all interfaces on the switch or for a specified interface.

To display IGMP profiles, perform this task:

Command	Purpose
Switch# show ip igmp profile [<i>profile number</i>]	Displays the specified IGMP profile or all IGMP profiles defined on the switch.

To display interface configuration, perform this task:

Command	Purpose
Switch# show running-configuration [interface interface-id]	Displays the configuration of the specified interface or all interfaces on the switch, including (if configured) the maximum number of IGMP groups to which an interface can belong and the IGMP profile applied to the interface.

This is an example of the **show ip igmp profile** privileged EXEC command when no profile number is entered. All profiles defined on the switch are displayed.

```
Switch# show ip igmp profile
IGMP Profile 3
  range 230.9.9.0 230.9.9.0
IGMP Profile 4
  permit
  range 229.9.9.0 229.255.255.255
```

This is an example of the **show running-config** privileged EXEC command when an interface is specified with IGMP maximum groups configured and IGMP profile 4 has been applied to the interface:

```
Switch# show running-config interface fastethernet2/12
Building configuration...
Current configuration : 123 bytes
!
interface FastEthernet2/12
no ip address
shutdown
snmp trap link-status
ip igmp max-groups 25
ip igmp filter 4
end
```

EIGRP Stub Routing

This feature module describes the EIGRP Stub Routing feature and includes the following sections:

- [Feature Overview](#)
- [Benefits](#)
- [Restrictions](#)
- [Related Features and Technologies](#)
- [Supported Platforms](#)
- [Supported Standards, MIBs, and RFCs](#)
- [Configuration Tasks](#)
- [Monitoring and Maintaining EIGRP Stub Routing](#)
- [Configuration Examples](#)

Feature Overview

The Enhanced Interior Gateway Routing Protocol (EIGRP) Stub Routing feature improves network stability, reduces resource utilization, and simplifies stub router configuration.

Stub routing is commonly used in a hub and spoke network topology. In a hub and spoke network, one or more end (stub) networks are connected to a remote router (the spoke) that is connected to one or more distribution routers (the hub). The remote router is adjacent only to one or more distribution routers. The only route for IP traffic to follow into the remote router is through a distribution router. This type of configuration is commonly used in WAN topologies where the distribution router is directly connected to a WAN. The distribution router can be connected to many more remote routers. Often, the distribution router will be connected to 100 or more remote routers. In a hub and spoke topology, the remote router must forward all nonlocal traffic to a distribution router, so it becomes unnecessary for the remote router to hold a complete routing table. Generally, the distribution router need not send anything more than a default route to the remote router.

When using the EIGRP Stub Routing feature, you need to configure the distribution and remote routers to use EIGRP, and to configure only the remote router as a stub. Only specified routes are propagated from the remote (stub) router. The router responds to queries for summaries, connected routes, redistributed static routes, external routes, and internal routes with the message “inaccessible.” A router that is configured as a stub will send a special peer information packet to all neighboring routers to report its status as a stub router.

Any neighbor that receives a packet informing it of the stub status will not query the stub router for any routes, and a router that has a stub peer will not query that peer. The stub router will depend on the distribution router to send the proper updates to all peers.

Figure 1 shows a simple spoke and hub configuration.

Figure 1 Simple Spoke and Hub Network

The stub feature by itself does not prevent routes from being advertised to the remote router. In the example in Figure 1, the remote router can access the corporate network and the Internet through the distribution router only. Having a full route table on the remote router, in this example, would have no functional purpose because the path to the corporate network and the Internet would always be through the distribution router. The larger route table would only increase the amount of memory required by the remote router.

Bandwidth and memory can further be conserved by summarizing and filtering routes on the distribution router. The remote router need not receive routes that have been learned from other networks because the remote router must send all nonlocal traffic, regardless of destination, to the distribution router. If a true stub network is desired, the distribution router should be configured to send only a default route to the remote router. The EIGRP Stub Routing feature does not automatically enable summarization on the distribution router. In most cases, the network administrator will need to configure summarization on the distribution routers.

Note

When configuring the distribution router to send only a default route to the remote router, you must use the **ip classless** command on the remote router. By default, the **ip classless** command is enabled in all Cisco IOS images that support the EIGRP Stub Routing feature.

Without the stub feature, even after the routes that are sent from the distribution router to the remote router have been filtered or summarized, a problem might occur. If a route is lost somewhere in the corporate network, EIGRP could send a query to the distribution router, which in turn will send a query to the remote router even if routes are being summarized. If there is a problem communicating over the WAN link between the distribution router and the remote router, an EIGRP stuck in active (SIA) condition could occur and cause instability elsewhere in the network. The EIGRP Stub Routing feature allows a network administrator to prevent queries from being sent to the remote router.

Dual-Homed Remote

In addition to a simple hub and spoke network where a remote router is connected to a single distribution router, the remote router can be dual-homed to two or more distribution routers. This configuration adds redundancy and introduces unique issues, and the stub feature helps to address some of these issues.

A dual-homed remote will have two or more distribution (hub) routers. However, the principles of stub routing are the same as they are with a hub and spoke topology. [Figure 2](#) shows a common dual-homed remote topology with one remote router, but 100 or more routers could be connected on the same interfaces on distribution router 1 and distribution router 2. The remote router will use the best route to reach its destination. If distribution router 1 experiences a failure, the remote router can still use distribution router 2 to reach the corporate network.

Figure 2 Simple Dual-Homed Remote Topology

[Figure 2](#) shows a simple dual-homed remote with one remote router and two distribution routers. Both distribution routers maintain routes to the corporate network and stub network (10.1.1.0/24).

Dual-homed routing can introduce instability into an EIGRP network. In [Figure 3](#), distribution router 1 is directly connected to network 10.3.1.0/24. If summarization or filtering is applied on distribution router 1, the router will advertise network 10.3.1.0/24 to all of its directly connected EIGRP neighbors (distribution router 2 and the remote router).

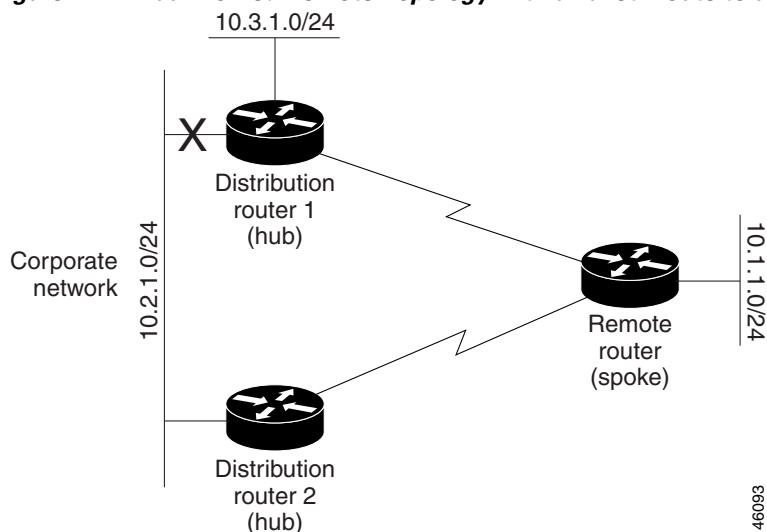

Figure 3 *Dual-Homed Remote Topology Where Distribution Router 1 Is Connected to 2 Networks*

Figure 3 shows a simple dual-homed remote topology where distribution router 1 is connected to both network 10.3.1.0/24 and network 10.2.1.0/24.

If the 10.2.1.0/24 link between distribution router 1 and distribution router 2 has failed, the lowest cost path to network 10.3.1.0/24 from distribution router 2 is through the remote router (see Figure 4). This route is not desirable because the traffic that was previously traveling across the corporate network 10.2.1.0/24 would now be sent across a much lower bandwidth connection. The overutilization of the lower bandwidth WAN connection can cause a number of problems that might affect the entire corporate network. The use of the lower bandwidth route that passes through the remote router might cause WAN EIGRP distribution routers to be dropped. Serial lines on distribution and remote routers could also be dropped, and EIGRP SIA errors on the distribution and core routers could occur.

Figure 4 *Dual-Homed Remote Topology with a Failed Route to a Distribution Router*

It is not desirable for traffic from distribution router 2 to travel through any remote router in order to reach network 10.3.1.0/24. If the links are sized to handle the load, it would be acceptable to use one of the backup routes. However, most networks of this type have remote routers located at remote offices with relatively slow links. This problem can be prevented if proper summarization is configured on the distribution router and remote router.

It is typically undesirable for traffic from a distribution router to use a remote router as a transit path. A typical connection from a distribution router to a remote router would have much less bandwidth than a connection at the network core. Attempting to use a remote router with a limited bandwidth connection as a transit path would generally produce excessive congestion to the remote router. The EIGRP Stub Routing feature can prevent this problem by preventing the remote router from advertising core routes back to distribution routers. Routes learned by the remote router from distribution router 1 will not be advertised to distribution router 2. Since the remote router will not advertise core routes to distribution router 2, the distribution router will not use the remote router as a transit for traffic destined for the network core.

Benefits

Greater Network Stability

In the event of network instability, the EIGRP Stub Routing feature prevents EIGRP queries from being sent over limited bandwidth links to nontransit routers. Instead, distribution routers to which the stub router is connected answers the query on behalf of the stub router. This feature greatly reduces the chance of further network instability due to congested or problematic WAN links.

Simplified Stub Router Configuration

The EIGRP Stub Routing feature simplifies the configuration and maintenance of hub and spoke networks. When stub routing is enabled in dual-homed remote configurations, it is no longer necessary to configure filtering on remote routers to prevent those remote routers from appearing as transit paths to the hub routers.

Restrictions

Supports Only Stub Routers

This feature should only be used on stub routers. A stub router is defined as a router connected to the network core or distribution layer through which core transit traffic should not flow. A stub router should not have any EIGRP neighbors other than distribution routers. Ignoring this restriction will cause undesirable behavior.

Multi-Access Interfaces

Multi-access interfaces, such as ATM, Ethernet, Frame Relay, ISDN PRI, and X.25, are supported by the EIGRP Stub Routing feature only when all routers on that interface, except the hub, are configured as stub routers.

Related Features and Technologies

The EIGRP Stub Routing feature is an extension of the Enhanced Interior Gateway Routing Protocol (EIGRP). For more information about configuring EIGRP and configuring route summarization and filtering, refer to the “Configuring EIGRP” chapter of the *Cisco IOS Release 12.0 Network Protocols Configuration Guide, Part 1* and *Cisco IOS Release 12.0 Network Protocols Command Reference, Part 1*.

-

Supported Platforms

This feature is supported on all platforms that support EIGRP in Cisco IOS Release 12.0(15)S, including the following platforms:

- Cisco 7200 series
- Cisco 7500 series
- Cisco 12000 series

Determining Platform Support Through Cisco Feature Navigator

Cisco IOS software is packaged in feature sets that are supported by specific platforms. To get updated information regarding platform support for this feature, access Cisco Feature Navigator. Cisco Feature Navigator dynamically updates the list of supported platforms as new platform support is added for the feature.

Cisco Feature Navigator is a web-based tool that enables you to determine which Cisco IOS software images support a specific set of features and which features are supported in a specific Cisco IOS image. You can search by feature or release. Under the release section, you can compare releases side by side to display both the features unique to each software release and the features in common.

To access Cisco Feature Navigator, you must have an account on Cisco.com. If you have forgotten or lost your account information, send a blank e-mail to cco-locksmith@cisco.com. An automatic check will verify that your e-mail address is registered with Cisco.com. If the check is successful, account details with a new random password will be e-mailed to you. Qualified users can establish an account on Cisco.com by following the directions at <http://www.cisco.com/register>.

Cisco Feature Navigator is updated regularly when major Cisco IOS software releases and technology releases occur. For the most current information, go to the Cisco Feature Navigator home page at the following URL:

<http://www.cisco.com/go/fn>

Availability of Cisco IOS Software Images

Platform support for particular Cisco IOS software releases is dependent on the availability of the software images for those platforms. Software images for some platforms may be deferred, delayed, or changed without prior notice. For updated information about platform support and availability of software images for each Cisco IOS software release, refer to the online release notes or, if supported, Cisco Feature Navigator.

Supported Standards, MIBs, and RFCs

Standards

No new or modified standards are supported by this feature.

MIBs

No new or modified MIBs are supported by this feature.

To obtain lists of supported MIBs by platform and Cisco IOS release, and to download MIB modules, go to the Cisco MIB website on Cisco.com at the following URL:

<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>

RFCs

No new or modified MIBs are supported by this feature.

Configuration Tasks

See the following sections for configuration tasks for the EIGRP Stub Routing feature. Each task in the list is identified as either optional or required:

- [Configuring EIGRP Stub Routing](#)(required)
- [Verifying EIGRP Stub Routing](#)(optional)

Configuring EIGRP Stub Routing

To configure a remote or spoke router for EIGRP stub routing, use the following commands beginning in router configuration mode:

	Command	Purpose
Step 1	router(config)# router eigrp <i>as-number</i>	Configures a remote or distribution router to run an EIGRP process.
Step 2	router(config-router)# network <i>network-number</i>	Specifies the network address of the EIGRP distribution router.
Step 3	router(config-router)# eigrp stub [receive-only connected static summary]	Configures a remote router as an EIGRP stub router.

Verifying EIGRP Stub Routing

To verify that a remote router has been configured as a stub router with the EIGRP Stub Routing feature, use the **show ip eigrp neighbor detail** command from the distribution router in privileged EXEC mode. The last line of the output will show the stub status of the remote or spoke router. The following example output is from the **show ip eigrp neighbor detail** command:

```
router# show ip eigrp neighbor detail
IP-EIGRP neighbors for process 1
H   Address                  Interface    Hold Uptime    SRTT    RTO  Q  Seq Type
                               (sec)          (ms)          Cnt Num
0   10.1.1.2                  Se3/1       11 00:00:59    1   4500  0   7
Version 12.1/1.2, Retrans: 2, Retries: 0
Stub Peer Advertising ( CONNECTED SUMMARY ) Routes
```

Monitoring and Maintaining EIGRP Stub Routing

To enable EIGRP stub packet debugging, use the following command in privileged EXEC mode:

Command	Purpose
Router# debug eigrp packet stub	Displays debug information about the stub status of peer routers.

Configuration Examples

A router that is configured as a stub with the **eigrp stub** command shares connected and summary routing information with all neighbor routers by default. Four optional keywords can be used with the **eigrp stub** command to modify this behavior:

- **receive-only**
- **connected**
- **static**
- **summary**

This section provides configuration examples for all forms of the **eigrp stub** command. The **eigrp stub** command can be modified with several options, and these options can be used in any combination except for the **receive-only** keyword. The **receive-only** keyword will restrict the router from sharing any of its routes with any other router in that EIGRP autonomous system, and the **receive-only** keyword will not permit any other option to be specified because it prevents any type of route from being sent. The three other optional keywords (**connected**, **static**, and **summary**) can be used in any combination but cannot be used with the **receive-only** keyword. If any of these three keywords is used individually with the **eigrp stub** command, connected and summary routes will not be sent automatically.

The **connected** keyword will permit the EIGRP Stub Routing feature to send connected routes. If the connected routes are not covered by a network statement, it may be necessary to redistribute connected routes with the **redistribute connected** command under the EIGRP process. This option is enabled by default.

The **static** keyword will permit the EIGRP Stub Routing feature to send static routes. Without the configuration of this option, EIGRP will not send any static routes, including internal static routes that normally would be automatically redistributed. It will still be necessary to redistribute static routes with the **redistribute static** command.

The **summary** keyword will permit the EIGRP Stub Routing feature to send summary routes. Summary routes can be created manually with the **summary address** command or automatically at a major network border router with the **auto-summary** command enabled. This option is enabled by default.

In the following example, the **eigrp stub** command is used to configure the router as a stub that advertises connected and summary routes:

```
router eigrp 1
network 10.0.0.0
eigrp stub
```

In the following example, the **eigrp stub** command is issued with the **connected** and **static** keywords to configure the router as a stub that advertises connected and static routes (sending summary routes will not be permitted):

```
router eigrp 1
network 10.0.0.0
eigrp stub connected static
```

In the following example, the **eigrp stub** command is issued with the **receive-only** keyword to configure the router as a receive-only neighbor (Connected, summary, and static routes will not be sent):

```
router eigrp 1
network 10.0.0.0 eigrp
eigrp stub receive-only
```

Configuring IPv6 Multicast Listener Discovery Snooping

Use Multicast Listener Discovery (MLD) snooping to enable efficient distribution of IP version 6 (IPv6) multicast data to clients and routers in a switched network on the Catalyst 4500 series switch.

This chapter includes these sections:

- [About MLD Snooping, page 30-1](#)
- [Configuring IPv6 MLD Snooping, page 30-5](#)
- [Displaying MLD Snooping Information, page 30-10](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About MLD Snooping

In IP version 4 (IPv4), Layer 2 switches can use Internet Group Management Protocol (IGMP) snooping to limit the flooding of multicast traffic by dynamically configuring Layer 2 interfaces so that multicast traffic is forwarded to only those interfaces associated with IP multicast devices. In IPv6, MLD snooping performs a similar function. With MLD snooping, IPv6 multicast data is selectively forwarded to a list of ports that want to receive the data, instead of being flooded to all ports in a VLAN. This list is constructed by snooping IPv6 multicast control packets.

MLD is a protocol used by IPv6 multicast routers to discover the presence of multicast listeners (nodes that want to receive IPv6 multicast packets) on its directly attached links and to discover which multicast packets are of interest to neighboring nodes. MLD is derived from IGMP; MLD version 1 (MLDv1) is equivalent to IGMPv2 and MLD version 2 (MLDv2) is equivalent to IGMPv3. MLD is a subprotocol of Internet Control Message Protocol version 6 (ICMPv6), and MLD messages are a subset of ICMPv6 messages, identified in IPv6 packets by a preceding Next Header value of 58.

The switch supports two versions of MLD snooping:

- MLDv1 snooping detects MLDv1 control packets and sets up traffic bridging based on IPv6 destination multicast addresses.
- MLDv2 basic snooping (MBSS) uses MLDv2 control packets to set up traffic forwarding based on IPv6 destination multicast addresses.

The switch can snoop on both MLDv1 and MLDv2 protocol packets and bridge IPv6 multicast data based on destination IPv6 multicast addresses.

Note

The switch does not support MLDv2 enhanced snooping (MESS), which sets up IPv6 source and destination multicast address-based forwarding.

MLD snooping can be enabled or disabled globally or per-VLAN. When MLD snooping is enabled, a per-VLAN IPv6 multicast MAC address table is constructed in software and a per-VLAN IPv6 multicast address table is constructed in software and hardware. The switch then performs IPv6 multicast-address based bridging in hardware.

These sections describe some parameters of IPv6 MLD snooping:

- [MLD Messages, page 30-2](#)
- [MLD Queries, page 30-3](#)
- [Multicast Client Aging, page 30-3](#)
- [Multicast Router Discovery, page 30-3](#)
- [MLD Reports, page 30-4](#)
- [MLD Done Messages and Immediate-Leave, page 30-4](#)
- [Topology Change Notification Processing, page 30-4](#)

MLD Messages

MLDv1 supports three types of messages:

- Listener Queries are the equivalent of IGMPv2 queries and are either General Queries or Multicast-Address-Specific Queries (MASQs).
- Multicast Listener Reports are the equivalent of IGMPv2 reports.
- Multicast Listener Done messages are the equivalent of IGMPv2 leave messages.

MLDv2 supports MLDv2 queries and reports, as well as MLDv1 Report and Done messages.

Message timers and state transitions resulting from messages being sent or received are the same as those of IGMPv2 messages. MLD messages that do not have valid link-local IPv6 source addresses are ignored by MLD routers and switches.

MLD Queries

The switch sends out MLD queries, constructs an IPv6 multicast address database, and generates MLD group-specific and MLD group-and-source-specific queries in response to MLD Done messages. The switch also supports report suppression, report proxying, Immediate-Leave functionality, and static IPv6 multicast MAC-address configuration.

When MLD snooping is disabled, all MLD queries are flooded in the ingress VLAN.

When MLD snooping is enabled, received MLD queries are flooded in the ingress VLAN, and a copy of the query is sent to the CPU for processing. From the received query, MLD snooping builds the IPv6 multicast address database. It detects multicast router ports, maintains timers, sets report response time, learns the querier IP source address for the VLAN, learns the querier port in the VLAN, and maintains multicast-address aging.

When a group exists in the MLD snooping database, the switch responds to a group-specific query by sending an MLDv1 report. When the group is unknown, the group-specific query is flooded to the ingress VLAN.

When a host wants to leave a multicast group, it can send out an MLD Done message (equivalent to IGMP Leave message). When the switch receives an MLDv1 Done message, if Immediate-Leave is not enabled, the switch sends an MASQ to the port from which the message was received to determine if other devices connected to the port should remain in the multicast group.

Multicast Client Aging

You can configure port membership removal from addresses based on the number of queries. A port is removed from membership to an address only when there are no reports to the address on the port for the configured number of queries. The default number is 2.

Multicast Router Discovery

MLD snooping performs multicast router discovery with these characteristics:

- Ports configured by a user never age out.
- Dynamic port learning results from MLDv1 snooping queries and IPv6 PIMv2 packets.
- If multiple routers exist on the same Layer 2 interface, MLD snooping tracks a single multicast router on the port (the router that most recently sent a router control packet).
- Dynamic multicast router port aging is based on a default timer of 5 minutes; the multicast router is deleted from the router port list if no control packet is received on the port for 5 minutes.
- IPv6 multicast router discovery only takes place when MLD snooping is enabled on the switch.
- Received IPv6 multicast router control packets are always flooded to the ingress VLAN, whether MLD snooping is enabled on the switch.
- After the discovery of the first IPv6 multicast router port, unknown IPv6 multicast data is forwarded only to the discovered router ports (before that time, all IPv6 multicast data is flooded to the ingress VLAN).

MLD Reports

The processing of MLDv1 join messages is essentially the same as with IGMPv2. When no IPv6 multicast routers are detected in a VLAN, reports are not processed or forwarded from the switch. When IPv6 multicast routers are detected and an MLDv1 report is received, an IPv6 multicast group address and an IPv6 multicast MAC address are entered in the VLAN MLD database. All IPv6 multicast traffic to the group within the VLAN is then forwarded using this address. When MLD snooping is disabled, reports are flooded in the ingress VLAN.

When MLD snooping is enabled, MLD report suppression, called listener message suppression, is automatically enabled. With report suppression, the switch forwards the first MLDv1 report received by a group to IPv6 multicast routers; subsequent reports for the group are not sent to the routers. When MLD snooping is disabled, report suppression is disabled, and all MLDv1 reports are flooded to the ingress VLAN.

The switch also supports MLDv1 proxy reporting. When an MLDv1 MASQ is received, the switch responds with MLDv1 reports for the address on which the query arrived if the group exists in the switch on another port and if the port on which the query arrived is not the last member port for the address.

MLD Done Messages and Immediate-Leave

When the Immediate-Leave feature is enabled and a host sends an MLDv1 Done message (equivalent to an IGMP leave message), the port on which the Done message was received is immediately deleted from the group. You enable Immediate-Leave on VLANs and (as with IGMP snooping), you should only use the feature on VLANs where a single host is connected to the port. If the port was the last member of a group, the group is also deleted, and the leave information is forwarded to the detected IPv6 multicast routers.

When Immediate Leave is not enabled in a VLAN (the case when multiple clients for a group exist on the same port) and a Done message is received on a port, an MASQ is generated on that port. The user can control when a port membership is removed for an existing address in terms of the number of MASQs. A port is removed from membership to an address when there are no MLDv1 reports to the address on the port for the configured number of queries.

The number of MASQs generated is configured by using the **ipv6 mld snooping last-listener-query count** global configuration command. The default number is 2.

The MASQ is sent to the IPv6 multicast address for which the Done message was sent. If no reports are sent to the IPv6 multicast address specified in the MASQ during the switch maximum response time, the port on which the MASQ was sent is deleted from the IPv6 multicast address database. The maximum response time is the time configured by using the **ipv6 mld snooping last-listener-query-interval** global configuration command. If the deleted port is the last member of the multicast address, the multicast address is also deleted, and the switch sends the address leave information to all detected multicast routers.

Topology Change Notification Processing

When topology change notification (TCN) solicitation is enabled by using the **ipv6 mld snooping tcn query solicit** global configuration command, MLDv1 snooping sets the VLAN to flood all IPv6 multicast traffic with a configured number of MLDv1 queries before it begins sending multicast data only to selected ports. You set this value by using the **ipv6 mld snooping tcn flood query count** global

configuration command. The default is to send two queries. The switch also generates MLDv1 global Done messages with valid link-local IPv6 source addresses when the switch becomes the STP root in the VLAN or when it is configured by the user. This process is similar to that in IGMP snooping.

Configuring IPv6 MLD Snooping

These sections describe how to configure IPv6 MLD snooping:

- [Default MLD Snooping Configuration, page 30-5](#)
- [MLD Snooping Configuration Guidelines, page 30-6](#)
- [Enabling or Disabling MLD Snooping, page 30-6](#)
- [Configuring a Static Multicast Group, page 30-7](#)
- [Configuring a Multicast Router Port, page 30-7](#)
- [Enabling MLD Immediate Leave, page 30-8](#)
- [Configuring MLD Snooping Queries, page 30-9](#)
- [Disabling MLD Listener Message Suppression, page 30-10](#)

Default MLD Snooping Configuration

[Table 30-1](#) shows the default MLD snooping configuration.

Table 30-1 *Default MLD Snooping Configuration*

Feature	Default Setting
MLD snooping (Global)	Disabled.
MLD snooping (per VLAN)	Enabled. MLD snooping must be globally enabled for VLAN MLD snooping to take place.
IPv6 Multicast addresses	None configured.
IPv6 Multicast router ports	None configured.
MLD snooping Immediate Leave	Disabled.
MLD snooping robustness variable	Global: 2; per-VLAN: 0. Note The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count.
Last listener query count	Global: 2; per-VLAN: 0. Note The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global count.
Last listener query interval	Global: 1000 (1 second); VLAN: 0. Note The VLAN value overrides the global setting. When the VLAN value is 0, the VLAN uses the global interval.
TCN query solicit	Disabled.
TCN query count	2.
MLD listener suppression	Disabled.

MLD Snooping Configuration Guidelines

When configuring MLD snooping, consider these guidelines:

- You can configure MLD snooping characteristics at any time, but you must globally enable MLD snooping by using the **ipv6 mld snooping** global configuration command for the configuration to take effect.
- MLD snooping and IGMP snooping act independently of each other. You can enable both features at the same time on the switch. The total number of IPv4 and IPv6 multicast groups entries that can coexist on the Catalyst 4500 series switch is limited to 16384.
- The supervisor engine with 512 MB of memory supports about 11000 MLD Snooping multicast groups. A supervisor engine with 1 GB memory supports 16384 MLD Snooping multicast groups.

Enabling or Disabling MLD Snooping

By default, IPv6 MLD snooping is globally disabled on the switch and enabled on all VLANs. When MLD snooping is globally disabled, it is also disabled on all VLANs. When you globally enable MLD snooping, the VLAN configuration overrides the global configuration. MLD snooping is enabled only on VLAN interfaces in the default state (enabled).

You can enable and disable MLD snooping on a per-VLAN basis, but if you globally disable MLD snooping, it is disabled in all VLANs. If global snooping is enabled, you can enable or disable VLAN snooping.

To globally enable MLD snooping on the switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ipv6 mld snooping	Globally enables MLD snooping on the switch.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To globally disable MLD snooping on the switch, use the **no ipv6 mld snooping** global configuration command.

To enable MLD snooping on a VLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ipv6 mld snooping	Globally enables MLD snooping on the switch.
Step 3	Switch(config)# ipv6 mld snooping vlan <i>vlan-id</i>	Enables MLD snooping on the VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094. Note MLD snooping must be globally enabled for VLAN snooping to be enabled.
Step 4	Switch(config)# end	Returns to privileged EXEC mode.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable MLD snooping on a VLAN interface, use the **no ipv6 mld snooping vlan *vlan-id*** global configuration command for the specified VLAN number.

Configuring a Static Multicast Group

Hosts or Layer 2 ports normally join multicast groups dynamically, but you can also statically configure an IPv6 multicast address and member ports for a VLAN.

To add a Layer 2 port as a member of a multicast group, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode
Step 2	Switch(config)# ipv6 mld snooping vlan <i>vlan-id</i> static <i>ipv6_multicast_address</i> interface <i>interface-id</i>	Statically configures a multicast group with a Layer 2 port as a member of a multicast group: <ul style="list-style-type: none"> <i>vlan-id</i> is the multicast group VLAN ID. The VLAN ID range is 1 to 1001 and 1006 to 4094. <i>ipv6_multicast_address</i> is the 128-bit group IPv6 address. The address must be in the form specified in RFC 2373. <i>interface-id</i> is the member port. It can be a physical interface or a port channel (1 to 64).
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show mac-address-table multicast mld-snooping	Verifies the static member port and the IPv6 address.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove a Layer 2 port from the multicast group, use the **no ipv6 mld snooping vlan *vlan-id* static *mac-address* interface *interface-id*** global configuration command. If all member ports are removed from a group, the group is deleted.

This example shows how to statically configure an IPv6 MAC address:

```
Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 2 static 3333.0000.0003 interface
gigabitethernet1/1
Switch(config)# end
```

Configuring a Multicast Router Port

Although MLD snooping learns about router ports through MLD queries and PIMv6 queries, you can also use the command-line interface (CLI) to add a multicast router port to a VLAN. To add a multicast router port (add a static connection to a multicast router), use the **ipv6 mld snooping vlan *mrouter*** global configuration command on the switch.

Note

Static connections to multicast routers are supported only on switch ports.

To add a multicast router port to a VLAN, follow these steps:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ipv6 mld snooping vlan <i>vlan-id mrouter interface interface-id</i>	Specifies the multicast router VLAN ID, and specify the interface to the multicast router. <ul style="list-style-type: none"> • The VLAN ID range is 1 to 1001 and 1006 to 4094. • The interface can be a physical interface or a port channel. The port-channel range is 1 to 64.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show ipv6 mld snooping mrouter <i>[vlan vlan-id]</i>	Verifies that IPv6 MLD snooping is enabled on the VLAN interface.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To remove a multicast router port from the VLAN, use the **no ipv6 mld snooping vlan *vlan-id* mrouter interface *interface-id*** global configuration command.

This example shows how to add a multicast router port to VLAN 200:

```
Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 200 mrouter interface gigabitethernet0/2
Switch(config)# exit
```

Enabling MLD Immediate Leave

When you enable MLDv1 Immediate Leave, the switch immediately removes a port from a multicast group when it detects an MLD Done message on that port. You should only use the Immediate Leave feature when there is a single receiver present on every port in the VLAN. When multiple clients exist for a multicast group on the same port, do not enable Immediate-Leave in a VLAN.

To enable MLDv1 Immediate Leave, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ipv6 mld snooping vlan <i>vlan-id</i> immediate-leave	Enables MLD Immediate Leave on the VLAN interface.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show ipv6 mld snooping vlan <i>vlan-id</i>	Verifies that Immediate Leave is enabled on the VLAN interface.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To disable MLD Immediate Leave on a VLAN, use the **no ipv6 mld snooping vlan *vlan-id* immediate-leave** global configuration command.

This example shows how to enable MLD Immediate Leave on VLAN 130:

```
Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 130 immediate-leave
Switch(config)# exit
```

Configuring MLD Snooping Queries

When Immediate Leave is not enabled and a port receives an MLD Done message, the switch generates MASQs on the port and sends them to the IPv6 multicast address for which the Done message was sent. You can optionally configure the number of MASQs that are sent and the length of time the switch waits for a response before deleting the port from the multicast group.

To configure MLD snooping query characteristics for the switch or for a VLAN, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# ipv6 mld snooping robustness-variable <i>value</i>	(Optional) Sets the number of queries that are sent before the switch deletes a listener (port) that does not respond to a general query. The range is 1 to 3; the default is 2.
Step 3	Switch(config)# ipv6 mld snooping vlan <i>vlan-id</i> robustness-variable <i>value</i>	(Optional) Sets the robustness variable on a VLAN basis, which determines the number of general queries that MLD snooping sends before aging out a multicast address when there is no MLD report response. The range is 1 to 3; the default is 0. When set to 0, the number used is the global robustness variable value.
Step 4	Switch(config)# ipv6 mld snooping last-listener-query-count <i>count</i>	(Optional) Sets the number of MASQs that the switch sends before aging out an MLD client. The range is 1 to 7; the default is 2. The queries are sent 1 second apart.
Step 5	Switch(config)# ipv6 mld snooping vlan <i>vlan-id</i> last-listener-query-count <i>count</i>	(Optional) Sets the last-listener query count on a VLAN basis. This value overrides the value configured globally. The range is 1 to 7; the default is 0. When set to 0, the global count value is used. Queries are sent 1 second apart.
Step 6	Switch(config)# ipv6 mld snooping last-listener-query-interval <i>interval</i>	(Optional) Sets the maximum response time that the switch waits after sending out a MASQ before deleting a port from the multicast group. The range is 100 to 32,768 thousands of a second. The default is 1000 (1 second).
Step 7	Switch(config)# ipv6 mld snooping vlan <i>vlan-id</i> last-listener-query-interval <i>interval</i>	(Optional) Sets the last-listener query interval on a VLAN basis. This value overrides the value configured globally. The range is 0 to 32,768 thousands of a second. The default is 0. When set to 0, the global last-listener query interval is used.
Step 8	Switch(config)# ipv6 mld snooping tcn query solicit	(Optional) Enables topology change notification (TCN) solicitation, which means that VLANs flood all IPv6 multicast traffic for the configured number of queries before sending multicast data to only those ports requesting to receive it. The default is for TCN to be disabled.
Step 9	Switch(config)# ipv6 mld snooping tcn flood query count <i>count</i>	(Optional) When TCN is enabled, specifies the number of TCN queries to be sent. The range is from 1 to 10; the default is 2.
Step 10	Switch(config)# end	Returns to privileged EXEC mode.
Step 11	Switch# show ipv6 mld snooping querier [<i>vlan vlan-id</i>]	(Optional) Verifies that the MLD snooping querier information for the switch or for the VLAN.
Step 12	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to set the MLD snooping global robustness variable to 3:

```
Switch# configure terminal
Switch(config)# ipv6 mld snooping robustness-variable 3
Switch(config)# exit
```

This example shows how to set the MLD snooping last-listener query count for a VLAN to 3:

```
Switch# configure terminal
Switch(config)# ipv6 mld snooping vlan 200 last-listener-query-count 3
Switch(config)# exit
```

This example shows how to set the MLD snooping last-listener query interval (maximum response time) to 2000 (2 seconds):

```
Switch# configure terminal
Switch(config)# ipv6 mld snooping last-listener-query-interval 2000
Switch(config)# exit
```

Disabling MLD Listener Message Suppression

MLD snooping listener message suppression is enabled by default. When it is enabled, the switch forwards only one MLD report per multicast router query. When message suppression is disabled, multiple MLD reports could be forwarded to the multicast routers.

To disable MLD listener message suppression, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# no ipv6 mld snooping listener-message-suppression	Disables MLD message suppression.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show ipv6 mld snooping	Verifies that IPv6 MLD snooping report suppression is disabled.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To reenabling MLD message suppression, use the **ipv6 mld snooping listener-message-suppression** global configuration command.

Displaying MLD Snooping Information

You can display MLD snooping information for dynamically learned and statically configured router ports and VLAN interfaces. You can also display MAC address multicast entries for a VLAN configured for MLD snooping.

To display MLD snooping information, use one or more of the privileged EXEC commands in [Table 30-2](#).

Table 30-2 **Commands for Displaying MLD Snooping Information**

Command	Purpose
<code>show ipv6 mld snooping [vlan <i>vlan-id</i>]</code>	Displays the MLD snooping configuration information for all VLANs on the switch or for a specified VLAN. (Optional) Enter vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.
<code>show ipv6 mld snooping mrouter [vlan <i>vlan-id</i>]</code>	Displays information on dynamically learned and manually configured multicast router interfaces. When you enable MLD snooping, the switch automatically learns the interface to which a multicast router is connected. These are dynamically learned interfaces. (Optional) Enter vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.
<code>show ipv6 mld snooping querier [vlan <i>vlan-id</i>]</code>	Displays information about the IPv6 address and incoming port for the most-recently received MLD query messages in the VLAN. (Optional) Enter vlan <i>vlan-id</i> to display information for a single VLAN. The VLAN ID range is 1 to 1001 and 1006 to 4094.

■ Displaying MLD Snooping Information

Configuring 802.1Q Tunneling, VLAN Mapping, and Layer 2 Protocol Tunneling

Virtual private networks (VPNs) provide enterprise-scale connectivity on a shared infrastructure, often Ethernet-based, with the same security, prioritization, reliability, and manageability requirements of private networks. Tunneling is a feature designed for service providers who carry traffic of multiple customers across their networks and who are required to maintain the VLAN and Layer 2 protocol configurations of each customer without impacting the traffic of other customers. This chapter describes how to configure 802.1Q, Layer 2 protocol tunneling, and VLAN mapping (or VLAN ID translation) on a Catalyst 4500 series switch.

This chapter contains these sections:

- [About 802.1Q Tunneling, page 31-1](#)
- [Configuring 802.1Q Tunneling, page 31-3](#)
- [About VLAN Mapping, page 31-6](#)
- [Configuring VLAN Mapping, page 31-9](#)
- [About Layer 2 Protocol Tunneling, page 31-13](#)
- [Configuring Layer 2 Protocol Tunneling, page 31-15](#)
- [Monitoring and Maintaining Tunneling Status, page 31-23](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About 802.1Q Tunneling

The VLAN ranges required by different customers in the same service provider network might overlap, and customer traffic through the infrastructure might be mixed. Assigning a unique range of VLAN IDs to each customer restricts customer configurations and could easily exceed the VLAN limit (4096) of the 802.1Q specification.

802.1Q tunneling enables service providers to use a single VLAN to support customers who have multiple VLANs, while preserving customer VLAN IDs and keeping traffic in different customer VLANs segregated.

A port configured to support 802.1Q tunneling is called a tunnel port. When you configure tunneling, you assign a tunnel port to a VLAN ID that is dedicated to tunneling. Each customer requires a separate service provider VLAN ID, but that service provider VLAN ID supports VLANs of all the customers.

Customer traffic tagged in the normal way with appropriate VLAN IDs comes from an 802.1Q trunk port on the customer device and into a tunnel port on the service provider edge switch. The link between the customer device and the edge switch is asymmetric because one end is configured as an 802.1Q trunk port, and the other end is configured as a tunnel port. You assign the tunnel port interface to an access VLAN ID that is unique to each customer (Figure 31-1).

Figure 31-1 802.1Q Tunnel Ports in a Service Provider Network

Packets coming from the customer trunk port into the tunnel port on the service provider edge switch are normally 802.1Q-tagged with the appropriate VLAN ID. When the tagged packets exit the trunk port into the service provider network, they are encapsulated with another layer of an 802.1Q tag (called the *metro tag*) that contains the VLAN ID that is unique to the customer. The original customer 802.1Q tag is preserved in the encapsulated packet. Packets entering the service provider network are double-tagged, with the metro tag containing the customer's access VLAN ID, and the inner VLAN ID being that of the incoming traffic.

When the double-tagged packet enters another trunk port in a service provider core switch, the metro tag is stripped as the switch processes the packet. When the packet exits another trunk port on the same core switch, the same metro tag is again added to the packet. Figure 31-2 shows the tag structures of the Ethernet packets starting with the original, or normal, frame.

Figure 31-2 Original (Normal), 802.1Q, and Double-Tagged Ethernet Packet Formats

When the packet enters the trunk port of the service provider egress switch, the metro tag is again stripped as the switch processes the packet. However, the metro tag is not added when the packet is sent out the tunnel port on the edge switch into the customer network. The packet is sent as a normal 802.1Q-tagged frame to preserve the original VLAN numbers in the customer network.

All packets entering the service provider network through a tunnel port on an edge switch are treated as untagged packets, whether they are untagged or already tagged with 802.1Q headers. The packets are encapsulated with the metro tag VLAN ID (set to the access VLAN of the tunnel port) when they are sent through the service provider network on an 802.1Q trunk port. The priority field on the metro tag is set to the interface class of service (CoS) priority configured on the tunnel port. (The default is zero if none is configured.)

In [Figure 31-1](#), Customer A was assigned VLAN 30, and Customer B was assigned VLAN 40. Packets entering the edge-switch tunnel ports with 802.1Q tags are double-tagged when they enter the service provider network, with the metro tag containing VLAN ID 30 or 40, appropriately, and the inner tag containing the original customer VLAN number, for example, VLAN 100. Even if Customers A and B both have VLAN 100 in their networks, the traffic remains segregated within the service provider network because the metro tag is different. Each customer controls its own VLAN numbering space, which is independent of the VLAN numbering space used by other customers and the VLAN numbering space used by the service provider network.

Configuring 802.1Q Tunneling

These sections describe 802.1Q tunneling configuration:

- [802.1Q Tunneling Configuration Guidelines, page 31-3](#)
- [802.1Q Tunneling and Other Features, page 31-5](#)
- [Configuring an 802.1Q Tunneling Port, page 31-5](#)

Note

By default, 802.1Q tunneling is disabled because the default switch port mode is dynamic auto. Tagging of 802.1Q native VLAN packets on all 802.1Q trunk ports is also disabled.

802.1Q Tunneling Configuration Guidelines

When you configure 802.1Q tunneling, you should always use asymmetrical links for traffic going through a tunnel and should dedicate one VLAN for each tunnel. You should also be aware of configuration requirements for native VLANs and maximum transmission units (MTUs). For more information about MTUs, see the [“System MTU” section on page 31-5](#).

Native VLANs

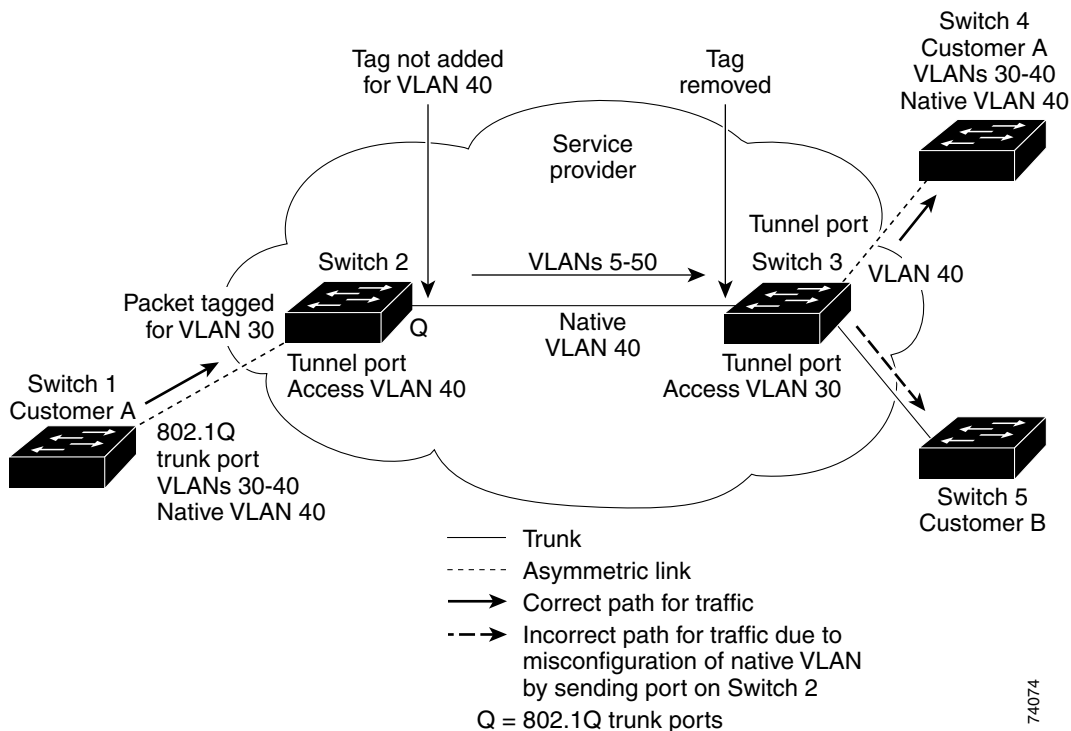

When configuring 802.1Q tunneling on an edge switch, you must use 802.1Q trunk ports for sending packets into the service provider network. However, packets going through the core of the service provider network can be carried through 802.1Q trunks, ISL trunks, or nontrunking links. When 802.1Q trunks are used in these core switches, the native VLANs of the 802.1Q trunks must not match any native VLAN of the nontrunking (tunneling) port on the same switch because traffic on the native VLAN is not tagged on the 802.1Q sending trunk port ([Figure 31-3](#)).

VLAN 40 is configured as the native VLAN for the 802.1Q trunk port from Customer A at the ingress edge switch in the service provider network (Switch 2). Switch 1 of Customer A sends a tagged packet on VLAN 30 to the ingress tunnel port of Switch 2 in the service provider network, which belongs to access VLAN 40. Because the access VLAN of the tunnel port (VLAN 40) is the same as the native VLAN of the edge-switch trunk port (VLAN 40), the metro tag is not added to tagged packets received from the tunnel port. The packet carries only the VLAN 30 tag through the service provider network to the trunk port of the egress-edge switch (Switch 3) and is misdirected through the egress switch tunnel port to Customer B.

These are some ways to solve this problem:

- Use ISL trunks between core switches in the service provider network. Although customer interfaces connected to edge switches must be 802.1Q trunks, we recommend using ISL trunks for connecting switches in the core layer.
- Use the **switchport trunk native vlan tag** per-port command and the **vlan dot1q tag native** global configuration command to configure the edge switch so that all packets going out an 802.1Q trunk, including the native VLAN, are tagged. If the switch is configured to tag native VLAN packets on all 802.1Q trunks, the switch ensures that all packets exiting the trunk are tagged and prevents the reception of untagged packets on the trunk port.
- Ensure that the native VLAN ID on the edge-switch trunk port is not within the customer VLAN range. For example, if the trunk port carries traffic of VLANs 100 to 200, assign the native VLAN a number outside that range.

Figure 31-3 Potential Problem with 802.1Q Tunneling and Native VLANs

System MTU

The default system MTU for traffic on the switch is 1500 bytes. You can configure the switch to support larger frames by using the **system mtu** global configuration command. Because the 802.1Q tunneling feature increases the frame size by 4 bytes when the metro tag is added, you must configure all switches in the service provider network to be able to process larger frames by increasing the switch system MTU size to at least 1504 bytes. The maximum allowable system MTU for Catalyst 4500 Gigabit Ethernet switches is 9198 bytes; the maximum system MTU for Fast Ethernet switches is 1552 bytes.

802.1Q Tunneling and Other Features

Although 802.1Q tunneling works well for Layer 2 packet switching, incompatibilities exist between some Layer 2 features and Layer 3 switching:

- A tunnel port cannot be a routed port.
- IP routing is not supported on a VLAN that includes 802.1Q ports. Packets received from a tunnel port are forwarded based only on Layer 2 information. If routing is enabled on a switch virtual interface (SVI) that includes tunnel ports, untagged IP packets received from the tunnel port are recognized and routed by the switch. Customers can access the Internet through the native VLAN. If this access is not needed, you should not configure SVIs on VLANs that include tunnel ports.
- Tunnel ports do not support IP access control lists (ACLs).
- Layer 3 quality of service (QoS) ACLs and other QoS features related to Layer 3 information are not supported on tunnel ports. MAC-based QoS is supported on tunnel ports.
- EtherChannel port groups are compatible with tunnel ports as long as the 802.1Q configuration is consistent within an EtherChannel port group.
- Port Aggregation Protocol (PAgP), Link Aggregation Control Protocol (LACP), and UniDirectional Link Detection (UDLD) are supported on 802.1Q tunnel ports.
- Dynamic Trunking Protocol (DTP) is not compatible with 802.1Q tunneling because you must manually configure asymmetric links with tunnel ports and trunk ports.
- Loopback detection is supported on 802.1Q tunnel ports.
- When a port is configured as an 802.1Q tunnel port, spanning-tree bridge protocol data unit (BPDU) filtering is automatically enabled on the interface. Cisco Discovery Protocol (CDP) is automatically disabled on the interface.

Configuring an 802.1Q Tunneling Port

To configure a port as an 802.1Q tunnel port, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode and the interface to be configured as a tunnel port. This should be the edge port in the service provider network that connects to the customer switch. Valid interfaces include physical interfaces and port-channel logical interfaces (port channels 1 to 64).
Step 3	Switch(config-if)# switchport access vlan <i>vlan-id</i>	Specifies the default VLAN, which is used if the interface stops trunking. This VLAN ID is specific to the particular customer.

	Command	Purpose
Step 4	Switch(config-if)# switchport mode dot1q-tunnel	Sets the interface as an 802.1Q tunnel port.
Step 5	Switch(config-if)# exit	Returns to global configuration mode.
Step 6	Switch(config)# vlan dot1q tag native	(Optional) Sets the switch to enable tagging of native VLAN packets on all 802.1Q trunk ports. When not set, and a customer VLAN ID is the same as the native VLAN, the trunk port does not apply a metro tag, and packets could be sent to the wrong destination.
Step 7	Switch(config)# end	Returns to privileged EXEC mode.
Step 8	Switch# show dot1q-tunnel	Displays the tunnel ports on the switch.
Step 9	Switch# show vlan dot1q tag native	Displays 802.1Q native-VLAN tagging status.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no vlan dot1q tag native** global command and the **no switchport mode dot1q-tunnel** interface configuration command to return the port to the default state of dynamic auto. Use the **no vlan dot1q tag native** global configuration command to disable tagging of native VLAN packets.

This example shows how to configure an interface as a tunnel port, enable tagging of native VLAN packets, and verify the configuration. In this configuration, the VLAN ID for the customer connected to Gigabit Ethernet interface 2/7 is VLAN 22.

```
Switch(config)# interface gigabitethernet2/7
Switch(config-if)# switchport access vlan 22
% Access VLAN does not exist. Creating vlan 22
Switch(config-if)# switchport mode dot1q-tunnel
Switch(config-if)# exit
Switch(config)# vlan dot1q tag native
Switch(config)# end
Switch# show dot1q-tunnel interface gigabitethernet2/7
Port
----
LAN Port(s)
----
Gi2/7
Switch# show vlan dot1q tag native
dot1q native vlan tagging is enabled globally
```

About VLAN Mapping

Note

VLAN mapping is supported only on Supervisor Engine 6-E and later engines.

In a typical deployment of VLAN mapping, you want the service provider to provide a transparent switching infrastructure that treats customers' switches at the remote location as a part of the local site. This allows customers to use the same VLAN ID space and run Layer 2 control protocols seamlessly across the provider network. In such scenarios, we recommend that service providers do not impose their VLAN IDs on their customers.

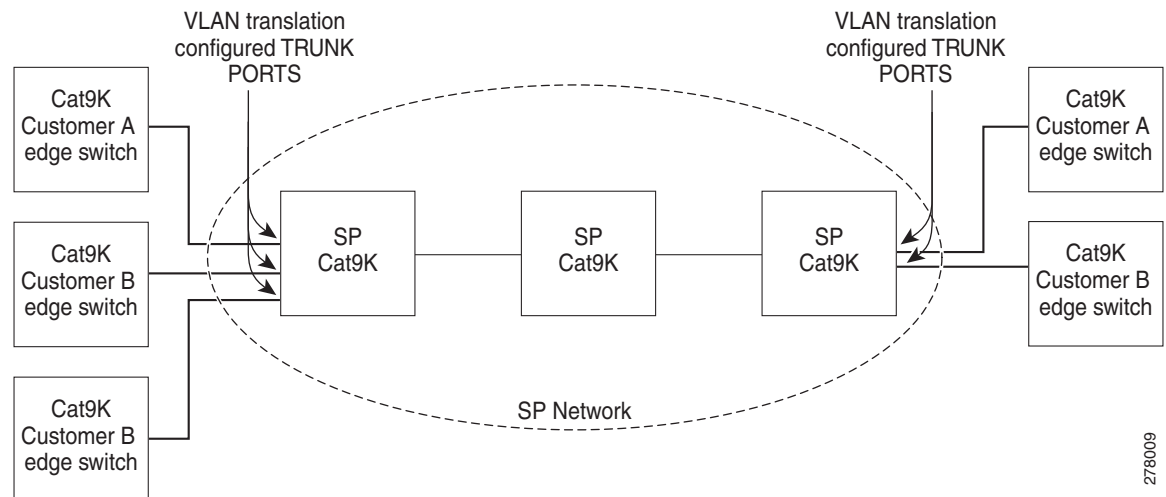

One way to establish translated VLAN IDs (S-VLANs) is to map customer VLANs to service-provider VLANs (called VLAN ID translation) on trunk ports connected to a customer network. Packets entering the port are mapped to a service provider VLAN (S-VLAN) based on the port number and the packet's original customer VLAN-ID (C-VLAN).

Service providers's internal assignments might conflict with a customer's VLAN. To isolate customer traffic, a service provider could decide to map a specific VLAN into another one while the traffic is in its cloud.

Deployment Example

In [Figure 31-4](#), the service provider provides Layer 2 VPN service to two different customers, A and B. The service provider separates the data and control traffic between the two customers and from the providers' own control traffic. The service provider network must also be transparent to the customer edge devices.

Figure 31-4 Layer 2 VPN Deployment

All forwarding operations on the Catalyst 4500 series switch are performed using S-VLAN and not C-VLAN information because the VLAN ID is mapped to the S-VLAN on ingress.

Note

When you configure features on a port configured for VLAN mapping, you always use the S-VLAN rather than the customer VLAN-ID (C-VLAN).

On an interface configured for VLAN mapping, the specified C-VLAN packets are mapped to the specified S-VLAN when they enter the port. Symmetrical mapping to the customer C-VLAN occurs when packets exit the port.

The switch supports these types of VLAN mapping on UNI trunk ports:

- One-to-one VLAN mapping occurs at the ingress and egress of the port and maps the customer C-VLAN ID in the 802.1Q tag to the service-provider S-VLAN ID. You can also specify that packets with all other Vlan Ids are dropped. See the [“One-to-One Mapping”](#) section on page 31-10.

- Traditional 802.1Q tunneling (QinQ) performs all-to-one bundling of C-VLAN IDs to a single S-VLAN ID for the port. The S-VLAN is added to the incoming unmodified C-VLAN. You can configure the UNI as an 802.1Q tunnel port for traditional QinQ, or you can configure selective QinQ on trunk ports for a more flexible implementation. Mapping takes place at ingress and egress of the port. All packets on the port are bundled into the specified S-VLAN. See the [“Traditional Q-in-Q on a Trunk Port”](#) section on page 31-11.
- Selective QinQ maps the specified customer VLANs entering the UNI to the specified S-VLAN ID. The S-VLAN is added to the incoming unmodified C-VLAN. You can also specify whether traffic carrying all other customer VLAN IDs should be dropped or not. See the [“Selective Q-in-Q on a Trunk Port”](#) section on page 31-12.

**Note**

Untagged packets enter the switch on the trunk native VLAN and are not mapped.

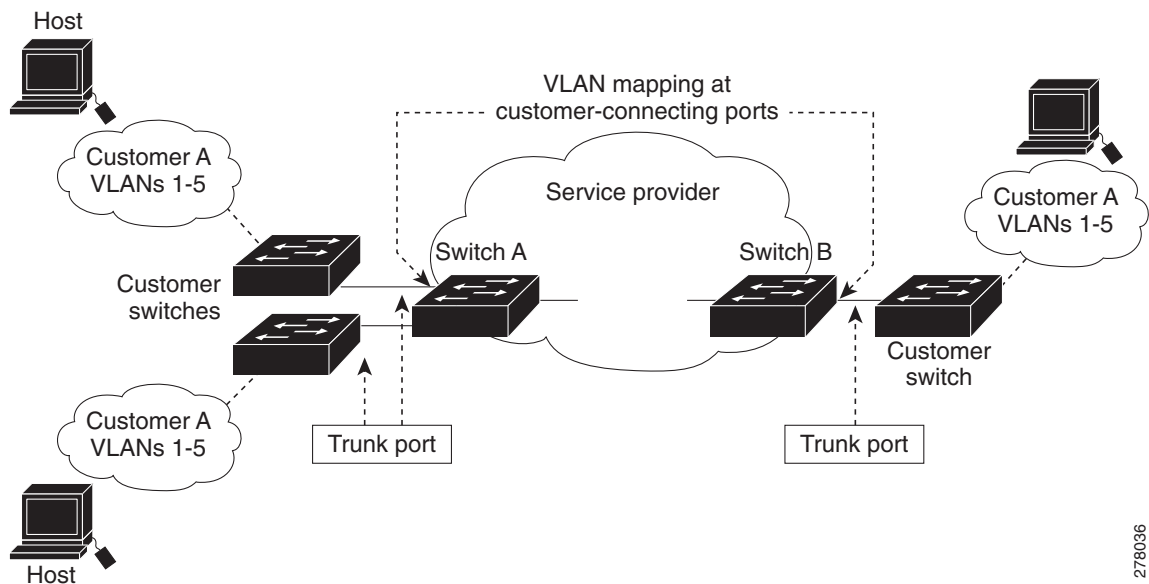

For quality of service (QoS), the switch supports flexible mapping between C-CoS or C-DSCP and S-CoS, and maps the inner CoS to the outer CoS for traffic with traditional QinQ or selective QinQ VLAN mapping.

Mapping Customer VLANs to Service-Provider VLANs

Figure 31-5 shows a topology where a customer uses the same VLANs in multiple sites on different sides of a service-provider network. You map the customer VLAN IDs to service-provider VLAN IDs for packet travel across the service-provider backbone. The customer VLAN IDs are retrieved at the other side of the service-provider backbone for use in the other customer site. Configure the same set of VLAN mappings at a customer-connected port on each side of the service-provider network.

The examples following the configuration steps illustrate how to use one-to-one mapping, traditional QinQ, or selective QinQ to map customer VLANs 1 to 5 to service-provider VLANs.

Figure 31-5 Mapping Customer VLANs

278036

Configuring VLAN Mapping

- [Default VLAN Mapping Configuration, page 31-9](#)
- [VLAN Mapping Configuration Guidelines, page 31-9](#)
- [Configuring VLAN Mapping, page 31-10](#)

Default VLAN Mapping Configuration

By default, no VLAN mapping is configured.

VLAN Mapping Configuration Guidelines

Guidelines include the following:

- Traditional QinQ uses 802.1Q tunnel ports; you configure one-to-one VLAN mapping and selective QinQ on 802.1Q trunk ports.
- To avoid mixing customer traffic, when you configure traditional Q-in-Q on a trunk port, you should configure the service provider S-VLAN ID as an allowed VLAN on the trunk port.
- When you configure VLAN mapping on an EtherChannel, the mapping applies to all ports in the port channel.
- You cannot configure encapsulation replicate on a SPAN destination port if the source port is configured as a tunnel port or has a 1-to-2 mapping configured. Encapsulation replicate is supported with 1-to-1 VLAN mapping.
- When configuring IEEE 802.1Q tunneling on an edge switch, you must use IEEE 802.1Q trunk ports for sending packets into the service-provider network. However, packets going through the core of the service-provider network can be carried through IEEE 802.1Q trunks, ISL trunks, or nontrunking links. When IEEE 802.1Q trunks are used in these core switches, the native VLANs of the IEEE 802.1Q trunks must not match any native VLAN of the nontrunking (tunneling) port on the same switch. It is because traffic on the native VLAN is not tagged on the IEEE 802.1Q sending trunk port.
- Ensure that the native VLAN for an IEEE 802.1Q trunk is the same on both ends of the trunk link. If the native VLAN on one end of the trunk is different from the native VLAN on the other end, spanning-tree loops might result.
- Layer 2 protocol tunneling must be configured for CDP, VTP, LLDP, or your switch detects the SP switches, which is not desirable:

```
interface GigabitEthernet1/23
switchport mode trunk
switchport vlan mapping 1 dot1q-tunnel 311
switchport vlan mapping 31 dot1q-tunnel 311
l2protocol-tunnel cdp
l2protocol-tunnel ll dp
l2protocol-tunnel vtp
```

- To process control traffic consistently, either enable Layer 2 protocol tunneling (recommended) or insert a BPDU filter for spanning tree, as follows:

```
Current configuration : 153 bytes
!
interface FastEthernet9/1
```

```

switchport trunk native vlan 40
switchport mode trunk
switchport vlan mapping 10 20
spanning-tree bpdufilter enable
end

```

- If you need to merge CVLAN and SVLAN spanning tree topology, you do not need to configure **spanning-tree bpdufilter enable**.
- To ensure consistent operation, do not use a native VLAN for translation.

Configuring VLAN Mapping

The following procedures show how to configure each type of VLAN mapping on trunk ports. To verify your configuration, enter either the **show interfaces interface-id vlan mapping** or the **show vlan mapping** privileged EXEC command. See the “[Monitoring and Maintaining Tunneling Status](#)” section on page 31-23 for the syntax of these commands. For more information about all commands in this section, see the *Catalyst 4500 Series Switch Software Command Reference* for this release.

The following VLAN mapping types are discussed:

- [One-to-One Mapping, page 31-10](#)
- [Traditional Q-in-Q on a Trunk Port, page 31-11](#)
- [Selective Q-in-Q on a Trunk Port, page 31-12](#)

One-to-One Mapping

To configure one-to-one VLAN mapping to map a customer VLAN ID to a service-provider VLAN ID, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface-id	Enters interface configuration mode for the interface connected to the service-provider network. You can enter a physical interface or an EtherChannel port channel.
Step 3	Switch(config-if)# switchport mode trunk	Configures the interface as a trunk port.
Step 4	Switch(config-if)# switchport vlan mapping vlan-id translated-id	<p>Enters the VLAN IDs to be mapped:</p> <ul style="list-style-type: none"> • <i>vlan-id</i>—the customer VLAN ID (C-VLAN) entering the switch from the customer network. The range is from 1 to 4094. • <i>translated-id</i>—the assigned service-provider VLAN ID (S-VLAN). The range is from 1 to 4094. <p>Note Packets with unconfigured <code>vlan_ids</code> are dropped.</p>
Step 5	Switch# end	Returns to privileged EXEC mode.
Step 6	Switch# show vlan mapping	Verifies the configuration.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no switchport vlan mapping *vlan-id translated-id*** command to remove the VLAN mapping information. Entering the **no switchport vlan mapping all** command deletes all mapping configurations.

This example shows how to map VLAN IDs 1 to 5 in the customer network to VLANs 101 to 105 in the service-provider network (Figure 31-5). You configure the same VLAN mapping commands for a port in Switch A and Switch B; the traffic on all other VLAN IDs is dropped.

```
Switch(config)# interface gigabitEthernet0/1
Switch(config-if)# switchport vlan mapping 1 101
Switch(config-if)# switchport vlan mapping 2 102
Switch(config-if)# switchport vlan mapping 3 103
Switch(config-if)# switchport vlan mapping 4 104
Switch(config-if)# switchport vlan mapping 5 105
Switch(config-if)# exit
```

In the previous example, at the ingress of the service-provider network, VLAN IDs 1 to 5 in the customer network are mapped to VLANs 101 to 105, in the service provider network. At the egress of the service provider network, VLANs 101 to 105 in the service provider network are mapped to VLAN IDs 1 to 5, in the customer network.

**Note**

Packets with unconfigured `vlan_ids` are dropped.

Traditional Q-in-Q on a Trunk Port

To configure VLAN mapping for traditional Q-in-Q on a trunk port or tunneling by default, perform the following task:

**Note**

Configuring tunneling by default bundles all packets on the port into the configured S-VLAN.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config) # interface <i>interface-id</i>	Enters interface configuration mode for the interface connected to the service provider network. You can enter a physical interface or an EtherChannel port channel.
Step 3	Switch(config-if)# switchport mode trunk	Configures the interface as a trunk port.
Step 4	Switch(config-if)# switchport trunk allowed vlan <i>vlan-id</i>	Configures the outer VLAN of the service provider network (S-VLAN) to to be allowed on the interface. This should be the same outer VLAN ID entered in the next step.
Step 5	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 6	Switch# show interfaces <i>interface-id</i> vlan mapping	Verifies the configuration.
Step 7	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Entering the **no switchport vlan mapping all** command deletes all mapping configurations.

Selective Q-in-Q on a Trunk Port

To configure VLAN mapping for selective Q-in-Q on a trunk port, perform this task:

Note

You cannot configure one-to-one mapping and selective Q-in-Q on the same interface.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode for the interface connected to the service provider network. You can enter a physical interface or an EtherChannel port channel.
Step 3	Switch(config-if)# switchport mode trunk	Configure the interface as a trunk port.
Step 4	Switch(config-if)# switchport vlan mapping <i>vlan-id</i> dot1q-tunnel <i>outer vlan-id</i>	Enters the VLAN IDs to be mapped: <ul style="list-style-type: none"> <i>vlan-id</i>—The customer VLAN ID (C-VLAN) entering the switch from the customer network. The range is from 1 to 4094. You can enter a string of VLAN-IDs. <i>outer-vlan-id</i>—The outer VLAN ID (S-VLAN) of the service provider network. The range is from 1 to 4094.
Step 5	Switch(config-if)# switchport vlan mapping default drop	Specifies that all packets on the port are dropped if they do not match the mapped VLANs (Step 4). By default, packets that do not match, are dropped. If the packets (that do not match) should not be dropped, enter the no version of the command.
Step 6	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 7	Switch# show interfaces <i>interface-id</i> vlan mapping	Verifies the configuration.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no switchport vlan mapping** *vlan-id* **dot1q-tunnel** *outer vlan-id* command to remove the VLAN mapping configuration. Entering the **no switchport vlan mapping all** command deletes all mapping configurations.

This example shows how to configure selective QinQ mapping on the port so that traffic with a C-VLAN ID of 1 to 5 enters the switch with an S-VLAN ID of 100. The traffic of any other VLAN ID is dropped.

```
Switch(config)# interface gigabitEthernet0/1
Switch(config-if)# switchport vlan mapping 1-5 dot1q-tunnel 100
Switch(config-if)# switchport vlan mapping default drop
Switch(config-if)# exit
```

This example shows how to configure selective QinQ mapping on the port so that traffic with a C-VLAN ID of 1 to 5 enters the switch with an S-VLAN ID of 100. The traffic of any other VLAN ID is allowed.

```
Switch(config)# interface gigabitEthernet0/1
Switch(config-if)# switchport vlan mapping 1-5 dot1q-tunnel 100
Switch(config-if)# no switchport vlan mapping default drop
Switch(config-if)# exit
```

About Layer 2 Protocol Tunneling

**Note**

IPsec VPN is supported for control plane traffic protection on the management port, and must be used for management purposes only.

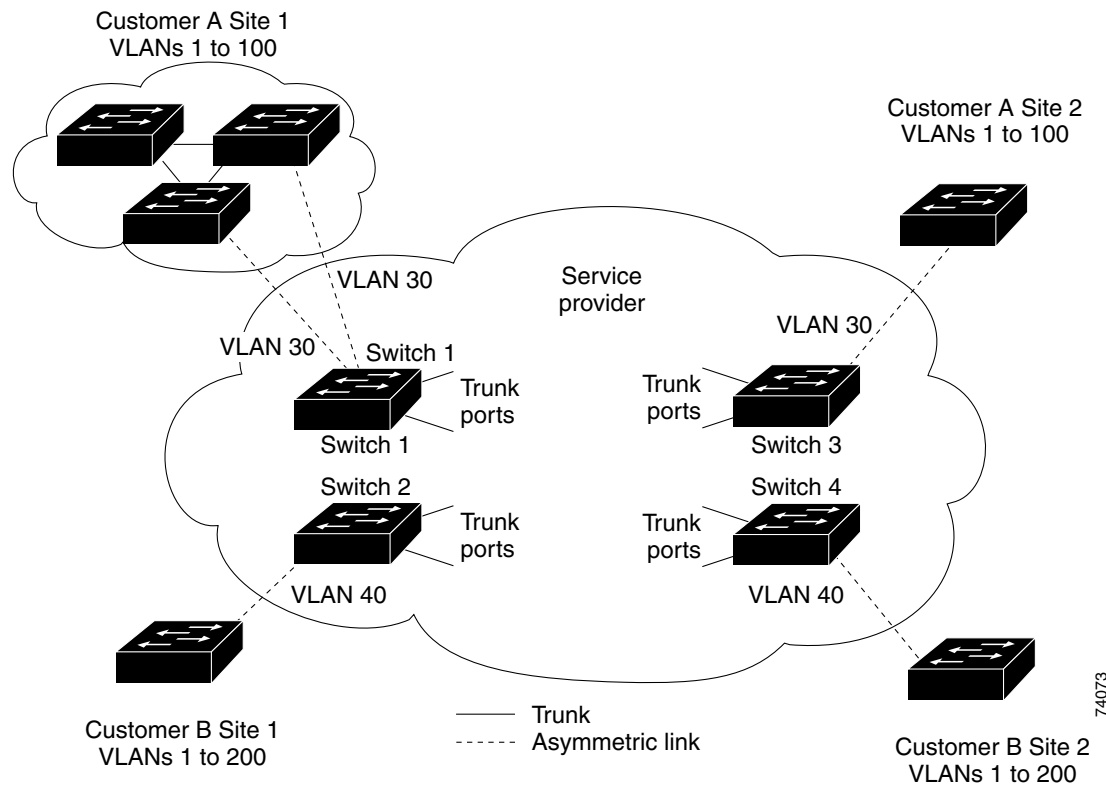

Customers at different sites connected across a service provider network need to use various Layer 2 protocols to scale their topologies to include all remote and local sites. STP must run properly, and every VLAN should build a proper spanning tree that includes the local site and all remote sites across the service provider network. Cisco Discovery Protocol (CDP) must discover neighboring Cisco devices from local and remote sites. VLAN Trunking Protocol (VTP) must provide consistent VLAN configuration throughout all sites in the customer network.

When protocol tunneling is enabled, edge switches on the inbound side of the service provider network encapsulate Layer 2 protocol packets with a special MAC address and send them across the service provider network. Core switches in the network do not process these packets but forward them as normal packets. Layer 2 protocol data units (PDUs) for CDP, STP, or VTP cross the service provider network and are delivered to customer switches on the outbound side of the service provider network. Identical packets are received by all customer ports on the same VLANs with these results:

- Users on each of a customer's sites can properly run STP, and every VLAN can build a correct spanning tree, based on parameters from all sites and not just from the local site.
- CDP discovers and shows information about the other Cisco devices connected through the service provider network.
- VTP provides consistent VLAN configuration throughout the customer network, propagating to all switches through the service provider.

Layer 2 protocol tunneling can be enabled on trunk, access and tunnel ports. If protocol tunneling is not enabled, remote switches at the receiving end of the service provider network do not receive the PDUs and cannot properly run STP, CDP, and VTP. When protocol tunneling is enabled, Layer 2 protocols within each customer's network are totally separate from those running within the service provider network.

As an example, Customer A in [Figure 31-6](#) has four switches in the same VLAN that are connected through the service provider network. If the network does not tunnel PDUs, switches on the far ends of the network cannot properly run STP, CDP, and VTP. For example, STP for a VLAN on a switch in Customer A's Site 1 builds a spanning tree on the switches at that site without considering convergence parameters based on Customer A's switch in Site 2. [Figure 31-6](#) shows one possible spanning tree topology.

Figure 31-6 Layer 2 Protocol Tunneling

Figure 31-7 Layer 2 Network Topology without Proper Convergence

74017

Configuring Layer 2 Protocol Tunneling

You can enable Layer 2 protocol tunneling (by protocol) on access ports, tunnel ports, or trunk ports that are connected to the customer in the edge switches of the service provider network. The service provider edge switches connected to the customer switch perform the tunneling process. Edge-switch tunnel ports or normal trunk ports can be connected to customer 802.1Q trunk ports. Edge-switch access ports are connected to customer access ports.

When the Layer 2 PDUs that entered the service provider inbound edge switch through the tunnel port or the access port exit through its the trunk port into the service provider network, the switch overwrites the customer PDU-destination MAC address with a well-known Cisco proprietary multicast address (01-00-0c-cd-cd-d0). If 802.1Q tunneling is enabled, packets are also double-tagged; the outer tag is the customer metro tag, and the inner tag is the customer's VLAN tag. The core switches ignore the inner tags and forward the packet to all trunk ports in the same metro VLAN. The edge switches on the outbound side restore the proper Layer 2 protocol and MAC address information and forward the packets to all tunnel or access ports in the same metro VLAN. This section includes these topics. The Layer 2 PDUs remain intact and are delivered across the service provider network to the other side of the customer network.

Figure 31-6 shows Customer A and Customer B in access VLANs 30 and 40. Asymmetric links connect the Customers in Site 1 to edge switches in the service provider network. The Layer 2 PDUs (for example, BPDUs) coming into Switch 2 from Customer B in Site 1 are forwarded to the infrastructure as double-tagged packets with the well-known MAC address as the destination MAC address. These double-tagged packets have the metro VLAN tag of 40, as well as an inner VLAN tag (for example, VLAN 100). When the double-tagged packets enter Switch 4, the metro VLAN tag 40 is removed. The well-known MAC address is replaced with the respective Layer 2 protocol MAC address, and the packet is sent to Customer B on Site 2 as a single-tagged frame in VLAN 100.

You can also enable Layer 2 protocol tunneling on access ports on the edge switch connected to access ports on the customer switch. The encapsulation and de-encapsulation process is the same as described in the previous paragraph, except that the packets are not double-tagged in the service provider network. The single tag is the customer-specific access VLAN tag.

In an SP (service-provider) network, you can use Layer 2 protocol tunneling to enhance the creation of EtherChannels by emulating a point-to-point network topology. When you enable protocol tunneling (PAgP or LACP) on the SP switch, remote customer switches receive the PDUs and can negotiate the automatic creation of EtherChannels.

For example, in the following figure (Layer 2 Protocol Tunneling for EtherChannels), Customer A has two switches in the same VLAN that are connected through the SP network. When the network tunnels PDUs, switches on the far ends of the network can negotiate the automatic creation of EtherChannels without needing dedicated lines.

Figure 31-8 Layer 2 Protocol Tunneling for EtherChannels

This section contains the following subsections:

- [Default Layer 2 Protocol Tunneling Configuration, page 31-16](#)
- [Layer 2 Protocol Tunneling Configuration Guidelines, page 31-16](#)
- [Configuring Layer 2 Tunneling, page 31-17](#)
- [Configuring Layer 2 Tunneling for EtherChannels, page 31-19](#)

Default Layer 2 Protocol Tunneling Configuration

[Table 31-1](#) shows the default configuration for Layer 2 protocol tunneling.

Table 31-1 Default Layer 2 Ethernet Interface VLAN Configuration

Feature	Default Setting
Layer 2 protocol tunneling	Disabled.
Shutdown threshold	None set.
Drop threshold	None set.
CoS value	If a CoS value is configured on the interface for data packets, that value is the default used for Layer 2 PDUs. If none is configured, the default is 5.

Layer 2 Protocol Tunneling Configuration Guidelines

These are some configuration guidelines and operating characteristics of Layer 2 protocol tunneling:

- The switch supports tunneling of CDP, STP, including multiple STP (MSTP), and VTP. Protocol tunneling is disabled by default but can be enabled for the individual protocols on 802.1Q tunnel ports, access ports or trunk ports.
- Dynamic Trunking Protocol (DTP) is not compatible with Layer 2 protocol tunneling because you must manually configure asymmetric links with tunnel ports and trunk ports.

- EtherChannel port groups are compatible with tunnel ports when the 802.1Q configuration is consistent within an EtherChannel port group.
- If an encapsulated PDU (with the proprietary destination MAC address) is received on a port with Layer 2 tunneling enabled, the port is shut down to prevent loops.
- The port also shuts down when a configured shutdown threshold for the protocol is reached. You can manually reenab the port (by entering a **shutdown** and a **no shutdown** command sequence). If errdisable recovery is enabled, the operation is retried after a specified time interval.
- Only decapsulated PDUs are forwarded to the customer network. The spanning-tree instance running on the service provider network does not forward BPDUs to Layer 2 protocol tunneling ports. CDP packets are not forwarded from Layer 2 protocol tunneling ports.
- When protocol tunneling is enabled on an interface, you can set a per-protocol, per-port, shutdown threshold for the PDUs generated by the customer network. If the limit is exceeded, the port shuts down. You can also limit the BPDU rate by using QoS ACLs and policy maps on a Layer 2 protocol tunneling port.
- When protocol tunneling is enabled on an interface, you can set a per-protocol, per-port, drop threshold for the PDUs generated by the customer network. If the limit is exceeded, the port drops PDUs until the rate at which it receives them is below the drop threshold.
- Because tunneled PDUs (especially STP BPDUs) must be delivered to all remote sites so that the customer virtual network operates properly, you can give PDUs higher priority within the service provider network than data packets received from the same tunnel port. By default, the PDUs use the same CoS value as data packets.

**Note**

If Layer 2 protocol tunneling is not configured on a system, Layer 2 protocol tunneling packets are handled as data packets and this situation does not apply.

Configuring Layer 2 Tunneling

To configure a port for Layer 2 protocol tunneling, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode, and enter the interface to be configured as a tunnel port. This should be the edge port in the service provider network that connects to the customer switch. Valid interfaces can be physical interfaces and port-channel logical interfaces (port channels 1 to 64).
Step 3	Switch(config-if)# switchport mode access or Switch(config-if)# switchport mode dot1q-tunnel or Switch(config-if)# switchport mode trunk	Configures the interface as an access port, an 802.1Q tunnel port or a trunk port.
Step 4	Switch(config-if)# l2protocol-tunnel [cdp point-to-point stp stp vtp]	Enables protocol tunneling for the desired protocol. If no keyword is entered, tunneling is enabled for all three Layer 2 protocols.

	Command	Purpose
Step 5	Switch(config-if)# l2protocol-tunnel shutdown-threshold [cdp point-to-point stp vtp] <i>value</i>	(Optional) Configures the threshold for packets-per-second accepted for encapsulation. The interface is disabled if the configured threshold is exceeded. If no protocol option is specified, the threshold applies to each of the tunneled Layer 2 protocol types. The range is 1 to 4096. The default is to have no threshold configured. Note If you also set a drop threshold on this interface, the shutdown-threshold value must be greater than or equal to the drop-threshold value.
Step 6	Switch(config-if)# l2protocol-tunnel drop-threshold [cdp point-to-point stp vtp] <i>value</i>	(Optional) Configures the threshold for packets-per-second accepted for encapsulation. The interface drops packets if the configured threshold is exceeded. If no protocol option is specified, the threshold applies to each of the tunneled Layer 2 protocol types. The range is 1 to 4096. The default is to have no threshold configured. Note If you also set a shutdown threshold on this interface, the drop-threshold value must be less than or equal to the shutdown-threshold value.
Step 7	Switch(config-if)# exit	Returns to global configuration mode.
Step 8	Switch(config)# errdisable recovery cause l2ptguard	(Optional) Configures the recovery method from a Layer 2 maximum-rate error so that the interface is reenabled and can try again. Errdisable recovery is disabled by default; when enabled, the default time interval is 300 seconds.
Step 9	Switch(config)# l2protocol-tunnel cos <i>value</i>	(Optional) Configures the CoS value for all tunneled Layer 2 PDUs. The range is 0 to 7; the default is the default CoS value for the interface. If none is configured, the default is 5.
Step 10	Switch(config)# end	Returns to privileged EXEC mode.
Step 11	Switch# show l2protocol	Displays the Layer 2 tunnel ports on the switch, including the protocols configured, the thresholds, and the counters.
Step 12	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no l2protocol-tunnel [cdp | stp | vtp]** interface configuration command to disable protocol tunneling for one of the Layer 2 protocols or for all three. Use the **no l2protocol-tunnel shutdown-threshold [cdp | stp | vtp]** and the **no l2protocol-tunnel drop-threshold [cdp | stp | vtp]** commands to return the shutdown and drop thresholds to the default settings.

This example shows how to configure Layer 2 protocol tunneling on an 802.1Q tunnel port for CDP, STP, VTP, and LLDP and how to verify the configuration:

```
Switch(config)# interface FastEthernet 1/1/11
Switch(config-if)# switchport mode dot1q-tunnel
Switch(config-if)# l2protocol-tunnel cdp
Switch(config-if)# l2protocol-tunnel stp
Switch(config-if)# l2protocol-tunnel vtp
Switch(config-if)# l2protocol-tunnel llbp
Switch(config-if)# l2protocol-tunnel shutdown-threshold 1500
Switch(config-if)# l2protocol-tunnel drop-threshold 1000
Switch(config-if)# exit
Switch(config)# l2protocol-tunnel cos 7
Switch(config)# end
Switch# show l2protocol
COS for Encapsulated Packets: 7
```

Drop Threshold for Encapsulated Packets: 0

Port	Protocol	Shutdown Threshold	Drop Threshold	Encaps Counter	Decaps Counter	Drop Counter
Gi1/1/11	cdp	1500	1000	2288	2282	0
	lldp	1500	1000	0	0	0
	stp	1500	1000	116	13	0
	vtp	1500	1000	3	67	0
---	---	----	----	----	----	----
---	---	----	----	----	----	----
---	---	----	----	----	----	----

Configuring Layer 2 Tunneling for EtherChannels

To configure Layer 2 point-to-point tunneling to facilitate the automatic creation of EtherChannels, you need to configure both the SP edge switch and the customer switch. This section includes the following tasks:

- [Configuring the SP Edge Switch, page 31-19](#)
- [Configuring the Customer Switch, page 31-21](#)

Configuring the SP Edge Switch

	Command	Purpose
Step 1	Switch# configure terminal	Enters the global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode. Enter the interface to be configured as a tunnel port. This should be the edge port in the service provider network that connects to the customer switch.
Step 3	Switch(config-if)# switchport mode dot1q-tunnel	Configures the interface as an 802.1Q tunnel port
Step 4	Switch(config-if)# l2protocol-tunnel point-to-point [pagp lacp udld]	(Optional) Enables point-to-point protocol tunneling for the desired protocol. If no keyword is entered, tunneling is enabled for all three protocols.
		 Caution To avoid a network failure, make sure that the network is a point-to-point topology before you enable tunneling for PAgP, LACP, or UDLD packets.
Step 5	Switch(config-if)# l2protocol-tunnel shutdown-threshold [point-to-point [pagp lacp udld]] <i>value</i>	(Optional) Configures the threshold for packets-per-second accepted for encapsulation. The interface is disabled if the configured threshold is exceeded. If no protocol option is specified, the threshold applies to each of the tunneled Layer 2 protocol types. The range is 1 to 4096. The default is to have no threshold configured.
		Note If you also set a drop threshold on this interface, the shutdown-threshold value must be greater than or equal to the drop-threshold value.

	Command	Purpose
Step 6	Switch(config-if)# l2protocol-tunnel drop-threshold [point-to-point [pagp lacp udld]] value	(Optional) Configures the threshold for packets-per-second accepted for encapsulation. The interface drops packets if the configured threshold is exceeded. If no protocol option is specified, the threshold applies to each of the tunneled Layer 2 protocol types. The range is 1 to 4096. The default is to have no threshold configured. Note If you also set a shutdown threshold on this interface, the drop-threshold value must be less than or equal to the shutdown-threshold value.
Step 7	Switch(config-if)# no cdp enable	Disables CDP on the interface.
Step 8	Switch(config-if)# spanning-tree bpdufilter	Enables BPDU filtering on the interface.
Step 9	Switch(config)# exit	Returns to global configuration mode.
Step 10	Switch(config)# errdisable recovery cause l2ptguard	(Optional) Configures the recovery mechanism from a Layer 2 maximum-rate error so that the interface is re-enabled and can try again. Errdisable recovery is disabled by default; when enabled, the default time interval is 300 seconds.
Step 11	Switch(config)# l2protocol-tunnel cos value	(Optional) Configures the CoS value for all tunneled Layer 2 PDUs. The range is 0 to 7; the default is the default CoS value for the interface. If none is configured, the default is 5.
Step 12	Switch(config)# end	Returns to privileged EXEC mode.
Step 13	Switch# show l2protocol	Displays the Layer 2 tunnel ports on the switch, including the protocols configured, the thresholds, and the counters.
Step 14	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no l2protocol-tunnel [point-to-point [pagp | lacp | udld]]** interface configuration command to disable point-to-point protocol tunneling for one of the Layer 2 protocols or for all three. Use the **no l2protocol-tunnel shutdown-threshold [point-to-point [pagp | lacp | udld]]** and the **no l2protocol-tunnel drop-threshold [point-to-point [pagp | lacp | udld]]** commands to return the shutdown and drop thresholds to their default settings.

This example shows how to configure the SP edge switch:

```
Switch(config)# interface gigabitEthernet 1/1/11
Switch(config-if)# switchport mode dot1q-tunnel
Switch(config-if)# switchport access vlan 10
Switch(config-if)# l2protocol-tunnel point-to-point
Switch(config-if)# l2protocol-tunnel shutdown-threshold point-to-point 3000
Switch(config-if)# l2protocol-tunnel drop-threshold point-to-point 2500
Switch(config-if)# exit
Switch# show l2protocol-tunnel
COS for Encapsulated Packets: 5
Drop Threshold for Encapsulated Packets: 0
```

Port	Protocol	Shutdown Threshold	Drop Threshold	Encaps Counter	Decaps Counter	Drop Counter
Gi1/1/11	---	----	----	----	----	----
	---	----	----	----	----	----
	---	----	----	----	----	----
	---	----	----	----	----	----

pagp	3000	2500	0	0	0
lacp	3000	2500	0	0	0
udld	3000	2500	0	0	0

Configuring the Customer Switch

	Command	Purpose
Step 1	Switch# configure terminal	Enters the global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode. Enter the interface to be configured as a tunnel port.
Step 3	Switch(config-if)# switchport mode trunk	Enables trunking on the interface.
Step 4	Switch(config-if)# udld enable	Enables UDLD in normal mode on the interface
Step 5	Switch(config-if)# channel-group <i>channel-group-number</i> mode desirable	Assigns the interface to a channel group, and specifies desirable for the PAgP mode.
Step 6	Switch(config-if)# exit	Returns to global configuration mode.
Step 7	Switch(config)# interface port-channel <i>port-channel number</i>	Enters port-channel interface mode.
Step 8	Switch(config-if)# shutdown	Shuts down the interface.
Step 9	Switch(config-if)# no shutdown	Enables the interface.
Step 10	Switch(config-if)# end	Returns to global configuration mode.
Step 11	Switch# show l2protocol	Displays the Layer 2 tunnel ports on the switch, including the protocols configured, the thresholds, and the counters.
Step 12	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no switchport mode trunk**, the **no udld enable**, and the **no channel group channel-group-number mode desirable** interface configuration commands to restore default interface settings.

This example shows you how to configure a customer switch:

```
Switch(config)# interface gigabitEthernet 2/14
Switch(config-if)# switchport mode trunk
Switch(config-if)# udld port
Switch(config-if)# channel-group 10 mode desirable
Switch(config-if)# exit
```

This example shows how to configure the SP edge switch 1 and edge switch 2. VLANs 17, 18, 19, and 20 are the access VLANs, Gigabit Ethernet interfaces 1/1/11 and 1/1/12 are point-to-point tunnel ports with PAgP and UDLD enabled, the drop threshold is 1000, and Fast Ethernet interface 1/1/13 is a trunk port.

SP edge switch 1 configuration:

```
Switch(config)# interface gigabitEthernet 1/1/11
Switch(config-if)# switchport access vlan 17
Switch(config-if)# switchport mode dot1q-tunnel
Switch(config-if)# l2protocol-tunnel point-to-point pagp
```

```

Switch(config-if)# l2protocol-tunnel point-to-point udld
Switch(config-if)# l2protocol-tunnel drop-threshold point-to-point pagp 1000
Switch(config-if)# exit
Switch(config)# interface gigabitEthernet 1/1/12
Switch(config-if)# switchport access vlan 18
Switch(config-if)# switchport mode dot1q-tunnel
Switch(config-if)# l2protocol-tunnel point-to-point pagp
Switch(config-if)# l2protocol-tunnel point-to-point udld
Switch(config-if)# l2protocol-tunnel drop-threshold point-to-point pagp 1000
Switch(config-if)# exit
Switch(config)# interface gigabitEthernet 1/1/13
Switch(config-if)# switchport mode trunk

```

SP edge switch 2 configuration:

```

Switch(config)# interface gigabitEthernet 1/1/11
Switch(config-if)# switchport access vlan 19
Switch(config-if)# switchport mode dot1q-tunnel
Switch(config-if)# l2protocol-tunnel point-to-point pagp
Switch(config-if)# l2protocol-tunnel point-to-point udld
Switch(config-if)# l2protocol-tunnel drop-threshold point-to-point pagp 1000
Switch(config-if)# exit
Switch(config)# interface gigabitEthernet 1/1/12
Switch(config-if)# switchport access vlan 20
Switch(config-if)# switchport mode dot1q-tunnel
Switch(config-if)# l2protocol-tunnel point-to-point pagp
Switch(config-if)# l2protocol-tunnel point-to-point udld
Switch(config-if)# l2protocol-tunnel drop-threshold point-to-point pagp 1000
Switch(config-if)# exit
Switch(config)# interface gigabitEthernet 1/1/13
Switch(config-if)# switchport mode trunk

```

This example shows how to configure the customer switch at Site 1. Gigabit Ethernet interfaces 1/1, 1/2, 1/3, and 1/4 are set for 802.1Q trunking, UDLD is enabled, EtherChannel group 1 is enabled, and the port channel is shut down and then enabled to activate EtherChannel configuration. See also [Figure 31-8](#).

```

Switch(config)# interface GigabitEthernet1/1
Switch(config-if)# switchport mode trunk
Switch(config-if)# udld enable
Switch(config-if)# channel-group 1 mode desirable
Switch(config-if)# exit
Switch(config)# interface GigabitEthernet1/2
Switch(config-if)# switchport mode trunk
Switch(config-if)# udld enable
Switch(config-if)# channel-group 1 mode desirable
Switch(config-if)# exit
Switch(config)# interface GigabitEthernet1/3
Switch(config-if)# switchport mode trunk
Switch(config-if)# udld enable
Switch(config-if)# channel-group 1 mode desirable
Switch(config-if)# exit
Switch(config)# interface GigabitEthernet1/4
Switch(config-if)# switchport mode trunk
Switch(config-if)# udld enable
Switch(config-if)# channel-group 1 mode desirable
Switch(config-if)# exit
Switch(config)# interface port-channel 1
Switch(config-if)# shutdown
Switch(config-if)# no shutdown
Switch(config-if)# exit

```

Monitoring and Maintaining Tunneling Status

Table 31-2 shows the commands for monitoring and maintaining 802.1Q and Layer 2 protocol tunneling.

Table 31-2 Commands for Monitoring and Maintaining Tunneling

Command	Purpose
Switch# clear l2protocol-tunnel counters	Clears the protocol counters on Layer 2 protocol tunneling ports.
Switch# show dot1q-tunnel	Displays 802.1Q tunnel ports on the switch.
Switch# show dot1q-tunnel interface interface-id	Verifies if a specific interface is a tunnel port.
Switch# show l2protocol-tunnel	Displays information about Layer 2 protocol tunneling ports.
Switch# show errdisable recovery	Verifies if the recovery timer from a Layer 2 protocol-tunnel error disable state is enabled.
Switch# show l2protocol-tunnel interface interface-id	Displays information about a specific Layer 2 protocol tunneling port.
Switch# show l2protocol-tunnel summary	Displays only Layer 2 protocol summary information.
Switch# show vlan dot1q native	Displays the status of native VLAN tagging on the switch.

Note

With Cisco IOS Release 12.2(20)EW, the BPDU filtering configuration for both dot1q and Layer 2 protocol tunneling is no longer visible in the running configuration as spanning-tree bpdupfilter enable. The configuration is visible in the output of the **show spanning tree int detail** command.

```
Switch# show spann int f6/1 detail
Port 321 (FastEthernet6/1) of VLAN0001 is listening
  Port path cost 19, Port priority 128, Port Identifier 128.321.
  Designated root has priority 32768, address 0008.e341.4600
  Designated bridge has priority 32768, address 0008.e341.4600
  Designated port id is 128.321, designated path cost 0
  Timers: message age 0, forward delay 2, hold 0
  Number of transitions to forwarding state: 0
  Link type is point-to-point by default
  ** Bpdu filter is enabled internally **
  BPDU: sent 0, received 0
```

Configuring Cisco Discovery Protocol

This chapter describes how to configure Cisco Discovery Protocol and Cisco Discovery Protocol Bypass on the Catalyst 4006 switch with Supervisor Engine III. It also provides guidelines, procedures, and configuration examples.

This chapter includes the following major sections:

- [About Cisco Discovery Protocol, page 32-2](#)
- [Configuring Cisco Discovery Protocol, page 32-2](#)
- [About Cisco Discovery Protocol Bypass, page 32-5](#)
- [Configuring Cisco Discovery Protocol Bypass, page 32-5](#)

Note

For complete syntax and usage information for the Cisco IOS commands used in this chapter, refer to the *Cisco IOS Configuration Fundamentals Configuration Guide*, Release 12.4:

http://www.cisco.com/en/US/docs/ios/fundamentals/configuration/guide/12_4/cf_12_4_book.html

and the *Cisco IOS Configuration Fundamentals Command Reference*, Release 12.2:

http://www.cisco.com/en/US/docs/ios/12_2/configfun/command/reference/ffun_r.html

Note

For complete syntax and usage information for the switch commands used in this chapter, see the *Cisco Catalyst 4500 Series Switch Command Reference* and related publications at this location:

<http://www.cisco.com/en/US/products/hw/switches/ps4324/index.html>

If a command is not in the *Catalyst 4500 Series Switch Command Reference*, you can locate it in the Cisco IOS library. See the *Command Reference for the Catalyst 4006 Switch with Supervisor Engine III* and related publications at this location:

<http://www.cisco.com/en/US/products/ps6350/index.html>

About Cisco Discovery Protocol

Cisco Discovery Protocol is a protocol that runs over Layer 2 (the data link layer) on all Cisco routers, bridges, access servers, and switches. Cisco Discovery Protocol allows network management applications to discover Cisco devices that are neighbors of already known devices, in particular, neighbors running lower-layer, transparent protocols. With Cisco Discovery Protocol, network management applications can learn the device type and the SNMP agent address of neighboring devices. Cisco Discovery Protocol enables applications to send SNMP queries to neighboring devices.

Cisco Discovery Protocol runs on all LAN and WAN media that support Subnetwork Access Protocol (SNAP).

Each Cisco Discovery Protocol-configured device sends periodic messages to a multi-cast address. Each device advertises at least one address at which it can receive SNMP messages. The advertisements also contain the time-to-live, or holdtime information, which indicates the length of time a receiving device should hold Cisco Discovery Protocol information before discarding it.

Configuring Cisco Discovery Protocol

The following sections describe how to configure Cisco Discovery Protocol:

- [Enabling Cisco Discovery Protocol Globally, page 32-2](#)
- [Displaying the Cisco Discovery Protocol Global Configuration, page 32-2](#)
- [Enabling Cisco Discovery Protocol on an Interface, page 32-3](#)
- [Displaying the Cisco Discovery Protocol Interface Configuration, page 32-3](#)
- [Monitoring and Maintaining Cisco Discovery Protocol, page 32-4](#)

Enabling Cisco Discovery Protocol Globally

To enable Cisco Discovery Protocol globally, use this command:

Command	Purpose
Switch(config)# [no] cdp run	Enables Cisco Discovery Protocol globally. Use the no keyword to disable Cisco Discovery Protocol globally.

This example shows how to enable Cisco Discovery Protocol globally:

```
Switch(config)# cdp run
```

Displaying the Cisco Discovery Protocol Global Configuration

To display the Cisco Discovery Protocol configuration, use this command:

Command	Purpose
Switch# show cdp	Displays global Cisco Discovery Protocol information.

This example shows how to display the Cisco Discovery Protocol configuration:

```
Switch# show cdp
Global Cisco Discovery Protocol information:
    Sending CDP packets every 120 seconds
    Sending a holdtime value of 180 seconds
    Sending CDPv2 advertisements is enabled
Switch#
```

For additional Cisco Discovery Protocol **show** commands, see the [“Monitoring and Maintaining Cisco Discovery Protocol”](#) section on page 32-4.

Enabling Cisco Discovery Protocol on an Interface

To enable Cisco Discovery Protocol on an interface, use this command:

Command	Purpose
Switch(config-if)# [no] cdp enable	Enables Cisco Discovery Protocol on an interface. Use the no keyword to disable Cisco Discovery Protocol on an interface.

This example shows how to enable Cisco Discovery Protocol on Fast Ethernet interface 5/1:

```
Switch(config)# interface fastethernet 5/1
Switch(config-if)# cdp enable
```

This example shows how to disable Cisco Discovery Protocol on Fast Ethernet interface 5/1:

```
Switch(config)# interface fastethernet 5/1
Switch(config-if)# no cdp enable
```

Displaying the Cisco Discovery Protocol Interface Configuration

To display the Cisco Discovery Protocol configuration for an interface, use this command:

Command	Purpose
Switch# show cdp interface <i>[type/number]</i>	Displays information about interfaces where Cisco Discovery Protocol is enabled.

This example shows how to display the Cisco Discovery Protocol configuration of Fast Ethernet interface 5/1:

```
Switch# show cdp interface fastethernet 5/1
FastEthernet5/1 is up, line protocol is up
    Encapsulation ARPA
```

```

Sending CDP packets every 120 seconds
Holdtime is 180 seconds
Switch#

```

Monitoring and Maintaining Cisco Discovery Protocol

To monitor and maintain Cisco Discovery Protocol on your device, enter one or more of the following commands:

Command	Purpose
Switch# clear cdp counters	Resets the traffic counters to zero.
Switch# clear cdp table	Deletes the Cisco Discovery Protocol table of information about neighbors.
Switch# show cdp	Displays global information such as frequency of transmissions and the holdtime for packets being transmitted.
Switch# show cdp entry <i>entry_name</i> [protocol version]	Displays information about a specific neighbor. The display can be limited to protocol or version information.
Switch# show cdp interface [<i>type/number</i>]	Displays information about interfaces on which Cisco Discovery Protocol is enabled.
Switch# show cdp neighbors [<i>type/number</i>] [detail]	Displays information about neighboring equipment. The display can be limited to neighbors on a specific interface and expanded to provide more detailed information.
Switch# show cdp traffic	Displays Cisco Discovery Protocol counters, including the number of packets sent and received and checksum errors.
Switch# show debugging	Displays information about the types of debugging that are enabled for your switch.

This example shows how to clear the Cisco Discovery Protocol counter configuration on your switch:

```
Switch# clear cdp counters
```

This example shows how to display information about the neighboring equipment:

```
Switch# show cdp neighbors
```

```

Capability Codes: R - Router, T - Trans Bridge, B - Source Route Bridge
                  S - Switch, H - Host, I - IGMP, r - Repeater

```

Device ID	Local Intrfce	Holdtme	Capability	Platform	Port ID

About Cisco Discovery Protocol Bypass

When a Cisco IP Phone is plugged into a port that is configured with a Voice VLAN and single-host mode, the phone will be silently allowed onto the network by way of a feature known as Cisco Discovery Protocol Bypass. The phone (or any device) that sends the appropriate Type Length Value (TLV) in a Cisco Discovery Protocol message will be allowed access to the voice VLAN.

In Cisco Discovery Protocol Bypass mode, Cisco Discovery Protocol packets are received and transmitted unchanged. Received packets are not processed. No packets are generated. In this mode, 'bump-in-the-wire' behavior is applied to Cisco Discovery Protocol packets. This is a backward compatible mode, equivalent to not having Cisco Discovery Protocol support.

In Cisco Discovery Protocol Bypass mode authentication sessions are established in single and multi-host modes for IP Phones. However, if voice VLAN and 802.1x on an interface port is enabled, then Cisco Discovery Protocol Bypass is enabled when the host mode is set to single or multi-host mode.

It is possible to use the Multi-Domain Authentication (MDA) feature instead of Cisco Discovery Protocol Bypass feature as it provides better Access Control, Visibility and Authorization.

**Note**

By default the host mode is set to single mode in legacy mode and multi-authentication in the edge mode.

Cisco Discovery Protocol Enhancement for Second Port Disconnect—Allows a Cisco IP phone to send a Cisco Discovery Protocol message to the switch when a host unplugs from behind the phone. The switch is then able to clear any authenticated session for the indirectly connected host, the same as if the host had been directly connected and the switch had detected a link down event. This is supported in latest IP telephones.

Cisco Discovery Protocol Bypass provides no support for third-party phones—Cisco Discovery Protocol Bypass works only with Cisco phones.

Configuring Cisco Discovery Protocol Bypass

The following sections describe how to configure Cisco Discovery Protocol Bypass

- [Enabling Cisco Discovery Protocol Bypass, page 32-6](#)
- [Displaying Cisco Discovery Protocol Neighbors, page 32-7](#)
- [Disabling Cisco Discovery Protocol Bypass, page 32-7](#)

Enabling Cisco Discovery Protocol Bypass

To enable Cisco Discovery Protocol Bypass, use these commands:

Command	Purpose
enable Example: Switch> enable	Enables privileged EXEC mode. Enter your password if prompted.
configure terminal Example: Switch# configure terminal	Enters the global configuration mode.
interface <i>interface-id</i> Example: Switch(config)# interface GigabitEthernet1/0/12	Specifies a physical port, and enters interface configuration mode. Valid interfaces are physical ports.
switchport mode access Example: Switch(config-if)# switchport mode access	Specifies that the interface is in access mode.
switchport access vlan <i>vlan id</i> Example: Switch(config-if)# switchport access vlan 10	Assigns all ports as static-access ports in the same VLAN If you configure the port as a static-access port, assign it to only one VLAN. The range is 1 to 4094.
switchport voice vlan <i>vlan-id</i> Example: Switch(config-if)# switchport voice vlan 3	Instruct the Cisco IP phone to forward all voice traffic through the specified VLAN. By default, the Cisco IP phone forwards the voice traffic with an 802.1Q priority of 5. Valid VLAN IDs are from 1 to 4094 when the enhanced software image (EI) is installed and 1 to 1001 when the standard software image is installed. Do not enter leading zeros.
authentication port-control auto Example: Switch(config-if)# authentication port-control auto	Enables 802.1x authentication on the port.

Command	Purpose
authentication host-mode {single-host multi-host} Example: Switch(config-if)# authentication host-mode single multi-host	The keywords allow the following: single-host -Single host (client) on an IEEE 802.1X-authorized port. multi-host -Multiple hosts on an 802.1X-authorized port after authenticating a single host.
dot1x pae authenticator or mab Example: Switch(config-if)# dot1x pae authenticator or Switch(config-if)# mab	Enables 802.1X authentication on the port with default parameters

Cisco Discovery Protocol Bypass is enabled by default once **authentication port-control auto** is configured with dot1x or MAB or if voice vlan is configured on the interface along with single/multiple host mode.

Displaying Cisco Discovery Protocol Neighbors

The following configuration example displays Cisco Discovery Protocol neighbors.

```
Switch# show cdp neighbors g1/0/37 detail
Switch ID: SEP24B657B038DF
Entry address(es):
Platform: Cisco IP Phone 9971, Capabilities: Host Phone Two-port Mac Relay Interface:
GigabitEthernet1/0/37, Port ID (outgoing port): Port 1 Holdtime : 157 sec
Second Port Status: Down<<

Disabling Cisco Discovery Protocol Bypass

To disable Cisco Discovery Protocol Bypass, enter the **no authentication port-control auto** command in interface configuration mode.

Configuring LLDP, LLDP-MED, and Location Service

This chapter describes how to configure the Link Layer Discovery Protocol (LLDP), LLDP Media Endpoint Discovery (LLDP-MED), and Location Service on the Catalyst 4500 series switch.

This chapter consists of these sections:

- [About LLDP, LLDP-MED, and Location Service, page 33-1](#)
- [Configuring LLDP and LLDP-MED, and Location Service, page 33-4](#)
- [Monitoring and Maintaining LLDP, LLDP-MED, and Location Service, page 33-14](#)
- [Cisco IOS Carries Ethernet Features in Cisco IOS XE 3.1.0SG, page 33-15](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Configuration Fundamentals Command Reference](#) and the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About LLDP, LLDP-MED, and Location Service

This section describes this information:

- [Restrictions for LLDP, page 33-1](#)
- [LLDP, page 33-2](#)
- [LLDP-MED, page 33-2](#)
- [Location Service, page 33-3](#)

Restrictions for LLDP

When Cisco Discovery Protocol and LLDP are both in use within the same switch, it is necessary to disable LLDP on interfaces where Cisco Discover Protocol is in use for power negotiation. LLDP can be disabled at interface level with the commands **no lldp tlv-select power-management** or **no lldp transmit / no lldp receive**.

LLDP

The Cisco Discovery Protocol (CDP) is a device discovery protocol that runs over Layer 2 (the data link layer) on all Cisco-manufactured devices (routers, bridges, access servers, and switches). CDP allows network management applications to automatically discover and learn about other Cisco devices connected to the network.

To support non-Cisco devices and to allow for interoperability between other devices, the switch supports the IEEE 802.1AB LLDP. LLDP is a neighbor discovery protocol that is used for network devices to advertise information about themselves to other devices on the network. This protocol runs over the data-link layer, which allows two systems running different network layer protocols to learn about each other.

LLDP supports a set of attributes that it uses to discover neighbor devices. These attributes contain type, length, and value descriptions and are referred to as *TLVs*. LLDP supported devices can use TLVs to receive and send information to their neighbors. Details such as configuration information, device capabilities, and device identity can be advertised using this protocol.

The switch supports the following basic management TLVs (which are optional):

- Port description TLV
- System name TLV
- System description TLV
- System capabilities TLV
- Management address TLV
- Power Management TLV

These organizationally specific LLDP TLVs are also advertised to support LLDP-MED:

- Port VLAN ID TLV ((IEEE 802.1 specific TLVs)
- MAC/PHY configuration/status TLV(IEEE 802.3 specific TLVs)

LLDP-MED

LLDP for Media Endpoint Devices (LLDP-MED) is an extension to LLDP that operates between endpoint devices such as IP phones and network devices such as switches. It specifically provides support for voice over IP (VoIP) applications and provides additional TLVs for capabilities discovery, network policy, power over Ethernet (PoE), inventory management, and location information. By default, all LLDP-MED TLVs are enabled.

LLDP-MED supports these TLVs:

- LLDP-MED capabilities TLV

Allows LLDP-MED endpoints to determine the capabilities that the connected device supports and what capabilities the device has enabled.

For configuration details, see the [“Configuring Network-Policy Profile” section on page 33-9](#).

- Network policy profile

Allows both network connectivity devices and endpoints to advertise VLAN configurations and associated Layer 2 and Layer 3 attributes for the specific application on that port. For example, the switch can notify a phone of the VLAN number that it should use. The phone can connect into any switch, obtain its VLAN number, and then start communicating with the call control.

By defining a network-policy profile TLV, you can create a profile for voice and voice-signalling by specifying the values for VLAN, class of service (CoS), differentiated services code point (DSCP), and tagging mode. These profile attributes are then maintained centrally on the switch and propagated to the phone.

For configuration details, see the [“Configuring Network-Policy Profile” section on page 33-9](#).

- Power management TLV

Enables advanced power management between LLDP-MED endpoint and network connectivity devices. Allows switches and phones to convey power information, such as how the device is powered, power priority, and how much power the device needs.

For configuration details, see the [“Configuring LLDP Power Negotiation” section on page 33-11](#).

- Inventory management TLV

Allows an endpoint to send detailed inventory information about itself to the switch, including information hardware revision, firmware version, software version, serial number, manufacturer name, model name, and asset ID TLV.

- Location TLV

Provides location information from the switch to the endpoint device. The location TLV can send this information:

- Civic location information

Provides the civic address information and postal information. Examples of civic location information are street address, road name, and postal community name information.

- ELIN location information

Provides the location information for a caller. The location is determined by the emergency location identifier number (ELIN), which is a phone number that routes an emergency call to the local public safety answering point (PSAP) and which the PSAP can use to call back the emergency caller.

For configuration details, see the [“Configuring Location TLV and Location Service” section on page 33-12](#).

**Note**

A switch cannot send LLDP and LLDP-MED simultaneously to an end-point device. By default, a network device sends only LLDP packets until it receives LLDP-MED packets from an end-point device. The network device then sends LLDP-MED packets until it receives only LLDP packets.

Location Service

The location service feature enables the switch to provide location and attachment tracking information for its connected devices to a Cisco Mobility Services Engine (MSE). The tracked device can be a wireless endpoint, a wired endpoint, or a wired switch or controller. The switch informs device link up and link-down events through Network Mobility Services Protocol (NMSP) location and attachment notifications to the MSE.

The MSE initiates the NMSP connection to the switch. When the MSE connects to the switch messages are exchanged to establish version compatibility, service exchange, and location information synchronization. After the connection is established, the switch sends location and attachment notifications periodically to the MSE. Any link-up event, link-down event, or location configuration change detected during the interval are aggregated and sent at the end of the interval using attachment or location notifications.

When the switch discovers the presence or absence of a device on a link-up or link-down event on a port, it obtains the client's MAC address, IP address, and 802.1x username if applicable. If the device is LLDP-MED or CDP enabled, the switch continues to gather client-specific information such as the model number and software version.

Depending on the device capabilities, the switch obtains this client attachment information at link up:

- Slot, port, and port-type
- Client's MAC address
- Client's IP address
- 802.1X username if applicable
- Device category is specified as a *wired station*
- State is specified as *Connected*
- Serial number, UDI
- Model number
- Software version
- VLAN ID and VLAN name

Depending on the device capabilities, the switch obtains this client information at link down:

- Slot and port that was disconnected
- Client's MAC address
- Client's IP address
- 802.1X username if applicable
- Device category is specified as a *wired station*
- State is specified as *Disconnected*
- Serial number, UDI
- Model number
- Software version
- VLAN ID and VLAN name

If an administrator changes a location address at the switch, the information is reported to the MSE. The switch sends a NMSP location notification message that identifies the list of ports affected by the change and the changed address information.

Configuring LLDP and LLDP-MED, and Location Service

This section contains this configuration information:

- [Default LLDP Configuration, page 33-5](#)
- [Configuring LLDP Characteristics, page 33-5](#)
- [Disabling and Enabling LLDP Globally, page 33-6](#)
- [Disabling and Enabling LLDP on an Interface, page 33-7](#)
- [Configuring LLDP-MED TLVs, page 33-8](#)
- [Configuring Network-Policy Profile, page 33-9](#)

- [Configuring LLDP Power Negotiation, page 33-11](#)
- [Configuring Location TLV and Location Service, page 33-12](#)
- [Monitoring and Maintaining LLDP, LLDP-MED, and Location Service, page 33-14](#)

Default LLDP Configuration

Table 33-1 shows the default LLDP configuration. To change the default settings, use the LLDP global configuration and LLDP interface configuration commands.

Table 33-1 **Default LLDP Configuration**

Feature	Default Setting
LLDP global state	Disabled
LLDP holdtime (before discarding)	120 seconds
LLDP timer (packet update frequency)	30 seconds
LLDP reinitialization delay	2 seconds
LLDP tlv-select	Enabled to send and receive all TLVs
LLDP interface state	Enabled
LLDP receive	Enabled
LLDP transmit	Enabled
LLDP med-tlv-select	Enabled to send all LLDP-MED TLVs

Configuring LLDP Characteristics

You can configure the frequency of LLDP updates, the amount of time to hold the information before discarding it, the initialization delay time. You can also select the LLDP and LLDP-MED TLVs for sending and receiving. The location service feature is available only when the switch is running the cryptographic (encrypted) software image.

To configure these characteristics, perform this task:

Note

Steps 2 through 5 can be performed in any order.

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# lldp holdtime <i>seconds</i>	(Optional) Specifies the amount of time a receiving device should hold the information sent by your device before discarding it. The range is 0 to 65535 seconds; the default is 120 seconds.
Step 3	Switch(config)# lldp reinit	(Optional) Specifies the delay time in seconds for LLDP to initialize on any interface. The range is 2 to 5 seconds; the default is 2 seconds.

	Command	Purpose
Step 4	Switch(config)# lldp timer <i>seconds</i>	(Optional) Sets the transmission frequency of LLDP updates in seconds. The range is 5 to 65534 seconds; the default is 30 seconds.
Step 5	Switch(config)# lldp tlv-select	(Optional) Specifies the LLDP TLVs to send or receive.
Step 6	Switch(config)# copy running-config startup-config	Saves your entries in the configuration file.
Step 7	Switch(config)# lldp med-tlv-select	(Optional) Specifies the LLDP-MED TLVs to send or receive.

Note

Use the **no** form of each of the LLDP commands to return to the default setting.

This example shows how to configure a holdtime of 120 seconds, a delay time of 2 seconds and an update frequency of 30:

```
Switch# configure terminal
Switch(config)# lldp holdtime 120
Switch(config)# lldp reinit 2
Switch(config)# lldp timer 30
Switch(config)# end
```

This example shows how to transmit only LLDP packets:

```
Switch# configure terminal
Switch(config)# no lldp receive
Switch(config)# end
```

This example shows how to receive LLDP packets again:

```
Switch# configure terminal
Switch(config)# lldp receive
Switch(config)# end
```

For additional LLDP **show** commands, see the [“Monitoring and Maintaining LLDP, LLDP-MED, and Location Service”](#) section on page 33-14.

Disabling and Enabling LLDP Globally

Note

LLDP is disabled by default.

To disable LLDP globally, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# no lldp run	Disables LLDP.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.

To enable LLDP once it has been disabled, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# lldp run	Enables LLDP.
Step 3	Switch(config)# end	Returns to privileged EXEC mode.

This example shows how to globally disable LLDP:

```
Switch# configure terminal
Switch(config)# no lldp run
Switch(config)# end
```

This example shows how to globally enable LLDP:

```
Switch# configure terminal
Switch(config)# lldp run
Switch(config)# end
```

Disabling and Enabling LLDP on an Interface

LLDP is disabled globally on all supported interfaces. You must enable LLDP globally to allow a device to send LLDP packets. However, no changes are required at the interface level.

You can configure the interface to selectively not to send and receive LLDP packets with the **no lldp transmit** and **no lldp receive** commands.

Note

If the interface is configured as a tunnel port, LLDP is automatically disabled.

To disable LLDP on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface-id	Specifies the interface on which you are disabling LLDP, and enter interface configuration mode.
Step 3	Switch(config)# no lldp transmit	Disallows sending LLDP packets on the interface.
Step 4	Switch(config)# no lldp receive	Disallows receiving LLDP packets on the interface.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch(config)# copy running-config startup-config	Saves your entries in the configuration file.

To enable LLDP on an interface once it has been disabled, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface-id	Specifies the interface on which you are enabling LLDP, and enter interface configuration mode.

	Command	Purpose
Step 3	Switch(config)# lldp transmit	Sends LLDP packets on the interface.
Step 4	Switch(config)# lldp receive	Receives LLDP packets on the interface.
Step 5	Switch(config)# end	Returns to privileged EXEC mode.
Step 6	Switch# copy running-config startup-config	Saves your entries in the configuration file.

This example shows how to enable LLDP on an interface:

```
Switch# configure terminal
Switch(config)# interface GigabitEthernet 1/1
Switch(config-if)# lldp transmit
Switch(config-if)# lldp receive
Switch(config-if)# end
```

Configuring LLDP-MED TLVs

By default, the switch only sends LLDP packets until it receives LLDP-MED packets from the end device. The switch continues to send LLDP-MED packets until it only receives LLDP packets.

By using the **lldp** interface configuration command, you can configure the interface not to send the TLVs listed in [Table 33-2](#).

Table 33-2 LLDP-MED TLVs

LLDP-MED TLV	Description
inventory-management	LLDP-MED inventory management TLV
location	LLDP-MED location TLV
network-policy	LLDP-MED network policy TLV
power-management	LLDP-MED power management TLV

To disable a TLV on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface-id	Specifies the interface on which you are configuring a LLDP-MED TLV, and enter interface configuration mode.
Step 3	Switch(config-if)# no lldp med-tlv-select tlv	Specifies the TLV to disable.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

To enable a TLV on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Specifies the interface on which you are configuring an LLDP-MED TLV, and enter interface configuration mode.
Step 3	Switch(config-if)# lldp med-tlv-select <i>tlv</i>	Specifies the TLV to enable.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable a TLV on an interface when it has been disabled:

```
Switch# configure terminal
Switch(config)# interface GigabitEthernet0/1
Switch(config-if)# lldp med-tlv-select inventory management
Switch(config-if)# end
```

Configuring Network-Policy Profile

To create a network-policy profile, configure the policy attributes, and apply it to an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# network-policy profile <i>profile number</i>	Specifies the network-policy profile number, and enter network-policy configuration mode. The range is 1 to 4294967295.

	Command	Purpose
Step 3	Switch(config-network-policy)# {voice voice-signaling} vlan [vlan-id {cos cvalue dscp dvalue}] [[dot1p {cos cvalue dscp dvalue}] none untagged]	Configures the policy attributes: voice —Specifies the voice application type. voice-signaling —Specifies the voice-signaling application type. vlan —Specifies the native VLAN for voice traffic. vlan-id —(Optional) Specifies the VLAN for voice traffic. The range is 1 to 4094. cos cvalue —(Optional) Specifies the Layer 2 priority class of service (CoS) for the configured VLAN. The range is 0 to 7; the default is 0. dscp dvalue —(Optional) Specifies the differentiated services code point (DSCP) value for the configured VLAN. The range is 0 to 63; the default is 0. dot1p —(Optional) Configures the telephone to use IEEE 802.1p priority tagging and use VLAN 0 (the native VLAN). none —(Optional) Do not instruct the IP telephone about the voice VLAN. The telephone uses the configuration from the telephone key pad. untagged —(Optional) Configures the telephone to send untagged voice traffic (the default for the telephone).
Step 4	Switch(config)# exit	Returns to global configuration mode.
Step 5	Switch# configure terminal	Enters global configuration mode.
Step 6	Switch(config)# interface interface-id	Specifies the interface on which you are configuring a network-policy profile, and enter interface configuration mode.
Step 7	Switch(config-if)# network-policy profile number	Specifies the network-policy profile number.
Step 8	Switch(config-if)# lldp med-tlv-select network-policy	Specifies the network-policy TLV.
Step 9	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 10	Switch# show network-policy profile	Verifies the configuration.
Step 11	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no** form of each command to return to the default setting.

This example shows how to configure VLAN 100 for voice application with CoS and to enable the network-policy profile and network-policy TLV on an interface:

```
Switch# configure terminal
Switch(config)# network-policy profile 1
Switch(config-network-policy)# voice vlan 100 cos 4
Switch(config)# exit
Switch# configure terminal
Switch# interface_id
Switch(config-if)# network-policy profile 1
Switch(config-if)# lldp med-tlv-select network-policy
```

This example shows how to configure the voice application type for the native VLAN with priority tagging:

```
Switch(config-network-policy)# voice vlan dot1p cos 4
```

```
Switch(config-network-policy)# voice vlan dot1p dscp 34
```

**Note**

As of Cisco IOS Release 12.2(54)SG, the Catalyst 4500 series switch supports only 2 applications: voice and voice signaling. The default cos/dscp values for a voice application is 5/46 and for voice signaling is 3/24. You must configure the network policy profile and attach it to the interface if you need to override the default values. These values are sent as a part of the network-policy TLV in LLDP MED.

Configuring LLDP Power Negotiation

Starting with Cisco IOS Release 12.2(54)SG, Catalyst 4500 series switches can perform inline power negotiation using LLDP as specified in the IEEE 802.3at standard. (The LLDP TLV used is DTE Power-via-MDI TLV.) With this feature, inline powered devices based on the IEEE standard can be powered in the PoE+ power range (12.95W to 25.5W at the device end) by the switch on PoE+ supported modules.

**Note**

To verify inline power utilization negotiated by using LLDP using the LLDP-MED TLV, use the **show lldp neighbors detail** command. To verify inline power utilization negotiated by using the IEEE 802.3at TLV, use the **show power inline interface detail** command. The **show power inline interface detail** command does not display power negotiated with LLDP.

**Note**

When an inline powered device that performs power negotiation using multiple protocols (CDP/LLDP 802.3at/LLDP-MED) is connected to a switch, the switch locks to the first protocol packet (CDP or LLDP) that contains the power negotiation TLV. The LLDP 802.3at power negotiation TLV overrides the LLDP-MED power negotiation TLV if both are received by the switch. If you need to use any single protocol for power negotiation each time, you must administratively disable the other power negotiation protocols on the switch interface or the end device.

To enable LLDP power negotiation, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Specifies the interface on which you are configuring LLDP power negotiation.
Step 3	Switch(config-if)# lldp tlv-select power-management	Enables LLDP power negotiation.
Step 4	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 5	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable LLDP power negotiation on interface Gigabit Ethernet 3/1:

```
Switch# config t
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# int gi 3/1
Switch(config-if)# lldp tlv-select power-management
```

Configuring Location TLV and Location Service

To configure location information for an end-point and to apply it to an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# location { admin-tag <i>string</i> civic-location identifier <i>id</i> elin-location <i>string</i> identifier <i>id</i> }	<p>Specifies the location information for an endpoint.</p> <ul style="list-style-type: none"> • admin-tag—Specify an administrative tag or site information. • civic-location—Specify civic location information. <p>Note The civic location identifier in the LLDP-MED TLV is limited to 250 bytes or less. To avoid receiving error messages regarding available buffer space during switch configuration, never allow the total length of all civic location information specified for each civic-location identifier to exceed 250 bytes.</p> <ul style="list-style-type: none"> • elin-location—Specify emergency location information (ELIN). • identifier <i>id</i>—Specify the ID for the civic location. • <i>string</i>—Specify the site or location information in alphanumeric format.
Step 3	Switch(config-civic)# exit	Returns to global configuration mode.
Step 4	Switch(config)# interface <i>interface-id</i>	Specifies the interface on which you are configuring the location information, and enter interface configuration mode.
Step 5	Switch(config-if)# location { additional-location-information <i>word</i> / civic-location-id <i>id</i> elin-location-id <i>id</i> }	<p>Enters location information for an interface:</p> <p>additional-location-information—Specifies additional information for a location or place.</p> <p>civic-location-id—Specifies global civic location information for an interface.</p> <p>elin-location-id—Specifies emergency location information for an interface.</p> <p><i>id</i>—Specifies the ID for the civic location or the ELIN location. The ID range is 1 to 4095.</p> <p><i>word</i>—Specifies a word or phrase that provides additional location information.</p>
Step 6	Switch(config-if)# end	Returns to privileged EXEC mode.
Step 7	Switch# show location	Verifies the configuration.
Step 8	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

Use the **no** form of each command to return to the default setting.

This example shows how to configure civic location information on the switch:

```
Switch# configure terminal
Switch(config)# location civic-location identifier 1
Switch(config-civic)# number 3550
Switch(config-civic)# primary-road-name "Cisco Way"
Switch(config-civic)# city "San Jose"
Switch(config-civic)# state CA
Switch(config-civic)# building 19
Switch(config-civic)# room C6
Switch(config-civic)# county "Santa Clara"
Switch(config-civic)# country US
Switch(config-civic)# end
```

To enable location service on the switch, perform this task:

Note

Your switch must be running the cryptographic (encrypted) software image in order to enable the location service feature. Your Cisco Mobility Service Engine (MSE) must be running Heitz 6.0 or later software image to support wired location service

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# nmosp enable	Enables the NMSP features on the switch.
Step 3	Switch(config)# ip device tracking	Enables IP device tracking.
Step 4	Switch(config)# nmosp notification interval {attachment location} interval-seconds	Specifies the NMSP notification interval. attachment —Specify the attachment notification interval. location —Specify the location notification interval. <i>interval-seconds</i> —Duration in seconds before a switch sends the location or attachment updates to the MSE. The range is 1 to 30; the default is 30.
Step 5	Switch(config)# interface interface-id	Specifies the interface on which you want to prevent all learned attachment information from being sent to the MSE.
Step 6	Switch(config-if)# nmosp attachment suppress	Prevents the attachment information learned on this interface from being sent to the MSE. Note Location service is intended for tracking end devices directly connected to the switch. Please apply this command on all trunk interfaces to avoid inaccurate tracking information.
Step 7	Switch# end	Returns to privileged EXEC mode.
Step 8	Switch# show nmosp notification	Verifies the notification interval configuration.
Step 9	Switch# show nmosp status	Verifies if NMSP is enabled.
Step 10	Switch# copy running-config startup-config	(Optional) Saves your entries in the configuration file.

This example shows how to enable NMSP on a switch and set the location notification time to 10 seconds:

```
Switch# configure terminal
Switch(config)# nmosp enable
Switch(config)# ip device tracking
Switch(config)# nmosp notification interval location 10
Switch(config)# end
```

Note

Location service tracks IP devices only on Layer 2 and Layer 3 physical ports. IP devices that are connected through SVIs or port-channels are not tracked and reported to the MSE.

Monitoring and Maintaining LLDP, LLDP-MED, and Location Service

To monitor and maintain LLDP, LLDP-MED, and location service on your device, perform one or more of the following commands in privileged EXEC mode:

Command	Description
clear lldp counters	Resets the traffic and error counters to zero.
clear lldp table	Deletes the LLDP table of information about neighbors.
clear nmosp statistics	Clears the NMSP statistic counters.
show lldp	Displays global information, such as frequency of transmissions, the holdtime for packets being sent, and the delay time for LLDP to initialize on an interface.
show lldp entry <i>entry-name</i>	Displays information about a specific neighbor. You can enter an asterisk (*) to display all neighbors, or you can enter the name of the neighbor about which you want information.
show lldp errors	Displays LLDP computational errors and overflows.
show lldp interface [<i>interface-id</i>]	Displays information about interfaces where LLDP is enabled. You can limit the display to the interface about which you want information.
show lldp neighbors [<i>interface-id</i>] [<i>detail</i>]	Displays information about neighbors, including device type, interface type and number, holdtime settings, capabilities, and port ID. You can limit the display to neighbors of a specific interface or expand the display to provide more detailed information.
show lldp traffic	Displays LLDP counters, including the number of packets sent and received, number of packets discarded, and number of unrecognized TLVs.
show location	Displays the location information for an endpoint.
show nmosp	Displays the NMSP information.
show power inline interface [<i>detail</i>]	Displays detailed information on the PoE status for the interface
show power inline module <i>mod</i> [<i>detail</i>]	Displays detailed information on the PoE consumption for the specified module.

Cisco IOS Carries Ethernet Features in Cisco IOS XE 3.1.0SG

This section provides a list of High Availability software features that are supported in Cisco IOS XE 3.1.0SG. Links to the feature documentation are included.

Feature guides may contain information about more than one feature. To find information about a specific feature within a feature guide, see the Feature Information table at the end of the guide.

Feature guides document features that are supported on many different software releases and platforms. Your Cisco software release or platform may not support all the features documented in a feature guide. See the Feature Information table at the end of the feature guide for information about which features in that guide are supported in your software release. Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to <http://www.cisco.com/go/cfn>. An account on Cisco.com is not required.

ANSI TIA-1057 LLDP-MED Support and IEEE 802.1ab LLDP (Link Layer Discovery Protocol)

Configuring UDLD

This chapter describes how to configure UniDirectional Link Detection (UDLD) Ethernet on the switch, and includes the following major sections:

- [About UDLD, page 34-1](#)
- [Default UDLD Configuration, page 34-3](#)
- [Configuring UDLD on the Switch, page 34-4](#)
- [Displaying UDLD Link Status, page 34-9](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About UDLD

UDLD is a Layer 2 protocol that initializes devices connected through fiber-optic or twisted-pair Ethernet cables. This protocol monitors a physical connection (such as wrong cabling) to detect unidirectional links to avoid spanning-tree topology loops or silent drop traffic.

All connected devices must support UDLD for the protocol to successfully identify the unidirectional links. When UDLD detects a unidirectional link, it can administratively shut down the affected port and send you a warning message.

With UDLD, the time to detect a unidirectional link can vary from a few seconds to several minutes depending on how the timers are configured. Link status messages are exchanged every couple of seconds.

Starting with Cisco IOS Release 12.2(54)SG, the enhancement Fast UDLD was added, which supports timers in the few-hundred milliseconds range, which enables subsecond unidirectional link detection. With Fast UDLD, the time to detect a unidirectional link can vary from less than one second to a few seconds (the detection time also depends on how the timers are configured). Link status messages are exchanged every couple of hundred milliseconds.

This section includes these topics:

- [UDLD Topology, page 34-2](#)
- [Fast UDLD Topology, page 34-2](#)
- [Operation Modes, page 34-3](#)
- [Default States for UDLD, page 34-3](#)

UDLD Topology

Each switch can send packets to a neighbor switch but cannot receive packets from the switch it is sending packets to. UDLD detects and disables these one-way connections. [Figure 34-1](#) illustrates a unidirectional link condition.

Figure 34-1 Unidirectional Link Topology

Fast UDLD Topology

[Figure 34-2](#) illustrates a typical Fast UDLD topology. Switch A and B are connected through a 2-port EtherChannel, and Fast UDLD is enabled on the individual ports. If one of the links becomes unidirectional, Fast UDLD detects this situation faster than regular UDLD and erdisables the link. Traffic is switched over to the second link by EtherChannel. Because this occurs very quickly, traffic loss is minimized.

Figure 34-2 Fast UDLD Topology

Note

For Fast UDLD, Supervisor Engine 6-E, Supervisor 6L-E, Supervisor 7-E, and Supervisor Engine 7L-E support up to 32 ports.

Operation Modes

UDLD and Fast UDLD support the following operation modes:

- **Normal**—A UDLD-capable port (A) periodically sends a UDLD probe to a second port (B). If B is not UDLD capable, no unidirectional link detection occurs. If both devices are UDLD capable and bidirectional connectivity exists, probe messages travel in both directions at the rate of the configured message time interval. When the UDLD protocol receives the probe, it attempts to synchronize the devices by sending echo messages to the peer port and waiting for an answer during the detection window. If unidirectional traffic is detected when the port link is still up (B longer sends traffic to A), B enters errdisable mode, and A is marked undetermined but does not enter errdisable mode. It continues to operate under its current STP status because this mode is informational only; it is potentially less disruptive although it does not prevent STP loops.

Note Bidirectional link failures cannot be detected using normal mode.

- **Aggressive**—If a port (A) loses its neighbor connectivity, it actively attempts to reestablish the relationship by sending a probe to a second port (B). If port B does not respond, the link is considered unidirectional and port A enters an errdisable state to avoid silent drop traffic.

Note Both unidirectional and bidirectional link failures can be detected in aggressive mode.

UDLD aggressive mode can interoperate with UDLD normal mode. When a unidirectional condition is detected, only the aggressive mode link shuts down.

Default States for UDLD

The following are the defaults for UDLD:

- UDLD is locally disabled on copper LAN ports to avoid sending unnecessary control traffic (BPDU control packets). This protocol is commonly used for access ports.
- UDLD is enabled on a fiber port if global UDLD is activated.
- Fast UDLD is disabled on all ports.

Default UDLD Configuration

Table 34-1 shows the UDLD default configuration.

Table 34-1 UDLD Default Configuration

Feature	Default Status
UDLD global enable state	Globally disabled.
UDLD per-interface enable state for fiber-optic media	Enabled on all Ethernet fiber-optic interfaces.
UDLD per-interface enable state for twisted-pair (copper) media	Disabled on all Ethernet 10/100 and 1000BASE-TX interfaces.
Fast UDLD per-interface enable state.	Disabled on all interfaces.

Configuring UDLD on the Switch

The following sections describe how to configure UDLD:

- [Fast UDLD Guidelines and Restrictions, page 34-4](#)
- [Enabling UDLD Globally, page 34-5](#)
- [Enabling UDLD on Individual Interfaces, page 34-6](#)
- [Disabling UDLD on Individual Interfaces, page 34-7](#)
- [Disabling UDLD on a Fiber-Optic Interface, page 34-7](#)
- [Configuring a UDLD Probe Message Interval Globally, page 34-8](#)
- [Resetting Disabled LAN Interfaces, page 34-8](#)

Fast UDLD Guidelines and Restrictions

When using (or configuring) Fast UDLD, consider these guidelines and restrictions:

- Fast UDLD is disabled by default.
- Configure fast UDLD only on point-to-point links between network devices that support fast UDLD.
- You can configure fast UDLD in either normal or aggressive mode.
- Do not enter the link debounce command on fast UDLD ports.
- Configure fast UDLD on at least two links between each connected network device. This reduces the number of link disablements due to false positives.
- Fast UDLD does not report a unidirectional link if the same error occurs simultaneously on more than one link to the same neighbor device.
- Fast UDLD is supported on a limited number of ports.

Enabling UDLD Globally

To enable UDLD in aggressive or normal mode and to set the configurable message timer on all fiber-optic interfaces on the switch, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters the global configuration mode.
Step 2	Switch(config)# udld {aggressive enable message time message-timer-interval} fast-hello error-reporting	<p>Specifies UDLD and Fast UDLD operation:</p> <ul style="list-style-type: none"> • aggressive —Enables UDLD in aggressive mode on all fiber-optic interfaces. • enable —Enables UDLD in normal mode on all fiber-optic interfaces on the switch. UDLD is disabled by default. <p>An individual interface configuration overrides the setting of the udld enable global configuration command.</p> <p>For more information about aggressive and normal modes, see the “Operation Modes” section on page 34-3.</p> <ul style="list-style-type: none"> • message time —<i>message-timer-interval</i>— Configures the period of time between UDLD probe messages on ports that are in the advertisement phase and are determined to be bidirectional. The range is from 1 to 90 seconds. <p>Note Prior to Cisco IOS Release 12.2(31)SGA, the timer range is 7 to 90 seconds. With Cisco IOS Release 12.2(31)SGA, the timer range is 1 to 90 seconds.</p> <ul style="list-style-type: none"> • fast-hello error reporting—If configured, Fast UDLD does not errdisable a unidirectional link. Instead, a log message informing link failure is displayed on the console (behavior for fast UDLD only).
Step 3	Switch(config)# end	Returns to privileged EXEC mode.
Step 4	Switch# show udld	Verifies the configuration.

Enabling UDLD on Individual Interfaces

To enable UDLD on individual interfaces, perform this task:

	Command	Purpose
Step 1	Switch(config-if)# udld port	Enables UDLD in normal mode on a specific interface. On a fiber-optic interface, this command overrides the udld enable global configuration command setting.
	Switch(config-if)# udld port aggressive	Enables UDLD in aggressive mode on a specific interface. On a fiber-optic interface, this command overrides the udld enable global configuration command setting.
	Switch(config-if)# udld fast-hello interval	<p>Enables Fast UDLD on the interface with message interval equal to the <i>interval</i> value in milliseconds.</p> <p>The interval value range is from 200 milliseconds to 1000 milliseconds.</p> <p>To enable Fast UDLD, UDLD must be enabled (explicitly configured or globally enabled) and operational (in bidirectional state) on the interface.</p> <p>Note Fast UDLD can only be enabled on individual interfaces (a global enable command does not exist).</p> <p>Note Fast UDLD can only be configured or enabled on a limited number of interfaces that depend on the type of supervisor installed. The number of supported interfaces for Fast UDLD can be displayed with the show udld fast-hello command.</p>
Step 2	Switch# show udld interface	Verifies the configuration.

Disabling UDLD on Individual Interfaces

To disable UDLD on individual interfaces, perform this task:

	Command	Purpose
Step 1	Switch(config-if)# no udld port	Disables UDLD on an interface. The following applies: <ul style="list-style-type: none"> On fiber-optic interfaces, the no udld port command reverts the interface configuration to the setting established with the udld enable global configuration command. For both UDLD and Fast UDLD, if aggressive mode is configured, then aggressive mode must be explicitly disabled with the no udld port aggressive command. If normal mode is configured, the no udld port command disables both UDLD and Fast UDLD.
	Switch(config-if)# no udld fast-hello	Disables Fast UDLD on an interface. The interface reverts to the UDLD configuration that was present before you enabled Fast UDLD.
Step 2	Switch# show udld interface	Verifies the configuration.

Disabling UDLD on a Fiber-Optic Interface

To disable UDLD on individual fiber-optic interfaces, perform this task:

	Command	Purpose
Step 1	Switch(config-if)# udld port disable	Disables UDLD on a fiber-optic interface and removes all UDLD and Fast UDLD related configuration on the interface. Note You can enable UDLD globally for all fiber-optic interfaces.
	Switch(config-if)# no udld fast-hello	Disables Fast UDLD on an interface, which reverts to the UDLD configuration that was present before you enabled Fast UDLD.
Step 2	Switch# show udld interface	Verifies the configuration.

Configuring a UDLD Probe Message Interval Globally

To configure the time between UDLD probe messages on ports that are in advertisement mode and are currently determined to be bidirectional, perform this task:

	Command	Purpose
Step 1	Switch(config)# udld message time interval	Configures the time between UDLD probe messages on ports that are in advertisement mode and are currently determined to be bidirectional; valid values are from 1 to 90 seconds. Note Prior to Cisco IOS Release 12.2(31)SGA, the time interval is 7 to 90 seconds. With Cisco IOS Release 12.2(31)SGA, the time interval is 1 to 90 second. The no udld message command returns the default value (15 seconds).
Step 2	Switch# show udld type-slot/interface	Verifies the configuration.

Enabling Fast UDLD Error Reporting

By default, fast UDLD error-disables ports with unidirectional links. You can globally enable fast UDLD to report unidirectional links with a message displayed on the console instead of error-disabling ports with unidirectional links.

Note

When fast UDLD error reporting is enabled, you must manually take the action appropriate for the state of the link.

To globally enable fast UDLD error reporting, perform this task:

Command	Purpose
Switch(config)# udld fast-hello error-reporting	Enables fast UDLD error reporting.

Resetting Disabled LAN Interfaces

To reset all LAN ports that have been errdisabled by UDLD, use this command:

Command	Purpose
Switch(config)# udld reset	Resets all LAN ports that have been errdisabled by UDLD and Fast UDLD.

Displaying UDLD Link Status

To verify link status reported by UDLD, enter the following command:

```
Switch# show udld neighbors
```

Port	Device Name	Device ID	Port ID	Neighbor State
Gi1/33	FOX10430380	1	Gi1/33	Bidirectional
Gi1/34	FOX10430380	1	Gi1/34	Bidirectional

To verify status for a particular link as reported by UDLD, enter the following command:

```
Switch# show udld g1/34
```

```
Interface Gi1/34
```

```
---
```

```
Port enable administrative configuration setting: Enabled / in aggressive mode
```

```
Port enable operational state: Enabled / in aggressive mode
```

```
Current bidirectional state: Bidirectional
```

```
Current operational state: Advertisement - Single neighbor detected
```

```
Message interval: 15000 ms
```

```
Time out interval: 5000 ms
```

```
Port fast-hello configuration setting: Disabled
```

```
Port fast-hello interval: 0 ms
```

```
Port fast-hello operational state: Disabled
```

```
Neighbor fast-hello configuration setting: Disabled
```

```
Neighbor fast-hello interval: Unknown
```

```
Entry 1
```

```
---
```

```
Expiration time: 43300 ms
```

```
Cache Device index: 1
```

```
Current neighbor state: Bidirectional
```

```
Device ID: FOX10430380
```

```
Port ID: Gi1/34
```

```
Neighbor echo 1 device: FOX104303NL
```

```
Neighbor echo 1 port: Gi1/34
```

```
TLV Message interval: 15 sec
```

```
No TLV fast-hello interval
```

```
TLV Time out interval: 5
```

```
TLV CDP Device name: Switch
```

To verify link status reported by Fast UDLD, enter the following command:

```
Switch# show udld fast-hello
```

```
Total ports on which fast hello can be configured: 16
```

```
Total ports with fast hello configured: 3
```

```
Total ports with fast hello operational: 3
```

```
Total ports with fast hello non-operational: 0
```

Port-ID	Hello	Neighbor-Hello	Neighbor-Device	Neighbor-Port	Status
Gi1/45	200	200	FOX104303NL	Gi1/45	Operational
Gi1/46	200	200	FOX104303NL	Gi1/46	Operational
Gi1/47	200	200	FOX104303NL	Gi1/47	Operational

To verify status for a particular link as reported by Fast UDLD, enter the following command:

```
Switch# show udld fast-hello gi1/33
```

```
Interface Gi1/33
```

```
---
```

```
Port enable administrative configuration setting: Enabled / in aggressive mode
```

```

Configuring Unidirectional Ethernet

Note

Unidirectional Ethernet is not supported on the following: Supervisor Engine 7-E and Supervisor Engine 7L-E uplinks.

This chapter describes how to configure Unidirectional Ethernet on the Catalyst 4500 series switch and contains these sections:

- [About Unidirectional Ethernet, page 35-1](#)
- [Configuring Unidirectional Ethernet, page 35-1](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Unidirectional Ethernet

You can set stubless Gigabit Ethernet ports to unidirectionally transmit or receive traffic. Unidirectional Ethernet uses only one strand of fiber for either transmitting or receiving one-way traffic for the Gigabit Ethernet Port, instead of two strands of fiber for a full-duplex Gigabit Ethernet Port. Configuring your Gigabit Ethernet Port either to transmit or receive traffic effectively doubles the amount of traffic capabilities for applications, such as video streaming, where most traffic is sent as unacknowledged unidirectional video broadcast streams.

Configuring Unidirectional Ethernet

Note

You must configure Unidirectional Ethernet on the non-blocking Gigabit Ethernet Port, which automatically disables UDLD on the port.

To enable Unidirectional Ethernet, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface { vlan <i>vlan_ID</i> { fastethernet gigabitethernet tengigabitethernet } <i>slot/interface</i> Port-channel <i>number</i> }	Selects the interface to configure.
Step 2	Switch(config-if)# [no] unidirectional { send-only receive-only }	Enables Unidirectional Ethernet. Use the no keyword to disable Unidirectional Ethernet.
Step 3	Switch(config-if)# end	Exits configuration mode.
Step 4	Switch# show interface { vlan <i>vlan_ID</i> { fastethernet gigabitethernet tengigabitethernet } <i>slot/interface</i> } unidirectional	Verifies the configuration.

This example shows how to set Gigabit Ethernet interface 1/1 to unidirectionally send traffic:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# unidirectional send-only
Switch(config-if)# end
```

Warning!

Enable 12 port unidirectional mode will automatically disable port udld.
You must manually ensure that the unidirectional link does not create
a spanning tree loop in the network.

Enable 13 port unidirectional mode will automatically disable ip routing
on the port. You must manually configure static ip route and arp entry
in order to route ip traffic.

This example shows how to set Gigabit Ethernet interface 1/1 to receive traffic unidirectionally:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface gigabitethernet 1/1
Switch(config-if)# unidirectional receive-only
Switch(config-if)# end
```

Warning!

Enable 12 port unidirectional mode will automatically disable port udld.
You must manually ensure that the unidirectional link does not create
a spanning tree loop in the network.

Enable 13 port unidirectional mode will automatically disable ip routing
on the port. You must manually configure static ip route and arp entry
in order to route ip traffic.

This example shows how to verify the configuration:

```
Switch> show interface gigabitethernet 1/1 unidirectional
show interface gigabitethernet 1/1 unidirectional
Unidirectional configuration mode: send only
CDP neighbor unidirectional configuration mode: receive only
```

This example shows how to disable Unidirectional Ethernet on Gigabit Ethernet interface 1/1:

```
Switch# configure terminal  
Enter configuration commands, one per line. End with CNTL/Z.  
Switch(config)# interface gigabitethernet 1/1  
Switch(config-if)# no unidirectional  
Switch(config-if)# end
```

This example shows the result of entering the **show interface** command for a port that does not support Unidirectional Ethernet:

```
Switch# show interface f6/1 unidirectional  
Unidirectional Ethernet is not supported on FastEthernet6/1
```

Configuring Layer 3 Interfaces

This chapter describes the Layer 3 interfaces on a Catalyst 4500 series switch. It also provides guidelines, procedures, and configuration examples.

This chapter includes the following major sections:

- [About Layer 3 Interfaces, page 36-1](#)
- [Configuration Guidelines, page 36-5](#)
- [Configuring Logical Layer 3 VLAN Interfaces, page 36-7](#)
- [Configuring Logical Layer 3 GRE Tunnel Interfaces, page 36-6](#)
- [Configuring VLANs as Layer 3 Interfaces, page 36-8](#)
- [Configuring Physical Layer 3 Interfaces, page 36-13](#)
- [Configuring Multipoint GRE, page 36-14](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Layer 3 Interfaces

The Catalyst 4500 series switch supports Layer 3 interfaces with the Cisco IOS IP and IP routing protocols. Layer 3, the *network* layer, is primarily responsible for the routing of data in packets across logical internetwork paths.

Layer 2, the *data link* layer, contains the protocols that control the *physical* layer (Layer 1) and how data is framed before being transmitted on the medium. The Layer 2 function of filtering and forwarding data in frames between two segments on a LAN is known as *bridging*.

The Catalyst 4500 series switch supports two types of Layer 3 interfaces. The logical Layer 3 VLAN interfaces integrate the functions of routing and bridging. The physical Layer 3 interfaces allow the Catalyst 4500 series switch to be configured like a traditional router.

Note

On a Catalyst 4500 series switch, a physical Layer 3 interface has MAC address learning enabled.

This section contains the following subsections:

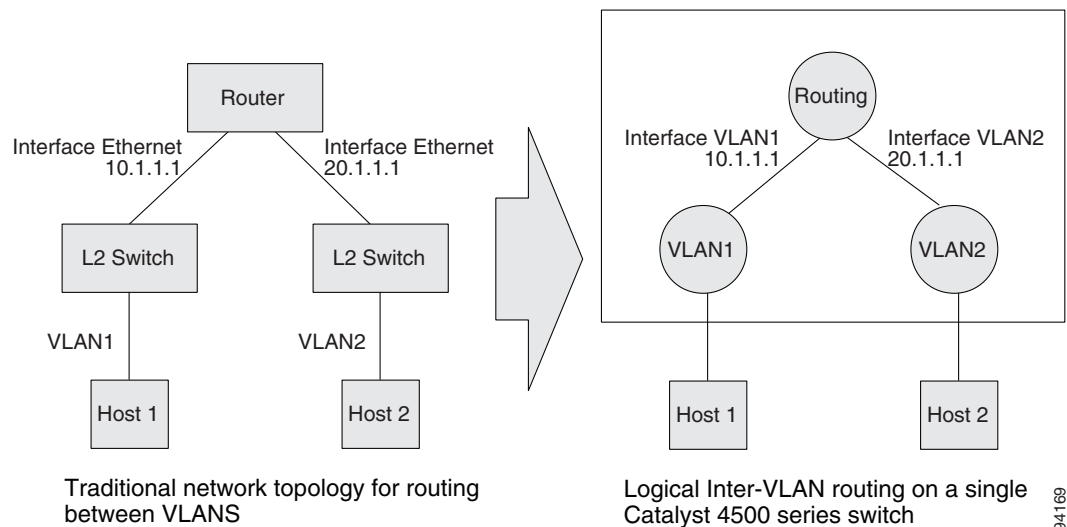

- [Logical Layer 3 VLAN Interfaces, page 36-2](#)
- [Physical Layer 3 Interfaces, page 36-2](#)
- [Understanding SVI Autostate Exclude, page 36-3](#)
- [Understanding Layer 3 Interface Counters, page 36-3](#)

Logical Layer 3 VLAN Interfaces

The logical Layer 3 VLAN interfaces provide logical routing interfaces to VLANs on Layer 2 switches. A traditional network requires a physical interface from a router to a switch to perform inter-VLAN routing. The Catalyst 4500 series switch supports inter-VLAN routing by integrating the routing and bridging functions on a single Catalyst 4500 series switch.

[Figure 36-1](#) shows how the routing and bridging functions in the three physical devices of the traditional network are performed logically on one Catalyst 4500 series switch.

Figure 36-1 Logical Layer 3 VLAN Interfaces for the Catalyst 4500 Series Switch

94169

Physical Layer 3 Interfaces

The physical Layer 3 interfaces support capabilities equivalent to a traditional router. These Layer 3 interfaces provide hosts with physical routing interfaces to a Catalyst 4500 series switch.

[Figure 36-2](#) shows how the Catalyst 4500 series switch functions as a traditional router.

Figure 36-2 Physical Layer 3 Interfaces for the Catalyst 4500 Series Switch

Physical Inter-VLAN Routing on a Catalyst 4500 series switch 94168

Understanding SVI Autostate Exclude

To be up/up, a router VLAN interface must fulfill the following general conditions:

- The VLAN exists and is active on the VLAN database of the switch.
- The VLAN interface exists on the router and is not administratively down.
- At least one Layer 2 (access port or trunk) port exists, has a link up on this VLAN, and is in spanning-tree forwarding state on the VLAN.

Note

The protocol line state for the VLAN interfaces comes up when the first switch port belonging to the corresponding VLAN link comes up and is in spanning-tree forwarding state.

Ordinarily, when a VLAN interface has multiple ports in the VLAN, the SVI goes down when all the ports in the VLAN go down. The SVI Autostate Exclude feature provides a knob to mark a port so that it is not counted in the SVI up and down calculation and applies to all VLANs that are enabled on that port.

A VLAN interface is brought up after the Layer 2 port has had time to converge (that is, transition from listening-learning to forwarding). This prevents routing protocols and other features from using the VLAN interface as if it were fully operational. It also prevents other problems from occurring, such as routing black holes.

Understanding Layer 3 Interface Counters

Note

Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, 6L-E, do not support Layer 2 interface counters. However, they do support Layer 3 (SVI) interface counters.

When you run IPv4 and IPv6 on Supervisor Engines 9-E, 8L-E, 8-E, 7-LE, 7-E, 6L-E, 6-E, packets are routed in hardware by the forwarding engine. They support the following statistics for counting routed packets with a maximum of 4092 interfaces:

- Input unicast
- Input multicast

- Output unicast
- Output multicast

For each counter type, both the number of packets and the total number of bytes received or transmitted are counted. You can collect these statistics uniquely for IPv4 and IPv6 traffic.

Because the total number of supported Layer 3 interfaces exceeds the number of counters supported by hardware, all Layer 3 interfaces might not have counters. You assign counters to Layer 3 interfaces; the default configuration for a Layer 3 interface has no counters.

You can configure collection statistics at an interface level in one of the four ways (see [Table 36-1](#)). The maximum number of interfaces applied to the configuration depends on the collection mode.

Table 36-1 **Configuring Statistics Collection Mode**

Counter Mode	Configuration CLI	Function	Maximum
IPv4 only	counter ipv4	Only IPv4 statistics are collected.	4092
IPv6 only	counter ipv6	Only IPv6 statistics are collected.	4092
IPv4 and IPv6 combined	counter	Both IPv4 and IPv6 statistics are collected but are displayed only as a sum.	4092
IPv4 and IPv6 separate	counter ipv4 ipv6 separate	Both IPv4 and IPv6 statistics are collected and can be displayed individually.	2046

When mixing these configured modes, the rule is as follows:

(number of v4/v6/v4v6combined interfaces) + 2*(number of v4v6separate interfaces) <= 4092

Note

To enable Layer 3 interface counters, you need to enter the **counter** command in interface mode. For instructions, see the [“Configuring Layer 3 Interface Counters”](#) section on page 36-11.

The hardware counters are displayed in the output of the **show interface** command, as shown in the following example. Counter fields that are updated when the counter configuration is present are highlighted.

```
Switch# show interface gi3/1
GigabitEthernet3/1 is up, line protocol is up (connected)
  Hardware is Gigabit Ethernet Port, address is 001f.9e9e.f43f (bia 001f.9e9e.f43f)
  Internet address is 10.10.10.2/24
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  Keepalive set (10 sec)
  Full-duplex, 1000Mb/s, link type is auto, media type is 10/100/1000-TX
  input flow-control is on, output flow-control is on
  Auto-MDIX on (operational: on)
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
```

```

Queueing strategy: fifo
Output queue: 0/40 (size/max)
5 minute input rate 53000 bits/sec, 122 packets/sec
5 minute output rate 53000 bits/sec, 122 packets/sec
L3 in Switched: ucast: 37522 pkt, 752892 bytes - mcast: 0 pkt, 0 bytes <==== (A)
L3 out Switched: ucast: 37522 pkt, 752892 bytes - mcast: 0 pkt, 0 bytes <==== (B)
IPv6 L3 in Switched: ucast: 24328 pkt, 145968 bytes - mcast: 0 pkt, 0 bytes <== (C)
IPv6 L3 out Switched: ucast: 24328 pkt, 145968 bytes - mcast: 0 pkt, 0 bytes <== (D)
103639 packets input, 6632896 bytes, 0 no buffer
Received 0 broadcasts (0 IP multicasts)
0 runts, 0 giants, 0 throttles
0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
0 input packets with dribble condition detected
103674 packets output, 6641715 bytes, 0 underruns
0 output errors, 0 collisions, 1 interface resets
0 babbles, 0 late collision, 0 deferred
0 lost carrier, 0 no carrier
0 output buffer failures, 0 output buffers swapped out

```

The output of the previous configuration depends on the counter configuration (Table 36-2).

Table 36-2 Fields Updated in Previous Configuration/Counter Configuration

Counter Configuration	Updated Fields
IPv4 only	(A) and (B) only
IPv6 only	(C) and (D) only
IPv4 and IPv6 combined	(A) and (B) only
IPv4 and IPv6 separate	(A) and (B) for IPv4 (C) and (D) for IPv6

Configuration Guidelines

The Catalyst 4500 series switch supports AppleTalk routing and IPX routing. For AppleTalk routing and IPX routing information, refer to “Configuring AppleTalk” and “Configuring Novell IPX” in the *Cisco IOS AppleTalk* and *Novell IPX* configuration guides at the following URLs:

http://www.cisco.com/en/US/docs/ios/at/configuration/guide/12_4/atk_12_4_book.html

http://www.cisco.com/en/US/docs/ios/novipx/configuration/guide/config_novellipx_ps6350_TSD_Products_Configuration_Guide_Chapter.html

Note

Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, 6L-E, and 6-E do not support AppleTalk and IPX routing.

- Catalyst 4500 series switches do not support subinterfaces or the **encapsulation** keyword on Layer 3 Fast Ethernet, Gigabit Ethernet, 10-Gigabit Ethernet interfaces.
- Starting IOS XE 3.11.0, Catalyst 4500 series switches do not support egress Access Controlled Lists (ACLs) on a tunnel interface and on the source interface of the tunnel.

Note

As with any Layer 3 interface running Cisco IOS software, the IP address and network assigned to an SVI cannot overlap those assigned to any other Layer 3 interface on the switch.

Configuring Logical Layer 3 GRE Tunnel Interfaces

Tunnels are point-to-point dedicated virtual links to transport packets from one endpoint to another. Generic Routing Encapsulation (GRE) is a tunneling protocol used to encapsulate network layer protocols inside virtual point-to-point links. A GRE tunnel only provides encapsulation and not encryption.

With GRE, devices running a given network layer protocol can communicate over a network running a different network layer protocol. A network receives and encapsulates the native packet into another network protocol and sends the encapsulated packet towards its de-encapsulation point. The encapsulation point is the tunnel entry and the de-encapsulation point is the tunnel exit.

Note

Beginning in Cisco IOS XE Release 3.7.1E, GRE tunnels are supported on the hardware on Cisco Catalyst 4500 Series switches.

When GRE is configured with tunnel options (such as key, checksum, etc.), packets are switched in software. When GRE is configured without tunnel options, packets are hardware-switched.

Restrictions and Limitations for Logical Layer 3 GRE Tunnel Interfaces:

- Multicast routing is not supported on GRE tunnels, so PIM configuration is not supported on a GRE tunnel interface.
- Limitation relating to GRE-encapsulated packets that are switched in hardware (applies only to Catalyst 4500-X Series Switches):

If a GRE tunnel is configured on a Catalyst 4500 switch and the ingress to this device is through a Layer 2 interface which has an SVI configured locally and is running HSRP (and is the current active), GRE encapsulated unicast traffic is not sent across the endpoints of the GRE tunnel, because of which routing adjacencies cannot be established and pings across the GRE tunnel do not work.

To work around this problem, configure the HSRP group to use the burned-in address (BIA) feature (**standby use-bia** interface configuration command). It enables HSRP groups to use an interface's burned-in MAC address (or physical MAC address) instead of a virtual MAC address. Note that configuring the **standby use-bia** interface configuration command may slow down convergence after an HSRP switchover, since the new active has to send a gratuitous ARP to refresh the ARP entries through the subnet. For more information, see:

<https://www.cisco.com/c/en/us/support/docs/ip/hot-standby-router-protocol-hsrp/9281-3.html>.

To configure a GRE tunnel, perform this task:

	Command	Purpose
Step 1	Switch(config)# interface tunnel <i>number</i>	Enables tunneling on the interface.
Step 2	Switch(config-if)# ipv6 address <i>ip_address</i> <i>subnet_mask</i>	Configures the IPv6 address and subnet mask.
Step 3	Switch(config-if)# ip address <i>ip_address</i> <i>subnet_mask</i>	Configures the IP address and IP subnet.
Step 4	Switch(config-if)# tunnel source { <i>ip-address</i> <i>type number</i> }	Configures the tunnel source.
Step 5	Switch(config-if)# tunnel destination { <i>hostname</i> <i>ip-address</i> }	Configures the tunnel destination.
Step 6	Switch(config-if)# tunnel mode gre ip	Configures the tunnel mode.
Step 7	Switch(config-if)# end	Exits configuration mode.

	Command	Purpose
Step 8	Switch# copy running-config startup-config	Saves your configuration changes to NVRAM.
Step 9	Switch# show running-config interface tunnel number	Verifies the configuration.

This example shows how to configure the logical Layer 3 GRE tunnel interface tunnel 2:

```
Switch> enable
Switch# config term
Switch(config)# interface tunnel 2
Switch(config-if)# ipv6 address 1001:1::1/64
Switch(config-if)# ip address 100.1.1.1 255.255.255.0
Switch(config-if)# tunnel source 10.10.10.1
Switch(config-if)# tunnel destination 10.10.10.2
Switch(config-if)# tunnel mode gre ip
Switch(config-if)# end
```

Configuring Logical Layer 3 VLAN Interfaces

Note

Before you can configure logical Layer 3 VLAN interfaces, you must create and configure the VLANs on the switch, assign VLAN membership to the Layer 2 interfaces, enable IP routing if IP routing is disabled, and specify an IP routing protocol.

To configure logical Layer 3 VLAN interfaces, perform this task:

	Command	Purpose
Step 1	Switch(config)# vlan vlan_ID	Creates the VLAN.
Step 2	Switch(config)# interface vlan vlan_ID	Selects an interface to configure.
Step 3	Switch(config-if)# ip address ip_address subnet_mask	Configures the IP address and IP subnet.
Step 4	Switch(config-if)# no shutdown	Enables the interface.
Step 5	Switch(config-if)# end	Exits configuration mode.
Step 6	Switch# copy running-config startup-config	Saves your configuration changes to NVRAM.
Step 7	Switch# show interfaces [type slot/interface] Switch# show ip interfaces [type slot/interface] Switch# show running-config interfaces [type slot/interface] Switch# show running-config interfaces vlan vlan_ID	Verifies the configuration.

This example shows how to configure the logical Layer 3 VLAN interface VLAN 2 and assign an IP address:

```
Switch> enable
Switch# config term
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# vlan 2
Switch(config)# interface vlan 2
Switch(config-if)# ip address 10.1.1.1 255.255.255.248
Switch(config-if)# no shutdown
Switch(config-if)# end
```

This example shows how to use the **show interfaces** command to display the interface IP address configuration and status of Layer 3 VLAN interface VLAN 2:

```
Switch# show interfaces vlan 2
Vlan2 is up, line protocol is down
  Hardware is Ethernet SVI, address is 00D.588F.B604 (bia 00D.588F.B604)
  Internet address is 172.20.52.106/29
  MTU 1500 bytes, BW 1000000 Kbit, DLY 10 usec,
    reliability 255/255, txload 1/255, rxload 1/255
  Encapsulation ARPA, loopback not set
  ARP type: ARPA, ARP Timeout 04:00:00
  Last input never, output never, output hang never
  Last clearing of "show interface" counters never
  Input queue: 0/75/0/0 (size/max/drops/flushes); Total output drops: 0
  Queueing strategy: fifo
  Output queue: 0/40 (size/max)
  5 minute input rate 0 bits/sec, 0 packets/sec
  5 minute output rate 0 bits/sec, 0 packets/sec
    0 packets input, 0 bytes, 0 no buffer
    Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 ignored
    0 packets output, 0 bytes, 0 underruns
    0 output errors, 0 interface resets
    0 output buffer failures, 0 output buffers swapped out
Switch#
```

This example shows how to use the **show running-config** command to display the interface IP address configuration of Layer 3 VLAN interface VLAN 2:

```
Switch# show running-config
Building configuration...

Current configuration : !
interface Vlan2
  ip address 10.1.1.1 255.255.255.248
  !
  ip classless
  no ip http server
  !
  !line con 0
  line aux 0
  line vty 0 4
  !
end
```

Configuring VLANs as Layer 3 Interfaces

This section consists of the following subsections:

- [Configuring SVI Autostate Exclude, page 36-9](#)
- [Configuring IP MTU Sizes, page 36-10](#)
- [Configuring Layer 3 Interface Counters, page 36-11](#)

Configuring SVI Autostate Exclude

Note

The SVI Autostate Exclude feature is enabled by default and is synchronized with the STP state.

The SVI Autostate Exclude feature shuts down (or brings up) the Layer 3 interfaces of a switch when the following port configuration changes occur:

- When the last port on a VLAN goes down, the Layer 3 interface on that VLAN is shut down (SVI- autostated).
- When the first port on the VLAN is brought back up, the Layer 3 interface on the VLAN that was previously shut down is brought up.

SVI Autostate Exclude enables you to exclude the access ports and trunks in defining the status of the SVI (up or down) even if it belongs to the same VLAN. If the excluded access port and trunk is in up state and other ports are in down state in the VLAN, the SVI state is changed to down.

To make the SVI state up, at least one port in the VLAN should be up and not excluded. This action helps to exclude the monitoring port status when you are determining the status of the SVI.

To apply SVI Autostate Exclude, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface interface-id	Enters interface configuration mode.
Step 3	Switch(config-if)# switchport autostate exclude	Excludes the access ports and trunks in defining the status of an SVI (up or down).
Step 4	Switch(config)# end	Exits configuration mode.
Step 5	Switch# show run interface	Displays the running configuration.
Step 6	Switch# show interface switchport	Verifies the configuration.

This example shows how to apply SVI Autostate Exclude on interface g3/1:

```
Switch# conf terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface g3/1
Switch(config-if)# switchport autostate exclude
Switch(config-if)# end
Switch# show run int g3/4
Building configuration...

Current configuration : 162 bytes
!
interface GigabitEthernet3/4
 switchport trunk encapsulation dot1q
 switchport trunk allowed vlan 2,3
 switchport autostate exclude
 switchport mode trunk
end
```

<=====

```

Switch# show int g3/4 switchport
Name: Gi3/4
Switchport: Enabled
Administrative Mode: trunk
Operational Mode: trunk

Disabled Capture VLANs Allowed: ALL
Autostate mode exclude

Unknown unicast blocked: disabled
Unknown multicast blocked: disabled
Appliance trust: none
Switch#

```

Configuring IP MTU Sizes

You can set the protocol-specific maximum transmission unit (MTU) size of IPv4 or IPv6 packets that are sent on an interface.

For information on MTU limitations, refer to “Maximum Transmission Units” on page 41.

Note

To set the nonprotocol-specific MTU value for an interface, use the **mtu** interface configuration command. Changing the MTU value (with the **mtu** interface configuration command) can affect the IP MTU value. If the current IP MTU value matches the MTU value, and you change the MTU value, the IP MTU value is modified automatically to match the new MTU. However, the reverse is not true; changing the IP MTU value has no effect on the value for the **mtu** command.

For information on how to configure MTU size, refer to “Configuring MTU Sizes” on page 43.

To set the protocol-specific maximum transmission unit (MTU) size of IPv4 or IPv6 packets sent on an interface, perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode.
Step 3	Switch(config-if)# [no] ip mtu <i>mtu_size</i> or Switch(config-if)# [no] ipv6 mtu <i>mtu_size</i>	Configures the IPv4 MTU size Configures the IPv6 MTU size. The no form of the command reverts to the default MTU size (1500 bytes).
Step 4	Switch(config-if)# exit	Exits configuration interface mode.
Step 5	Switch(config)# end	Exits configuration mode.
Step 6	Switch# show run interface <i>interface-id</i>	Displays the running configuration.

This example shows how to configure IPv4 MTU on an interface:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface vlan 1
Switch(config-if)# ip mtu 68
Switch(config-if)# exit
Switch(config)# end
Switch# show ip interface vlan 1
Vlan1 is up, line protocol is up
  Internet address is 10.10.10.1/24
  Broadcast address is 255.255.255.255
  Address determined by setup command
  MTU is 68 bytes
  Helper address is not set
  .....(continued)
```

The following example shows how to configure IPv6 MTU on an interface:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface vlan 1
Switch(config-if)# ipv6 mtu 1280
Switch(config)# end
```

This example shows how to verify the configuration

```
Switch# show ipv6 interface vlan 1
Vlan1 is up, line protocol is up
  IPv6 is enabled, link-local address is FE80::214:6AFF:FEBC:DEEA
  Global unicast address(es):
    1001::1, subnet is 1001::/64
  Joined group address(es):
    FF02::1
    FF02::1:FF00:1
    FF02::1:FFBC:DEEA
  MTU is 1280 bytes
  .....(continued)
```

Note

When IPv6 is enabled on an interface using any CLI command, you may see the following message:

```
% Hardware MTU table exhausted
```

In this situation, the IPv6 MTU value programmed in hardware differs from the IPv6 interface MTU value. This situation occurs if no room exists in the hardware MTU table to store additional values. You must free up some space in the table by unconfiguring some unused MTU values and subsequently disable and reenabling IPv6 on the interface or reapplying the MTU configuration.

Configuring Layer 3 Interface Counters

Note

Supervisor Engine 9-E, 8L-E, 8-E, 7-LE, 7-E, 6L-E, 6-E, do not support Layer 2 interface counters.

To configure Layer 3 interface counters (assign counters to a Layer 3 interface), perform this task:

	Command	Purpose
Step 1	Switch# configure terminal	Enters global configuration mode.
Step 2	Switch(config)# interface <i>interface-id</i>	Enters interface configuration mode.
Step 3	Switch(config-if)# counter { ipv4 ipv6 ipv4 ipv6 separate }	Enables counters. counter — Enables collection of IPv4 and IPv6 statistics and displays them as a sum counter ipv4 — Enables collection of IPv4 statistics only counter ipv6 — Enables collection of IPv6 statistics only counter ipv4 ipv6 separate — Enables collection of IPv4 and IPv6 statistics and displays them individually
Step 4	Switch(config)# end	Exits configuration mode.
Step 5	Switch# show run interface <i>interface-id</i>	Displays the running configuration.

This example shows how to enable counters on interface VLAN 1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface vlan 1
Switch(config-if)# counter ipv4
Switch(config-if)# end
Switch#
00:17:15: %SYS-5-CONFIG_I: Configured from console by console
Switch# show run interface vlan 1
Building configuration...

Current configuration : 63 bytes
!
interface Vlan1
 ip address 10.0.0.1 255.0.0.0
 counter ipv4
end
```

Note

To remove the counters, use the **no counter** command.

If you have already assigned the maximum number of counters, the **counter** command fails and displays an error message:

```
Switch# config terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# interface fa3/2
Switch(config-if)# no switchport
Switch(config-if)# counter ipv6
Counter resource exhausted for interface fa3/2
Switch(config-if)# end
Switch#
00:24:18: %SYS-5-CONFIG_I: Configured from console by console
```

In this situation, you must release a counter from another interface for use by the new interface.

Configuring Physical Layer 3 Interfaces

Note

Before you can configure physical Layer 3 interfaces, you must enable IP routing if IP routing is disabled, and specify an IP routing protocol.

To configure physical Layer 3 interfaces, perform this task:

	Command	Purpose
Step 1	Switch(config)# ip routing	Enables IP routing (required only if disabled)
Step 2	Switch(config)# interface { fastethernet gigabitethernet tengigabitethernet } <i>slot/port</i> { port-channel <i>port_channel_number</i> }	Selects an interface to configure.
Step 3	Switch(config-if)# no switchport	Converts this port from physical Layer 2 port to physical Layer 3 port.
Step 4	Switch(config-if)# ip address <i>ip_address</i> <i>subnet_mask</i>	Configures the IP address and IP subnet.
Step 5	Switch(config-if)# no shutdown	Enables the interface.
Step 6	Switch(config-if)# end	Exits configuration mode.
Step 7	Switch# copy running-config startup-config	Saves your configuration changes to NVRAM.
Step 8	Switch# show interfaces [<i>type slot/interface</i>] Switch# show ip interfaces [<i>type slot/interface</i>] Switch# show running-config interfaces [<i>type slot/interface</i>]	Verifies the configuration.

This example shows how to configure an IP address on Fast Ethernet interface 2/1:

```
Switch# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Switch(config)# ip routing
Switch(config)# interface fastethernet 2/1
Switch(config-if)# no switchport
Switch(config-if)# ip address 10.1.1.1 255.255.255.248
Switch(config-if)# no shutdown
Switch(config-if)# end
Switch#
```

This example shows how to use the **show running-config** command to display the interface IP address configuration of Fast Ethernet interface 2/1:

```
Switch# show running-config
Building configuration...
!
interface FastEthernet2/1
  no switchport
  ip address 10.1.1.1 255.255.255.248
!
...
ip classless
no ip http server
!
!
line con 0
line aux 0
```

```
line vty 0 4
!  
end
```

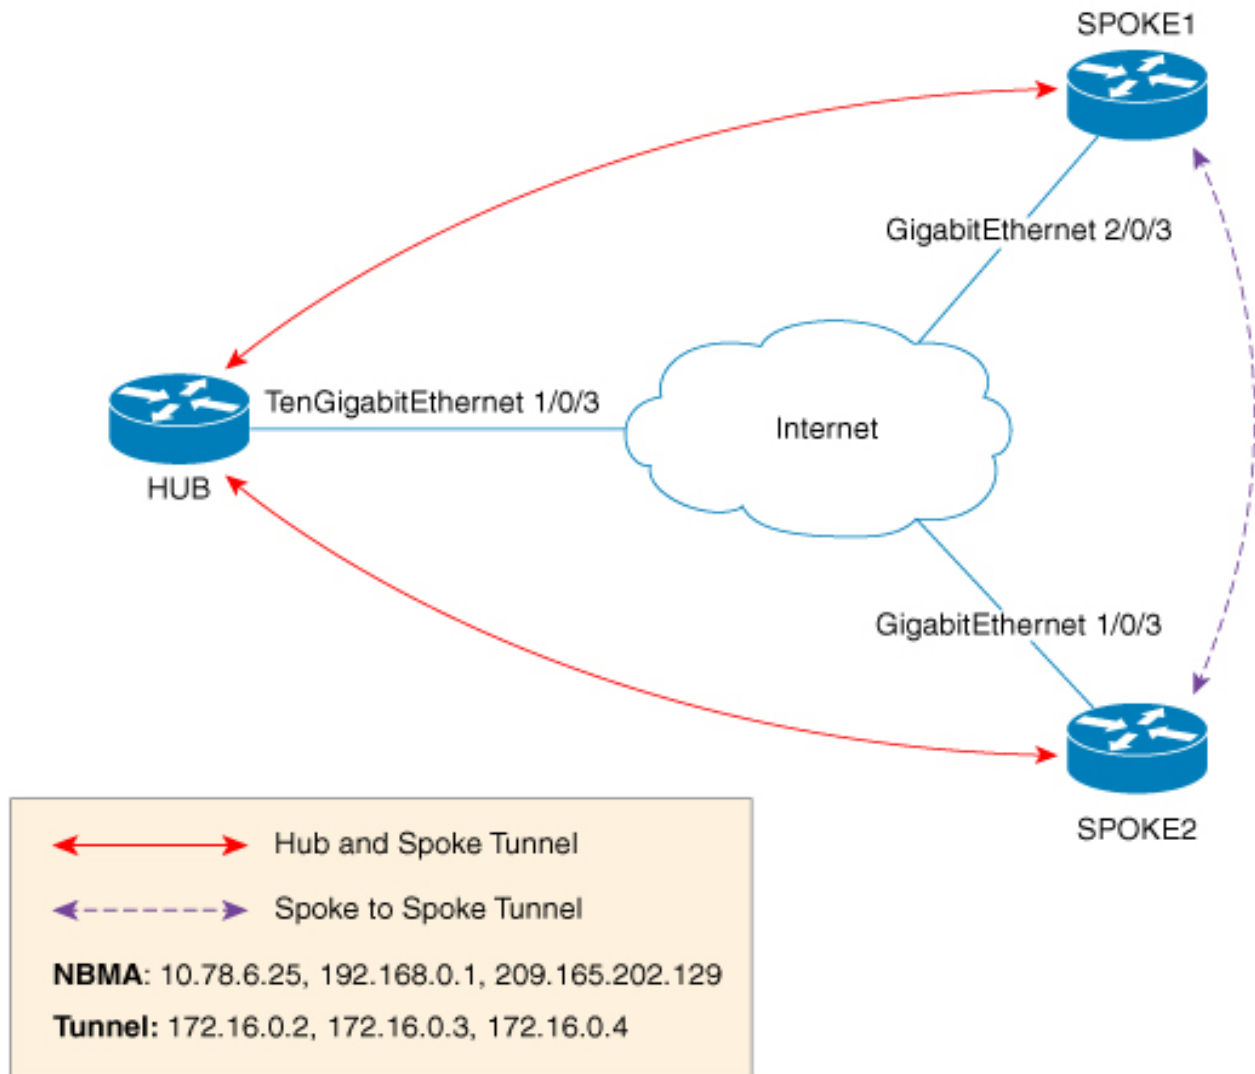

Configuring Multipoint GRE

This section consists of the following subsections:

- [About Multipoint GRE](#)
- [Configuring Unicast mGRE at Hub](#)
- [Configuring Unicast mGRE at Spoke](#)
- [Sample mGRE Configuration at Hub and Spokes](#)

About Multipoint GRE

Point-to-Multipoint (P2MP) is a hub-n-spoke topology that uses Multipoint GRE protocol (mGRE). mGRE is built over IPv4 core/underlying network and allows multiple destinations to be grouped into a single multipoint interface. It supports Open Shortest Path First (OSPF) and Enhanced Interior Gateway Routing Protocol (EIGRP) protocols, IPv4 and IPv6 unicast payload, and IPv4 multicast payload. mGRE does static and dynamic Next Hop Resolution Protocol (NHRP) tunneling for hub-to-spoke and spoke-to-spoke technologies, providing scalability and also reducing configuration complexity. Spokes dynamically register themselves with the hub and individual spokes also dynamically learn about other spokes using the NHRP protocol forming a dynamic-mesh network, that is, a non-broadcast multi-access network (NBMA). In NBMA, all routing protocols send their updates to a physical NBMA address. mGRE in conjunction with IPSEC and NHRP can be used in Dynamic Multipoint VPN (DMVPN).

In this figure, each spoke acts as a Next Hop Client (NHC) and is configured with static mapping information (hub's tunnel IP address and NBMA address) to reach hub which acts as Next Hop Server (NHS). NHCs send Next Hop Resolution Protocol (NHRP) registration request to NHS which allows NHS to learn mapping information of the spoke and form a tunnel (hub and spoke) dynamically.

In addition to NHRP registration of NHCs (spokes) with NHS (hub), NHRP provides the capability for NHC to dynamically discover another NHC on demand and form spoke-to-spoke tunnel. Without this discovery, IP packets traversing from hosts behind one spoke to hosts behind another spoke have to traverse by way of the NHS router. This increases the utilization of the hub's physical bandwidth and CPU to process these packets that come into the hub on the multipoint interface and go right back out the multipoint interface. This is often called hairpinning. With NHRP, systems attached to an NBMA network dynamically learn the NBMA address of the other systems that are part of that network,

allowing these systems to directly communicate without requiring traffic to use an intermediate hop. This alleviates the load on the intermediate hop (NHS) and can increase the overall bandwidth of the NBMA network to be greater than the bandwidth of the hub router and effectively creates a full-mesh-capable network without having to discover all possible connections beforehand.

This is called a dynamic-mesh network, where there is a base hub-and-spoke network of NHCs and NHSs for transporting NHRP, dynamic routing protocol information, data traffic, and dynamic direct spoke-to-spoke links that are built when there is data traffic to use the link and torn down when the data traffic stops.

Configuring Unicast mGRE at Hub

	Command	Purpose
Step 1	enable Device> enable	Enables privileged EXEC mode..
Step 2	configure terminal Device# configure terminal	Enters global configuration mode.
Step 3	interface type number Device(config)# interface tunnel 1	Configures an interface and enters interface configuration mode.
Step 4	ip nhrp map ip-address nbma-address Device(config-if)# ip nhrp map 10.0.0.1	Configures multipoint GRE as the tunnel mode.
Step 5	ip ospf network point-to-multipoint Device(config-if)# ip ospf network point-to-multipoint	If the underlying protocol is OSPF, execute this command to set the network type to point-to-multipoint.
Step 6	ip address address mask Device(config-if)# ip address 10.1.1.1 255.255.255.255	Configures IP address of the tunnel.
Step 7	ipv6 address address prefix Device(config-if)# ipv6 address 2001:DB8:1::1	Configures IPv6 address of the tunnel.
Step 8	tunnel source address Device(config-if)# tunnel source 172.16.1.3	Configures the source IP address of the tunnel.
Step 9	tunnel mode gre multipoint Device(config-if)# tunnel mode gre multipoint	Configures multipoint GRE as the tunnel mode.

	Command	Purpose
Step 10	{ip ipv6} nhrp network-id <i>id</i> Switch(config-if)# ip nhrp network id 1	Defines the NHRP domain which differentiates if multiple NHRP domains (GRE tunnel interfaces) are available on the same NHRP router.
Step 11	{ip ipv6} nhrp registration timeout <i>seconds</i> Device(config-if)# ip nhrp registration timeout 30	Changes the interval that NHRP NHCs take to send NHRP registration requests to configured NHRP NHSs..
Step 12	{ip ipv6} nhrp holdtime <i>seconds</i> Device(config-if)# ip nhrp holdtime 400#	Changes the number of seconds that NHRP NBMA addresses are advertised as valid in positive NHRP responses
Step 13	{ip ipv6} nhrp authentication <i>string</i> Device(config-if)# ip nhrp authentication DMVPN	Specifies an authentication string.
Step 14	ip pim nbma-mode Device(config-if)# ip pim nbma-mode	Configures a multiaccess WAN interface to be in non-broadcast multiaccess (NBMA) mode.
Step 15	ip nhrp map multicast dynamic Device(config-if)# ip nhrp map multicast dynamic	(Optional) Enables NHRP server (hub) to create a broadcast/multicast mapping for the spoke when spoke routers register their unicast NHRP mapping with the hub.
Step 16	ip next-hop self eigrp <i>number</i> Device(config-if)# ip next-hop self eigrp 10	(Optional) Enables the hub to use the next received hop while sending routing protocol updates of one spoke to another, so that hosts behind hosts can reach directly.
Step 17	ip split-horizon eigrp <i>number</i> Device(config-if)# ip split-horizon eigrp 10	(Optional) Enables routing protocol updates of one spoke to be sent to another spoke.
Step 18	end Device(config-if)# end	Exits interface configuration mode and returns to user EXEC mode.

Configuring Unicast mGRE at Spoke

	Command	Purpose
Step 1	enable Device> enable	Enables privileged EXEC mode..
Step 2	configure terminal Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Device(config)# interface tunnel1	Configures an interface and enters interface configuration mode. Ensure that this configuration is on a tunnel interface.
Step 4	ip nhrp map <i>ip-address nbma-address</i> Device(config-if)# ip nhrp map 10.0.0.1 192.0.0.1	Configures static IP-to-NBMA address mapping of hub on spoke.
Step 5	{ip ipv6} nhrp map multicast <i>nbma-address</i> Device(config-if)# ip nhrp map multicast 10.0.0.2	Enables IP multicast and broadcast packets (example: routing protocol information) to be sent from spoke to hub.
Step 6	ip nhrp nhs <i>nhs-address</i> Device(config-if)# ip nhrp nhs 192.0.2.1	Enables spoke to send NHRP registration request to hub. Here nhs-address is the hub tunnel' s address.
Step 7	tunnel source <i>address</i> Device(config-if)# tunnel source 172.16.1.3	Configures the source IP address of the tunnel.
Step 8	tunnel mode gre multipoint Device(config-if)# tunnel mode gre multipoint	Configures multipoint GRE as the tunnel mode.
Step 9	end Device(config-if)# end	Exits interface configuration mode and returns to user EXEC mode.

Sample mGRE Configuration at Hub and Spokes

On SPOKE 1:

```
interface Tunnel1
 ip address 192.168.1.3 255.255.255.0
 no ip redirects
 ip nhrp map 192.168.1.1 172.16.1.1
 ip nhrp network-id 1
 ip nhrp holdtime 600
```

```
ip nhrp nhs 192.168.1.1
ip nhrp registration timeout 30
tunnel source 172.16.1.3
tunnel mode gre multipoint
end
```

On SPOKE 2:

```
interface Tunnel1
 ip address 192.168.1.2 255.255.255.0
 no ip redirects
ip nhrp map 192.168.1.1 172.16.1.1
ip nhrp network-id 1
ip nhrp holdtime 600
ip nhrp nhs 192.168.1.1
ip nhrp registration timeout 30
tunnel source 172.16.1.2
tunnel mode gre multipoint
```

On HUB:

```
interface Tunnel1
 ip address 192.168.1.1 255.255.255.0
 no ip redirects
ip nhrp network-id 1
ip nhrp holdtime 600
ip nhrp registration timeout 30
ip ospf 1 area 0
tunnel source 172.16.1.1
tunnel mode gre multipoint
end
```

Configuring Cisco Express Forwarding

This chapter describes Cisco Express Forwarding (CEF) on the switch. It also provides guidelines, procedures, and examples to configure this feature.

This chapter includes the following major sections:

- [About CEF, page 37-1](#)
- [Catalyst 4500 Series Switch Implementation of CEF, page 37-3](#)
- [CEF Configuration Restrictions, page 37-6](#)
- [Configuring CEF, page 37-6](#)
- [Monitoring and Maintaining CEF, page 37-8](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About CEF

This section contains information on the two primary components that comprise the CEF operation:

- [CEF Features, page 37-1](#)
- [Forwarding Information Base, page 37-2](#)
- [Adjacency Tables, page 37-2](#)

CEF Features

CEF is advanced Layer 3 IP switching technology that optimizes performance and scalability for large networks with dynamic traffic patterns or networks with intensive web-based applications and interactive sessions.

CEF provides the following features:

- Improves performance over the caching schemes of multilayer switches, which often flush the entire cache when information changes in the routing tables.

- Provides load balancing that distributes packets across multiple links based on Layer 3 routing information. If a network device discovers multiple paths to a destination, the routing table is updated with multiple entries for that destination. Traffic to that destination is then distributed among the various paths.

CEF stores information in several data structures rather than the route cache of multilayer switches. The data structures optimize lookup for efficient packet forwarding.

Forwarding Information Base

The Forwarding Information Base (FIB) is a table that contains a copy of the forwarding information in the IP routing table. When routing or topology changes occur in the network, the route processor updates the IP routing table and CEF updates the FIB. Because there is a one-to-one correlation between FIB entries and routing table entries, the FIB contains all known routes and eliminates the need for route cache maintenance that is associated with switching paths, such as fast switching and optimum switching. CEF uses the FIB to make IP destination-based switching decisions and maintain next-hop address information based on the information in the IP routing table.

On the Catalyst 4500 series switches, CEF loads the FIB in to the Integrated Switching Engine hardware to increase the performance of forwarding. The Integrated Switching Engine has a finite number of forwarding slots for storing routing information. If this limit is exceeded, CEF is automatically disabled and all packets are forwarded in software. In this situation, you should reduce the number of routes on the switch and then reenable hardware switching with the **ip cef** command.

Adjacency Tables

In addition to the FIB, CEF uses adjacency tables to prepend Layer 2 addressing information. Nodes in the network are termed *adjacent* if they are within a single hop from each other. The adjacency table maintains Layer 2 next-hop addresses for all FIB entries.

Adjacency Discovery

The adjacency table is populated as new adjacent nodes are discovered. Each time an adjacency entry is created (such as using the Address Resolution Protocol (ARP), a link-layer header for that adjacent node is stored in the adjacency table. Once a route is determined, the link-layer header points to a next hop and corresponding adjacency entry. The link-layer header is subsequently used for encapsulation during CEF switching of packets.

Adjacency Resolution

A route might have several paths to a destination prefix, such as when a router is configured for simultaneous load balancing and redundancy. For each resolved path, a pointer is added for the adjacency corresponding to the next-hop interface for that path. This method is used for load balancing across several paths.

Adjacency Types That Require Special Handling

In addition to adjacencies for next-hop interfaces (host-route adjacencies), other types of adjacencies are used to expedite switching when certain exception conditions exist. When the prefix is defined, prefixes requiring exception processing are cached with one of the special adjacencies listed in [Table 37-1](#).

Table 37-1 Adjacency Types for Exception Processing

Adjacency Type	Processing Method
Null adjacency	Packets destined for a Null0 interface are dropped. A Null0 interface can be used as an effective form of access filtering.
Glean adjacency	When a router is connected directly to several hosts, the FIB table on the router maintains a prefix for the subnet rather than for each individual host. The subnet prefix points to a glean adjacency. When packets must be forwarded to a specific host, the adjacency database is gleaned for the specific prefix.
Punt adjacency	Features that require special handling or features that are not yet supported by CEF switching are sent (punted) to the next higher switching level.
Discard adjacency	Packets are discarded.
Drop adjacency	Packets are dropped.

Unresolved Adjacency

When a link-layer header is prepended to packets, FIB requires the prepend to point to an adjacency corresponding to the next hop. If an adjacency was created by FIB and was not discovered through a mechanism such as ARP, the Layer 2 addressing information is not known and the adjacency is considered incomplete. When the Layer 2 information is known, the packet is forwarded to the route processor, and the adjacency is determined through ARP.

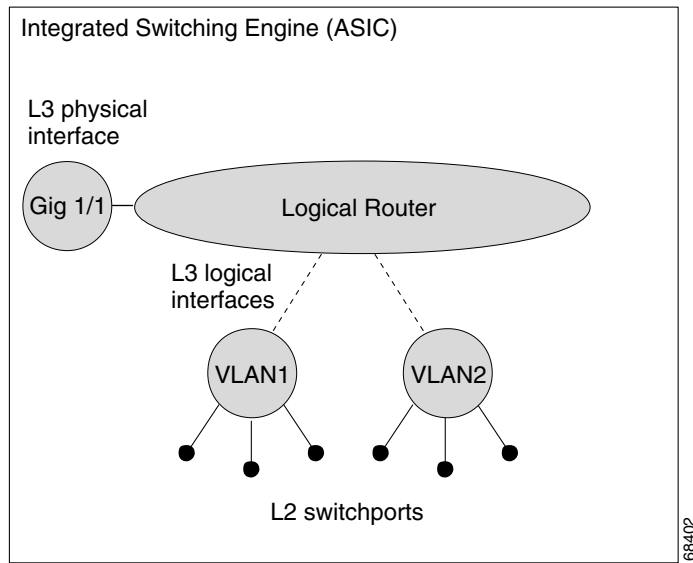

Catalyst 4500 Series Switch Implementation of CEF

Catalyst 4500 series switch support an ASIC-based Integrated Switching Engine that provides these features:

- Ethernet bridging at Layer 2
- IP routing at Layer 3

Because the ASIC is specifically designed to forward packets, the Integrated Switching Engine hardware can run this process much faster than CPU subsystem software.

[Figure 37-1](#) shows a high-level view of the ASIC-based Layer 2 and Layer 3 switching process on the Integrated Switching Engine.

Figure 37-1 Logical L2/L3 Switch Components

The Integrated Switching Engine performs inter-VLAN routing on logical Layer 3 interfaces with the ASIC hardware. The ASIC hardware also supports a physical Layer 3 interface that can be configured to connect with a host, a switch, or a router.

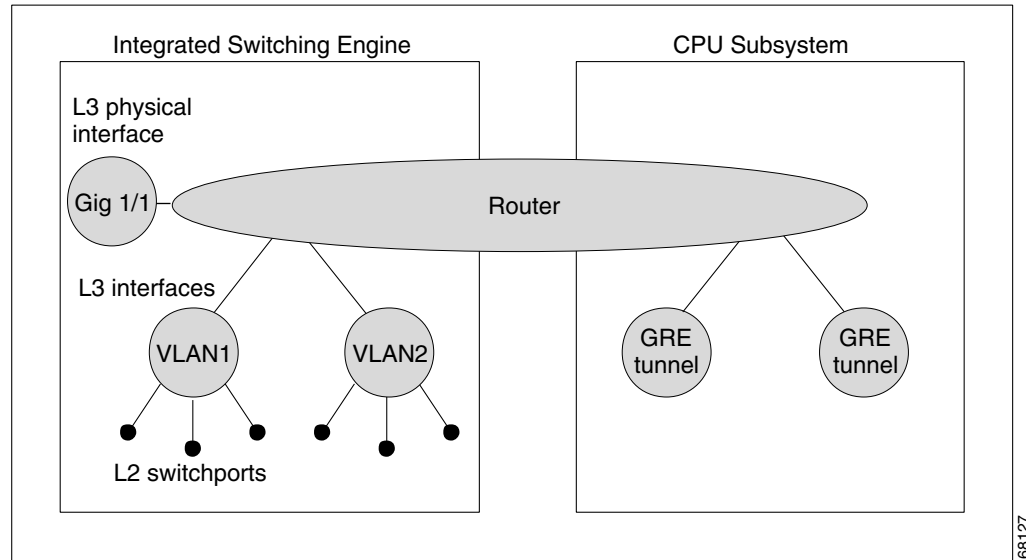

This section contains the following subsections:

- [Hardware and Software Switching, page 37-4](#)
- [Load Balancing, page 37-6](#)
- [Software Interfaces, page 37-6](#)

Hardware and Software Switching

For the majority of packets, the Integrated Switching Engine performs the packet forwarding function in hardware. These packets are hardware-switched at very high rates. Exception packets are forwarded by the CPU subsystem software. Statistic reports should show that the Integrated Switching Engine is forwarding the vast majority of packets in hardware. Software forwarding is significantly slower than hardware forwarding, but packets forwarded by the CPU subsystem do not reduce hardware forwarding speed.

[Figure 37-2](#) shows a logical view of the Integrated Switching Engine and the CPU subsystem switching components.

Figure 37-2 Hardware and Software Switching Components

The Integrated Switching Engine performs inter-VLAN routing in hardware. The CPU subsystem software supports Layer 3 interfaces to VLANs that use Subnetwork Access Protocol (SNAP) encapsulation. The CPU subsystem software also supports generic routing encapsulation (GRE) tunnels.

Hardware Switching

- Hardware switching is the normal operation for switches with supervisor engines.
- Beginning in Cisco IOS XE Release 3.7.1E, GRE tunnels are supported on the hardware on Catalyst 4500 series switches. When GRE is configured without tunnel options, packets are hardware-switched. Otherwise, packets are switched in the software.

Software Switching

Software switching occurs when traffic cannot be processed in hardware. The following types of exception packets are processed in software at a much slower rate:

- Packets that use IP header options

Note Packets that use TCP header options are switched in hardware because they do not affect the forwarding decision.

- Packets that have an expiring IP time-to-live (TTL) counter
- Packets that are forwarded to a tunnel interface.

Note When GRE tunnels are configured without tunnel options, packets are hardware-switched.

- Packets that arrive with non-supported encapsulation types
- Packets that are routed to an interface with non-supported encapsulation types

- Packets that exceed the MTU of an output interface and must be fragmented
- Packets that require an IGMP redirect for routing
- 802.3 Ethernet packets

Load Balancing

The Catalyst 4500 series switch supports load balancing for routing packets in the Integrated Switching Engine hardware. Load balancing is always enabled. It works when multiple routes for the same network with different next-hop addresses are configured. These routes can be configured either statically or through a routing protocol such as OSPF or EIGRP.

The hardware makes a forwarding decision by using a hardware load sharing hash function to compute a value, based on the source and destination IP addresses and the source and destination TCP port numbers (if available). This load sharing hash value is then used to select which route to use to forward the packet. All hardware switching within a particular flow (such as a TCP connection) is routed to the same next hop, which reduces the chance that packet reordering occurs. Up to eight different routes for a particular network are supported.

Software Interfaces

Cisco IOS for the Catalyst 4500 series switch supports GRE and IP tunnel interfaces that are not part of the hardware forwarding engine. All packets that flow to or from these interfaces must be processed in software and have a significantly lower forwarding rate than that of hardware-switched interfaces. Also, Layer 2 features are not supported on these interfaces.

CEF Configuration Restrictions

The CEF Integrated Switching Engine supports only ARPA and ISL/802.1q encapsulation types for Layer 3 switching in hardware. The CPU subsystem supports a number of encapsulations such as SNAP for Layer 2 switching that you can use for Layer 3 switching in software.

Configuring CEF

These sections describe how to configure CEF:

- [Enabling CEF, page 37-6](#)
- [Configuring Load Balancing for CEF, page 37-7](#)

Enabling CEF

By default, CEF is enabled globally on the Catalyst 4500 series switch. No configuration is required.

To reenabling CEF, perform this task:

Command	Purpose
Switch(config)# ip cef distributed	Enables standard CEF operation.

Configuring Load Balancing for CEF

CEF load balancing is based on a combination of source and destination packet information; it allows you to optimize resources by distributing traffic over multiple paths for transferring data to a destination. You can configure load balancing on a per-destination basis. Load-balancing decisions are made on the outbound interface. You can configure per-destination load balancing for CEF on outbound interfaces.

The following topics are discussed:

- [Configuring Per-Destination Load Balancing, page 37-7](#)
- [Configuring Load Sharing Hash Function, page 37-7](#)
- [Viewing CEF Information, page 37-8](#)

Configuring Per-Destination Load Balancing

Per-destination load balancing is enabled by default when you enable CEF. To use per-destination load balancing, you do not perform any additional tasks once you enable CEF.

Per-destination load balancing allows the router to use multiple paths to achieve load sharing. Packets for a given source-destination host pair are guaranteed to take the same path, even if multiple paths are available. Traffic destined for different pairs tend to take different paths. Per-destination load balancing is enabled by default when you enable CEF; it is the load balancing method of choice in most situations.

Because per-destination load balancing depends on the statistical distribution of traffic, load sharing becomes more effective as the number of source-destination pairs increases.

Use per-destination load balancing to ensure that packets for a given host pair arrive in order. All packets for a certain host pair are routed over the same link or links.

Configuring Load Sharing Hash Function

When multiple unicast routes exist to a particular destination IP prefix, the hardware sends packets matching that prefix across all possible routes, which shares the load across all next hop routers. By default, the route used is chosen by computing a hash of the source and destination IP addresses and using the resulting value to select the route. This preserves packet ordering for packets within a flow by ensuring that all packets within a single IP source/destination flow are sent on the same route, but it provides a near-random distribution of flows to routes.

You can change the load-sharing hash function. So, in addition to the source and destination IP addresses, the source TCP/UDP port, the destination TCP/UDP port, or both can also be included in the hash.

To the configure load sharing hash function to use the source and/or destination ports, perform this task:

Command	Purpose
Switch (config)# [no] ip cef load-sharing algorithm include-ports source destination	Enables load sharing hash function to use source and destination ports. Use the no keyword to set the switch to use the default Cisco IOS load-sharing algorithm.

**Note**

The **include-ports** option does not apply to software-switched traffic on the Catalyst 4500 series switches.

Viewing CEF Information

You can view the collected CEF information. To view CEF information, perform this task:

Command	Purpose
Switch# show ip cef	Displays the collected CEF information.

Monitoring and Maintaining CEF

To display information about IP traffic, perform this task:

Command	Purpose
Switch# show interface type slot/interface begin L3	Displays a summary of IP unicast traffic.

This example shows how to display information about IP unicast traffic on interface Fast Ethernet 3/3:

```
Switch# show interface fastethernet 3/3 | begin L3
L3 in Switched: ucast: 0 pkt, 0 bytes - mcast: 12 pkt, 778 bytes mcast
L3 out Switched: ucast: 0 pkt, 0 bytes - mcast: 0 pkt, 0 bytes
4046399 packets input, 349370039 bytes, 0 no buffer
Received 3795255 broadcasts, 2 runs, 0 giants, 0 throttles
<...output truncated...>
Switch#
```

**Note**

The IP unicast packet count is updated approximately every five seconds.

Displaying IP Statistics

IP unicast statistics are gathered on a per-interface basis. To display IP statistics, perform this task:

Command	Purpose
Switch# show interface <i>type number</i> counters detail	Displays IP statistics.

This example shows how to display IP unicast statistics for fastethernet 3/1:

Switch# **show interface fastethernet 3/1 counters detail**

```

Fa3/1                0
Switch#

```

To display CEF (software switched) and hardware IP unicast adjacency table information, perform this task:

Command	Purpose
Switch# show adjacency [<i>interface</i>] [detail internal summary]	Displays detailed adjacency information, including Layer 2 information, when the optional detail keyword is used.

This example shows how to display adjacency statistics:

Switch# **show adjacency gigabitethernet 3/5 detail**

```

Protocol Interface          Address
IP          GigabitEthernet9/5  172.20.53.206(11)
                                     504 packets, 6110 bytes
                                     00605C865B82
                                     000164F83FA50800
ARP          03:49:31

```

Note

Adjacency statistics are updated approximately every 10 seconds.

Configuring Unicast Reverse Path Forwarding

This chapter describes the Unicast Reverse Path Forwarding (Unicast RPF) feature. The Unicast RPF feature helps to mitigate problems that are caused by malformed or forged IP source addresses that are passing through a switch.

For a complete description of the Unicast RPF commands in this chapter, refer to the chapter “Unicast Reverse Path Forwarding Commands” of the *Cisco IOS Security Command Reference*. To locate documentation of other commands that appear in this chapter, use the command reference master index or search online.

To identify the hardware platform or software image information associated with a feature, use the Feature Navigator on Cisco.com to search for information about the feature or refer to the software release notes for a specific release. For more information, see the “Identifying Supported Platforms” section in the chapter “Using Cisco IOS Software.”

This chapter includes the following sections:

- [About Unicast Reverse Path Forwarding, page 38-1](#)
- [Unicast RPF Configuration Tasks, page 38-9](#)
- [Monitoring and Maintaining Unicast RPF, page 38-11](#)
- [Unicast RPF Configuration Example: Inbound and Outbound Filters, page 38-12](#)
- [Unicast RPF with ACL Support Configuration Example:, page 38-13](#)
- [Feature Information for Unicast Reverse Path Forwarding, page 38-13](#)

Note

For complete syntax and usage information for the switch commands used in this chapter, see the [Cisco IOS Command Reference Guides for the Catalyst 4500 Series Switch](#).

If a command is not in the *Cisco Catalyst 4500 Series Switch Command Reference*, you can locate it in the [Cisco IOS Master Command List, All Releases](#).

About Unicast Reverse Path Forwarding

The Unicast RPF feature helps to mitigate problems that are caused by the introduction of malformed or forged (spoofed) IP source addresses into a network by discarding IP packets that lack a verifiable IP source address. For example, a number of common types of denial-of-service (DoS) attacks, including Smurf and Tribal Flood Network (TFN), can take advantage of forged or rapidly changing source IP addresses to allow attackers to thwart efforts to locate or filter the attacks. For Internet service providers

(ISPs) that provide public access, Unicast RPF deflects such attacks by forwarding only packets that have source addresses that are valid and consistent with the IP routing table. This action protects the network of the ISP, its customer, and the rest of the Internet.

This section covers the following information:

- [How Unicast RPF Works, page 38-2](#)
- [Unicast Reverse Path Forwarding with ACL Support, page 38-4](#)
- [Unicast Reverse Path Forwarding with ACL Support, page 38-4](#)
- [Restrictions, page 38-8](#)
- [Related Features and Technologies, page 38-8](#)
- [Prerequisites to Configuring Unicast RPF, page 38-9](#)

How Unicast RPF Works

When Unicast RPF is enabled on an interface, the switch examines all packets received as input on that interface to make sure that the source address and source interface appear in the routing table and match the interface on which the packet was received. This ability to look backwards is available only when Cisco Express Forwarding (CEF) is enabled on the switch, because the lookup relies on the presence of the Forwarding Information Base (FIB). CEF generates the FIB as part of its operation.

Note

Unicast RPF is an input function and is applied only on the input interface of a switch at the upstream end of a connection.

Unicast RPF checks to see if any packet received at a switch interface arrives on the best return path (return route) to the source of the packet. Unicast RPF does this by doing a reverse lookup in the CEF table. If the packet was received from one of the best reverse path routes, the packet is forwarded as normal. If there is no reverse path route on the same interface from which the packet was received, it might mean that the source address was modified. If Unicast RPF does not find a reverse path for the packet, the packet is dropped.

Note

With Unicast RPF, all equal-cost “best” return paths are considered valid. This means that Unicast RPF works in cases where multiple return paths exist, provided that each path is equal to the others in terms of the routing cost (number of hops, weights, and so on) and as long as the route is in the FIB. Unicast RPF also functions where EIGRP variants are being used and unequal candidate paths back to the source IP address exist.

When a packet is received at the interface where Unicast RPF and ACLs have been configured, the following actions occur:

- Step 1** Input ACLs configured on the inbound interface are checked.
- Step 2** Unicast RPF checks to see if the packet has arrived on the best return path to the source, which it does by doing a reverse lookup in the FIB table.
- Step 3** CEF table (FIB) lookup is carried out for packet forwarding.
- Step 4** Output ACLs are checked on the outbound interface.

Step 5 The packet is forwarded.

This section provides information about Unicast RPF enhancements:

- Access control lists and logging
- Per-interface statistics

Figure 38-1 illustrates how Unicast RPF and CEF work together to validate IP source addresses by verifying packet return paths. In this example, a customer has sent a packet having a source address of 192.168.1.1 from interface Gigabit Ethernet 1/1. Unicast RPF checks the FIB to see if 192.168.1.1 has a path to Gigabit Ethernet 1/1. If there is a matching path, the packet is forwarded. If there is no matching path, the packet is dropped.

Figure 38-1 Unicast RPF Validating IP Source Addresses
